This has the following effect: equation `constr01` will become an indicator constraint and becomes active in a solution where the binary variable takes the value 0. If the value of y in a solution is 1, the constraint is not active.

Note that this way of entering an indicator constraint is dangerous since the option files changes the model (usually an option file has some effect on the performance of the algorithm). Therefore, the solver will abort if there is a problem processing the indicator options in the solver option file.

Attention

> If the model is given to a solver without the option file containing the indicator mapping (or to a solver that does not understand the `indic` keyword, a very different model will be solved. The current implementation of indicator constraints requires a significant amount of caution from the user.

There are two ways of entering the equation/binary variable mapping in a solver option file: with an indexed format and using labels.

The *indexed format* is a convenient shorthand notation which borrows its syntax from the GAMS syntax. It requires that the indices for the binary variable are already present in the index set of the equation.

Consider the following example of an invalid GAMS syntax with an endogenous variable in the dollar condition:

```
equ1(i,j,k)$(ord(i) < ord(j) and bin1(i,k)=1).. lhs =l= rhs;
```

This may be specified with the following equation in the GAMS file:

```
equ1(i,j,k)$(ord(i) < ord(j)).. lhs =l= rhs;
```

plus a solver option file with the following entry:

```
indic equ1(i,j,k)$bin1(i,k) 1
```

The *label format* is used in cases where the binary variable indices are not present in the equation indices or the binary variable is adjusted with lags or leads. In these cases the mapping of all individual equations and variables of the indicator constraints need to be specified. An example follows.

```
Set             i /i1*i3/, j /j1*j2/;
Binary variable bin1(j);
Equation        equ1(i,j);

equ1(i,j)$(bin1(j++1)=0)..   lhs =e= 0;
```

Note that the example above is not valid GAMS code. Instead, we will combine a valid GAMS equation and a solver option file using the label format as follows:

```
equ1(i,j).. lhs =e= 0;
```

and the solver option file

```
indic equ1('i1','j1')$bin1('j2') 0
indic equ1('i1','j2')$bin1('j1') 0
indic equ1('i2','j1')$bin1('j2') 0
indic equ1('i2','j2')$bin1('j1') 0
indic equ1('i3','j1')$bin1('j2') 0
indic equ1('i3','j2')$bin1('j1') 0
```

Note that the lines in such option files need not be entered manually. They may be easily generated using the GAMS The Put Writing Facility. For example, the lines above may be generated as follows:

```
file fcpx / cplex.opt /;
fcpx.pc=8;
loop((i,j), put fcpx 'indic' equ1(i,j) '$' bin1(j++1) '0'/);
putclose fcpx;
```

Attention

Mixing and matching between indexed format and label format is not possible. While expressions like `eq(i,j,k)$x(i,k)` and `eq('i1','j2','k3')$x('i1','k6')` are valid, combinations such as `eq(i,'j2',k)$x(i,k)` are not supported.

There are situations where the indicator binary variable exist in the indicator constraint only and hence will *not* be *generated* by GAMS to be passed on to the solver. In such cases the solver will issue the following error message:

```
Error: Column is not of type Variable
```

There is an easy way to fix this problem: adding the binary indicator variable artificially to the model. For example, it may be added with the coefficient `eps` to the objective:

```
defobj.. z =e= ... + eps*sum(j, bin1(j));
```

4.37.5.2 An Example for Indicator Constraints with GAMS

In this subsection we will comment on parts of the model [**TRNSINDIC**]. This model uses big M formulations and indicator constraints to solve the same problem. In addition, a formulation that makes it easy to switch between these two is presented. It is a fixed-charge network example based on the well-known model [**TRNSPORT**].

Recall that `i` is the set of canning plants and `j` is the set of markets where cases of some product are to be shipped. First, the basic model is reformulated to a MIP by introducing the binary variable `use(i,j)` and two new equations:

```
Binary Variable use(i,j)     is 1 if arc is used in solution;

Equations       minship(i,j) ensure minimum shipping
                maxship(i,j) ensure zero shipping if use variable is 0;

minship(i,j)..  x(i,j) =g= minshipping*use(i,j);
maxship(i,j)..  x(i,j) =l= bigM*use(i,j);
```

Note that `minshipping` is a scalar denoting the minimum amount of cases that may be shipped and `bigM` is a sufficiently large number, as usual.

Next, the same problem is solved with indicator constraints: the two new equations are reformulated and a CPLEX option file with information on indicator constraints is added:

```
Equations  iminship(i,j) ensure minimum shipping using indicator constraints
           imaxship(i,j) ensure zero shipping if use variable is 0 using indicator constraints;

iminship(i,j)..   x(i,j) =g= minshipping;
imaxship(i,j)..   x(i,j) =e= 0;

Model indicatorModel /cost, supply, demand, iminship, imaxship/ ;

file fcpx Cplex Option file / cplex.opt /;
putclose fcpx 'indic iminship(i,j)$use(i,j) 1' / 'indic imaxship(i,j)$use(i,j) 0';
indicatorModel.optfile = 1;

Solve indicatorModel using mip minimizing z ;
```

Note that the option file contains an entry for each of the two equations. Note further, that the binary variable `use` moved from the equations to the option file. However, it also features in the objective equation of the model, therefore this is not problematic. Observe that the indexed format for the equation/binary variable mapping was used in the option file. Alternatively, the label format may be used:

```
loop((i,j),
     put fcpx 'indic ' iminship.tn(i,j) '$' use.tn(i,j) yes
            / 'indic ' imaxship.tn(i,j) '$' use.tn(i,j) no / );
  putclose fcpx;
```

In a final step the model is reformulated again such that the same problem may be solved with and without indicator constraints. This can be especially useful for debugging a model with indicator constraints. For details, see [**TRNSINDIC**].

Another example of a model with indicator constraints is the model [**BILINEAR**] where various formulations to represent bilinear product terms are demonstrated.

4.38 GAMS Output

4.38.1 Introduction

The output from GAMS contains many components in support for checking and comprehending a model. This chapter discusses the components of the GAMS output file generated from a GAMS run as well as ways to control the amount of diagnostic output produced. A GAMS run also generates a log which serves as a useful first step in analysing a GAMS run. The details regarding the log can be found in the GAMS log chapter.

The output file generated from a GAMS run is called *listing file*. The listing file has the file extension `.lst` and can be read using any text editor. By default the listing file has the same file name as the input file, but this can be changed using the command line parameter Output. See chapter The GAMS Call and Command Line Parameters for more information. The main components in the listing file are:

1. Compilation. The compilation output contains an echo print of the input file, possibly error messages, along with lists of GAMS objects and cross reference maps.
2. Execution. The execution output contains the results of display statements and possibly execution error messages.
3. Model Generation. The output generated during model generation contains listings of equations and variable listings as well as model statistics and possibly generation execution error messages.
4. Solution. The output generated when an external solver program processes the model is the solution report including the solve summary, the solver report, the solution listing and the report summary.
5. Post-Solution. The final components added to the listing file are the final execution summary and the file summary.

A small nonlinear program [**ALAN**] will be used to illustrate every component of the listing file. The possibilities for extension to large models with voluminous output (which is when the diagnostics are really useful) should be apparent. After covering all the components of the listing file we will discuss error reporting and conclude the chapter with a compiled list of how to customize the output file.

This chapter does not cover the output that can be generated by the user through display statements and put statements. This output is covered in the chapters The Display Statement and The Put Writing Facility respectively.

4.38.2 An Illustrative Model

[**ALAN**] is a portfolio selection model whose objective is to choose a portfolio of investments whose expected return meets a target while minimizing the variance. We will discuss a simplified version of this model. The input file is listed for reference.

```

dvar..     sum(i, x(i)*sum(j,v(i,j)*x(j)))   =e=  variance;

Model portfolio  / fsum, dmean, dvar / ;
Solve portfolio using nlp minimizing variance;
display x.l, variance.l;
```

4.38.3 Compilation Output

The compilation output is the output produced during the initial check of the program, often referred to as compilation. It contains the following parts: the echo print of the input file, the symbol reference map, the symbol listing map, the unique element listing map, and the include file summary.

By default only the echo print and the include file summary is shown, the other parts are suppressed and may be turned on with dollar control options. See also section Customizing the Output File on how to control the appearance and amount of detail in the output file produced by the GAMS compiler.

4.38.3.1 The Echo Print of the Input File

The *echo print* of the program is always the first part of the output file. It is a listing of the input with added line numbers. It is possible to control the listing output using $offlisting to suppress the echo print and $onlisting to turn the echo print on again. The first few lines of the echo print of the Illustrative Model follow:

```
A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)
C o m p i l a t i o n

   2
   4
      This is a mini mean-variance portfolio selection problem described in
      'GAMS/MINOS:Three examples' by Alan S. Manne, Department of Operations
       Research, Stanford University, May 1986.
  10
  11  * This model has been modified for use in the documentation
```

The default header of the GAMS listing file is `General Algebraic Modeling System`. This may be replaced using the $title at the start of a line. The text on that line will be the new header, as demonstrated above. After the header the compilation output is announced with the title `Compilation`.

The first three line numbers refer to empty lines in the input and line 11 is a comment line. If the lines on the input file are counted, it can be seen that this comment line appears after ten lines of dollar directives, comments and empty lines.

The dollar control options that follow in the model are used to display more information in the output file than the default and will be discussed in the subsections below.

Note

> By default, dollar control option lines are not listed in the echo print. The $onDollar and $offDolar controls the echoing of Dollar Control Options lines in the listing file. Dollar control option lines are also listed if they contain errors.

The block comment enclosed by $ontext and $offtext is listed without line numbers, while single line comments starting with asterisks (*) are listed with the respective line numbers. Observe that line numbers always refer to the physical line number in the input file. The remainder of the echo print follows:

```
12
13  Set i  securities   /hardware, software, show-biz, t-bills/;
14  alias (i,j);
15
16  Scalar target     target mean annual return on portfolio % /10/,
17         lowyield   yield of lowest yielding security,
18         highrisk   variance of highest security risk ;
19
20  Parameters  mean(i)  mean annual returns on individual securities (%)
21        / hardware   8
22          software   9
23          show-biz  12
24          t-bills    7 / ;
25
26  Table v(i,j)  variance-covariance array (%-squared annual return)
27                    hardware  software  show-biz  t-bills
28         hardware      4         3         -1        0
29         software      3         6          1        0
30         show-biz     -1         1         10        0
31         t-bills       0         0          0        0 ;
32
33  lowyield = smin(i, mean(i)) ;
34  highrisk = smax(i, v(i,i)) ;
35  display lowyield, highrisk ;
36
37  Variables  x(i)       fraction of portfolio invested in asset i
38             variance   variance of portfolio ;
39  Positive Variable x ;
40
41  Equations  fsum    fractions must add to 1.0
42             dmean   definition of mean return on portfolio
43             dvar    definition of variance;
44
45  fsum..     sum(i, x(i))                      =e=  1.0;
46  dmean..    sum(i, mean(i)*x(i))              =e=  target;
47  dvar..     sum(i, x(i)*sum(j,v(i,j)*x(j)))   =e=  variance;
48
49  Model portfolio  / fsum, dmean, dvar / ;
50  Solve portfolio using nlp minimizing variance;
51  display x.l, variance.l;
```

Lines in the echo print can be set to double space using $double and then reset to single space with $single. If errors were detected, the explanatory messages would be found at the end of the echo print. All discussions of error messages have been grouped together in the section Error Reporting below.

4.38.3.2 The Symbol Reference Map

The other parts of the compilation outputs are maps. They are extremely useful for users looking at a model written by someone else or trying to make changes in their own model after spending some time away from it. By default all maps are suppressed and can be turned on with dollar control options that are specified below.

The first map is the *symbol cross reference*. It can be turned on with the dollar control option $onSymXRef at the beginning of the program. The symbol cross reference map lists all identifiers (symbols) from the model in alphabetical order, identifies them as to data type, shows the line numbers where the symbols appear and classifies each appearance. The map that was generated as part of the output of our Illustrative Model is shown below:

```
Symbol Listing

SYMBOL      TYPE   REFERENCES

dmean        EQU   declared       42  defined       46 impl-asn       50      ref       49
dvar         EQU   declared       43  defined       47 impl-asn       50      ref       49
fsum         EQU   declared       41  defined       45 impl-asn       50      ref       49
highrisk     PARAM declared       18 assigned       34      ref       35
i            SET   declared       13  defined       13      ref       14       20       26       33
37     45     2*46     2*47  control       33       34       45       46       47
j            SET   declared       14      ref       26     2*47  control       47
lowyield     PARAM declared       17 assigned       33      ref       35
mean         PARAM declared       20  defined       21      ref       33       46
portfolio    MODEL declared       49  defined       49 impl-asn       50      ref       50
target       PARAM declared       16  defined       16      ref       46
v            PARAM declared       26  defined       26      ref       34       47
variance     VAR   declared       38 impl-asn       50      ref       47       50       51
x            VAR   declared       37 impl-asn       50      ref       39       45       46     2*47
```

In the first two columns the name and type of each identifier are given. For example, the last symbol listed is `x` which is defined to be of type `VAR`, a shorthand symbol for variable. The complete list of data types and their shorthand symbols is given below:

Shorthand Symbol	GAMS Data Type
ACRNM	acronym
EQU	equation
FILE	put file
MODEL	model
PARAM	parameter
SET	set
VAR	variable

For further details on data types in GAMS, see section Data Types and Definitions.

The symbol `highrisk` was declared as a `scalar`, but is listed as a `parameter` in the map above. Recall that `parameters`, `scalars`, and `tables` are three *input formats* for the data type `parameter`. For more information, see the overview Parameters, Scalars and Tables.

After the name and type of the identifier, a list of references to the symbol is given. References are grouped by reference type and identified by the line number in the output file. The actual reference can be found by referring to the echo print of the program, which has line numbers on it. In the case of the symbol `x` in the example above, the list of references as shown in the symbol reference map are as follows:

```
declared       37
impl-asn       50
ref            39       45       46     2*47       51
```

This means that `x` is declared on line 37, implicitly assigned through a `solve` statement on line 50 and referenced on lines 39, 45, 46, 47, and 51. The entry `2*47` means that there are two references to `x` on line 47 of the input file.

The complete list of reference types and their shorthand symbols in GAMS Output is given below:

Shorthand Symbol	Reference Type	Description
`declared`	Declaration	The identifier is declared as to type. This must be the first appearance of the identifier.
`defined`	Definition	An initialization (for a table or a data list between slashes) or symbolic definition (for an equation) starts for the identifier.
`assigned`	Assignment	Values are replaced because the identifier appears on the left-hand side of an assignment statement.
`impl-asn`	Implicit Assignment	An equation or variable will be updated as a result of being referred to implicitly in a solve statement.
`control`	Control	A set is used as (part of) the driving index in an assignment, equation, loop or indexed operation.
`ref`	Reference	The symbol has been referenced on the right-hand side of an assignment or in a display, equation, model, solve statement or put statetement.
`index`	Index	Like `control`, but used only for set *labels*. Appears only in the cross reference map of unique elements. See section The Unique Element Listing Map for details.

Note that the symbol reference map may be useful in model development, documentation preparation, and to make sure that all declared items are actually used in the model (by checking that they all have reference symbols in addition to `declared` and `defined`).

4.38.3.3 The Symbol Listing Map

The second optional map is the *symbol listing*. In the symbol listing map all identifiers are grouped alphabetically by data type and listed with their explanatory texts. This is another very useful aid for trying to understand a large model prepared by someone else. Note that expressive explanatory text is particularly helpful here. The symbol listing map can be turned on by entering a line containing the dollar control option $onSymList at the beginning of the program. The symbol listing map generated from our Illustrative Model follows:

```
SETS

i             securities
j             Aliased with i

PARAMETERS

highrisk      variance of highest security risk
lowyield      yield of lowest yielding security
mean          mean annual returns on individual securities (%)
target        target mean annual return on portfolio %
v             variance-covariance array (%-squared annual return)

VARIABLES

variance      variance of portfolio
x             fraction of portfolio invested in asset i

EQUATIONS

dmean         definition of mean return on portfolio
```

```
dvar          definition of variance
fsum          fractions must add to 1.0

MODELS

portfolio
```

4.38.3.4 The Unique Element Listing Map

The last optional map is the *Unique Element* (UEL) Listing. The unique element listing can be turned on by entering a line containing the dollar control option $onUELList at the beginning of the program. All unique elements are first grouped in entry order and then in sorted order with their explanatory texts:

```
Unique Element Listing

Unique Elements in Entry Order

1  hardware    software    show-biz    t-bills

Unique Elements in Sorted Order

1  hardware    show-biz    software    t-bills
```

In addition, a map with references for every label is given if the dollar control option $onUELXRef appears at the beginning of the program.

```
ELEMENT   REFERENCES

hardware  declared       13      ref       21       27       28
show-biz  declared       13      ref       23       27       30
software  declared       13      ref       22       27       29
t-bills   declared       13      ref       24       27       31
```

The unique element list is important in the context of ordered sets. For details see section Ordered and Unordered Sets.

4.38.3.5 The Include File Summary

Often the GAMS program includes a text file specified by the dollar control option $include. Consider the following example:

```
$include 'file1.inc'
Set i / i1*i10 /;
Scalar a; a = 7;
$include 'file2.inc'
```

The file `file1.inc` contains the following two lines:

```
Set j  / j1*j5 /;
Parameter k(j);
```

The file `file2.inc` contains the following line:

```
a = a+3;
```

The echo print follows:

```
INCLUDE    C:\models\file1.inc
   2  Set j  / j1*j5 /;
   3  Parameter k(j);
   4  Set i / i1*i10 /;
   5  Scalar a; a = 7;
INCLUDE    C:\models\file2.inc
   7  a = a+3;
```

Note that the contents of the two include files are expanded in the echo print and the include file names and their path is echoed in the lines with the dollar control option $include. If we insert the dollar control option $offInclude in the first line of the code, the echo print will not include the lines with the names of the include files any more, but the contents will still be echoed:

```
   3  Set j  / j1*j5 /;
   4  Parameter k(j);
   5  Set i / i1*i10 /;
   6  Scalar a; a = 7;
   8  a = a+3;
```

If the program contains include files, there will be an `Include File Summary` at the end of the compilation output. The include file summary of the simple example above (without the line $offInclude) follows. If `$offInclude` is active, it will be suppressed.

```
Include File Summary

   SEQ   GLOBAL TYPE      PARENT   LOCAL  FILENAME

     1        1 INPUT          0       0  C:\models\test.gms
     2        1 INCLUDE        1       1  .C:\models\file1.inc
     3        6 INCLUDE        1       4  .C:\models\file2.inc
```

In the first column the sequence number of the input files is given. Note that the parent file called by the GAMS call is always listed first. The second column gives the global (expanded) line number which contains the respective option `include` or one of its variants. The third column indicates the type of the respective file. An overview of the file types is given below:

File Type	Description
INPUT	The GAMS input file that was called with the GAMS call.
EXIT	Exit from compilation
INCLUDE	A file that was inserted with the dollar command option $include.
BATINCLUDE	A file that was inserted with the dollar command option $batinclude.
LIBINCLUDE	A file that was inserted with the dollar command option $libinclude.

File Type	Description
SYSINCLUDE	A file that was inserted with the dollar command option $sysinclude.
CALL	A program that was called with the dollar command option $call
CALL.ASYNC	A program that was called asynchronously with the dollar command option $call.Async
CALLTOOL	A GAMS tool was called with the dollar command option $callTool
GDXIN	A GDX file that was opened for input with the dollar command option $gdxIn
GDXOUT	A GDX file that was opened for output with the dollar command option $gdxOut
IF EXIST	Operator used to test whether a given file name exists
IF DEXIST	Operator used to test whether a given directory name exists
FUNCLIBIN	A file that was inserted with the dollar command option $funcLibIn
TERMINATE	Terminate compilation and execution
STOP	Stop compilation

The next column, named PARENT, provides the sequence number of the respective parent file. The column with the header LOCAL gives the local line number in the parent file where the file was included. The last column shows the path and the name of the respective file.

Note that compilation error messages in include files have additional information about the name of the include file and the local line number. For information on compilation errors, see section Compilation Errors below.

4.38.4 Execution Output

The execution output follows the compilation output in the GAMS listing file. It is introduced with the title Execution. The execution output is the output generated while GAMS is performing data manipulations and results from display statements. The output from the display statement on line 33 of our Illustrative Model is shown below.

```
E x e c u t i o n

----     33 PARAMETER lowyield             =        7.000  yield of lowest yielding security
            PARAMETER highrisk             =       10.000  variance of highest security risk
```

If errors are detected because of illegal data operations, a brief message indicating the cause and the line number of the offending statement will appear. For further information on execution errors, see section Execution Errors below.

Note

In case there is no display statement before The Solve Statement in the model and there are no execution errors, there will be no execution output in the GAMS listing file.

4.38.5 Model Generation Output

The model generation output, the solution report, and the post-solution Output are produced when a solve statement is executed. The actions that are initiated by a solve statement are presented in section Actions Triggered by the Solve Statement. All output generated as a result of a solve is labeled with a subtitle identifying the model, its type and the line number of the solve statement.

The output generated during model generation includes equations listing, variable listing, and model statistics.

4.38.5.1 The Equation Listing

The *equation listing* is the first part of the output generated by a solve statement. It is marked with the subtitle `Equation Listing`. By default, the first three equations in every block are listed. This can be modified with the option limrow. If there are three or fewer single equations in any equation block, then all the single equations are listed.

Note that by studying the equation listing the user may determine whether the model generated by GAMS is the the model that the user has intended - an extremely important question. This component of the output shows the specific equations generated within the model when the current values of the sets and parameters are plugged into the general algebraic form of the model.

The equation listing from our Illustrative Model is given below. In our case we have three equation blocks, each producing one single equation.

```
A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)
Equation Listing    SOLVE portfolio Using NLP From line 50

---- fsum  =E=  fractions must add to 1.0

fsum..  x(hardware) + x(software) + x(show-biz) + x(t-bills) =E= 1 ; (LHS = 0, INFES = 1 ****)

---- dmean  =E=  definition of mean return on portfolio

dmean..  8*x(hardware) + 9*x(software) + 12*x(show-biz) + 7*x(t-bills) =E= 10 ; (LHS = 0, INFES = 10

---- dvar  =E=  definition of variance

dvar..  (0)*x(hardware) + (0)*x(software) + (0)*x(show-biz) - variance =E= 0 ; (LHS = 0)
```

Note

> The equation listing is an extremely useful debugging aid. It shows the variables that appear in each constraint. In addition, it shows what the individual coefficients and right-hand side values evaluate to after the data manipulations have been done.

Each equation block is marked with four dashes which are useful for mechanical searching. The name, type of equation and explanatory text is shown, followed by the individual equations.

Note

> All the terms that depend on variables are collected on the left-hand side and all the constant terms are combined into one number on the right-hand side, any necessary sign changes being made.

Four places of decimals are shown if necessary, but trailing zeroes following the decimal point are suppressed. E-format is used to prevent small numbers to be displayed as zeros.

Note

Nonlinear equations are treated differently. If the coefficient of a variable in the equation listing is enclosed in parentheses, then the corresponding constraint is nonlinear, and the value of the coefficient depends on the activity levels of one or more of the variables. The listing is not algebraic, but shows the partial derivative of each variable evaluated at their current level values.

Note that in the equation listing from our example the equation `dvar` is nonlinear. A simpler example will help to clarify the point. Consider the following equation and associated level values.

```
eq1.. 2*sqr(x)*power(y,3) + 5*x - 1.5/y =e= 2; x.l = 2; y.l = 3 ;
```

This equation will appear in the equation listing as:

```
eq1.. (221)*x + (216.1667)*y  =E=  2 ; (LHS = 225.5 ***)
```

The coefficient of x is determined by first differentiating the equation above with respect to x. This results in $2 \times (2 \times x.l) \times (y.l)^3 + 5$, which evaluates to 221, given that $x.l$ equals 2 and $y.l$ equals 3. Similarly, the coefficient of y is obtained by differentiating the equation above with respect to `y`, which results in $2 \times (x.l)^2 \times 3 \times (y.l)^2 + \frac{1.5}{(y.l)^2}$, giving 216.1667. Observe that the coefficient of y could not have been determined if its level had been left at zero. The attempted division by zero would have produced an error and premature termination. For further information on modeling NLP problems with GAMS, see the tutorial Good NLP Formulations.

The result of evaluating the left-hand side of the equation at the initial point is shown at the end of each individual equation listing. In the example above it is 225.5, and the three asterisks(***) are a warning that the constraint is infeasible at the starting point.

Note

The order in which the equations are listed depends on how the model was defined. If it was defined with a list of equation names, then the listing will be in the order of that list. If it was defined as `/all/`, then the list will be in the order of declaration of the equations. The order of the entries for the individual constraints is determined by the label entry order.

4.38.5.2 The Column Listing

The *column listing* or *variable listing* is the next part of the output. It is marked with the title `Column Listing` and contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default the first three entries for each variable are shown, along with their lower bound `.lo`, upper bound `.up` and current level values `.l`. Note that the default number of entries shown may be modified with the option limcol.

The format for the coefficients is exactly as in the equation listing, with the nonlinear coefficients enclosed in parentheses and the trailing zeroes dropped. The column listing from our Illustrative Model follows.

```
A Quadratic Programming Model for Portfolio Analysis (ALAN,SEQ=124a)
Column Listing      SOLVE portfolio Using NLP From line 50

---- x  fraction of portfolio invested in asset i

x(hardware)
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
        1       fsum
        8       dmean
       (0)      dvar

x(software)
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
        1       fsum
        9       dmean
       (0)      dvar

x(show-biz)
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
        1       fsum
       12       dmean
       (0)      dvar

REMAINING ENTRY SKIPPED

---- variance  variance of portfolio

variance
                (.LO, .L, .UP, .M = -INF, 0, +INF, 0)
       -1       dvar
```

Note

The order in which the variables appear is the order in which they were declared.

4.38.5.3 The Range Statistics

This block shows a statistic about the range of values seen in the model. Namely, it prints the range of absolute non-zero values for the bounds, right hand sides and matrix coefficients. Zero values are marked explicitly. This is the example output when running the model [**TRNSPORT**]:

```
Range Statistics    SOLVE transport Using LP From line 71

RANGE STATISTICS (ABSOLUTE NON-ZERO FINITE VALUES)

RHS       [min, max] : [ 2.750E+02, 6.000E+02] - Zero values observed as well
Bound     [min, max] : [        NA,        NA] - Zero values observed as well
Matrix    [min, max] : [ 1.260E-01, 1.000E+00]
```

Note the `NA` range for the bounds: For this model, the bounds are either `0` or `+INF`. Both values are excluded in this range calculation. Therefore we see the `NA` here.

4.38.5.4 The Model Statistics

The final information generated while a model is being prepared for solution is the statistics block. It is marked with the title `Model Statistics`. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of our Illustrative Model follow:

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Model Statistics    SOLVE portfolio Using NLP From line 50

MODEL STATISTICS

BLOCKS OF EQUATIONS           3     SINGLE EQUATIONS            3
BLOCKS OF VARIABLES           2     SINGLE VARIABLES            5
NON ZERO ELEMENTS            12     NON LINEAR N-Z              3
CODE LENGTH                  25     CONSTANT POOL              17

GENERATION TIME      =        0.004 SECONDS      4 MB

EXECUTION TIME       =        0.005 SECONDS      4 MB
```

The `BLOCK` counts indicate the number of GAMS symbols (`equations` and `variables`, respectively) appearing in the problem generated. The `SINGLE` counts indicate the number of individual rows and columns in the problem generated. The `NON ZERO ELEMENTS` entry refers to the number of nonzero coefficients in the problem matrix. To understand the remaining elements, some background will be useful.

For linear models, the model can be completely specified by the problem matrix and vectors for the RHS, etc. More is needed for noninear models. GAMS passes the nonlinear expressions defining the model algebra to the solvers in the form of *NL code* - opcode/address pairs in a simple stack-based language. For example, the expression `exp(x*y-1.675)` results in code similar to this:

```
PUSHV  column-index-of-x
MULV   column-index-of-y
SUBC   index-of-1.675
FUNC1  index-of-exp-function
STOR   index-of-row
```

In addition to containing indices refering to the rows and columns of the model, the NL code contains indices of constants used to define the model algebra. These constants are not contained in the NL code directly but rather in a separate pool or list of constants used for the model.

There are three entries that provide additional information about nonlinear models. The `NON LINEAR N-Z` entry refers to the number of nonlinear matrix entries in the model. Nonlinear models may differ in the complexity or size of the nonlinear expressions defining them. For example, `x*y` is a simpler form of nonlinearity than `exp(x*y)` and will require a shorter list of instructions to define, even though both of these terms result in two nonlinear entries in the matrix (one for x and one for y). The `CODE LENGTH` entry indicates the length of the NL code (i.e. number of instuctions) required to define the model algebra, while the `CONSTANT POOL` indicates the length of the constant pool that is used by the NL code. In general, the more nonlinear a problem is, the more difficult it tends to be to solve.

The times that follow statistics are also useful. The `GENERATION TIME` is the time used since compilation (syntax check) is finished. This includes the time spent in generating the model. The measurement units are given and represent ordinary clock time on personal computers or central processor usage (CPU) time on other machines. Memory use is given in megabytes.

4.38.6 The Solution Report

The *solution report* is the next part of the output. It is marked with the title `Solution Report` and includes the solve summary, the solver report, the solution listing, and the report summary.

4.38.6.1 The Solve Summary

The *solve summary* contains details about the solution process and is marked with the title `SOLVE SUMMARY`. The first part of the solve summary is common to all solvers and is discussed in this subsection. The second part of the solve summary is solver specific, it is covered in the subsection Solver Report below. The first part of the solve summary for our Illustrative Model follows.

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Solution Report     SOLVE portfolio Using NLP From line 50

               S O L V E      S U M M A R Y

     MODEL   portfolio           OBJECTIVE  variance
     TYPE    NLP                 DIRECTION  MINIMIZE
     SOLVER  MINOS               FROM LINE  50

**** SOLVER STATUS     1 Normal Completion
**** MODEL STATUS      2 Locally Optimal
**** OBJECTIVE VALUE                2.8990

 RESOURCE USAGE, LIMIT          0.188      1000.000
 ITERATION COUNT, LIMIT         5    2000000000
 EVALUATION ERRORS              0             0
```

The entry `MODEL` contains the name of the model being solved, `TYPE` provides the model type of the model, `SOLVER` shows the name of the solver used to solve the model, `OBJECTIVE` gives the name of the objective variable being optimized, `DIRECTION` shows the direction of optimization being performed and the entry `FROM LINE` provides the line number of the solve statement the solve summary refers to.

Note that the four asterisks make it easy to find the solve summary if it is searched for mechanically.

The entries `SOLVER STATUS` and `MODEL STATUS` contain the solver and model status for the problem respectively. Their possible values are given in Model Status table and Solver Status tables below. The entry `OBJECTIVE VALUE` provides the value of the objective function at the termination of the solve. This value is the optimum value for the problem provided the solver and model have the right status.

The entry `RESOURCE USAGE, LIMIT` reports the amount of wall clock time (in seconds) taken by the solver and the upper limit allowed for the solver. Note that the solver will stop as soon as the limit on time usage has been reached. The default limit may be changed with the option reslim. Observe that the option statement `option reslim = x;` - where `x` is the desired limit in wall clock seconds - must be entered in the model *before* the solve statement.

The entry `ITERATION COUNT, LIMIT` provides the number of iterations used by the solver and the upper limit allowed for the solver. The solver will stop as soon as this limit is reached. The default limit on iterations used is practically infinity. This limit may be changed with the option iterlim. Observe that the option statement `option iterlim = n;` - where `n` is the desired limit of the iterations used - must be entered in the model *before* the solve statement.

Finally, the entry `EVALUATION ERRORS` reports the number of numerical errors encountered by the solver and the upper limit allowed for the solver. These errors result from numerical problems like division by zero. Note that this is suppressed for LP, RMIP and MIP models since evaluation errors are not applicable for these model types. The default limit on evaluation errors used is zero. This limit may be changed with the option domlim. Observe that the option statement `option domlim = n;` - where `n` is the desired limit of the evaluation errors allowed - must be entered in the model *before* the solve statement.

Model Status

Value	Message	Description
1	OPTIMAL	The solution is optimal, that is, it is feasible (within tolerances) and it has been proven that no other feasible solution with better objective value exists. Note that the latter criterion is not influenced by the optcr and optca options.
2	LOCALLY OPTIMAL	A local optimum for an NLP has been found. That is, a solution that is feasible (within tolerances) and it has been proven that there exists a neighborhood of this solution in which no other feasible solution with better objective value exists.
3	UNBOUNDED	The solution is unbounded. This message is reliable if the problem is linear, but occasionally it appears for difficult nonlinear problems that are not truly unbounded, but that lack some strategically placed bounds to limit the variables to sensible values.
4	INFEASIBLE	The problem has been proven to be infeasible. If this was not intended, something is probably misspecified in the logic or the data.
5	LOCALLY INFEASIBLE	No feasible point could be found for the NLP problem from the given starting point. It does not necessarily mean that no feasible point exists.
6	INTERMEDIATE INFEASIBLE	The current solution is not feasible, but the solver stopped, either because of a limit (for example, iteration or resource) or because of some sort of difficulty. The solver status will give more information.
7	FEASIBLE SOLUTION	A feasible solution to a problem without discrete variables has been found.
8	INTEGER SOLUTION	A feasible solution to a problem with discrete variables has been found. There is more detail following about whether this solution satisfies the termination criteria (set by options optcr and optca).
9	INTERMEDIATE NON-INTEGER	An incomplete solution to a problem with discrete variables. A feasible solution has not yet been found. See section Model Termination Conditions for MIPs for more information.
10	INTEGER INFEASIBLE	It has been proven that there is no feasible solution to a problem with discrete variables. See section Model Termination Conditions for MIPs for more information.
11	LIC PROBLEM - NO SOLUTION	The solver cannot find the appropriate license key needed to use a specific subsolver.
12	ERROR UNKNOWN	After a solver error the model status is unknown.
13	ERROR NO SOLUTION	An error occurred and no solution has been returned. No solution will be returned to GAMS because of errors in the solution process.
14	NO SOLUTION RETURNED	A solution is not expected for this solve. For example, the CONVERT solver only reformats the model but does not give a solution.

Value	Message	Description
15	SOLVED UNIQUE	Indicates the solution returned is unique, i.e. no other solution exists. Used for CNS models. Examples where this status could be returned include non-singular linear models, triangular models with constant non-zero elements on the diagonal, and triangular models where the functions are monotone in the variable on the diagonal.
16	SOLVED	Indicates the model has been solved: used for CNS models. The solution might or might not be unique. If the solver uses status 17 - SOLVED SINGULAR wherever possible then this status implies that the Jacobian is non-singular, i.e. that the solution is at least locally unique.
17	SOLVED SINGULAR	Indicates the CNS model has been solved, but the Jacobian is singular at the solution. This can indicate that other solutions exist, either along a line (for linear models) or a curve (for nonlinear models) including the solution returned.
18	UNBOUNDED - NO SOLUTION	The model is unbounded and no solution can be provided.
19	INFEASIBLE - NO SOLUTION	The model is infeasible and no solution can be provided.

Note that the model status is stored in the model attribute modelStat. For details on model attributes, see section Model Attributes. Observe that there are compile-time constants that are related to this model attribute.

Solver Status

Value	Message	Description
1	NORMAL COMPLETION	The solver terminated in a normal way: it was not interrupted by a limit (resource, iterations, nodes or other) or by internal difficulties. The model status describes the characteristics of the accompanying solution.
2	ITERATION INTERRUPT	The solver was interrupted because it used too many iterations. The option iterlim may be used to increase the iteration limit if everything seems normal.
3	RESOURCE INTERRUPT	The solver was interrupted because it used too much time. The option reslim may be used to increase the time limit if everything seems normal.
4	TERMINATED BY SOLVER	The solver encountered some difficulty and was unable to continue. More details will appear following the message.
5	EVALUATION INTERRUPT	Too many evaluations of nonlinear terms at undefined values. We recommend to use variable bounds to prevent forbidden operations, such as division by zero. The rows in which the errors occur are listed just before the solution.
6	CAPABILITY PROBLEMS	The solver does not have the capability required by the model. For example, some solvers do not support certain types of discrete variables or support a more limited set of functions than other solvers.
7	LICENSING PROBLEMS	The solver cannot find the appropriate license key needed to use a specific subsolver.
8	USER INTERRUPT	The user has sent a message to interrupt the solver via the interrupt button in the IDE or sending a Control+C from a command line.

Value	Message	Description
9	ERROR SETUP FAILURE	The solver encountered a fatal failure during problem set-up time.
10	ERROR SOLVER FAILURE	The solver encountered a fatal error.
11	ERROR INTERNAL SOLVER FAILURE	The solver encountered an internal fatal error.
12	SOLVE PROCESSING SKIPPED	The entire solve step has been skipped. This happens if execution errors were encountered and the GAMS parameter ExecErr has been set to a nonzero value or the property MaxExecError has a nonzero value.
13	ERROR SYSTEM FAILURE	This indicates a completely unknown or unexpected error condition.

Note that the solver status is stored in the model attribute solveStat. For details on model attributes, see section Model Attributes. Observe that there are compile-time constants that are related to this model attribute.

4.38.6.2 Solver Report

The next section in the listing file is the part of the solve summary that is particular to the solver program that has been used. This section normally begins with a message identifying the solver and its authors: MINOS and QUADMINOS was used in the example here. There will also be diagnostic messages in plain language if anything unusual was detected and specific performance details, some of them probably technical. The solver manual of the respective solver will help explain these. In case of serious trouble, the GAMS listing file will contain additional messages printed by the solver. This may help identify the cause of the difficulty. If the solver messages do not help, a perusal of the solver documentation or help from a more experienced user is recommended. The solver report from our Illustrative Model follows.

```
GAMS/MINOS
M I N O S  5.6      (Nov 2014)

    GAMS/MINOS 5.6, Large Scale Nonlinear Solver
    B. A. Murtagh, University of New South Wales
    P. E. Gill, University of California at San Diego,
    W. Murray, M. A. Saunders, and M. H. Wright,
    Systems Optimization Laboratory, Stanford University

 Work space allocated           --     0.77 Mb

 EXIT - Optimal Solution found, objective:        2.899038
```

Note that the line `Work space allocated -- 0.77 MB` provides the amount of memory used by the solver for the problem. The solver estimates the amount of memory it will need to solve the problem. If this amount is not available on the machine used, GAMS will return a message saying that not enough memory was allocated. In addition, GAMS will return the maximum amount of memory available on the machine. The user may direct the solver to use less memory with the model attribute `.workspace`:

```
mymodel.workspace = x;
```

Here `mymodel` is the name of the model being solved as specified by the model statement and `x` is the amount of memory in Megabytes. Note that the solver will attempt to solve the problem with `x` MB of memory. However, it is not guaranteed to succeed since the problem may require more memory.

Note that more information for a successful run may be obtained using the option sysout. As usual, the respective option statement should be placed *before* the solve statement.

4.38.6.3 The Solution Listing

The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed with four pieces of information. The solution listing may be suppressed with the option solPrint:

```
option solprint = off ;
```

This option statement should be placed *before* the solve statement. The solution listing generated from our Illustrative Model is shown below.

```
                            LOWER          LEVEL          UPPER         MARGINAL

---- EQU fsum                1.0000         1.0000         1.0000       -13.5288
---- EQU dmean              10.0000        10.0000        10.0000         1.9327
---- EQU dvar                  .              .              .           -1.0000

  fsum  fractions must add to 1.0
  dmean  definition of mean return on portfolio
  dvar  definition of variance

---- VAR x  fraction of portfolio invested in asset i

                LOWER          LEVEL          UPPER         MARGINAL

hardware           .            0.3029         +INF             .
software           .            0.0865         +INF     6.217249E-15
show-biz           .            0.5048         +INF             .
t-bills            .            0.1058         +INF           EPS

                            LOWER          LEVEL          UPPER         MARGINAL

---- VAR variance          -INF            2.8990         +INF             .

  variance  variance of portfolio
```

The order of the equations and variables is the same as in the symbol listing map.

The four columns associated with each entry correspond to the equation and variable attributes and have the following meaning:

`LOWER` lower bound (`.lo`)

`LEVEL` level value (`.l`)

`UPPER` upper bound (`.up`)

`MARGINAL` marginal (`.m`)

For variables, the values in the `LOWER` and `UPPER` columns refer to the lower and upper bounds. For equations, they are obtained from the (constant) right-hand side value and from the relational type of the equation. For details see section Variable Attributes and Equation Attributes. Note that instead of `level` values, `slack` values may be shown in equations. For more information, see section Customizing the Output File below.

Note

The LEVEL and MARGINAL values have been determined by the solver and the values shown are used to update the GAMS values. In the list they are shown with fixed precision, but the values are returned to GAMS with full machine accuracy. The single dots '.' on the list represent zeros.

EPS is the GAMS extended value used for a stored zero. It is common to see a marginal value given as EPS, since GAMS uses the convention that marginals are necessarily zero for basic variables and typically non-zero for other variables.

Note

EPS is used to indicate non-basic variables whose marginal values are at or close to zero, and for nonlinear problems to indicate superbasic variables whose marginals are at or close to zero. A superbasic variable is one between its bounds at the final point but not in the basis.

Note that in the Glossary there are brief explanations of technical terms that were used in this section.

For models that are not solved to optimality or for models types without an objective, some constraints may additionally be marked with certain flags. The list of these flags and their description is given in the following table.

Shorthand Symbol	Description
INFES	The row or column is **infeasible**. This mark is made for any entry where the level value is not between the upper and lower bounds.
NOPT	The row or column is **non-optimal**. This mark is made for any non-basic entries for which the marginal sign is incorrect, or superbasic ones for which the marginal value is too large.
UNBND	The row or column can increase without limit (e.g. in an unbounded ray) or has an excessively large magnitude.
REDEF	The equation type has been ignored or redefined for this solution point, e.g. because this is an MCP
REDIR	The equation has been flipped (i.e. negated or reoriented) in the model statement: useful for MCP and EMP
DEPND	The row or column is dependent on other rows or columns in the system: see CNS

4.38.6.4 Report Summary

The final section of the solution report is the report summary, marked with four asterisks (as are all important components of the output) followed by the title REPORT SUMMARY. It shows the count of rows or columns that have been marked INFES, NOPT or UNBND in the solution listing. For model types like MCP where REDEFs and REDIRs are possible, the counts for these markers may also be shown. The sum of infeasibilities will be shown if the reported solution is infeasible. The domain error count is only shown if the problem is nonlinear. If there are variables or equations where the levels were projected to one of the bounds, the count of those is also shown here.

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
Solution Report     SOLVE portfolio Using NLP From line 50

**** REPORT SUMMARY :        0     NONOPT
```

```
    0 INFEASIBLE
    0  UNBOUNDED
    0     ERRORS
   42  PROJECTED
```

4.38.7 Post-Solution Output

The final part of the listing file is the post-solution output. It contains Final Execution Summary and the File Summary.

4.38.7.1 Final Execution Summary

The final execution summary is marked with the title `Execution` and contains the output from display statements that were placed *after* the solve statement in the model, allowing simple reporting. In addition, it shows the final exection time and memory use. The respective ouput from our Illustrive Model follows.

```
A Quadratic Programming Model for Portfolio Analysis ALAN,SEQ=124a)
E x e c u t i o n

----     51 VARIABLE x.L  fraction of portfolio invested in asset i

hardware 0.303,    software 0.087,    show-biz 0.505,    t-bills  0.106

----     51 VARIABLE variance.L            =        2.899  variance of portfolio

EXECUTION TIME       =        0.001 SECONDS      3 MB
```

For further information on this output and ways to customize it, see chapter The Display Statement.

4.38.7.2 File Summary

The file summary is the very last part of the output file. If output has been written to put files, there will be a `REPORT FILE SUMMARY` that is marked with four asterisks. The report will list the put files with their internal names and the full paths of their external names.

All listing files have a `FILE SUMMARY` that is marked with four asterisks and that reports the names of the input and output (listing) files.

```
**** FILE SUMMARY

Input      C:\PROGRAM FILES\\gamsIDE\ALAN.GMS
Output     C:\PROGRAM FILES\\gamsIDE\ALAN.LST
```

If work files (save or restart) have been used, they will be listed in the file summary as well.

4.38.8 Error Reporting

All comments and descriptions about errors have been collected in this section for easy reference when disaster strikes.

Effective error detection and recovery are important parts of any modeling system. GAMS is designed around the assumption that the *error state* is the normal state of modeling. Experience shows that most compilations during the early stages of development will produce errors. Not to worry! The computer is much better at checking details than the human mind and should be able to provide positive feedback and suggestions about how to correct errors or avoid ambiguities. Developing a model is like writing a paper or an essay; many drafts and rewrites are required until the arguments are presented in the most effective way and meet all the requirements of proper English. GAMS acts like a personal assistant with knowledge of mathematical modeling and of the syntactic and semantic details of the language.

Errors are detected at various stages in the modeling process. Most of them are caught at the compilation stage, which behaves like the proofreading stage of the modeling process. Once a problem has passed through the rigorous test of this stage, the error rate drops to almost zero. Most of the execution runs, which are much more expensive than compilation, proceed without difficulties because GAMS *knows* about modeling and has anticipated problems. Many of the typical errors made with conventional programming languages are associated with concepts that do not exist in GAMS. Those error sources – like address calculations, storage assignment, subroutine linkages, input-output and flow control – create problems at execution time, are difficult to locate, often lead to long and frustrating searches, and leave the computer user intimidated. GAMS takes a radically different approach. Errors are spotted as early as possible, they are reported in a way that is comprehensible to the user, including clear suggestions for how to correct the problem and a presentation of the source of the error in terms of the problem of the user.

Note

All errors are marked with four asterisks '****' at the beginning of a line in the output listing.

As soon as an error is detected, processing will be stopped at the next convenient opportunity. A model will never be solved after an error has been detected. The only remedy is to fix the error and repeat the run.

Errors are grouped into the three phases of GAMS modeling: compilation, execution and model generation (which includes the solution that follows). In the following subsections we will discuss the errors that may occur in each of these phases.

4.38.8.1 Compilation Errors

Compilation errors are discussed in some detail in the tutorial A GAMS Tutorial by Richard E. Rosenthal and the tutorial Fixing Compilation Errors. Note that there is some overlap between the material in the tutorials and this section. Several hundred different types of errors can be detected during compilation and can often be traced back to just one specific symbol in the GAMS input. Most of the errors are caused by simple mistakes: forgetting to declare an identifier, putting indices in the wrong order, leaving out a necessary semicolon or misspelling a label. For errors that are not caused by such simple mistakes, the explanatory error message text will help diagnose the problem and correct it.

Note

When a compilation error is discovered, a dollar symbol and error number are printed below the offending symbol (usually to the right) on a separate line that begins with four asterisks.

If more than one error is encountered on a line (possibly because the first error caused a series of other spurious errors) the dollar signs may be suppressed and error number squeezed. GAMS will not list more than 10 errors on any one line.

Note

A list of all error numbers encountered and a description of the probable cause of each error is printed at the end of the echo print of the program. The error messages are self-explanatory. For further information on compilation errors and advice on how to resolve them, see the tutorial Fixing Compilation Errors.

It is worth noting that it is easy to produce a model that does not do what you want it to do, but does not contain errors in the sense that the term is being used in this section. The best precaution is to check your work carefully and build in as many automatic consistency checks as possible.

Note that if a GAMS reserved word is accidentally used for the name of a label or an identifier it is impossible to provide helpful error messages for technical reasons. This may cause confusion. We recommend users to familiarize themselves with the reserved words.

Attention

In some cases an error may not be detected until the statement following its occurrence, where it may produce a number of error conditions whose explanations seem quite silly. We recommend to always check carefully for the cause of the first error in such a group. If nothing obvious is wrong, look at the previous statement and particularly watch out for missing semicolons.

The following example illustrates the general reporting format for compilation errors.

```
   1  Set c crops / wheat, corn, wheat, longaname /
****                                  $172
   2  Parameter price(c) / wheat 200, cotton 700 /
****                                       $170
   3
Error Messages

170  Domain violation for element
172  Element is redefined

**** 2 ERROR(S)   0 WARNING(S)
..
**** USER ERROR(S) ENCOUNTERED
```

4.38.8.2 Compilation Time Errors

The reporting format for errors found while analyzing solve statements is more complicated than for normal compilation errors, mainly because many things must be checked. All identifiers referenced must be defined or assigned, the mathematics in the equations must match the model class, and so on. More elaborate reporting is required to accurately describe any problems found. The solve statement is only checked if the model has been found to be error free up to this point. This is not only because the check is comparatively expensive, but also because many erroneous and confusing messages can be produced while checking a solve in a program containing other errors.

Attention

Compiler error messages related to a solve statement are reported in two places and in two formats:

1. They are shown immediately after the solve statement with a short text including the name of any offending identifier and the type of model involved. This will be sufficient in most cases.
2. A longer message with some hints appears with the other error messages at the end of the compilation.

The example below illustrates the general reporting format for compiler errors associated with a solve statement.

```
   1  Variables x, y, z ;
   2  Equations eq1 , eq2 ;
   3
   4  eq1.. x**2 - y =e= z ;
   5  eq2.. min(x,y) =l= 20 ;
   6
   7  Model silly / all / ;
   8  solve silly using lp maximizing z ;
****                                  $54,51,256
**** THE FOLLOWING LP ERRORS WERE DETECTED IN MODEL SILLY:
**** 54 IN EQUATION EQ1         .. ENDOG OPERANDS FOR **
**** 51 IN EQUATION EQ2         .. ENDOG ARGUMENT(S) IN FUNCTION
   9

Error Messages

 51  Endogenous function argument(s) not allowed in linear models
 54  Endogenous operands for ** not allowed in linear models
256  Error(s) in analyzing solve statement. More detail appears
     Below the solve statement above

**** 3 ERROR(S)   0 WARNING(S)
**** USER ERROR(S) ENCOUNTERED
```

4.38.8.3 Execution Errors

Execution time errors are usually caused by illegal arithmetic operations such as division by zero or taking the log of a negative number. GAMS prints a message on the output file with the line number of the offending statement and continues execution. A GAMS program should never abort with an unintelligible message from the computer's operating system if an invalid operation is attempted. GAMS has rigorously defined an extended algebra that contains all operations including illegal ones. Note that the model **[CRAZY]** contains all non-standard operations and should be executed to study for its exceptions. For advice on detecting and resolving execution errors, see the tutorial Finding and Fixing Execution Errors and Performance Problems.

Recall that the GAMS arithmetic is defined over the closed interval [-INF,+INF] and contains the extendedn range arithmetic values EPS (small but not zero), NA (not available) and UNDF (the result of an illegal operation). The results of illegal operations are propagated through the entire system and can be displayed with standard display statements. However, observe that, if errors have been previously detected, a model cannot be solved and a work file cannot be saved.

4.38.8.4 Solve Errors

The execution of a `solve` statement can trigger additional errors called *matrix errors*. They report on problems encountered during transformation of the model into a format required by the solver. Problems are most often caused by illegal or inconsistent bounds, or by an extended range value that is used as a matrix coefficient. The example below shows the general format of these errors:

```
   1  Variable x;
   2  Equation eq1;
   3
   4  eq1.. x =l= 10 ;
   5  x.lo = 10 ;
   6  x.up = 5 ;
   7  Model wrong /eq1/;
   8  solve wrong using lp maximizing x ;
   9

**** Matrix error - lower bound > upper bound
x   (.LO, .L, .UP = 10, 0, 5)
...
**** SOLVE from line 8 ABORTED, EXECERROR = 1
...
**** USER ERROR(S) ENCOUNTERED
```

Some `solve` statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the solution report. Note that by default the subsystems will interrupt the solution process if arithmetic exceptions are encountered. This may be changed with the option domlim. They are then reported on the listing as shown in the following example:

```
   1  Variable x, y;
   2  Equation one;
   3
   4  one.. y =e= sqrt(10/x);
   5  x.l = 10;
   6  x.lo = 0;
   7
   8  Model divide /  all / ;
   9  solve divide maximizing y using nlp;

               S O L V E      S U M M A R Y

     MODEL   divide              OBJECTIVE  y
     TYPE    NLP                 DIRECTION  MAXIMIZE
     SOLVER  MINOS               FROM LINE  9

**** SOLVER STATUS     5 Evaluation Interrupt
**** MODEL STATUS      7 Feasible Solution
**** OBJECTIVE VALUE    3.1622776602E+0149

 RESOURCE USAGE, LIMIT          0.182      1000.000
 ITERATION COUNT, LIMIT         0    2000000000
 EVALUATION ERRORS              2             0

EXIT - Function evaluation error limit exceeded.
```

```
**** ERRORS/WARNINGS IN EQUATION one
     2 error(s): div: FUNC SINGULAR: x/y, |y| <= 1e-150 (RETURNED 1E299)

**** REPORT SUMMARY :         1     NONOPT ( NOPT)
                              0 INFEASIBLE
                              0  UNBOUNDED
                              1     ERRORS ( ****)
```

Note that the solver status returned with a value of 5, meaning that the solver has been interrupted because more than `domlim` evaluation errors have been encountered. The type of evaluation error and the equation causing the error are also reported.

In case the solver returns an intermediate feasible solution because of evaluation errors, the following solve will still be attempted. The only fatal GAMS error that can be caused by a solver program, is the failure to return any solution at all. If this happens all possible information is listed on the GAMS output file and any solves that follow will not be attempted.

4.38.9 Customizing the Output File

This section reviews the most commonly used dollar control options, options, and command line parameters to customize output in the listing file. Table 1 lists dollar control options, options, and command line parameters that are used in the input file to control the amount of detail in the output file produced by the GAMS compiler. Table 2 lists dollar control options and command line parameters that can change the layout and appearance of the output. The first column of the two tables shows the purpose of customizing the output that differs from the GAMS default behavior.

The output generated by display statements can also be customized. This topic is covered in section Display Controls from chapter The Display Statement. See also the complete list of dollar control options that affect the output format in section Dollar Control Options Affecting the Output Format.

Table 1: ***Customization of output to be included in the listing file***

Customization	Method	Further Details
suppress the echo print	$offlisting	$onlisting restores the default behavior. Any lines between $offlisting and $onlisting will not appear in the echo print.
suppress include files in the echo print	$offinclude	$oninclude restores the default behavior.
activate the symbol reference map	$onSymXRef	Maps are most often turned on or off at the beginning of the program and left as initially set. $onSymXRef activates the symbol reference map and $offSymXRef restores the default behavior.
activate the symbol listing map	$onSymList	Maps are most often turned on or off at the beginning of the program and left as initially set. $onSymList activates the symbol listing map and $offSymList restores the default behavior.
activate the unique element listing	$onUELList	Maps are most often turned on or off at the beginning of the program and left as initially set. $onUELList activates the unique element listing and $offUELList restores the default behavior.

Customization	Method	Further Details
activate the unique element reference map	$onUELXRef	Maps are most often turned on or off at the beginning of the program and left as initially set. $onUELXRef activates the unique reference map $offUELXRef restores the default behavior.
suppress or expand the equation listing	option limrow	The statement `option limrow = 0;` will suppress the equation listing; the statement `option limrow = n;` will expand it to `n` equations. The statement must be placed *before* The Solve Statement.
suppress or expand the column listing	option limcol	The statement `option limcol = 0;` will suppress the column listing; the statement `option limcol = n;` will expand it to `n` columns. The statement must be placed *before* The Solve Statement.
suppress the solution listing	option solPrint	The statement `option solPrint = off;` will suppress the solution listing. The statement must be placed *before* The Solve Statement.
restrict output to just a few displays	save restart feature	With this strategy the listing file will contain only the output generated by the desired display statements. This facilitates concentrating on a narrow set of output while remaining capable of generating a lot more output. For details see section Generating Concise Listing Files in chapter The Save and Restart Feature.
show slack variables in the solution listing	option solslack	The statement `option solslack = 1;` causes the equation output in the solution listing to show slack (`.slack`) variable values instead of level (`.l`) values. The statement must be placed *before* The Solve Statement.

Table 2: ***Customization that changes the output layout***

Customization	Method	Further Details
change the default header	$title	The directive $title causes every page on the output to have the header specified in `text`. The header may be reset later by using another line starting with $title . Currently, the `text` may have up to 80 characters.
add a subheader	$stitle	The statement `$stitle text` causes every page on the output to have the subheader specified in `text`. The header may be reset later by using another line starting with $stitle. Currently, the `text` may have up to 80 characters.

Customization	Method	Further Details
start a new page in the echo print	$eject	
start a new page in LST file if less than n lines are left	$lines	The directive is $lines, where n is the number of lines left on the current page.
change width and length of a page	command line parameters PageWidth and PageSize	The general syntax is: gams mymodel pw=n ps=m. Here n is desired page width and the desired page length is m. Note that pw and ps are synonyms of PageWidth and PageSize respectively.
change the echo print to upper case only	$onUpper	The directive $offUpper restores the default.
change lines in the echo print to be double spaced	$double	The directive $single restores the default beahvior.
change the marker ****	$stars	

4.39 GAMS Log

4.39.1 Introduction

The GAMS log provides the log of a GAMS run including the GAMS job description, defined command line parameters, license information, solver log, and GAMS compilation and execution output. Looking at the log gives a brief idea about the success of a GAMS run and is usually a useful first step in debugging a GAMS model. The detailed output from GAMS is displayed in the output file. Log output can be obtained in the form of a text file (typically with .log extension) that is generated with each GAMS run based on the command line parameters logOption and logFile. The GAMS log consists of three major sections: header, compilation log, and execution log.

4.39.2 Header

The header of the GAMS log consists of information that is independent of the content of the executed GAMS file. It contains the job description, parameter log, and license log.

4.39.2.1 Job Description

In this line, the name of the GAMS file being run along with a timestamp, the GAMS version and operating system information is provided.

```
--- Job trnsport.gms Start 08/30/21 17:29:15 36.1.0 r2c0a44a WEX-WEI x86 64bit/MS Windows
```

4.39.2.2 Parameter Log

The default parameters for the operating system and configuration are obtained via parameter file (gmsprmNT.txt on Windows, gmsprmun.txt on Linux, gmsprmun.txt on macOS) and gamsconfig.yaml files. The parameter log explicitly lists all additional parameters in the following lines. For example, input displays the full path of the GAMS input file. In the example log provided below, the output file option PageSize is set to 0. ScrDir is the full path to the scratch directory; SysDir is the full path to the systems directory, logOption is defined that controls the location of the output log.

```
--- Applying:
    C:\GAMS\36\gmsprmNT.txt
    C:\Users\jsmith\Documents\GAMS\gamsconfig.yaml
--- GAMS Parameters defined
    Input C:\test\trnsport.gms
    PageSize 0
    ScrDir C:\test\225a\
    SysDir C:\GAMS\36\
    LogOption 3
    ErrMsg 1
    ErrorLog 99
    IDE 1
    LstTitleLeftAligned 1
```

4.39.2.3 License Log

This section provides information about the license such as licensee, the organization, and the license number is provided on the second line. The full path to the license file that is being read is provided on the third line. The last line in the image shows the GAMS license type being used.

```
Licensee: John Smith                                    G201001/0001CS-GEN
          The ACME Corporation, USA                                 DC0000
          C:\Users\jsmith\Documents\GAMS\gamslice.txt
          Other time limited license
```

4.39.2.4 Processor Information and GAMS version

This section provides information about the processor and GAMS version being used.

```
Processor information: 1 socket(s), 8 core(s), and 16 thread(s) available
GAMS 36.1.0   Copyright (C) 1987-2021 GAMS Development. All rights reserved
```

4.39.3 Compilation Log

A GAMS run consists of two phases: compilation and execution. The following lines provide details about the compilation, memory usage, the time elapsed in compilation. The number in parentheses refers to the line number in the echo print of the input file. In addition to the above-mentioned output, this part of the log also contains information about the output such as as GDX files, the files included using $include, and outputs of commands such as $call as shown in the following lines.

```
--- Starting compilation
--- clad.gms(27) 2 Mb
--- $echo File C:\test\includefilename.gms
--- clad.gms(30) 2 Mb
--- . includefilename.gms(1) 2 Mb
--- clad.gms(32) 2 Mb
--- call echo "hello!"
"hello!"
--- clad.gms(45) 3 Mb
--- GDXin=C:\test\claddat.gdx
--- GDX File ($gdxIn) C:\test\claddat.gdx
--- clad.gms(164) 3 Mb
```

4.39.4 Execution Output

The beginning of the execution phase of the GAMS run is clearly indicated in the GAMS log:

```
--- Starting execution: elapsed 0:00:00.010
```

In general, the execution log output indicates the progress of the GAMS job, including line numbers, memory usage, elapsed time for the run, and time required for long-running statements. Several statements also result in specific log output.

Output of GDX files generated using execute_unload is shown in the log as follows.

```
--- GDX File (execute_unload) path\to\outputfile.gdx
```

The output for reference files generated is shown in the log as follows.

```
--- RefFile  path\to\trnsport.ref
```

Similarly, the information about a file written using the Put writing facility is mentioned in the log as follows.

```
--- Putfile results  path\to\results.txt
```

The output of the program flow control features such as abort is shown as follows.

```
*** Error at line 61: Execution halted: abort$1 'model not solved as expected'
```

If there are loops in the program, the log shows information about the current iteration as follows.

```
--- LOOPS scen = s1
```

Similar to the output of call command shown during compilation phase, the output for execute command is shown in the execution phase. The following line of GAMS code

```
execute "echo output of execute command";
```

will result in the following output in the log.

```
--- trnsport.gms(67) 4 Mb
output of execute command
```

For each solve statement, there will also be a solver log embedded in the execution output (see below for details regarding the solver log). After a solver log, the execution output continues. It ends with the status of the GAMS Job (here `*** Status:  Normal completion`), a timestamp and the total run time of the GAMS job.

```
--- Executing after solve: elapsed 0:00:02.892
--- trnsport.gms(66) 4 Mb
*** Status: Normal completion
--- Job trnsport.gms Stop 08/30/21 17:29:18 elapsed 0:00:02.892
```

4.39.4.1 Solver Log

One of the most important GAMS statements is the solve statement: a solve results in a substantial amount of log output.

The first line in the execution output is about model generation. Model generation can take a long time in which case the log also shows progress and equations that take long to generate.

```
--- Generating LP model transport
--- trnsport.gms(64) 4 Mb
---   6 rows  7 columns  19 non-zeroes
```

This is followed by some statistics about the range of values seen in the model:

```
--- Range statistics (absolute non-zero finite values)
--- RHS       [min, max] : [ 2.750E+02, 6.000E+02] - Zero values observed as well
--- Bound     [min, max] : [        NA,        NA] - Zero values observed as well
--- Matrix    [min, max] : [ 1.260E-01, 1.000E+00]
```

After model generation, the solver name and solveLink are displayed.

```
--- Executing CPLEX (Solvelink=2): elapsed 0:00:02.066
```

The log output following this line is specific to the solver and will usually display the objective function value.

```
Optimal solution found
Objective:          153.675000
```

4.40 The GAMS Call and Command Line Parameters

There are multiple ways to trigger the run of a GAMS model: Running a model via `F9` from GAMS Studio, executing `GAMSJob.Run` method in the object oriented APIs or calling the `gams` executable from a command line. In all cases the same GAMS engine runs the user's model. Several options are available to customize the GAMS run. Depending on the particular way GAMS is triggered these options are supplied in different ways. For example, in Studio via the parameter editor in the toolbar, in the object oriented API through the GAMSOptions class, and from the command line via command line arguments. In order to avoid confusion with the often used word *option* we refer to these entities as *command line parameters* and demonstrate their use from the command line. Although details will vary with the type of computer and operating system used, the general operating principles are the same on all machines.

In this chapter we will introduce how GAMS is called from the command line and how parameters may be specified on the command line or in other ways. In addition, we will discuss user-defined command line parameters, compile-time variables and compile-time constants, which are GAMS specialties, and environment variables in GAMS. Moreover, most of the chapter is dedicated to the detailed description of all GAMS options (i.e. options available via command line parameters, option statement, and model attribute.

In almost all cases such a run continues from start to end without any user interaction. A GAMS run usually consists of two phases: the compilation and execution phase.

4.40.1 The Generic GAMS Call

The simplest way to start GAMS from a command shell is to enter the following command from the system prompt:

```
> gams myfile
```

GAMS will compile and execute the GAMS statements in the file `myfile`. If a file with this name cannot be found, GAMS will look for a file with the extended name `myfile.gms`. During the run GAMS will print a log to the console and create a listing file that is written by default to the file `myfile.lst`. For example, the following statements retrieves and runs the model [**TRNSPORT**] from the GAMS model library with the responds from the GAMS system:

```
> gamslib trnsport
Copy ASCII : trnsport.gms
> gams trnsport
--- Job trnsport Start 06/21/17 06:23:45 24.8.4 r60966 WEX-WEI x86 64bit/MS Windows
GAMS 24.8.4   Copyright (C) 1987-2017 GAMS Development. All rights reserved

```

Note

GAMS can also run source files that have been compressed with Posix utility `gzip` or have been encrypted with tool ENDECRYPT, for example

```
> gamslib trnsport
> gzip trnsport.gms
> gams trnsport.gms.gz
```

results in

- retrieval of the [**TRNSPORT**] model from the **GAMS Model Library**
- compression the source file `trnsport.gms`
- GAMS running the compressed file `trnsport.gms.gz`.

Observe that some GAMS options may be specified on the command line as part of the GAMS call. In addition, command line parameters may be set by specifying a secondary customization parameter file and by modifying the GAMS system parameter file. As command line parameters may be specified in several different ways, there are rules of precedence in case of conflicting instructions. We will discuss these topics in the next four subsections.

4.40.1.1 Specifying Options Through the Command Line

GAMS permits certain options to be passed through the command line. The syntax of the simple GAMS call is extended as follows:

```
> gams myfile key1=value1 key2=value2 ...
```

Here `key1` is the name of the option that is being set on the command line and `value1` is the value to which the option is set. Depending on the option, `value1` could be a character string, an integer number or a real number. Note that the options that may be set on the command line are called *GAMS command line parameters*.

For example, consider the following commands to run the transportation model [**TRNSPORT**]:

```
> gams trnsport  o myrun.lst  logOption 2
> gams trnsport -o myrun.lst -logOption 2
> gams trnsport /o myrun.lst /logOption 2
> gams trnsport  o=myrun.lst  logOption=2
> gams trnsport -o=myrun.lst -logOption=2
> gams trnsport /o=myrun.lst /logOption=2
```

All six commands above are equivalent: each directs the output listing to the file `myrun.lst`. Note that `o` is the synonym of the command line parameter output and it is set to the value `myrun.lst`. In addition, the parameter LogOption is set to 2, which has the effect that the log output is redirected to the file `trnsport.log`. Please also note that the option name can be specified without consideration of the casing of the option. Hence `logoption` works as well as `LogOption` or any other casing. The way options are specified can vary with each option. So a mixed alternative, e.g. `gams trnsport -o=myrun.lst /logoption 3` is valid too.

In addition to predefined command line parameters, GAMS also allows user-defined command line parameters which work in tandem with compile-time variables. User-defined parameters, also called *double dash parameters*, and compile-time variables are introduced in section Double Dash Parameters, Compile-Time Variables and Environment Variables below.

Option Values with Spaces

One may want to set string valued options including double dash parameters to an empty string or a string containing spaces, even trailing or leading spaces. All this requires the use of quotes. Quotes may be handled differently, depending on the operating system. Users should be attentive when using such string values. This is also important if GAMS is called from within a GAMS program with $call [=]gams ... and execute [=]gams ... because platform independence might be violated.

A platform independent way to set a string value with spaces is to use the variant that separates the option name and option value by a space, e.g. `opt ""`. The variant without space, e.g. `opt=""` might cause issues on some Unix shells. Consider the following example where `spacy.gms` contains only the following line to write the content of the double dash parameter dd to the log:

```
$log value of dd: >%dd%<
```

Here is a sequence of GAMS runs with a variety of string values

```
> gams spacy --dd normal
> gams spacy --dd "normal"
> gams spacy --dd ""
> gams spacy --dd " leading"
> gams spacy --dd "trailing "
> gams spacy --dd " leading and trailing "
> gams spacy --dd "   "
```

that result on all platforms in the following log output (only relevant part):

```
value of dd: >normal<
value of dd: >normal<
value of dd: ><
value of dd: > leading<
value of dd: >trailing <
value of dd: > leading and trailing <
value of dd: >   <
```

An even better way to pass arguments to a GAMS run without the system shell interfering with interpretation of some characters is described in the next section.

Attention

> GAMS options specifying file names may also contain leading and trailing blanks. Please be aware that while leading blanks in a file name are significant on all platforms, trailing blanks are only significant on some platforms (e.g. Linux). Hence `output "mymodel.lst "` and `output "mymodel.lst"` refer to the same file on Windows and to different files on Linux.

4.40.1.2 Specifying Options Through a Secondary Parameter File

Command line parameters may also be set by specifying a secondary customization parameter file. For example, we will create a file with the following two lines, call it `moreOptions.txt` and save it in the current working directory.

```
limCol=0
limRow=0
```

Note that setting limcol and limrow to zero will suppress the column listing and equation listing respectively. Moreover, note that we can specify the option in different way in this secondary parameter file, even have multiple options on one line. In the next step we will use the following command to run the transportation model [**TRNSPORT**]:

```
> gams trnsport parmFile=moreOptions.txt
```

Note that this call has the same effect as the following specification:

```
> gams trnsport limCol=0 limRow=0
```

Observe that command line parameter include files are particularly useful if modelers wish to use the same set of command line parameters repeatedly.

If options are listed multiple times on the command line, the last specification sets the option. This is important in particular in combination with a secondary parameter file. In the following example, GAMS will operate with `limRow=0`:

```
> gams trnsport limRow=10 parmFile=moreOptions.txt
```

while with the order reversed, GAMS operates with `limrow=10`:

```
> gams trnsport parmFile=moreOptions.txt limRow=10
```

4.40.1.3 Specifying Options Through the GAMS System Parameter File

A third way to specify command line parameters is by modifying the GAMS system parameter file, which is part of the GAMS system. It has different names depending on the operating system: `gmsprmnt.txt` for Windows and `gmsprmun.txt` for UNIX/Linux and macOS. The parameter file may be modified in the following way:

```
*****************************************************************
* GAMS 2.50 default Unix parameter file                         *
* Gams Development Corp.                                        *
* Date : 4 May, 1998                                            *
*****************************************************************
* entries required by CMEX, put in by the gams script
* SYSDIR
* SCRDIR
* SCRIPTNEXT
* INPUT
PageWidth 95
ParmFile "c:\some\central\location\moreOptions.txt"
```

Note that the last two lines were added to the standard GAMS system parameter file. As a consequence, each GAMS run will have a print width of 95 columns on the pages of the listing file. In addition, the command line parameters specified in the file `moreOptions.txt` will now apply to each GAMS run.

4.40.1.4 The GAMS Configuration in YAML Format

The GAMS configuration file `gamsconfig.yaml` written in the YAML format is easy to process by humans and computers. The GAMS Configuration Editor can be used to view and edit the GAMS configuration file but any other text editor can be used as well. This file has three configuration sections: command line parameters (`commandLineParameters`), operating system environment variables (`environmentVariables`), and external solver configuration (`solverConfig`). The latter is only relevant if you need to make a solver available to GAMS that is not shipped with the GAMS distribution. The COIN-OR GAMSlinks project has solver (links), e.g. Couenne, that could be added this way.

The first two sections are most easily described by an example:

```
commandLineParameters:
  - intVarUp:
      value: 1
  - eolCom:
      value: '//'
      maxVersion: 31
  - eolCom:
      value: '#'
      minVersion: 32
environmentVariables:
  - GDXCOMPRESS:
      value: 1
      maxVersion: 31
  - GDXCOMPRESS:
      value: 0
      minVersion: 32
  - PATH:
      value: /my/path/to/R/bin:/my/path/to/R/site-bin
      minVersion: 31.1.0
      maxVersion: 31.1.0
      pathVariable: True
```

In this example, the `gamsconfig.yaml` initializes some command line parameters and some environment variables. It initializes intVarUp unconditionally to 1. It also sets eolCom to the character sequence `//` for GAMS version 31 and earlier, while it uses the character `#` for GAMS version 32 and later. The keywords `minVersion` and `maxVersion` allow to have different entries for the same command line parameter for different versions. Also the file `gamsconfig.yaml` allows the repetition of entries. Hence, when GAMS runs it will filter all entries with appropriate `minVersion` and `maxVersion` and applies the setting of entries in sequence, so the last entry wins. Similarly, GAMS sets the environment variables `GDXCOMPRESS` to 0 or 1 depending on the actual version of GAMS. The last entry to set the `PATH` environment variable will be only applied for the GAMS version 31.1.0. Moreover, the indicator `pathVariable` set to `True` will result in prefixing the environment variable `PATH` with `/my/path/to/R/bin:/my/path/to/R/site-bin`.

The YAML syntax for the `gamsconfig.yaml` file is straightforward. Each section starts with a fixed name (`commandLineParameters` or `environmentVariables`) and is followed by a list of entries. Each entry starts with `-` and the name of the command line parameter or the name of the environment variable followed by a colon `:`. The next lines start with a keyword (`value`, `minVersion`, `maxVersion` and for environment variables also `pathVariable`) followed by a colon `:` and a value. The syntax of YAML files is very simple but it is crucial to use a consistent alignment. So all entries of a section must be perfectly aligned. Please be careful when mixing spaces and the tab character. If GAMS complains during the processing of a `gamsconfig.yaml` file with e.g. `System problems in yaml_parser_parse: mapping values are not allowed in this context` most likely your alignment is off as in the following erroneous example:

```
commandLineParameters:
  - eolCom:
      value: '//'
        maxVersion: 31
```

The lines with `value` and `maxVersion` need to start in the same column. There are plenty of online syntax checkers for YAML files. Use your favorite search engine and search for `yaml validator` (check the popular YAML validator) and copy and paste your problematic `gamsconfig.yaml` to get more insight into the YAML syntax problem. Moreover, the `gamsconfig.yaml` file has some required fields and some requirements for the value of some keys. In fact there is a schema file that validates that a syntactically correct `gamsconfig.yaml` fulfills the GAMS schema for configuration files. The schema file is part of the distribution and can be found in the system directory (`gamsconfig_schema.json`). One can validate a `gamsconfig.yaml` against this schema via a Python program (you might need to install additional Python packages `jsonschema` and `ruamel.yaml`):

```
import jsonschema
from ruamel.yaml import YAML
import json

with open('gamsconfig_schema.json') as f:
  schema = json.load(f)

yaml = YAML(typ="safe")
with open('gamsconfig.yaml') as f:
  config = yaml.load(f)

print(jsonschema.validate(instance=config, schema=schema))
```

Besides the required fields like `value` the schema also imposes restrictions on some value types (e.g. `True` and `False` for `pathVariable` and a proper release number for `minVersion` and `maxVersion`). The form of the release number can be just the major release (e.g. `31`), the major and minor release number (e.g. `31.1`) or the full detailed release number, e.g. `31.1.0`. So if `maxVersion` is set to e.g. `31` then all releases of `31` fulfill this version requirement.

Some parts of the GAMS system react on environment variables, e.g. the environment variable GMSPYTHONLIB decides about the Python library and installation used for embedded Python code. At the start of a GAMS run environment variables are set to the values given in the `gamsconfig.yaml` file. This is a convenient way to manage GAMS-related environment variables without utilizing OS-specific ways to set environment variables.

GAMS will process a sequence of `gamsconfig.yaml` files. It starts with the file in the GAMS system directory and then searches through some system-wide and user-specific standard locations.

Note

With GAMS 32 new defaults for several options were introduced. We have collected these options and their old or legacy default values in the file `gamsLegacyConfig.yaml` located in the GAMS system directory. Copy this file as `gamsconfig.yaml` to a location searched by GAMS to continue to work with the legacy defaults. The `minVersion` keyword in this file indicates when the new default became active.

Adding Solvers via gamsconfig.yaml

The third section in the GAMS configuration file gamsconfig.yaml allows to make a solver not shipped with GAMS available to the GAMS system. For that, an interface between an instantiation of a GAMS model and a solver needs to be implemented by use of libraries GMO and GEV. The COIN-OR GAMSlinks project provides examples of such solver interfaces. For the remainder of this section assume that we want to introduce a new version of the MINLP/MIQCP solver SHOT. GAMS knows about available solvers from the sub-system configuration file gmscmpNT.txt (gmscmpun.txt for non-Windows platforms). Here is a section from this file for the MINLP/MIQCP solver SHOT on Windows:

```
SHOT 1001 5 000102030405 1 0 2 MINLP MIQCP
gmsgennt.cmd
gmsgennx.exe
shtcclib64.dll sht 1 1
```

The gamsconfig.yaml file provides the same information in a more descriptive way:

```
solverConfig:
  - SHOT2:
      minVersion: 33
      fileType: 1001
      dictType: 5
      licCodes: 000102030405
      defName: optshot.def
      scriptName: gmsgennt.cmd
      executableName: gmsgennx.exe
      library:
        libName: D:\Users\janeDoe\Downloads\gamslink\GamsShot-20.dll
        auditCode: sht
        solverInterfaceType: 1
        threadSafeIndic: True
      modelTypes:
        - MINLP
        - MIQCP
```

The new solver will be called SHOT2 and has almost the identical information as the solver SHOT that comes with GAMS. We could also use the name SHOT again. This would hide the original solver SHOT and use the one described by gamsconfig.yaml. In addition to the solver information, this section allows the keywords min/maxVersion that instructs whether to include the solver depending on the GAMS version.

The fileType (line 1 second item in the section of gmscmpNT.txt) determines the type of the scratch files that contain the model instance. The one-digit determines binary (1) or text (0) format of the scratch files. The ten-digit determines whether GAMS puts the initial marginal information into the scratch files (1 for writing, 0 for not writing). The scratch file with the constraint matrix is stored column wise, the hundred-digit instructs GAMS to write (if at 1) the row count per column, so the solver can layout memory in advance for storing the constraint matrix. With GAMS' current libraries gmo and gev this information is not used and hence the hundred-digit should be at 0. The thousand-digit is about scaling. A non-zero value instructs GAMS to write the information stored in the .scale/.prior/.stage variable and equation attributes into the scratch files. With a value of 1 this is only done if scaleOpt/priorOpt are on. With a value of 2 this information is written independently of scaleOpt/priorOpt. With a value of 3 for models with variable and matching information (e.g. MCP) the reported marginals will be scaled by GAMS. The ten thousand-digit is always 0 and the hundred thousand-digit (if set to 1) instructs GAMS to write the variable/equation matching information to the scratch files for models that need this information (e.g. MCP). The leading zeros of the value for key fileType should be omitted.

The dictType (line 1 third item in the section of gmscmpNT.txt) decides about the type of the dictionary scratch file that contains the mapping information between the GAMS names and the variable and equation indexes seen by the solver. For example, this helps the solver to form good variable and equation names for error messages. Four values are allowed:

- 0: no dictionary information
- 5: dictionary with all labels that are used in the model instance
- 15: dictionary with all labels that are used in GAMS program
- 25: dictionary with all labels that are used in GAMS model plus an extra GDX file with the entire GAMS database (similar to `execute_unload "everything";` prior to the solve statement)

The `licCode` (line 1 fourth item in the section of `gmscmpNT.txt`) gives a guess about what license codes are required to run the solver. This is not the actual license information but allows other programs like e.g. "GAMS Studio" to list the solvers available with a particular license. In most cases solvers that are added this way should list the GAMS BASE license codes "000102030405".

The `defName` (line 2 second item in the section of `gmscmpNT.txt`) points to a file that contains all the solver options for the solver. This key does not need to be provided (same in `gmscmpNT.txt`) if the `defName` is `opt` + solvername + `.def` and the file resides in the GAMS system directory. Since we use the name `SHOT2` GAMS would expect the solver options to be in `optshot2.def`. If there were an `optshot.def` in the GAMS system directory for the original `SHOT`, we could reuse that file and list `optshot.def` for the `defName` key. The `defName` provided here is used by other programs like "GAMS Studio" that can assist with building solver options files.

The next three items on line 1 in the section of `gmscmpNT.txt` are for internal purposes and not discussed here in detail. They can be set via `gamsconfig.yaml` via the keys `defaultOkFlag` and `hiddenFlag` with values `True` or `False`.

GAMS has different ways of calling a solver controlled by the solveLink option. The `scriptName` (line 2 in the section of `gmscmpNT.txt`) contains the name of the script that calls the solver (in case of `solveLink=0` (chainScript) or 1 (callScript)). For solvers that are capable of `solveLink=5` (loadLibrary) a generic script `gmsgennt.cmd` (or `gmsgenus.run`) can be used. The `executableName` (line 3 in the section of `gmscmpNT.txt`) provides the name of the solver executable. Again for solvers capable of `solveLink=5` (loadLibrary) a generic executable `gmsgennx.exe` (or `gmsgenux.out`) can be used.

The section library is necessary only for solvers capable of `solveLink=5` (loadLibrary). The `libName` contains the name of the solver library file (line 3 first item in the section of `gmscmpNT.txt`). The `auditCode` (line 3 second item in the section of `gmscmpNT.txt`) is the prefix of the functions in the solver library (e.g. `shtCallSolver`). The `solverInterfaceType` (line 3 third item in the section of `gmscmpNT.txt`) defines the API implemented by the solver library and loaded by GAMS. Currently, there are only two types: 1 (`xyzReadyApi` and `xyzCallSolver`) and 2 (`xyzCallSolver` only). The `threadSafeIndic` (line 3 third item in the section of `gmscmpNT.txt`) indicates whether the solver library is thread-safe and can be used in combination with `solveLink=6` (aSyncThreads).

The final section `modelTypes` is about the model types the solver can handle. This information can be found in line 1 after item 7 in `gmscmpNT.txt`.

4.40.1.5 Order of Precedence for Options

The order of precedence for command line parameters including customization specifications in the GAMS IDE is as follows:

1. Command line parameters that are specified on the command line or in the Studio/IDE command line field.
2. Command line specifications in the IDE options window `Execute` (this is reached through File|Options|Execute).

3. Command line specifications in the specific IDE dialogs, e.g. `Output` (this is reached through File|Options|...).
4. Entries in the GAMS configuration files `gamsconfig.yaml`.
5. Entries in the GAMS system parameter file.

Many command line parameters initialize the `default` for a GAMS Option also accessible inside the GAMS program. For example, the system default for option MIQCP is `SBB`. If the command line parameter `MIQCP` has been set, e.g. to `DICOPT`, `DICOPT` will be new default MIQCP solver. Inside the GAMS program, one can reset the MIQCP via `option MIQCP=SHOT;` but setting it back to the default will result in `DICOPT` (not `SBB`) being the default solver: `option MIQCP=default;`.

4.40.2 Double Dash Parameters, Compile-Time Variables and Environment Variables

In this section we will cover double-dash parameters that enable users to set values for specific variables on the command line. These variables are substituted with their respective specified values at *compile* time. We will also discuss how operating system specific environment variables may be accessed and modified from a GAMS program.

4.40.2.1 Double Dash Parameters and Compile-Time Variables: A Simple Example

We will introduce double dash parameters and compile-time variables using as an example the well-known transportation model [**TRNSPORT**]. Assume we wish to explore how the solution changes if the demand assumes various values. To model this, we will introduce the compile-time variable `DMULT`, a multiplier for the demand `b`:

```
$set DMULT 1
...
demand(j) ..   sum(i, x(i,j))  =g=  %DMULT% * b(j) ;
```

Note that `DMULT` is defined with the dollar control option $set and its value is set to 1, which corresponds to the base line. Observe that the compile-time variable is referenced in the equation with the `%...%` notation. `%DMULT%` will be replaced at compile time by its value, in this case 1. We are now in the position to run the program multiple times by just changing the value of `DMULT` in the first line, which will automatically change the multiplier in the equation to the respective value.

GAMS offers a more convenient way for setting a compile-time variable like `DMULT` to a variety of values:

```
$if not set DMULT $set DMULT 1
...
demand(j) ..   sum(i, x(i,j))  =g=  %DMULT% * b(j) ;
```

Note that we set a default value for `DMULT` using conditional compilation. We may change this default on the command line when calling GAMS by specifying `DMULT` as a double dash parameter as follows:

```
> gams trnsport.gms --DMULT=0.9
```

Observe that with the specification `--DMULT=0.9` the compile-time variable `DMULT` is set and therefore the default does not apply. Thus the double dash parameter facilitates changing the value of a compile-time variable directly on the command line as part of the GAMS call while the respective GAMS file remains unchanged.

Assume that the model contains a second compile-time variable called `METHOD` that acts as a switch for various methods of solving the model and it may take the values 1, 2 and 3. In this case both compile-time variables may be set on the command line as follows:

```
> gams trnsport.gms --DMULT=1.12 --METHOD=3
```

In the next two subsections we will discuss double dash parameters and compile-time variables in more detail.

4.40.2.2 Double Dash Parameters

Double dash parameters are user-defined command line parameters that are used to define scoped compile-time variables or to assign values to scoped compile-time variables. The general syntax is:

```
> gams myfile --NAME=value
```

Here `NAME` is the name of the double dash parameter and `value` is its assigned value that may be any string. If the string contains spaces or other token terminating characters, the string value should be quoted. Consider the following simple example:

```
> gams myfile --keycity=Boston --myvalue=7.6 --dothis="display x;"
```

Suppose that `myfile.gms` contains the following lines with the scoped compile-time variables `keycity`, `myvalue` and `dothis`:

```
x("%keycity%")=%myvalue%;
%dothis%
```

Note that the compile-time variables are referenced using the notation `%...%`. The GAMS call above has the effect that at compile time the compile-time variables are substituted with the values specified through the double dash parameters resulting in the following:

```
x("Boston")=7.6;
display x;
```

GAMS offers three alternative syntax variants for defining double dash parameters:

```
> gams myfile //NAME=value
> gams myfile /-NAME=value
> gams myfile -/NAME=value
```

Note that the four syntax variants may be used interchangeably and have the same effect.

Double dash parameters are particularly useful for specifying granularity when modeling a discretization of time and or space. For example, in the model **[CHAIN]** the problem is to find the chain with minimal potential energy, assuming the chain has uniform density, is suspended between two points and has a given length `L`. Consider the following code snippet:

```
$if not set nh $set nh 50
Set nh / i0*i%nh% /;
```

The first two lines use conditional compilation to set a default value for the compile-time variable `nh`. Note that the value of `nh` determines the cardinality of the set `nh`, which is used for the discretization. The value of `nh` may be easily set on the command line to any desired value using `nh` as a double dash parameter:

```
> gams chain --nh=100
```

Note that the double dash functionality supersedes the command line parameters user1, ..., user5 which are accessible in the source file via `%gams.user1%, ..., %gams.user5%`. The example above would work with `user1` in the following way:

```
$set nh 50
$if not "%gams.user1"=="" $set nh %gams.user1%
Set nh / i0*i%nh% /;
```

The modified code could be called with:

```
> gams chain user1=100
```

Note that the double dash parameters facilitate using meaningful names instead of the generic names `user1, ..., user5`. This is especially useful if there are multiple parameters to pass on to the GAMS program.

Observe that the dollar control option $setDDList may be used to ensure that a model can only be run with the listed double dash parameters:

```
$setDDList nh
$if not errorFree $log *** Only allowed double dash options is: --nh=value
```

4.40.2.3 Compile-Time Variables

Compile-time variables are special variables that are substituted with their values at compile-time. They are not declared and defined with regular declaration statements like standard symbols (sets, parameters, ...), but they are defined with the dollar control option $set and its variants. There are three kinds of compile-time variables that differ in their scope level: local, scoped and global. An overview is given in Table 1.

Scope	Availability	Defined with	Removed from the system with
Local	Available only in the input file where they are defined	$setLocal.	$dropLocal
Scoped	Available in the input file where they are defined and in all include files of the input file.	$set	$drop
Global	Available in the input file where they are defined, in all parent files and in all include files.	$setGlobal	$dropGlobal

Table 1: Scope Levels for Compile-Time Variables in GAMS

Note that *scoped* compile-time variables may also be defined on the command line with double dash parameters. For example, in the example above the compile-time variable `DMULT` may be referenced in the equation `demand` without being defined with the dollar control option `$set` as long as it is defined and set on the command line. Note further, that *global* compile-time variables are saved in work files.

While the scope of a compile-time variable cannot be directly changed, but dropping and adding variables in different scopes accomplishes the same. Consider the following example:

```
$set MYVAR xxx

* From scoped to global
$ifThen set MYVAR
$  setGlobal MYVAR %MYVAR%
$  show
$  drop MYVAR
$  show
$endIf

* From global to local
$ifThen setGlobal MYVAR
$  setLocal MYVAR %MYVAR%
$  show
$  dropGlobal MYVAR
$  show
$endIf
```

Note that the compile-time variable MYVAR is first defined as a scoped variable with the value xxx. The dollar control option ifThen tests whether MYVAR was defined with $set and since this is TRUE the next four dollar control statements are processed: a new *global* compile-time variable called MYVAR is defined and is set to the value of the *scoped* compile-time variable MYVAR, the resulting compile-time variables are shown, the *scoped* compile-time variable is removed from the system with the option $drop and the resulting compile-time variables are shown again. A similar procedure is followed to change the *global* compile-time variable MYVAR to a *local* compile-time variable with the same name and value.

The output generated by the four dollar control options $show follows:

```
Level SetVal                            Type       Text
-------------------------------------------------------
    0 MYVAR                             SCOPED     xxx
    0 MYVAR                             GLOBAL     xxx

Level SetVal                            Type       Text
-------------------------------------------------------
    0 MYVAR                             GLOBAL     xxx

Level SetVal                            Type       Text
-------------------------------------------------------
    0 MYVAR                             LOCAL      xxx
    0 MYVAR                             GLOBAL     xxx

Level SetVal                            Type       Text
-------------------------------------------------------
    0 MYVAR                             LOCAL      xxx
```

Observe that this report is called *Environment Report*. This name is unfortunate, since the variables reported are in fact compile-time variables. Environment variables in GAMS are discussed in section Environment Variables in GAMS below.

Note that if a compile-time variable is referenced with %MYVAR%, it could reference a global, scoped or local compile-time variable called MYVAR. GAMS will always access the compile-time variable MYVAR with the most local scope. Thus if all three scopes are defined, the local compile-time variable is accessed first, then the scoped and then the global, as demonstrated in the following example:

```
$set XXX scoped
$setLocal XXX local
$setGlobal XXX global
$log %XXX%
$dropLocal XXX
$log %XXX%
$drop XXX
$log %XXX%
$dropGlobal XXX
$log %XXX%
```

The resulting log output will be:

```
local
scoped
global
%XXX%
```

Note that how %XXX% will be handled if no compile-time variable XXX is defined, is determined by the command line parameter stringChk.

For a full list of dollar control options that affect compile-time variables, see section Dollar Control Options for Compile-Tim

4.40.2.4 Environment Variables in GAMS

GAMS programs have access to operating system environment variables via %sysEnv.NAME%. Operating system environment variables may be modified or new environment variables may be defined with the dollar control option $setEnv. Consider the following artificial example:

```
$log %sysEnv.GEORGE%
$setEnv GEORGE Dantzig
$log %sysEnv.GEORGE%
$dropEnv GEORGE
$log %sysEnv.GEORGE%
```

Note that the dollar control option $dropEnv removes an environment variable. The log output follows:

```
%sysEnv.GEORGE%
Dantzig
%sysEnv.GEORGE%
```

There are two environment variables in GAMS that are specific to the GDX facility: GDXCONVERT and GDXCOMPRESS. Since GDX is used by utilities and other programs some general customization can be achieved via these environment variables. Their values determine the type of GDX files that are written. These environment variables may be overwritten through the command line parameters gdxConvert and gdxCompress or inside the GAMS file with the dollar control option $setEnv. Consider the following example that uses the latter functionality:

```
Scalar x /1/;
$log %sysEnv.GDXCONVERT%
$log %sysEnv.GDXCOMPRESS%
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

$setEnv GDXCONVERT v6
$setEnv GDXCOMPRESS 1
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"

$setEnv GDXCONVERT v7
$setEnv GDXCOMPRESS 0
$gdxOut x.gdx
$unLoad x
$gdxOut
$call gdxdump x.gdx -v | grep "File format\|Compression"
```

Note that `gdxdump` is a GDX utility that writes the contents of a GDX file as a GAMS formatted text file. The switch `-v` lets `gdxdump` print the file version information. With the `grep` utility we filter the lines that contain either `File format` or `Compression`. This code is run with the following call that initializes `GDXCOMPRESS` and `GDXCONVERT`:

```
> gams gdxenv.gms gdxCompress=0 gdxConvert=v6 lo=3
```

The output follows:

```
--- Starting compilation
v6
0
--- gdxenv.gms(7) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
*  File format    :    6
*  Compression    :    0
--- gdxenv.gms(14) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
*  File format    :    6
*  Compression    :    1
--- gdxenv.gms(21) 2 Mb
--- call gdxdump x.gdx -v | grep "File format\|Compression"
*  File format    :    7
*  Compression    :    0
--- gdxenv.gms(22) 2 Mb
--- Starting execution - empty program
```

4.40.3 Compile-Time Constants

Compile-time constants are constants that are related to some functions, model attributes or options. They have a fixed value and are referenced as `%prefix.constant%`. Here `prefix` is the name of the respective function, model attribute or option and `constant` is the name of the constant.

For example, the function handleStatus is used in the context of grid computing. Typically, a collection loop may take the following form:

```
loop(pp$(handleStatus(h(pp)) = 2), ... );
```

Alternatively, the following formulation may be used:

```
loop(pp$(handleStatus(h(pp)=%handleStatus.ready%), ... );
```

Observe that the compile-time constant `%handleStatus.ready%` equals the value of 2. See the table below for other compile-time constants that are related to the function `handleStatus`.

Note

Compile-time constants are replaced at compile time and cannot be manipulated or reassigned.

Though compile-time constants are most often used in the context of the function, model attribute or option indicated with the prefix, they are in fact context free and may be used anywhere where an integer is expected. Consider the following example:

```
Scalar x / %solPrint.on% /; display x;
```

A complete list of the compile-time constants is given in Table 2.

Table 2: Compile-Time Constants

Compile-Time Constant	value
%handleStatus.unknown%	0
%handleStatus.running%	1
%handleStatus.ready%	2
%handleStatus.failure%	3
%modelStat.optimal%	1
%modelStat.locallyOptimal%	2
%modelStat.unbounded%	3
%modelStat.infeasible%	4
%modelStat.locallyInfeasible%	5
%modelStat.intermediateInfeasible%	6
%modelStat.feasibleSolution%	7
%modelStat.integerSolution%	8
%modelStat.intermediateNonInteger%	9
%modelStat.integerInfeasible%	10
%modelStat.licensingProblem%	11
%modelStat.errorUnknown%	12
%modelStat.errorNoSolution%	13
%modelStat.noSolutionReturned%	14
%modelStat.solvedUnique%	15
%modelStat.solved%	16
%modelStat.solvedSingular%	17
%modelStat.unboundedNoSolution%	18
%modelStat.infeasibleNoSolution%	19

Compile-Time Constant	value
%platformCode.unknown%	0
%platformCode.DEX%	1
%platformCode.LEX%	2
%platformCode.WEX%	3
%platformCode.DAX%	4
%solPrint.off%	0
%solPrint.on%	1
%solPrint.silent%	2
%solPrint.summary% (deprecated)	0
%solPrint.report% (deprecated)	1
%solPrint.quiet% (deprecated)	2
%solveLink.chainScript%	0
%solveLink.callScript%	1
%solveLink.callModule%	2
%solveLink.asyncGrid%	3
%solveLink.asyncSimulate%	4
%solveLink.loadLibrary%	5
%solveLink.aSyncThreads%	6
%solveLink.threadsSimulate%	7
%solveOpt.replace%	0
%solveOpt.merge%	1
%solveOpt.clear%	2
%solveStat.normalCompletion%	1
%solveStat.iterationInterrupt%	2
%solveStat.resourceInterrupt%	3
%solveStat.terminatedBySolver%	4
%solveStat.evaluationInterrupt%	5
%solveStat.capabilityProblems%	6
%solveStat.licensingProblems%	7
%solveStat.userInterrupt%	8
%solveStat.setupFailure%	9
%solveStat.solverFailure%	10
%solveStat.internalSolverFailure%	11
%solveStat.solveProcessingSkipped%	12
%solveStat.systemFailure%	13

4.40.3.1 Command Line Parameters as Compile-Time Constants

The value of a command line parameter that was passed to the model can be accessed at compile time using the prefix `'gams'` and the name of the command line parameter: `%gams.parameter%`. Example:

```
> gams trnsport gdx=output.gdx
```

Trnsport.gms:

```
$setNames "%gams.input%" filepath filename fileextension
$log The input file '%filename%' is located in the directory %filepath%
$log All results are written to %gams.gdx%
```

Which results in the following log output:

```
The input file 'trnsport' is located in the directory C:\Users\robin\Documents\GAMS\Studio\workspace
All results are written to C:\Users\robin\Documents\GAMS\Studio\workspace\output.gdx
```

In addition to compile time, the value of a command line parameter can also be accessed at execution time.

4.40.4 GAMS Compile Time and Execution Time Phase

The GAMS log indicates different phases of a job run in the log file:

```
...
--- Starting compilation
...
--- Starting execution: elapsed 0:00:00.056
...
```

During compilation GAMS converts the GAMS user program into lower-level instructions that are executed during execution time. Before the user program is converted into lower-level instructions the compiler processes the input: the compile time variables and macros are substituted and comments are removed. Moreover, during compilation any dollar control option present in the user code is *executed*. Many of these dollar control options impact the behavior of the compilation phase (e.g. $include instructs the compiler to process a file before continuing processing the remaining part of the current file). The code the compiler actually converts into lower-level instructions is echoed (by default) to the listing file. The compiler also assembles the list of user symbols (sets, parameters, variables, ...) and the list of labels. These lists become immutable after the compiler finishes. So during execution time, for example, no new labels can be added. The only exception from this is during a continued compilation/execution using the save and restart facility. The separation between compile time and execution time is confusing especially for novice users and mistakes as the following are frequent:

```
file fInput / data.txt /;
scalar iCnt; for (iCnt=1 to 100, put fInput iCnt:0:0 /); putClose fInput;
set i /
$include data.txt
      /;
```

The intention of the code, that does *not* work, is clear: The put facility is used to create the input file `data.txt` that is included via the $include instruction. The problem with this code is that the `$include` instruction is *executed* at compile time while the code using the put statement is executed at execution time, i.e. after the compilation phase is over. Hence, the compiler tries to include this file *before* the put instructions are executed. If the file `data.txt` is not present, the compiler will terminate with a compilation error, but if a file with name `data.txt` is present this one will be processed by the `$include` and a mistake like this might remain undiscovered for a long time.

Most of the time GAMS performs compilation and execution in one GAMS job which makes it even harder to grasp the concept of compile and execution time. The command line parameter action can be used to separate the compilation and execution phase into multiple jobs.

4.40.5 List of Command Line Parameters

In the following two subsections we will present an overview of the command line parameters with brief descriptions. Detailed descriptions of all command line parameters follow in section Detailed Descriptions of All Options below.

Note

The value of a command line parameter that was passed to the model can be accessed at compile time and at execution time.

4.40.5.1 General Options

Option	Description
action	GAMS processing request
appendExpand	Expand file append option
appendLog	Log file append option
appendOut	Output file append option
asyncSolLst	Print solution listing when asynchronous solve (Grid or Threads) is used
captureModelInstance	Switch to capture all model instances within a run
case	Output case option for LST file
cErr	Compile time error limit
charSet	Character set flag
checkErrorLevel	Check errorLevel automatically after executing external program
connectIn	Specify YAML Connect script file processed at start of GAMS
connectOut	Specify YAML Connect script file processed at end of GAMS
curDir	Current directory
decryptKey	Key to decrypt a text file that was encrypted via $encrypt
dFormat	Date format
digit	Switch default for "$on/offDigit"
docFile	Filename stem for documentation files
dumpOpt	Writes preprocessed input to the file input.dmp
dumpOptGDX	Defines a GDX file name stem created when using DumpOpt
dumpParms	GAMS parameter logging
dumpParmsLogPrefix	Prefix of lines triggered by DumpParms>1
ECImplicitLoad	Allow implicit loading of symbols from embedded code or not
empty	Switch default for "$on/offEmpty"
encryptKey	Key to encrypt a text file using $encrypt
eolCom	Switch default for "$on/offEolCom" and "$eolCom"
eolOnly	Single key-value pairs (immediate switch)
epsToZero	Treat eps as zero when unloading to GDX
errMsg	Placing of compilation error messages
errNam	Name of error message file
error	Force a compilation error with message
errorLog	Max error message lines written to the log for each error
etLim	Elapsed time limit in seconds
execMode	Limits on external programs that are allowed to be executed
expand	Expanded (include) input file name

Option	Description
fdDelta	Step size for finite differences
fdOpt	Options for finite differences
fErr	Alternative error message file
fileCase	Casing of file names and paths (put, gdx, ref, $include, etc.)
fileStem	Sets the file stem for output files which use the input file name as stem by default
fileStemApFromEnv	Append a string read from an environment variable to the "FileStem"
filtered	Switch between filtered and domain-checked read from GDX
forceWork	Force GAMS to process a save file created with a newer GAMS version or with execution errors
forLim	GAMS looping limit
G205	Use GAMS version 2.05 syntax
GDX	GAMS data exchange file name
gdxCompress	Compression of generated GDX file
gdxConvert	Version of GDX files generated (for backward compatibility)
gdxSymbols	Select symbols that get exported when command line parameter GDX is set
gdxUels	Unload labels or UELs to GDX either squeezed or full
gridDir	Grid file directory
gridScript	Grid submission script
heapLimit	Maximum Heap size allowed in MB
IDCGDXInput	GDX file name with data for implicit input
IDCGDXOutput	GDX file name for data for implicit output
IDCGenerateGDX	Specify GDX file name of input and output side of data contract
IDCGenerateGDXInput	Specify GDX file name of input side of data contract
IDCGenerateGDXOutput	Specify GDX file name of output side of data contract
IDCGenerateJSON	Specify JSON file name of data contract
IDCJSON	Specify JSON file name to verify data contract
IDCProtect	Flag to control assignment protection of external input symbols
IDE	Integrated Development Environment flag
implicitAssign	Switch default for "$on/offImplicitAssign"
inlineCom	Switch default for "$on/offInline" and "$inlineCom"
input	Input file
inputDir, inputDir1..40	Input file directories
interactiveSolver	Allow solver to interact via command line input
jobTrace	Job trace string to be written to the trace file at the end of a GAMS job
keep	Controls keeping or deletion of process directory and scratch files
libIncDir	LibInclude directory
license	Use alternative license file
listing	Switch default for "$on/offListing"
logFile	Log file name
logLine	Amount of line tracing to the log file
logOption	Log option
lstTitleLeftAligned	Write title of LST file all left aligned
maxExecError	Execution time error limit
maxGenericFiles	Maximum number of generic file names tried at execution time file creation
maxProcDir	Maximum number of 225∗ process directories

Option	Description
MCPRHoldFx	Print list of rows that are perpendicular to variables removed due to the holdfixed setting
MIIMode	Model Instance Mode
multi	Switch default for "$on/offMulti[R]"
multiPass	Multipass facility
noNewVarEqu	Triggers a compilation error when new equations or variable symbols are introduced
on115	Generate errors for unknown unique element in an equation
output	Listing file name
pageContr	Output file page control option
pageSize	Output file page size (=0 no paging)
pageWidth	Output file page width
parmFile	Command Line Parameter include file
pLicense	Privacy license file name
prefixLoadPath	Prepend GAMS system directory to library load path
previousWork	Indicator for writing workfile with previous workfile version
procDir	Process Directory
procDirPath	Directory to create process directory in
procTreeMemMonitor	Monitor the memory used by the GAMS process tree
procTreeMemTicks	Set wait interval between memory monitor checks: ticks = milliseconds
profile	Execution profiling
profileFile	Write profile information to this file
profileTol	Minimum time a statement must use to appear in profile generated output
putDir	Put file directory
putND	Number of decimals for put files
putNR	Numeric round format for put files
putPS	Page size for put files
putPW	Page width for put files
reference	Symbol reference file
referenceLineNo	Controls the line numbers written to a reference file
replace	Switch between merge and replace when reading from GDX into non-empty symbol
scrDir	Scratch directory
scrExt	Scratch file extension to be used with temporary files
scrNam	Work file names stem
seed	Random number seed
showOSMemory	Show the memory usage reported by the Operating System instead of the internal counting
stepSum	Summary of computing resources used by job steps
strictSingleton	Error if assignment to singleton set has multiple elements
stringChk	String substitution options
suffixAlgebraVars	Switch default for "$on/offSuffixAlgebraVars"
suffixDLVars	Switch default for "$on/offSuffixDLVars"
suppress	Compiler listing option
symbol	Symbol table file
sys10	Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer

Option	Description
sys11	Dynamic resorting if indices in assignment/data statements are not in natural order
sys12	Pass model with generation errors to solver
sys15	Automatic switching of data structures used in search records
sys16	Disable search record memory (aka execute this as pre-GAMS 24.5)
sys17	Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)
sys18	Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers
sys19	Disable permutation on Column Generation (aka execute this as pre-GAMS 36)
sysDir	GAMS system directory where GAMS executables reside
sysIncDir	SysInclude directory
tabIn	Tab spacing
tFormat	Time format
threadsAsync	Limit on number of threads to be used for asynchronous solves (solveLink=6)
timer	Instruction timer threshold in milli seconds
trace	Trace file name
traceLevel	Modelstat/Solvestat threshold used in conjunction with action=GT
traceOpt	Trace file format option
user1..5	User strings
warnings	Number of warnings permitted before a run terminates
workDir	Working directory
writeOutput	Switch to write output file
zeroRes	The results of certain operations will be set to zero if abs(result) LE ZeroRes
zeroResRep	Report underflow as a warning when abs(results) LE ZeroRes and result set to zero

4.40.5.2 Solver-Related Options

Option	Description
bRatio	Basis detection threshold
CNS	Constrained Nonlinear Systems - default solver
DNLP	Non-Linear Programming with Discontinuous Derivatives - default solver
domLim	Domain violation limit solver default
EMP	Extended Mathematical Programs - default solver
forceOptFile	Overwrites other option file section mechanism
holdFixed	Treat fixed variables as constants
holdFixedAsync	Allow HoldFixed for models solved asynchronously as well
integer1..5	Integer communication cells
intVarUp	Set mode for default upper bounds on integer variables
iterLim	Iteration limit of solver
limCol	Maximum number of columns listed in one variable block
limRow	Maximum number of rows listed in one equation block
LP	Linear Programming - default solver
MCP	Mixed Complementarity Problems - default solver

Option	Description
MINLP	Mixed-Integer Non-Linear Programming - default solver
MIP	Mixed-Integer Programming - default solver
MIQCP	Mixed Integer Quadratically Constrained Programs - default solver
MPEC	Mathematical Programs with Equilibrium Constraints - default solver
NLP	Non-Linear Programming - default solver
nodLim	Node limit in branch and bound tree
optCA	Absolute Optimality criterion solver default
optCR	Relative Optimality criterion solver default
optDir	Option file directory
optFile	Default option file
QCP	Quadratically Constrained Programs - default solver
resLim	Wall-clock time limit for solver
RMINLP	Relaxed Mixed-Integer Non-Linear Programming - default solver
RMIP	Relaxed Mixed-Integer Programming - default solver
RMIQCP	Relaxed Mixed Integer Quadratically Constrained Programs - default solver
RMPEC	Relaxed Mathematical Programs with Equilibrium Constraints - default solver
savePoint	Save solver point in GDX file
scriptExit	Program or script to be executed at the end of a GAMS run
scriptFrst	First line to be written to GAMSNEXT file.
solPrint	Solution report print option
solveLink	Solver link option
solver	Default solver for all model types that the solver is capable to process
solverCntr	Solver control file name
solverDict	Solver dictionary file name
solverInst	Solver instruction file name
solverMatr	Solver matrix file name
solverSolu	Solver solution file name
solverStat	Solver status file name
subSys	Name of subsystem configuration file
sysOut	Solver Status file reporting option
threads	Number of processors to be used by a solver
workFactor	Memory Estimate multiplier for some solvers
workSpace	Work space for some solvers in MB

4.40.5.3 Save and Restart Options

Option	Description
fSave	Creates a forced work file, i.e., the file is saved even if execution errors or other errors occured
restart	Name of a restart file, see The Save and Restart Feature
restartNamed	Name of another matching restart file, see Obfuscated Work Files
save	Creates a work file, see The Save and Restart Feature
saveObfuscate	Creates an obfuscated work file, see Obfuscated Work Files
symPrefix	Prefix all symbols encountered during compilation by the specified string in work file
xSave	Creates a compressed work file
xSaveObfuscate	Creates a compressed obfuscated work file

4.40.6 Detailed Descriptions of All Options

In this section we will give detailed descriptions of all options that may be used as command line parameters, in option statements or as model attributes.

Note

- We indicate for each entry the context in which the option is available.
- The options are listed in alphabetical order for easy reference.
- Synonyms apply only to options set via the command line.

action *(string)*: GAMS processing request

Synonym: A

Available: Command line

This option controls the way GAMS processes the input file. In particular GAMS currently processes the input file in multiple phases and this allows one to restrict the phases used. The two phases in order are:

- *Compilation* During this pass, the file is compiled, and syntax errors are checked for. Data initialization statements like scalar, parameter, and table statements are also processed during this stage.
- *Execution* During this stage, all execution time statements including assignments, loops, and solves are executed.

The special action `GT` is related to the creation of trace reports. See also option traceLevel for details.

Default: `CE`

Value	Meaning
`R`	Restart After Solve
`C`	CompileOnly
`E`	ExecuteOnly
`CE`	Compile and Execute
`GT`	Trace Report

appendExpand *(boolean)*: Expand file append option

Synonym: AE

Available: Command line

This option controls the manner of file opening of the option expand.

Default: `1`

Value	Meaning
`0`	Reset expand file
`1`	Append to expand file

appendLog *(boolean)*: Log file append option

Synonym: AL

Available: Command line

This option is used in conjunction with the setting of logOption to 2 and 4, where the log from the GAMS run is redirected to a file. Setting this option to 1 will ensure that the log file is appended to and not overwritten (replaced).

Default: `0`

Value	Meaning
`0`	Reset log file
`1`	Append to logfile

appendOut *(boolean)*: Output file append option

Synonym: AO

Available: Command line

Setting this option to 1 will ensure that the listing file is appended to and not overwritten (replaced).

Default: `0`

Value	Meaning
`0`	Reset listing file
`1`	Append to listing file

asyncSolLst *(boolean)*: Print solution listing when asynchronous solve (Grid or Threads) is used

Available: Command line, Option statement

This option determines whether the solution listing is printed in the listing file when an asynchronous (grid or threads) solve is used and the function handleCollect or command execute_loadHandle successfully collect the results.

Default: `0`

Value	Meaning
`0`	Do not print solution listing into lst file for asynchronous solves
`1`	Print solution listing into lst file for asynchronous solves

bRatio *(real)*: Basis detection threshold

Available: Command line, Option statement, Attribute statement (use before solve)

The `bRatio` value is used to detect whether the initial point (levels and marginals) passed to the solver represents a basis suitable for use by the solver.

Certain (pivotal) solution procedures can restart from an advanced basis that is constructed automatically using existing basis information, i.e. they do a *warm start*. This option is used to influence whether a warm start is done or not. GAMS provides a hint to the solver to suggest whether a basis can or might be extracted from the initial point. The hint is based on the number of rows with nonzero marginals and is computed internally as:

```
hint := (0 == bRatio) or (rowsWithNonzeroMarg > nRows * bratio)
```

Note that setting `bRatio` to 1 causes the hint to be false, while setting `bRatio` to 0 causes the hint to be true. Note also that this is only a hint to the solver: some solvers (e.g. barrier methods) do not use this hint value.

Default: `0.25`

captureModelInstance *(boolean)*: Switch to capture all model instances within a run

Available: Command line

This option is a debugging option that helps to capture, if set to 1, the model instances that are generated and solved during the execution of the `solve` commands in a GAMS run. This is particularly important if one needs to make a model instance available to GAMS technical support to investigate a solver failure or analyze poor solver performance. The model instances are stored in separate files with names `gams`*NNN*`.gms` where *NNN* is an increasing number. So sorting the files by time or name will correspond to the order in which these instances have been generated and solved. The format of the model instance is the GAMS scalar format and the instance is captured *before* the instance is solved by the selected solver, hence it contains the starting point but not the solution point.

Another way of capturing model instances becomes useful (and is triggered independent of this option) in case the user model does modularization by calling other GAMS programs that execute a solve statement via the GAMS executable. Since options are not automatically passed on to the GAMS subprocesses one might miss capturing some model instances. Moreover, due to constant folding and rounding in the scalar model format, the run of a scalar model instance might not reproduce a particular problematic issue of the original solve. Hence GAMS can capture the binary scratch files produced by the solve statement when executed under solveLink=0 in a ZIP file. This is activated by setting a system environment variable named `ZIPSCRDIR_PGAMS` (e.g. `set ZIPSCRDIR_PGAMS=mymodel`). The content of this environment variable is used as a prefix for the ZIP file names, e.g. `mymodel`*NNN*`.zip` where *NNN* is an increasing number. Such ZIP files can help GAMS support staff to execute the model and have an increased chance to reproduce a problematic issue.

Note

`CaptureModelInstance` cannot be used with solveLink=6/7. If this was set, GAMS will reset `solveLink` to `3/4` automatically.

Default: `0`

Value	Meaning
0	Do not capture model instances
1	Capture model instances

case *(boolean)*: Output case option for LST file

Available: Command line

This option controls the case of the text in the listing file.

Default: `0`

Value	Meaning
0	Write listing file in mixed case
1	Write listing file in upper case only

cErr *(integer)*: Compile time error limit

Available: Command line

The compilation will be aborted after `n` errors have occurred. By default, there is no error limit and GAMS compiles the entire input file and collects all the compilation errors that occur. If the file is too long and the compilation process is time consuming, `cerr` could be used to set to a low value while debugging the input file.

Default: `0`

Value	Meaning
0	No error limit (default)
n	Stop after n errors

charSet *(boolean)*: Character set flag

Available: Command line

This option specifies whether foreign language characters are permitted in comments and text items. For a list of standard GAMS characters, see table Legal Characters.

Default: `1`

Value	Meaning
0	Use limited GAMS characters set
1	Accept any character in comments and text items (foreign language characters)

cheat *(real)*: Cheat value, i.e. minimum solution improvement threshold

Available: Attribute statement (use before solve)

For a branch-and-bound based solver, each new feasible solution must be at least the value of `cheat` better than the current best feasible solution. Note that this may speed up the search, but may cause some solutions, including optimal ones, to be missed. If a model has been solved with a nonzero cheat value, then the optimal solution will be within the cheat value or less of the found solution. Observe that the option `cheat` is specified in absolute terms (like the option optCA), therefore non-negative values are appropriate for both minimization and maximization models. Note that using this option will invalidate any reporting of the dual bound or optimality gaps. Further, certain solver options can override the cheat setting, e.g., the Cplex option objDif, and some solvers may ignore the `cheat` option.

Default: `0`

checkErrorLevel *(boolean)*: Check errorLevel automatically after executing external program

Available: Command line, Option statement

If this option is set to 1, the errorLevel is checked implicitly after executing an external program or via execute, put_utility exec and put_utility shell. The same holds for the execution of a tool from the GAMS tools library via executeTool. An execution error is triggered and the execution is aborted, if it is not 0. So, with `checkErrorLevel = 1` the before mentioned statement behave like execute.checkErrorLevel, put_utility exec.checkErrorLevel, put_utility shell.checkErrorLevel, and executeTool.checkErrorLevel, respectively.

Also, if this option is set as a command line parameter it initializes the state of the dollar control option $on/offCheckErrorLevel. So, with `checkErrorLevel = 1`, the errorLevel is checked implicitly after $call and $hiddenCall. The same holds for calls to a tool from the GAMS tools library via $callTool and $hiddenCallTool. A compilation error is triggered and the compilation is aborted if that is not 0. So, the dollar control options mentioned before behave like $call.checkErrorLevel, $hiddenCall.checkErrorLevel, $callTool.checkErrorLevel, and $hiddenCallTool.checkErrorLevel respectively.

Default: `0`

Value	Meaning
`0`	Do not check errorLevel automatically after execution of external program
`1`	Check errorLevel automatically after execution of external program

CNS *(string)*: Constrained Nonlinear Systems - default solver

Available: Command line, Option statement

The default solver for models of the type Constrained Nonlinear Systems is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

connectIn *(string)*: Specify YAML Connect script file processed at start of GAMS

Available: Command line

The YAML file provided by this command line parameter is passed to and processed by Connect. This allows Connect to prepare data for import at the beginning of a GAMS job. The GAMS program itself does not need to know where the various data files (CSV, Excel, etc) are located. The supply side of the *data contract* is encapsulated in the YAML script.

Here is an example. The content of the file `p.yaml` that is supplied via the option `connectIn` could look like this:

```
- ExcelReader:
    file: myworkbook.xlsx
    symbols:
        - name: p
          range: Sheet1!A1
          rowDimension: 1
          columnDimension: 1
- GDXWriter:
    file: input.gdx
    symbols:
        - name: p
```

The GDX file `input.gdx` can be loaded at the beginning of a GAMS job using gdxLoad:

```
Set i, j;
Parameter p(i<,j<);
$gdxLoad input.gdx p
display p;
```

Alternatively, this can be nicely combined with the IDCGDXInput to load external input symbols. The GDX file `input.gdx` can be specified as value for `IDCGDXInput` (`gams mymodel connectIn=p.yaml IDCGDXInput=input.gdx`):

```
Set i, j;
$onExternalInput
Parameter p(i<,j<) / i1.j1 1 /;
$offExternalInput
display p;
```

The YAML code in the `connectIn` file can also utilize the `GAMSReader` agent. Normally, there are no symbols to read at the job's start, but in case the job *restarts* from an existing work file (see command line option restart) the symbols available from the work file can be read into the Connect database with the `GAMSReader` agent. The YAML code in the `connectIn` file can utilize the `GAMSWriter` agent. It will update the symbols and data read from the restart file at the beginning of the GAMS compilation phase.

connectOut *(string)*: Specify YAML Connect script file processed at end of GAMS

Available: Command line

The YAML file provided by this command line parameter is passed to and processed by Connect. This allows Connect to take the GAMS data at the end of the GAMS job and export it to various formats (CSV, Excel, etc) according to the instructions in the YAML file.

Here is an example. The content of the file `p.yaml` that is supplied via the option `connectOut` could look like this:

```
- GDXReader:
    file: output.gdx
    symbols:
        - name: p
- ExcelWriter:
    file: myworkbook.xlsx
    symbols:
        - name: p
          range: Sheet!A1
          columnDimension: 1
```

The GDX file `output.gdx` can be written at the end of a GAMS job using execute_unload:

```
Set i /i1*i10/, j /j1*j10/;
Parameter p(i,j); p(i,j) = uniform(0,1);
execute_unload 'output.gdx', p;
```

Alternatively, this can be nicely combined with the IDCGDXOutput to process external output symbols. The GDX file `output.gdx` can be specified as value for `IDCGDXOutput` (`gams mymodel connectOut=p.yaml IDCGDXOutput=output.gdx`):

```
Set i /i1*i10/, j /j1*j10/;
$onExternalOutput
Parameter p(i,j); p(i,j) = uniform(0,1);
$offExternalOutput
```

The YAML code in the `connectOut` file can also utilize the `GAMSReader` agent. This reads directly from GAMS memory (without the detour via GDX) and processes any symbol available at the end of the GAMS run. The YAML code in the `connectOut` file cannot utilize the `GAMSWriter` agent.

curDir *(string)*: Current directory

Synonym: CDir

Available: Command line

This option sets the current working directory. It is useful when GAMS is called from an external system like Visual Basic. If it is not specified, it will be set to the directory the GAMS module is called from.

cutOff *(real)*: Cutoff value for branch and bound

Available: Attribute statement (use before solve, reset by solve statement)

Within a branch-and-bound based solver, the parts of the tree with an objective value worse than the cutoff value are ignored. Note that this may speed up the initial phase of the branch and bound algorithm (before the first integer solution is found). However, the true optimum may be beyond the cutoff value. In this case the true optimum will be missed and moreover, no solution will be found.

Observe that this option is specified in absolute terms (like the option optCA).

Default: `0`

decimals *(integer)*: Decimal places for display statements

Available: Option statement

This option specifies the number of decimals that will be printed for numeric values that do not have a specific print format attached. The range is `[0,8]`.

Default: `3`

decryptKey *(string)*: Key to decrypt a text file that was encrypted via $encrypt

Available: Command line

This option provides a key to decrypt a GAMS input file that has been encrypted with a key provided by encryptKey and $encrypt. For more information, see Encrypting Files.

defPoint *(integer)*: Indicator for passing on default point

Available: Attribute statement (use before solve, reset by solve statement)

This option determines the point that is passed to the solver as a basis. By default, the levels and marginals from the current basis are passed to the solver. In some circumstances (mostly during debugging), it can be useful to pass a standard default input point, i.e. with all levels set to 0 or lower bound.

Value	Meaning
0	Pass user defined levels and marginals to solver
1	Pass default levels and marginals to solver
2	Pass default marginals to solver

dFormat *(integer)*: Date format

Synonym: DF

Available: Command line

This option controls the date format in the listing file. The three date formats correspond to various conventions used around the world. For example, the date December 2, 1996 will be written as `12/02/96` with the default `df` value of 0, as `02.12.96` with `df=1`, and as `96-12-02` with `df=2`.

Default: `0`

Value	Meaning
0	Date as mm/dd/yy
1	Date as dd.mm.yy
2	Date as yy-mm-dy

dictFile *(real)*: Force writing of a dictionary file if dictfile > 0

Available: Attribute statement (use before solve, reset by solve statement)

If this option is set to a value that is larger than zero, it will instruct GAMS to make the GAMS names of variables and equations that have been generated by the solve statement available to the solver. In many solver links these names are registered with the solver and hence messages from the solver that involve variables and equations (e.g. an infeasible row or duplicate columns) can be easily interpreted by the user. Consider the following example:

```
Row 'demand(new-york)' infeasible, all entries at implied bounds.

Duplicate columns x(san-diego.new-york) and x(san-diego.chicago) make problem unbounded.
```

If we have `modelname.dictfile=0` the same messages will read as follows:

```
Row 'c4' infeasible, all entries at implied bounds.

Duplicate columns x4 and x5 make problem unbounded.
```

Sometimes a dictionary is required for a successful run. Some solver option use the original GAMS names and need to be matched with the variables `1..n` and equations `1..m` in the solver. The dictionary file with its API allows to calculate such a mapping. Note that this is done automatically inside the solver links, so users do not need to be concerned with it.

For example, in the indicator constraints implementation a binary indicator variable is matched to a constraint. In the model [**INDIC01**] from the GAMS test library, this matching is done in the following GAMS/Cplex option file `cplex.opt`:

```
indic eq3(dice,f,fp)$comp(dice,f,fp) 1
```

Observe that if no dictionary is available, we will get an error:

```
**** Unable to read dictionary file required for indicator constraints
```

However, the dictionary comes at a price. Generating the names and calculating and storing the map takes time and space. In addition, GAMS names take up space in the solver. Thus, if the user needs very fast generation and does not need names, setting `dictFile` to zero is a good option.

Further, note that some solvers allow to suppress the loading of names (using the solver option `names=no`). Suppressing the loading of names facilitates to use the name mapping features required for models like `INDIC01` above, but does not load the names into the solver name space for better reporting (and hence saves some space).

digit *(string)*: Switch default for "$on/offDigit"

Available: Command line

For more info see $on/offDigit.

Default: `off`

Value	Meaning
`off`	Activate $offDigit
`on`	Activate $onDigit

dispWidth *(integer)*: Number of characters to be printed in the column labels of all subsequent display statements

Available: Option statement

This option controls the number of characters that are shown for a label in a column in the context of the display statement. Consider the following example:

```
Set i / thislabelhas24characters /;
Parameter p(i,i) / thislabelhas24characters.thislabelhas24characters 2/;
display p;

option dispWidth=24;
display p;
```

The two display statements in this code will generate the following output:

```
----      3 PARAMETER p

                           thislabel~

thislabelhas24characters       2.000

----      6 PARAMETER p

                           thislabelhas24characters

thislabelhas24characters                    2.000
```

Observe that in the first display, the label in the column is cut off after 10 characters, while in the second display it is shown in full.

Note that the default value is 10 and the range is `[10,31]`.

Default: `10`

dmpOpt *(no value)*: Debugging option: causes GAMS to echo the runtime option settings

Available: Option statement

This debugging option has the effect that all available option statements and their current values are listed in the listing file.

dmpSym *(no value)*: Debugging option: causes GAMS to echo the symbol table to the listing file

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect that GAMS will report the number of elements that are stored for each identifier at the point in the program where this option is inserted together with a memory estimate. The report that is generated in this way is called a *memory dump*. This is similar to the option dmpUserSym, but prints GAMS internal symbols and information as well. For details, see section Finding the Causes for Excessive Memory Use.

dmpUserSym *(no value)*: Debugging option: causes GAMS to echo the symbol table to the listing file for user defined symbols only

Available: Option statement

This debugging option is especially useful for diagnosing memory problems. It has the effect that GAMS will report the number of elements that are stored for each identifier at the point in the program where this option is inserted together with a memory estimate. The report that is generated in this way is called a *memory dump*. This is similar to the option dmpSym, but prints user defined symbols only and also leaves out some very technical information which are mostly for internal use. For details, see section Finding the Causes for Excessive Memory Use.

DNLP *(string)*: Non-Linear Programming with Discontinuous Derivatives - default solver

Available: Command line, Option statement

The default solver for models of the type Nonlinear Programs with Discontinuous Derivatives is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

docFile *(string)*: Filename stem for documentation files

Available: Command line

domLim *(integer)*: Domain violation limit solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the maximum number of domain errors (undefined operations like division by zero) a nonlinear solver will perform, while calculating function and derivative values, before it terminates the run and returns solver status `5 EVALUATION ERROR LIMIT`. Nonlinear solvers have difficulties recovering after attempting an undefined operation. Note that some solvers operate in a mode where trial function evaluations are performed. These solvers will not move to points at which evaluation errors occur, thus the evaluation errors at trial points are not counted against the limit.

Default: ∞

domUsd *(integer)*: Number of domain violations

Available: Attribute statement (use after solve)

This model attribute returns the number of domain violations after a solve.

dualCheck *(integer)*: Output on the reduced cost condition

Available: Option statement

If this option is set to 1, the reduced cost condition for each variable in the column listing will be evaluated using the equation marginals. The default value is zero, which means that the calculation will be omitted.

Default: `0`

dumpOpt *(integer)*: Writes preprocessed input to the file input.dmp

Available: Command line

This option with value larger than 9 creates a GAMS input file of that will reproduce results encapsulating all `include` files into one GAMS file. If activated, a file will be written containing GAMS source code for the entire problem. The file name is the input file name with the extension `dmp`. For values smaller than 10, this option tries to encapsulate all the items from a restart file that are needed to execute a solve.

For the values smaller than 10, consider the following example. We will split the transportation model [**TRNSPORT**] into two files and run them with the save and restart feature. Then we will illustrate the option `dumpOpt`. The first file called `trans1.gms` contains the first part of the model up to and including the model statement:

```
Sets
       i   canning plants   / seattle, san-diego /
       j   markets          / new-york, chicago, topeka / ;

Parameters
       a(i)  capacity of plant i in cases
         /    seattle     350
              san-diego   600  /

       b(j)  demand at market j in cases
         /    new-york    325
              chicago     300
              topeka      275  / ;

Table d(i,j)  distance in thousands of miles
                    new-york       chicago      topeka
      seattle          2.5           1.7          1.8
      san-diego        2.5           1.8          1.4  ;

Scalar f  freight in dollars per case per thousand miles  /90/ ;

Parameter c(i,j) transport cost in thousands of dollars per case ;
c(i,j) = f * d(i,j) / 1000 ;

Variables
    x(i,j)  shipment quantities in cases
    z       total transportation costs in thousands of dollars ;
Positive Variable x ;
```

```
Equations
    cost        define objective function
    supply(i)   observe supply limit at plant i
    demand(j)   satisfy demand at market j ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

model transport /all/ ;
```

Note that we removed all comments for brevity. The second file called `trans2.gms` contains the solve statement and the display statement:

```
solve transport using lp minimizing z ;
display x.l, x.m ;
```

We run the first file with the command line parameter save and thus generate a work file. For details on work files, see chapter The Save and Restart Feature. Then we run `trans2.gms` restarting from the saved work file. The result will be equivalent to running the original model [**TRNSPORT**].

Note

The option `dumpOpt` can only be used effectively, if the first line in the second file, `trans2.gms`, is the solve statement.

Now, we will illustrate the use of the option `dumpopt`, by running the second file with the following command:

```
> gams trans2 r=trans dumpopt=1
```

Here `trans` is the name of the saved files generated from the file `trans1.gms`. As a result of this call, a new file will be created. It is called `trans2.dmp` and has the following content:

```
* This file was written with DUMPOPT=1 at 11/25/21 15:15:17
*
*      INPUT = C:\tmp\trans2.gms
*       DUMP = C:\tmp\trans2.dmp
*    RESTART = C:\tmp\0.g0?
*
*           with time stamp of 11/16/21 17:18:53
*
* You may have to edit this file and the input file.

* There are 5 labels

Set WorkFileLabelOrder dummy set to establish the proper order /
   seattle,san-diego,new-york,chicago,topeka /;

Model transport;

Variable z 'total transportation costs in thousands of dollars';

Set i(*) 'canning plants' /
   seattle,san-diego /;

Set j(*) 'markets' /
```

```
   new-york,chicago,topeka /;

Parameter c(i,j) 'transport cost in thousands of dollars per case' /
   seattle.new-york 0.225,seattle.chicago 0.153,seattle.topeka 0.162,san-diego.new-york 0.225,sa

Positive Variable x(i,j) 'shipment quantities in cases';

Parameter a(i) 'capacity of plant i in cases' /
   seattle 350,san-diego 600 /;

Parameter b(j) 'demand at market j in cases' /
   new-york 325,chicago 300,topeka 275 /;

Equation demand(j) 'satisfy demand at market j';

Equation supply(i) 'observe supply limit at plant i';

Equation cost 'define objective function';

*      *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***
```

Note that all the data that enters the model in the solve statement has been regenerated. Observe that the parameter `d` has not been regenerated since it does not appear in the model. Changing the value of the parameter `dumpopt` will have the effect that other names are used for the identifiers in the regenerated file, see table below.

Note

If $onVerbatim is active, `DumpOpt = 11` behaves like `DumpOpt = 21` (comments are kept)

See also dumpOptGDX.

Default: `0`

Value	Meaning
0	No dumpfile
1	Extract referenced data from the restart file using original set element names
2	Extract referenced data from the restart file using new set element names
3	Extract referenced data from the restart file using new set element names and drop symbol text
4	Extract referenced symbol declarations from the restart file
11	Write processed input file without comments
21	Write processed input file with all comments
22	Write processed input with all comments into a separate dump file for each block

dumpOptGDX *(string)*: Defines a GDX file name stem created when using DumpOpt

Available: Command line

This parameter works together with the dumpOpt parameter. If that is set to `1`, `11` or `21` while `dumpOptGDX` is set, GAMS will create a GDX file with the data used in the dump file instead of data statements, and the dump file will load the data from that GDX file. So, with the parameter `dumpOptGDX=trns2` the example above would generate the following dump file:

```
* This file was written with DUMPOPT=1 at 11/25/21 15:14:11
*
*      INPUT = C:\tmp\trans2.gms
*       DUMP = C:\tmp\trans2.dmp
*    RESTART = C:\tmp\0.g0?
* DUMPOPTGDX = trans2
*
*           with time stamp of 11/16/21 17:18:53

$gdxIn trans2.gdx

*
* You may have to edit this file and the input file.

* There are 5 labels

Set WorkFileLabelOrder dummy set to establish the proper order;
$loadDCR WorkFileLabelOrder=*

Model transport;

Variable z 'total transportation costs in thousands of dollars';

Set i(*) 'canning plants';
$loadDCR i

Set j(*) 'markets';
$loadDCR j

Parameter c(i,j) 'transport cost in thousands of dollars per case';
$loadDCR c

Positive Variable x(i,j) 'shipment quantities in cases';

Parameter a(i) 'capacity of plant i in cases';
$loadDCR a

Parameter b(j) 'demand at market j in cases';
$loadDCR b

Equation demand(j) 'satisfy demand at market j';

Equation supply(i) 'observe supply limit at plant i';

Equation cost 'define objective function';

$gdxIn

*      *** EDITS FOR INPUT FILE ***

*** END OF DUMP ***
```

Note that more than one GDX file could be created with a common file stem defined by this parameter. This will be necessary if the source model has multiple data definitions for the same symbol like in this simple example:

```
Set       i    / i1*i3/;
Parameter a(i) / i1 1, i2  2/;
$onMulti
```

```
Parameter a(i) / i1 0, i3  3/;
Scalar    b    /  7 /;
Scalar    b    / 77 /;
```

Running this as

```
   > gams dummy dumpOpt=11 dumpOptGDX=dummyIn
```

will generate this dump file:

```
* This file was written with DUMPOPT=11 at 11/25/21 15:26:02
*
*       DUMP = C:\tmp\dummy.dmp
*      INPUT = C:\tmp\dummy.gms
*    RESTART =
* DUMPOPTGDX = dummyIn
*

$gdxIn dummyIn.gdx

Set       i
$loadDCR i
;
Parameter a(i)
$loadDCR a
;
$onMulti
Parameter a(i)
$gdxIn dummyIn_m1.gdx
$loadDCR a
;
Scalar    b
$loadDCR b
;
Scalar    b
$gdxIn dummyIn_m2.gdx
$loadDCR b
;
* *** EXIT       C:\Data\gspTest\dummy.gms

$gdxIn
*** END OF DUMP ***
```

And this is the data found in the GDX files:

dummyIn.gdx:

```
Set i(*) /
'i1',
'i2',
'i3' /;

Parameter a(*) /
'i1' 1,
'i2' 2 /;
```

dummyIn_m1.gdx:

```
Parameter a(*) /
'i2' 2,
'i3' 3 /;

Scalar b / 7 /;
```

dummyIn_m2.gdx:

```
Scalar b / 77 /;
```

dumpParms *(integer)*: GAMS parameter logging

Synonym: DP

Available: Command line

This option lists the settings of all command line parameters that were changed or set by the user, GAMS or an IDE during the current run. Note that with `dp=2` all file operations are listed, including the full path of each file on which any operation is performed.

Default: `0`

Value	Meaning
0	No logging
1	Lists accepted/set parameters
2	Log of file operations plus list of accepted/set parameters

dumpParmsLogPrefix *(string)*: Prefix of lines triggered by DumpParms>1

Synonym: DPLP

Available: Command line

This option prefixes in the log file the list of all command line parameters that were changed or set by the user, GAMS or an IDE during the current run. Note that the option dumpParms must be greater than 1 for `dumpParmsLogPrefix` to have an effect.

Default: ***

ECImplicitLoad *(string)*: Allow implicit loading of symbols from embedded code or not

Available: Command line, Option statement

The command line parameter ECImplicitLoad initializes both, the option ECImplicitLoad and the dollar control option $on/offECImplicitLoad for the compile-time equivalent behavior.

Default: `on`

Value	Meaning
off	Do not allow implicit loading from embedded code
on	Allow implicit loading from embedded code

eject *(no value)*: Inject a page break into the LST file

Available: Option statement

This option has the effect that a page break is inserted in the listing file.

EMP *(string)*: Extended Mathematical Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Extended Mathematical Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

empty *(string)*: Switch default for "$on/offEmpty"

Available: Command line

For more info see $on/offEmpty.

Default: `on`

Value	Meaning
`off`	Activate $offEmpty
`on`	Activate $onEmpty

encryptKey *(string)*: Key to encrypt a text file using $encrypt

Available: Command line

This option provides a key to encrypt a text file via $encrypt. For more information, see Encrypting Files.

eolCom *(string)*: Switch default for "$on/offEolCom" and "$eolCom"

Available: Command line

If this is set to on `on` or `off` it sets the state of $on/offEOLCom. Other strings (with not more than two characters) will set $EOLCom.

Default: `off`

Value	Meaning
`off`	Activate $offEolCom
`on`	Activate $onEolCom using default EOL comment character
`other`	Activate $onEolCom setting specific EOL comment character(s)

eolOnly *(integer)*: Single key-value pairs (immediate switch)

Synonym: EY

Available: Command line

This option controls formatting of parameters on the command line and is useful in conjunction with the option parmFile.

This option acts as an immediate switch that forces only one option-value pair to be read on a line. Note that by default, any number of option-value pairs may be present on the same line and termination characters and quoting is necessary to determine the end of key/value pair. With this option active the remainder after the key is used as the value independent of quoting or termination characters.

Default: `0`

Value	Meaning
`0`	Any number of keys or values
`1`	Only one key-value pair on a line

epsToZero *(string)*: Treat eps as zero when unloading to GDX

Available: Command line, Option statement

When this is set to `on`, `EPS` values are written as zero when unloading parameters or variable and equation levels to GDX at execution time. The command line parameter `EpsToZero` initializes both, the option `EpsToZero` and the dollar control option $on/offEpsToZero for the compile-time equivalent behavior.

Default: `off`

Value	Meaning
`off`	Treat Eps as Eps
`on`	Treat Eps as Zero

errMsg *(integer)*: Placing of compilation error messages

Available: Command line

This option controls the position of the compilation error messages in the listing file. To illustrate the option, consider the following slice of GAMS code:

```
Set       i     / 1*10 / ;
Set       j(i)  / 10*11 /;
Parameter a(jj) / 12 25.0 / ;
```

After running this code, the listing file will contain the following lines:

```
   1  Set       i     / 1*10 / ;
   2  Set       j(i)  / 10*11 /;
****                         $170
   3  Parameter a(jj) / 12 25.0 / ;
****               $120
   4

120  Unknown identifier entered as set
170  Domain violation for element

**** 2 ERROR(S)   0 WARNING(S)
```

Note that numbers $170 and $120 flag the two errors as they occur, but the errors are explained only at the end of the compilation output. However, if the code is run using the option errmsg=1, the resulting listing file will contains the following:

```
   1  Set       i     / 1*10 / ;
   2  Set       j(i)  / 10*11 /;
****                        $170
**** 170  Domain violation for element
   3  Parameter a(jj) / 12 25.0 / ;
****               $120
**** 120  Unknown identifier entered as set
   4
**** 2 ERROR(S)   0 WARNING(S)
```

Observe that the explanation for each error is provided immediately following the error marker.

Default: 1

Value	Meaning
0	Place error messages at the end of compiler listing
1	Place error messages immediately following the line with the error
2	Suppress error messages

errNam *(string)*: Name of error message file

Available: Command line

This option specifies the name of a file defining the internally used compiler error messages. It is used to change the name from the default name gamserrs.txt.

error *(string)*: Force a compilation error with message

Available: Command line

This option forces a parameter error with a specified message. It is useful in the context of incorporating a GAMS file within another batch file where the user needs to have control over the conditions when GAMS is called. See also section Conditional Compilation.

To illustrate, the default GAMS log file from running a model with the option error=Hallo will look as follows:

```
gams: **** Error: Parameter error(s)
    :             Reading parameter(s) from "command line"
    :             *** Error Hallo
    :             Finished reading from "command line"
```

errorLog *(integer)*: Max error message lines written to the log for each error

Synonym: ER

Available: Command line

This option controls the number of error message lines that are written to the log file.

Under GAMS Studio, the default is reset to 99.

Default: 2147483647

Value	Meaning
0	No error messages to LOG file
n	Number of lines for each error that will be written to LOG file

etAlg *(real)*: Solver dependent timing information

Available: Attribute statement (use after solve)

Unlike etSolve and etSolver, this attribute is set by the individual solver links. If not set, it defaults to NA. This attribute was intended to allow solvers to return the elapsed time used by the solve algorithm without including any model generation, communication, or setup time. However, solvers are free to adapt this convention and return time-related information (but not necessarily elapsed time) for executing the solve algorithm. Please inspect your solver manual for the actual meaning of the value returned in this attribute.

etLim *(real)*: Elapsed time limit in seconds

Synonym: ETL

Available: Command line

This option controls the time limit for a GAMS job. The system will terminate with a compilation or execution error if the limit is reached. A GAMS job will terminate if the elapsed time in seconds exceeds the value of etLim. If a solve statement gets executed, and the resLim for the model to be solved is greater than etLim - timeElapsed, resLim will be reduced automatically.

Default: ∞

etSolve *(real)*: Elapsed time it took to execute a solve statement in total

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time it took to execute a solve statement in total. This time includes the model generation time, the time to read and write files, the time to create the solution report and the time taken by the actual solve. The time is expressed in seconds of wall-clock time.

etSolver *(real)*: Elapsed time taken by the solver only

Available: Attribute statement (use after solve)

This model attribute returns the elapsed time taken by the solver only. This does not include the GAMS model generation time and the time taken to report and load the solution back into the GAMS database. The time is expressed in seconds of wall-clock time.

execMode *(integer)*: Limits on external programs that are allowed to be executed

Available: Command line

A higher value denotes a more restrictive alternative. If the restriction level n is chosen, then the restriction levels less than n will also be active. For example, if restriction level 3 is chosen, then restrictions 2 and 1 will apply too.

Default: 0

Value	Meaning
0	Everything allowed
1	Interactive shells in $call and execute commands are prohibited
2	Embedded Code and all $call and execute commands are prohibited
3	$echo or put commands can only write to directories in or below the working or scratchdir
4	$echo and put commands are not allowed

expand *(string)*: Expanded (include) input file name

Synonym: EF

Available: Command line

This option generates a file that contains information about all the input files processed during a particular compilation. By default, the names of the input files are composed by completing the name with the current directory.

Consider the following exmaple:

```
$call rm expfile.txt
$onecho > file1.inc
a = a*2; display a;
$include file2.inc
$offecho
$onecho > file2.inc
a = a+1; display a;
$include file3.inc
$offecho
$onecho > file3.inc
a = a**2; display a ;
$offecho
parameter a / 1 /;
$include file3.inc
$include file2.inc
$include file1.inc
```

If the model is run with the command line parameter `ef=expfile.txt`, a file called `expfile.txt` will be generated. This file will contain the following lines:

```
1 INPUT       0     0        0        1       29  C:\GAMS\Examples\expand.gms
2 CALL        0     1        1        1        1  rm expfile.txt
3 INCLUDE     1     1       14       14       15  C:\GAMS\Examples\file3.inc
4 INCLUDE     1     1       15       16       19  C:\GAMS\Examples\file2.inc
5 INCLUDE     2     4        2       18       19  C:\GAMS\Examples\file3.inc
6 INCLUDE     1     1       16       20       25  C:\GAMS\Examples\file1.inc
7 INCLUDE     2     6        2       22       25  C:\GAMS\Examples\file2.inc
8 INCLUDE     3     7        2       24       25  C:\GAMS\Examples\file3.inc
9 EXIT        0     1       20       29       29  C:\GAMS\Examples\expand.gms
```

Note that the first row always refers to the parent file, in this case the file `expand.gms`. The first column gives the sequence number of the input files that were encountered. The second column refers to the type of file that is referenced. The following file types are possible:

```
0   INPUT
1   EXIT
2   INCLUDE
3   BATINCLUDE
4   LIBINCLUDE
5   SYSINCLUDE
6   CALL
7   CALL.ASYNC
7   CALLTOOL
8   GDXIN
9   GDXOUT
10   IF EXIST
11   IF DEXIST
12   FUNCLIBIN
13   TERMINATE
14   STOP
```

Observe that `$call` is also listed. The third column describes the depth for nested include files. The fourth column provides the sequence number of the parent file for the file being referenced. The fifth column gives the local line number in the parent file where the dollar control option $include appeared. The sixth column gives the global (expanded) line number which contained `$include`. The seventh column provides the total number of lines in the file after it is processed. The last column provides the name of the file.

Note that the listing in the expand file is similar to the include file summary in the listing file of the model. And like the include file summary, this file will not be written, if $offInclude is set in the model.

fdDelta *(real)*: Step size for finite differences

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control the step size while the numerical Hessian and numerical derivatives are computed in the context of the function suffixes `.hessn` and `.gradn`. For functions with one argument, GAMS evaluates the function at `f(x-d)` and `f(x+d)` for the numerical gradient. If function values are used for the numerical Hessian, GAMS will evaluate at `f(x-2d)`, `f(x)` and `f(x+2d)`. For functions with multiple arguments, the same calculations are performed for the components of the input argument vector.

Default: `1.0E-05`

fdOpt *(integer)*: Options for finite differences

Available: Command line, Option statement, Attribute statement (use before solve)

This option allows users to control how numerical derivatives are computed. The values provide choice regarding the scaling of steps, Hessian calculation method and the use of numerical first derivatives.

Default: `0`

Value	Meaning
0	All derivatives analytically, for numerical Hessian use gradient values, scale delta
1	All derivatives analytically, for numerical Hessian use function values, scale delta
2	Gradient analytically, force Hessian numerically using gradient values, scale delta
3	Gradient analytically, force Hessian numerically using function values, scale delta
4	Force gradient and Hessian numerically, scale delta
10	Same as 0, but no scale of delta
11	Same as 1, but no scale of delta
12	Same as 2, but no scale of delta
13	Same as 3, but no scale of delta

fErr *(string)*: Alternative error message file

Available: Command line

This option redirects the compilation error messages to a file and names the file. By default, the file name is composed by completing the name with the scratch directory and the scratch extension. Note that under default settings such a file with compilation error messages is not generated. This option can be used when GAMS is being integrated into other environments like Visual Basic. The error messages that are reported in the listing file may be extracted with this option and their display may be controlled from the environment that is calling GAMS.

To illustrate, consider the slice of GAMS code that we used to explain the option errMsg. If we call this code with the command line parameter `ferr=myfile.err`, a file called `myfile.err` will be created in the scratch directory. This file will contain the following lines:

```
0     0      0      0 D:\GAMS\NEW.LST
1     1    170     31 D:\GAMS\NEW.GMS
2     2    120     14 D:\GAMS\NEW.GMS
```

Note that the first column refers to the global row number of the error in the listing file. The second column refers to the row number of the error in the individual file where the problem occured. This will be different from the first column only if the error occured in an include file. In this case, the second column will contain the line number in the include file where the error occurred, while the first number will contain the global line number (as reported in the listing file) where the error occured. The number in the third column refers to the error number of the compilation error. The fourth number refers to the column number of the error in the source file. The last column contains the individual file in which the error occurred.

fileCase *(integer)*: Casing of file names and paths (put, gdx, ref, $include, etc.)

Available: Command line

This option facilitates modifying the case of file names and paths. It applies to files created by a GAMS Job such as for example put files, GDX files and reference files. Under Windows, the casing of a created file will only be affected if the file does not yet exist, i.e. `fileCase=2` won't create `trnsport.ref` if there is already a file `TRNSPORT.ref`. It should be noted that `fileCase` also applies to existing files that are used but not created by a GAMS job such as for example $include files or $batInclude files.

Note that many other file names and paths are affected by this option (e.g. the scratch directory (scrDir) or the GAMS system directory (sysDir)) and that it is recommended to use this option with caution.

Default: `0`

Value	Meaning
0	Causes GAMS to use default casing
1	Causes GAMS to upper case file names including path of the file
2	Causes GAMS to lower case file names including path of the file
3	Causes GAMS to upper case file names only (leave the path alone)
4	Causes GAMS to lower case file names only (leave the path alone)

fileStem *(string)*: Sets the file stem for output files which use the input file name as stem by default

Available: Command line

By default, some output files use the input file name as base. If the names of these output files were not set explicitly, then this option may be used to set another name than the input file name as base for these output files. In particular, the names for the following files may be set with `fileStem`: dump files (see option dumpOpt), GDX files (if the option GDX was set to `default`), log files (see option logFile), lst files (see option output), reference files (if the option reference was set to `default`) and trace summary files (see also option trace).

fileStemApFromEnv *(string)*: Append a string read from an environment variable to the "FileStem"

Available: Command line

This option for users that submit GAMS job via mpirun/mpiexec. Such commands will spawn multiple instances of GAMS (the precise number is an argument to mpirun/mpiexec). Each invokation of GAMS will run the identical job and only the contents of an environment variable (`PMI_RANK`) will differentiate the run. Since GAMS will normally write to `modelname.log/lst` if we run the GAMS file `modelname.gms` we will have many jobs writing to the same file. Therefore we use this option to append the content of a particular environment variable (name given by this option) to the default file names (see fileStem). Hence GAMS will create `modelname0.log/lst`, `modelname1.log/lst`, and so forth when started with mpirun/mpiexec and `fileStemApFromEnv` is set to the environment variable that provides the MPI rank of the invokation. We allow to specify the name of the environment variable because different MPI implementations use different variable names (e.g. `PMI_RANK` or `OMPI_COMM_WORLD_RANK`).

filtered *(string)*: Switch between filtered and domain-checked read from GDX

Available: Command line, Option statement

The command line parameter Filtered initializes both, the option Filtered to control the behvior of `gdxLoad` and the dollar control option $on/offFiltered for the compile-time equivalent behavior.

Default: `on`

Value	Meaning
`off`	Load domain checked
`on`	Load filtered

forceOptFile *(integer)*: Overwrites other option file section mechanism

Available: Command line

Default: `0`

forceWork *(boolean)*: Force GAMS to process a save file created with a newer GAMS version or with execution errors

Synonym: FW

Available: Command line

Work files generated by GAMS using the command line parameter save are saved in binary format. The information inside these files will change from one GAMS version to another GAMS version. GAMS makes every attempt to be backward compatible and ensure that all new GAMS systems are able to read save files generated by older GAMS systems. However, this cannot be guaranteed the other way around. Thus, GAMS does not allow to process a save file, that was generated by a newer version of GAMS in general. This can be changed by setting `forceWork` to 1. Also, GAMS does not continue after processing a save while with an execution error by default. This behavior can be changed as well by setting `forceWork=1`.

Attention

Forcing GAMS to continue after reading a save file from a newer GAMS version or a save file with execution errors may lead to unexpected behavior. If it is about the GAMS version and you can recreate the save file you may write it using GAMS command line parameter previousWork=1.

Default: `0`

Value	Meaning
`0`	No translation
`1`	Try translation

forLim *(integer)*: GAMS looping limit

Available: Command line, Option statement

This option specifies the maximum number of permitted executions of control structures with a for statement, a while statement or a repeat statement before GAMS signals an execution error and terminates the control structure.

Default: ∞

fSave *(boolean)*: Creates a forced work file, i.e., the file is saved even if execution errors or other errors occured

Available: Command line

This option allows to save a file even in the face of execution or other errors. How it works depends on the command line parameter save.

Note that the option value of 1 is mainly used by solvers that can be interrupted from the terminal.

Default: `0`

Value	Meaning
`0`	Workfile only written to file specified by SAVE if no errors occur
`1`	Workfile always written to file specified by SAVE or if SAVE is not present to a name made up by GAMS

G205 *(integer)*: Use GAMS version 2.05 syntax

Available: Command line

This option sets the level of the GAMS syntax and is mainly used to ensure backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when they are run with the latest version of GAMS. This option enables users to run such old models.

For example, the word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting the option `g205=1` allows the word "if" to be used as an identifier since it was not a keyword in Release 2.05. As another example, the word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting the option `g205=2` allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.

Note

If the values 1 or 2 are specified for option `g205`, then it will not be permitted to use enhancements of the GAMS language that were introduced in later versions.

Default: `0`

Value	Meaning
`0`	Use only latest syntax
`1`	Allow version 2.05 syntax only
`2`	Allow version 2.25 syntax only

GDX *(string)*: GAMS data exchange file name

Available: Command line

This option specifies the name of the GAMS data exchange file and causes a GDX file to be written hat contains all data in the model at the end of the job. Setting `gdx` to the string 'default' causes GAMS to create a GDX file with the gms file root name and a gdx extension. Thus gams the call

```
> gams trnsport gdx=default
```

will cause GAMS to write the GDX file `trnsport.gdx`.

gdxCompress *(boolean)*: Compression of generated GDX file

Available: Command line

This option specifies whether the GDX files are compressed or not.

Default: `0`

Value	Meaning
`0`	Do not compress GDX files
`1`	Compress GDX files

gdxConvert *(string)*: Version of GDX files generated (for backward compatibility)

Available: Command line

This option specifies in which format the GDX files will be written.

Default: `v7`

Value	Meaning
`v5`	Version 5 GDX file, does not support compression
`v6`	Version 6 GDX file
`v7`	Version 7 GDX file

gdxSymbols *(string)*: Select symbols that get exported when command line parameter GDX is set

Available: Command line

This option specifies which symbols get exported when command line parameter GDX is set. By default, all symbols get written to the specified GDX file, but it can be limited to only the ones that were created or updated during the model run, or even to just the ones changed during execution time.

Default: `all`

Value	Meaning
`all`	Write all symbols
`newOrChanged`	Write only symbols that are new or got modified during compile or execution time
`assigned`	Write only symbols that got modified during execution time

gdxUels *(string)*: Unload labels or UELs to GDX either squeezed or full

Available: Command line, Option statement

This option specifies the UEL export mode. Note that `gdxUels` only works for execute_unload* statements during execution time and not for the command line parameter GDX or dollar control options $gdxOut/$unload/$gdxUnload.
The UEL table may be written to a GDX file in two different modes. In `squeezed` mode, only the UELs that are required by the exported symbols are exported. In `full` mode, all UELs are exported. The following code snippet illustrates the difference:

```
Set       i    / i1*i5 /;
Parameter p(i) / i3 3 /;

option gdxuels = squeezed;
execute_unload 'squeezed' p;
execute 'gdxdump squeezed UelTable=i';

option gdxuels = full;
execute_unload 'full' p;
execute 'gdxdump full UelTable=i';
```

The file `squeezed.gdx` will contain the following lines:

```
Set i /
  'i3' /;

Parameter p(*) /
'i3' 3 /;
```

The file `full.gdx` on the other hand, will contain the following lines:

```
Set i /
  'i1' ,
  'i2' ,
  'i3' ,
  'i4' ,
  'i5' /;

Parameter p(*) /
'i3' 3 /;
```

Default: `squeezed`

Value	Meaning
`Squeezed`	Write only the UELs to Universe, that are used by the exported symbols
`Full`	Write all UELs to Universe

gridDir *(string)*: Grid file directory

Synonym: GDir

Available: Command line

This option sets the grid file directory. Note that each GAMS job has only one grid file directory.

gridScript *(string)*: Grid submission script

Synonym: GScript

Available: Command line

This option provides the name of a script file that is used to submit grid computing jobs. If only the file name is given the file is assumed to be located in the system directory. A fully qualified name can be given as well. The script needs to be similar to the file `gmsgrid.cmd` on Windows machines with arguments that give name and location of the solver executable, the solver control file name and the name of the scratch directory. For an example of such a script, see section The Grid Facility: Architecture and Customization. However, note that advanced knowledge of how GAMS sets up and calls solvers is needed for successful use.

Default: `gmsgrid`

handle *(real)*: Unique handle number of SOLVE statement

Available: Attribute statement (use after solve)

The model attribute `handle` contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The handle number may be used by the functions handleCollect, handleStatus, handleDelete, handleSubmit and readyCollect. For details see chapter The Grid and Multi-Threading Solve Facility.

heapLimit *(real)*: Maximum Heap size allowed in MB

Synonym: HL

Available: Command line

This option allows to limit the amount of memory a GAMS job may use during compilation and execution. If the needed data storage exceeds this limit, the job will be terminated.

Default: ∞

holdFixed *(boolean)*: Treat fixed variables as constants

Available: Command line, Attribute statement (use before solve)

This option facilitates treating fixed variables as constants. Thus the problems size may be reduced.

Default: `0`

Value	Meaning
0	Fixed variables are not treated as constants
1	Fixed variables are treated as constants

holdFixedAsync *(boolean)*: Allow HoldFixed for models solved asynchronously as well

Available: Command line, Option statement

By default, holdFixed is automatically deactivated if a model is solved asynchronously, since this could lead to inconsistent solutions otherwise. To allow this anyway, this parameter can be set to 1.

Default: 0

Value	Meaning
0	Ignore HoldFixed setting for async solves
1	Allow HoldFixed for async solves

IDCGDXInput *(string)*: GDX file name with data for implicit input

Available: Command line

Specify the name of a GDX file that is used for implicit loading of input data. Details about this are described with $onExternalInput.

IDCGDXOutput *(string)*: GDX file name for data for implicit output

Available: Command line

Specify the name of a GDX file that is used for implicit writing of output data. Details about this are described with $onExternalOutput.

IDCGenerateGDX *(string)*: Specify GDX file name of input and output side of data contract

Available: Command line

Specify the name of a GDX file that is used to store all symbols that are declared as external input or external output at the end of a GAMS run.

IDCGenerateGDXInput *(string)*: Specify GDX file name of input side of data contract

Available: Command line

Specify the name of a GDX file that is used to store all symbols that are declared as external input at the end of a GAMS run.

IDCGenerateGDXOutput *(string)*: Specify GDX file name of output side of data contract

Available: Command line

Specify the name of a GDX file that is used to store all symbols that are declared as external output at the end of a GAMS run.

IDCGenerateJSON *(string)*: Specify JSON file name of data contract

Available: Command line

Specify the name of a JSON file that is used to store the information (but not the data) about all symbols that are declared as external input or external output at the end of a GAMS run.

IDCJSON *(string)*: Specify JSON file name to verify data contract

Available: Command line

Specify the name of a JSON file that is read and used to verify that the implicit data contract given by the GAMS model by declaring symbols as external input or external output matches the expected symbol information given by this specified file. This is the expected schema of that file:

```
{
  "$schema":"http://json-schema.org/draft-07/schema#",
  "title":"Input/Output configuration file schema",
  "description":"Configuration file is automatically generated by GAMS and describes the data contract.",
  "type":"object",
  "definitions": {
    "symbolHeader":{
      "description":"Symbol header",
      "type":"object",
      "properties":{
        "alias":{
          "description":"Explanatory text of the header",
          "type":"string",
          "minLength":1
        },
        "type":{
          "description":"GAMS input type",
          "type":"string",
          "enum":[
            "string",
            "numeric"
          ]
        }
      },
      "required": ["alias", "type"]
    },
    "symbol":{
      "description": "Symbol definition",
      "type": "object",
      "properties": {
        "alias":{
          "description": "Explanatory text of the symbol",
          "type":"string",
          "minLength":1
        },
        "symtype":{
          "description": "Symbol type",

          { "$ref": "#/definitions/scalarSymbol" },
          { "$ref": "#/definitions/symbol"}
        ]
      }
    }
  },
  "required":["modelTitle", "inputSymbols", "outputSymbols"]
}
```

IDCProtect *(boolean)*: Flag to control assignment protection of external input symbols

Available: Command line, Option statement

By default, it is not allowed to change symbols which are declared as external input at execution time. This parameter allows to ignore this restriction. It sets the initial state for the dollar control options $on/offIDCProtect.

Default: 1

Value	Meaning
0	Allow to change external input symbols at execution time
1	Protect external input symbols from being changed at execution time

IDE *(boolean)*: Integrated Development Environment flag

Available: Command line

This option instructs GAMS to write special instructions to the log file that are in turn read by an IDE.

Default: 0

Value	Meaning
0	Unknown environment
1	Runs under GAMS IDE

implicitAssign *(string)*: Switch default for "$on/offImplicitAssign"

Available: Command line

For more info see $on/offImplicitAssign.

Default: off

Value	Meaning
off	Activate $offImplicitAssign
on	Activate $onImplicitAssign

inlineCom *(string)*: Switch default for "$on/offInline" and "$inlineCom"

Available: Command line

If this is set to on `on` or `off` it sets the state of $on/offInline. Other strings (a pair with not more than two characters each) will set $inlineCom.

Default: off

Value	Meaning
off	Activate $offInline
on	Activate $onInline using default inline comment characters
other	Activate $onInline setting specific inline comment characters

input *(string)*: Input file

Synonym: I

Available: Command line

Completing the input file name with the current directory composes the final name. If such a file does not exist and the extension was not specified, the standard input extension will be attached and a second attempt will be made to open an input file.

inputDir, inputDir1..40 *(string)*: Input file directories (searched at compile time)

Synonym: IDIR

Available: Command line

In general, GAMS searches for input and include files in the current working directory only. This option allows the user to specify additional directories for GAMS to search for include and batinclude files as well as GDX file via $gdxIn. A maximum of 40 separate directories may be included. The directories are separated by Operating System specific symbols. For example, on a PC the separator is a semicolon (;) character and under Unix it is the colon (:) character. Note that libinclude and sysinclude files are handled differently. Their paths are specified with the command line parameters libIncDir and sysIncDir respectively.

Consider the following illustration:

```
> gams myfile idir \mydir;\mydir2
```

Note that the search order for the file `myfile.gms` and all included files in PC systems will be as follows: (1) the current directory, (2) the directories specified by `inputdir` in their respective order (here the directories: `\mydir` and `\mydir2`). Under Unix, the corresponding GAMS call will be:

```
> gams myfile idir \mydir:\mydir2
```

Note that the information in the option `inputDir` may be also transferred to GAMS by entering the individual directories separately. A maximum of 40 directories may be passed on in this manner. The number appended to `InputDir` is important since the earlier `InputDir` directories will be searched first.

The example above may alternatively be formulated in the following way:

```
> gams myfile idir1 mydir1 idir2 mydir2
```

Note that in this case the search order will be as follows:

1. `current directory`
2. `mydir1`
3. `mydir2`

Observe that we could modify the command in the following way:

```
> gams myfile idir3 \mydir1 idir2 \mydir2
```

Note that in this case the search order will be as follows:

1. `current directory`
2. `mydir2`
3. `mydir3`

Thus it is not the order in which the directories are specified that matters, but the number of the option `inputDir` that they have been assigned to.

integer1..5 *(integer)*: Integer communication cell N

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an integer communication cell that may contain any integer number.

interactiveSolver *(boolean)*: Allow solver to interact via command line input

Available: Command line

Default: `0`

Value	Meaning
0	Interaction with solvelink 0 is not supported
1	Interaction with solvelink 0 is supported

intVarUp *(integer)*: Set mode for default upper bounds on integer variables

Available: Command line, Option statement

Default: 0

Value	Meaning
0	Set default upper bound for integer variables to +INF
1	Pass a value of 100 instead of +INF to the solver as upper bound for integer variables
2	Same as 0 but writes a message to the log if the level of an integer variable is greater than 100
3	Same as 2 but issues an execution error if the level of an integer variable is greater than 100

iterLim *(integer)*: Iteration limit of solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the maximum number of permitted solver iterations, before the solver terminates the run. If this limit is reached, the solver will terminate and will return solver status `2 ITERATION INTERRUPT`. Note that the definition of what constitutes an interation depends on the solver. For LP solvers, `iterlim` often refers to the number of simplex iterations (i.e., pivots). For MIP solvers, `iterlim` often refers to the cumulative number of simplex iterations over all solves of LP relaxations. Observe that `iterlim` does not apply to all iterations. For example, it might not apply to barrier iterations and major iterations in nonlinear solvers. For these iterations solver-specific options need to be set. Moreover, some solver links might *reinterpret* the value of this option. For example, if left at default, the solver link might use the default iteration limit of the solver.

Default: 2147483647

iterUsd *(integer)*: Number of iterations used

Available: Attribute statement (use after solve)

This model attribute returns the number of iterations used after a solve.

jobTrace *(string)*: Job trace string to be written to the trace file at the end of a GAMS job

Synonym: JT

Available: Command line

This option specifies a string that is written to the trace file at the end of a GAMS job.

keep *(boolean)*: Controls keeping or deletion of process directory and scratch files

Available: Command line

This option controls whether to keep the process directory. In the process directory the temporary/scratch files are located, unless the options scrDir or procDir were used.

Default: 0

Value	Meaning
0	Delete process directory
1	Keep process directory

libIncDir *(string)*: LibInclude directory

Synonym: LDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for $libInclude files that do not have a full path specification. An absolute or relative path may be specified. If the option `libIncDir` is not set, it will be set to the subdirectory `inclib` in the GAMS standard locations. A relative path is relative to the GAMS system directory.

Note that if the option `libIncDir` parameter is set, the default library include directories will only be searched, if the libInclude file cannot be found in the specified folder.

Attention

Only *one* directory may be set with the option `libIncDir`. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

```
> gams myfile libIncDir mydir
```

Note that GAMS will search for any referenced libInclude file in the directory <`GAMS System Directory`>`/mydir` first.

license *(string)*: Use alternative license file

Available: Command line

This option specifies the name the file that contains the GAMS license. It may be used to point to an explicit license file rather letting GAMS search for the default `gamslice.txt` in various locations including the GAMS system directory. The locations ("Data directories") can be printed by running `gamsinst -listdirs`, see installation notes for details. The `license` option should only be used by advanced users attempting to override internal license information.

limCol *(integer)*: Maximum number of columns listed in one variable block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of columns that are listed for each variable in the column listing in the listing file. Note that the value of zero will suppress the column listing.

Default: `3`

limRow *(integer)*: Maximum number of rows listed in one equation block

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of rows that are listed for each equation in the equation listing in the listing file. Note that the value of zero will suppress the equation listing.

Default: `3`

line *(integer)*: Line number of last solve of the corresponding model

Available: Attribute statement (use after solve)

This model attribute returns the line number of the last solve of the respective model.

linkUsed *(integer)*: Integer number that indicates the value of SolveLink used for the last solve

Available: Attribute statement (use after solve)

This model attribute returns an integer number that indicates the value of the option solveLink that was used for the last solve.

listing *(string)*: Switch default for "$on/offListing"

Available: Command line

For more info see $on/offListing.

Default: `on`

Value	Meaning
`off`	Activate $offListing
`on`	Activate $onListing

logFile *(string)*: Log file name

Synonym: LF

Available: Command line

This option is used in conjunction with the option logOption or short `LO`. If `lo` is set to 2 or 4, this option will specify the name of the log file name. The name provided by the option is completed using the current directory. If no logfile is given, but the value of `lo` is 2 or 4, then the file name will be the input file name with the extension `.log`.

Consider the following GAMS call:

```
> gams trnsport lo=2 lf=myfile.log
```

Note that the resulting log file will redirected to the file `myfile.log`. It will contain the following lines:

```
--- Starting compilation

```

logLine *(integer)*: Amount of line tracing to the log file

Synonym: LL

Available: Command line

This option may be used to limit the number of line tracing sent out to the log file during the compilation phase of a GAMS run. Note that setting this option to zero will cause the line tracing to be suppressed for all phases of the GAMS processing.

The log file that results from running the model [**TRNSPORT**] with the option `ll=0` is shown below.

```
 --- Starting compilation
--- Starting execution: elapsed 0:00:00.018
--- Generating LP model transport
---   6 rows  7 columns  19 non-zeroes
--- Executing CPLEX: elapsed 0:00:00.060

```

If we compare this output to the output shown in the example of option logFile, we will observe that the line numbers are missing from this log file.

Default: 2

Value	Meaning
0	No line tracing
1	Minimum line tracing
2	Automatic and visually pleasing

logOption *(integer)*: Log option

Synonym: LO

Available: Command line

This option controls the location of the output log of a GAMS run. By default, GAMS directs the log of the run to the standard output. If `logOption` is set to 2, the log will be redirected to a file. Note that if no file name is provided for the log through the option logFile, the file name will be the input file name with the extension `.log`. Observe that the settings zero and 2 may be used to permit jobs to run in the background.

To illustrate, consider the following call:

```
> gams trnsport lo=2
```

Note that the resulting log file, `trnsport.log`, will be identical to the file `myfile.log` that is shown as part of the description of the option logFile.

Default: 3

Value	Meaning
0	No log output
2	Log output to logfile
3	Log output to standard output
4	Log output to logfile and standard output

LP *(string)*: Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Linear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

lstTitleLeftAligned *(boolean)*: Write title of LST file all left aligned

Available: Command line

Default: `1`

Value	Meaning
`0`	Split LST title into left and right aligned part
`1`	Write LST title completely left aligned

marginals *(integer)*: Indicator for marginals present

Available: Attribute statement (use after solve)

maxExecError *(integer)*: Execution time error limit

Synonym: ExecErr

Available: Command line

This option puts an upper limit on the number of errors that may be found during execution or preprocessing associated with a solve statement. If more than `maxExecError` errors have been found GAMS will abort when hitting the next `solve` statement. If `maxExecError` is greater than the number of pending execution errors, the `solve` will be skipped, but the execution continues afterwards. This value can be overwritten with the function maxExecError.

Default: `0`

Value	Meaning
`0`	No errors allowed limit
`n`	Max number allowed

maxGenericFiles *(integer)*: Maximum number of generic file names tried at execution time file creation

Available: Command line, Option statement

In case of a failed writing of put files and GDX files via execute_unload (e.g. because the given path is invalid or the file is open by another program), GAMS tries to write to a generic file name instead. The number of file names tried can be specified with this option. To avoid this completely and throw an error right away, if the given name is invalid, set this to `0`.

Default: `20`

maxInfes *(real)*: Maximum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the maximum number of infeasibilities after a solve.

maxProcDir *(integer)*: Maximum number of 225∗ process directories

Available: Command line

This option controls the maximum number of work file directories that may be generated by GAMS. By default they are called 225a, 225b, ..., 225aa, 225ab ... Note that the label `225` may be changed with the option procDir.

Default: `700`

MCP *(string)*: Mixed Complementarity Problems - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Complementarity Problems is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

MCPRHoldFx *(boolean)*: Print list of rows that are perpendicular to variables removed due to the holdfixed setting

Available: Command line, Option statement, Attribute statement (use before solve)

If option holdfixed is true, fixed columns in row.column matches are removed from MCP models but the matching rows remain. These rows are ignored by the solver. This option causes a list of such rows to be included in the listing file prior to the solve summary.

Default: `0`

meanInfes *(real)*: Mean of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the mean of the infeasibilities after a solve.

measure *(no value)*: Output of time and memory use since the last measure statement or the program beginning

Available: Option statement

This option has the effect that three measurements will be displayed: the memory and time usage since the last option statement `measure` and the total time used. See also the related option profile.

memoryStat *(no value)*: Show memory statistics in the LST file

Available: Option statement

This option has the effect that memory statistics will be shown in the listing file.

MIIMode *(string)*: Model Instance Mode

Available: Command line

This parameter is used in conjunction with the GAMS Model Instance Inspector (MII). The MII needs to have access to the scratch directory and requires a dictionary for the model instance to analyze. So, this parameter forces other parameters to be set:

- Keep is forced to `1`.
- DictFile is forced to `1`.
- SolveLink is forced to `2` with `MIIMode=singleMI` and to `4` with `MIIMode=multiMI`.

Default: `off`

Value	Meaning
`off`	Default behavior
`singleMI`	Setup to inspect a single model instance
`multiMI`	Setup to inspect multiple model instances from one model

MINLP *(string)*: Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

MIP *(string)*: Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

MIQCP *(string)*: Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Mixed Integer Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

modelStat *(integer)*: Integer number that indicates the model status

Available: Attribute statement (use after solve)

This model attribute returns the model status after a solve. Observe that there are compile-time constants that are related to `modelStat`. Note that additional information to the values given in the table below is provided in section Model Status.

Value	Meaning
1	Optimal
2	Locally Optimal
3	Unbounded
4	Infeasible
5	Locally Infeasible
6	Intermediate Infeasible
7	Feasible Solution

Value	Meaning
8	Integer Solution
9	Intermediate Non-Integer
10	Integer Infeasible
11	Licensing Problem
12	Error Unknown
13	Error No Solution
14	No Solution Returned
15	Solved Unique
16	Solved
17	Solved Singular
18	Unbounded - No Solution
19	Infeasible - No Solution

MPEC *(string)*: Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type Mathematical Program with Equilibrium Constraints is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

multi *(string)*: Switch default for "$on/offMulti[R]"

Available: Command line

If this is set to on `on` or `off` it sets the state of $on/offMulti. The value `onR` activates $onMultiR.

Default: `off`

Value	Meaning
`off`	Activate $offMulti
`on`	Activate $onMulti
`onR`	Activate $onMultiR

multiPass *(boolean)*: Multipass facility

Synonym: MP

Available: Command line

This option may be used to instruct GAMS to use a quick syntax checking compilation facility which does not require all items to be declared. This alternative is useful when a large model is assembled from smaller pieces. It allows slices of GAMS code to be independently checked for syntax errors.

Consider the following example:

```
a(i) = b(i)*5 ;
b(i) = c(j) ;
```

By default, running a file containing just these two statements will generate the following listing file:

```
   1  a(i) = b(i)*5 ;
****  $140,120,140
   2  b(i) = c(j) ;
****         $140,120,149

120  Unknown identifier entered as set
140  Unknown symbol
149  Uncontrolled set entered as constant

**** 6 ERROR(S)   0 WARNING(S)
```

Note that both sets `i` and `j` have not been defined or initialized. In addition, the identifiers `a`, `b` and `c` have not been defined either. Further, an assignment cannot be made without the right-hand side of the assignment being known. However, in both assignments there is no data available for the right-hand side. If we run the same two lines with the option `mp=1`, we will get the following listing file:

```
   1  a(i) = b(i)*5 ;
   2  b(i) = c(j) ;
****            $149

149  Uncontrolled set entered as constant

**** 1 ERROR(S)   0 WARNING(S)
```

Observe that the statements have now been processed independently of their context. They are now checked only for consistency. GAMS now assumes that the sets `i` and `j`, as well as the identifiers `a`, `b`, and `c` have been defined and, if necessary, initialized elsewhere. The only error that is reported is the inconsistency of indices in the second statement.

Default: `0`

Value	Meaning
0	Standard compilation
1	Check-out compilation
2	As 1, and skip $call and ignore missing file errors with $include and $gdxin as well as unknown dimension errors with empty data statements

NLP *(string)*: Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

nodLim *(integer)*: Node limit in branch and bound tree

Available: Command line, Attribute statement (use before solve)

This option specifies the maximum number of nodes that are to be processed in the branch and bound tree search for a MIP problem. Note that setting `nodLim` can stop solutions that are exhibiting "excessive" iterations: if the limit is reached the algorithm will terminate, without obtaining optimality. In this case the solver status will be `4 TERMINATED BY SOLVER`. Observe that a value of zero is interpreted as 'not set'.

Default: `0`

nodUsd *(integer)*: Number of nodes used by the MIP solver

Available: Attribute statement (use after solve)

This model attribute returns the number of nodes used by the MIP solver after a solve.

noNewVarEqu *(integer)*: Triggers a compilation error when new equations or variable symbols are introduced

Available: Command line

Default: `0`

Value	Meaning
`0`	AllowNewVarEqu
`1`	DoNotAllowNewVarEqu

number *(real)*: Model instance serial number

Available: Attribute statement (use after solve)

This model attribute returns the model instance serial number. Note that the first model solved is assigned number 1, the second number 2 etc. The user may also set a value `n` and the next model solved will be assigned the number `n+1`.

numDepnd *(integer)*: Number of dependencies in a CNS model

Available: Attribute statement (use after solve)

This model attribute returns the number of dependencies identified in a CNS model after a solve.

numDVar *(integer)*: Number of discrete variables

Available: Attribute statement (use after solve)

This model attribute returns the number of discrete variables after a solve.

numEqu *(integer)*: Number of equations

Available: Attribute statement (use after solve)

This model attribute returns the number of equations after a solve.

numInfes *(integer)*: Number of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the number of infeasibilities after a solve.

numNLIns *(integer)*: Number of nonlinear instructions

Available: Attribute statement (use after solve)

This model attribute returns the number of nonlinear instructions after a solve.

numNLNZ *(integer)*: Number of nonlinear nonzeros

Available: Attribute statement (use after solve)

This model attribute returns the number of nonlinear nonzeros after a solve.

numNOpt *(integer)*: Number of nonoptimalities

Available: Attribute statement (use after solve)

This model attribute returns the number of nonoptimalities after a solve.

numNZ *(integer)*: Number of nonzero entries in the model coefficient matrix

Available: Attribute statement (use after solve)

This model attribute returns the number of nonzero entries in the model coefficient matrix after a solve.

numRedef *(integer)*: Number of MCP redefinitions

Available: Attribute statement (use after solve)

This model attribute returns the number of MCP equation-type redefinitions after a solve.

numVar *(integer)*: Number of variables

Available: Attribute statement (use after solve)

This model attribute returns the number of variables after a solve.

numVarProj *(integer)*: Number of bound projections during model generation

Available: Attribute statement (use after solve)

This model attribute returns the number of bound projections during model generation.

objEst *(real)*: Estimate of the best possible solution for a mixed-integer model

Available: Attribute statement (use after solve)

This model attribute returns the estimate of the best possible solution for a MIP or other models with discrete variables. The model attribute is mainly used after solve.

Some GAMS solvers implement algorithms (e.g. branch-and-bound) that generate a bound on the objective function value for the best possible solution. Users may access this bound by using the model attribute `objEst`. Note that this is mainly used for models with discrete variables (e.g. MIP and MINLP), but some global solvers implement spatial branch-and-bound algorithms that also provide such a bound for purely continuous problems. In case the solver does not set the attribute, its value is `na`.

objVal *(real)*: Objective function value

Available: Attribute statement (use after solve)

This model attribute returns the objective function value after a solve.

on115 *(boolean)*: Generate errors for unknown unique element in an equation

Available: Command line

This option generates errors for unknown unique elements in an equation.

Default: `0`

Value	Meaning
0	No error messages
1	Issue error messages

optCA *(real)*: Absolute Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies an *absolute termination tolerance* for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The absolute gap is defined to be |PB-DB|. Here the primal bound PB is the objective function value of the best feasible solution found thus far and the dual bound DB is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization).

If the absolute gap is not greater than optCA, the solver will terminate and return solver status 1 NORMAL COMPLETION and model status 8 INTEGER SOLUTION (for a problem with discrete variables) or 2 LOCAL OPTIMAL or 7 FEASIBLE SOLUTION (for a problem without discrete variables). Note that this is a termination test only; setting this option should not change the global search.

Note

As this is an *absolute* criterion, setting the value to 100 means that the objective value will be within the 100 units of the true objective value.

Observe that a nonzero value for optCA will reduce solution time. However, it may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by optCA of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: 0

optCR *(real)*: Relative Optimality criterion solver default

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies a *relative termination tolerance* for a global solver. General problems are often extremely difficult to solve and proving that a solution that was found for a nonconvex problem is indeed the best possible solution can use enormous amounts of resources. The precise definition of optCR depends on the solver. GAMS and some solvers use the following formula to compute the *optimality gap*:

```
|PB-DB| / max(|PB|,|DB|)
```

Here the primal bound PB is the objective function value of the best feasible solution found thus far and the dual bound DB is the current bound on the optimal value of the problem (i.e., lower bound in case of minimization and upper bound in case of maximization). However, two other formulas are also widely used, namely

```
|PB-DB| / |PB|
```

and

```
|PB-DB| / |DB|
```

Different adjustments when the denominator approaches zero or bounds are of different signs will be applied. The solver will stop as soon as it has found a feasible solution proven to be within optCR of optimal, that is, the optimality gap falls below optCR.

Note

As `optCR` is specified in *proportional* terms relative to the objective value, a value of 0.1 means that the objective value will be within 10% of the true objective value.

Observe that the solver will stop after finding a solution proven to be optimal within the tolerance specified with `optCR` and thus the solution time may be reduced. However, setting this option may cause the true integer optimum to be missed. This will be the case if at the time the solution algorithm stops, the value of the true integer optimum is within the tolerance specified by `optCR` of the best current solution. Therefore the reported solution could be the best, but it is guaranteed only to be within the tolerance of the true optimal solution.

Default: `1.0E-04`

optDir *(string)*: Option file directory

Available: Command line

This option may be used to specify the name of the directory for solver option files. By default, the directory will be set to the current working directory.

optFile *(integer)*: Default option file

Available: Command line, Attribute statement (use before solve)

This option instructs the solver to read an option file. The value of `optFile` determines which option file is used (see table below). Solver options allow users to manipulate the way solvers work. This may affect various solver functions including the choice of the branch and bound tree handling strategies. Please consult the solver manuals for options for each solver.

Note that this option is availabe as model attribute and command line parameter. Consider the following GAMS call:

```
> gams myfile optfile=1
```

Observe that the value of 1 for `optFile` means that the option file with the name `solverName.opt` will be used. Here `solverName` is the name of the respective solver. For example, if the solver CONOPT is used, the name of the respective option file is `conopt.opt`.

Note

If `optFile` is set with the model attribute in the GAMS input file, the value of the model attribute will override any `optFile` specifications on the command line.

Different values for `optFile` allow access to different option files for the same solver. Note that the following rule is used: if we specify `optfile = n`, then `solvername.opt` will be used for `n=1`, otherwise `solvername.opX`, `solvername.oXX` or `solvername.XXX` will be used, where `X`'s are the characters representing the value of `n`, for `n` $>$ `1`. Observe that no option file will be used if the value of `optFile` is zero.

Default: `0`

Value	Meaning
0	No option file will be used
1	The option file solvername.opt will be used
2	The option file solvername.op2 will be used
3	The option file solvername.op3 will be used
15	The option file solvername.o15 will be used
222	The option file solvername.222 will be used
1234	The option file solvername.1234 will be used

output *(string)*: Listing file name

Synonym: OO

Available: Command line

By default, the name of the output file (or listing file) is automatically created by combining the name of the input file with the current directory and applying the standard output file extension `.lst`. This option may be used to specify an alternative name for the output file. If the value is a file name without an absolute path, the current directory will compose the final name. If the absolute path is included in the file name, then the name is used as specified.

Consider the following examples:

```
gams trnsport
gams trnsport o=trnsportOut
gams trnsport o=c:\test\trnsport.out
```

Note that the first call will create an output file called `trnsport.lst` (for PC and Unix platforms) in the current directory. The second call will create a file called `trnsportOut` (without extension) in the current directory. The last call will create the file as listed. If the directory `c:\test` does not exist, GAMS will exit with a parameter error.

Creation of the output file can be suppressed by setting the command line parameter writeOutput to `0`.

pageContr *(integer)*: Output file page control option

Synonym: PC

Available: Command line

This option affects the page control in the listing file.

Default: `2`

Value	Meaning
0	No page control, with padding
1	FORTRAN style line printer format
2	No page control, no padding
3	Formfeed character for new page

pageSize *(integer)*: Output file page size (=0 no paging)

Synonym: PS

Available: Command line

This option specifies the number of lines that are used on a page for printing the listing file. The lower bound is zero, which is interpreted as +inf. That means that everything is printed to one page.

Default: `0`

pageWidth *(integer)*: Output file page width

Synonym: PW

Available: Command line

This option sets the print width on a page in the listing file with a possible range from 72 to 32767. If the value is outside the allowed range, the default value will be used.

Note that `.pw` is also a put file attribute. In the context of the put writing facility, it may be used to set the page width of a put file. See page width for further details.

Default: `32767`

parmFile *(string)*: Command Line Parameter include file

Synonym: PF

Available: Command line

This option specifies the name of a secondary customization parameter file to use. It is used to augment the command line adding more command line parameters from a file. It is read from the current directory unless a path is specified. For an example, see section Specifying Options Through a Secondary Parameter File.

pLicense *(string)*: Privacy license file name

Available: Command line

This option gives the name of a privacy license file that contains file encryption codes. A full path should be used. For more information, see Encrypting Files.

prefixLoadPath *(boolean)*: Prepend GAMS system directory to library load path

Available: Command line

The OS environment variable to locate shared libraries used to be prefixed with the GAMS system directory. The option controls if this done or not. For the Windows platform, setting this option has no impact.

Default: `0`

Value	Meaning
`0`	Do not set GAMS system directory at beginning of library load path
`1`	Set GAMS system directory at beginning of library load path

previousWork *(boolean)*: Indicator for writing workfile with previous workfile version

Available: Command line

When GAMS creates a workfile (e.g. using command line parameter restart) by default it uses the most recent version of the workfile format. GAMS is backward compatible with respect to workfile formats, i.e. newer GAMS versions can process workfiles generated by older GAMS version. As long as the workfile format has not changed older GAMS versions can even process workfiles generated by newer GAMS versions (using the forceWork=1 command line parameter). This particular command line parameter allows to create a workfile using the *previous* workfile format with the current GAMS version, so the previous GAMS version

(and probably a few more versions back) will properly restart from this workfile even without issueing a warning.

This option is mostly used in combination with submissions to the NEOS server. Setting this option to 1 allows to submit NEOS jobs with a restart file even if the NEOS version is somewhat older than the local GAMS version.

Default: `0`

Value	Meaning
`0`	Write workfile using the current version
`1`	Write workfile using the previous workfile version

priorOpt *(real)*: Priority option for variable attribute .prior

Available: Attribute statement (use before solve)

Instructs the solver to use the priority branching information passed by GAMS through variable suffix values variable.prior. If and how priorities are used is solver-dependent.

Default: `0`

procDir *(string)*: Process Directory

Available: Command line

This option specifies the name of the process directory. If specified, the directory must already exist and it will not be deleted when GAMS cleans up. By default, the process directory name is chosen automatically from the list 225a, 225b, ..., 225aa, 225ab ..., by skipping over existing entries, and the directory will be deleted during cleanup if the option keep is not used. Very little is written to the process directory, but the scratch directory is used more, and the option scrDir takes its default from the process directory.

procDirPath *(string)*: Directory to create process directory in

Available: Command line

This option specifies the directory where the process directory should be created. If specified, the directory must already exist. While the process directory does not get cleaned automatically if the option procDir is set, this is not the case if the option `procDirPath` is used instead. Thus it allows to conveniently change the location of the process directory without changing the GAMS cleanup behavior. Note that if the location of the process directory is changed, the location of the default scratch directory will be changed accordingly (see option scrDir).

procTreeMemMonitor *(boolean)*: Monitor the memory used by the GAMS process tree

Available: Command line

Setting this option to 1 will cause GAMS to record the high-memory mark for the GAMS process tree (i.e. the `gams` or `gams.exe` process and all its children) and note this information in the log just prior to finishing. This is done via a separate thread that runs periodically (use option procTreeMemTicks to control how often) to construct the GAMS process tree and compute the memory usage for each process in it. There is some overhead with this so it is suggested to use this option only when needed and with a procTreeMemTicks value not smaller than the default.

In addition to the memory high-water marks (measured using both the size of the resident set and the virtual set used by each process in the tree) the report indicates the number of times this measurement was taken and any failures during this computation. For details on how to interpret the resident set and virtual set sizes, see showOSMemory.

Default: `0`

Value	Meaning
0	Do not monitor memory usage for the GAMS process tree
1	Start a thread to monitor memory usage for the GAMS process tree

procTreeMemTicks *(integer)*: Set wait interval between memory monitor checks: ticks = milliseconds

Available: Command line

Sets the wait interval in milliseconds between checks of the GAMS process tree memory usage: see procTreeMemMonitor for details.

Default: 2000

procUsed *(integer)*: Integer number that indicates the used model type

Available: Attribute statement (use after solve)

Value	Meaning
1	LP
2	MIP
3	RMIP
4	NLP
5	MCP
6	MPEC
7	RMPEC
8	CNS
9	DNLP
10	RMINLP
11	MINLP
12	QCP
13	MIQCP
14	RMIQCP
15	EMP

profile *(integer)*: Execution profiling

Available: Command line, Option statement

The *execution profile* of a GAMS run contains the individual and cumulative time required to execute the sections of the GAMS model, as well as information on memory use. The option `profile` controls whether an execution profile will be generated in the listing file. Observe that `profile` is available as command line parameter and option statement.

Note

The value for `profile` that is specified with an option statement in the GAMS input file overrides the value of `profile` that is passed through the command line.

Observe that an execution profile will be generated if the option `profile` is assigned a value larger than zero (zero is the default). Setting `profile` to 1 has the effect that execution times for each statement and the number of set elements over which the particular statement is executed will be reported. However, statements in programming flow control structures like loops will be omitted. Information on the execution of these statements will be included in

the profile if the value is n, with n > 1. Note that an overview of the values for profile is given in the table at the end of this description.

Consider the following GAMS call:

```
> gams trnsport profile=1
```

This call causes the following additional lines to appear in the listing file:

```
----      1 InitE                    0.000     0.000 SECS      3 MB
----      1 ExecInit                 0.000     0.000 SECS      3 MB
----     44 Assignment c             0.011     0.011 SECS      4 MB       6
----     63 Assignment transport     0.000     0.011 SECS      4 MB       3
----     65 Solve Init transport     0.000     0.012 SECS      4 MB
----     57 Equation   cost          0.001     0.013 SECS      4 MB       1
----     58 Equation   supply        0.000     0.013 SECS      4 MB       2
----     59 Equation   demand        0.000     0.013 SECS      4 MB       3
----     65 Solve Fini transport     0.009     0.022 SECS      4 MB      19
----     65 GAMS Fini               0.001     0.001 SECS      4 MB
----      1 InitE                   0.000     0.000 SECS      2 MB
----      1 ExecInit                0.000     0.000 SECS      2 MB
----     65 Solver     transport     0.000     0.000 SECS      2 MB
----     65 Solve Read transport     0.002     0.002 SECS      2 MB
----     67 Display                 0.000     0.002 SECS      3 MB
----     69 Display                 0.000     0.002 SECS      3 MB
----     69 GAMS Fini               0.001     0.001 SECS      3 MB
```

Observe that the first column provides the line number in the input file of the statement that is executed.

The second column reports the type of the respective statement. For an overview of all GAMS statements, see section Classification of GAMS Statements. In addition, ExecInit denotes the beginning of the execution phase of the GAMS input file and GAMS Fini denotes the end of this phase. Note that as soon as a solve statement is processed, GAMS will pass control to the solver system. Once the solver has completed its task, GAMS will restart. Thus we have two ExecInit/ GAMS Fini pairs in our example. Note that only equations are listed, and not variables. This reflects the fact that GAMS uses an equation based scheme to generate a model.

The third and fourth columns show the individual time needed to execute the statement and the cumulative time taken by the GAMS system so far.

The last column gives the number of assignments that were generated in the specified line.

In addition to the lines above, a *profile summary* is created at the end of the listing file. This summary contains (up to) ten of the slowest execution steps. The profile summary from trnsport.lst follows:

```
---- Profile Summary (17 records processed)
     0.011   0.004GB        44 Assignment c (6)
     0.009   0.004GB        65 Solve Fini transport (19)
     0.002   0.002GB        65 Solve Read transport
     0.001   0.004GB        65 GAMS Fini
     0.001   0.004GB        57 Equation   cost (1)
     0.001   0.003GB        69 GAMS Fini
```

Note that execution profiles and profile summaries are particularly useful for detecting the sources of performance problems. For further details, see section Finding the Causes for Slow Program Execution.

Default: 0

Value	Meaning
0	No profiling
1	Minimum profiling
n	Profiling depth for nested control structures

profileFile *(string)*: Write profile information to this file

Synonym: PFILE

Available: Command line

This option causes profiling information to be written to a file. Note that profiling information is only created with the setting `profile=1` or `profile=2`. For example such a file may have the following conten:

```
  1        -1        0.000    0.003 ExecInit
 45         6        0.000    0.004 Assignment c
 66        -1        0.000    0.004 Solve Init transport
 58         1        0.000    0.004 Equation   cost
 60         2        0.000    0.004 Equation   supply
 62         3        0.000    0.004 Equation   demand
 66        19        0.015    0.004 Solve Fini transport
 66        -1        0.000    0.004 GAMS Fini
  1        -1        0.000    0.002 ExecInit
 66        -1        0.000    0.002 Solve Read transport
 68        -1        0.000    0.003 Display
 68        -1        0.000    0.003 GAMS Fini
```

profileTol *(real)*: Minimum time a statement must use to appear in profile generated output

Synonym: PTOL (only available on the command line)

Available: Command line, Option statement

This option sets the profile tolerance in seconds. All statements that take less time to execute than this tolerance are not reported in the listing file. Note that this option is only effective if the value of the option profile is larger than zero.

Default: `0`

putDir *(string)*: Put file directory

Synonym: PDir

Available: Command line

By default, put files are generated and saved in the current working directory. This option may be used to specify an alternative directory. Note that this option does not work if an absolute file name is provided through the file statement.

putND *(integer)*: Number of decimals for put files

Available: Command line

This sets the default for the put file attribute .nd.

Default: `2`

putNR *(integer)*: Numeric round format for put files

Available: Command line

This sets the default for the put file attribute .nr.

Default: `1`

Value	Meaning
0	Item is displayed in F or E format
1	Item is rounded to fit given width and decimals
2	Item is displayed in scientific notation
3	Item is rounded to fit given width
4	Item is displayed in F or E format ignoring given decimals

putPS *(integer)*: Page size for put files

Available: Command line

This sets the default for the put file attribute .ps.

Default: `58`

putPW *(integer)*: Page width for put files

Available: Command line

This sets the default for the put file attribute .pw.

Default: `32767`

QCP *(string)*: Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

real1..5 *(real)*: Real communication cell N

Available: Option statement, Attribute statement (use before solve)

This option specifies a real communication cell that may contain any real number.

reference *(string)*: Symbol reference file

Synonym: RF

Available: Command line

If this option is specified, all symbol references will be written to the specified file. Setting `rf` or `Reference` to the string 'default' will cause GAMS to create a reference file with the file root name of the GAMS input file and the extension `ref`. Thus the call

```
> gams trnsport rf=default
```

will generate the reference file `trnsport.ref`.

The reference file consists of three sections: The information about the code compiled, the information about the symbols in the GAMS program (also known as `symbol table`) and a list of all files included.

The information about the code compiled consists of records with 11 fields. The meaning of the fields is:

- record count
- symbol index
- symbol name
- symbol type
- reference type (available: declared, defined, impl-asn, assigned, ref, control)
- global listing line
- local line
- local column position (due to macros this many not be always 100% correct)
- include nesting level
- index in the file summary
- file name

The symbol table starts with the line that is indicated by a `0` in the record count/first field, followed by the number of records in this symbol table and the text "size of symboltable". The records for the symbol table consists of:

- internal symbol index
- symbol name
- symbol type (numerical)
- symbol type (string)
- dimension (0 for functions and models)
- cardinality (0 for functions, card(sym) for regular symbols, and number of equation symbols for models)
- list of length dimension with the internal symbol index of the domain set (0 if universe)
- symbol text

The list of files included starts with the line that is indicated by a `0` in the record count/first field, followed by the number of records in this file list and the text "input files". The records for the following list has the same information as the Include File Summary.

With the reference file viewer, GAMS Studio offers a convenient tool for inspecting the reference file.

referenceLineNo *(string)*: Controls the line numbers written to a reference file

Synonym: RFLN

Available: Command line

Default: `actual`

Value	Meaning
actual	Actual line number of symbol reference
start	Line number where the statement with the reference starts

reform *(integer)*: Reformulation level

Available: Option statement, Attribute statement (use before solve)

This option triggers an objective function reformulation. The interpretation depends on the solver. The solvers MINOS and SNOPT support this option. Note that the default value is zero and the range is [-2147483647,2147483647].

replace *(string)*: Switch between merge and replace when reading from GDX into non-empty symbol

Available: Command line, Option statement

The command line parameter Replace initializes the option Replace to control the behvior of gdxLoad.

Default: on

Value	Meaning
off	Merge into existing data when loading
on	Replace existing data when loading

resCalc *(real)*: Time spent in function and derivative calculations (deprecated)

Available: Attribute statement (use after solve)

resDeriv *(real)*: Time spent in derivative calculations (deprecated)

Available: Attribute statement (use after solve)

resGen *(real)*: Time GAMS took to generate the model in wall-clock seconds

Available: Attribute statement (use after solve)

This model attribute returns the time GAMS took to generate the model in wall-clock seconds.

resIn *(real)*: Time to import model (deprecated)

Available: Attribute statement (use after solve)

resLim *(real)*: Wall-clock time limit for solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies the time in seconds that the solver can run before it can terminate and return the solver status 3 RESOURCE INTERRUPT. The solver should start the clock soon after it starts, so the time required to read in the problem and do any reformulations, preprocessing or presolving is included in the time limit. Where possible, the time limit applies to the wall-clock time: this behavior translates well to multi-threaded solves. Moreover, some solver links might *reinterpret* the value of this option. For example, if left at default (1e+10), the solver link might use the default time limit of the solver.

Note

This value could be automatically reduced, if required because of etLim.

Default: `10000000000`

resOut *(real)*: Time to export solution (deprecated)

Available: Attribute statement (use after solve)

restart *(string)*: Name of a restart file, see The Save and Restart Feature

Synonym: R

Available: Command line

This option specifies the name of a work file that was written with the option save that will be used to restart the GAMS program. The work file is also called *restart file*. For more information including examples, see chapter The Save and Restart Feature.

restartNamed *(string)*: Name of another matching restart file, see Obfuscated Work Files

Synonym: RN

Available: Command line

resUsd *(real)*: Time the solver used to solve the model in seconds

Available: Attribute statement (use after solve)

This model attribute returns the time in seconds used by the solver. Wherever possible, the units used (wall-clock time vs. CPU time) will be the same as used by the reslim option.

RMINLP *(string)*: Relaxed Mixed-Integer Non-Linear Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Nonlinear Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

RMIP *(string)*: Relaxed Mixed-Integer Programming - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

RMIQCP *(string)*: Relaxed Mixed Integer Quadratically Constrained Programs - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mixed Integer Quadratically Constrained Programs is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

RMPEC *(string)*: Relaxed Mathematical Programs with Equilibrium Constraints - default solver

Available: Command line, Option statement

The default solver for models of the type Relaxed Mathematical Program with Equilibrium Constraints is set during installation. The user may change this default by setting this option to the desired solver.

Observe that if the solver was changed using an option statement, the default solver may be reset later in the program with another option statement, where the value of the option is set to `default`.

rngBndMax *(real)*: Maximum absolute non-zero value of bounds passed to the solver (excluding infinity)

Available: Attribute statement (use after solve)

rngBndMin *(real)*: Minimum absolute non-zero value of bounds passed to the solver

Available: Attribute statement (use after solve)

rngMatMax *(real)*: Maximum absolute non-zero value of coefficients in the model matrix passed to the solver (excluding infinity)

Available: Attribute statement (use after solve)

Note

For non-linear models, the value of the coefficients looked at depends on the activity levels of one or more of the variables. More details are described here.

rngMatMin *(real)*: Minimum absolute non-zero value of coefficients in the model matrix passed to the solver

Available: Attribute statement (use after solve)

Note

For non-linear models, the value of the coefficients looked at depends on the activity levels of one or more of the variables. More details are described here.

rngRhsMax *(real)*: Maximum absolute non-zero value of right hand sides passed to the solver (excluding infinity)

Available: Attribute statement (use after solve)

rngRhsMin *(real)*: Minimum absolute non-zero value of right hand sides passed to the solver

Available: Attribute statement (use after solve)

rObj *(real)*: Objective function value from the relaxed solve of a mixed-integer model when the integer solver did not finish

Available: Attribute statement (use after solve)

This model attribute returns the objective function value from the relaxed solve of a MIP when the integer solver did not finish.

save *(string)*: Creates a work file, see The Save and Restart Feature

Synonym: S

Available: Command line

This option specifies the name of a work file to be written. The work file is intended to be used later to restart the GAMS program and it is also frequently referred to as *save file* or *restart file*. If no explicit file extension is provided, the default file extension `.g00` is used. If no specific file path is provided the work file is created in the current directory.

Note

- The character "?" is not allowed in save file names - that use was intended for old (pre-GAMS 21.7) save files only.
- Save files are platform-independent.

For further information including examples, see chapter The Save and Restart Feature.

saveObfuscate *(string)*: Creates an obfuscated work file, see Obfuscated Work Files

Synonym: SO

Available: Command line

savePoint *(integer)*: Save solver point in GDX file

Synonym: SP (only available on the command line)

Available: Command line, Option statement, Attribute statement (use before solve)

This option instructs GAMS to save a point format GDX file that contains the information on the current solution point.

Default: `0`

Value	Meaning
`0`	No point GDX file is to be saved
`1`	A point GDX file from the last solve is to be saved
`2`	A point GDX file from every solve is to be saved
`3`	A point GDX file from the last solve is to be saved in the scratch directory
`4`	A point GDX file from every solve is to be saved in the scratch directory

scaleOpt *(boolean)*: Employ user specified variable and equation scaling factors

Available: Attribute statement (use before solve)

This option determines whether GAMS will employ user-specified variable and equation scaling factors. It must be set to a nonzero value if scaling factors are to be used. For more details on scaling, see section Model Scaling - The Scale Option.

Default: `0`

scrDir *(string)*: Scratch directory

Synonym: SD

Available: Command line

This option specifies the name of the scratch directory. The scratch directory is used by GAMS for intermediate files that are generated during execution. The scratch directory and all its contents are usually deleted at the end of the GAMS run. By default, the scratch directory takes its value from the process directory that is specified with the option procDir. If neither the scratch directory nor the process directory are specified, the scratch directory will be set to a subdirectory of the current working directory with an internally generated name. If the scratch directory is specified, the respective directory must already exist and neither the content nor the directory itself will be deleted by GAMS at the end of the run.

Note that the option solveLink may be used to reduce or eliminate the need for intermediate files.

scrExt *(string)*: Scratch file extension to be used with temporary files

Synonym: SE

Available: Command line

This option specifies the name of the extension for the temporary files that GAMS is generating during execution.

Default: `dat`

scriptExit *(string)*: Program or script to be executed at the end of a GAMS run

Available: Command line

By default, GAMS does not call an exit script anymore. If this is required, the option `scriptExit` has to be set explicitly to the script that should be called after GAMS terminates. Note that an empty template of an exit script is in the GAMS system directory: it is called `gmsxitnt.cmd` for Windows and `gmsxitus.run` for Unix.

scriptFrst *(string)*: First line to be written to GAMSNEXT file.

Synonym: SF

Available: Command line

This option specifies the first line written to `gamsnext`. The default is an empty string and the *first* line is not written.

scrNam *(string)*: Work file names stem

Synonym: SN

Available: Command line

This option specifies the name stem that is used to complete the names of intermediate work files. Note that the name stem must have at least one '?'. The name will be completed with the scratch directory and the standard scratch name extension.

seed *(integer)*: Random number seed

Available: Command line, Option statement

This option specifies the seed that is used for the pseudo random number generator.

Default: `3141`

showOSMemory *(integer)*: Show the memory usage reported by the Operating System instead of the internal counting

Available: Command line

GAMS keeps track of how much dynamic memory it has allocated and shows this in the log file at various points. With this option, memory usage statistics from the operating system can be shown instead. This is useful if the dynamic memory allocation is known or suspected to significantly underestimate the total memory usage of the GAMS process.

The resident set size (RSS) of a process is that part of the process address space actually residing in main memory (RAM). It excludes things like memory allocated but never used, memory that has been swapped out to disk, and parts of the executable that have never been loaded.

The virtual set size (VSS) is a measure of the entire address space used by the process, whether that space resides in physical memory or not. On Linux, it is essentially the RSS plus the items excluded from the RSS, i.e. the parts of the process address space that are not currently in physical memory. On macOS, the VSS seems to be a wild overestimate - we don't recommend using VSS on this platform. On Windows, we take VSS from the `PagefileUsage` reported by the OS. The `PagefileUsage` for each process does not include some major contributions to the process address space, such as mapped files. For this reason, the process RSS may be larger than its VSS on Windows, but VSS is still a good measure of dynamic memory allocation done by a process.

Default: `0`

Value	Meaning
0	Show memory reported by internal accounting
1	Show resident set size reported by operating system
2	Show virtual set size reported by operating system

solPrint *(integer or string)*: Solution report print option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the printing of the solution listing to the listing file.

N.B: the command line accepts the string and numeric value, the option statement only the string value, and the attribute statement accepts the numeric value and compile-time constant.

The table below offers an overview of the different types of values and a description of the associated meaning.

String Value	Numeric Value	Compile-Time Constant	Meaning
off	0	solprint.Off	Remove solution listings following solves
on	1	solprint.On	Include solution listings following solves
silent	2	solprint.Silent	Suppress all solution information

Default: On

solSlack *(boolean)*: Causes the equation output in the listing file to contain slack variable values instead of level values

Available: Option statement

If the value of this option is set to 1, the equation output in the listing file will contain slack variable values instead of level values.

Default: 0

Value	Meaning
0	includes equation levels in the solution part of the LST file following solves
1	includes equation slacks in the solution part of the LST file following solves

solveLink *(integer)*: Solver link option

Synonym: SL (only available on the command line)

Available: Command line, Option statement, Attribute statement (use before solve)

This option specifies what solver linking conventions are used when GAMS executes a solve statement. Note that values 3 and 6 are relevant for grid computing and multi-threaded solves, respectively. Observe that there are compile-time constants that are associated with this option. When the model instance is saved to the scratch directory (values 0, 1, 2, and 3), the solution produced by the solve is also written to the scratch directory and read in by GAMS when the execution resumes.

Default: 2

Value	Meaning
0	Model instance and entire GAMS state saved to scratch directory, GAMS exits (and vacates memory), and the solver script is called. After the solver terminates, GAMS restarts from the saved state and continues to executing
1	Model instance saved to scratch directory, the solver is called from a shell while GAMS remains open
2	Model instance saved to scratch directory, the solver is called with a spawn (if possible) or a shell (if spawn is not possible) while GAMS remains open - If this is not supported by the selected solver, it gets reset to 1 automatically
3	Model instance saved to scratch directory, the solver starts the solution and GAMS continues
4	Model instance saved to scratch directory, the solver starts the solution and GAMS waits for the solver to come back but uses same submission process as 3 (test mode)

Value	Meaning
5	The model instance is passed to the solver in-memory - If this is not supported by the selected solver, it gets reset to 2 automatically
6	The model instance is passed to the solver in-memory, the solver starts the solution and GAMS continues
7	The model instance is passed to the solver in-memory, the solver starts the solution and GAMS waits for the solver to come back but uses same submission process as 6 (test mode)

solveOpt *(integer or string)*: Multiple solve management

Available: Command line, Option statement, Attribute statement (use before solve)

This option will instruct GAMS how to manage the model solution if only part of the variables and equations in the particular problem are solved.

Observe that this option is available as model attribute, option statement and command line parameter. The values for model attributes are numeric, while the values for option statements are text strings. The command line parameter accepts both, numeric and text values. In addition, there are compile-time constants that are associated with this option. The first of the two tables below offers an overview of how the different types of values are related and the second table gives the values in numerical terms and a description of the associated meaning.

Numeric Value	String Value	Compile-Time Constant
0	replace	solveOpt.Replace
1	merge	solveOpt.Merge
2	clear	solveOpt.Clear

Default: Merge

Value	Meaning
0	The solution information for all equations appearing in the model is completely replaced by the new model results; variables are only replaced if they appear in the final model
1	The solution information for all equations and variables is merged into the existing solution information
2	The solution information for all equations appearing in the model is completely replaced; in addition, variables appearing in the symbolic equations but removed by conditionals will be removed

solver *(string)*: Default solver for all model types that the solver is capable to process

Available: Command line, Option statement

The command line parameter solver=abc initializes the default solver for the model types the solver "abc" is capable of to abc. This initialization is done before the default solvers of individual model types are set via command line parameters. Consider the following example:

```
> gams trnsport lp=conopt solver=soplex
```

Note that this GAMS call will first set the solver SOPLEX as the solver for the model types LP and RMIP, since these are the model types that SOPLEX can handle. Then Conopt will

be reset as the default solver for LPs. Observe that the order of these parameters on the command line is irrelevant. If multiple occurrences of the option `solver` appear, the last entry will set the value of the option.

In addition, the solver for multiple model types may be set in the GAMS model source code via the following statement:

```
option solver = abc;
```

This statement sets the solver for the model types the solver abc can handle to `abc`. Note that in such an option statement the order of other solver setting options is significant. Consider the following example:

```
option lp=conopt, solver=soplex;
```

This statement will first set the solver for LPs to Conopt and in the next step to SOPLEX because SOPLEX is capable of handling the model type LP. In some cases it makes sense to set a solver twice. Consider the following example:

```
option solver=conopt, solver=cbc;
```

This option statement has the effect that models of the types CNS, DNLP, NLP, QCP, RMIQCP or RMINLP will be solved with Conopt and models of the types LP, RMIP or MIP will be solved with CBC.

Note that as usual, a specification of a solver through an option statement in the GAMS source takes precedence over a specification on the command line.

solverCntr *(string)*: Solver control file name

Synonym: SCNTR

Available: Command line

This option specifies the solver control file name. Note that the name is completed with the scratch directory and the scratch extension.

solverDict *(string)*: Solver dictionary file name

Synonym: SDICT

Available: Command line

This option specifies the solver dictionary file name. Note that the name completed with the scratch directory and the scratch extension.

solverInst *(string)*: Solver instruction file name

Synonym: SINST

Available: Command line

This option specifies the solver instruction file name. Note that the name is completed with the scratch directory and the scratch extension.

solverMatr *(string)*: Solver matrix file name

Synonym: SMATR

Available: Command line

This option specifies the solver matrix file name. Note that the name is completed with the scratch directory and the scratch extension.

solverSolu *(string)*: Solver solution file name

Synonym: SSOLU

Available: Command line

This option specifies the solver solution file name. Note that the name is completed with the scratch directory and the scratch extension.

solverStat *(string)*: Solver status file name

Synonym: SSTAT

Available: Command line

This option specifies the solver status file name. Note that the name is completed with the scratch directory and the scratch extension.

solveStat *(integer)*: Indicates the solver termination condition

Available: Attribute statement (use after solve)

This model attribute indicates the solver termination condition. Observe that there are compile-time constants that are related to `solveStat`. Note that additional information to the values given in the table below is provided in section Solver Status.

Value	Meaning
1	Normal Completion
2	Iteration Interrupt
3	Resource Interrupt
4	Terminated By Solver
5	Evaluation Interrupt
6	Capability Problems
7	Licensing Problems
8	User Interrupt
9	Setup Failure
10	Solver Failure
11	Internal Solver Failure
12	Solve Processing Skipped
13	System Failure

stepSum *(boolean)*: Summary of computing resources used by job steps

Available: Command line

This option controls the generation of a step summary of the processing times taken by GAMS during a given run.

For example, the call

```
> gams trnsport stepsum=1
```

will generate the following *step summaries* in the listing file:

```
STEP SUMMARY:     0.016       0.016 STARTUP
                  0.005       0.005 COMPILATION
                  0.065       0.065 EXECUTION
                  0.001       0.001 CLOSEDOWN
                  0.087       0.087 TOTAL SECONDS
                  0.089       0.089 ELAPSED SECONDS
                  3.942       3.942 MAX HEAP SIZE (MB)
```

Note that this step summary will be printed before the model is sent to the solver, thus it may be found before the solve summary. The second step summary will be printed after solution, it will appear at the very end of the listing file:

```
STEP SUMMARY:     0.004       0.020 STARTUP
                  0.000       0.005 COMPILATION
                  0.003       0.068 EXECUTION
                  0.000       0.001 CLOSEDOWN
                  0.007       0.094 TOTAL SECONDS
                  0.239       0.328 ELAPSED SECONDS
                  2.899       3.942 MAX HEAP SIZE (MB)
```

Observe that the first column reports the time for the individual section of the run, while the second column reports accumulated times including previous sections.

Default: `0`

Value	Meaning
0	No step summary
1	Step summary printed

strictSingleton *(boolean)*: Error if assignment to singleton set has multiple elements

Available: Command line, Option statement

This option affects the behavior of a membership assignment to a singleton set. If the value is set to zero, GAMS will not complain about a singleton set with more than one element, but will take only the first element. However, if the value is set to 1, a singleton set definition with more than one element will cause an error. Also, if this option is set as a command line parameter it initializes the state of the dollar control option $on/offStrictSingleton. So, it influences the singleton set checking at both compile- and execution time.

Default: `1`

Value	Meaning
0	Take first record if assignment to singleton set has multiple elements
1	Error if assignment to singleton set has multiple elements

stringChk *(integer)*: String substitution options

Available: Command line

This option affects the result of the check for %xxx% symbols. Note that %xxx% symbols may be environment variables (also at execution time) or compile-time variables.

Default: 0

Value	Meaning
0	No substitution if symbol undefined and no error
1	Error if symbol undefined
2	Remove entire symbol reference if undefined and no error

subSys *(string)*: Name of subsystem configuration file

Available: Command line

This option specifies the name of the configuration file that contains solver defaults and other information. This option should be used only by advanced users who attempt to override internal subsystem information. In case you want to add a solver to your GAMS system, please inspect the section Adding Solvers via gamsconfig.yaml.

subSystems *(no value)*: Lists all solvers available as well as the current default and active solvers in the LST file

Available: Option statement

This option has the effect that all available subsystems will be displayed in the listing file. Note that a solver is considered a subsystem.

suffixAlgebraVars *(string)*: Switch default for "$on/offSuffixAlgebraVars"

Available: Command line

For more info see $on/offSuffixAlgebraVars.

Default: on

Value	Meaning
off	Activate $offSuffixAlgebraVars
on	Activate $onSuffixAlgebraVars

suffixDLVars *(string)*: Switch default for "$on/offSuffixDLVars"

Available: Command line

For more info see $on/offSuffixDLVars.

Default: off

Value	Meaning
off	Activate $offSuffixDLVars
on	Activate $onSuffixDLVars

sumInfes *(real)*: Sum of infeasibilities

Available: Attribute statement (use after solve)

This model attribute returns the sum of infeasibilities after a solve.

suppress *(boolean)*: Compiler listing option

Available: Command line

If set to 1, this option will suppress the echoing of the contents of the input file(s) to the listing file. Note that this option is similar in functionality to the dollar control option $offlisting.

Note

The dollar control options $on/offlisting will affect the echo print in the listing file only if `suppress` is set to zero. If `suppress` is set to 1, the input file(s) will not be echoed to the listing file and the dollar control options will not have any effect on the listing file.

Default: `0`

Value	Meaning
0	Standard compiler listing
1	Suppress compiler listing

symbol *(string)*: Symbol table file

Available: Command line

This option specifies the name of a partial symbol table that may be written in conjunction with reference files.

symPrefix *(string)*: Prefix all symbols encountered during compilation by the specified string in work file

Available: Command line

sys10 *(boolean)*: Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer

Available: Command line, Option statement

Default: `0`

Value	Meaning
0	Disable conversion
1	Enable conversion

sys11 *(integer)*: Dynamic resorting if indices in assignment/data statements are not in natural order

Available: Command line, Option statement

Speed-up for expressions containing constant indices or indices that are not in the natural order at the cost of increased memory use.

Default: `0`

Value	Meaning
0	Automatic optimization/restructuring of data
1	No optimization
2	Always optimize/restructure

sys12 *(integer)*: Pass model with generation errors to solver

Synonym: noSolveSkip (only available on the command line)

Available: Command line, Option statement

Default: 0

sys15 *(integer)*: Automatic switching of data structures used in search records

Available: Command line, Option statement

Default: 0

Value	Meaning
0	Automatic switching to dense data structures
1	No switching
2	Always switch
1x	Print additional information in lst file

sys16 *(integer)*: Disable search record memory (aka execute this as pre-GAMS 24.5)

Available: Command line, Option statement

Default: 0

sys17 *(integer)*: Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)

Available: Command line, Option statement

Default: 0

sys18 *(integer)*: Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers

Available: Command line, Option statement

By default GAMS accepts floating-point numbers with arbitrarily many digits and converts them to correctly-rounded double-precision values. This option selects a backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers (see also the offDigit dollar control option).

Default: 0

Value	Meaning
0	Use modern scheme for reading floating-point numbers
1	Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers

sys19 *(integer)*: Disable permutation on Column Generation (aka execute this as pre-GAMS 36)

Available: Command line, Option statement

Default: `0`

sysDir *(string)*: GAMS system directory where GAMS executables reside

Available: Command line

This option sets the GAMS system directory. It is useful if there are multiple systems installed on the machine or when GAMS is called from an external system like Visual Basic.

sysIdent *(real)*: Solver identification number

Available: Attribute statement (use after solve)

sysIncDir *(string)*: SysInclude directory

Synonym: SDIR

Available: Command line

This option specifies the name of the directory to be used by GAMS for sysinclude files that do not have a full path specification. An absolute or relative path may be specified. If this option is not set, it will be set to the GAMS system directory.

Note that if this option is set, the default system include directory will not be searched.

Attention

Only *one* directory may be set with the option `sDir`. Thus the string specified will be treated as one directory. If additional directories are added, errors will be reported.

Consider the following example:

```
> gams myfile sdir mydir
```

Note that GAMS will search for any referenced sysinclude file in the directory `mydir`.

sysOut *(boolean or string)*: Solver Status file reporting option

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls whether additional solver generated output (the solver status file) is included in the listing file. Note that the contents of the solver status file are useful for debugging or to get additional information about a solver run. Normally, only those messages flagged by the solver as destined for the listing file will be listed. If the solver crashes or encounters any unexpected difficulties, the contents of the solver status file will be automatically sent to the listing file.

Note that the boolean values (`off`: 0 and `off`: 1) are deprecated, they are only relevant for backward compatibility. The table below gives the boolean values and the associated meaning.

String Value	Meaning
`off`	Suppress additional solver generated output
`on`	Include additional solver generated output

Default: `Off`

sysVer *(real)*: Solver version

Available: Attribute statement (use after solve)

tabIn *(integer)*: Tab spacing

Available: Command line

This option sets the tab spacing. The default value is 8, which means that the tabs are at columns 1, 9, 17, ... and the intermediate columns are replaced by blanks.

Default: `8`

Value	Meaning
`0`	Tabs are not allowed
`1`	Tabs are replaced by blanks
`n`	Tabs are 1, n+1, 2n+1,.. (default: n=8)

tFormat *(boolean)*: Time format

Synonym: TF

Available: Command line

This option controls the time format in the listing file. The three date formats correspond to the various conventions used around the world. For example, the time 7:45∼PM will be written as 19:45:00 with the default `tf` value of zero and as 19.45.00 with `tf=1`.

Default: `0`

Value	Meaning
`0`	Time as hh:mm:ss
`1`	Time as hh.mm.ss

threads *(integer)*: Number of processors to be used by a solver

Available: Command line, Option statement, Attribute statement (use before solve)

This option controls the number of processors to be used by a solver, often by using several threads for parallel computations. If the number is greater than the number of available processors, it will be reduced to the number of processors available. A value of zero means that the solver or solver-link will decide on the number of processors to use.

Default: `0`

Value	Meaning
`0`	Solver decides on number of processors to use
`n`	Use n processors
`minus_n`	Number of processors to leave free for other tasks

threadsAsync *(integer)*: Limit on number of threads to be used for asynchronous solves (solveLink=6)

Available: Command line, Option statement

Default: `-1`

Value	Meaning
`0`	Use number of available processors
`n`	Use n threads
`minus_n`	Number of processors to leave free for other tasks

timer *(integer)*: Instruction timer threshold in milli seconds

Available: Command line

This option specifies an instruction timer threshold in milli seconds. That means that only details about internal GAMS intructions that took more than `n` milli seconds are echoed to the log.

Default: `0`

Value	Meaning
`0`	Interpreted as +inf, no details echoed
`n`	Echo all details about internal GAMS instructions that took more than n milli seconds to the log

tolInfeas *(real)*: Infeasibility tolerance for an empty row of the form a.. 0∗x =e= 0.0001;

Available: Attribute statement (use before solve)

This option specifies the infeasibility tolerance for an empty row of the following form:

```
a.. 0*x =e= 0.0001;
```

If the option is not set, a tolerance of 10 times the machine precision will be used. Empty rows that fail this infeasibility check will be flagged with the listing file message `Equation infeasible due to rhs value`.

tolInfRep *(real)*: This attribute sets the tolerance for marking infeasible in the equation listing

Available: Attribute statement (use before solve)

This option sets the tolerance for marking an equation `infeasible` in the equation listing. Note that the default value is 1.0e-13.

Default: `1.0E-13`

tolProj *(real)*: Tolerance for setting solution values to a nearby bound when reading a solution

Available: Attribute statement (use before solve)

When a solution is returned from a solver, equation and variable level values that are very close to their lower or upper bounds are projected or moved to that bound, and a count of the projections/moves made is included in the solution report's `REPORT SUMMARY`. This option controls the relative tolerance used in testing for closeness: project if `abs(level-bound)` $<$ `tolproj`$*$`(1+abs(level))`. For MCP models, this projection is also applied to the variable marginal values. In this case the projection count is not incremented and the test is an absolute and not a relative test: project if `abs(marginal)` $<$ `tolproj`.

Default: `0`

trace *(string)*: Trace file name

Available: Command line

This option specifies the trace file name and causes a trace file to be written. Note that if a previous trace file of the same name already exists, then all new data output will be appended. Therefore, users should be careful to delete all old versions of the trace file if the a file name is reused and they do wish the new data to be appended.

traceLevel *(integer)*: Modelstat/Solvestat threshold used in conjunction with action=GT

Synonym: TL

Available: Command line

Default: `0`

traceOpt *(integer)*: Trace file format option

Available: Command line

This option specifies the format of the trace file. Note that several different types of trace files may be created, depending on what output information is desired.

Default: `0`

Value	Meaning
0	Solver and GAMS step trace
1	Solver and GAMS exit trace
2	Solver trace only
3	Solver trace only in format used for GAMS performance world
5	Gams exit trace with all available trace fields

tryInt *(real)*: Whether solver should make use of a partial integer-feasible solution

Available: Attribute statement (use before solve, reset by solve statement)

Signals the solver to make use of a partial or near-integer-feasible solution stored in current variable values to get a quick integer-feasible point. The exact form of implementation depends on the solver and may be partly controlled by solver settings or options. See the solver manuals for details.

tryLinear *(real)*: Examine empirical NLP model to see if there are any NLP terms active. If there are none the default LP solver will be used

Available: Attribute statement (use before solve)

If this option is set to 1, empirical NLP models will be examined to determine if there are any active NLP terms. If there are none, the default LP solver will be used. The procedure also checks to see if QCP and DNLP models can be reduced to an LP; MIQCP and MINLP can be solved as a MIP; RMIQCP and RMINLP can be solved as an RMIP. Note that the default value is zero.

user1..5 *(string)*: User string N

Synonym: U1

Available: Command line

This option permits users to enter a text for up to 5 user-defined options. The double dash parameters supersede these parameters.

warnings *(integer)*: Number of warnings permitted before a run terminates

Available: Command line

This option specifies the maximum number of allowable warnings, before the run terminates.

Default: ∞

workDir *(string)*: Working directory

Synonym: WDir

Available: Command line

This option sets the working directory. This option is useful when GAMS is called from an external system like Visual Basic. If it is not specified, the working directory will be set to the directory curDir.

workFactor *(real)*: Memory Estimate multiplier for some solvers

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace to allocate for problem solution relative to the solver-computed estimate. For example, setting the value to 2 will double the memory estimate. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect. Note that in cases where both options `workfactor` and workSpace are specified, the value for `workSpace` will take precedence.

Default: `1`

workSpace *(real)*: Work space for some solvers in MB

Available: Command line, Attribute statement (use before solve)

This option instructs the solver how much workspace in Megabytes to allocate. If it is not speicified by the user, the solver will estimate the size. In cases where a solver allocates memory dynamically as it is needed, this option will have no effect, or it may be used as a memory limit.

writeOutput *(boolean)*: Switch to write output file

Available: Command line

This option controls whether to write the output file.

Default: `1`

Value	Meaning
`0`	Suppress output file creation
`1`	Write output file

xSave *(string)*: Creates a compressed work file

Synonym: XS

Available: Command line

This option specifies the name of a save file written in ASCII format in older GAMS systems (versions older than 21.7), in order for the save file to be platform independent and may be moved to machines with different operating systems.

In GAMS systems from release 22.3 and newer this option has the effect that compressed save files are written.

xSaveObfuscate *(string)*: Creates a compressed obfuscated work file

Synonym: XSO

Available: Command line

zeroRes *(real)*: The results of certain operations will be set to zero if abs(result) LE ZeroRes

Available: Command line

This option specifies the threshold value for internal rounding to zero in certain operations.

Default: `0`

zeroResRep *(boolean)*: Report underflow as a warning when abs(results) LE ZeroRes and result set to zero

Available: Command line

This option causes GAMS to issue warnings whenever a rounding occurs because of the setting of the option zeroRes.

Default: `0`

Value	Meaning
`0`	No warning when a rounding occurs because of ZeroRes
`1`	Issue warnings whenever a rounding occurs because of ZeroRes

zeroToEps *(string)*: Treat zero as eps

Available: Option statement

When this is set to `on`, zero values are interpreted as `EPS` when loading non-scalar parameters from GDX or embedded code at execution time. Also, when deriving a set from a parameter in a GDX file at execution time, set records will be created for parameter records with value 0, if `zeroToEps` is set to `on`, but not, if it is `off`.

See dollar control option $onEps for the compile-time equivalent.

Default: `off`

Value	Meaning
`off`	Treat Zero as Zero
`on`	Treat Zero as Eps

4.40.7 Executing an External Program

External programs may be run during a GAMS job either using the `$call`, `Execute` or `Put_utility` syntax. The $call procedure is executed at the moment that is encountered during compilation. The Execute and Put_utility commands causes the external program to be run during GAMS program execution. The contrast between these statements is important in two ways.

- Influence on results that can be included in a GAMS program – Anything run with $Call can generate files that can be included in the subsequent compilation. On the other hand files generated with Execute and Put_utility cannot be included because $Include operates only at compile time (unless you use Save and Restart).
- Influence on results that can be fed into the external program – Obviously when one is running an external program there is the desire to pass it data depicting results of the GAMS execution. $Call cannot do this as the data passed have to exist at compile time and cannot use the result of any GAMS calculations and solves in the current program. Execute commands on the other hand can use any data generated during a run which arise before the Execute and Put_utility command's position in the file through passage via put files or other mechanisms.

The big difference between the `$call` and `execute` is

- $call
  - can generate results to be immediately incorporated back into GAMS
  - cannot use GAMS results generated within this run because the $Call is executed at compile time.
- `execute` and `put_utility`
  - can cause a program to be started using results generated by the GAMS program (note such results do have to have been saved in an external file using a command like put)
  - cannot generate results which can be immediately reincluded into the GAMS program because new material can only be added compile time.

4.40.7.1 Execute

This command uses the syntax

```
execute[.async[NC]|.checkErrorLevel] "[=]command_to_execute"
```

to execute a program specified by command_to_execute. The execution occurs during the GAMS execution phase.

- The `=` will call the program directly, while without the `=` GAMS calls a shell that executes the program. When a program is executed in a shell, mechanisms like redirection (>) and pipe (|) will work.
- The `.async` suffix makes GAMS go ahead without waiting.
- The `.asyncNC` option tells the operating system to start the run a new console rather than sharing the console of the parent process allowing use of multiple processors. This is available under Windows only.
- The `.checkErrorLevel` suffix checks the errorLevel implicitly, raises an execution error and aborts the execution, if that is not 0.
- Since this occurs during execution one cannot use the compile time $Include to incorporate the results of that external run into the GAMS code except through a **GAMS from GAMS** approach as discussed below or through save and restart use (see the Save Restart chapter).

4.40.7.2 Asynchronous Execution

The `.async` variant of `$call` and `execute` start a job without waiting for the result. One can continue in the GAMS program and collect the return code of the job later. There are three ways to start a job asynchronously:

- `$call.async` ... (compile phase)
- `execute.async` '...'; (execution phase)
- 'put_utility fx 'exec.async' / '...'; / put_utility fx 'shell.async' / '...';` (execution phase)

After each of those the function JobHandle can be used to get the Process ID (pid) of the last job started. With `jobStatus(pid)` one could check for the status of a job. Possible return values are:

- 0: error (input is not a valid PID or access is denied)
- 1: process is still running
- 2: process is finished with return code which could be accessed by errorLevel
- 3: process not running anymore or was never running, no return code available

With `jobTerminate(pid)` a interrupt signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

With `jobKill(pid)` a kill signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.

The model [**ASYNCEXEC**] from the GAMS Test Library demonstrates the use of this feature.

4.40.8 Executing a GAMS Tool

To call tools from the GAMS Tool Library, there are counterparts to the $call and Execute, namely $callTool and ExecuteTool. The behavior is identical to the methods explained in the introduction of Executing an External Program.

4.40.8.1 ExecuteTool

This command uses the syntax

```
executeTool[.checkErrorLevel] '[toolCategory.]toolName tool_arguments';
```

to execute a tool specified by `[toolCategory.]toolName` together with the arguments `tool_arguments`. The execution occurs during the GAMS execution phase.

- The `.checkErrorLevel` suffix checks the errorLevel implicitly, raises an execution error and aborts the execution, if that is not 0.
- Since this occurs during execution one cannot use the compile time $Include to incorporate the results of that external run into the GAMS code except through save and restart use (see the Save Restart chapter).

For examples please refer to the GAMS Tools Library chapter.

4.41 Dollar Control Options

4.41.1 Introduction

Dollar control options are used to indicate compiler directives and options. Dollar control options are not part of the GAMS language and must be entered on separate lines marked with the symbol $ in the first column. A dollar control option line may be placed anywhere within a GAMS program and it is processed during the compilation of the program. The symbol $ is followed by one or more options separated by spaces. Since the dollar control options are not part of the GAMS language, they do not appear on the compilation output in the listing file unless an error has been detected or the user has requested them to be shown (with the option $onDollar).Note that dollar control option lines are not case sensitive and a continued compilation uses the previous settings.

This chapter is organized as follows. First an overview of the dollar control options will be given in section List of Dollar Control Options, where the options will be presented in groups reflecting their major functional categories. Section Detailed Description of Dollar Control Options will contain a reference list of all dollar control options in alphabetical order with detailed description for each.

We will conclude this chapter with separate sections for two important topics: Conditional Compilation, Macros in GAMS, Compressing and Decompressing Files, and Encrypting Files.

4.41.1.1 Syntax

In general, the syntax in GAMS for dollar control statements is as follows:

```
$option_name argument_list {option_name argument_list}
```

The symbol $ in the first column indicates that this is a dollar control statement. It is followed by the name of the dollar control option `option_name` and the list of arguments `argument_list` of the option. Depending on the particular option, the number of arguments required can vary from 0 to many. More than one dollar control option may be activated in one statement. Note that in this case the symbol $ is not repeated. Observe that some dollar control options require that they be the first option on a line.

Note

- No blank space is permitted between the character $ and the first option that follows.
- The effect of the dollar control option is felt immediately after the option is processed.
- Dollar control options are not part of the GAMS language they instruct the compiler to perform some task. Therefore, dollar control options are not terminated with a semicolon as real GAMS language statements.

A simple example of a list of dollar control options is shown below:

```
$title Example to illustrate dollar control options
$onsymxref onsymlist
```

Note that there is no blank space between the character $ and the option that follows. The first dollar control option $title sets the title of the pages in the listing file to the text that follows the option name. In the second line of the example above, two options are set: $onSymXRef and $onSymList. These options turn on the echoing of the symbol cross reference table and symbol listing in the compilation output in the listing file.

Observe that it is also permitted to place a dollar control statement in a column other than column 1. However, in this case the statement must begin with the symbols $$, like in this example

```
    $$title Example showing that dollar control option can start in any column with an extra $ added
```

4.41.2 List of Dollar Control Options

The dollar control options are grouped into nine major functional categories affecting

- the input comment format
- the input data format
- the output format
- reference maps
- program control
- GDX operations
- compile-time variables and environment variables
- macro definitions
- compressing and encrypting source files

The following subsections briefly describe the options in each of the categories.

4.41.2.1 Dollar Control Options Affecting the Input Comment Format

Option	Description
comment	Set the comment character
eolCom	Set the end-of-line comment character(s)
inlineCom	Set the in-line comment characters
maxCol	Set the right-hand margin of the input file
minCol	Set left-hand margin of the input file
offEolCom	Turn end-of-line comments off
offInline	Turn in-line comments off
offMargin	Turn margin marking off
offNestCom	Turn nested comments off
offText	Turn text mode off
onEolCom	Turn end-of-line comments on
onInline	Turn in-line comments on
onMargin	Turn margin marking on
onNestCom	Turn nested comments on
onText	Turn text on: the following lines are comment

Note that comments in GAMS are introduced in section Comments.

4.41.2.2 Dollar Control Options Affecting the Input Data Format

Option	Description
dollar	Set the 'dollar' character
offDelim	Turn delimited data statement syntax off
offDigit	Turn the number precision check off

Option	Description
offEmbedded	No embedded text or data allowed
offEmpty	Disallow empty data initialization statements
offEnd	Disallow alternate program control syntax
offEps	Disallow interpretation of EPS as zero
offExternalInput	End of external input section
offGlobal	Disallow inheritance of parent file settings
offIDCProtect	Allow to change external input symbols at execution time
offImplicitAssign	Trigger compilation error 141 if symbol has not been assigned
offSuffixDLVars	Do not allow domain limited variables with suffixes in model
offSuffixAlgebraVars	Do not allow variables with suffixes in model algebra
offTroll	Do not recognize Troll periodicity in set definitions using sequences
offUNDF	Do not allow UNDF as input
offUni	Do not allow domain violations in assignments
offWarning	Do not convert domain errors into warnings
onDelim	Turn delimited data statement syntax on
onDigit	Turn number precision check on
onEmbedded	Allow embedded text or data in set and parameter statements
onEmpty	Allow empty data initialization statements
onEnd	Allow alternate program control syntax
onEps	Interpret zero as EPS
onExternalInput	Start of external input section
onGlobal	Force inheritance of parent file settings
onIDCProtect	Protect external input symbols from being changed at execution time
onImplicitAssign	Suppress compilation errors 141 and implicitly assign symbol if symbol has not been assigned
onSuffixDLVars	Allow domain limited variables with suffixes in model
onSuffixAlgebraVars	Allow variables with suffixes in model algebra
onTroll	Recognize Troll periodicity in set definitions using sequences
onUNDF	Allow UNDF as input
onUni	Allow domain violations in assignments
onWarning	Convert certain domain errors into warnings
use205	Language syntax of release 2.05
use225	Language syntax of release 2.25 Version 1
use999	Latest language syntax
version	Test GAMS compiler version number

4.41.2.3 Dollar Control Options Affecting the Output Format

Option	Description
double	Double-spaced listing follows
echo	Echo text to a file
echoN	Echo text to a file without ending the line
eject	Advance to next page
hidden	Ignore text and do not list
lines	Next number of lines have to fit on the page
log	Send message to the log
offDollar	Turn the listing of dollar control option lines off

Option	Description
offEcho	End of block echo
offExternalOutput	End of external output section
offEpsToZero	Do not interpret `EPS` as zero when writing to GDX
offInclude	Turn the listing of include file names off
offListing	Turn echoing input lines to listing file off
offLog	Turn line logging off
offPut	End of block put
offUpper	Following print to listing file is mixed cased
offVerbatim	Stop verbatim copy
onDollar	Turn the listing of dollar control option lines on
onEcho	Start of block echo with substitution
onEchoS	Start of block echo with substitution
onEchoV	Start of block echo without substitution
onEpsToZero	Interpret `EPS` as zero when writing to GDX
onExternalOutput	Start of external output section
onInclude	Include file name echoed to listing file
onListing	Input lines echoed to listing file
onLog	Reset line logging
onPut	Start of block `put` without substitution
onPutS	Start of block `put` with substitution
onPutV	Start of block `put` without substitution
onUpper	Following print to listing file is all upper cased
onVerbatim	Start verbatim copy if dumpopt $\geq$ 10
remark	Comment line with suppressed line number
[x]save[.keepCode]	Create a (compressed) save file during compilation with and without execution code compiled so far
single	Single-spaced listing follows
stars	Set "****" characters in listing file
sTitle	Set subtitle and reset page
title	Set title and reset page

4.41.2.4 Dollar Control Options Affecting the Listing of Reference Maps

Option	Description
offSymList	Turn symbol list off
offSymXRef	Turn symbol cross reference listing off
offUElList	Turn unique element listing off
offUElXRef	Turn unique element cross reference off
onSymList	Turn symbol list on
onSymXRef	Turn symbol cross reference listing on
onUElList	Turn unique element listing on
onUElXRef	Turn unique element cross reference on

4.41.2.5 Dollar Control Options Affecting Program Control

Option	Description
abort[.noError]	Issue an (error) message and abort compilation
batInclude	Include file with substitution arguments
call	Execute another program during compilation
call.Async[NC]	Execute another program asynchronously during compilation
call.checkErrorLevel	Execute another program during compilation and raise error in case of problem
callTool	Execute a GAMS tool during compilation
callTool.checkErrorLevel	Execute a GAMS tool during compilation and raise error in case of problem
clear	Reset all data for an identifier to its default value
clearError[s]	Clear compilation errors
else	Else clause
elseIf	ElseIf structure with case sensitive comparison
elseIfE	ElseIf structure with expression evaluation
elseIfI	ElseIf structure with case insensitive comparison
endif	Close ifThen/ifThenE/ifThenI control structure
error	Issue an error message
exit	Exit from compilation
funcLibIn	Load extrinsic function library
goto	Go to line with given label name
hiddenCall	Execute another program (hidden) during compilation
hiddenCall.Async[NC]	Execute another program (hidden) asynchronously during compilation
hiddenCall.checkErrorLevel	Execute another program (hidden) during compilation and raise error in case of problem
hiddenCallTool	Execute a GAMS tool (hidden) during compilation
hiddenCallTool.checkErrorLevel	Execute a GAMS tool (hidden) during compilation and raise error in case of problem
if	Conditional processing, case sensitive
ifE	If statement with expression evaluation
ifI	Conditional processing, case insensitive
ifThen	IfThen-elseIf structure with case sensitive comparison
ifThenE	IfThen-elseIf structure with expression evaluation
ifThenI	IfThen-elseIf structure with case insensitive comparison
include	Include file
kill	Kill data connected with identifier
label	Label name as entry point from $goto .
libInclude	Include file from library directory
offCheckErrorLevel	Do not check errorLevel automatically after $[hidden]call
offECImplicitLoad	Do not allow implicit loading from embedded code
offEmbeddedCode	Ends embedded code section
offFiltered	Turn behavior of $[gdx]load* to domain checked read
offMulti	Turn redefinition of data off
offOrder	Allow `lag` and `lead` operations on dynamic or unordered sets
offRecurse	Disable recursive include files
offStrictSingleton	Take first label if data statement for singleton set has multiple elements
onCheckErrorLevel	Throw compilation error, if errorLevel is not 0 after $[hidden]call

Option	Description
onECImplicitLoad	Allow implicit loading from embedded code
onEmbeddedCode	Starts embedded code section with substitution
onEmbeddedCodeS	Starts embedded code section with substitution
onEmbeddedCodeV	Starts embedded code section without substitution
onFiltered	Turn behavior of $[gdx]load* to filtered read
onMulti	Turn redefinition of data on (merging into existing data)
onMultiR	Turn redefinition of data on (replacing existing data)
onOrder	`lag` and `lead` operations on constant and ordered sets only
onRecurse	Enable recursive include files
onStrictSingleton	Error if data statement for singleton set has multiple elements
maxGoTo	Maximum number of jumps to the same label
phantom	Define a phantom element
shift	bat/lib/sysInclude argument shift operation
stop	Stop compilation
sysInclude	Include file from system directory
terminate	Terminate compilation and execution
warning	Issue compilation warning

Note that conditional compilation in GAMS is discussed in section Conditional Compilation below.

4.41.2.6 Dollar Control Options for GDX Operations

Option	Description
declareAndLoad	Declare and load all symbols from specified GDX file
gdxIn	Open GDX file for input
gdxLoad	Load specified symbols from specified GDX file
gdxLoadAll	Load all symbols which are known to GAMS from specified GDX file
gdxOut	Open GDX file for output
gdxUnload	Unload symbols into specified GDX file.
load	Load symbols from previously opened GDX file
loadDC	Load symbols from previously opened GDX file - domain checked
loadDCM	Load symbols from previously opened GDX file - domain checked - merge
loadDCR	Load symbols from previously opened GDX file - domain checked - replace
loadFiltered	Load symbols from previously opened GDX file - domain filtered
loadFilteredM	Load symbols from previously opened GDX file - domain filtered - merge
loadFilteredR	Load symbols from previously opened GDX file - domain filtered - replace
loadIdx	Load symbols from previously opened GDX file which has been written using an indexed write
loadM	Load symbols from previously opened GDX file - merge
loadR	Load symbols from previously opened GDX file - replace
offExternalInput	End of external input section
offExternalOutput	End of external output section
offFiltered	Turn behavior of $[gdx]load* to domain checked read
onExternalInput	Start of external input section
onExternalOutput	Start of external output section
onFiltered	Turn behavior of $[gdx]load* to filtered read
unLoad	Unload symbols into previously opened GDX file.

Note that GDX facilities and utilities are introduced in chapter GAMS Data eXchange (GDX).

4.41.2.7 Dollar Control Options for Compile-Time Variables and Environment Variables

Option	Description
drop	Drop a scoped compile-time variable
dropGlobal	Drop a global compile-time variable
dropLocal	Drop a local compile-time variable
dropEnv	Drop an OS environment variable
escape	Define the % escape symbol
eval	Evaluate and define a scoped compile-time variable
eval.Set	Evaluate and define a scoped compile-time variable based on a GAMS set
evalGlobal	Evaluate and define a global compile-time variable
evalGlobal.Set	Evaluate and define a global compile-time variable based on a GAMS set
evalLocal	Evaluate and define a local compile-time variable
evalLocal.Set	Evaluate and define a local compile-time variable based on a GAMS set
prefixPath	Prefix the environment variable `PATH`.
scratchFileName	Set a name for a temporary file in the scratch directory using the scratch file extension
setArgs	Define local compile-time variables using argument list
setComps	Unpack dotted names into compile-time variables
setDDList	Check double dash GAMS parameters
setDDList.Cont	Start list of identifiers to check double dash GAMS parameters
setEnv	Define an OS environment variable
set	Define a scoped compile-time variable
setGlobal	Define a global compile-time variable
setLocal	Define a local compile-time variable
setNames	Unpack a filename into local compile-time variables
show	Show current GAMS compile-time variables, macros, and active files
showFiles	Show active input and include files
showMacros	Show current macros
showVariables	Show current GAMS compile-time variables
splitOption	Unpack a key/value pair into scoped environment variables

See also sections Compile-Time Variables and Environment Variables in GAMS.

4.41.2.8 Dollar Control Options for Macro Definitions

Option	Description
macro	Preprocess macro definition
offDotL	Do not assume `.l` for variables in assignments
offDotScale	Assume `.scale` for variables and equations in assignments
offExpand	Do not expand macros when processing macro arguments
offLocal	Limit `.local` nesting to one
offMacro	Do not recognize macros for expansion
onDotL	Assume `.l` for variables in assignments and put statements

Option	Description
onDotScale	Assume `.scale` for variables and equations in assignments and put statements
onExpand	Expand macros when processing macro arguments
onLocal	No limit on `.local` nesting
onMacro	Recognize macros for expansion

Note that macros are introduced in section Macros in GAMS below.

4.41.2.9 Dollar Control Options for Compressing and Encrypting Source Files

Option	Description
compress	Create compressed GAMS system file
decompress	Decompress a GAMS system file
encrypt	Create an encrypted GAMS system file
expose	Remove all access control restrictions
hide	Hide objects from the user
protect	Protect objects from being modifiied by the user
purge	Remove the objects and all associated data

4.41.3 Detailed Description of Dollar Control Options

In this section we will describe each dollar control option in detail. Note that the dollar control options are listed in alphabetical order for easy reference. Note further, that in each entry the default value, if applicable, is given in parentheses.

$abort[.noError]

Syntax:

```
$abort[.noError] [text]
```

If used as `$abort`, this option will issue a compilation error and abort the compilation. It may be followed by a text.

Example:

```
$if not %system.fileSys% == UNIX
$abort We only do UNIX
```

This stops compilation if the operating system is not Unix. Running the example above on Windows will result in the compilation being aborted and the following lines in the listing file:

```
    2  $abort We only do UNIX
****        $343

Error Messages
343  Abort triggered by above statement
```

This option has a variant: `$abort.noError`. If the extension `.noError` is used the compilation will be aborted as well, but there will be no error. If a save file is written, all remaining unexecuted code will be flushed. This allows effective reuse of the save file.

Note that there is also an abort statement in GAMS, it is used to terminate the execution of a program.

See also $exit, $error, $stop, and $terminate.

$batInclude

Syntax:

```
$batInclude external_file {arg}
```

The `$batInclude` facility performs the same task as the $include facility: it inserts the contents of the specified file `external_file` at the location of the call. However, in addition, the option `$batInclude` also passes on arguments `arg` which may be used inside the include file. `External_file` is the name of the batch include file, it may be quoted or unquoted. The arguments `arg` are passed on to the batch include file. These arguments are treated as character strings that are substituted by numbers inside the included file. The arguments may be single unbroken strings (quoted or unquoted) or quoted multi-part strings.

Note that the syntax has been modeled after the DOS batch facility. Inside the batch file, a parameter substitution is indicated by using the character `%` followed immediately by an integer value corresponding to the order of parameters on the list where `%1` refers to the first argument, `%2` to the second argument, and so on. If an integer value is specified that does not correspond to a passed parameter, then the parameter flag is substituted with a null string. The parameter flag `%0` is a special case that will substitute a fully expanded file name specification of the current batch included file. The flag `%$` is the current `$` symbol (see $dollar). Observe that parameters are substituted independent of context and the entire line is processed before it is passed to the compiler. There is one exception: parameter flags that appear in comments are not substituted.

Attention

- GAMS requires that processing the substitutions must result in a line of less than or equal to the maximum input line length.
- The case of the passed parameters is preserved, thus it may be used in string comparisons.

Example:

```
$batInclude "file1.inc" abcd "bbbb" "cccc dddd"
```

Note that `file1.inc` is included with `abcd` as the first parameter, `bbbb` as the second parameter and `cccc dddd` as the third parameter.

```
Parameter a,b,c ;
a = 1 ; b = 0 ; c = 2 ;
$batInclude inc2.inc b a
display b ;
$batInclude inc2.inc b c
display b ;
$batInclude inc2.inc b "a+5"
display b ;
```

The external file `inc2.inc` contains the following line:

```
%1 = sqr(%2) - %2 ;
```

The echo print in the corresponding listing file follows:

```
 1  Parameter a,b,c ;
 2  a = 1 ; b = 0 ; c = 2 ;
BATINCLUDE C:\tmp\inc2.inc
 4  b = sqr(a) - a ;
 5  display b ;
BATINCLUDE C:\tmp\inc2.inc
 7  b = sqr(c) - c ;
 8  display b ;
BATINCLUDE C:\tmp\inc2.inc
 10  b = sqr(a+5) - a+5 ;
 11  display b ;
```

Note that the option `$batInclude` appears three times with different arguments. GAMS is interprets the contents of the batch include file in turn as:

```
b = sqr(a) - a ;
b = sqr(c) - c ;
b = sqr(a+5) - a+5 ;
```

Note that the third call is not interpreted as `sqr(a+5)-(a+5)`, but instead as `sqr(a+5)-a+5`. The results of the display statement are shown at the end of the listing file are given below:

```
----      5 PARAMETER b                  =        0.000
----      8 PARAMETER b                  =        2.000
----     11 PARAMETER b                  =       40.000
```

Observe that the third call leads to `b = sqr(6)-1+5`, thus the final value of `b` is 40. Suppose the statement in the batch include file is modified to read as follows:

```
%1 = sqr(%2) - (%2) ;
```

With this modification the output generated by the display statement will be as follows:

```
----      5 PARAMETER b                  =        0.000
----      8 PARAMETER b                  =        2.000
----     11 PARAMETER b                  =       30.000
```

Note that the third call leads to `b = sqr(6)-6` which results in `b` taking a value of 30.

Note

The option `$batInclude` without any arguments is equivalent to the option $include.

See also $include, $libInclude, $sysInclude.

$call

Syntax:

```
$call [=]command
```

This option passes a `command` to the current operating system command processor and interrupts compilation until the command has been completed. If the command string is empty or omitted, a new interactive command processor will be loaded.

Example:

```
$call dir
```

This command creates a directory listing on a PC.

Note that the command string may be passed to the system and executed directly without using a command processor by prefixing the command with an '=' sign. Compilation errors will be issued if the command or the command processor cannot be loaded and executed properly.

```
$call gams trnsport
$call =gams trnsport
```

The first call will run the model [**TRNSPORT**] in a new command shell. The DOS command shell does not send any return codes from the run back to GAMS. Therefore any errors in the run are not reported back. The second call, however, will send the command directly to the system. The return codes from the system will be intercepted correctly and they will be available to the GAMS system through the errorLevel function.

Attention

- Some commands (like `copy` on a PC and `cd` in Unix) are shell commands and cannot be spawned off to the system. Using these in a system call will create a compilation error.

  ```
  $call 'copy myfile.txt mycopy.txt'
  $call '=copy myfile.txt mycopy.txt'
  ```

  The first call will work on a PC, but the second will not. The copy command may be used only from a command line shell. The system is not aware of this command (Try this command after clicking Run under the Start menu in Windows. You will find that it does not work).
- One has to take special care when the first argument of the `command` contains spaces (for example an executable with absolute path), e.g.:

  ```
  $call C:\path with spaces\gams.exe trnsport.gms
  ```

  This would fail, since the command processor would try to call `C:\path` as the executable. So, one might think that protecting the spaces using quotes will resolve this problem:

  ```
  $call "C:\path with spaces\gams.exe" trnsport.gms
  ```

  However, the quotes delimit the entire `$call command`, so that `trnsport.gms` gets interpreted as new dollar control option instead of an argument for the executable. The solution is to use nested quotes: One pair to delimit the `$call command` and another one to protect the spaces of the executable like this:

  ```
  $call '"C:\path with spaces\gams.exe" trnsport.gms'
  ```

  It gets even more complicated if the argument contains spaces as well, e.g. if we have `my model.gms` instead of `trnsport.gms`. Another pair of quotes solves this:

  ```
  $call '"C:\path with spaces\gams.exe" "my model.gms"'
  ```

See also $call.Async, $call.checkErrorLevel, $hiddenCall.

$call.Async[NC]

Syntax:

```
$call.Async[NC] command
```

`$call.Async` works like $call but allows asynchronous job handling. This means users may start a job `command` without having to wait for the result, they may continue in their model and collect the return code of the job later. The function jobHandle may be used to get the process ID (pid) of the last job started. The status of the job may be checked using the function jobStatus(pid). An interrupt signal to a running job may be sent with the function jobTerminate(pid). With the function jobKill(pid) a kill signal may be sent to a running job.

The difference between `$call.Async` and `$call.AsyncNC` is, that the latter starts processes in a *new console*, rather than sharing the console of the parent process.

Note

On non-Windows platforms `$call.AsyncNC` and `$call.Async` are synonyms.

$call.checkErrorLevel

Syntax:

```
$call.checkErrorLevel [=]command
```

`$call.checkErrorLevel` works like $call but checks the errorLevel implicitly, raises a compilation error and aborts compilation, if that is not 0.

Example:

```
$call.checkErrorLevel gams trnsport
```

This is doing the same as:

```
$call gams trnsport
$ifE errorLevel<>0 $abort 'Problem calling gams trnsport'
```

$callTool

Syntax:

```
$callTool command
```

This option calls a tool of the GAMS Tools Library at compile time.

Example:

```
$callTool [data.]ExcelDump excelFile [gdxOut=fileOut.gdx]
```

This tool writes all worksheets of an Excel workbook to GAMS symbols.

Note

- Similar to $call, `$callTool` returns a shell code that can be checked via `errorLevel`. In case one expects the tools to perform without error, it is recommended to add the suffix .checkErrorLevel. This will stop the entire execution of GAMS if an error occurs while executing the tool.
- `$callTool[.checkErrorLevel] [...]` is ignored while $onExternalInput is active and IDCGDXInput is set.

Attention

- $callTool is only available for calling tools from the GAMS Tools Library. For general commands to the operating system $call must be used.

See also $callTool.checkErrorLevel, $hiddenCallTool.

$callTool.checkErrorLevel

Syntax:

```
$callTool.checkErrorLevel command
```

$callTool.checkErrorLevel works like $callTool but checks the errorLevel implicitly, raises a compilation error and aborts compilation, if that is not 0.

Example:

```
$callTool.checkErrorLevel [data.]ExcelDump excelFile [gdxOut=fileOut.gdx]
```

This is doing the same as:

```
$callTool [data.]ExcelDump excelFile [gdxOut=fileOut.gdx]
$ifE errorLevel<>0 $abort 'Problem calling gams trnsport'
```

$clear

Syntax:

```
$clear  ident {ident}
```

This option resets all data for the identifiers ident to their default values. Note that only the following data types may be reset: sets, parameters, variables and equations. Note further, that the clearing is carried out during compile time and not when the GAMS program executes.

Example:

```
Set    i  / 1*20 /;
Scalar a  / 2 /;
$clear i a
display i, a;
```

The option $clear resets i and a to their default values: an empty set for i and zero for a. The output generated by the display statement follows:

```
----      4 SET i
                                                    ( EMPTY )

----      4 PARAMETER a                  =        0.000
```

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Both the dollar control options and the data initialization is done in the first pass, and assignments in the second, irrespective of their relative locations. This is an issue particularly with $clear since data can be both initialized and assigned.

```
Scalar a / 12 /;
a = 5;
$clear a
display a;
```

Note that the scalar data initialization statement is processed during compilation and the assignment statement a = 5; during execution. In the order that it is processed, the example above is read by GAMS as:

```
* compilation step
Scalar a /12/ ;
$clear a
* execution step
a = 5;
display a ;
```

Therefore the result is that a takes the value of 5. The output from the display statement is as follows:

```
----      4 PARAMETER a                   =        5.000
```

Compare also $kill and the execution time option clear.

$clearError[s]

Syntax:

```
$clearError[s]
```

This option ($clearError and $clearErrors are synonyms) clears GAMS awareness of compiler errors and turn them into warning messages instead.

Example:

```
Scalar z / 11 /;
$eval x sqrt(-1)
$clearError
$log %x%
Display z;
```

Note that without the use of $clearError the program above would not continue with the execution after line 2.

$comment (∗)

Syntax:

```
$comment char
```

This option changes the symbol indicating a single line comment from the default ∗ to the single character char. Note that after this option is used, the new comment character char cannot be used in column 1 as before, since it got a special meaning. Note further, that the case of the character does not matter if it is used as a comment character. This option should be used with great care and we recommend to reset the symbol quickly to the default.

Attention

The case of the start-of-line comment character does not matter when being used.

Example:

```
$comment c
c now we use a FORTRAN style comment symbol
$comment *
* now we are back to the default
```

See also section Comments.

$compress

Syntax:

```
$compress source target
```

This option causes the file `source` to be compressed into the packed file `target`.

Example: Consider the following example where the well-known model [**TRNSPORT**] is used:

```
$call gamslib trnsport
$compress trnsport.gms t2.gms
$include t2.gms
```

The first command retrieves the file `trnsport.gms` and the second command compresses it. Note that a compressed GAMS file is treated like any other GAMS file, therefore it may be included and executed as usual. Large data files that do not change often can be compressed this way to save disk space.

The following example serves as a little utility to compress and decompress files:

```
$ifthen set decompress
$  if not set input  $set input file_c.gms
$  if not exist %input% $abort No file input file %input% exist
$  if not set output $set output file.gms
$  log Decompressing %input% into %output%
$  decompress %input% %output%
$else
$  if not set input  $set input file.gms
$  if not exist %input% $abort No file input file %input% exist
$  if not set output $set output file_c.gms
$  log Compressing %input% into %output%
$  compress %input% %output%
$endif
```

The program (saved to a file called `compress.gms`) can be used as follows:

```
> gams compress.gms --input myfile.gms --output myfile_c.gms
> gams compress.gms --decompress=1 --input myfile_c.gms --output myfile.gms
```

See also $decompress. Further details are given in chapter Compressing and Decompressing Files.

$declareAndLoad

Syntax:

```
$declareAndLoad GDXFileName
```

This option loads all symbols from a specified GDX file. It is similar to $gdxLoadAll, but does not only load the symbols declared so far but also declares symbols found in the GDX file on the fly if they were unknown. If a symbol already exists in GAMS the GDX declaration better matches it's previous GAMS declaration exactly (same rules as if we would write the second declaration in source, e.g. different symbol text is allowed or incremental declaration first `Variable x;` and in GDX `Positive Variable x;`) otherwise we trigger an error.

Example:

If there is a GDX file `trnsport` created from the [**TRNSPORT**] model, the following code will declare and load all symbols seen in the trnsport model before:

```
$declareAndLoad trnsport.gdx

option DmpUserSym;
```

This can be seen in the `.lst` file afterwards:

```
SYMBOL TABLE DUMP (USER SYMBOLS ONLY), NR ENTRIES = 12
ENTRY                                ID   TYPE DIM  LENGTH MEMORYEST DEFINED ASSIGNED DATAKNOWN
  138                                 i    SET   1       2      0 MB    TRUE    FALSE      TRUE
  139                                 j    SET   1       3      0 MB    TRUE    FALSE      TRUE
  140                                 a  PARAM   1       2      0 MB    TRUE    FALSE      TRUE
  141                                 b  PARAM   1       3      0 MB    TRUE    FALSE      TRUE
  142                                 d  PARAM   2       6      0 MB    TRUE    FALSE      TRUE
  143                                 f  PARAM   0       1      0 MB    TRUE    FALSE      TRUE
  144                                 c  PARAM   2       6      0 MB    TRUE    FALSE      TRUE
  145                                 x    VAR   2       6      0 MB    TRUE    FALSE      TRUE
  146                                 z    VAR   0       1      0 MB    TRUE    FALSE      TRUE
  147                              cost    EQU   0       1      0 MB    TRUE    FALSE      TRUE
  148                            supply    EQU   1       2      0 MB    TRUE    FALSE      TRUE
  149                            demand    EQU   1       3      0 MB    TRUE    FALSE      TRUE
END OF SYMBOL TABLE DUMP
```

See also $(on|off)Filtered, $(on|off)Multi, and $onMultiR.

$decompress

Syntax:

```
$decompress source target
```

This option causes the compressed file `source` to be decompressed into the unpacked file `target`.

Example: Consider the following example where the well-known model [**TRNSPORT**] is used:

```
$call gamslib trnsport
$compress trnsport.gms t2.gms
$decompress t2.gms t3.gms
$call diff t3.gms trnsport.gms
$if errorlevel 1 $abort t3.gms and trnsport.gms are not identical!
```

The first command retrieves the file `trnsport.gms`, the second command compresses it and the third command decompresses the compressed file. Note that the resulting file, `t3.gms`, is identical to the original file `trnsport.gms` which is tested via the `diff` program.

See also $compress. Further details are given in chapter Compressing and Decompressing Files.

$dollar ($)

Syntax:

```
$dollar char
```

This option changes the current 'dollar' symbol to the single character `char`.

Note

The special %$ substitution symbol can be used to get the current 'dollar' symbol.

Example:

```
$dollar #
#log now we can use '%$' as the '$' symbol
```

$double

Syntax:

```
$double
```

The lines following this option will be echoed double spaced to the echo print in the listing file.

Example:

```
Set    i / 1*2 / ;
Scalar a / 1   / ;
$double
Set    j / 10*15 / ;
Scalar b / 2     / ;
```

The resulting echo print in the listing file looks as follows:

```
1  Set i /1*2/ ;
2  Scalar a /1/ ;

4  Set j /10*15/ ;

5  Scalar b /2/ ;
```

Note that lines before the option $double are listed single spaced, while the lines after the option are listed with double space.

See also $single.

$drop

Syntax:

```
$drop VARNAME
```

This option destroys (removes from the program) the scoped compile-time variable VARNAME that was defined with the dollar control option $set.

Example:

```
$set NAME my name
$if set NAME $log Scoped compile-time variable NAME is set to "%NAME%"
$drop NAME
$if not set NAME $log Scoped compile-time variable NAME is not available anymore
```

See also $set, $dropGlobal, and $dropLocal.

$dropEnv

Syntax:

```
$dropEnv VARNAME
```

This dollar control option destroys (removes from the program) the operating system environment variable `VARNAME`. For detailed information, see the dollar control option .

Example:

```
$if setEnv GDXCOMPRESS $dropEnv GDXCOMPRESS
```

See also $setEnv, and $if setEnv.

$dropGlobal

Syntax:

```
$dropGlobal VARNAME
```

This option destroys (removes from the program) the global compile-time variable `VARNAME` that was defined with the dollar control option $setGlobal.

Example:

```
$setGlobal NAME my name
$if setGlobal NAME $log Global compile-time variable NAME is set to "%NAME%"
$dropGlobal NAME
$if not setGlobal NAME $log Global compile-time variable NAME is not available anymore
```

See also $setGlobal, and $drop.

$dropLocal

Syntax:

```
$dropLocal VARNAME
```

This option destroys (removes from the program) the local compile-time variable `VARNAME` that was defined with the dollar control option $setLocal.

```
$setLocal NAME my name
$if setLocal NAME $log Local compile-time variable NAME is set to "%NAME%"
$dropLocal NAME
$if not setLocal NAME $log Local compile-time variable NAME is not available anymore
```

See also $setLocal, and $drop.

$echo

Syntax:

```
$echo text >[>] external_file
```

This option allows to write the text `text` to a file `external_file`. The text and the file name may both be quoted or unquoted. The file name is expanded using the working directory. The option `$echo` tries to minimize file operations by keeping the file open in anticipation of another `$echo` to be appended to the same file. The file will be closed at the end of the compilation or when an option $call or any variant of the option $include is encountered. The redirection symbols > and >> have the usual meaning of starting at the beginning or appending to an existing file respectively.

Example:

```
$echo                                                    > echo.txt
$echo  The message written goes from the first non blank >> echo.txt
$echo 'to the first > or >> symbol unless the text is'   >> echo.txt
$echo "is quoted. The input File is %gams.input%. The"   >> echo.txt
$echo 'file name "echo.txt" will be completed with'      >> echo.txt
$echo  %gams.workdir%.                                   >> echo.txt
$echo                                                    >> echo.txt
```

The content of the resulting file `echo.txt` is the following:

```
The message written goes from the first non blank
to the first > or >> symbol unless the text is
is quoted. The input File is C:\tmp\echoTest.gms. The
file name "echo.txt" will be completed with
C:\tmp\.
```

See also $on/offEcho, and $echoN.

$echoN

Syntax:

```
$echoN text >[>] external_file
```

This option sends a text message `text` to an file `external_file` like $echo but writes no end of line marker so the line is repeatedly appended to by subsequent commands. The redirection symbols > and >> have the usual meaning of starting at the beginning or appending to an existing file respectively. Note that the text and the file name may be quoted or unquoted. By default the file will be saved in the working directory.

Example:

```
$echoN 'Text to be sent'           > 'aaa.txt'
$echoN 'More text'                >> aaa.txt
$echoN And more and more and more >> aaa.txt
$echo This was entered with $echo >> 'aaa.txt'
$echo This too                    >> aaa.txt
```

The created file `aaa.txt` contains the following text:

```
Text to be sentMore textAnd more and more and moreThis was entered with $echo
This too
```

See also $on/offEcho, and $echo.

$eject

Syntax:

```
$eject
```

This option advances the echo print to the next page.

Example:

```
$eject
Set       i,j ;
Parameter Data(i,j) ;
$eject
Scalar a;
a = 7;
```

The statements following the first `$eject` will be listed on one page in the echo print of the listing file and the statements following the second `$eject` will be listed on the next page.

$else

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option always appears together with the option $ifThen[E/I]. It is followed by an instruction which is executed if the conditional expression of the matching option $ifThen[E/I] is not true. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen, $elseIf and section Conditional Compilation.

$elseIf

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option always appears together with the option $ifThen[E/I]. It is followed by another condition and instruction. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen, $else, $elseIfE, $elseIfI and section Conditional Compilation.

$elseIfE

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option does the same as $elseIf but evaluates numerical values of the control variables.

See also $elseIf and section Conditional Compilation.

$elseIfI

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option does the same as $elseIf but it is case insensitive.

See also $elseIf and section Conditional Compilation.

$encrypt

Syntax:

```
$encrypt source target
```

This option causes a file to be converted into an encrypted file. Here `source` is the name of the source file to be encrypted and `target` is the name for the resulting encrypted file. Note that encryption requires the *secure* option to be licensed and is available for commercial licenses only. The command line parameter pLicense specifies the target license to be used for encryption. The encrypted file can only run on a system licensed with the license file used for encryption. No special action is required on the executing system since GAMS recognizes whether a file is encrypted and will process it accordingly. There is no option to *decrypt* an encrypted file, so better keep the original unencrypted file.

Further details and examples are given in chapter Encrypting Files.

$endIf

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This must option must be matched with one of the options $ifThen, $ifThenE or $ifThenI. For an example, see section Conditional Compilation with $ifThen and $else.

See also $ifThen and section Conditional Compilation.

$eolCom (!!)

Syntax:

```
$eolCom char[char]
```

This option redefines and activates the end-of-line comment symbol, which may be one character or a sequence of two characters. By default, this is initialized to `!!`, but is not active. The option $onEolCom is used to activate the end-of-line comments. If `$eolCom` is used, $onEolCom is set automatically.

Example:

```
$eolCom //
Set i /1*2/ ;     // set declaration
Parameter a(i) ;  // parameter declaration
```

Here the character sequence `//` serves as the end-of-line-comment indicator.

Attention

It is not allowed to reset the end-of-line comment symbol to the current end-of-line comment symbol. This would cause an compilation error as in the following example:

```
$eolCom //
$eolCom //
```

Some end of line character settings can cause confusion. The widely used end of line character sequence `//` is also legal GAMS syntax in `put` statement to indicate two line breaks:

```
file fx; put fx;
put 'first line' // 'second line' //;
$eolCom //
put 'third line' // 'fourth line';
```

results in a put file with the following content:

```
first line

second line

third line
```

This can also confuse syntax highlighting in editors (or on thsi web page). Other popular end of line characters like `#` and `@` are also used as GAMS syntax, see Controlling the Cursor On a Page.

The default for dealing with end-of-line comments can be set using the command line parameter eolCom.

See also section Comments for more about comments in GAMS.

$error

Syntax:

```
$error [text]
```

This option will issue a compilation error and will continue with the next line.

Example:

```
$if not exist myfile
$error File myfile not found - will continue anyway
```

Note that the first line checks if the file `myfile` exists. If the file does not exist, it will generate an error with the comment `File myfile not found - will continue anyway` and then the compilation will continue with the next line.

See also $abort, $exit, $terminate, and $stop.

$escape

Syntax:

```
$escape character
```

This option allows users to work with text sequences containing % without substitution.

This causes all subsequent commands of the form %symbol% to not have parameter substitution done for them. As a consequence, no parameter substitutions are performed in GAMS statements (mostly useful in display and put statements) and the outcome of such statements where %symbol% is used is just %symbol%.

Note that the effect of the option $escape may be reversed with the option $escape %.

Example:

```
$set tt DOIT

file it; put it;

display "first %tt%";
display "second %&tt%&";
put "display one ", "%system.date%" /;
put "display two " "%&system.date%&"/;

$escape &
display "third %tt%";
display "fourth %&tt%&";
put "display third ", "%system.date%" /;
put "display fourth " "%&system.date%&"/;

$escape %
display "fifth %tt%";
display "sixth %&tt%&";
put "display fifth ", "%system.date%" /;
put "display sixth " "%&system.date%&"/;
```

The output generated by the display statements follows:

```
----      6 first DOIT

----      7 second %&tt%&

----     12 third DOIT

----     13 fourth %tt%

----     18 fifth DOIT

----     19 sixth %&tt%&
```

The file it.put will contain the following lines:

```
display one 08/10/17
display two %&system.date%&
display third 08/10/17
display fourth %system.date%
display fifth 08/10/17
display sixth %&system.date%&
```

Note that this option was introduced to facilitate writing GAMS code (or command.com/cmd.exe batch scripts) from GAMS including unsubstituted compile-time variables. Text can also be written at compile-time without parameter substitution via option $on/offEchoV and at run-time via $on/offPutV.

Note

In GAMS the escape character *follows* the character (%) that needs to be escaped. In many other languages the escape character precedes the to be escaped character.

$eval

Syntax:

```
$eval VARNAME expression
```

This option evaluates a numerical expression at compile time and places it into a *scoped* compile-time variable. In turn the option $ifE may be used to do numeric testing on the value of this variable.

`VARNAME` is the name of a compile-time variable and `expression` is an expression that consists of constants, functions, operators and other compile-time variables with numerical values. Note that no whitespace is allowed in the expression which can be overcome by additional parentheses.

Example:

```
$eval b1 ifthen(uniform(0,1)<0.5,0,1)
$eval b2 ifthen(uniform(0,1)<0.5,0,1)
$eval b3 (%b1%)xor(%b2%)
$log b1=%b1% b2=%b2% b1 xor b2=%b3%
```

The first two lines use the `uniform` function to generate a random number between 0 and 1 and assign `0` if this number is less than 0.5 otherwise `1` via the `ifthen` function to the scoped compile-time variable `b1` and `b1`. In the third line we apply the logical `xor` operator to `b1` and `b2` and store the result in `b3`. The parentheses are required because the more natural expression `%b1% xor %b2%` contains spaces. In the forth line we print the values and result to the log.

```
b1=1 b2=1 b1 xor b2=0
```

The expression are evaluated using IEEE nonstop arithmetic, so no evaluation errors are triggered as demonstrated in the following example:

```
$eval OneDividedByZero 1/0
$log 1/0=%OneDividedByZero%
```

This produces the following log:

```
1/0=+INF
```

The `$eval` and related dollar control options give access to a reduced set of GAMS functions: abs, card, ceil, cos, errorlevel, exp, fact, floor, frac, gamsrelease, gamsversion, gday, gdow, ghour, gleap, gmillisec, gminute, gmonth, gsecond, gyear, ifthen, jdate, jnow, jobhandle, jobkill, jobstatus, jobterminate, jstart, jtime, log, log10, log2, max, min, mod, numcores, pi, power, round, sameas, sign, sin, sleep, sqr, sqrt, tan, trunc, and uniform. The available operators are: +, -, *, /, ** and even ^ (integer power) which is not available in regular GAMS expression and requires the use of the function `ipower`. The comparison relations are <, >, <=, >=, <>, and =. The logical operators are **not**, **and**, **or**, **xor**, **imp**, and **eqv**.

The expression also allows the use of dollar on the right. In the following example we replace the `ifthen` function by a dollar one the right:

```
$eval b1 1$(uniform(0,1)>=0.5)
$eval b2 1$(uniform(0,1)>=0.5)
$eval b3 (%b1%)xor(%b2%)
$log b1=%b1% b2=%b2% b1 xor b2=%b3%
```

Moreover, the `$eval` has access to data available at compile time. The expression can access the value of scalars and for other symbols we can use the `card` function to access the cardinality (at this point) of the symbol. Here is an example:

```
Scalar ac 'Avogadro constant' / 6.0221409e+23 /;
$eval log_ac round(log10(ac))
$log round(log10(ac))=%log_ac%
Set d / d0*d%log_ac% /;
$eval card_d card(d)
$log card(d)=%card_d%
```

Access to individual records of symbols is not possible. The embedded code facility allows access to symbol records at compile time.

The user has the possibility to hide some of the GAMS functions by symbols with the same name. In this case, the GAMS function can still be accessed, but needs to be prefixed with `system.` as in the following example:

```
Scalar pi /3/;

$eval myPi pi
$eval GAMSPi system.pi
$log myPi   = %myPi%
$log GAMSPi = %GAMSPi%
```

This is the resulting output in the log:

```
myPi   = 3
GAMSPi = 3.14159265358979
```

See also $eval.Set, $evalGLobal, $evalLocal, $ifE, and $set.

$eval.Set

Syntax:

```
$eval.Set VARNAME SETID[.[First|Last]TE|[First|Last]TL|[First|Last]TN|TS]
```

This option evaluates an attribute of a GAMS set at compile time and places it into a *scoped* compile-time variable. `VARNAME` is the name of a compile-time variable and `SETID` is the identifier of a GAMS set. The following attributes are allowed in this context:

Attribute	Description
`[First OR Last]TE`	Explanatory text of the first or last element of the set `SETID`
`[First OR Last]TL`	Label of the first or last element of the set `SETID`
`[First OR Last]TN`	Set identifier with with element labels of the first or last element of the set `SETID`
`TS`	Explanatory text of the set `SETID`. This is also the default, if no attribute is specified

Note

- `First??` and `??` are synonyms in the table above. It always accesses the first element of the referenced set.
- `Last??` always accesses the last element of the referenced set.
- For Singleton Sets `First??`, `Last??` and `??` are synonyms.

Example:

```
Singleton Set h Greeting / Hello          'Welcome' /;
Set           p Person   / Mr.President   'Male'
                           Mrs.Chancellor 'Female'  /;

$eval.Set X h.TE
$log %X%
$eval.Set X p.lastTL
$log %X%
$eval.Set X p.FirstTN
$log %X%
```

This will generate the following in the log:

```
Welcome
Mrs.Chancellor
p('Mr','President')
```

See also $eval, $evalGLobal.Set, $evalLocal.Set, and $set.

$evalGlobal

Syntax:

```
$evalGlobal VARNAME expression
```

This option evaluates a numerical expression at compile time and places it into a *global* compile-time variable. The syntax and behavior otherwise is identical to $eval.

$evalGlobal.Set

Syntax:

```
$evalGlobal.Set VARNAME SETID[.[First|Last]TE|[First|Last]TL|[First|Last]TN|TS]
```

This option evaluates an attribute of a GAMS set at compile time and places it into a *global* compile-time variable. The syntax and behavior otherwise is identical to $eval.Set.

$evalLocal

Syntax:

```
$evalLocal VARNAME expression
```

This option evaluates a numerical expression at compile time and places it into a *local* compile-time variable. The syntax and behavior otherwise is identical to $eval.

$evalLocal.Set

Syntax:

```
$evalLocal.Set VARNAME SETID[.[First|Last]TE|[First|Last]TL|[First|Last]TN|TS]
```

This option evaluates an attribute of a GAMS set at compile time and places it into a *local* compile-time variable. The syntax and behavior otherwise is identical to $eval.Set.

$exit

Syntax:

```
$exit
```

This option will cause the compiler to exit (stop reading) from the current file. This is equivalent to having reached the end of file.

Example:

```
Scalar a ;
a = 5 ;
display a ;
$exit
a = a+5 ;
display a ;
```

Note that the lines following the option `$exit` will not be compiled.

Observe that there is a difference to the dollar control option $stop. If there is only one input file, `$stop` and `$exit` will have the same effect. If the option `$exit` occurs *within* an include file, it acts like an end-of-file on the include file. However, if the option `$stop` occurs *within* an include file, GAMS will stop reading all input.

See also $abort, $error, $terminate, and $stop.

$expose

Syntax:

```
$expose all | ident1 ident2 ...
```

This option removes all privacy restrictions from identifiers.

With explicit identifiers the privacy restrictions are removed only for the listed identifiers and with `all` the restrictions are removed for *all* identifiers. The privacy restrictions may be set with the dollar control options $hide or $protect. Note that a special license file is needed for this feature to work and that the `expose` only takes effect in subsequent restart files. For further information, see chapter Secure Work Files.

$funcLibIn

Syntax:

```
$FuncLibIn InternalLibName ExternalLibName
```

This makes extrinsic function libraries available to a model. `InternalLibName` is the internal name of the library in the GAMS code and `ExternalLibName` is the name of the shared library in the file system. See Using Function Libraries for more information.

$gdxIn

Syntax:

```
$gdxIn [GDXFileName]
```

This option is used in a sequence to load specified items from a GDX file. Here `GDXFileName` denotes the name of the GDX file (with or without the extension `.gdx`) and the command opens the specified GDX file for reading. The use of `$gdxIn` without a file name closes the currently open GDX file. The command is used in conjunction with the option $load or one of its variants.

Example:

```
set i,j; parameters a(i), b(j), d(i,j), f;
$gdxIn mydata.gdx
$load i j a b d f
$gdxIn
```

See also $load, and $gdxOut.

$gdxLoad

Syntax:

```
$gdxLoad GDXFileName [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option loads specified symbols from a specified GDX file. It basically combines $gdxIn and $load in one call. This can be particularly useful for $[bat|lib]include files when you want to be sure, to not interfere with potentially previously opened GDX files. For example, a $load after a "$gdxLoad" will still load the symbols from the GDX file opened before:

```
$gdxIn A.gdx
$load a b c
$gdxLoad B.gdx d
* The following $load gets the symbols e, f, and g from GDX file A.gdx
$load e f g
```

See also $(on|off)Filtered, $(on|off)Multi, and $onMultiR.

$gdxLoadAll

Syntax:

```
$gdxLoadAll GDXFileName
```

This option loads all symbols known from a specified GDX file. It is similar to $gdxLoad, but does not need/allow a list of symbols to be loaded. Instead it compares the list of previous declared symbols with the symbols in the specied GDX file and loads all symbols that match. If we have incompatibilities between symbols in GDX and GAMS (the incompatibilities are the same as if we would do an explicit `$load sym`) CMEX triggers an error. Symbols in GDX that don't exist in GAMS are just ignored.

Example:

If there is a GDX file `trnsport` created from the **[TRNSPORT]** model, the following code will load the symbols `i`, `j` and `c`. All other symbols are ignored:

```
Set       i,j,k;
Parameter c(i,j);
$gdxLoadAll trnsport.gdx
```

See also $(on|off)Filtered, $(on|off)Multi, and $onMultiR.

$gdxOut

Syntax:

```
$gdxOut [GDXFileName]
```

This option is used in a sequence to unload specified items to a GDX file at compile time. Here `GDXFileName` denotes the name of the GDX file (with or without the extension GDX) and the command opens the specified GDX file for writing. The use of `$gdxOut` without a file name closes the currently open output GDX file and initiates the actual writing of the sequence of symbols. The command is used in conjunction with the dollar control option $unLoad.

Example:

```
set i /i1*i3/; parameters a(i) /i1 3, i2 87, i3 1/;
$gdxOut mydata.gdx
$unLoad i a
$gdxOut
```

See also $unLoad, and $gdxIn.

$gdxUnload

Syntax:

```
$gdxUnload GDXFileName [sym1[,] sym2=gdxSym2[,] ...]
```

This option unloads symbols from a specified GDX file. It basically combines $gdxOut and $unload in one call. This can be particularly useful for $[bat|lib]include files when you want to be sure, to not interfere with potentially previously opened GDX files. For example, a $unload after a "$gdxUnload" will still unload the symbols to the GDX file opened before:

```
$gdxOut A.gdx
$unload a b c
$gdxUnload B.gdx d
* The following $unload puts the symbols e, f, and g into GDX file A.gdx
$unload e f g
```

$goto

Syntax:

```
$goto id
$label id
```

This option will cause GAMS to search for a line starting with `$label id` and then continue reading from there. This option can be used to skip over or repeat sections of the input files. In $batinclude files the target labels or label arguments can be passed as parameters because of the manner in which parameter substitution occurs in such files. In order to avoid infinite loops, jumps to the same label are restricted to a maximum of 100 times by default. This maximum may be changed with the option $maxGoto.

Example:

```
Scalar a ;
a = 5;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;
```

Note that GAMS will continue from line `$label next` after reading line `$goto next`. Observe that all lines in between are ignored. Therefore the final value of `a` in the example above will be 15.

Attention

The lines `$goto` and $label have to be in the same file. If the target label is not found in the current file an error will be issued.

See also $label, $maxGoto.

$hidden

Syntax:

```
$hidden text
```

A line starting with this option will be ignored and will not be echoed to the listing file. This option is used to enter information only relevant to the person manipulating the file.

Example:

```
$hidden You need to edit the following lines if you want to:
$hidden
$hidden     1. Change form a to b
$hidden     2. Expand the set
```

The lines above serve as comments to the person who wrote the file. However, these comments will not be visible in the listing file and are therefore hidden from view.

Note

This option is particularly useful when the input file is encrypted.

$hiddenCall

Syntax:

```
$hiddenCall [=]command
```

This option does the same as $call but the statement is neither shown on the log nor the listing file.

$hiddenCall.Async[NC]

Syntax:

```
$hiddenCall.Async[NC] command
```

This option does the same as $call.Async[NC] but the statement is neither shown on the log nor the listing file.

$hiddenCall.checkErrorLevel

Syntax:

```
$hiddenCall.checkErrorLevel [=]command
```

This option does the same as $call.checkErrorLevel but the statement is neither shown on the log nor the listing file.

$hiddenCallTool

Syntax:

```
$hiddenCallTool command
```

This option does the same as $callTool but the statement is neither shown on the log nor the listing file.

$hiddenCallTool.checkErrorLevel

Syntax:

```
$hiddenCallTool.checkErrorLevel command
```

This option does the same as $callTool.checkErrorLevel but the statement is neither shown on the log nor the listing file.

$hide

Syntax:

```
$hide all | ident1 ident2 ...
```

This option hides identifiers so they cannot be displayed or computed, but they may still be used in model calculations (i.e. commands when the solve statement is executed).

With explicit identifiers the listed identifiers are hidden and with `all` all identifiers are hidden. These restrictions may be removed with the dollar control options expose or purge. Note that a special license file is needed for this feature to work.

For further information, see chapter Secure Work Files.

$if

Syntax:

```
$if [not] conditional_expression new_input_line
```

This dollar control option provides the greatest amount of control over conditional processing of the input file(s).

For more information on the `conditional expressions` allowed, details on the `new_input_line` and examples, see section Conditional Compilation below.

See also $ifE, $ifI, $ifThen.

$ifE

Syntax:

```
$ifE [not] conditional_expression new_input_line
```

This dollar control option does the same as the option $if but allows constant expression evaluation. The `conditional_expression` may take two different forms:

```
expr1 == expr2      TRUE   if (expr1-expr2)/(1+abs(expr2)) < 1e-12
expr                TRUE   if expr1 <> 0
```

Example:

```
Scalar a;
$ifE (log2(16)^2)=16           a=0; display a;
$ifE log2(16)^2 == 16          a=1; display a;
$ifE NOT round(log2(16)^2-16)  a=2; display a;
$ifE round(log2(16)^2-16)      a=3; display a;
$ifE round(log2(16)^2-17)      a=4; display a;
```

This will create the following output:

```
----      3 PARAMETER a                  =        1.000

----      4 PARAMETER a                  =        2.000

----      6 PARAMETER a                  =        4.000
```

See also $if and section Conditional Compilation.

$ifI

Syntax:

```
$ifI [not] conditional_expression new_input_line
```

This option is working like the option $if. The only difference is that $if makes comparisons involving text in a case sensitive fashion while `$ifI` is case insensitive.

See also $if and section Conditional Compilation.

$ifThen

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option is a form of the option $if that controls whether a number of statements are active. The syntax for the condition is generally the same as for the option $if. Like `$if`, it is case sensitive. Often it is followed by one or more of the following dollar control options: $else, $elseIf, $elseIfI, $elseIfE. The option `$ifThen` must be matched with the option $endIf that marks the end of the construct. An example is given in section Conditional Compilation with $ifThen and $else.

Note that users may add a tag to the `$ifThen` and $endIf. For example, `$ifThen.tagOne` has to match with `$endif.tagOne`.

Example:

```
$ifThen.one x == y
display "it1";
$elseIf.one a == a
display "it2";
$ifThen.two c == c
display "it3";
$endIf.two
$elseIf.one b == b
display "it4";
$endIf.one
```

The resulting listing file will contain the following lines:

```
----      2 it2

----      4 it3
```

Note that the first condition (`x == y`) is obviously not true and the fourth condition (`b == b`) is not tested because the second condition (`a == a`) was already true.

Also note that the false clause is not interpreted by the compiler. So the following code would compile without problems:

```
$ifThen x == y
$the
$compiler
doesn't
complain
$endIf
```

See also $if, $ifThenE, $ifThenI, $else, $elseIF and section Conditional Compilation.

$ifThenE

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option does the same as the option $ifThen but evaluates numerical values of the control variables.

See also $ifThen and section Conditional Compilation.

$ifThenI

Syntax:

```
$ifThen[E|I] cond
  ...
{ $elseIf[E|I] cond
  ... }
[ $else
  ... ]
$endIf
```

This option does the same as the option $ifThen but it is case insensitive.

See also $ifThen and section Conditional Compilation.

$include

Syntax:

```
$include external_file
```

This option inserts the contents of a specified text file at the location of the call. Note that text files that have been compressed with Posix utility `gzip` or have been encrypted with tool ENDECRYPT are also allowed. `External_file` is the name of the file that is included. It can be quoted or unquoted. Note that include files may be nested.

The include file names are processed in the same way like the input file. The names are expanded using the working directory. If the file cannot be found and no extension is given, the standard GAMS input extension is tried. However, if an incomplete path is given, the file name is completed using the include directory. By default, the library include directory is set to the working directory. The default directory search path may be extended with the command line parameter InputDir.

Note that the start of the include file is marked and the include file is echoed to the echo print in the listing file. This reference to the include file may be omitted by using the option $offInclude.

Example:

```
$include myfile
$include "myfile"
```

Both statements above are equivalent and the search order for the include file is as follows:

1. `myfile` in current working directory
2. `myfile.gms` in current working directory
3. `myfile` and `myfile.gms` (in that order) in directories specified by the command line parameter InputDir.

Attention

The current settings of the dollar control options are passed on to the lower level include files. However, the dollar control options set in the lower level include file are passed on to the parent file only if the option $onGlobal is set.

Note that details on the compilation output of include files are given in section The Include File Summary.

See also $batInclude, $libInclude, $sysInclude.

$inlineCom (/* */)

Syntax:

```
$inlineCom char[char] char[char]
```

This option redefines and activates the in-line comment symbols. These symbols are placed at the beginning and the end of the in-line comment and are one character or a two character sequence at the beginning and the end. By default, the system is initialized to ' /*' and ' */', but is not active. The option $onInline is used to activate the in-line comments. If `$inlineCom` is used, $onInline is set automatically.

Example:

```
$inlineCom {{ }}
Set {{ this is an inline comment }} i / 1*2 / ;
```

Note that the character pairs {{ }} serve as the indicator for in-line comments.

Attention

It is not allowed to reset the option `$inlineCom` to the current symbol for in-line comments. This would cause an compilation error as in the following example:

```
$inlinecom {{  }}
$inlinecom {{  }}
```

Note

The option $onNestCom enables the use of nested comments.

The default for dealing with inline comments can be set using the command line parameter inlineCom.

See also section Comments.

$kill

Syntax:

```
$kill ident {ident}
```

This option removes all data for the identifiers `ident`, only the type and dimension are retained (this means that these identifiers will be declared but not defined anymore). Note that only the data of the following data types may be removed: sets, parameters, variables and equations. Note further that the data removal is carried out during compile time and not when the GAMS program executes.

Example:

```
Set i / 1*20 /;
Scalar a /2/;
$kill i a
```

Note that the effect of the third line above is that all data from `a` and `i` is removed, so the set `i` and the scalar `a` are declared, but not initialized or assigned to. Note that after `i` and `a` have been killed, a display statement for them will trigger an error. However, new data may be assigned to identifiers that were previously killed. Thus the following statements are valid if appended to the code above:

```
Set i / i1 *i3 /;
a = 7;
```

Observe that this option needs to be distinguished from the dollar control option $clear, that *resets* the data to the default values.

$label

Syntax:

```
$goto id
$label id
```

This option marks a line to be jumped to by a dollar control option $goto. Any number of labels may be used in files and not all of them need to be referenced. Re-declaration of a label identifier will not generate an error and only the first occurrence encountered by the GAMS compiler will be used for future $goto references.

Example:

```
Scalar a ;
a = 5 ;
display a ;
$goto next
a = a+5 ;
display a ;
$label next
a = a+10 ;
display a ;
```

When GAMS reaches the line `$goto next`, it continues from the line `$label next`. All lines in between are ignored. Therefore in the example above, the final value of `a` is 15.

Attention

If several dollar control options appear in one line and `label` is one of them, then `label` must be listed first.

See also $goto, $maxGoto.

$libInclude

Syntax:

```
$libInclude external_file {arg}
```

This option is mostly equivalent to the option $batInclude. However, if an incomplete path is given, the file name is completed using the library include directory. By default, the library include directory is set to the directory `inclib` in the GAMS standard locations. Note that the list of default directories searched may be prepended with the command line parameter libIncDir.

Example:

```
$libInclude abc x y
```

This call will first look for the include file `inclib/abc` in the standard locations. If this file does not exist there GAMS will look for the file `inclib/abc.gms` in the standard locations. The arguments `x` and `y` are passed on to the include file and are interpreted as explained in the detailed description of the option $batInclude.

See also $include, $batInclude, $sysInclude.

$lines

Syntax:

```
$lines n
```

This option starts a new page in the listing file if less than `n` lines are available on the current page.

Example:

```
$hidden Never split the first few lines of the following table
$lines 5
Table io(i,j) Transaction matrix
...
;
```

This will ensure that if there are less than five lines available on the current page in the listing file before the next statement (in this case, the table statement) is echoed to it, the contents of this statement are echoed to a new page.

$load

Syntax:

```
$load [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is preceded and succeeded by the option $gdxIn that open the GDX file for reading. The option `$load` loads specified items from the GDX file. Note that more than one instance of `$load` may occur. A listing of the GDX file contents will be created if the option `$load` is not followed by arguments.

Examples

Consider the following example, where `transsol` is the GDX file of the transportation model [**TRNSPORT**]

```
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i j a b d f
$gdxIn
```

A comma between the symbols is optional. The follow example works identically:

```
$gdxIn transsol
$load
Sets i, j; Parameters a(i), b(j), d(i,j), f;
$load i, j, a, b, d, f
$gdxIn
```

The $load without any arguments produces a table of contents of the GDX container in the listing file:

```
Content of GDX C:\Users\default\Documents\gamsdir\projdir\transsol.gdx
               5 UELs

    Number Type       Dim       Count  Name
         1 Set          1           2  i           canning plants
         2 Set          1           3  j           markets
         3 Parameter    1           2  a(i)        capacity of plant i in cases
         4 Parameter    1           3  b(j)        demand at market j in cases
         5 Parameter    2           6  d(i,j)      distance in thousands of miles
         6 Parameter    0           1  f           freight in dollars per case per thousand mile
         7 Parameter    2           6  c(i,j)      transport cost in thousands of dollars per ca
         8 Variable     2           6  x(i,j)      shipment quantities in cases
         9 Variable     0           1  z           total transportation costs in thousands of do
        10 Equation     0           1  cost        define objective function
        11 Equation     1           2  supply(i)   observe supply limit at plant i
        12 Equation     1           3  demand(j)   satisfy demand at market j
```

Symbols may be loaded with new names with the following syntax: $load i=gdx_i j=j_gdx. The universal set may be loaded using $load uni=*.

```
$gdxIn transsol
Sets i, jj, uni; Parameters a(i), bb(jj), d(i,jj), f;
$load i jj=j uni=* a bb=b d f
$gdxIn
display uni;
```

This results in a display of all used labels:

```
----      5 SET uni
Seattle  ,    San-Diego,    New-York ,    Chicago  ,    Topeka
```

The syntax sym<[=]GDXSym[.dimI] allows to load a one dimensional set from a symbol in the GDX file that has even a higher dimensionality. GAMS tries to find the set sym as a domain in the symbol GDXSym and uses the labels from this index position (with < the first domain set from the right and with <= from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix .dimI allows to pick a fixed index position.

In the following we work with a GDX file created by the following code:

```
set i / i1*i3 /, ii(i,i) / i1.i2, i2.i3 /;
execute_unloadDI 'ii', i, ii;
```

Now use use this GDX file to load the first and second index from ii:

```
set i, i1;
$gdxIn ii
* Load first index from ii as i
$load i<=ii i1<ii.dim1
display i, i1;
```

the display lists all labels from the first index of ii:

```
----      5 SET i  Domain loaded from ii position 1
i1,    i2

----      5 SET i1  Domain loaded from ii position 1
i1,    i2
```

Now we match from the right and get the second index of ii:

```
set i, i2;
$gdxIn ii
* Load second index from ii as i
$load i<ii i2<ii.dim2
display i, i2;
```

The resulting listing file will contain the following lines:

```
----      5 SET i  Domain loaded from ii position 2
i2,    i3

----      5 SET i2  Domain loaded from ii position 2
i2,    i3
```

This type of projection loading can be useful to extract the domain sets from a single parameter that is stored in a GDX file:

```
set i,j,k; parameter data(i,j,k);
$gdxIn data
$load i<data.dim1 j<data.dim2 k<data.dim3 data
```

Attention

Loading an item that was already initialized will cause a compilation error.

For example, the following code snippet will cause a compilation error:

```
Set j / 1*5 /;
$gdxIn transsol
$load j
$gdxIn
```

Note that GAMS offers variants of $load that do not cause a compilation error in such a case: $loadM and $loadR.

Note

One can load the level values of a variable into a parameter of the same dimension using the syntax parametername=var.l as follows

```
parameter storexlevel(i,j);
$gdxin trnsport
$load storexlevel=x.l
$gdxin
display storexlevel;
```

Loading the level values for a variable into the same variable (x=x.l) works but loads everything including bounds, scales, marginals and levels.

$loadDC

Syntax:

```
$loadDC [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of $load. It performs domain checking when items are loaded. Any domain violations will be reported and flagged as compilation errors. This is basically the opposite of $loadFiltered. All other features are the same as discussed under $load .

Example: Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set i, j;
Parameter b(i), a(j);
$gdxIn transsol
$load i b
$loadDC j a
$gdxIn
```

Note that in contrast to the example above, the parameter `a` is indexed over the set `i` and the parameter `b` is indexed over the set `j` in the file `transsol`. While `$load i b` does not generate an error and `b` is just empty, the option `$loadDC j a` triggers a domain violation error because in `transsol` `a` is indexed over `i` and produces a list of errors in the listing file:

```
--- LOAD  a = 3:a
**** Unique domain errors for symbol a
 Dim  Elements
   1  seattle, san-diego

   5  $loadDC j a
****           $649
```

$loadDCM

Syntax:

```
$loadDCM [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *merging* as in $loadM and domain checking as in $loadDC.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set i, uni 'all labels';
Parameter abFail(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load i abFail=a
$loadDCM abFail=b
$loadDCM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;
```

Here we try to merge parameters `a` and `b` together into one parameter. The first attempt (to merge it into parameter `abFail`) would fail because of line 5 and result into a domain violation report as described with dollar control option $loadDC. In the second attempt we first merge the sets `i` and `j` into set `uni` and then merge the parameters `a` and `b` into `ab`. If one comments line 5 the resulting display looks as follows:

```
----      8 SET uni  all labels
seattle  ,    san-diego,    new-york ,    chicago  ,    topeka

----      8 PARAMETER ab  capacity and demand
seattle   350.000,    san-diego 600.000,    new-york  325.000
chicago   300.000,    topeka    275.000
```

$loadDCR

Syntax:

```
$loadDCR [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *replacing* data as in $loadR and domain checking as in $loadDC.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a
$loadDCR ab=b
$gdxIn
display uni, ab;
```

Here we try to read twice into the parameter `ab`. First GDX symbol `a` and `b` are read into `ab`. GDX symbol `b` is read with *replace* and hence the parameter `ab` contains the elements of `b` only.

$loadFiltered

Syntax:

```
$loadFiltered [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of $load, in particular, it works like `$load` while $onFiltered is set. That means, when items are loaded, domain violations are not flagged as compilation errors, but items violating the domain definition are just filtered out. This is basically the opposite of $loadDC. All other features are the same as discussed under $load .

Example: Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set i / seattle /
    j / new-york, chicago /;
Parameter a(i), b(j);
$gdxIn transsol
$loadFiltered a
$loadDC       b
$gdxIn
```

While `$loadFiltered a` does not generate an error, but just ignores the data that does not match the defined domain, `$loadDC b` triggers a domain violation error.

See also $loadFilteredM and $loadFilteredR.

$loadFilteredM

Syntax:

```
$loadFilteredM [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *merging* as in $loadM and domain filtering as in $loadFilterd.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set i, uni 'all labels';
Parameter abFilter(i), ab(uni) 'capacity and demand';
$gdxIn transsol
$load          i abFilter=a
$loadFilteredM abFilter=b
$loadFilteredM uni=i uni=j ab=a ab=b
$gdxIn
Display uni, ab, abFilter;
```

Here we try to merge parameters `a` and `b` together into one parameter. The first attempt (to merge it into parameter `abFilter`) does not add anything, since the elements in b do not match the defined domain `i` (compare $loadFilterd). In the second attempt we first merge the sets `i` and `j` into set `uni` and then merge the parameters `a` and `b` into `ab`. The `Display` statement produces the following output:

```
----     31 SET uni  all labels

seattle  ,    san-diego,    new-york ,    chicago  ,    topeka

----     31 PARAMETER ab  capacity and demand

seattle   350.000,    san-diego 600.000,    new-york  325.000,    chicago   300.000,    topeka

----     31 PARAMETER abFilter  capacity of plant i in cases

seattle   350.000,    san-diego 600.000
```

$loadFilteredR

Syntax:

```
$loadFilteredR [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option combines the functionality of *replacing* data as in $loadR and domain filtering as in $loadFilterd.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set       uni     'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadFilteredM uni=i uni=j ab=a
$loadFilteredR ab=b
$gdxIn

Display uni, ab;
```

Here we try to read twice into the parameter `ab`. First GDX symbol `a` and `b` are read into `ab`. GDX symbol `b` is read with *replace* and hence the parameter `ab` contains the elements of `b` only:

```
----     31 SET uni  all labels

seattle  ,    san-diego,    new-york ,    chicago  ,    topeka

----     31 PARAMETER ab  capacity and demand

new-york 325.000,    chicago  300.000,    topeka   275.000
```

$loadIdx

Syntax:

```
$loadIdx [sym1[,] sym2=gdxSym2[,] ...]
```

This option is an alternative form of $load. Each symbol in the GDX file to read must be a parameter and should have been written using an indexed write; see also execute_unloadidx.

See Example 3 - Reading a GDX File and [**ldidx01**] on how to use `$loadidx`.

$loadM

Syntax:

```
$loadM [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is an alternative form of $load. Instead of replacing an item or causing a *symbol redefined* error if the item was already initialized it *merges* the contents. Records that would result in domain violations will be ignored.

Example:

Consider the following example where `transsol` is the GDX file of the transportation model [**TRNSPORT**].

```
Set i, uni 'all labels';
Parameter ab(uni) 'capacity and demand';
$gdxIn transsol
$loadM uni=i uni=j ab=a ab=b
$gdxIn
display uni, ab;
```

Here we merge parameters `a` and `b` together into one parameter `ab`. We first merge the sets `i` and `j` into set `uni` and then merge the parameters `a` and `b` into `ab`. The resulting display looks as follows:

```
----      6 SET uni  all labels
seattle  ,    san-diego,    new-york ,    chicago  ,    topeka

----      6 PARAMETER ab  capacity and demand
seattle   350.000,    san-diego 600.000,    new-york  325.000
chicago   300.000,    topeka    275.000
```

$loadR

Syntax:

```
$loadR [sym1[,] sym2=gdxSym2[,] sym3<[=]gdxSym3[.dimI][,] ...]
```

This option is a variant of the option $load. With `$loadR` we can have multiple loads into the same symbols and the data stored in GAMS will be replaced with the one from the GDX container.

Example:

Consider the following example, where `transsol` is the GDX file of the transportation model [**TRNSPORT**]:

```
Sets i  / 1*3 /
     j  / 1*2 /;
$gdxIn transsol
$loadR i j
$gdxIn
display i, j;
```

The resulting listing file will contain the following lines:

```
----      6 SET i  canning plants
Seattle  ,    San-Diego

----      6 SET j  markets
New-York,    Chicago ,    Topeka
```

$log

Syntax:

```
$log text
```

This option will send a message `text` to the log file. Recall that by default, the log file is the console. The default log file may be reset with the command line parameters logOption and logFile.

Attention

- Leading blanks are ignored when the text is written out to the log file as a result of using the `$log` option.
- All special `%` symbols will be substituted before the text passed through the `$log` option is sent to the log file.

Example:

```
$log
$log       The following message will be written to the log file
$log  with leading blanks ignored. All special % symbols will
$log  be substituted before this text is sent to the log file.
$log  This was line %system.incLine% of file %system.incName%
$log
```

The log file that results by running the lines above will contain the following lines:

```
The following message will be written to the log file
with leading blanks ignored. All special % symbols will
be substituted before this text is sent to the log file.
This was line 5 of file C:\tmp\logTest.gms
```

Note that `%system.incLine%` is replaced by 5 which is the line number where the string replacement was requested. Note further that `%system.incName%` is substituted with the name of the file completed with the absolute path. Observe that the leading blanks on the second line of the example are ignored.

$macro

Syntax:

```
$macro name(arg1,arg2,arg3, ...) macro_body
```

This option defines a macro in GAMS. Here `name` is the name of the macro, `arg1,arg2,arg3,...` are the arguments and `macro_body` defines what the macro should do. The macro names follow the rules for identifiers. The macro `name` cannot be used for other symbols. For further details and examples, see section Macros in GAMS below.

$maxCol (80001)

Syntax:

```
$maxCol n
```

This option restricts the valid range of input columns at the *right* margin. Note that all input after column `n` is treated as comment, therefore it is ignored.

Example:

```
$maxCol 30
Set    i  / vienna, rome /;   set definition
Scalar a  / 2.3          /;   scalar definition
```

Observe that the text strings `set definition` and `scalar definition` are treated as comments and are ignored since they begin on or after column 31.

Any changes in the margins via `$maxCol` or $minCol will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option `$minCol 20 maxCol 110` will trigger the following message:

```
NEW MARGINS: 20-110
```

Note

- GAMS requires that the right margin set by `$maxCol` is greater than 15.
- GAMS requires that the right margin set by `$maxCol` is greater than the left margin set by $minCol.

See also $on/offMargin and section Comments.

$maxGoto 100

Syntax:

```
$maxGoTo n
```

This option sets the maximum number of jumps to the same label and is used in the context of the options $goTo and $label. Once the maximum number is reached a compilation error is triggered. Such a limit has been implemented to avoid infinite loops at compile time.

Example:

```
Scalar a / 1 /;
$maxGoTo 5
$label label1
a = a+10;
display a ;
$goTo label1
```

Note that a compilation error is triggered if `$goTo label1` is called for the fifth time.

$minCol (1)

Syntax:

```
$minCol n
```

This option restricts the valid range of input columns at the *left* margin. Note that all input before column `n` is treated as comment, therefore it is ignored.

Example:

```
$minCol 30
Set definition              Set    i / vienna, rome /;
Scalar definition           Scalar a / 2.3          /;
```

Observe that the text strings `set definition` and `scalar definition` are treated as comments and are ignored since they are placed before column 30.

Any changes in the margins via the option $maxCol or `$minCol` will be reported in the listing file with the message that gives the valid range of input columns. For example, the dollar control option `$minCol 20 maxCol 110` will trigger the message:

```
NEW MARGINS: 20-110
```

Attention

GAMS requires that the left margin set by the option `$minCol` is smaller than the right margin set by the option $maxCol.

See also $on/offMargin and section Comments.

$(on|off)CheckErrorLevel ($offCheckErrorLevel)

Syntax:

```
$onCheckErrorLevel
$offCheckErrorLevel
```

If the option `$onCheckErrorLevel` is active, the errorLevel is checked implicitly after $call, $hiddenCall, $callTool and $hiddenCallTool. A compilation error is triggered and the compilation is aborted if it is not 0. With `$offCheckErrorLevel`, this is not done, but one can do it explicitly. So, with `$onCheckErrorLevel` $call behaves like $call.checkErrorLevel, $hiddenCall behaves like $hiddenCall.checkErrorLevel, $callTool behaves like $callTool.checkErrorLevel and $hiddenCallTool behaves like $hiddenCallTool.checkErrorLevel.

The default for dealing with error levels can be set using the command line parameter checkErrorLevel.

$(on|off)Delim ($offDelim)

Syntax:

```
$onDelim
$offDelim
```

This option controls whether data in table statements may be entered in delimited format. As delimiter one can use `"."`, `","`, or `"TAB"`.

Example:

```
Sets  plant  'plant locations' / NEWYORK, CHICAGO, LOSANGELES /
      market 'demands'         / MIAMI, HOUSTON, PORTLAND     /;

Table dist(plant,market)
$onDelim
,MIAMI,HOUSTON,PORTLAND
NEWYORK,1300,1800,1100
CHICAGO,2200,1300,700
LOSANGELES,3700,2400,2500
$offDelim
;

Display dist;
```

The resulting listing file will contain the following output:

```
----     12 PARAMETER dist

                MIAMI     HOUSTON    PORTLAND

NEWYORK      1300.000    1800.000    1100.000
CHICAGO      2200.000    1300.000     700.000
LOSANGELES   3700.000    2400.000    2500.000
```

$(on|off)Digit ($onDigit)

Syntax:

```
$onDigit
$offDigit
```

Historically, GAMS has run on widely different platforms where even the floating-point arithmetic varied. To ensure the precision specified in the GAMS input didn't exceed what could be stored and computed with as GAMS ran, we limited the precision (i.e. the number of significant digits used for numbers) that could be specified in the GAMS source. This limit could be relaxed by using the `$offDigit` control.

Modern computers all support IEEE double-precision arithmetic, and GAMS uses this internally. It's a well-accepted and familiar standard, and the current behavior - to convert the decimal value in the GAMS source into the nearest double-precision value, regardless of the number of digits in the GAMS source - is what is generally expected. There is a limit (currently 40) on the number of digits treated as potentially significant: digits beyond this point are quietly treated as zero.

The `$offDigit` control remains useful for changing how GAMS handles numbers with very large or small magnitude. With `$onDigit`, GAMS throws compiler warnings/errors for these values. With `$offDigit`, GAMS quietly converts them to UNDF or EPS, respectively.

Example:

```
scalar aboveTheLimit / 222e299 /;
scalar tiny / 1.0e-275 /;
scalar tinier / 1.0e-285 /;
$offdigit
scalar uberTheLimit / 222e299 /;
scalar klein   / 1.0e-275 /;
scalar kleiner / 1.0e-285 /;
```

The resulting listing file will contain the following lines:

```
   1  scalar aboveTheLimit / 222e299 /;
****                                $106
   2  scalar tiny / 1.0e-275 /;
****                         $595
   3  scalar tinier / 1.0e-285 /;
****                           $594
   5  scalar uberTheLimit / 222e299 /;
   6  scalar klein   / 1.0e-275 /;
   7  scalar kleiner / 1.0e-285 /;
Error Messages
106  abs(number) out of range
        abs(number) must be less than 1E300
        $offdigit can be used to replace large numbers with UNDF
594  Exponent very very small - rejected
       $offdigit can be used to replace with EPS
595  Exponent very small
       $offdigit can be used to quietly accept very small values
```

The default for dealing with digits can be set using the command line parameter digit.

$(on|off)Dollar ($offDollar)

Syntax:

```
$onDollar
$offDollar
```

This option controls the echoing of dollar control option lines in the listing file.

Example:

```
$hidden This line will not be displayed
$onDollar
$hidden This line will be displayed
$offDollar
$hidden This line will not be displayed
```

The compilation output of the resulting listing file will contain the following lines:

```
2  $onDollar
3  $hidden This line will be displayed
```

Note that all lines between the option `$onDollar` and the option `$offDollar` are echoed in the listing file. Note further that the effect of this option is immediate: the line `$onDollar` is echoed in the listing file, while the line `$offDollar` is not.

$(on|off)DotL ($offDotL)

Syntax:

```
$onDotL
$offDotL
```

This option activates or deactivates the automatic addition of the attribute `.L` to variables on the right-hand side of assignments and in put statement. It is most useful in the context of macros. For further information, see section Macros in GAMS below.

Example:

Consider the following code snippet which can be added to the end if the **[TRNSPORT]** model:

```
$onDotL
file fx; put fx;
loop((i,j),
   put / x(i,j)
);
$offDotL
file fx; put fx;
loop((i,j),
   put / x(i,j)
);
```

This is the generated output:

```
        50.00
       300.00
         0.00
       275.00
         0.00
       275.00
x('seattle','new-york')
x('seattle','chicago')
x('seattle','topeka')
x('san-diego','new-york')
x('san-diego','chicago')
x('san-diego','topeka')
```

First, we see the `level` for each `x` record. After setting `$offDotL` we are back at the default which means, that the .tn attribute is used implicitly.

$(on|off)DotScale ($offDotScale)

Syntax:

```
$onDotScale
$offDotScale
```

This option activates or deactivates the automatic addition of the attribute `.Scale` to variables and equations on the right-hand side of assignments and in put statements. As with on|offDotL It is most useful in the context of macros. For further information, see section Macros in GAMS below.

$(on|off)Echo[S|V][.tag]

Syntax:

```
$onEcho[S|V][.tag]  >[>] external_file
text
{text}
$offEcho[.tag]
```

This option is used to send one or more lines of `text` to an file `external_file`. The text and the file name may be quoted or unquoted. The external file is not closed until the end of the compilation or when the option $call or any variant of the option $include is encountered. Note that the redirection symbols > and >> have the usual meaning: > creates a new file and writes to it or - in case there exists already a file with the respective name - overwrites the existing file and >> appends to a file. Note further that parameter substitutions are permitted with `$onEcho`. The option `$onEcho` has two more variants: `$onEchoS` and `$onEchoV`. `$onEchoS` allows parameter substitutions like `$onEcho`, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended `S`. The option `$onEchoV` does not allow parameter substitutions but writes the text verbatim.

Example:

```
$set it TEST
$onEchoS  > externalfile1.txt
send %it% to external file
line 2 to send
$offEcho

$onEchoV  > externalfile2.txt
send %it% to external file
line 2 to send
$offEcho
```

The `externalfile1.txt` will contain the following lines:

```
send TEST to external file
line 2 to send
```

The `externalfile2.txt` will contain these lines:

```
send %it% to external file
line 2 to send
```

Observe that in the first case `%it%` is substituted with `TEST`, but in the second case there is no substitution.

Note that by default the external file will be placed in the current working directory if there is no path specified.

One may add a `tag` to the `$onEcho[S|V]` and `$offEcho`. This allows to use nested echo blocks like this:

```
$onEcho.outer > outerFile.gms
$onEcho.inner > innerFile.txt
Line 1 of text
Line 2 of text
$offEcho.inner
$offEcho.outer
```

The resulting file `outerFile.gms` looks like this:

```
$onEcho.inner > innerFile.txt
Line 1 of text
Line 2 of text
$offEcho.inner
```

See also options $echo, and $echoN.

$(on|off)ECImplicitLoad ($onECImplicitLoad)

Syntax:

```
$onECImplicitLoad
$offECImplicitLoad
```

This option enables or disables the implicit loading of symbols set in embedded code sections, which are not loaded explicitly with $offEmbeddedCode.

Example:

```
Set i(*);

$offECImplicitLoad
$onEmbeddedCode Python:
i = ['a','b']
print(i)
gams.set("i", i)
$offEmbeddedCode
```

This will result in a compilation error, since `i` is set in the embedded code block (by `gams.set("i", i)`), but not loaded with `$offEmbeddedCode`. If `$onECImplicitLoad` would be active, `$offEmbeddedCode` would be treated like `$offEmbeddedCode i` here.

See also ECImplicitLoad.

$(on|off)Embedded ($offEmbedded)

Syntax:

```
$onEmbedded
$offEmbedded
```

This option enables or disables the use of embedded values in parameter and set data statements. If enabled, the explanatory text for set elements is concatenated with blank separators. For parameters, the embedded values get multiplied.

Example:

```
Set k / a,b /
    l / a   /;
Set       i(k,l) / a.a 'aaaa cccc dddd'
                   b.a 'bbbb cccc dddd' /;
Parameter m(k,l) / a.a 12
                   b.a 24 /;
$onEmbedded
Set       j(k,l) / (a aaaa, b bbbb).(a cccc) dddd /;
Parameter n(k,l) / (a 1,    b 2)   .(a 3)    4    /;
```

Note that the explanatory text of the set elements in `i` and `j` as well as the values of the parameters `m` and `n` are identical.

$(on|off)EmbeddedCode[S|V][.tag]

Syntax:

```
$onEmbeddedCode[S|V][.tag] Connect|Python: [arguments]
Embedded code
{Embedded code}
$offEmbeddedCode[.tag] {symbol[<[=]embSymbol[.dimX]]}
```

This option is used to execute one or more lines of embedded code (e.g. Python code) while GAMS stays alive. The embedded code has access to GAMS symbols and can read and change them.

Note that parameter substitutions are permitted with `$onEmbeddedCode`. The option `$onEmbeddedCode` has two more variants: `$onEmbeddedCodeS` and `$onEmbeddedCodeV`. `$onEmbeddedCodeS` allows parameter substitutions like `$onEmbeddedCode`, so it is just a synonym which makes it more obvious that parameter substitution is allowed with the appended `S`. The option `$onEmbeddedCodeV` does not allow parameter substitutions but passes the code verbatim to the embedded code engine. The optional `arguments` given to `$onEmbeddedCode[S|V]` can be accessed in the Python code.

`$offEmbeddedCode` can be followed by a GAMS symbol or a list of GAMS symbols. If GAMS symbols are specified they get updated in the GAMS database after the embedded code got executed. The syntax `symbol<[=]embSymbol[.dimX]` allows to load a one dimensional set from a symbol which was set in the embedded code that has even a higher dimensionality (here we call `<[=]` the `projection operator`). GAMS tries to find the set `symbol` as a domain in the symbol `embSymbol` and uses the labels from this index position (with `<` the first domain set from the right and with `<=` from the left). If no domain information is stored in the GDX file or the domain information does not match the suffix `.dimX` allows to pick a fixed index position (`X` needs to be replaced by the desired index position).

One may add a `tag` to the `$onEmbeddedCode[S|V]` and `$offEmbeddedCode`. For example, `$onEmbeddedCode.tagOne` would match with `$offEmbeddedCode.tagOne`.

Example:

```
Set cc      / "France - Paris", "France - Lille", "France - Toulouse"
              "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
              "USA - Washington DC", "USA - Houston", "USA - New York",
              "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
    country
    city
    mccCountry(cc,country<)  Mapping between country and related elements in set cc
    mccCity(cc,city<)        Mapping between city and related elements in set cc;

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
  r = str.split(cc, " - ", 1)
  mccCountry.append((cc,r[0]))
  mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode mccCountry mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry, mccCity;
```

The data definition of the sets `country` and `city` happen while loading the set `mccCountry` and `mccCity` implicitly because of the implicit set definition in declarations of `mccCountry` and `mccCity`. Also note, that the list of output symbols does not need to be explicitly specified (for most embedded code engines). Performing the actual write in the embedded code (here via `gams.set`) is sufficient to signal GAMS to load the symbols. Providing an explicit list of symbols can be required (for embedded code engines without implicit loading) and be advantageous for code readability even for embedded code engines that support this. With the dollar control option $offECImplicitLoad providing an explicit list of output symbols can be enforced and setting symbols inside the embedded code not in the explicit list will lead to compilation errors.

The program above will result in the following listing file:

```
----     25 SET country
Spain  ,    USA    ,    Germany,    France

----     25 SET city
Berlin       ,    Bilbao       ,    Cordoba      ,    Madrid
New York     ,    Washington DC,    Paris        ,    Houston
Munich       ,    Lille        ,    Seville      ,    Bonn
Toulouse

----     25 SET mccCountry
France - Paris     .France
France - Lille     .France
France - Toulouse  .France
Spain - Madrid     .Spain
Spain - Cordoba    .Spain
Spain - Seville    .Spain
Spain - Bilbao     .Spain
USA - Washington DC.USA
USA - Houston      .USA
USA - New York     .USA
Germany - Berlin   .Germany
Germany - Munich   .Germany
Germany - Bonn     .Germany

----     25 SET mccCity
France - Paris     .Paris
France - Lille     .Lille
France - Toulouse  .Toulouse
Spain - Madrid     .Madrid
Spain - Cordoba    .Cordoba
Spain - Seville    .Seville
Spain - Bilbao     .Bilbao
USA - Washington DC.Washington DC
USA - Houston      .Houston
USA - New York     .New York
Germany - Berlin   .Berlin
Germany - Munich   .Munich
Germany - Bonn     .Bonn
```

Using the `projection operator` on the `$offEmbeddedCode` line the same task could be done like this:

```
Set cc      / "France - Paris", "France - Lille", "France - Toulouse"
              "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
              "USA - Washington DC", "USA - Houston", "USA - New York",
              "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
    country
    city
    mccCountry(cc,country)  Mapping between country and related elements in set cc
    mccCity(cc,city)        Mapping between city and related elements in set cc;

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
  r = str.split(cc, " - ", 1)
  mccCountry.append((cc,r[0]))
  mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
```

```
gams.set("mccCity",mccCity)
$offEmbeddedCode country<mccCountry city<mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry, mccCity;
```

Please note that due to implicit output symbol loading, see $offECImplicitLoad, the symbols `mccCountry` and `mccCity` are not only used to define `country` and `city` but are also loaded into GAMS because the embedded code uses `gams.set` to write to these symbols.

See also chapter Embedded Code Facility for more details.

$(on|off)Empty ($onEmpty)

Syntax:

```
$onEmpty
$offEmpty
```

`$onEmpty` allows empty data statements for list or table formats (default). When setting `$offEmpty`, empty data statements will cause a compilation error.

Example:

```
Set       i    / 1,2,3 / ;
Set       j(i) /       / ;
Parameter x(i)   "empty parameter" /  / ;
Table     y(i,i) "headers only"
     1   2   3
;
$offEmpty
*offEmpty from here on
Set       k(i) /  / ;
Parameter xx(i)   "empty parameter" /  / ;
Table     yy(i,i) "headers only"
     1   2   3
;
```

The resulting listing file will contain the following lines:

```
   1  Set       i    / 1,2,3 / ;
   2  Set       j(i) /       / ;
   3  Parameter x(i)   "empty parameter" /  / ;
   4  Table     y(i,i) "headers only"
   5       1   2   3
   6  ;
   8  *offEmpty from here on
   9  Set       k(i) /  / ;
****                    $460
**** 460  Empty data statements not allowed. You may want to use $ON/OFFEMPTY
  10  Parameter xx(i)   "empty parameter" /  / ;
****                                      $460
**** 460  Empty data statements not allowed. You may want to use $ON/OFFEMPTY
  11  Table     yy(i,i) "headers only"
  12       1   2   3
  13  ;
****  $462
**** 462  The row section in the previous table is missing
```

Empty data statements are most likely to occur when data is being entered into the GAMS model by an external program.

Note

The empty data statement may only be used with symbols which have a known dimension. If the dimension is also derived from the data, the option $phantom should be used to generate 'phantom' set elements.

The option `$onEmpty` in conjunction with the option $onMulti and the save and restart feature may be used to set up a model and add data later.

The default for dealing with empty data statements can be set using the command line parameter empty.

$(on|off)End ($offEnd)

Syntax:

```
$onEnd
$offEnd
```

This option offers an alternative syntax for flow control statements. The option `$onEnd` causes the following words to be regarded as keywords: `do`, `endLoop`, `endIf`, `endFor` and `endWhile`. They are used to close the language constructs `loop`, `if`, `for` and `while` respectively.

Example:

Note

The standard syntax is given as an end-of-line comment.

```
Set       i    / 1*3 /;
Scalar    cond / 0 /;
Parameter a(i) / 1 1.23, 2 2.65, 3 1.34/;

$eolCom //
$onEnd

loop i do                                  // loop (i,
  display a;                               //   display a;
endLoop;                                   // );

if (cond) then                             // if (cond,
  display a;                               //   display a;
else                                       // else
  a(i) = a(i)/2;                           //   a(i) = a(i)/2;
  display a;                               //   display a;
endIf;                                     // );

for cond = 1 to 5 do                       // for (cond = 1 to 5,
  a(i) = 2 * a(i);                         //   a(i) = 2 * a(i);
endFor;                                    // );

while cond > 3 do                          // while (cond > 3,
  a(i) = a(i) / 2;                         //   a(i) = a(i) / 2;
  cond = cond-1;                           //   cond = cond-1;
endWhile;                                  // );
```

Observe that the alternative syntax is more in line with the syntax used in some of the popular programming languages.

Attention

Setting the option `$onEnd` will make the alternative syntax valid, and at the same time it will make the standard syntax invalid. Therefore the two forms of the syntax will never be valid simultaneously.

$(on|off)EolCom ($offEolCom)

Syntax:

```
$onEolCom
$offEolCom
```

This option acts as a switch to control the use of end-of-line comments. Note that by default, the end-of-line comment symbol is set to `!!` but the processing is disabled.

Example:

```
$onEolCom
Set       i    /1*2/ ;  !! set declaration
Parameter a(i)       ;  !! parameter declaration
```

Observe that after the option `$onEolCom` has been specified, comments may be entered on the same line as GAMS code.

Note

The option $eolCom automatically sets `$onEolCom`.

The default for dealing with end-of-line comments can be set using the command line parameter eolCom.

See also section Comments.

$(on|off)Eps ($offEps)

Syntax:

```
$onEps
$offEps
```

This option is used to interpret zero values as `EPS` when non-scalar parameters, variable attributes, or equation attributes are defined or loaded (e.g. from GDX or embedded code) at compile time. This can for example be useful if the value of zero is overloaded with existence interpolation.

See option zeroToEps for the execution-time equivalent.

Example 1:

Consider the following example where zero values are defined for a one dimensional parameter, once under `$onEps` and `$offEps`.

```
Set       i    / one, two, three, four /;
Parameter a(i) /
$onEps
      one     0
$offEps
      two     0
      three   EPS   /;
Display a ;
```

The outcome generated by the display statement follows:

```
----      8 PARAMETER a

one   EPS,    three EPS
```

Note that only those entries specifically entered as 0 are treated as EPS.

Example 2:

Consider the following example where zero values are loaded from a GDX file, once under $offEps (default) and $onEps (derived from test library model [**ZEROTOEPS1**]).

```
Set s,t;
Parameter p(s<,t<)
          pOnEps(s,t);
$gdxIn zeropar.gdx
$onText
P looks like this:
   t1        t2        t3
s1 0         0.843267
s2 0.224053  0.349831  0
s3           0         5
$offText
$load p
$onEps
$load pOnEps=p
display p, pOnEps;
```

The outcome generated by the display statement follows:

```
----     15 PARAMETER p

            t1          t2          t3

s1                    0.843
s2        0.224       0.350
s3                                5.000

----     15 PARAMETER pOnEps

            t1          t2          t3

s1          EPS       0.843
s2        0.224       0.350         EPS
s3                      EPS       5.000
```

Example 3:

Consider the following example where zero values are loaded from embedded Python code, once under `$offEps` (default) and `$onEps` (derived from test library model [**ZEROTOEPS1**]).

```
Set s / s1*s3 /;
Parameter pEC(s)
          pECOnEps(s);
$onEmbeddedCode Python:
p = [('s1',1), ('s3',0)]
gams.set('pEC',p)
$offEmbeddedCode pEC
$onEps
$onEmbeddedCode Python:
p = [('s1',1), ('s3',0)]
gams.set('pECOnEps',p)
$offEmbeddedCode pECOnEps

display pEC, pECOnEps;
```

The outcome generated by the display statement follows:

```
----     14 PARAMETER pEC

s1 1.000

----     14 PARAMETER pECOnEps

s1 1.000,    s3   EPS
```

$(on|off)EpsToZero ($offEpsToZero)

Syntax:

```
$onEpsToZero
$offEpsToZero
```

This option is used to write `EPS` values as zero when parameters, or variable and equation levels get written to GDX at compile time.

See option EpsToZero for the execution-time equivalent.

Example:

Usually GAMS squeezes out 0 values when writing to GDX. To get them written anyway, one can define them as `EPS` (e.g. by using `$onEps`) and set `$onEpsToZero`:

```
Set       i    / zero, one, two /;
$onEps
Parameter a(i) / zero    0
                 one     1
                 two     2  /;

$onEpsToZero
$gdxUnload 'zero.gdx' a
```

$(on|off)Expand ($offExpand)

Syntax:

```
$onExpand
$offExpand
```

This option changes the processing of macros that appear in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch `$onExpand` enables the recognition and expansion of macros in the macro argument list and `$offExpand` will restore the default behavior.

Example:

```
variable x(*,*);
$macro  f(i)   sum(q, x(i,q))
$macro equ(x)  equation equ_&x; equ_&x.. &x =e= 0;
equ(f(i))
```

The macro expansion of the code above will result in an equation definition that reads as follows:

```
equation equ_f(I); equ_f(i).. f(i) =e= 0;
```

If we compile the code under `$onExpand` the argument `f(i)` is expanded before the macro `equ()` gets expanding resulting in the following (incorrect) code:

```
equation equ_sum(q, x(i,q)); equ_sum(q, x(i,q)).. sum(q, x(i,q)) =e= 0;
```

For further information, see section Macros in GAMS below.

$(on|off)ExternalInput ($offExternalInput)

Syntax:

```
$onExternalInput
$offExternalInput
```

`$onExternalInput` and `$offExternalInput` mark the beginning and end of a well defined section in which data is loaded implicitly from an external data source, namely from a GDX file specified by the command line parameter IDCGDXInput.

Note

- If none of the command line parameters IDCGDXInput, IDCGenerateGDXInput, IDCJSON, IDCGenerateJSON, or IDCGenerateGDX is set, nothing - but a few checks for consistency - will happen by setting `$onExternalInput` and `$offExternalInput`.
- If at least one of the before mentioned command line parameters is set, an additional license check will be triggered: Without the `MIRO Connector License` not more than 10 indexed symbols can be declared as external input or external output.

For symbols, which are declared, while `$onExternalInput` is active, data in data statements of the declaration is ignored. Instead, the data is loaded from the GDX file specified by IDCGDXInput. Also for those symbols, if they are referenced with $load* or $offEmbeddedCode while `$onExternalInput` is active, the data is loaded from the GDX file specified by IDCGDXInput instead of the defined data source and symbol renaming as well as the projection operator are ignored in this case.

In addition, the following dollar control options are ignored, while `$onExternalInput` is active and IDCGDXInput is set:

- $batInclude
- $call
- $call.Async[NC]
- $call.checkErrorLevel
- $callTool
- $callTool.checkErrorLevel
- $gdxIn
- $hiddenCall
- $hiddenCall.Async[NC]
- $hiddenCall.checkErrorLevel
- $hiddenCallTool
- $hiddenCallTool.checkErrorLevel
- $include
- $libInclude
- $onEmbeddedCode[S|V] (including the following embedded code until `$offEmbeddedCode` is hit)
- $sysInclude

Example:

Lets look at a modified version of the simple example presented here:

```
Set
   i 'canning plants'
   j 'markets';

$onExternalInput
$call mdb2gms I=Sample.accdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i<,j<) 'distance in thousands of miles' /
$include distances.inc
/;
$offExternalInput

display d;
```

Without setting a command line parameter, this runs in the same way as described in the other chapter, so by default, setting `$onExternalInput` and `$offExternalInput` does not make much of a difference. Now, lets run it with IDCGDXInput being set to `transsol`, which is a GDX file generated by running the transportation model [**TRNSPORT**]. There will be some new messages in the log:

```
--- GDXin=transsol.gdx
--- Distances1.gms(7) 2 Mb
--- Ignoring $call in externalInput section
--- Distances1.gms(9) 2 Mb
--- Ignoring $include in externalInput section
```

First, we notice, that the file `transsol.gdx` will be opened for input. This happens implicitly with `$onExternalInput`. Then, both the `$call` as well as the `$include` lines were ignored, since we do not want to query the data source explicitly defined in the model, but the GDX file defined by IDCGDXInput. Note, that the data statement in the declaration of `d` is actually empty when we ignore the `$include` statement. While `$onExternalInput` this does not lead to an error, but behaves as if $onEmpty was set. Looking at the output of the `display` statement in the `lst` file, one can see that the expected data was loaded:

```
----     13 PARAMETER d  distance in thousands of miles

             new-york      chicago       topeka

seattle         2.500        1.700        1.800
san-diego       2.500        1.800        1.400
```

If any of the options IDCGDXInput, IDCGDXOutput, IDCJSON or their `Generate` versions, e.g. IDCGenerateGDXInput, has been set, a MIRO connector license is required.

See also $(on|off)ExternalOutput.

$(on|off)ExternalOutput ($offExternalOutput)

Syntax:

```
$onExternalOutput
$offExternalOutput
```

`$onExternalOutput` and `$offExternalOutput` mark the beginning and end of a well defined section in which data is written implicitly to an external data file, namely to a GDX file specified by the command line parameter IDCGDXOutput or IDCGenerateGDXOutput.

Note

- If none of the command line parameters IDCGDXOutput, IDCGenerateGDXOutput, IDCJSON, IDCGenerateJSON, or IDCGenerateGDX is set, nothing - but a few checks for consistency - will happen by setting `$onExternalOutput` and `$offExternalOutput`.
- If at least one of the before mentioned command line parameters is set, an additional license check will be triggered: Without the `MIRO Connector License` not more than 10 indexed symbols can be declared as external output or external input.

Example:

This is a slightly modified code snippet of the transportation model [**TRNSPORT**]:

```
...
$onExternalOutput
Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

Variable
   x(i,j) 'shipment quantities in cases'
```

```
$offExternalOutput
   z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
$onExternalOutput
   cost      'define objective function'
$offExternalOutput
   supply(i) 'observe supply limit at plant i'
   demand(j) 'satisfy demand at market j';
...
```

Without setting a command line parameter, this runs in the same way as the original model, so by default, setting `$onExternalOutput` and `$offExternalOutput` does not make much of a difference. Now, lets run it with IDCGDXOutput being set to `transOut.gdx`. This generate the file `transOut.gdx` with the following content:

Entry	Name	Type	Dim	Records	Text
1	c	Parameter	2	6	transport cost in ...
3	cost	Equation	0	1	define objective ...
2	x	Variable	2	6	shipment quanti...

i	j	Level	Marginal	Lower	Upper	Scale
seattle	new-york	50	0	0	+INF	1
seattle	chicago	300	0	0	+INF	1
seattle	topeka	0	0.036	0	+INF	1
san-diego	new-york	275	0	0	+INF	1
san-diego	chicago	0	0.009	0	+INF	1
san-diego	topeka	275	0	0	+INF	1

So, this implicit generation of the output file is basically equivalent to the following explicit statement:

```
execute_unload 'transOut.gdx', c, x, cost;
```

If any of the options IDCGDXInput, IDCGDXOutput, IDCJSON or their `Generate` versions, e.g. IDCGenerateGDXInput, has been set, a MIRO connector license is required.

See also $(on|off)ExternalInput.

$(on|off)Filtered ($onFiltered)

Syntax:

```
$onFiltered
$offFiltered
```

This dollar control option controls how GAMS loads data from GDX with gdxLoad, $load, $loadR, and $loadM. With `$onFiltered` the `$load*` calls behave like $loadFiltered* calls. With `$offFiltered` the `$load*` calls behave like $loadDC* calls. This dollar control option also controls how GAMS loads symbols on the $offEmbeddedCode line. With `$onFiltered` data is read filtered while `$offFiltered` triggers a domain check of the data. The gams.set Python function allows to overwrite the setting of this dollar control option with the argument `domCheck=DomainCheckType.CHECKED` or `domCheck=DomainCheckType.FILTERED`.

The default of how GAMS loads data from GDX can be set with the command line parameter filtered.

$(on|off)Global ($offGlobal)

Syntax:

```
$onGlobal
$offGlobal
```

When an include file is inserted, it inherits the dollar control options from the higher level file. However, the dollar control option settings specified in the include file do not affect the higher level file. This convention is common among most scripting languages or command processing shells. In some cases, it may be desirable to break this convention. This option allows an include file to change the options of the parent file as well.

Example:

```
$include 'inc.inc'
$hidden after first call to include file
$onGlobal
$include 'inc.inc'
$hidden after second call to include file
```

The file `inc.inc` contains the following lines:

```
$onDollar
$hidden text inside include file
```

The the echo print of the resulting listing file follows:

```
INCLUDE    D:\GAMS\INC.INC
    2  $onDollar
    3  $hidden text inside include file
INCLUDE    D:\GAMS\INC.INC
    7  $onDollar
    8  $hidden text inside include file
    9  $hidden after second call to include file
```

Note that the dollar control option $onDollar inside the include file does not affect the parent file until `$onGlobal` is set. The text following the option $hidden is then echoed to the listing file.

$(on|off)IDCProtect ($onIDCProtect)

Syntax:

```
$onIDCProtect
$offIDCProtect
```

This controls if symbols which are declared as external input can be changed at execution time. With `$onIDCProtect` external input symbols are protected from being changed; `$offIDCProtect` allows it.

The initial state of this can be set with the command line parameter IDCProtect.

$(on|off)ImplicitAssign ($offImplicitAssign)

Syntax:

```
$onImplicitAssign
$offImplicitAssign
```

This controls if the compiler issues or ignores the 141 error in case an unassigned symbol in the code is referenced (e.g. on the right hand side of an assignment statement). With `$onImplicitAssign` the error is ignored.

The initial state of this can be set with the command line parameter ImplicitAssign.

$(on|off)Include ($onInclude)

Syntax:

```
$onInclude
$offInclude
```

This option controls the listing of the expanded include file name in the listing file.

Example:

```
$include 'inc.inc'
$offInclude
$include 'inc.inc'
```

We assume that the file `inc.inc` contains the following lines:

```
$onDollar
$hidden Text inside include file
```

The resulting listing file will contain the following lines:

```
INCLUDE    C:\tmp\inc.inc
   2  $onDollar
   3  $hidden Text inside include file
   6  $onDollar
   7  $hidden Text inside include file
```

Note that the include file name is echoed the first time the include file is used. However, the include file name is not echoed after `$offInclude` has been set. Also, the include file summary and the creation of an Expanded Include File is suppressed if `$offInclude` is set.

$(on|off)Inline ($offInline)

Syntax:

```
$onInline
$offInline
```

This option acts as switch to control the use of in-line comments. Note that by default, the in-line comment symbols are set to the two character pairs /* and */ but the processing is disabled. In-line comments may span several lines till the end-of-comment characters are encountered.

Example:

```
$onInline
Set i /* The default comment symbols are now
         active. These comments can continue
         to additional lines till the closing
         comments are found.  */ / i1*i3 / ;
```

Note

- The option $inlineCom automatically sets `$onInline`.
- *Nested* in-line comments are illegal unless the option $onNestCom is set.

The default for dealing with inline comments can be set using the command line parameter inlineCom.

See also section Comments.

$(on|off)Listing ($onListing)

Syntax:

```
$onListing
$offListing
```

This option controls the echoing of input lines to the compilation output of the listing file. Note that suppressed input lines do not generate entries in the symbol and reference sections that appear at the end of the compilation output. Lines with errors will always be listed.

Example:

```
Set i /0234*0237/
    j /a,b,c/     ;
Table x(i,j) "very long table"
        a   b   c
 0234   1   2   3
$offListing
 0235   4   5   6
 0236   5   6   7
$onListing
 0237   1   1   1
;
```

The resulting listing file will contain the following lines:

```
    1  Set i /0234*0237/
    2      j /a,b,c/     ;
    3  Table x(i,j) very long table
    4          a   b   c
    5   0234   1   2   3
   10   0237   1   1   1
```

Note that the lines in the source file between the options `$offListing` and `$onListing` are not echoed to the listing file.

Note

For some projects the listing file can become huge and can take significant time to be written. This time can be saved by setting `$offListing` at the beginning of the input file and `$onListing` just before the parts one is interested in, or not at all, if one does not look at the listing file anyway.

The default for dealing with the compilation output of the listing file can be set using the command line parameter listing.

$(on|off)Local ($onLocal)

Syntax:

```
$onLocal
$offLocal
```

The suffix `.local` attached to the name of a controlling set will use an *implicit alias* within the scope of the indexed operation or on the left-hand side of an assignment statement. This feature is particularly useful in the context of nested macros.

Example:

```
Set i /1*3/; alias(i,j);
Parameter xxx(i,j) / 1.1 1, 2.2 2, 3.3 3, 1.3 13, 3.1 31 /;
display xxx;

Parameter p(i);
p(i.local) = sum(j, xxx(i,j));
display p;
```

Note that in the assignment statement the set `i` on the right-hand side is controlled by `i.local` on the left-hand side. Thus we have the following values for the two parameters:

```
----      3 PARAMETER xxx
            1           2           3
1       1.000                  13.000
2                   2.000
3      31.000                   3.000

----      7 PARAMETER p
1 14.000,    2  2.000,    3 34.000
```

In the example above, the suffix `.local` appeared one time on the left-hand side. The option `$onLocal` allows the suffix `.local` to appear more that one time attached to the same symbol. Consider the following example that extends the example above:

```
Parameter g(i,i);
g(i.local-1,i.local) = xxx(i,i);
display g;
```

Note that in the assignment statement of `g` the suffix `.local` attached to the set `i` appears two times on the left-hand side. The question arises whether the reference to the set `i` on the right-hand side refers to the first or the second instance of `.local` on the left-hand side. The assignment statement may alternatively be written in the following way using an *explicit* alias statement:

```
alias (i,i1,i2);
g(i1-1,i2) = xxx(i2,i2);
```

Thus is becomes clear that the symbol on the right-hand side refers to the controlling index that enters last (here the second one). The output generated by the display statement follows:

```
----      10 PARAMETER g
            1           2           3
1       1.000       2.000       3.000
2       1.000       2.000       3.000
```

Observe that the multiple use of the suffix `.local` on the same symbol is considered an error with the option `$offLocal`.

Note that it is also allowed to combine the original index with an index suffixed with `.local`. Consider the following alternative formulation:

```
g(i.local-1,i) = xxx(i,i);
```

Note that in this case the index suffixed with `.local` takes precedence and the reference of `i` on the right-hand side refers to the index `i.local` even though `i` is entered last. Observe that this statement even works with `$offLocal` as the suffix `.local` appears only once.

See also section Macros in GAMS below.

$(on|off)Log ($onLog)

Syntax:

```
$onLog
$offLog
```

This option acts as a switch that controls logging information about the line number and memory consumption during compilation. This is scoped like the option $on/offListing applying only to included files and any subsequent included files but reverting to the setting `$onLog` in the parent files (if it was not changed there as well).

Example:

```
Set i /i1*i20000000/;
$include inc.inc
Set l /l1*l20000000/;
```

The file `inc.inc` looks like this:

```
Set j /j1*j20000000/;
$offLog
Set k /k1*k20000000/;
```

The generated log will contain the following lines:

```
--- test.gms(1) 1602 Mb  5 secs
--- test.gms(2) 1602 Mb
--- .inc.inc(1) 3122 Mb  6 secs
--- test.gms(3) 6161 Mb  14 secs
```

Note that the first line of both the parent and the include file got logged, but not the third line of the include file, after `$offLog` was set. The last line of the parent file got logged again.

$(on|off)Macro ($onMacro)

Syntax:

```
$onMacro
$offMacro
```

Enables or disables the expansion of macros defined by $macro.

Example:

```
$macro oneoverit(y) 1/y
$offMacro
y = oneoverit(x1);
display y;
```

causes an error because the macro `oneoverit` in line 3 can not be expanded.

$(on|off)Margin ($offMargin)

Syntax:

```
$onMargin
$offMargin
```

This option controls margin marking, that means if margins set by the options $minCol and $maxCol, should be marked in the lst file.

Example:

```
$onmargin mincol 20 maxcol 51
Now we have        Set       i "plant" / US, UK /; This defines I
turned on the      Scalar    x         / 3.145  /; A scalar example.
margin marking.    Parameter a, b;                  Define some
                                                    parameters.
$offmargin
```

The lst file will contain this:

```
  2 Now we have        |Set       i "plant" / US, UK /; |This defines I
  3 turned on the      |Scalar    x         / 3.145  /; |A scalar example.
  4 margin marking.    |Parameter a, b;                 |Define some
  5                    |                                |parameters.
```

Note that any statements between columns 1 and 19 and any input beyond column 52 are treated as comments. These margins are marked with | on the left and right.

See also section Comments.

$(on|off)Multi ($offMulti)

Syntax:

```
$onMulti
$offMulti
```

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements are merged with entries of the previous ones. Note that all multiple data statements are performed before any other statement is executed.

Note

- There is also $onMultiR, which behaves similarly, but replaces existing data instead of merging into it. Compare the example here and there to see the difference.
- When `$onMulti` is active $load behaves like a $loadM.
- The initial state of this dollar control option can be set through the command line parameter multi.

Example:

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol x after the data statement has been processed:

```
$eolCom //
Set i / i1*i10 /;
Parameter x(i) / i1*i3  1 /   // /i1 1,i2 1,i3 1/
$onMulti
Parameter x(i) / i7*i9  2 /   // /i1 1,i2 1,i3 1,i7 2,i8 2,i9 2/
Parameter x(i) / i2*i6  3 /   // /i1 1,i2 3,i3 3,i4 3,i5 3,i6 3,i7 2,i8 2,i9 2/
Parameter x(i) / i3*i5  0 /   // /i1 1,i2 3,i6 3,i7 2,i8 2,i9 2/
$offMulti
display x;
```

Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option `$onMulti`. The result of the display statement in the listing file follows:

```
----      8 PARAMETER x

1 1.000,    2 3.000,    6 3.000,    7 2.000,    8 2.000,    9 2.000
```

Note that `x("i1")` is assigned the value of 1 with the first data and is not affected by any of the subsequent data statements. `x("i3")` on the other hand is reset to 3 by the third data statement and wiped out with 0 in the fourth data statement.

Attention

The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option `$onMulti` since it allows data initializations to be performed more than once. See section GAMS Compile Time and Execution Time Phase for details.

Consider the following example:

```
Scalar a /12/;
a=a+1;
$onMulti
Scalar a /20/;
display a;
```

Note that the two `scalar` data initialization statements and the option `$onMulti` are processed before the assignment statement `a=a+1`. As a result, the final value of `a` will be 21. The output of the display statement follows:

```
----      5 PARAMETER a                   =       21.000
```

Observe that the option $onEmpty in conjunction with the option `$onMulti` and the save and restart feature may be used to set up a model and add data later. See example in section Advanced Separation of Model and Data for details.

$onMultiR|offMulti ($offMulti)

Syntax:

```
$onMultiR
$offMulti
```

This option controls multiple data statements or tables. By default, GAMS does not allow data statements to be redefined. If this option is activated the second or subsequent data statements replace the previous ones. Note that all multiple data statements are performed before any other statement is executed.

Note

- There is also $onMulti, which behaves similarly, but *merges* into existing data instead of replacing it. Compare the example here and there to see the difference.
- In contrast to $onMulti, `$onMultiR` also allows to redefine an equation and a macro.
- The initial state of this dollar control option can be set through the command line parameter multi.

Example:

Consider the following slice of code. The list after the end of line comment describes the complete content of the symbol x after the data statement has been processed:

```
$eolCom //
Set i / i1*i10 /;
Parameter x(i) / i1*i3  1 /   // /i1 1,i2 1,i3 1/
$onMultiR
Parameter x(i) / i7*i9  2 /   // /i7 2,i8 2,i9 2/
Parameter x(i) / i2*i6  3 /   // /i2 3,i3 3,i4 3,i5 3,i6 3/
Parameter x(i) / i3*i5  0 /   // ( ALL       0.000 )
$offMulti
display x;
```

Note that the repeated parameter statements would have resulted in a compilation error without the presence of the option `$onMultiR`. The result of the display statement in the listing file follows:

```
----      9 PARAMETER x

( ALL       0.000 )
```

Note

- When using a redefinition with `$onMulitR` to remove elements from a set, which was used as domain of another symbol, also the dependent symbol gets reduced. This can happen through data statements, but also with $clear and $load/$loadDC.
- When `$onMultiR` is active $load behaves like a $loadR with the exception of the previous note. So, the only way to allow for a redefiniton of a domain set is to activate `$onMultiR`. If that is not active `$loadR` for a domain set would trigger an error.

Example:

```
Set i          / i1*i5 /;
Parameter p(i) / #i 3  /;

$onMultiR

Set i          / i3*i6 /;
Display p;
```

Looking at the output from the `Display` statement one can see, that the entries for `i1` and `i2` were removed by the second definition of `i`:

```
----      7 PARAMETER p

i3 3.000,    i4 3.000,    i5 3.000
```

Attention

> The two-pass processing of a GAMS file may lead to seemingly unexpected results. Dollar control options and data initialization are both done in the first pass and assignments in the second, irrespective of their relative locations. This is an issue particularly with the option `$onMultiR` since it allows data initializations to be performed more than once. See section GAMS Compile Time and Execution Time Phase for details.

Consider the following example:

```
Scalar a /12/;
a=a+1;
$onMultiR
Scalar a /20/;
display a;
```

Note that the two `scalar` data initialization statements and the option `$onMultiR` are processed before the assignment statement `a=a+1`. As a result, the final value of `a` will be 21. The output of the display statement follows:

```
----      5 PARAMETER a                  =       21.000
```

Observe that the option $onEmpty in conjunction with the option `$onMultiR` and the save and restart feature may be used to set up a model and add data later. See example in section Advanced Separation of Model and Data for details.

$(on|off)NestCom ($offNestCom)

Syntax:

```
$onNestCom
$offNestCom
```

This option controls nested in-line comments. It makes sure that the open-comment and close-comment characters match.

Example:

```
$inlineCom { } onNestCom
  { nesting is now possible in comments { braces
    have to match } }
```

See also $inlineCom, $onInline and section Comments.

$(on|off)Order ($onOrder)

Syntax:

```
$onOrder
$offOrder
```

Lag and lead operations and the ord operator require the referenced set to be ordered and constant. In some special cases users might want to use those operations on dynamic and/or unordered sets. The option `$on/offOrder` has been added to locally relax the default requirements. The use of this option comes with a price, the system will not be able to diagnose odd and incorrect formulations and data sets.

Example:

```
Set       t1    / 1987, 1988, 1989, 1990, 1991 /
          t2    / 1983, 1984, 1985, 1986, 1987 /;
Parameter p(t2);
$offOrder
p(t2) = ord(t2);
display t2,p;
```

Without the `$offOrder` the compilation of the line `p(t2) = ord(t2);` would have triggered a compilation error. The ordinal numbers assigned here are probably not what one expects. The element `1987` gets ordinal number 1 although it seems to be last last in the set. The ordinal numbers are assigned in the order the set is stored internally in GAMS. This order is also used when displaying the set `t2`:

```
----      6 SET t2
1987,    1983,    1984,    1985,    1986

----      6 PARAMETER p
1987 1.000,    1983 2.000,    1984 3.000,    1985 4.000,    1986 5.000
```

$(on|off)Put[S|V][.tag]

Syntax:

```
File myputfile;
put myputfile;
$onPut[S|V][.tag]
text
{text}
$offPut[.tag]
```

The pair `$onPut[S|V]` - `$offPut` causes a block of text to be placed in a put file at run-time. The is one of the few dollar control options that operate at run time. The `$` in the first column usually indicates action at compile time.

Note that parameter substitutions are not permitted with `$onPut`. The option `$onPut` has two more variants: `$onPutS` and `$onPutV`. `$onPutS` allows parameter substitutions while the option `$onPutV` does not allow parameter substitutions, like `$onPut`, so it is just a synonym which makes it more obvious that the text is written verbatim with the appended `V`.

Example:

```
$set it TEST
File myputfile;
put myputfile;
$onPutS
Line 1 of text "%it%"
Line 2 of text %it%
$offPut
```

This code generates the put file `myputfile.put` with the following content:

```
Line 1 of text "TEST"
Line 2 of text TEST
```

Note that the compile-time variable `%it%` was replaced by `TEST`. However, if the option `$onPutV` is used instead, then `%it%` will not be substituted:

```
$set it TEST
File myputfile
put myputfile
$onPutV
Line 1 of text "%it%"
Line 2 of text %it%
$offPut
```

The resulting file `myputfile.put` will contain the following lines:

```
Line 1 of text "%it%"
Line 2 of text %it%
```

One may add a `tag` to the `$onPut[S|V]` and `$offPut`. This allows to use nested put blocks like this:

```
File myputfile / outer.gms /;
put myputfile;
$onPut.outer
File myputfile;
put myputfile;
$onPut.inner
Line 1 of text
Line 2 of text
$offPut.inner
$offPut.outer
```

The resulting file `outer.gms` looks like this:

```
File myputfile;
put myputfile;
$onPut.inner
Line 1 of text
Line 2 of text
$offPut.inner
```

$(on|off)Upper ($offUpper)

Syntax:

```
$onUpper
$offUpper
```

GAMS code echoed to the listing file is written in upper case after `$onUpper`. The default of mixed code echoing is restored with `$offUpper`.

Note

The default case of the echo print can be set using the command line option case.

Example:

```
Set
   i 'Canning plants' / seattle,  san-diego /
   j 'Markets'        / new-york, chicago, topeka /;

$onupper
Parameter
   a(i) 'Capacity of plant i in cases'
        / seattle    350
          san-diego  600 /

$offupper
   b(j) 'Demand at market j in cases'
        / new-york   325
          chicago    300
          topeka     275 /;
```

The generated listing file looks like this:

```
   1  Set
   2     i 'Canning plants' / seattle,  san-diego /
   3     j 'Markets'        / new-york, chicago, topeka /;
   4
   6  PARAMETER
   7     A(I) 'CAPACITY OF PLANT I IN CASES'
   8          / SEATTLE    350
   9            SAN-DIEGO  600 /
  10
  12     b(j) 'Demand at market j in cases'
  13          / new-york   325
  14            chicago    300
  15            topeka     275 /;
```

$(on|off)Recurse ($offRecurse)

Syntax:

```
$onRecurse
$offRecurse
```

This option controls whether it is permitted for a file to include itself.

Example:

The following GAMS program result in a recursive inclusion of the program itself:

```
$onRecurse
$include "%gams.input%"
```

Note that the maximum include nesting level is 40 and if it is exceeded an error is triggered.

In the following example that prints a string and then the reverse string the nesting level is less that 40 and one get some kind of recursion at compile time:

```
$onEchoV > reverse.gms
$ifthene %1=%3+1
  put ' '
$ exit
$endif
loop(map(chars,code)$(code.val=ord("%2",%1)), put chars.tl:0);
$eval posPlus1 %1+1
$batInclude reverse %posPlus1% %2 %3
loop(map(chars,code)$(code.val=ord("%2",%1)), put chars.tl:0);
$offEcho

set chars / A*Z /, code / 65*90 /, map(chars,code) / #chars:#code /;
file fx /''/; put fx;
$onRecurse
$batInclude reverse 1 RACECAR 7
put /;
$batInclude reverse 1 LAGER 5
```

The log will print the following lines:

```
--- Starting execution: elapsed 0:00:00.067
RACECAR RACECAR
LAGER REGAL
*** Status: Normal completion
```

$(on|off)StrictSingleton ($onStrictSingleton)

Syntax:

```
$onStrictSingleton
$offStrictSingleton
```

If the option `$onStrictSingleton` is active, a compilation error is triggered if a data statement for a singleton set contains more than one element. After activating the option `$offStrictSingleton` GAMS will take the *first* element of a singleton set that was declared with multiple elements as the valid element, the other elements are disregarded and there is no error. The option to change the initial state of `$(on|off)StrictSingleton` and/or to control this behavior at runtime is strictSingleton.

Example:

The *first* element is not always the one that appears in the data statement first as the following example shows:

```
set i /1,2/
$offStrictSingleton
singleton set ii(i) /2,1/;
display ii;
```

The set `ii` contains the element `1` because it is the first in the GAMS label order as the display statements shows:

```
----      4 SET ii
1
```

$(on|off)SuffixDLVars ($offSuffixDLVars)

Syntax:

```
$onSuffixDLVars
$offSuffixDLVars
```

This option controls if it is allowed to use suffixes on variables with limited domains in a model. By default this is not allowed but this can be changed by setting `$onSuffixDLVars`.

Example:

```
Set n        / n1*n100 /
    t        / t1*t10  /
    sub(n,t) / #n:#t   /;

Variable z, x(n,t);
Equation obj;

x.up(n,t) = uniformInt(7,13);
obj.. z =e= sum((n,t),x(n,t)/x.up(n,t));

Model m / all, x(sub) /;
Solve m min z use lp;
```

This causes the following error by default:

```
*** Problem in Model Generation: Variable "x" appears with suffix "Up".
*** Error at line 12: Cannot use domain limited variables with suffix in model - use $onSuffixDL
```

The purpose is to make the user aware of the fact, the she uses `x.l`, which would also be affected by the domain restriction of `x(sub)` in the model statement. So, if the user made sure, that this is all intended, setting `$onSuffixDLVars` before the solve statements overcomes this error. Though, with the example given here, this would actually lead to a "division by zero" error, since some `x.up` were excluded leaving a `0` as divisor.

The default for dealing with suffixes on variables with limited domains can be set using the command line parameter SuffixDLVars.

$(on|off)SuffixAlgebraVars ($onSuffixAlgebraVars)

Syntax:

```
$onSuffixAlgebraVars
$offSuffixAlgebraVars
```

This option controls if it is allowed to use suffixes in equations. By default this is allowed but it can be changed by setting `$offSuffixAlgebraVars`. Activating `$offSuffixAlgebraVars` can be useful to ensure, that no decision variable in a model was replaced by one of its attributes, for example if one is dealing with a model written by someone else.

Example:

```
Variable x / 1 0 /, z / 1 0 /;
Equation e;

e.. z =e= sqr(1-x.l);

Model m /e/;
solve m min z use nlp;
```

This runs, but might give a different solution than expected.

Activating `$offSuffixAlgebraVars` will point to a potential problem:

```
   5  e.. z =e= sqr(1-x.l);
****                     $917
**** 917  Cannot use variable with suffix in model algebra -
****         Use $onSuffixAlgebraVars to allow this
```

See also related command line parameter SuffixAlgebraVars.

$(on|off)SymList ($offSymList)

Syntax:

```
$onSymList
$offSymList
```

This option controls whether the symbol listing map appears in the compilation output of the listing file. The symbol listing map contains the complete listing of all symbols that have been defined and their explanatory text. The entries are in alphabetical order and grouped by symbol type.

Example:

The symbol listing map generated by running [**TRNSPORT**] with `$onSymList` is as follows:

```
Symbol Listing

SETS

i             canning plants
j             markets

PARAMETERS

a             capacity of plant i in cases
b             demand at market j in cases
c             transport cost in thousands of dollars per case
d             distance in thousands of miles
f             freight in dollars per case per thousand miles

VARIABLES

x             shipment quantities in cases
z             total transportation costs in thousands of dollars

EQUATIONS

cost          define objective function
demand        satisfy demand at market j
supply        observe supply limit at plant i

MODELS

transport
```

This serves as a simple description of the symbols used in a model and may be used in reports and other documentation. For further information, see section The Symbol Listing Map.

$(on|off)SymXRef ($offSymXRef)

Syntax:

```
$onSymXRef
$offSymXRef
```

This option controls the following:

- Collection of cross references for symbols like sets, parameters, variables, acronyms, equations, models and put files.
- Symbol cross reference report of all collected symbols in the compilation output of the listing file. For details, see section The Symbol Reference Map.
- Listing of all referenced symbols and their explanatory text by symbol type in listing file. This listing may also be activated with the option $onSymList.

Example:

```
$onSymXRef
Set i / 1*6 /, k;
$offSymXRef
Set j(i) "will not show" / 1*3 /;
$onSymXRef
k('1') = yes;
```

The resulting listing file will contain the following symbol reference map and symbol listing map:

```
SYMBOL      TYPE   REFERENCES

i            SET   declared        2  defined        2
k            SET   declared        2 assigned        6

SETS

i
k
```

Note that the set `j` does not appear in these listings because the listing was deactivated with the option `$offSymXRef` in line 3 of the code above.

$(on|off)Text

Syntax:

```
$onText
$offText
```

The pair `$onText` - `$offText` encloses comment lines. Line numbers in the compiler listing are suppressed to mark skipped lines.

Example:

```
* Standard comment line
$onText
Everything here is a comment
until we encounter the closing $offText
like the one below
$offText
* Another standard comment line
```

The echo print of the resulting listing file will contain the following lines:

```
1  * Standard comment line
   Everything here is a comment
   until we encounter the closing $offText
   like the one below
7  * Another standard comment line
```

Attention

GAMS requires that every `$onText` has a matching `$offText` and vice versa.

See also section Comments.

$(on|off)Troll ($offTroll)

Syntax:

```
$onTroll
$offTroll
```

This option controls whether to recognize Troll periodicity in set definitions using sequences (`id*id`). Leap years are taken into account. Supported formats are `yyyyA` (annual), `yyyyQq` (quartely), `yyyyMmm` (monthly) and `yyyyWww` (weekly).

Example:

```
$onTroll
Set
  trollw / 1990w49*1991w4 /
  trollm / 1990m10*1991m5 /
  trollq / 1990q1*1991q4 /
;

Display trollw, trollm, trollq;
```

The resulting listing file will contain the following output:

```
----     25 SET trollw

1990W49,    1990W50,    1990W51,    1990W52,    1991W1 ,    1991W2 ,    1991W3 ,    1991W4

----     25 SET trollm

1990M10,    1990M11,    1990M12,    1991M1 ,    1991M2 ,    1991M3 ,    1991M4 ,    1991M5

----     25 SET trollq

1990Q1,    1990Q2,    1990Q3,    1990Q4,    1991Q1,    1991Q2,    1991Q3,    1991Q4
```

$(on|off)UElList ($offUElList)

Syntax:

```
$onUElList
$offUElList
```

This option controls the complete listing of all set elements that have been entered in the compilation output of the listing file. For details see section The Unique Element Listing Map.

Example:

The unique element listing in the listing file generated by running the model [**TRNSPORT**] with `$onUElList` follows:

```
Unique Element Listing

Unique Elements in Entry Order

1  seattle     san-diego   new-york    chicago     topeka

Unique Elements in Sorted Order

1  chicago     new-york    san-diego   seattle     topeka
```

Note that the sorted order is not the same as the entry order. For more information, see section Ordered and Unordered Sets.

$(on|off)UElXRef ($offUElXRef)

Syntax:

```
$onUElXRef
$offUElXRef
```

This option controls the collection and listing of cross references of set elements in the compilation output. For more information, see section The Unique Element Listing Map.

Example:

```
Set i "set declaration" / one, two, three /, k(i);
$onUElXRef
k('one') = yes;
$offUElXRef
k('two') = yes;
$onUElXRef
k('three') = yes;
```

The resulting listing file will contain the following unique element reference report:

```
Unique Element Listing

ELEMENT   REFERENCES

one           index        3
three         index        7
```

Note that the element `two` does not appear in this listing because the listing was deactivated with the option `$offUElXRef` in line 4 of the code above.

$(on|off)UNDF ($offUNDF)

Syntax:

```
$onUNDF
$offUNDF
```

This option controls the use of the special value UNDF which indicates a result is undefined. For details see section Extended Range Arithmetic. By default, UNDF is not permitted to be used in assignments. This may be changed with the option `$onUNDF`.

Example:

```
Scalar x;
$onUNDF
x = UNDF;
Display x;
```

The output of the display statement follows:

```
----      4 PARAMETER x                   =          UNDF
```

Note that an error would have been triggered without the use of `$onUNDF`. The option `$offUNDF` will return the system to the default, where `UNDF` may not be used in assignments.

$(on|off)Uni ($offUni)

Syntax:

```
$onUni
$offUni
```

This controls whether the compiler checks the referential integrity (see section Domain Checking) of the code. This is an essential part of good GAMS programming and it is highly recommend to declare symbols with proper domains. With the universe as a domain the compiler does not help the user with easy-to-make mistakes, like swapping indexes, `a(i,j)` versus `a(j,i)`. By default something like this would generate an error, if `a` was declared as `a(i,j)`. Such an error could be ignored, by setting `$onUni`, which can be useful in few situations, when accessing a symbol with a set that is not the domain or a subset of the domain. For example, we could read data of a union of sets that already exist. We could use the universe as the domain for that symbol, but perhaps we need to protect the referential integrity of this symbol too.

Example:

```
Set       fruit   / apple, pear /
          veggie  / carrot, pea /
          produce / #fruit, #veggie /;
Parameter produceCalories(produce) "per 100g" / apple 52, pear 57, carrot 41, pea 81 /
          fc(fruit)  "calories per 100g"
          vc(veggie) "calories per 100g";
$onUni
fc(fruit)  = produceCalories(fruit);
vc(veggie) = produceCalories(veggie);
$offUni
display fc, vc;
```

So when assigning `fc` we only access `produceCalories` with `fruit`. We could reverse the order of declaration of `fruit`, `veggie` and `produce` and use a proper subdomain, but sometimes data flow and input don't allow that.

Attention

When the GAMS compiler operates under $onUni it treats all symbols as being declared over the universe. So all domain checking is gone. We can set elements in a symbols that normally can't be entered. This can also lead to strange effects:

```
set       i / 1*2 /
          j / a,b /;
parameter pi(i);
$onuni
pi(j) = 1;
$offuni
* We will see elements from j in pi
Display pi;
* The following should only clear the i-elements from pi, but it clears the
* entire symbol, because GAMS knows it's doing this to the entire domain and
* takes a shortcut.
pi(i) = no;
Display pi;
```

$(on|off)Verbatim

Syntax:

```
$onVerbatim
$offVerbatim
```

These options are used in conjunction with the GAMS command line parameter DumpOpt to suppress the input preprocessing for input lines that are copied to the dmp file. This feature is mainly used to maintain different versions of related models in a central environment.

Note

- The options `$on/offVerbatim` are only recognized for `DumpOpt` $\geq$ 10 and apply only to lines in the file between the two options
- If `$onVerbatim` is active, `DumpOpt = 11` behaves like `DumpOpt = 21` (comments are kept)

Observe that the use of the options $goto and `$on/offVerbatim` are incompatible and may produce unexpected results.

Example:

```
$set f 123
$log %f%
$onVerbatim
$log %f%
$offVerbatim
$log %f%
```

The corresponding dmp file will contain the following lines:

```
$log 123
$onVerbatim
$log %f%
$offVerbatim
$log 123
```

See also command line parameter DumpOpt.

$(on|off)Warning ($offWarning)

Syntax:

```
$onWarning
$offWarning
```

This option acts as a switch for data domain checking. In some cases it may be useful to accept domain errors in data statements that are imported from other systems and report warnings instead of errors. Data will be accepted and stored, even though it is outside the domain.

Attention

- This switch effects three types of domain errors usually referred to as error numbers 116, 170 and 171, see example below.
- This may have serious side affects and we recommend to exercise great care when using this feature.

Example:

```
Set i     / one, two, three /
$onWarning
    j(i)  / four, five /
    k     / zero /;
Parameter x(i) "Messed up Data" / one 1.0, five 2.0 /;
x('six') = 6;
x(j) = 10;
x('two') = x('seven');
j(k) = yes;
$offWarning
display i,j,x;
```

Note that the set `j`, although specified as a subset of `i`, contains elements not belonging to its domain. Similarly, the parameter `x` contains data elements outside the domain of `i`. The skeleton listing file that results from running this code follows:

```
 1  Set i     / one, two, three /;
   3      j(i)  / four, five /
****                 $170  $170
   4      k     / zero /;
   5  Parameter x(i) "Messed up Data" / one 1.0, five 2.0 /;
****                                          $170
   6  x('six') = 6; x(j) = 10; x('two') = x('seven');
****       $170                               $116,170
   7  j(k) = yes;
****     $171
   9  display i,j,x;

 Error Messages

116  Label is unknown
170  Domain violation for element
171  Domain violation for set

**** 0 ERROR(S)   7 WARNING(S)

E x e c u t i o n
```

```
----      9 SET i
one   ,    two   ,    three

----      9 SET j
four,    five,    zero

----      9 PARAMETER x  Messed up Data
one   1.000,    four 10.000,    five 10.000,    six   6.000
```

Observe that the domain violations are marked like normal compilation errors but are only treated as warnings and it is permitted to execute the code.

For an introduction to domain checking in GAMS, see section Domain Checking.

$phantom id

Syntax:

```
$phantom id
```

This option is used to designate `id` as a *phantom* set element. Syntactically, a phantom element is handled like any other set element. Semantically, however, it is handled like it does not exist. This is sometimes used to specify a data template that initializes the phantom records to default values.

Example:

```
$phantom null
Set i / null /
    j / a, b, null /;
display i,j;
```

The output generated by the display statement is shown below:

```
----      4 SET i
                                                    ( EMPTY )

----      4 SET j
a,    b
```

Note that `null` does not appear in the listing file.

Attention

Statements that assign values to phantom labels are ignored.

Consider the following extension to the previous example:

```
Parameter p(j) / a 1, null 23 /;
display p;
```

The output generated by the display statement is shown below:

```
----      6 PARAMETER p
a 1.000
```

The system attribute system.empty is an implicitly defined phantom element. The following code works even without specifying $phantom:

```
Set i / system.empty /
    j / a, b, system.empty /;
display i,j;
```

Another way to specify empty data statements makes use of on/offEmpty. The following example produces the same data as the data statement with the phantom label. In contrast to the example we $phantom we need to provide the dimensionality of the symbol i explicitly via the (*):

```
$onEmpty
Set i(*) / /
    j / a, b /;
display i,j;
```

$prefixPath

Syntax:

```
$prefixPath directoryPath
```

This option augments the search path in PATH environment variable. The effect is that the text directoryPath is added to the beginning of the search path.

Example:

```
$log %sysenv.PATH%
$prefixPath C:\somewhereelse\anotherpath
$log %sysenv.PATH%
```

The log contains the following two relevant lines:

```
C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\System32\WindowsPowerShell\v1
C:\somewhereelse\anotherpath;C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Windows\
```

The option setEnv and %sysEnv.VARNAME% allow to modify system environment variables but the length of the environment variable value is limited in GAMS to 255 characters. The PATH environment variable is often much longer and therefore this special $prefixPath option exists.

This works on all platforms but the path separator depends on the operating system (; for Windows and : for Unix).

$protect

Syntax:

```
$protect all | ident1 ident2 ...
```

This option creates a privacy setting: it freezes all values of identifiers with the result that modifications are no longer allowed but the parameters may still be used in model calculation (for example, equation definitions). Here ident1 and ident2 are specific GAMS identifiers previously defined in the program and the keyword all denotes all identifiers.

Note that this option is mainly used in the context of secure work files. The privacy restrictions may be removed with the options $expose or $purge.

$purge

Syntax:

```
$purge all | ident1 ident2 ...
```

This option removes the identifiers and all associated data in a privacy setting. With explicit identifiers the listed identifiers are removed, and with `all` all identifiers are removed.

Note that this option is used in the context of secure work files. A special license file is needed for this feature to work, the removal only takes effect in the restart files.

$remark

Syntax:

```
$remark text
```

This option performs a parameter substitution and writes a comment `text` to the compilation output of the listing file. Note that the line numbers of the comment are suppressed.

Example:

```
$set it TEST
$remark Write %it% to the listing file
```

The resulting listing file will contain the following line:

```
Write TEST to the listing file
```

$[x]save[.keepCode]

Syntax:

```
$[x]save[.keepCode] saveFileName
```

This option creates a work file with all of the GAMS components compiled up to this point. Without the suffix `keepCode` no execution code is written, hence a restart from this work file has nothing to execute. `$xsave` writes a compressed work file, while work files created with `$save` are uncompressed.

Example:

```
set i /1*5/; parameter p(i) / #i 1 /;
p(i) = 2;
$save mywork
$onEcho > create_put.gms
file f / p.txt /; put f;
loop(i, put i.tl p(i) /);
$offEcho
$call.checkErrorLevel gams create_put.gms lo=2 restart=mywork
```

The resulting file `p.txt` will contain the following lines:

```
1                   1.00
2                   1.00
3                   1.00
4                   1.00
5                   1.00
```

Adding the suffix `.keepCode` in this example, i.e. `$save.keepCode mywork` will also write out unexecuted execution code, so a restart from this work file will execute this code. This option with suffix cannot be used *inside* a loop or if statement. This will trigger a compilation error. The example with the `.keepCode` suffix will result in the `p.txt` file containing the following lines:

```
1                    2.00
2                    2.00
3                    2.00
4                    2.00
5                    2.00
```

$scratchFileName

Syntax:

```
$scratchFileName VARNAME [fileStem]
```

This option establishes or redefines the content of a *scoped* compile-time variable that is accessible in the code where the command appears and all code included therein. Here `VARNAME` is any user chosen variable name; `fileStem` is optional and used to built the name for a file in the scratch directory with a scratch extension (unless an extension is set explicitly). If it is omitted, the system will make up a random file name.

So,

```
$scratchFileName fn abc
```

is equivalent to

```
$set fn %gams.scrDir%abc.%gams.scrExt%
```

Example:

```
* Set fileStem explicitly
$scratchFileName fn1 abc
$log %fn1%

* Omit fileStem
$scratchFileName fn2
$log %fn2%
```

The log will show:

```
C:\Data\t m p\225a\abc.dat
C:\Data\t m p\225a\__sFN__-0_313342928588555.dat
```

See also $set and section Compile-Time Variables.

$set

Syntax:

```
$set VARNAME text
```

This option establishes or redefines contents of a *scoped* compile-time variable that is accessible in the code where the command appears and all code included therein. Here `VARNAME` is any user chosen variable name; `text` is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that scoped compile-time variables may be destroyed (removed from the program) with the option $drop.

Note that in contrast to the option $eval the option `$set` does not evaluate the expression at compile time.

Note that GAMS allows scoped, local and global compile-time variables to be defined with the same name and therefore in some cases needs to prioritize. When referencing a compile-time variable via `%VARNAME%` a *local* variable hides *scoped* and *global* variables and a *scoped* variables hides the *global* variable as the following example demonstrates.

Example:

```
$setLocal myvar this is a local variable
$set myvar this is a scoped variable
$setGlobal myvar this is a global variable
$log %myvar%
$droplocal myvar
$log %myvar%
$drop myvar
$log %myvar%
```

The log will look as follows:

```
this is a local variable
this is a scoped variable
this is a global variable
```

If one wants to set a compile-time variable in an include file that is visible to the program after the `$include` one need to use `$setglobal`:

```
$onEchoV > setvar.gms
$setArgs varname varvalue
$setglobal %varname% %varvalue%
$offEcho
$batInclude setvar MYVAR one
$log %MYVAR%
```

The log will show

```
one
```

An inventory of all defined compile-time variables and their type (local, scoped, and global) is available with the option $show.

See also $setGlobal, $setLocal, and section Compile-Time Variables.

$setArgs

Syntax:

```
$setArgs id1 id2 id3 ...
```

With this option parameters that may be substituted are defined as GAMS compile-time variables. Note that `$setArgs` may only be used in external files that are included with the option $batInclude, $libInclude, and $sysInclude.

Example:

```
Scalar a /2/, b /4/, c /5/;
$batInclude test3 a b c
```

The file `test3.gms` contains the following lines:

```
Scalar x;
x = %1 + %2 * %3 ;
display x;
$setArgs aa bb cc
x = %aa% - %bb% * %cc%  ;
display x;
x = %1 + %2 * %3 ;
display x;
```

The option `$setArgs` allows the batInclude file to use the more descriptive compile-time variables `%aa%` instead of `%1`, `%bb%` instead of `%2` and `%cc%` instead of `%3`. Note that the use of `%1`, `%2` etc. is still allowed. The program listing looks as follows:

```
   1  Scalar a /2/, b /4/, c /5/;
BATINCLUDE C:\Users\default\Documents\gamside\projdir\test3.gms
   3  Scalar x;
   4  x = a + b * c ;
   5  display x;
   7  x = a - b * c  ;
   8  display x;
   9  x = a + b * c ;
  10  display x;
```

and the output generated by the display statements follows:

```
----      5 PARAMETER x                  =       22.000
----      8 PARAMETER x                  =      -18.000
----     10 PARAMETER x                  =       22.000
```

See also $set, $batInclude.

$setComps

Syntax:

```
$setComps perioddelimstring id1 id2 id3 ...
```

This option establishes or redefines compile-time variables so they contain the components of a period delimited string.

Here `perioddelimstring` is any period delimited string like the set specification of a multi-dimensional parameter, `id1` is the name of a scoped compile-time variable that will contain the name of the set element in the first position, `id2` is the name of a scoped compile-time variable that will contain the name of the set element in the second position and `id3` is the name of a scoped compile-time variable that will contain the name of the set element in the third position. The items may be recombined back into the original filename string by using `%id1%.%id2%.%id3%`.

Example:

```
$setComps period.delim.string id1 id2 id3
$log id1=%id1%
$log id2=%id2%
$log id3=%id3%
$set name %id1%.%id2%.%id3%
$log name=%name%
```

The resulting log file will contain the following lines:

```
id1=period
id2=delim
id3=string
name=period.delim.string"
```

See also $set.

$setDDList[.Cont]

Syntax:

```
$setDDList.Cont id1 id2 ...
$setDDList      id3 id4 id5 ...
```

This option causes GAMS to look for misspelled or undefined double dash GAMS parameters.

Example: Consider the following example where three double dash GAMS parameters are defined on the command line:

```
> gams mymodel.gms --one=11 --two=22 --three=33  --four=44
```

The corresponding GAMS file follows:

```
$log %one%
$log %two%
$setDDList three
$log %three%
$log %four%
```

Note that the option `$setDDList three` checks if all double dash parameters have been used so far except for `three`. An error is triggered because `four` has not been used so far, the log file will contain the following:

```
*** 1 double dash variables not referenced
    --four=44
```

`$setDDList.Cont` can be used to define a list of parameters to be checked over multiple lines. So, the following two examples do the same thing:

```
$setDDList one two three four
```

```
$setDDList.Cont one
$setDDList.Cont two three
$setDDList      four
```

Note

`$setDDList.Cont` does not do anything without a `$setDDList` statement.

See also section Double Dash Parameters.

$setEnv

Syntax:

```
$setEnv VARNAME value
```

This option defines an operating system environment variable. Here `VARNAME` is a user chosen environment variable name and `value` may contain text or a number. Note that system environment variables are destroyed (removed from the program) with the option $dropEnv or when GAMS terminates.

Example:

```
$ondollar
$set env this is very silly
$log %env%
$setenv verysilly %env%
$log %sysenv.verysilly%
$if not "%env%"=="%sysenv.verysilly%" $error "$setEnv did not work"

$dropenv verysilly
$if setenv verysilly $error should not be true
```

The following output is echoed to the log file:

```
--- Starting compilation
this is very silly
this is very silly
```

See also $dropEnv and section Environment Variables in GAMS.

$setGlobal

Syntax:

```
$setGlobal VARNAME text
```

This option establishes or redefines contents of a *global* compile-time variable that is accessible in the code where the command appears and all code included therein and all parent files. Here `VARNAME` is any user chosen variable name; `text` is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that global compile-time variables may be destroyed (removed from the program) with the option $dropGlobal.

The difference between local, scoped, and global compile-time variable is explained with the option $set.

See also $set, $setLocal, $dropGlobal and section Compile-Time Variables.

$setLocal

Syntax:

```
$setLocal VARNAME text
```

This option establishes or redefines contents of a *local* compile-time variable that is accessible only in the code module (source file) where it is defined. Here `VARNAME` is any user chosen variable name; `text` is optional and may contain any text. The text may contain spaces. The text can not be longer than 255 characters otherwise a compilation error is triggered. Observe that local compile-time variables may be destroyed (removed from the program) with the option $dropLocal.

The difference between local, scoped, and global compile-time variable is explained with the option $set.

See also $set, $setGlobal, $dropLocal and section Compile-Time Variables.

$setNames

Syntax:

```
$setNames file filepath filename fileextension
```

This option establishes or redefines three scoped compile-time variables so they contain the drive subdirectory, filename and extension of a file named with full path. Here `file` is any filename, `filepath` is the name of a scoped compile-time variable that will contain the name of the subdirectory where the file is located, `filename` is the name of a scoped compile-time variable that will contain the root name of the file and `fileextension` is the name of a scoped compile-time variable that will contain the extension of the file.

Example:

```
$setNames "%gams.input%" filepath filename fileextension
$set name %filepath%%filename%%fileextension%
$log %name%
```

The log will show

```
C:\Users\default\Documents\gamside\projdir\
Untitled_1
.gms
C:\Users\default\Documents\gamside\projdir\\Untitled_1.gms
```

Note that `file` is separated into its three components placing `C:\Users\default\Documents\gamside\projdir\` into `filepath`, `Untitled_1` into `filename` and `.gms` into `fileextension`. The three items may be recombined back into the original filename by using `%filepath%%filename%%fileextension%` as shown in the example.

If the file is missing a path, name, or extension the corresponding variable is defined but remains empty as demonstrated in the following example:

```
$onEchoV > showfileparts.gms
$setNames "%1" filepath filename fileextension
$log path=%filepath%
$log name=%filename%
$log ext=%fileextension%
$offEcho
$batInclude showfileparts "C:\tmp\"
$batInclude showfileparts "Untitled_1"
$batInclude showfileparts "Untitled_1.gms"
$batInclude showfileparts "Untitled_1.gms.txt"
```

The log shows:

```
--- Untitled_1.gms(7) 2 Mb
path=C:\tmp
name=
ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(8) 2 Mb
path=
name=Untitled_1
ext=
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(9) 2 Mb
path=
name=Untitled_1
ext=.gms
--- .showfileparts.gms(4) 2 Mb
--- Untitled_1.gms(10) 2 Mb
path=
name=Untitled_1.gms
ext=.txt
```

Note that if a file contains multiple `.` the last one will be assigned to the `fileextension` as shown in the example with `Untitled_1.gms.txt`.

$shift

Syntax:

```
$shift
```

This option is similar to the command.com/cmd.exe shift operator (see [en.wikipedia.org/wiki/COMMAND.COM::Bat
(https://en.wikipedia.org/wiki/COMMAND.COM#Batch_file_commands). It shifts the order of all parameters passed once to the *left*. This effectively drops the lowest numbered parameter in the list.

Example:

```
Scalar a, b, c ; a = 1 ;
$batInclude inc.inc a b c
display a, b, c ;
```

The batch include file `inc.inc` follows:

```
%2 = %1 + 1 ;
$shift
%2 = %1 + 1 ;
```

The resulting listing file will contains the following echo print:

```
    1  Scalar a, b, c ; a = 1 ;
BATINCLUDE C:\Users\default\Documents\gamsdir\projdir\inc.inc
    3  b = a + 1 ;
    5  c = b + 1 ;
    6  display a, b, c ;
```

Note that in the first statement in the include file, `%1` is the first argument in the $batInclude call and in this case it is interpreted as `a`. `%2` is the second argument in the $batInclude call and is interpreted as `b`. This leads to the overall assignment being interpreted as `b=a+1`. The dollar control option `$shift` shifts the arguments to the left. As a result, `%1` is interpreted as `b`, and `%2` is interpreted as `c`. This leads to the second assignment being interpreted as `c=b+1`.

Therefore the outcome generated by the display statement in the input file is as follows:

```
----      6 PARAMETER a                       =        1.000
            PARAMETER b                       =        2.000
            PARAMETER c                       =        3.000
```

See also $batInclude.

$show

Syntax:

```
$show
```

This option causes current values of the compile-time variables plus a list of the macros and active input and include files to be shown in the compilation output, where "active" means, that `$show` was either directly in that file or that file is a parent that includes the file with `$show`.

Example:

```
$set it 1
$setLocal yy
$setGlobal gg what
$include myinclude
$macro addx(x)  x+x
$show
```

The file `myinclude.gms` follows:

```
$set inincs
$setLocal inincsl
$setGlobal inincsg
$macro multx(x)  x*x
$show
```

The resulting listing file will contain the following *environment reports* in the compilation output:

```
---- Begin of Active File List
Level Type         Line  Filename
-----------------------------------
    1 INCLUDE         5  C:\Users\default\Documents\gamside\projdir\myinclude.gms
    0 INPUT           4  C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
---- End of Active File List

---- Begin of Compile-time Variable List
Level SetVal                          Type       Text
-------------------------------------------------------
    1 inincsl                         LOCAL
    1 inincs                          SCOPED
    0 yy                              LOCAL
    0 it                              SCOPED     1
    0 gg                              GLOBAL     what
    0 inincsg                         GLOBAL
---- End of Compile-time Variable List

---- Begin of Macro List
$macro multx(x)  x*x
---- End of Macro List
```

and

```
---- Begin of Active File List
Level Type         Line  Filename
---------------------------------
    0 INPUT           6  C:\Users\default\Documents\gamside\projdir\Untitled_1.gms
---- End of Active File List

---- Begin of Compile-time Variable List
Level SetVal                          Type       Text
-------------------------------------------------------
    0 yy                              LOCAL
    0 it                              SCOPED     1
    0 gg                              GLOBAL     what
    0 inincsg                         GLOBAL
---- End of Compile-time Variable List

---- Begin of Macro List
$macro multx(x)  x*x
$macro addx(x)  x+x
---- End of Macro List
```

Note that only the macros and the item defined with the option $setGlobal in the included file carries over.

If one needs only parts of this report, the dollar control options $showFiles, $showMacros and $showVariables can be used.

See also section Compile-Time Variables.

$showFiles

Syntax:

```
$showFiles
```

This option prints the active files to the lst file as described at $show.

$showMacros

Syntax:

```
$showMacros
```

This option prints a list of macros to the lst file as described at $show.

$showVariables

Syntax:

```
$showVariables
```

This option prints a list current values of the compile-time variables to the lst file as described at $show.

$single

Syntax:

```
$single
```

The lines following this option will be echoed single spaced in the compilation output. Note that this is the default. The option is only useful as a switch to deactivate the option $double.

Example:

```
Set    i / 1*2 / ;
Scalar a / 1   / ;
$double
Set    j / 10*15 / ;
Scalar b / 2     / ;
$single
Set    k / 5*10 / ;
Scalar c / 3    / ;
```

The echo print in the resulting listing file will look as follows:

```
1  Set i / 1*2 / ;
2  Scalar a /1/ ;

4  Set j / 10*15 / ;

5  Scalar b /2/ ;
7  Set k / 5*10 / ;
8  Scalar c /3/ ;
```

Note that lines between the options $double and `$single` are listed double spaced, while the lines after the option `$single` revert back to being listed single spaced.

See also $double.

$splitOption

Syntax:

```
$splitOption KEYVALPAIR optname optvalue
```

Establishes or redefines two scoped compile-time variables so they contain the name and value of an option key/value pair specified in various formats. `KEYVALPAIR` is a string formatted as `-opt=val` or `-opt val` (instead of `-` one can also use `/`). `optname` is the name of a scoped compile-time variable that will contain the name of the option and `optvalue` is the name of a scoped compile-time variable that will contain the value of the option. This is useful in particular in combination with batInclude files.

Example:

```
$onechoV > myinclude.gms
* Default values for named arguments
$setGlobal a1 1
$setGlobal a2 2
$setGlobal a3 nothing
$setGlobal positionalArgs
$label ProcessNamedArguments
$  splitOption "%1" key val
$  if x%key%==x $goto FinishProcessNamedArguments
$  ifThenI.NamedArguments %key%==a1
$    setGlobal a1 %val%
$  elseIfI.NamedArguments %key%==a2
```

```
$    setGlobal a2 %val%
$  elseIfI.NamedArguments %key%==a3
$    setGlobal a3 %val%
$  else.NamedArguments
$    error Unkown named argument "%key%"
$  endIf.NamedArguments
$  shift
$goTo ProcessNamedArguments
$label FinishProcessNamedArguments
$setGlobal positionalArgs %1 %2 %3
$offEcho
$batInclude myinclude "-a3=some things" -a2=3.14 i j k
$log Using named arguments a1:>%a1%< a2:>%a2%< a3:>%a3%< positionalArgs:>%positionalArgs%<
```

Now when calling this piece of code as a batInclude one can specify optionally some named arguments (in any order) right after the name of the batInclude file and before the positional arguments as demonstrated by the log output:

```
Using named arguments a1:>1< a2:>3.14< a3:>some things< positionalArgs:>i j k<
```

stars (****)

Syntax:

```
$stars char[char][char][char]
```

This option is used to redefine the **** marker in the GAMS listing file. By default, important lines like those that denote errors and the solver and model status are prefixed with ****. A new marker consists of one to four characters.

Example:

```
$stars *###*
garbage
```

The resulting listing file follows:

```
    2  garbage
*###*         $140
*###*  $36,299  UNEXPECTED END OF FILE (1)

Error Messages
 36  '=' or '..' or ':=' or '$=' operator expected
     rest of statement ignored
140  Unknown symbol
299  Unexpected end of file
```

$sTitle

Syntax:

```
$sTitle text
```

This option sets the subtitle in the page header of the listing file to `text`. Note that the next output line will appear on a new page in the listing file.

Example:

```
$sTitle Data tables for input/output
```

See also $title.

$stop

Syntax:

```
$stop [text]
```

This option stops program compilation without creating an error. Note there is a difference to the option $exit. If there is only one input file, `$stop` and `$exit` will have the same effect. In an include file the option $exit acts like an end-of file on the include file. However, the option `$stop` in an include file will cause GAMS to stop reading all input but continue the execution phase of the so far compiled program. The text followed by `$stop` is ignored.

Example:

```
$ifthen not set EXPORTEXCEL
$  stop No export to Excel
$else
$  call gdxxrw ...
$endif
```

See also $abort, $error, $exit, and $terminate.

$sysInclude

The syntax of this dollar control option is equivalent to the syntax of $batinclude:

Syntax:

```
$sysinclude external_file arg1 arg2 ...
```

However, if an incomplete path is given, the file name is completed using the system include directory. By default, the system include directory is set to the GAMS system directory. Note that the default directory may be reset with the command line parameter sysIncDir.

Example:

The only relevant include file in the GAMS system directory is `mpsgeset` for MPSGE models, see for example [**HARMGE**]:

```
$sysInclude mpsgeset KAMIYA
```

Note that this call will first look for the include file `[GAMS System Directory]/mpsgeset`. If this file does not exist, it will looks for `[GAMS System Directory]/mpsgeset.gms`. The argument `KAMIYA` is passed on to the include file and are interpreted as explained for the dollar control option $batInclude.

Consider the following example:

```
$sysInclude C:\Users\default\Documents\mpsgeset KAMIYA
```

This call will first look specifically for the include file `C:\Users\default\Documents\mpsgeset` and next for `C:\Users\default\Documents\mpsgeset.gms`.

See also $batInclude.

$terminate

Syntax:

```
$terminate [text]
```

This option terminates compilation and also does not execution to program compiled so far without giving an error.

Example:

```
$if set JUSTTERMINATE $terminate
```

See also $abort, $error, $exit, and $stop.

$title

Syntax:

```
$title text
```

This option sets the title in the page header of the listing file to `text`. Note that the next output line will appear on a new page in the listing file.

Example:

```
$title  Production Planning Model
$sTitle Set Definitions
```

See also $sTitle.

$unLoad

Syntax:

```
$unLoad [sym1[,] sym2=gdxSym2[,] ...]
```

This option unloads specified items to a GDX file. Note that `$unLoad` must be used in conjunction with the option $gdxOut: `$gdxOut` must precede `*$unLoad*`. More than one option `$unload` may appear in between. Symbols can be renamed via the `sym=GDXSym` syntax. A `$unLoad` without arguments unloads the entire GAMS database into the GDX file.

Example: Consider the following slice of code:

```
Sets i   'canning plants'   / seattle, san-diego /
     j   'markets'          / new-york, chicago, topeka / ;

Parameters
     a(i)  'capacity of plant i in cases'
       /    seattle     350
            san-diego   600  /

     b(j)  'demand at market j in cases'
       /    new-york    325
            chicago     300
            topeka      275  / ;

Table d(i,j)  'distance in thousands of miles'
                    new-york       chicago      topeka
     seattle           2.5           1.7          1.8
     san-diego         2.5           1.8          1.4  ;

$gdxOut tran
$unLoad i j=k
$unLoad b=dem a=sup
$unLoad d
$gdxout tranX
$unLoad
```

Note that the last lines will create a file named `tran.gdx` that contains `i`, `j` (now named `k`) and `d` and the parameters `a` and `b` which are now named `dem` and `sup`. The `$unLoad` in the very last line creates a GDX file `tranX.gdx` with all symbols (with their original names). The table of content (via `$gdxIn` and `$load` without parameters) of these two files looks as follows:

```
Content of GDX C:\Users\default\Documents\gamsdir\projdir\tran.gdx
              5 UELs

    Number Type       Dim       Count  Name
         1 Set          1           2  i           canning plants
         2 Set          1           3  k           markets
         3 Parameter    1           3  dem(j)      demand at market j in cases
         4 Parameter    1           2  sup(i)      capacity of plant i in cases
         5 Parameter    2           6  d(i,j)      distance in thousands of miles

Content of GDX C:\Users\default\Documents\gamsdir\projdir\tranX.gdx
              5 UELs

    Number Type       Dim       Count  Name

         1 Set          1           2  i           canning plants
         2 Set          1           3  j           markets
         3 Parameter    1           2  a(i)        capacity of plant i in cases
         4 Parameter    1           3  b(j)        demand at market j in cases
         5 Parameter    2           6  d(i,j)      distance in thousands of miles
```

Both listings show domain information for the various symbols but only the file `tranX.gdx` created with `$unLoad` without arguments has consistent or *full* domain information while `tran.gdx` may have inconsistent or *relaxed* domain information. Domain matching when loading with the `$load sym<[=]symGDX`, see $load for details, can be used in both cases but can become subtle with the relaxed domain information from `tran.gdx`.

Starting with GAMS 34 the behavior of `$gdxOut` and `$unload` changed compare to previous versions. In order to write consistent domain information and write aliases as such, the actual writing of the symbols to GDX is *delayed* until the GDX files is about to be closed either through an explicit `$gdxOut` (potentially with a another filename) or through the end of the compilation phase. The advantage of the delayed writing is that the compiler can now better analyze the symbols and e.g. write alias symbols as aliases with the aliased set is also written to the GDX file (aliases were always written as sets before GAMS 34).

This new behavior can result in different GDX files. Here are two examples:

```
Set i /1,2,3/; Parameter p(i);
$gdxOut x.gdx
$unload
Parameter p(i) /1 1, 2 2, 3 3/;
```

In the GAMS versions before 34 the export GDX happened when the compiler processed the `$unload` command. At this point the parameter `p` did not have any data yet, so the GDX symbol `p` had no records. With the new behavior, the actual writing happens when the GDX file will be closed. Since there is no explicit close via a `$gdxOut` the GDX file is closed at the end of the compilation phase. By then the compiler has processed the statement `Parameter p(i) /1 1, 2 2, 3 3/;` and has filled `p` with data that will show up in the GDX file. In such a case an explicit `$gdxOut` after the `$unload` helps to get the old behavior back.

```
Set i /1,2,3/; Parameter p(i) / 1 1/;
$gdxOut x.gdx
$unload p=p1
$onmulti
Parameter p(i) / 2 2/;
$unload p=p2
```

In the GAMS versions before 34 the GDX file `x.gdx` contains two parameters `p1` with record `1 1` and `p2` with record `1 1, 2 2`. With the new behavior the symbols are written again at the end of the compilation phase and by then the parameter `p` has the records `1 1, 2 2` and will write to GDX the parameters `p1` and `p2` with the two records each. The only way to accomplish the old behavior in this case is to write `p1` and `p2` to different GDX files:

```
Set i /1,2,3/; Parameter p(i) / 1 1/;
$gdxOut x1.gdx
$unload p=p1
$gdxOut x2.gdx
$onMulti
Parameter p(i) / 2 2/;
$unload p=p2
```

This delayed writing also influence other options like $onEpsToZero. The state of this becomes relevant when the file is actually written, not when a symbol is added to the list of symbols to be exported with `$unload`. This can be seen in the following example:

```
Set       i      / i1*i3 /;
Parameter p1(i)  / i1 0, i2 EPS, i3 1  /
          p2(i)  / i1 0, i2 EPS, i3 1  /;

$gdxOut out.gdx
$onEpsToZero
$unload p1
$offEpsToZero
$unload p2
$gdxOut

$call.checkErrorLevel gdxdump out.gdx
```

Here is the output from `gdxdump` at the end:

```
Parameter p1(*) /
'i2' Eps,
'i3' 1 /;

Parameter p2(*) /
'i2' Eps,
'i3' 1 /;
```

$use205

Syntax:

```
$use205
```

This option sets the GAMS syntax to the syntax of Release 2.05. This is mainly used for backward compatibility. New keywords have been introduced in the GAMS language since Release 2.05. Models developed earlier that use identifiers that have since become keywords will cause errors when run with the latest version of GAMS. This option will allow to run such models.

Example:

```
$use205
Set if /1.2.3/;
Scalar x ;
```

The word "if" is a keyword in GAMS that was introduced with the first version of Release 2.25. Setting option `$use205` allows "if" to be used as an identifier since it was not a keyword in Release 2.05.

$use225

Syntax:

```
$use225
```

This option sets the GAMS syntax to the syntax of the first version of Release 2.25. This is mainly used for backward compatibility. New keywords have been introduced in the GAMS language since the first version of Release 2.25. Models developed earlier that use identifiers that have since become keywords will cause errors when run with the latest version of GAMS. This option will allow to run such models.

Example:

```
$use225
Set for /1.2.3/;
Scalar x ;
```

The word "for" is a keyword in GAMS that was introduced with the later versions of Release 2.25. Setting option `$use225` allows "for" to be used as an identifier since it was not a keyword in the first version of Release 2.25.

$use999

Syntax:

```
$use999
```

This option sets the GAMS syntax to the syntax of the latest version of the compiler. Note that this setting is the default.

Example:

```
$use225
Set for /1.2.3/;
Scalar x ;
$use999
for (x=1 to 3, display x) ;
```

Note that the word "for" is used as a set identifier after setting the option `$use225` and later the keyword `for` is used in a looping construct after having set the language syntax to that of the latest version using the option `$use999`.

$version

Syntax:

```
$version n
```

This issues a compilation error if `n` is greater than the current GAMS version. This can be useful to ensure that a model is run only with new versions of GAMS, because, e.g., a particular feature which did not exist in older versions is needed.

Example:

```
* With GAMS 24.8.1 the function numCores was added to the system.
* Make sure, that we use this GAMS version or newer.
$version 248

Scalar nc "Number of cores";
nc = numCores;
Display nc;
```

$warning

Syntax:

```
$warning text
```

This dollar control option issues a compilation warning to the log and listing but continues compilation and execution.

Example

```
$ifthen not set INPUTFILE
$ set INPUTFILE default.txt
$ warning Using default INPUTFILE "default.txt". Use --INPUTFILE=myfile.txt to overwrite default
$endif
```

The GAMS log file will issue a warning:

```
*** Error 332 in C:\Users\default\Documents\gamsdir\projdir\myinput.gms
    $Warning encountered - see listing for details
```

with the details in the listing file:

```
   3  $ warning Using default INPUTFILE "default.txt". Use --INPUTFILE=myfile.txt to overwrite d
****       $332
```

4.41.4 Conditional Compilation

GAMS offers several dollar control options that facilitate conditional compilation. In this section we will first introduce the general syntax, present an overview of all relevant options and list the conditional expressions that may be used to perform tests. Then we will give several examples to illustrate how these options are used and to demonstrate their power. This section is meant as an introduction to conditional compilation in GAMS and complements the detailed descriptions of the dollar control options listed in Table 1 below.

4.41.4.1 Conditional Compilation: General Syntax and Overviews

The dollar control option `$if` and its variants provide a great amount of control over conditional processing of the input file(s). The syntax in GAMS is similar to the `IF` statement of the DOS Batch language:

```
$if [not] <conditional expression> new_input_line
```

The dollar control statement begins with `$if`. Note that `$if` may be replaced by one of its variants that are listed in Table 1 below. The operator `not` is optional and makes it possible to negate the `conditional expression` that follows. The conditional expression may take various forms, a complete list is given in Table 2. The result of the conditional test is used to determine whether to process or not the remainder of the line, `new_input_line`, which may be any valid GAMS input line.

Attention

The first non-blank character on the line following the conditional expression is considered to be the first column position of the GAMS input line. Therefore, if the first character encountered is the dollar control character, the line is treated as a dollar control line. Likewise, if the first character encountered is a comment character (default: *) the remainder of the line is treated as a comment line. If a multiplication is to be performed in the true clause instead of a comment, the $ifThen condition needs to be used:

```
$setglobal mult on
Scalar P_test;
P_test = 10
$iftheni %mult%==on
  * 5
$endif
;
```

Alternatively, the `new_input_line` may be placed in the next line. The corresponding syntax follows:

```
$if [not] <conditional expression>
new_input_line
```

Note that in this version the space after the conditional expression is left blank. If the conditional is found to be false, either the remainder of the line (if any) will be skipped or the next line will not be processed.

The overviews in Table1 and Table 2 conclude this subsection. Examples are given in the next subsection.

Table 1: $*if and Related Dollar Control Options*

Dollar Control Option	Description
$if	This option is used to do case sensitive comparisons. Several examples are given in the next subsection.
$ifE	This variant does the same as $if but allows numerical constant expression evaluation. For an example, see the detailed description of this option.
$ifI	This variant is the same as $if, but it is case insensitive.
$ifThen	This variant controls whether a block of statements will be processed or not. It is used to do case sensitive comparisons. Most often it is followed by one or more of the following dollar control options: $else, $elseIf, $elseIfI, $elseIfE. The option `$ifThen` must be matched with the option $endIf that marks the end of the block. An example is given below.
$ifThenE	This is a variant of `$ifThen` and is used for numerical comparisons. Like `$ifThen`, it is often followed by the option $else or one of its variants and must be matched with the option $endIf that marks the end of the construct.
$ifThenI	This is a variant of `$ifThen` and is used to do case insensitive comparisons. Like `$ifThen`, it is often followed by the option $else or one of its variants and must be matched with the option $endIf that marks the end of the construct.
$endIf	This option must be matched with a preceding option $ifThen, $ifThenE or $ifThenI and marks the end of the `if - then` construct. Note that the option `$endIf` is *not* followed by a conditional expression, but it may be follwowed by a `new_input_line`. This GAMS input is restricted to other dollar control statements. An example is given below.

Dollar Control Option	Description
$else	This option follows the option $ifThen, $ifThenE or $ifThenI. It is followed by an instruction which is executed if the conditional expression of the matchining `$ifThen` statement is not true. Note that therefore this dollar control statement does *not* contain a conditional expression. An example is given below.
$elseIf	This option follows the option $ifThen, $ifThenE or $ifThenI. It is follwed by another conditional expression and instruction. Note that this option is case sensitive. An example is given below.
$elseIfE	This is a variant of $elseIf that evaluates numerical values.
$elseIfI	This is a variant of $elseIf that is case insensitive.

Table 2: ***Conditional Expressions in Conditional Compilation***

Conditional Expression	Description
`acrType id`	True if `id` is an acronym.
`decla_OK`	True if a declaration statement is permitted in the current line. Note that declaration statements are not permitted within programming flow control structures like if statements or loop statements. An example is given below.
`declared id`	True if `id` was declared.
`defined id`	True if `id` was defined. An example is given below.
`dExist directoryname`	True if a directory with the name `directoryname` exists.
`dimension n id`	True if `id` has `n` dimensions. Note that `n` may take values from 0 to maximum number of possible indexes (see Dimensions).
`equType id`	True if `id` is an equation.
`errorFree`	True if compilation up to this point has been free of errors.
`errorLevel n`	True if the return code of a program called via $call is equal to or larger than `n`. For lists of GAMS return codes, see chapter GAMS Return Codes. An example is given below.
`exist filename`	True if a file with the name `filename` exists and is readable in the working directory or an input file directory. If no extension is specified, also `filename.gms` is checked. An example is given below.
`filType id`	True if `id` is the name of a put file.
`funType id`	True if `id` is a GAMS function.
`gamsVersion n`	True if current GAMS version is greater than or equal to `n`. GAMS versions are referenced with a single number. For example, if it should be tested whether the current GAMS version is 24.7 or newer, `n` will equal 247. Maintenance version numbers, e.g. 24.7.**4** do not count.
`gdxDimension n id`	True if `id` exists in a GDX file previously opened with $gdxIn and has `n` dimensions. Note that `n` may take values from 0 to maximum number of possible indexes (see Dimensions).
`gdxEquType id`	True if `id` exists in a GDX file previously opened with $gdxIn and is an equation.
`gdxParType id`	True if `id` exists in a GDX file previously opened with $gdxIn and is a parameter.
`gdxSetType id`	True if `id` exists in a GDX file previously opened with $gdxIn and is a set.
`gdxSymExist id`	True if `id` exists in a GDX file previously opened with $gdxIn.
`gdxVarType id`	True if `id` exists in a GDX file previously opened with $gdxIn and is a variable.
`macType id`	True if `id` is a macro.

Conditional Expression	Description
`modType id`	True if `id` is a model.
`onState key`	True if the state of `key` is `on` (i.e. activated by `$onKey`). An example is given below.
`parType id`	True if `id` is a parameter.
`preType id`	True if `id` is a one of the predefined symbols in GAMS. Details are given below.
`putOpen`	True if both a file statement and at least one put statement have been compiled. Note that this does not guarantee that a file will be open at runtime.
`readable id`	True if `id` was correctly initialized, i.e. the symbol has a data statement or appeared on the left-hand side of an assignment statement, and may therefore be used on the right-hand side of an assignment statement. An example is given below.
`set varname`	True if the scoped compile-time variable `varname` was set with the dollar control option $set, $setGlobal or $setLocal.
`setEnv varname`	True if the environment variable `varname` was set in the systems environment, e.g. with the dollar control option $setEnv.
`setGlobal varname`	True if the control variable `varname` was set with the dollar control option $setGlobal.
`setLocal var_name`	True if the control variable `var_name` was set with the dollar control option $setLocal.
`setType id`	True if `id` is a set.
`solver solver_name`	True if a solver named `solver_name` exists in the GAMS system. An example is given below.
`uelExist id`	True if unique element `id` exists in current GAMS database.
`varType id`	True if `id` is a variable.
`warnings`	True if the compilation until this point has been free of warnings.
`xxxType id`	True if `id` is an unknown type. For more information, see below.
`string1 == string2`	True only if `string1` matches `string2` exactly. Note that the strings may be quoted or unquoted. Null (empty) strings may be indicated by an empty quote: `""` or `''`. The case of the strings provided either explicitly or, more likely, through a parameter substitution, is preserved and therefore will affect the string comparison. Quoted strings with leading and trailing blanks are not trimmed and the blanks are considered part of the string. Note that the string may have the form `%VARNAME%`, where `VARNAME` refers to a compile-time variable including GAMS command line parameters and system attribute. An example for a string comparison with a command line parameter is given below. An example for a string comparison with a system attribute is given below.
`string`	True only if `string` is an empty string (`""` or `''`), otherwise False.

4.41.4.2 Conditional Compilation: Examples

File Operation Test

The operator `exist` may be used to test whether a given file name exists. Consider the following example:

```
$if exist myfile.dat $include myfile.dat
```

Observe that the effect of this dollar control statement is that the file `myfile.dat` is included if it exists. Note that the character `$` at the beginning of the option $include is the first non-blank character after the conditional expression `exist myfile.dat` and therefore it is treated as the first column position. The statement above may also be written as follows:

```
$if exist myfile.dat
$include myfile.dat
```

Conditional Compilation and Batch Include Files

In the next example we will illustrate how the option `$if` is used inside a batch include file where parameters are passed through the option $batInclude from the parent file:

```
$if not "%1a" == a $goto labelname
$if exist %1 file.ap=1;
```

Note that in the first line the `$if` condition uses the string comparison `"%1a" == a` to check if the parameter is empty. This test may also be done in the following way: `%1 == ""`. If the parameter is not empty, the option $goto is processed.

Note

> The option $label cannot be part of the conditional input line. However, if the option $label appears on the next line, the condition decides once if the label is placed or not and subsequent instances of `$goto` will find the label without reevaluating the condition.

The second line illustrates the use of standard GAMS statements if the conditional expression is valid. If the file name passed as a parameter through the $batInclude call exists already, the GAMS will execute the `file.ap=1;` statement which will append to the file.

The next example demonstrates how an unknown number of file specifications may be passed on to a batch include file that will include each of them if they exist. The batch include file could look as follows:

```
* Batch Include File - inclproc.gms
* include and process an unknown number of input files
$label nextfile
* Quote everything because file name might have blanks
$if exist "%1"  $include "%1"
$shift
$if not "%1a" == a $goto nextfile
```

The call to this file in the parent file could take the following form:

```
$batInclude inclproc "file 1.inc" file2.inc file3.inc file4.inc
```

Testing Whether an Item Has Been Defined

The next example shows how to test if a named item was declared and/or defined.

```
Set i;
$if defined  i $log First: set i is defined
$if declared i $log First: set i is declared
Set i /seattle/;
$if defined  i $log Second: set i is defined
$if declared i $log Second: set i is declared
```

Note that after the first declaration of `i` only `declared i` evaluates to true when after the second declaration with a data statement both `defined i` and `declared i` are true.

Testing the state of a flag set by a dollar control option

The expression `onState key` tests whether the state of `key` is `on`. So the following example could be done with any `key` available as a `$(on|off)Key` dollar control option:

```
$if onState listing $log Listing is active at checkpoint 1
$if onState listing $set reactivateListing
$offListing
* Do something which should not be seen in the listing
$if onState listing $log Listing is active at checkpoint 2
* Reactivate listing if it was active at the start only
$if set reactivateListing $onListing
$if onState listing $log Listing is active at checkpoint 3
```

Testing Whether an Item May Be Used in an Assignment

The expression `readable id` tests whether data were assigned to an item and therefore the item may be used on the right-hand side of an assignment statement. Consider the following example:

```
Scalar f;
$if not readable f $log f cannot be used on the right
Scalar f /1/;
$if readable f $log f can be used on the right
$kill f
$if not readable f $log f cannot be used on the right after clear
f = 1;
$if readable f $log f can be used on the right after assignment
```

Note that in the first test the set `f` was declared, but there was no data statement, hence it is not `readable`. After a declaration with a data statement the test `readable f` evaluates to `TRUE`. With $kill we can revert `f` to a data less state and hence `not readable f` is `TRUE` after the "$kill". The assignment statement `f = 1;` make the scalar `f` readable again.

Testing Whether an Identifier May Be Declared

In programming flow control structures, like if statements or loop statements declaration statements are not permitted. The test `decla_ok` may be used to test whether the current environment allows declaration statements. Consider the following example:

```
$if decla_ok $log declarations are possible
if(1,
$  if not decla_ok $log declarations are not allowed
);
```

Note that the conditional expression in the both `$if` tests will evaluate to `TRUE`. However, the second test of `decla_ok` itself will be `FALSE` because it is processed while compiling an `if` statement, but with the `not` the entire expression evaluated to `TRUE`. For more information, see chapter Programming Flow Control Features.

Comments in the Context of Conditional Compilation

In-line and end-of-line comments are stripped out of the input file before processing the `new_input_line`. If either of these forms of comments appear, they will be treated as blanks. Consider the following example:

```
Parameter a ;
a=10 ;
$eolCom // inlineCom /*  */
$if exist myfile.dat  /* in line comments */  // end of line comments
a = 4 ;
display a;
```

Note that the comments on line 3 are ignored and the fourth line with the assignment statement will be processed if the conditional expression is true Hence the outcome generated by the display statement will list `a` with a value of 4 if the file `myfile.dat` exists and a value of 10 if the file does not exist.

Error Level Test

Consider the following example:

```
$call gams mymodel.gms lo=2
$if errorlevel 1 $abort one or more errors encountered
```

Note that the errorlevel is retrieved from the previous system call via $call. The conditional statement `errorlevel 1` is true if the returned errorlevel is equal to or larger than 1. In case of calling GAMS this means that something was not quite right with the execution of GAMS (either a compilation or execution error or other more exotic errors, see GAMS return codes. If this is the case, this GAMS program will be aborted immediately at compilation time.

Usually programs return 0 on success and non-zero on failure. The `$if errorlevel 1` checks for strictly positive return codes. There are rare cases with failures and negative return codes (e.g. on Windows if some DLL dependencies of the program can't be resolved). In such a case `$if errorlevel 1` will evaluate to false and not continue with the `$abort` instruction. It might be better to access the program return code via the errorLevel function in the following way:

```
$call gams mymodel.gms lo=2
$ifE errorLevel<>0 $abort one or more errors encountered
```

Solver Test

The following example illustrates how to check if a solver exists.

```
$if solver ZOOM
```

Note that the conditional expression is false since the solver named ZOOM does not exists in the GAMS system (anymore).

Command Line Parameters in String Comparison Tests

Assume we include the following dollar control statements in a GAMS file called myfile.gms:

```
$if not '%gams.ps%'==''  $log Page size set to  %gams.ps%
$if not '%gams.pw%'==''  $log Page width set to %gams.pw%
$if not '%gams.mip%'=='' $log MIP solver default is %gams.mip%
```

Then we run the program with the following call:

```
> gams myfile pageSize=60  pageWidth=85 mip=cbc
```

Note that we specified values for the command line parameters pageSize, pageWidth, and MIP. We can either use the short or long name on the command line and in the compile-time variable. If we do not specify the option on the command line we will get the default value for option page size and page width. The MIP solver line will not show because %gams.mip% remains empty. The log with option setting on the command line will include the following lines:

```
Page size set to  60
Page width set to 85
MIP solver default is cbc
```

Command line parameters are introduced in chapter The GAMS Call and Command Line Parameters.

System Attributes in String Comparison Tests

Compile-time system attributes may also be used in string comparison tests. The system attribute that is most useful in this context is .fileSys. It identifies the name of the operating system being used. Consider the following example:

```
$ifthen not %gams.logOption%==3
$  ifi %system.fileSys%==UNIX  $set nullFile > /dev/null
$  ifi %system.fileSys%==MSNT  $set nullFile > nul
$  if not set nullFile $abort %system.fileSys% not recognized
$else
$  set nullFile
$endif
$call gamslib trnsport %nullFile%
```

These dollar control statements allow the definition of a NULL file destination that is dependent on the operating system that is being used. Note that the control variable nullFile contains an operating-system-dependent name. This is useful when making an external program that writes to STDOUT quiet in case the GAMS log does not go to STDOUT (logOption=3). This example could also have used the system attribute %system.nullFile% which contains the operating-system-dependent NULL file destination:

```
$set nullFile
$if not %gams.logOption%==3 $set nullfile > %system.nullFile%
$call gamslib trnsport %nullfile%
```

System attributes in general are introduced in chapter System Attributes.

Conditional Compilation with $ifThen and $else

Consider the following example which illustrates the use of `$ifThen`, `$elseIf`, `$else` and `$endif`:

```
$set x a
$label test
$ifThen %x% == a $set x 'c' $log $ifThen   with x=%x%
$elseIf %x% == b $set x 'k' $log $elseIf 1 with x=%x%
$elseIf %x% == c $set x 'b' $log $elseIf 2 with x=%x%
$else            $set x 'e' $log $else     with x=%x%
$endIf $if not %x% == e $goTo test
```

Note that the resulting log file will contain the following lines:

```
$ifthen   with x=a
$elseif 2 with x=c
$elseif 1 with x=b
$else     with x=k
```

Observe that the options `$else` and `$endIf` are not followed by conditional expressions and the instruction following the option `$endIf` contains a dollar control statement. Moreover, note that the '$set x 'c' has the text to be set in quotes. GAMS needs to know where the text ends and the next dollar control option (in this case $log`) starts.

Type of Identifiers

The type of a symbol can be retrieved via `$if ...Type`. Consider the following example:

```
Set diag / 1*3 /;
Parameter p(diag) / 1 1, 2 4, 3 8 /;
$if     setType diag    $log diag   is a set
$if not varType diag    $log diag   is not a variable
$if     preType diag    $log diag   is a predefined type
$if     parType p       $log p      is a parameter
$if     setType sameAs  $log sameAs is a set
$if     preType sameAs  $log sameAs is a predefined type
```

Note that for predefined symbols more than one type applies (e.g. `sameAs` is of set and predefined type). Please also note that `diag` is a set even though there is a predefined symbol named `diag` but that becomes invisible with a user defined symbol with the same name.

Normally there is no way to get a symbol into the GAMS symbols table without a proper type. However, if the dollar command line parameter multiPass is set to a value larger than zero, then the compiler will just check for some integrity and will try to deduce the symbol type from the context. If it is not able to do so, the symbol type will remain unknown. For example, compiling the following lines with `multiPass=1`

```
display x;
$if xxxType x $log x is of unknown type
```

result in the line `x is of unknown type` in the GAMS log.

4.41.5 Macros in GAMS

Macros are widely used in computer science to define and automate structured text replacements. The GAMS macro processors function similarly to the popular C/C++ macro preprocessor. Note that the GAMS macro facility has been inspired by the [GAMS-F] (http://www.mpsge.org/inclib/gams-f.htm) preprocessor for function definition developed by Michael Ferris, Tom Rutherford and Collin Starkweather, 1998 and 2005. The GAMS macro facility incorporates the major features of the GAMS-F preprocessor into the standard GAMS release as of version 22.9. GAMS macros act like a standard macro when defined. However, their recognition for expansion is GAMS syntax driven.

4.41.5.1 Syntax and Simple Examples

The definition of a macro in GAMS takes the following form:

```
$macro name  macro_body
$macro name(arg1,arg2,arg3,...) macro_body with tokens arg1, ...
```

The dollar symbol `$` followed by `macro` indicate that this line is a macro definition. The name of the macro has to be unique, similar to other GAMS identifiers like sets and parameters. The macro name is immediately followed by a list of replacement arguments `arg1,arg2,arg3,...` that are enclosed in parentheses. The macro body is not further analyzed after removing leading and trailing spaces.

The recognition and following expansion of macros is directed by GAMS syntax. The tokens in the macro body to be replaced by the actual macro arguments follow the standard GAMS identifier conventions. Consider the following simple example of a macro with one argument:

```
$macro reciprocal(y) 1/y
```

Here the name of the macro is `reciprocal`, `y` is the argument and the macro body is `1/y`. This macro may be called in GAMS statements as follows:

```
$macro reciprocal(y) 1/y
scalar z, x1 /2/, x2 /3/;
z = reciprocal(x1) + reciprocal(x2);
```

As GAMS recognizes `reciprocal(x1)` and `reciprocal(x2)` as macros, the assignment statement will expand to:

```
z = 1/x1 + 1/x2;
```

Note that the macro use cannot be spread over multiple lines. Single line use with more complex arguments as in

```
z = reciprocal(x1+x2);
```

is recognized and will expanded to:

```
z = 1/x1+x2;
```

Note that z will be equal to 3.5 in this example as division takes precedence over addition. But breaking the argument of the macro over multiple lines as follows will trigger a macro expansion error:

```
z = reciprocal(x1
              +x2);
```

The next example illustrates macros with multiple arguments:

```
$macro ratio(x,y) x/y
scalar z, x1 /2/, x2 /3/;
z = ratio(x1,x2);
```

The assignment above will expand to:

```
z= x1/x2;
```

Note that the macro definition may extend over several lines with the symbol '\' acting as a continuation string. Consider the following example:

```
$macro myxor(a,b)  (a or b) \
               and (not a or not b)
scalar z;
z = myxor(1,0);
display z;
```

The z assignment expands to

```
z = (x1 or x2) and (not x1 or not x2);
```

Note that although the macro has been defined over two lines, the expansion happens by combining the lines after stripping leading white spaces of the second line as demonstrated in the next example (because and has a higher precedence than or we can omit the parenthesis):

```
$macro myxor(a,b)  not a and b \
                or a and not b
scalar z;
z = myxor(1,0);
display z;
```

The z assignment expands to this:

```
z = not 1 and 0 or 1 and not 0;
```

The &, explained in more detail in the next section can be used to preserve (some of the) leading white spaces (but not the line breaks) if that is desired:

```
$macro myxor(a,b)  not a and b \
       &        or a and not b
```

4.41.5.2 Nested Macros

Macros may be nested. Consider the following example:

```
$macro product(a,b) a*b
$macro addup(i,x,z) sum(i,product(x(i),z))
set j /j1*j10/;
Parameter a1(j) / #j 1 /, z, x1 /5/;
z = addup(j,a1,x1);
```

Observe that the macro `product` is nested in the macro `addup`. The assignment will expand to:

```
z = sum(j,a1(j)*x1);
```

Note that nested macros may result in an expansion of infinite length. An example follows.

```
$macro a  b,a
display a;
```

This will expand into:

```
display b,b,b,b,b,b,b,b,b,b,b,b,b,b,b,b,b,...
```

In such a case GAMS will eventually refuse to do more substitutions and will issue a compilation error:

```
732  Too many edits on one single line - possible recursion in macro calls
        compilation will be terminated
```

4.41.5.3 Ampersands in Macro Definitions

The expansion of arguments may be more carefully controlled by the use of ampersands `&` in the macro body. A single ampersand `&` is used as a concatenation or separation symbol to indicate tokens that are to be replaced. Consider the following example:

```
$macro  f(i)  sum(j, x(i,j))
$macro equ(q)  equation equ_&q;  \
               equ_&q.. q =e= 0;
set i /i/, j /j/;
variable x(i,j);
equ(f(i))
```

This will expand into:

```
equation equ_f(i);equ_f(i).. sum(j, x(i,j)) =e= 0;
```

Note that without the ampersand notation, GAMS would have recognized only the third occurrence of `q` and hence the expansion would have been:

```
equation equ_q;equ_q.. sum(j, x(i,j)) =e= 0;
```

Two ampersands `&&` immediately preceding a token will drop the most outer matching single or double quotes of the replacement argument. This makes it possible to include expressions with spaces, commas and unbalanced parentheses. The latter one is something users should really avoid doing. An example follows.

```
$macro d(q) display &&q;
$macro ss(q) &&q)
set i /i/, k /k/;
parameter a1(i) / i 1/, z;
d('"here it is" , i,k')
d('"(zz"')
z=ss('sum(i,a1(i)');
z=ss('prod(i,a1(i)');
```

Note that the expressions `d` contain quotes, spaces and commas and the expression `ss` has unbalanced parentheses within the quoted parts. In turn these expand to become:

```
display "here it is" , i,k;
display "(zz";
z=sum(i,a1(i));
z=prod(i,a1(i));
```

4.41.5.4 Additional Macro Features

Deeply nested macros may require aliased sets in indexed operations like `sum` and `prod`. A minor syntax extension allows the implicit use of aliases. The suffix `.local` on a controlling set will use an implicit alias within the scope of the indexed operation. Consider the following example:

```
$macro ratio(a,b) a/b
$macro total(q) sum(i,q(i))
set i /i1*i15/;
parameter a(i) / #i 1 /, b(i) / #i 2 /, r(i), asum;
asum = total(a);
r(i) = ratio(total(a), b(i));
```

The assignment statement will expand to:

```
asum = sum(i,a(i));
r(i) = sum(i,a(i))/b(i);
```

The second line will not compile because the `i` in the sum is already controlled from the `i` on the left. The intention was the `total` macro is to add up the elements of a parameter indexed over `i`. As in the `r(i)` assignment the macro might be used in a statement where `i` is already controlled hence when doing the `sum` in the macro we want to use an alias of `i`. If we change the macro definition to

```
$macro total(q) sum(i.local,q(i))
```

The code works as expected because the `i` in the sum refers to the `i.local` and not the outside `i`.

Note that the the modifier `.local` is not limited to macros and may be used in any context. For further details and more examples, see the detailed description of the dollar command option $on/offLocal.

Another feature of macros is the implicit use of the suffix `.L` in report writing and other data manipulation statements. This allows using the same algebra in model definitions and assignment statements. The following code illustrates this feature:

```
$macro sumIt(i,term) sum(i,term)
cost ..        z  =e=  sumIt((i,j), (c(i,j)*x(i,j))) ;
supply(i) ..   sumIt(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sumIt(i, x(i,j))  =g=  b(j) ;
Model transport /all/ ;
solve transport using lp minimizing z ;
Parameter tsupply(i) total demand for report
          tdemand(j) total demand for report;
$onDotL
tsupply(i)=sumIt(j, x(i,j));
tdemand(j)=sumIt(i, x(i,j));
```

The option $onDotL enables the implicit suffix `.L` for variables. This feature was introduced for macros with variables to be used in equation definitions as well as assignment statements. The matching option $offDotL will disable this feature. Similarly, $offDotScale will access the `.scale` suffix of a variable or equation in an assignment statement.

Three more switches are relevant to macros. The option $show will list any GAMS macros defined. The option $on/$offMacro will enable or disable the expansion of macros; the default is `$onMacro`. Finally, the option $on/offExpand will change the processing of macros appearing in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch `$onExpand` enables the recognition and expansion of macros in the macro argument list. The option `$offExpand` will restore the default behavior.

Note that macro definitions are preserved in a save/restart file and are available again for a continued compilation.

Summarizing, macros shares the name space of GAMS symbols, like sets, parameters, variables, etc. Macros are recognized and expanded anywhere a proper GAMS identifier may be used. This may be suppressed with the option $on/offMacro. The body of macros is only used during expansion. Hence, macro definitions are not order dependent. Variables in macro bodies will have an implicit suffix `.L` when they are used in assignment statements. This GAMS feature needs to be activated with the option $onDotL.

4.41.6 Compressing and Decompressing Files

GAMS provides two dollar control options for compressing and decompressing GAMS input files:

Dollar Control Option	Description
$compress <source> <target>	The file `source` is compressed into the packed file `target`.
$decompress <source> <target>	The compressed file `source` is decompressed into the unpacked file `target`.

Attention

Spaces are interpreted as separators between the source and target file names, hence quotes (single or double) have to be used if the file names contain spaces.

Note that GAMS will recognize whether a file is compressed and will processes it accordingly.

Note

Like any other GAMS input files, all compressed files are platform-independent.

4.41.6.1 Compressing and Decompressing Files: A Simple Example

We use the well-known transportation model [**TRNSPORT**] to illustrate. First we copy the model from the GAMS Model Library and then we create a compressed version of the original:

```
> gamslib trnsport
> echo $compress trnsport.gms t1.gms > t2.gms
> gams t2
```

Alternatively, the following code snippet may be used from within a GAMS file:

```
$call 'gamslib trnsport'
$compress trnsport.gms t1.gms
$include t1.gms
```

Note that the compressed input file `t1.gms` can be treated like any other GAMS input file. If it is executed, the listing file will be identical to the listing file of the original input file `trnsport.gms`, since a *decompressed* input is reported in the echo print. As usual, the parts of the model that are marked with the dollar control option $on/offListing will not appear in the echo print.

The compressed file `t1.gms` can be decompressed as follows:

```
> echo $decompress t1.gms. t3.gms > t4.gms
> gams t4
```

Alternatively, from within a GAMS file:

```
$decompress t1.gms t3.gms
```

Observe that the decompressed file `t3.gms` is identical to the original file `trnsport.gms`. This can easily be tested with the following command:

```
> diff trnsport.gms t3.gms
```

4.41.6.2 Compressing and Decompressing Files: The Model CEFILES

The following more elaborate example is self-explanatory. It is adapted from model [**CEFILES**] and can easily be modified to test the use of compressed files.

```
* --- get model
$call gamslib -q trnsport

* --- compress and run model
$compress   trnsport.gms t1.gms
$decompress t1.gms       t1.org
$call       diff trnsport.gms t1.org > %system.nullFile%
$if         errorLevel 1 $abort files trnsport and t1 are different

* --- check to see if we get the same result
$call gams trnsport gdx=trnsport lo=%gams.lo%
$if   errorLevel 1 $abort model trnsport failed
$call gams t1       gdx=t1       lo=%gams.lo%
$if   errorLevel 1 $abort model t1 failed
$call gdxdiff trnsport t1 %system.reDirLog%
$if   errorLevel 1 $abort results for trnsport and t1 are not equal

* --- also works with include files
$echo $include t1.gms > t2.gms
$call gams t2 gdx=t2 lo=%gams.lo%
$if   errorLevel 1 $abort model t2 failed
$call gdxdiff trnsport t2 %system.reDirLog%
$if   errorLevel 1 $abort results for trnsport and t2 are not equal
$terminate
```

4.41.7 Encrypting Files

When models are distributed to users other than the original developers, issues of privacy, security, data integrity and ownership arise. To address these concerns, secure work files may be used and GAMS input files may be encrypted. Note, that the encryption follows the work file security model and requires special licensing.

Note

Like any other GAMS input files, all compressed and encrypted files are platform-independent.

Encryption is only available if a system is licensed for secure work files. There are two way to encrypt a file: Encryption for a particular user group that is identified by a target license file or for a general wide audience. In the prior case the key for encryption and decryption is extracted from the target license (specified by command line parameter pLicense) while for the latter the key for encryption and decryption is passed to GAMS via the command line parameters encryptKey and decryptKey. Note that once a file has been encrypted it cannot be decrypted any more. GAMS provides the following dollar control option to encrypt an input file:

```
$encrypt <source> <target>
```

Here the name of the input file to be encrypted is `source` and the name of the resulting encrypted file is `target`.

4.41.7.1 Encrypting Files: A Simple Example

We use again the transportation model [**TRNSPORT**] to illustrate. First we copy the model from the GAMS Model Library and then we create an encrypted version of the original via a target license:

```
> gamslib -q trnsport
> echo $encrypt trnsport.gms t1.gms > t2.gms
> gams t2 pLicense=target lo=%gams.logOption%
```

Note that the first two lines are similar to the directives that we have used to compress the model above. In the third line, the command line parameter pLicense specifies the target or privacy license to be used as a user key for encrypting. Thus the new encrypted file `t1.gms` is locked to the license key `target` and it can only be executed with the license file `target:`

```
> gams t1 license=target dumpOpt=11
```

Note that the command line parameter license is used to override the default GAMS license file `gamslice.txt` that can be located in various system wide and user locations. Note further that the command line parameter dumpOpt is usually used for debugging and maintenance. The value 11 causes a clean copy of the input to be written to the file `t1.dmp`, where all include files and macros are expanded. Observe that if some lines have been marked with the dollar control options $on/offListing in the original file, then these lines will be suppressed in the file `t1.dmp`.

An alternative approach to encrypt GAMS source file without a target license is done by the pair of command line parameters encryptKey and decryptKey:

```
> gamslib -q trnsport
> echo $encrypt trnsport.gms t1.gms > t2.gms
> gams t2 encryptKey=ThisIsAPasswordSomeoneNeedsToRunTheModel lo=%gams.logOption%
```

In the third line, the command line parameter encryptKey specifies the encryption key. Thus the new encrypted file `t1.gms` is locked and requires this key to successfully decrypt via command line parameter decryptKey:

```
> gams t1 decryptKey=ThisIsAPasswordSomeoneNeedsToRunTheModel
```

Anyother key will result in a failure with the message `Integrity check failed`.

Note

> Once a file has been encrypted, it cannot be decrypted any more. There is no inverse mechanism to recover the original file from the encrypted file. An attempt to decompress it using $decompress will fail.

Observe that decrypting is done on the fly into memory when the GAMS system files are read. GAMS will recognize if a file is just plain text or compressed and/or encrypted and will validate and process the files accordingly.

4.41.7.2 Encrypting Files: The Model ENCRYPT

The following more elaborate example is self-explanatory; it is model [**ENCRYPT**] from the GAMS Model Library.

```
$title Input File Encryption Demo (ENCRYPT,SEQ=318)

$onText
Input files can be encrypted with an encryption key. Either the
privacy license file mechanism or the command line parameter pair
encryptKey/decryptKey can be for managing the password. Similar to
compression, we offer an $encrypt utility to lock any file to a
specific key. Once a file has been encrypted it can only be read
by a gams program that has the matching license file or the matching
decryption key. There is no inverse operation possible: you cannot recover
the original GAMS file from the encrypted version.

To create an encrypted file, we need a license file which has the
security option enabled.

Keywords: GAMS language features, input file encryption

$call grep "this is hidden" t3.lst > %system.nullfile%
$if not errorLevel 1 $abort did not hide in listing
$call grep "this is hidden" t3.dmp > %system.nullfile%
$if not errorLevel 1 $abort did not hide in dump file
```

4.42 The Put Writing Facility

4.42.1 Introduction

While the GDX facility is widely used to exchange bulk GAMS data with other programs the put writing facility allows to generate sophisticated reports in GAMS. The result are external ASCII files that are structured using information that is stored by the GAMS system. The put writing facility offers users numerous ways to control three format layers: the format of the external file that is written to, the format of the pages of the external files and the format of output items. Hence the structure of the put writing facility is more complex and requires more programming than the display statement, but there is much more flexibility and control over the output. The put writing facility generates external files automatically when the GAMS program is executed. The files are written sequentially, a single page at a time. The current page is stored in a buffer, which is automatically written to an external file when the page is full. Thus, the put writing facility has only control over the current page and does not have the ability to go back to alter former pages. However, while a particular page is current, information placed on it may be overwritten or removed at will.

This chapter is organized as follows. We will first introduce the file statement and the put statement, which are at the core of the put writing facility. Then we will present a simple example that will serve as illustration. We will also introduce some widely used features as we comment on the example. The remainder on the chapter will cover in detail the external report files, also called put files, the structure of put file pages and ways to control their format, types of output items and their formatting controls, and the put_utility statement, a variant of the put statement that allows to special communication of formatted elements with the outside

world. In addition, we will briefly discuss exception handling in the context of put statements and GAMS errors that are specific to put statements. We will conclude the chapter with an elaborate example. Note that put file attributes play a crucial role, since they are used for most formatting controls. A complete list of all file attributes is given in section Put File Attributes.

4.42.2 The Syntax

The basic structure of the put writing facility in its simplest form is as follows:

```
File file_name {,file_name};
put file_name;
put item {,item};
```

Note that the first line is a file statement. File statements define one or more external files that will be written to and specify internal names for them. These internal names wil be used in the GAMS model to reference the external files when they are written to. The second line is a put statement that assigns the file with the name `file_name` as the current file. The third line is a put statement that writes one or more items to the current file. Items are any type of output like explanatory text, set labels, parameters, and variable, equation values and model attributes.

Next, we will present more details on the file statement and the put statement in the following two subsections and then we will turn to a first example that will illustrate how the the put writing facility works.

4.42.2.1 The File Statement: Defining Put Files

External files that are written to with the put writing facility are called *put files*. They are defined with a file statement. The syntax for a file statement is as follows:

```
File[s] file_name ["text"] [external_file_name]
  {,file_name ["text"] [external_file_name] } ;
```

The keyword `file` or `files` indicates that this is a file statement. It is follwed by the internal name for the put file, `file_name`. The internal file name is a handle for the put file, it is used in the GAMS model to refer to the put file. The optional explanatory text may be used to describe the put file for future reference and to ease readability. The final part of the file statement is the actual name of the put file. Naming the external file is optional. In case it is omitted, by default, GAMS will create a name by appending the extension `.put` to the internal name. Consider the following example:

```
File results;
```

Note that in this statement no external file name is specified. Thus GAMS will create the external file `results.put` in the current working directory. Observe that by default, all put files are stored in the current working directory. There are several ways to specify alternative directories for put files. For details see section Choosing Where Put Files are Saved below.

Note

Multiple put files may defined with one file statement.

Consider the following example:

```
File  class1
      class2   "this defines a specific external file"  /report.txt/
      log      "this defines access to the GAMS log file" /''/;
```

Observe that the internal name of the first file is `class1`. As no external name is specified, GAMS will assign the absolute name `class1.put` to this file. The second file will be referenced in the model with the name `class2` and it corresponds to the external file `report.txt`. The third file is special: the internal name `''` is reserved for writing output to the GAMS log. Note that writing to the GAMS log can be useful to monitor how the solution process of the model is progressing.

For further details on put files, see section Put Files below.

4.42.2.2 The Put Statement

The put statement is at the core of the put writing facility. It has two different functions: it specifies which of the previously defined put files is the current file and it writes output to that file. The syntax for the first function is simple:

```
put file_name;
```

The keyword `put` indicates that this is a put statement, `file_name` is the internal name of a put file that was previously defined with a file statement. This put statement has the effect that the specified file is now ready to be written to. Note that this put statement is necessary even if only one put file has been previously defined. For an example of how it is used when output is written to several different files, see the next section.

The basic syntax for a put statement that is used to write output to a file is as follows:

```
put item {,item};
```

The statement begins with the keyword `put` followed by one or more items. Items may be a text (like a quoted text, an explanatory text, the name of a set element), a numerical value (like the value of a parameter, the value of an attribute, the solution status of the model) or a set value (`YES` or `NO` indicating whether a label is an element of a specific set). These items are discussed in detail in section Output Items below. In addition, GAMS facilitates writing a *text block* to a put file and including the content of an external file in a put file. For details see sections Text Items: Text Blocks and The Put_Utility Statement respectively.

Note that it is also allowed to use only one put statement to assign one file as the current file *and* write to it. The syntax follows:

```
put file_name item {,item};
```

In addition, it is permitted to use just one put statement to write to multiple files sequentially. Thus the most general form of a put statement is as follows:

```
put file_name item {,item} {,file_name item {,item}};
```

Note that only one file is current at a time. When a file is current, the output items following the name of this file will be written to the file. After this has been completed, the current file is reassigned to the next internal file name in the statement. The last internal file name used in a put statement continues to be the current file until a subsequent put statement uses an internal file name.

Observe that the keyword `put` has several variants: putclose, puttl, puthd, putpage and put_utility.

4.42.3 A First Example

We will use a small example to introduce the basic features of the put writing facility. The example is based on the well-known transportation model [**TRNSPORT**]. The following code segment could be placed at the end of the transportation model to create a report:

```
File factors /factors.dat/,
     results /results.dat/;
put factors;
put 'Transportation Model Factors' / /
    'Freight cost  ', f,
    @1#6, 'Plant capacity'/;
loop(i, put @3, i.tl, @15, a(i)/);
put /'Market demand'/;
loop(j, put @3, j.tl, @15, b(j)/);

put results;
put 'Transportation Model Results' / / ;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 /);
```

In the first line, the file statement defines the internal file names `factors` and `results` and connects them to the external files `factors.dat` and `results.dat` respectively. These internal file names are used inside the model to reference files which are external to the model.

In the second line, the put statement assigns the file `factors` as the current file, that is the file which is currently available to be written to.

In the third line, the put statement starts the actual writing to the put file. The first item that is written is the quoted text string `'Transportation Model Factors'`. The item is followed by two slashes. A slash instructs the cursor to move to the first column of the next line. Two slashes have the effect that the cursor is moved to the first column of the second line, thus introducing a blank line.

Attention

> Two slashes `//` are a popular end of line comment character sequence. So an intended blank line can result in a comment in the GAMS code. A safe way to use slashes in put statement is to separate the slashes by a space.

The next item is the string `'Freight cost '` followed by the value of the scalar `f`. Note that these output items are separated by commas. Blanks and commas serve as delimiters for separating different output items. These delimiters leave the cursor at the next column position in the file following the last item written. In most cases, a blank and a comma may be used interchangeably. However, the comma is the stronger form and will eliminate any ambiguities.

In the fifth line, the code above starts with the instruction `@1#6`. In the context of put statements, the symbols `@` and `#` serve to reposition the cursor to a specific column and row respectively. Thus in our case, the cursor is repositioned to column 1 of row 6 of the put file. Then another text string is written and a new line is started. The semicolon terminates the put statement. More details on cursor positioning are given in section Controlling the Cursor On a Page.

In line 6, the next put statement is embedded within a loop statement. Note that the set `i` is the looping set. The put statement writes at column position 3 the set label name and at column position 15 the value of the parameter `a(i)` for each element of the set `i`. Observe that set element labels are referenced with the name of the set and the suffix `.te`. For more information on identifier suffixes, see section Text Items below. Note that the put statement has to be placed within a looping structure, since only one element of the index set may be written with a put statement.

In line 7, the first symbol after the keyword `put` is a slash, that has the effect that a blank line is inserted before the text string `'Market demand'` is written.

In line 8, we have again a put statement within a loop structure: the values of the parameter `b` are written in a similar way to those of parameter `a` in line 6.

After execution, the put file `factors.dat` will look as follows:

```
Transportation Model Factors

Freight cost          90.00

Plant capacity
  Seattle            350.00
  San-Diego          600.00

Market demand
  New-York           325.00
  Chicago            300.00
  Topeka             275.00
```

Note that this output has been formatted using the default file format values. GAMS offers several ways to customize the format, see sections Global Item Formatting Controls and Local Item Formatting Controls below for further information.

In the last three lines of the code above, the file `results.dat` is made current and the level values associated with the variable `x` along with their corresponding set element index labels are written line by line. Note that the format of the output results of the variable `x` is customized by specifying a field width of 8 spaces with 4 of these spaces reserved for decimal places. This is an example of local formatting. The put file `results.dat` will contain the following lines:

```
Transportation Model Results

Seattle    New-York     50.0000
Seattle    Chicago     300.0000
Seattle    Topeka        0.0000
San-Diego  New-York    275.0000
San-Diego  Chicago       0.0000
San-Diego  Topeka      275.0000
```

This small example has demonstrated the main features of the put writing facility. However, its surface has just barely been scratched. In the remainder of this chapter we will describe in detail the many features of the put writing facility. Observe that in section Creating a Report for the Model MEXSS at the end of this chapter we will present a more elaborate report.

4.42.4 Put Files

As mentuioned earlier, external files that are written to with the put writing facility are called *put files*. They are defined with a file statement and are made current with a put statement. Once they are current, they may be written to. By default, put files are saved in the current working directory. In this section we will cover more details on put files. We will discuss ways to specify other directories for put files, introduce the putclose statement, a variant of the put statement that closes the current file, and we will show how to append to an existing external file instead of replacing (overwriting) it. In addition, we will introduce the notion of put file attributes including a list of all attributes.

4.42.4.1 Choosing Where Put Files are Saved

Recall that by default, put files are saved in the current working directory. GAMS offers several ways to specify other directories for put files. The easiest way to specify another directory is by including the absolute or relative path in the file statement. Consider the following example:

```
File report / C:\Documents\GAMS\Output\report.dat /;
```

Note that the put file `report.dat` with the internal name `report` will be stored in the directory specified in the file statement instead of the current working directory.

An alternative directory for *all* put files in a model may be specified with the command line parameter PutDir. Assume we wish to write some ouput from running the well-known transportation model [**TRNSPORT**] to the file `results` defined above. Consider the following GAMS call:

```
> gams trnsport PutDir=c:\output
```

Note that the file `results.put` will be stored in the directory specified in the GAMS call. Observe that storing put files in the directory specified with `PutDir` is applies to all file that are not specified via an absolute file name. For more information on command line parameters, see chapter The GAMS Call and Command Line Parameters. scratchdir as putdir option (`.pdir`) lets GAMS write put files into the scratch directory.

The content of a put file will be sent to the GAMS log file if the put file is specified in the following way:

```
File name / '' /;
```

For example, the following code snippet may be added to the transportation model [**TRNSPORT**]:

```
File name / '' /;
put name ;
put 'instructions that will go to the GAMS log' /;
put 'more instructions that will go to the GAMS log' /
```

As a result, the respective GAMS log will contain the following lines:

```
...
instructions that will go to the log file
more instructions that will go to the log file
*** Status: Normal completion
--- Job trnsport.gms Stop 01/25/17 15:46:09 elapsed 0:00:00.320
```

4.42.4.2 The Putclose Statement: Closing a Put File

Recall that the file statement and the put statement are at the core of the put writing facility. The putclose statement is a variant of the put statement, it is used to close a put file. The syntax is as follows:

```
putclose [file_name]  {item} {file_name item {item}};
```

If the `file_name` is missing, `putclose` will close the current file. Often the putclose statement is used in this simple form. Consider the following example:

```
File report;
put report;
put "This is a report."
putclose;
```

Note that the last line has the effect that the file `report.put` is closed. The file may be used again later. As usual, it has to be assigned as the current file and then it may be written to. By default, an existing file is overwritten (replaced). Alternatively, it may be appended to. For details see section Writing to an Existing Put File below. The briefest version of the above code is

```
File report; putclose report "This is a report."
```

Closing a put file is useful for example when writing a solver option file from within the GAMS model. Consider the following example, where we will create and close an option file for the solver MINOS.

```
File opt 'Minos option file'  / minos.opt /;
put opt 'Iteration limit          500'/
        'Feasibility tolerance    1.0E-7'/ ;
putclose opt;
```

Note that the file `minos.opt` is closed with a simple putclose statement. This will make the file available to be used by the solver. Observe that the code snippet above has to be placed *before* the respective solve statement.

Now, the last three lines in the example above may be reduced to two lines in the following way:

```
putclose opt 'Iteration limit          500'/
             'Feasibility tolerance    1.0E-7'/ ;
```

In this formulation, the putclose statement makes the file `minos.opt` current, writes to it and then closes the file after the last item has been written. Even though this is shorter, many users prefer the first formulation, since it is clearer.

Similarly to the put statement, the putclose statement may also be used to write to several files subsequently. The only difference to the put statement is, that the last current file will be closed after is has been written to.

Observe that GAMS automatically closes the put files of a model when it exits, even without a putclose statement.

4.42.4.3 Writing to an Existing Put File

When the put writing facility is used to write to a file that is not empty, by default, the existing content is overwritten (replaced). However, GAMS provides the option to append to the file instead via the file attribute append option (`.ap`). Consider the following example:

```
File append /append.dat/
put append;
put "This is the first line." /;
putclose;
append.ap = 1;
put append;
put "This is the second line.";
```

Note that the putclose statement in line 4 closes the file `append.dat`. The assignment in the next line instructs the put writing facility to append to the file if the file is opened again and written to. Thus the following output is generated:

```
This is the first line.
This is the second line
```

For information on file attributes in general, see section Put File Attributes below.

4.42.4.4 Put File Attributes

Put files have attributes that are mainly used to customize the format of put files, put file pages and output items. Put file attributes are accessed in the

following way:

```
file_name.attribute
```

Here `file_name` is the internal name of the put file and `.attribute` is the specific attribute that is to be accessed. We can also access the specific attribute of the current file by `file.attribute`. This useful in particular in batincludes that are used for multiple put files. Put file attributes may be used on the left-hand side and right-hand side of assignments. Consider the following example:

```
factors.nw = 10;
scalar x; x = factors.nw;
```

In the first line, the attribute numeric field width (`.nw`) of the put file with the internal name `factors` is assigned the value of 10. In the second line, the value of the attribute `.nw` is assigned to a scalar parameter `x`. In addition, put file attributes may be used as output items. For an example, see section Controlling the Cursor with File Attributes below. A complete list of put file attributes is given in Table 1.

Table 1: Put File Attributes

Put File Attribute	Symbol	Description	Default Value	Optional Values
Append option	.ap	Allows to append to an existing file, instead of replacing (overwriting) it. For more information, see section Writing to an Existing Put File.	0	0: Overwrite 1: Append
Bottom margin	.bm	Number of blank lines to be placed in the bottom margin of the page. The bottom margin lines are in adition to the lines specified with the file attribute page size (.ps). Note that this attribute is functional only if the value of the suffix print control (.pc) is zero.	0	
Alphabetic case	.case	Specifies the case in which alphabetic characters are displayed in the put file, regardless of the input. Note that the meaning of 1 and 2 differs from the one for lcase.	0	0: Mixed case 1: Upper case 2: Lower case
Current column	.cc	This attribute may be used to return or set the current cursor column in the main window. For more information, see Current Cursor Column.	0	Value may be between 1 and the page width.
Current row	.cr	This attribute may be used to return or set the current cursor row in the main window. For more information, see Current Cursor Row.	1	Value may be between 1 and the page size minus any header rows, title rows and margins.
Number of put errors	.errors	See section Put Errors for details and an example.	0	
Header current column	.hdcc	This attribute may be used to return or set the current cursor column in the header block. For more information, see Current Cursor Column.	0	Value may be between 1 and the page width.

Put File Attribute	Symbol	Description	Default Value	Optional Values
Header current row	`.hdcr`	This attribute may be used to return or set the current cursor row in the header block. For more information, see Current Cursor Row.	1	Value may be between 1 and the size of the header.
Header last line	`.hdll`	This attribute may be used to return the number of the last line of the page header or reset the last row written in the page header. For more information, see Last Line Control.	0	
Alphabetic label case	`.lcase`	Specifies the case in which alphabetic characters of a label are displayed in the put file, regardless of the original casing.	0	0: Mixed case 1: Lower case 2: Upper case
Label justification	`.lj`	Alignment of set labels.	2	1: Right, 2: Left, 3: Center
Last line	`.ll`	This attribute may be used to return the number of the last line of the main window or reset the last row written in the main window. For more information, see Last Line Control.	0	
Left margin	`.lm`	Number of empty columns to be placed on the left of the page.	0	
Last page	`.lp`	Returns the number of pages that are already in the put file. Note that setting this attribute to zero does *not* delete the pages that have been written to the file.		
Label field width	`.lw`	Field width of set label output. For more information, see section Global Item Formatting Controls.	12	Values may be 0 or larger.

Put File Attribute	Symbol	Description	Default Value	Optional Values
Number of decimals	.nd	Sets the number of decimals that are displayed for numeric items. A value of zero entails that fixed-format output will show the number rounded to the nearest integer. For an example, see section Global Item Formatting Controls.	2	Values may be between 0 and 20.
Numeric justification	.nj	Alignment of numeric output.	1	1: Right, 2: Left, 3: Center
Numeric round format	.nr	Selects the formatting used for numeric output. For example, one can choose to use scientific notation (i.e. E-format) for all numbers: this is especially useful for numbers so small that they display as only zeros in fixed format with the specified suffix number of decimals (.nd). For more information and an example, see section Global Item Formatting Controls.	1	0: Item is displayed in F or E format to fit given width and decimals. 1: Item is rounded to fit given width and decimals. 2: Item is displayed in E format to fit given width and decimals. 3: Item is rounded to fit given width. 4: Item is displayed in F or E format to fit given width.
Numeric field width	.nw	Field width of numeric output. For more information, see section Global Item Formatting Controls.	12	Values may be 0 or larger.
Numeric zero tolerance	.nz	Sets the tolerance level for which a number will be rounded to zero for display purposes. Note that in case this attribute is set to zero, rounding will be determined by the field width.	1.0e-10	
PutDir becomes scratch directory	.pdir	Setting this to nonzero will result in resetting the PutDir to the scratch directory. Since the scratch directory is unknown while parameters are provided, this allows to use the scratch directory as PutDir.	0	

Put File Attribute	Symbol	Description	Default Value	Optional Values
Print control	.pc	Specifies the format of the put file. The options 4, 5, 6 and 8 create delimited files, which are especially useful when preparing output for the direct importation into other computer programs such as spreadsheets. For an example, see section Creating a Report for the Model MEXSS.	2	0: Standard paging based on the current page size. Partial pages are padded with blank lines. Note that the file suffix bottom margin (.bm) is only functional when used with this print control option. 1: FORTRAN page format. This option places the numeral one in the first column of the first row of each page in the standard FORTRAN convention. 2: Continuous page. This option is similar to .pc option zero, with the exception that partial pages in the file are not padded with blank lines to fill out the page. 3: ASCII page control characters inserted. 4: Formatted output; non-numeric output is quoted and each item is delimited with a blank space. 5: Formatted output; non-numeric output is quoted and each item is delimited with commas. 6: Formatted output; non-numeric output is quoted and each item is delimited with tabs. 7: Fixed width, fills up line with trailing blanks. 8: Formatted output; each item is delimited with a blank space.

Put File Attribute	Symbol	Description	Default Value	Optional Values
Page size	.ps	Number of rows (lines) that may be placed on a page of the put file. It may be reset by the user at any place in the program.Observe that the specification of this attribute is only effective if the attribute print control (.pc) has a value other than its default value. Note that a put error will result if it is set to value that is smaller than the number of rows which have already been written to the current page.	60	Any value between 1 and 130.
Page width	.pw	Number of columns (characters) that may be placed on a single row of the page. It may be reset by the user at any place in the program. Note that a put error will result if it is set to value that is smaller than the number of columns which have already been written to the current page. Observe that if a value is specified that is above the upper limit, then the value will be reset to the upper limit.	32767	Any value between 1 and 32767.
Set value justification	.sj	Alignment of set values.	1	1: Right, 2: Left, 3: Center
Set value field width	.sw	Field width of set values. For more information, see section Global Item Formatting Controls.	12	Values may be between 0 and 20.

Put File Attribute	Symbol	Description	Default Value	Optional Values
Text fill	.tf	Controls what content will be displayed, if there is no explanatory text for a set element, but a text item with suffix .te was specified. Note that options 4, 5 and 6 are useful if the output is intended to be included in a GAMS model at a later time.	2	0: Blanks are displayed. 1: Blanks will be displayed if the specified element does not exist, otherwise the name of the element will be displayed. 2: The name of the element is displayed. 3: The name of the element is displayed even if an explanatory text exists. 4: Like option 3, but displays output in quotes with comma separators. 5: Like option 4, but with periods as separators. 6: Like option 4, but with blanks as separators.
Text justification	.tj	Alignment of quoted text and explanatory text.	2	1: Right, 2: Left, 3: Center
Title current column	.tlcc	This attribute may be used to return or set the current cursor column in the title block. For more information, see Current Cursor Column.	0	Value may be between 1 and the page width.
Title current row	.tlcr	This attribute may be used to return or set the current cursor row in the title block. For more information, see Current Cursor Row.	1	Value may be between 1 and the size of the header.
Title last line	.tlll	This attribute may be used to return the number of the last line of the page title or reset the last row written in the page title. For more information, see Last Line Control.	0	

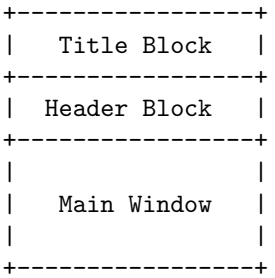
Put File Attribute	Symbol	Description	Default Value	Optional Values
Top margin	.tm	Number of blank lines to be placed at the top margin of the page. These lines are in addition to the number of lines specified with the file attribute page size (.ps).	0	
Text field width	.tw	Field width for quoted text and explanatory text. Note that a value of zero forces the field width to match the exact size of the item being displayed. For more information, see section Global Item Formatting Controls.	0	Value may be 0 or larger.
Window size	.ws	Returns the number of rows that may be written to the main window given the number of rows in the title and header blocks and the page size. Note that this attribute is computed by GAMS and cannot be changed by the user.		

4.42.5 Put File Pages

In this section we will discuss the structure of put file pages, in particular how to write titles and headers. In addition, we will give details on how users may control many aspects of the format of a put file page.

4.42.5.1 Adding Titles and Headers

Titles and headers are widely used when there are sections of a page that remain relatively constant throughout a document. There are three independent writing areas on each page of a put file: the title block, the header block and the main window. The layout of a page is shown in the following diagram.



Note that the put statement writes to the main window. There are two variants of the put statement that write to the title block and header block respectively: the puttl statement and the puthd statement.

Observe that every page must have an entry in the main window. If a page has no output in its main window, the page will not written, regardless of whether there are output items in the title or header blocks. To force a page that has an empty window out to file, we recommend to simply write something innocuous to the window, like the following:

```
put ''; // space
```

This will initiate the main window of the page and thus the page will be written.

Further, note that the size of any area of a page is based on the number of lines written to it and the total number of lines has to be smaller than the specified page size. A new page is started automatically whenever a page is full. For details on *manual* pagination, see section The Putpage Statement: Controlling Paging. Each area of a page is maintained independently. For example, we may write to the title block first, then to the header block and then again to the title block. However once we have written to the main window, all subsequent entries to the title and header are written to the *next* page, not the current page.

The Puttl Statement: Writing to the Title Block

The puttl (or `putTitle` which can be used as a synonym) statement is a variant of the put statement that writes to the title block of a page. The syntax is as follows:

```
puttl [file_name] item {item};
```

The keyword `puttl` indicates that this is a puttl statement. The internal name of the file, `file_name`, may be omitted if the desired file is already current. Like in the put statement, the content that is written is one or more `items`, that may be a text string, a numerical value or a set value. For more information on items, see section Output Items below. Consider the following example:

```
puttl factors 'GAMS Put Example';
```

If this line is placed *before* the put statement that writes to the main window in the example above, then `GAMS Put Example` will be written to the title block.

Observe that title blocks often contain the name of the model and the number of the put page. Once content is placed in the title block, it will be repeated on every page unless it is modified or deleted. For details on how to write output like the page number to a put file, see section System Suffixes as Output Items below.

Note

> If content has already been written to the main window of a page, the items in the puttl statement will appear in the title block starting from the *next* page. Thus the title has to be written *before* any entries in the main window if it is to appear on the current page.

Observe that if the title and header blocks contain too many lines given the page size, the page will overflow resulting in a put error.

The Puthd Statement: Writing to the Header Block

Like the puttl statement, the puthd (or `putHeader` which can be used as a synonym) statement is a variant of the put statement. Puthd statements write to the header block of a page. The syntax is as follows:

```
puthd [file_name] item {item};
```

The keyword `puthd` indicates that this is a puthd statement. The internal name of the file, `file_name`, may be omitted if the desired file is already current. Like in the put statement, the content that is written is one or more `items`. See section Output Items below for more information on items.

Observe that title blocks often contain a disclaimer or an instruction that is meant to be repeated on every page. Once content is placed in the header block, it will be repeated on every page unless it is modified or deleted.

Note

> If content has already been written to the main window of a page, the items in the puthd statement will appear in the header block starting from the *next* page. Thus the header has to be written *before* any entries in the main window if it is to appear on the current page.

Observe that if the title and header blocks contain too many lines given the page size, the page will overflow resulting in a put error.

The Putclear Statement: Deleting Title and Header Blocks

The `putclear` (or `putfmcl` which can be used as a synonym) statement may be used to delete the title and header blocks. The syntax is simple:

```
putclear;
```

If the keyword `putclear` is inserted after a title and/or header block has been written, but *before* the main window has been written to, then the title and/or header blocks of the *current* page will be deleted. If the main window has already been written to, the the title and/or header block of the *next* and all subsequent pages will be deleted. Note that if the user wishes to delete either only the title or only the header block, the put file attributes .tlll and .hdll respectively may be set to zero. For more information, see Last Line Control.

4.42.5.2 The Putpage Statement: Controlling Paging

A new page is started automatically if the bottom of a page is reached. Alternatively, a new page may be started early using a variant of the put statement: the `putpage` statement. The syntax is as follows:

```
putpage [file_name] {item};
```

The keyword `putpage` indicates that this is a putpage statement. In its simplest form, the putpage statement consists of just the keyword. If only the keyword is used, the current page will be terminated. The optional `file_name` makes the put file with the internal name `file_name` current. If output items follow, they will be written to the current page and a new page will be made available for the next put statement.

Consider the following example:

```
File example / example.txt /;
putpage example "This text is placed in the main window and the page ends here.";
put "Here starts a new page in the same putfile."
```

Observe that three file attributes are helpful for manual paging: last page (`.lp`), window size (`.ws`) and last line (`.ll`).

4.42.5.3 Controlling the Format of a Put File Page

While GAMS established gracious defaults, there are numerous ways to customize the format of a put file page. In this section we will present the put file attributes that facilitate the control of various aspects of page formatting and ways to control the position of the cursor.

Controlling Page Size, Page Width and Margins

By default, 60 rows (lines) may be written on a put file page. At any point in the program the file attribute page size (`.ps`) may be used to reset this value. Note that the upper limit is 130. Note further, that a put error will result if the attribute is set to value that is smaller than the number of rows which have already been written to the current page. Observe that the specification of `.ps` is only effective if the attribute print control (`.pc`) has a value other than its default value.

By default, 255 characters (colums) may be written to each line of a put file page. Like the page size, the page width may be reset at any point. GAMS provides the file attribute page width (`.pw`) to do this. Note that the upper limit is 32767. Note further, that a put error will result if the attribute is set to value that is smaller than the number of columns which have already been written to the current page.

By default, put file pages do not have top, bottom and left margins. However, it is easy to specify blank lines for the margins with the file attributes top margin (`.tm`) and bottom margin (`.bm`). Note that the lines reserved for the margins are in addition to the value specified for the page size (`.ps`). Observe that the file attribute `.bm` is only functional if the value of the file attribute print control (`.pc`) is set to zero. In addition, the number of empty columns for left margins may be specified with the file attribute left margin (`.lm`)

Controlling the Print Format and the Use of Capital and Lower Case Letters

By default, GAMS prints continuous pages. However, the file attribute print control (`.pc`) offers several alternative options. For a full list, see the respective entry in Table Put File Attributes above. Note in particular that the options 4, 5, 6 and 8 create delimited files, which are useful for importing output to other applications like spreadsheets. For an example, see section Creating a Report for the Model MEXSS.

By default, alphabetic characters are displayed in the case they were inputted. Note that the value of 1 for the file attribute alphabetic case (`.case`) will display all output in capital letters, regardless of the input, and the value of 2 will result in only lower case letters being displayed.

Assume that we wish a put file `report.txt` to have pages with 72 characters to a row and 58 lines, ASCII page control characters to be inserted at the end of every page, an additional top margin of 6 lines and all output displayed in upper case. The following assignments will implement these specifications:

```
File report /report.txt/;
report.pw = 72; report.ps = 58; report.pc = 3;
report.tm = 6;  report.case = 1;
```

Controlling the Cursor On a Page

There are three ways to control the position of the cursor: with cursor control characters, with the system attribute `system.tab` and with file attributes. In this section we will give details on cursor control characters, while inserting tabs and file attributes that are relevant for cursor control will be discussed in the next two sections.

By default, the cursor is moved to the space immediately following the last character written. GAMS provides the control characters listed in Table 2 to specify another position for the cursor.

Symbol	Description
`#n`	Move cursor position to row `n` of current page.
`@n`	Move cursor position to column `n` of current line.
`/`	Move cursor to first column of next line.

Table 2: Cursor Control Characters

Note that the numeric value `n` that follows the characters `#` and `@` may be any expression or symbol with a numeric value. An example is given below. Note further, that the character `@` is commonly used to align columns if the column headings have different widths. For an example, see section Creating a Report for the Model MEXSS. Observe that the character `@` may be used to overwrite output items that were written earlier. Consider the following example:

```
File out /out.dat/;
put out;
put 'Good' @3 'morning everybody!';
```

This code snippet will generate the following output:

```
Gomorning everybody!
```

Observe that cursor control characters are also used and discussed in the example at the beginning of this chapter.

Controlling the Cursor with a System Attribute: Inserting Tabs

The system attribute `system.tab` may be used to insert tabs. Consider the following example:

```
File test / test.dat /;
put test;
put "1" system.tab "2" system.tab "3" ;
```

The put file will contain the following line, separating 1, 2, and 3 by tabs.

```
1    2    3
```

Controlling the Cursor with File Attributes

In addition to cursor control characters and tabs, the position of the cursor may be controlled using the file attributes that will be discussed in this section. These file attributes refer to the current column, the current row and the last line in the title block, the header block and the main window.

Current Cursor Column

As there are three independent writing areas on each put file page, there are three file attributes that refer to the current column. They are listed in Table 3.

Symbol	Description
.cc	Current cursor column in the *main window*.
.hdcc	Current cursor column in the *header block*
.tlcc	Current cursor column in the *title block*

Table 3: File Attributes for the Column Position of the Cursor

Note that the values for these attributes are numeric and they are updated only at the *end* of a put statement. Consequently, their values will remain constant during a put statement, even if multiple items or lines are displayed. Observe that the attributes may be used on the left-hand side and on the right-hand side of an assignment statement to set the current column position and return it respectively.

The following example illustrates the updating of the cursor control suffixes and the use of cursor control characters. The example is trivial but instructive:

```
Scalar  lmarg  'left margin'   /6/;
File out; put out;
put @(lmarg+2) 'out.cc = ', out.cc:0:0 '  ';
put @out.cc 'x'/ @out.cc 'y'/ @out.cc 'z  ';
put 'out.cc = ' out.cc:0:0;
```

The resulting file `out.put` will contain the following lines:

```
out.cc = 1  x
            y
            z  out.cc = 23
```

Note that the scalar `lmarg` is set to a specific value that will be used as an alignment tab. Symbols which hold common alignment values such as margins or tabs are often useful for large structured documents. The first put statement uses the cursor control character `@` to relocate the cursor to column 8 where the text item `out.cc` and the respective value for the file attribute `.cc` are displayed. Note that the numerical value of the file attribute is formatted locally with the effect that only integers are displayed. We observe that at the start of the first put statement the file attribute `out.cc` equals 1.

The second put statement illustrates the updating of the cursor control suffixes by writing the letters `x`, `y` and `z` on three different lines. Each is preceded by moving the cursor to the value of the file attribute `.cc`. Note that at the end of the first put statement the value of `out.cc` is updated to 20. Hence, `out.cc` is 20 at the start of the second put statement. As a single put statement is used to write all three letters, the value of `out.cc` remains constant and thus the letters are written in the same column. At the end of the second put statement the value of `out.cc` value is updated to 23 (observe that there are two blank spaces after the letter `z`).

The third put statement writes the current value of the file attribute `out.cc`, which is the value at the start of the put statement.

Current Cursor Row

As there are three independent writing areas on each put file page, there are three file attributes that refer to the current row. They are listed in Table 4.

Symbol	Description
.cr	Current cursor row in the *main window*
.hdcr	Current cursor row in the *header block*
.tlcr	Current cursor row in the *title block*

Table 4: File Attributes for the Row Position of the Cursor

Note that the values for these attributes are numeric and they updated only at the *end* of a put statement. Consequently, their values will remain constant during a put statement regardless of how many rows are displayed. Observe that the attributes may be used on the left-hand side and on the right-hand side of an assignment statement to set the current row and return it respectively. The files attributes for the row postion of the cursor behave similarly to those for the column position.

Last Line Control

Like the file attributes for the current column and row position, the file attributes for the last line have three variants, one for each writing area. They are given in Table 5.

Symbol	Description
`.ll`	Last line in the *main window*
`.hdll`	Last line in the *header block*
`.tlll`	Last line in the *title block*

Table 5: File Attributes for the Last Line

Note that unlike the row and column controls, the last line attributes are updated continuously. Last line attributes are especially useful for modifying the three writing areas of a page. They may be used on the left-hand side and on the right-hand side of an assignment statement to set the current last line and return it respectively. Rows will be deleted if the last line attribute is set to a value that is lower than the current row.

Attention

> The file attributes `.tlll` and `.hdll` may not hold values applicable to the current page, because when the title or header blocks are modified, they will correspond to the title or header blocks of the *next* page if the main window has been written to on the current page.

As mentioned above, in addition to determining the last line in a writing area, these file attributes may be used to delete lines within a writing area. In the following example, the header block will be completely deleted by resetting the attribute `.hdll` to zero.

```
File out;
puthd out 'This header statement will be eliminated';
out.hdll = 0;
```

Note that a header is written initially. However, by changing the attribute `.hdll` to zero, the cursor is reset to the top of the header block. As a result, the header will not be written unless something new is added to the header block.

4.42.6 Output Items

Output items are the items in the put statement that are written to the put file. They may be a text, a numerical value or a set value. In this section we will provide more information on these three types of items. Observe that system suffixes and command line parameters are either text strings or have a numerical value. They may also be used as output items.

4.42.6.1 Text Items

Text items may be a quoted text, an explanatory text of identifiers and labels or names of set elements. In this section we will give details on each of these text items. In addition, text items may be system attributes or command line parameters. For these text items, see sections System Suffixes as Output Items and Command Line Parameters as Output Items respectively. Details on default field widths and alignments for text items and global and local customizing controls are given in section Customizing the Format of Output Items.

Text Items: Quoted Text

The simplest text output item is a quoted text. A quoted text is any combination of characters or numbers set apart by a pair of single (') or double (") quotes with each the items needing to use a matching pair. Thus the following three lines are all exactly equivalent.

```
put 'Run on ' system.date ' using source file ' system.ifile;
put "Run on " system.date " using source file " system.ifile;
put 'Run on ' system.date " using source file " system.ifile;
```

Note that there is a limit on the length of all output items: output items may not exceed the page width. In case this limit is exceeded, a put error will be reported in the listing file. Put errors are introduced and discussed in section Put Errors.

Text Items: Identifier Attributes

Text items like the explanatory text of an identifier, the name of a set element and the explanatory text of a set element are specified with identifier attributes. The identifier attributes are listed in Table 6.

Identifier Attribute	Symbol	Description
Explanatory text of an identifier	`.ts`	Displays the descriptive text associated with any identifier (like a set, a parameter, a variable, an equation, a model).
Name of a set element	`.tl`	Displays the names of the individual elements of a set. Observe that the put statement must be embedded in a loop statement, where the respective set is the looping set or the set is a singleton set.

Identifier Attribute	Symbol	Description
Explanatory text of a set element	`.te(index_list)`	Displays the explanatory text associated with a set element. Note that this attribute requires the specification of a driving index. If the set is a simple set, the set name itself will have to be specified as index (see example below). If the set is defined over an index, then the index or a subset of the index may be specified. A special case arises in case users wish to gain access to the explanatory text that appears in the definition of another set (see example below). Observe that if there is no explanatory text for a set element in the set definition, then either the name of the set element (default) or a blank will be displayed, depending on the value of the file attribute text fill (`.tf`). Note that with `.tf=3` even if an explanatory text exists, the name of the element will be displayed. Observe that the put statement must be embedded in a loop statement, where the respective set is the looping set or the set is a singleton set.
Indexed identifier with label combination	`.tn`	Displays the name of the identifier with all individual label combinations. Observe that the put statement must be embedded in a loop statement, where the respective index is the looping set or the set is a singleton set. See example below.

Table 6: Identifier Attributes

Consider the following example:

```
Set  i     master set of sites / i1  Seattle, i2  Portland
                                 i3  San Francisco, i4  Los Angeles, i5 /
     j     subset of sites     / i3 * i5 / ;

File out; put out i.ts /;
loop(i, put i.tl, i.te(i) /);
```

The resulting put file `out.put` will contain the following output:

```
master set of sites
i1          Seattle
i2          Portland
i3          San Francisco
i4          Los Angeles
i5          i5
```

Note that the explanatory text of the set `i` is written first, followed by the label names of the set `i` and their respective explanatory texts. Note further that even though the set `i` does not have an index (it is a simple set), an index is required for the attribute `.te`. In this case we specify as index the set itself. Observe that the set element `i5` was defined without an explanatory text. By default, GAMS inserts the name of the element instead. This may be changed by alterning the code in the following way:

```
put out i.ts /;
out.tf = 0;
loop(i, put i.tl, i.te(i) /);
```

Note that we assign the value of zero to the file attribute text fill (`.tf`) *before* the put statement where one of the items refers to the explanatory text of a set element. As a result, a blank will be displayed where the explanatory text of the set element `i5` is supposed to appear:

```
master set of sites
i1          Seattle
i2          Portland
i3          San Francisco
i4          Los Angeles
i5
```

Assume we also wish to display the elements of the set `j` and their explanatory texts. We could just adapt the code above for the set `j` and add the following two lines:

```
put / j.ts /;
loop(j, put j.tl, j.te(j) /);
```

These lines will result in the follwing output to be appended to the put file:

```
subset of sites
i3
i4
i5
```

Note that the explanatory text associated with the set elements is missing, since there is no explanatory text for the elements in the definition of the set `j` and the value of zero for text fill is still valid. However, we may gain access to the explanatory text of the set elements in the definition of the set `i` in the following way:

```
put / j.ts /;
loop(j, put j.tl, i.te(j) /);
```

Note that the the specification `i.te(j)` singles out the explanatory texts of the elements of the set `i` that are also elements of the set `j`. Hence we will obtain the desired output:

```
subset of sites
i3          San Francisco
i4          Los Angeles
i5
```

The following example illustrates the use of the identifier attribute `.tn`. The model [**MEXSS**] is a simplified representation of the Mexican steel sector, where five steel plants have to satisfy the demand for steel in three markets. Each steel plant `i` has several productive units `m` and the capacity of every unit in every plant is specified with the parameter `k(m,i)`. Assume we wish to write to a put file a list of all nonzero capacities. We could add the following code to the model:

```
File out /out.dat/;
put out 'Capacity (in metric tons)' / /;
loop((m,i)$k(m,i),
   put k.tn(m,i), @30 '=' k(m,i) /;
)
```

Note that we restrict the loop statement with a logical condition to exclude entries of zero. The put file `out.dat` will contain the following lines:

```
Capacity (in metric tons)

k('blast-furn','ahmsa')      =        3.25
k('blast-furn','fundidora')  =        1.40
k('blast-furn','sicartsa')   =        1.10
k('openhearth','ahmsa')      =        1.50
k('openhearth','fundidora')  =        0.85
k('bof','ahmsa')             =        2.07
k('bof','fundidora')         =        1.50
k('bof','sicartsa')          =        1.30
k('direct-red','hylsa')      =        0.98
k('direct-red','hylsap')     =        1.00
k('elec-arc','hylsa')        =        1.13
k('elec-arc','hylsap')       =        0.56
```

Observe that a more elaborate report for the model [**MEXSS**] is given in section Creating a Report for the Model MEXSS at the end of this chapter. The identifier attribute `.tn` is particularly useful when creating scalar EMP info files.

Text Items: Text Blocks

The easiest way to write blocks of text to a put file is with the dollar control options $onPut and $offPut. Consider the following example:

```
File fx; put fx;
$onPut
We will write four
lines of text to the put file,

including a blank line.
$offPut
```

The put file `fx.put` will contain the following lines.

```
We will write four
lines of text to the put file,

including a blank line.
```

Note that these dollar control options have a variant that allows the substitution of compile-time variables. For details see the description of $on/offPut.

4.42.6.2 Numeric Items

Numeric items may be values of parameters, variable and equation attributes or model attributes and expressions of such elemens. These numeric items will be discussed in this section. In addition, numeric items may be command line parameters. For these numeric items, see section Command Line Parameters as Output Items. Details on default field widths and alignments for numeric items and global and local customizing controls are given in section Customizing the Format of Output Items.

Numeric Items: Parameters and Functions

In our first example in this chapter, one of the output items was the parameter `f`. For convenience, we repeat the respective code below:

```
put 'Freight cost  ', f;
```

Note that the simple name of the parameter is sufficient. In the same example we also had two parameters that were defined over an index: `a(i)` and `b(i)`. The respective lines of code follow:

```
loop(i, put @3, i.tl, @15, a(i)/);
* ...
loop(j, put @3, j.tl, @15, b(j)/);
```

Note that indexed parameters must be specified with their index and a put statement with an indexed parameter has to be embedded within a loop structure.

Numeric Items: Variable and Equation Attributes

Recall that data associated with variables and equations is stored in variable attributes and equation attributes respectively. A full list is given in sections Variable Attributes and Equation Attributes.

Suppose we wish to generate a report with the demand for each market in the transportation model [**TRNSPORT**], the satisfied demand after solution of the model and the marginal cost of meeting the demand. Recall that the demand data for each market is saved in the parameter `b(j)` and the relationship between shipment quantities and demand is encoded in equation `demand(j)`. The following code will generate the desired report:

```
File report /report.dat/; put report;
loop(j,
   put 'Report for ' j.tl /
       'Demand'                          @35 b(j):10:0        /
       'Demand satisfied'                @35 demand.l(j):10:0 /
       'Marginal Cost of meeting demand' @35 demand.m(j):10:2 / /;
);
```

Note that we use three numeric output items: the parameter `b(j)`, the level value of the equation `demand.l(j)` and the marginal value of the equation `demand.m(j)`. Note further, that all three items are indexed over the set `j` and thus the put statement has to be placed within a loop statement. Observe that we customize the formatting of the items. For details see section Local Item Formatting Controls. The put file `report.dat` will contain the following output:

```
Report for New-York
Demand                                  325
Demand satisfied                        325
Marginal Cost of meeting demand        0.23

Report for Chicago
Demand                                  300
Demand satisfied                        300
Marginal Cost of meeting demand        0.15

Report for Topeka
Demand                                  275
Demand satisfied                        275
Marginal Cost of meeting demand        0.13
```

Numeric Items: Model Attributes

GAMS models have many model attributes. An introduction and a complete list is given in section Model Attributes. While in principle all model attributes may be used as output items, the attributes `.modelStat` and `.solveStat` with their string valued counter parts `.TModStat` and `.TSolStat` are used most frequently. They refer to the model status and solver termination condition after solution respectively. For a complete list of their values, see sections Model Status and Solver Status.

Suppose we wish to generate a report that contains the time it took to execute the solve statement of the transportation model [**TRNSPORT**], the objective value and the corresponding string valued model and solver status. Recall that the name of the model is `transport`. The following code will generate the desired report:

```
File report /report.dat/; put report;
put 'elapsed time in seconds of solve statement : ' transport.etSolve:0 /
    'objective value:                             : ' transport.objVal:0  /
    'model status:                                : ' transport.tmodstat  /
    'solver status:                               : ' transport.tsolstat  ;
```

Observe that we customize the formatting of the first two items. For details see section Local Item Formatting Controls. The put file `report.dat` will contain the following output:

```
elapsed time in seconds of solve statement : 0.11
objective value:                             : 153.68
model status:                                : 1 Optimal
solver status:                               : 1 Normal Completion
```

4.42.6.3 Set Value Items

There are only two set values: `YES` and `NO`. The set value will be `YES` if a label is an element of a specific set and `NO` otherwise. Consider the following example which is adapted from the example in section Text Items: Identifier Attributes above:

```
Set  i     master set of sites / i1  Seattle, i2  Portland
                                 i3  San Francisco, i4  Los Angeles, i5 /
     j     subset of sites     / i3 * i5 / ;

File out2 / out2.dat /;
put out2 j.ts /;
out2.tf = 0;
loop(i, put i.tl, j(i), '   ',  i.te(i) /);
```

Note that within the loop structure, the put statement writes each element of the set `i`, determines whether it is a member of the set `j` and displays the respective set value, and adds the explanatory text for the label. Hence the resulting put file `out2.dat` will look as follows:

```
subset of sites
i1      NO  Seattle
i2      NO  Portland
i3     YES  San Francisco
i4     YES  Los Angeles
i5     YES
```

Observe that the set values in the second column reflect set membership of the set `j`. Observe further, that the missing explanatory text for label `i5` is displayed as a blank, since the value of the file suffix text fill (`.tf`) equals zero.

4.42.6.4 System Suffixes as Output Items

System suffixes contain information about a GAMS run, they are introduced and discussed in chapter System Attributes. System suffixes may be used as output items in the context of put statements. They are accessed in the following two ways:

```
system.attribute
%system.attribute%
```

Here `system` is a keyword and `.suffix` is a specific system suffixes. Note that `system.suffix` references the *execution-time* version (which can be of type string or numeric) of the system suffixes and `%system.suffix%` (which is interpreted by the compiler as part of the input string) references the *compile-time* version. For further details on the difference between execution-time and compile-time system suffixes, see chapter System Attributes. A complete list of all system suffixes is given in section List of all System Suffixes, in Table 7 we present a list of the most common system suffixes.

System Attribute	Description
`.date`	Program execution date
`.ifile`	Input file name
`.ofile`	Output file name
`.rdate`	Restart file date
`.rfile`	Restart file name
`.sfile`	Save file name
`.title`	Title of the model as specified by $title

Table 7: A Selection of System Suffixes

To illustrate how system suffixes are used, assume we wish to include the program execution date, the name of the input (GAMS) file, and the page number of the current put statement in the input file to the report `results.dat` in section A First Example above. We will modify the code in the following way:

```
File factors /factors.dat/, results /results.dat/;
* ...
put results;
puthd 'Program Execution Date:', @26, system.date /
    'Source File:', @26, system.ifile /;
    'Page Number:', @26, system.page / /;
put 'Transportation Model Results' / / ;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 /);
```

The file `results.dat` will then contain the following lines:

```
Program Execution Date:  01/13/17
Source File:             C:\Documents\GAMS\Models\trnsport.gms
Page Number:             1

Transportation Model Results

Seattle    New-York     50.0000
Seattle    Chicago     300.0000
Seattle    Topeka        0.0000
San-Diego  New-York    275.0000
San-Diego  Chicago       0.0000
San-Diego  Topeka      275.0000
```

Note that the date is given in the American format: `month/day/year` and can be reset via the command line parameter DFormat. Also note that including the page number in the header block of a put file will have the effect that the pages of the put file will be numbered. Of course, this is especially useful for longer put files.

It is also possible to read environment variables at execution time in a put context using `sysEnv.name` as in the following example:

```
$setEnv hello world
put_utility 'log' / sysEnv.hello;
```

If the environment variable queried is not defined, the result depends on the value of the command line parameter stringChk.

4.42.6.5 Command Line Parameters as Output Items

Command line parameters may also be used as output items. They are introduced and discussed in chapter The GAMS Call and Command Line Parameters. For an overview of all GAMS command line parameters, see section List of Command Line Parameters. Like system suffixes , command line parameters are referenced in the context of a put statement either compile-time strings or in an execution time version as follows:

```
put "%gams.parameter%";
put gams.parameter;
```

Here `parameter` is a GAMS command line parameter. To illustrate how command line parameters are used, assume we wish to include the page size of the input file, the name of the input file and the name of the restart file in the report `results.dat` in section A First Example above. We will modify the code in the following way:

```
File factors /factors.dat/, results /results.dat/ ;
* ...
put results;
put 'Transportation Model Results'// ;
loop((i,j), put i.tl, @12, j.tl, @24, x.l(i,j):8:4 //);
put / "Page size         = %gams.ps%"
    / "GAMS input file   = %gams.input%"
    / "GAMS restart file = %gams.restart%";
```

The last three lines of the put file `results.dat` follow:

```
Page size         = 58
GAMS input file   = C:\Documents\GAMS\Models\trnsport.gms
GAMS restart file =
```

Note that there was no restart file in the GAMS run, thus the value for `%gams.restart%` is the empty string.

In this example it actually makes no difference if one uses the compile- or execution time version to query the value of a command line parameter. This might be different, when doing the compile and execution phase separately, e.g. when using remote execution. Here is a toy example showing the difference:

```
$onEchoV > logScrDir.gms
put_utility 'log' / '%gams.scrDir%';
put_utility 'log' / gams.scrDir;
$offEcho

$call gams logScrDir.gms a=c s=1 keep=1
$call gams logScrDir.gms a=e r=1
```

In the log, one will see that `%gams.scrDir%` is evaluated in the first run at compile time already, while `gams.scrDir` is evaluated at execution time in the second run:

```
--- logScrDir.gms(1) 3 Mb
    C:\Data\t m p\225d\
--- logScrDir.gms(2) 3 Mb
    C:\Data\t m p\225e\
```

4.42.6.6 Customizing the Format of Output Items

GAMS provides global and local controls to modify the default format of output items. *Global* controls are set with file attributes and apply to all output items in a put file that follow the assignment of a file attribute. *Local* controls are used to change the format of only one specific output item.

Global Item Formatting Controls

The alignment (justification) of the field and the width of the field may be modified for all types of output items. The attributes that control field alignment are listed in Table 8. Note that possible values are 1 (right), 2 (left) and 3 (center).

Type of Output Item	Symbol	Default Value
Text items: set labels	`.lj`	2: Left
Text items: quoted and explanatory text	`.tj`	2: Left
Numeric values	`.nj`	1: Right
Set values	`.sj`	1: Right

Table 8: File Attributes for Field Alignment

The width of the field is specified with the number of spaces to be allocated. The attributes that control field width are liste in Table 9.

Type of Output Item	Symbol	Default Value
Text items: set labels	`.lw`	12
Text items: quoted and explanatory text	`.tw`	0
Numeric values	`.nw`	12
Set values	`.sw`	12 (maximum 20)

Table 9: File Attributes for Field Width

Note that the value of zero signifies a *variable* field width, matching the the exact size of the item being displayed. If a text output item does not fit within the specified field, truncation will occur to the right. For numeric output items, the decimal portion of a number is rounded or scientific notation is used to fit the number within the given field. If a number is still too large, asterisks will replace the value in the output file.

For example, the following assignment will set the field width for numeric items in the file `out.put` globally to 4:

```
out.nw = 4;
```

In addition to field alignment and field width, there are further global controls that apply to numeric output items only. They are given in Table 10.

File Attribute	Symbol	Description	Default Value	Optional Values
Number of decimals	`.nd`	Sets the number of decimals that are displayed for numeric items. A value of zero entails that fixed-format output will show the number rounded to the nearest integer.	2	Values may be between 0 and 20.

File Attribute	Symbol	Description	Default Value	Optional Values
Numeric round format	.nr	Selects the formatting used for numeric output. For example, one can choose to use scientific notation (i.e. E-format) for all numbers: this is especially useful for numbers so small that they display as only zeros in fixed format with the value specified for number of decimals (.nd). The default rounding format will treat small values in this way, but in many situations, it is important to be aware that such small values exist.	1	0: Item is displayed in F or E format to fit given width and decimals. 1: Item is rounded to fit given width and decimals. 2: Item is displayed in E format to fit given width and decimals. 3: Item is rounded to fit given width. 4: Item is displayed in F or E format to fit given width.
Numeric zero tolerance	.nz	Sets the tolerance level for which a number will be rounded to zero for display purposes. Note that in case this attribute is set to zero, rounding is determined by the field width.	1.0e-10	

Table 10: File Attributes for Global Format Control Specific to Numeric Items

Note that numeric items are always formatted to fit within the specified width limit, but their display may use fewer characters. Similarly, for some values of .nr, the number of digits shown is limited by the choice of the .nd parameter, but fewer digits may be shown. At most 17 significant digits are included - this is enough to represent any double-precision value unambiguously, i.e. as a base-10 string that converts back into this same double. With this in mind, any number can be represented fully in E-format using at most 24 digits, e.g. -1.25E+102.

With .nr=0, the formatting routines honor the decimals limit. Values closer to 1 are displayed in fixed format. Values so small they would display only zeros in fixed format are displayed in E-format, as are values too large for the width limit. Formatting with .nr=1 is similar, but small values are shown in fixed format even if they show all zeros. With .nr=2 E-format is used for all values, with the number of trailing digits respecting the decimals limit .nd. The decimals limit is ignored for .nr=3, and fixed format is used unless the value is so large that E-format output is shorter. Finally, .nr=4 is intended to be used with larger output widths, e.g. 18 or 24, in order to show values of all magnitudes in as full a precision as possible: it ignores the decimal limit and uses whatever format allows more significant digits in the specified width.

The following example illustrates the result of different combinations of numeric file attributes. Note that we will use five combinations of the file attributes .nd, .nz, .nr and .nw to display three numerical values.

```
Set  c  suffix combinations  / comb1 * comb9 /
```

```
     v  value indices        / value1 * value5 / ;

Table   suffix(c,*)   numeric suffix combinations
           nd      nz      nr      nw
comb1       3       0       0      12
comb2       3    1e-5       0      12
comb3       3    1e-5       1      12
comb4       8       0       0      10
comb5       6    1e-5       1      12
comb6       0    1e-5       1      12
comb7      10       0       2      18
comb8       0       0       3      14
comb9       0       0       4      18 ;

Parameter  value(v)   test values
      / value1     1.2345678901e14
        value2     [pi]
        value3      -0.1234567
        value4       0.0001234567
        value5       1.234567e-13 / ;

File out; put out;
out.nj=2; out.lw=10; out.cc=11;
loop (v, put v.tl:21);
loop (c,
  out.nd=suffix(c,"nd");
  out.nz=suffix(c,"nz");
  out.nr=suffix(c,"nr");
  out.nw=suffix(c,"nw");
  put / c.tl;
  loop (v,
    put @(ord(v)*21-10), value(v)
  )
);
```

Observe that we have chosen to align the values to the left. This will enhance readability as the model loops through the suffix combinations that entail different field widths. The resulting output file `out.put` follows:

```
          value1               value2               value3               value4               value5
comb1     1.234568E+14         3.142                -0.123               1.2345670E-4         1.2345
comb2     1.234568E+14         3.142                -0.123               1.2345670E-4         0.000
comb3     1.234568E+14         3.142                -0.123               0.000                0.000
comb4     1.2346E+14           3.14159265           -0.1234567           0.00012346           1.2346
comb5     1.234568E+14         3.141593             -0.123457            0.000123             0.0000
comb6     1.234568E+14         3                    -0                   0                    0
comb7      1.2345678901E+14     3.1415926536E+00    -1.2345670000E-01     1.2345670000E-04     1.2345
comb8     1.23456789E+14       3.141592653590       -0.12345670000       0.000123456700       0.0000
comb9     123456789010000      3.141592653589793    -0.12345678          1.234567E-4          1.2345
```

Note that in `comb1` the display of values switches to the exponential notation when the value becomes smaller than the number of decimal places allowed. This is a result of `.nr=0`. Note further, that `value4` is greater than the zero tolerance level (`.nz`), but smaller than the number of decimals allowed (`.nd`) in both, `comb2` and `comb3`. However, `.nr=0` results in the exponential notation in the display of `comb2`, while `.nr=1` has the effect that this small value is rounded to zero. Observe that in `comb6` fixed-format is used whenever allowed by the width limit, and in these cases the output is rounded to integer because `.nd` is

set to zero. With `comb7` E-format is used in all cases: a leading space is added for positive values and a minus sign to negative values, and the magnitude is indicated with an explicit plus/minus and two digits (three if necessary). With `comb8` we see fixed-format used whenever possible and as many digits (significant or not) as allowed by the width. With `comb9` we see only significant digits, with the format chosen to allow the display of as many digits as possible.

Local Item Formatting Controls

The local item formatting controls allow to format specific output items. Note that local formatting overrides global format settings. The syntax is as follows:

```
item:{<>}width:decimals;
```

Here `item` is the output item, followed by a colon, an alignment (justification) symbol, the field width, a colon and the number of decimals to be displayed. Note that the limit on the number of the decimal places is only valid for numeric output. Note further, that if a component of the local formatting feature is omitted, then the respective global formatting settings will be used. The local alignment symbols are listed in Table 11.

Symbol	Alignment
>	Right
<	Left
<>	Center

Table 11: Local Alignment Symbols

Observe that similar to global formatting, a field width of zero means that the field width will be variable, depending on the item to be displayed.

The following example serves as illustration. Observe that we use end-of-line comments to annotate the code.

```
File out; put out;

$eolCom //
Set       i    / i1*i3 /;
Parameter d(i) / i1 1426, i2 1347, i3 900 /;
Scalar    f    / 17.6745 /;

loop(i, put d(i):0:0 /);  // default justification and a field width
                          // of variable size with no decimals

put / 'Right Justified Comment':>50
    / 'Center Justified Truncated Comment':<>20;

put / / f:<6:2;           // left aligned scalar with 6 spaces for field width
                          // and two decimals
```

4.42.7 The Put_Utility Statement

The `put_utility` statement is a variant of the put statement that may be used to execute external programs. The syntax is as follows:

```
put_utility [file_name] 'command' / 'arguments' {/ 'command' / 'arguments'};
```

The keyword `put_utility` and its synonym `put_utilities` indicate that this is a put_utility statement. The keyword is followed by the internal name of an external file, `file_name`. Note that `file_name` may be omitted. It is not required for the `put_utility` statement but might be used to activate a file to be used with following `put` statements. `Command` denotes one of the commands listed in Table 12 below. Commands are followed by a slash and their respective `arguments`. Observe that a put_utility statement may contain multiple command / argument pairs. An example is given below.

The following simple example illustrates the put_utility statement:

```
File test / test.txt /;
put test "This is the original file."

put_utility 'ren' / 'test.dat';
putclose "This is the renamed file.";
test.ap = 1;
put "Write to the renamed file.";
```

Note that first the put file `test.txt` with the internal name `test` is defined, made current and written to. Then the put_utility statement uses the command ren to *rename* the current put file. The new name is `test.dat` and the internal name `test` will from now on reference the new file `test.dat`. However, the original file `test.txt` is not deleted. Hence, the code above will create two external files: `test.txt` and `test.dat`. The file `test.txt` will contain the following line:

```
This is the original file.
```

The file `test.dat` will have the following content:

```
This is the renamed file.
Write to the renamed file.
```

Note

If Put File Attributes are specified, they are also considered for the `put_utility` commands and arguments. This could lead to surprising results in some cases, like in this example:

```
File test / test.txt /;
test.pc = 5;
put test "This is the original file."

put_utility 'ren' / 'test.dat';
putclose "This is the renamed file.";
```

This will trigger the following errors:

```
*** Error at line 5: Put_Utilities: Unknown request ""ren""
*** Error at line 5: Put_Utilities: Unknown request ""test.dat""
```

The problem is, that `test.pc = 5;` puts quotes around non-numeric output, and thus `"ren"` (including the quotes) is not recognized as command anymore. To overcome this issue `test.pc` should be set back to default for the `ren` command like this:

```
File test / test.txt /;
test.pc = 5;
put test "This is the original file.";

test.pc = 2;
put_utility 'ren' / 'test.dat';
test.pc = 5;
putclose "This is the renamed file.";
```

We will present a list of all commands and their arguments in Table 12 and give examples for most commands below.

Table 12: List of Commands and their Arguments

Command	Description of Command	Description of Arguments
`assignText`	Allows to set the explanatory or label text of a singleton set element. See example below.	Name of singleton set symbol and text.
`click`	Adds a clickable file reference to the process window of the IDE. See example below.	File name of the file to which the reference will point.
`dropEnv`	Removes an environment variable at execution time.	Name of the environment variable.
`ECArguments`	Allows to set the arguments for execution time embedded code execution. See example in section Embedded Code at Execution Time.	Text for the embedded code argument.
`exec`	Passes a command to the operating system for execution. GAMS will wait until the command is executed. See example below. Note that the distinction between `exec` and shell is technical and may be operating system specific. Typically, the ability to use redirect of standard input output and the error console is involved.	Command to be executed with arguments.
`exec.aSync`	Passes a command to the operating system for execution. However, GAMS will *not* wait until the command is executed.	Command to be executed with arguments. Job control is handled identical to jobs spawned via `execute.async`.
`exec.aSyncNC`	Passes a command to the operating system for execution using a different console than the parent process (Windows only). GAMS will *not* wait until the command is executed, thus using multiple processors is possible. Job control is handled identical to jobs spawned via `execute.async`.	Command to be executed with arguments.
`exec.checkErrorLevel`	Passes a command to the operating system for execution. GAMS will wait until the command is executed, raises an execution error and aborts the execution, if the errorLevel returned is not 0.	Command to be executed with arguments.

Command	Description of Command	Description of Arguments
gdxIn	Accesses the GDX file specified in the argument. A subsequent directive execute_load or execute_loadpoint without a specified file name will unload data from the GDX file thus accessed. See example below.	Name of the GDX file that data will be loaded from.
gdxOut	Creates a new GDX file or accesses an existing GDX file specified in the argument. A subsequent directive execute_unload without a specified file name will write to the GDX file thus created or accessed. Note that if an existing GDX file is accessed, it will be overwritten. See example below.	Name of the GDX file to which data will be unloaded.
glb	Used by GAMS to facilitate building the model library - not intended for users.	–
htm	Used by GAMS to facilitate building the model library - not intended for users.	–
inc	Includes the contents of an external file in the currently active put file. See example below.	File name of external file.
incLog	Includes the contents of an external file in the currently log file . See example below.	File name of external file.
incMsg	Includes the contents of an external file in the currently listing file . See example below.	File name of external file.
incMsgLog	Includes the contents of an external file in both, the log file and the listing file. See example below.	File name of external file.
log	Sends a message to the log file. See example below.	Text of message.
msg	Sends a message to the listing file. See example below.	Text of message.
msgLog	Sends a message to both, the log file and the listing file. See example below.	Text of message.
ren	Creates a new external name for the *current* put file. The internal name will reference the new external file. Any subsequent put statements will write to the new file. See the simple example above and a more complex example below.	External file name.
save	Writes a save file of the current state of execution.	Name of save file.
setEnv	Sets an environment variable at execution time.	Name of the environment variable and its value.

Command	Description of Command	Description of Arguments
`shell`	Passes a command to the command shell processor, where it is processed. The processed form of the command is then passed to the operating system for execution. See example below. Note that the distinction between `shell` and exec is technical and may be operating system specific. Typically, the ability to use redirect of standard input output and the error console is involved.	Command to be executed with arguments.
`shell.checkErrorLevel`	Passes a command to the command shell processor, where it is processed. The processed form of the command is then passed to the operating system for execution. GAMS checks the errorLevel returned implicitly, raises an execution error and aborts the execution, if is not 0.	Command to be executed with arguments.
`solver`	Selects a solver for a given or all model types (use $*$) by name. See example below.	Model type or $*$ and solver name.
`stdOut`	Sends a message to stdOut independent of the log file.	Text of message.
`stdErr`	Sends a message to stdErr independent of the log file.	Text of message.
`title`	Changes the title on the DOS window.	New name for window.
`winMsg`	Sends a message to a window on a Windows machine. For examples, see models [**ASYNNTRP**] and [**MRW01**] in the GAMS Test Library.	Window name and message.
`xsave`	Writes a compressed save file of the current state of execution.	Name of compressed save file.

In the remainder of this section we will present examples.

Exec: Creating Empty Files by Executing External Program touch

Consider the following example:

```
Set i / 1*3 /;
loop(i, put_utility 'exec' / 'touch ' i.tl:0 '.txt');
```

Note that the command to be executed is `touch`. Thus this code snippet will create three empty files called `1.txt`, `2.txt` and `3.txt`.

Exec and Ren: Creating Directories and Renaming Files

Consider the following example:

```
File test / test.txt /; put test;
Set i / i01*i07 /;

loop(i,
   put_utilities 'exec' / 'mkdir ' 'test-':0 i.tl:0;
   put_utilities 'ren' / 'test-':0 i.tl:0 '%system.dirSep%test-':0 i.tl:0 '.txt':0 ;
   put 'this should be ' i.tl );
```

Observe that as the loop is executed, the first put_utitily statement will create seven subdirectories called `test-i01`, ..., `test-i07`. The second put_utility statement will create a text file for each of the new subdirectories. The text file in subdirectory `test-i01` is called `test-i01.txt`, the text file in subdirectory `test-i02` is called `test-i02.txt`, etc. The put statement in the last line will write to each text file. For example, the following line will be generated for the text file `test-i01.txt`:

```
this should be i01
```

Note that at the end of the loop, the external file associated with the internal file name `test` is the put file `test-i07.txt`, since this file was the last current put file.

Inc: Including the Content of a File

In this example, we first create the external file `recall.txt`, write to it and close it. Then we create a new external file called `report.dat`. In a third step we include the content of the first file in the second file.

```
File recall /recall.txt/;
putclose recall "I am the external content."

File report /report.dat/;
put report "Here we include content from an external file.";
put_utility 'inc' / 'recall.txt' ;
```

Note that the file `report.dat` will contain the following lines:

```
Here we include content from an external file.
I am the external content.
```

IncMsg, IncLog and IncMsglog: Including the Content of a File to the Log File and Listing file

In this example, we first create the external file `recall.txt`, write to it and close it. Then we include the content of `recall.txt` into the log and listing file.

```
File recall /recall.txt/;
putclose recall "I am the external content." / "I go over more than one line.";

display 'before the include';
put_utility 'incMsg' / 'recall.txt' ;
display 'after the include';
```

The listing file of this model shows the content of `recall.txt`:

```
----      4 before the include
*** Start of include of file recall.txt
I am the external content.
I go over more than one line.
*** End of include of file recall.txt

----      6 after the include
```

Msg, Log and Msglog: Writing to the Log File and Listing file

Consider the following example:

```
put_utility 'msg'    / 'This message is for the lst file.'
          / 'log'    / 'This message is for the log file.'
          / 'msgLog' / 'And this message is for the lst and the log file.' ;
```

Note that the following two lines will be generated in the log file:

```
This message is for the log file.
And this message is for the lst and the log file.
```

In addition, the listing file will contain the following two lines just before the report file summary.

```
This message is for the lst file.
And this message is for the lst and the log file.
```

Gdxout: Creating GDX Files and Unloading Data to them

Consider the following example:

```
Set j / 2005*2007 /;
Scalar random;

loop(j,
   put_utility 'gdxOut' / 'data' j.tl:0;
   random = uniform(0,1);
   execute_unload random;
);
```

This code will create the GDX files `data2005.gdx`, `data2006.gdx` and `data2007.gdx`. Note that each GDX file will contain a value between zero and 1 for the scalar `random`. For example, the file `data2005.gdx` (exported to an ASCII via `gdxdump`) will have the following content:

```
Scalar random / 0.171747132 /;
```

Gdxin: Loading Data from GDX Files

Note that the following example is an extension of the previous example that demonstrated the use of the command `gdxout`.

```
loop(j,
   put_utility 'gdxIn' / 'data' j.tl:0 ;
   execute_load random;
   display random;
);
```

This code loads the values of the scalar `random` from the GDX files `data2005.gdx`, `data2006.gdx` and `data2007.gdx` and displays them in the listing file of the GAMS input file:

```
----     19 PARAMETER random                =        0.172
----     19 PARAMETER random                =        0.843
----     19 PARAMETER random                =        0.550
```

Shell: Writing to Various Files

Consider the following example:

```
Set j / j1*j5 /;
Scalar random;

loop(j,
   random = uniformint(0,100);
   put_utility 'shell' / 'echo ' random:0:0 ' > ' j.tl:0;
);
```

Observe that the shell script command `echo` outputs an integer between zero and 100 to the files `j1`, ..., `j5`.

Click: Adding a Clickable Link

Assume that there is a file called `sets.html` in our working directory. Consider the following code snippet:

```
put_utility 'click' / 'sets.html' ;
```

If we run this code snippet with the GAMS IDE, the following clickable link will appear in the IDE process window:

```
>>> File sets.html
```

Solver: Select a solver by name at execution time

The `solver` keyword allows to select a solver at execution time by name. Normally, the option statement `option solver=xpress, lp=cplex;` is used to select the current solver, but in case where you want to programatically change the solver as in this example, this put_utility keyword can be useful. Consider the following code snippet which extends the [**DICE**] model:

```
...
set slv 'MIP solvers to run' / cplex, cbc, gurobi, mosek, scip, xpress /;
parameter rep 'report status, time, objective value, and more';
option bratio=1;
loop(slv,
   put_utility 'solver' / 'mip' / slv.tl:0;
   solve xdice using mip max wnx;
   rep(slv,'sstat')     = xdice.solveStat;
   rep(slv,'mstat')     = xdice.modelStat;
   rep(slv,'obj')       = xdice.objVal;
   rep(slv,'time')      = xdice.etSolve;
   rep(slv,'solver id') = xdice.sysIdent;
);
display rep;
```

If we run this code we get a report like this:

```
----     82 PARAMETER rep  report status, time, objective value, and more

             sstat       mstat         obj        time   solver id

cplex        1.000       1.000      21.000       0.455      19.000
cbc          1.000       8.000      21.000       2.804       6.000
gurobi       1.000       1.000      21.000       0.631      32.000
mosek        1.000       1.000      21.000       4.425      48.000
scip         1.000       1.000      21.000       3.907      65.000
xpress       1.000       1.000      21.000       2.571      71.000
```

If one want's to set a solver for all possible model types (similar to `option solver=xpress;`) specific model type has to be replaced by $*$: `put_utility 'solver' / '*' / 'xpress';`.

AssignText: Assigns label text to an element of a singleton set

GAMS has no string data type. The explanatory or label text of an element can serve in several situations as a poor man's string type and used in `put` and `put_utility` statements. The example below extends the [**TRNSPORT**] model and disables flow on a particular connection. The solution point file created by savePoint gets renamed to e.g. `sol_seattle_new-york.gdx`. The filename is assembled using the `assigntext` keyword. This has been packaged for better readability in some `STRING` macros:

```
...
$macro STRINGDEF(sym)         singleton set sym / sym /
$macro STRING(sym)            sym.te(sym)
$macro STRINGASSIGN(sym,text) put_utility 'assignText' / 'sym' / text
$macro STRINGAPPEND(sym,text) put_utility 'assignText' / 'sym' / sym.te(sym) text
alias (i,ii), (j,jj);
transport.savePoint = 1;
STRINGDEF(fname);
loop((ii,jj),
   x.up(ii,jj) = 0;
   solve transport min z using lp;
   x.up(ii,jj) = inf;
   STRINGASSIGN(fname,'sol');
   STRINGAPPEND(fname,'_' ii.tl:0);
   STRINGAPPEND(fname,'_' jj.tl:0 '.gdx');
   put_utility 'shell' / 'mv transport_p.gdx ' STRING(fname);
);
```

4.42.8 Conditional Put Statements

In GAMS, shorthand notation for conditional statement are dollar conditions, as introduced in chapter Conditional Expressions, Assignments and Equations. Dollar conditions may also be used in the context of a put statement and its variants. The syntax in its most general form is as follows:

```
put $ logical_condition [file_name] item {item} {file_name item {item}};
```

Note that like all put statements, the *conditional* put statement begins with the keyword `put`. The keyword is followed by the dollar operator and a logical condition. If the logical condition is `TRUE` the put statement will be executed, otherwise the put statement will be ignored. For details on logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. Observe that the remainder of the conditional put statement is identical to the regular put statement introduced in section The Put Statement.

The following example demonstrates how dollar conditions are used in the context of put statements.

```
put$(a > 10) 'Some output items';
```

Note that the quoted text will only be written to the put file if the scalar or variable `a` is greater than 10.

4.42.9 Errors Associated with Put Statements

There are two types of errors that may occur when the put writing facility is used: syntax errors and put errors. In this section we will discuss these errors.

4.42.9.1 Syntax Errors in Put Statements

Syntax errors are caused by the incorrect usage of the GAMS language, including unmatched parentheses, undefined identifiers, uncontrolled sets or the incorrect use of a keyword. These errors are detected during program compilation and are always fatal to program execution. For more information on compilation errors, see section Compilation Errors and the tutorials A GAMS Tutorial by Richard E. Rosenthal and Fixing Compilation Errors.

4.42.9.2 Put Errors

Put errors are unique to the put writing facility. They are detected during program execution and are caused when the specifications of file attributes are violated. Typical errors include assigning inappropriate values to file attributes and attempts to write outside a page, like moving the cursor with the cursor control character `@` to a location beyond the page width. Consider the following example:

```
File out /out.dat/;
out.pw = 8;
put out "Let's try this.";
```

Note that we specify the page width (`.pw`) to be just 8 characters. However, the quoted text has clearly more than 8 characters. In such a case the GAMS code will be compiled and the log file will report "Normal completion". At the appropriate position in the listing file the following error will be reported:

```
**** PUT ERROR FOR FILE out AT LINE 5: PUT LINE OVERFLOW - LOOK FOR **** ON PUTFILE, YOU CAN RESET .
```

The put file `out.dat` will contain the following line:

```
Let'****
```

As put errors are not fatal and are not emphasized in the log file, they may be easily overlooked. Especially in large put files, put errors may go undetected. GAMS provides the file attribute `.errors` that facilitates the display of the numer of put errors. Consider the following example:

```
File out /out.dat/;
out.pw = 8;
put out "Let's try this.";

abort$(out.errors) "Put errors in out:", out.errors;
```

Users may choose to output the number of put errors in a put file or display statement or even trigger an execution error as in the example above.

4.42.10 Creating a Report for the Model MEXSS

We started this chapter with a simple example and we will complete it with a more elaborate example. In this section we will show how the put writing facility may be used to create a report for the model [**MEXSS**]. The code for the report may be inserted at the end of the original model and is shown below in its entirety.

The model [**MEXSS**] analyzes the relative efficiency of five different plants for meeting the product requirements of ingot steel in three different markets. The model may be used to identify the major bottlenecks that constrain production in the system of plants. It will find the production levels in the steel mills and shipments from the mills to the markets that will meet the market requirements at least cost. We will create a report for this model that will present details on the available capacities of the productive units at the five plants, the unused capacities and the marginal values of the capacities. This report may be extended to include other data and results and the code may be reused to create new reports if the data in the model is changed. For models that are run periodically, say, weekly or monthly, reusable reports can be invaluable.

We will start the code for the report with defining the put file, setting the file attributes print control and page size and making the the put file current. Then we will specify some global formatting settings. We will continue with writing a title block and finally turn to the core of the report: a table with three subtables. Note that we will use in-line comments to annotate the code. The code follows:

```
$eolcom //
File out /out.dat/;
out.pc=3; out.ps=54;       // print control, page size
put out;

* Global Format Settings:
Scalars   indent1    indent to first column of units display
          indent2    indent to first column of field labels
          indent3    indent to first column of first numeric field
          textwide   wide text       / 80 /
          textnarr   narrow text     / 30 / ;
```

```
out.nr  = 0;               // numeric round format
out.tw  = textwide;        // width of text field
out.lw  = 11;              // width of label field
out.nw  = 11;              // width of numeric field
out.nd  = 2;               // number of decimals displayed
indent1 = 3;
indent2 = 30;
indent3 = 27;

* Title Block
puttl   'MEXICO STEEL - SMALL STATIC MODEL':<> /
        system.date:<>/ / /;

* Main Window
out.tj = 3;                // alignment of text: center
put

out.cc = indent2;          // current column
loop(i, put i.tl:<>);      // column headings

put / / 'CAPACITY (metric tons)';                        // Capacity
loop(m,
   put / @indent1, m.te(m), @indent3;  // row headings
   loop(i, put k(m,i));                // numeric values
);

* Header Block with column headings for next page (will be used only if necessary)
puthd 'Table 1 (continued).  Plant Data and Results':0 /
      '--------------------'/;
out.hdcc = indent2;
loop(i, put i.tl:<>);      // column headings
puthd /'';

* Main Window continued
if(out.ll+card(m)+sum((m,p)$b(m,p), 1)+3 > out.ws,
   putpage;                // manual paging
   else put / /;
);

put 'UNUSED CAPACITY (metric tons)';                      // Unused Capacity
```

```
loop(m,
   put / @indent1, m.te(m), @indent3;   // row headings
   loop(i, put (k(m,i)-cc.l(m,i)));     // numeric values
);

if(out.ll+card(m)+4 > out.ws,
   putpage;               // manual paging
   else put / /;
);

put 'MARGINAL VALUE OF CAPACITY'/ @indent1 '(US$/ton)';   // Marginal Value of Capacity
loop(m,
   put / @indent1, m.te(m), @indent3;   // row headings
   loop(i, put abs(cc.m(m,i)));         // numeric values
);
```

Note that we set print control (.pc) to ASCII formfeed. Below we illustrate how to use one of the print control settings that generate a delimited file. Observe that we group all global format parameters and settings near the top of the code. This way of organizing the code will make it easy to modify the structure of the report in the future as needed. Observe further, that the output items in the title block are locally formatted to be center aligned.

In the remainder of the code the actual report is written in the main window. The block of text at the beginning serves as a brief introduction to the report. Note that the core of the report is a table consisting of three subtables, where the subtables share the column headings. Before writing the table, we insert a test - the conditional putpage statement - to determine whether there is a sufficient number of lines on the current page to accommodate the size of the first subtable. Thus the put writing facility would start a new page if there were not enough rows. We repeat similar tests before the code for the other two subtables. Observe that we insert a header block with the column headings. If a new page had to be started since there were not enough rows for the second or the third subtable, the header block would contain the column headings of the table. (Users might want to experiment by reducing the file attribute page size (.ps) to say, 30.) The report that will be generated follows:

```
                    MEXICO STEEL - SMALL STATIC MODEL
                                 01/31/17

          This report is based on selected data and results from the model
     MEXSS in the GAMS Library. This model analyzes the relative efficiency
     of five different plants in meeting the product requirements for ingot
     steel in three different markets. The model aims to find the pattern
     of production levels in the mills and shipments from the mills to the
     markets that will meet the market requirements at the least cost.

      of Investment Programs in the Steel Industry, John Hopkins Universi-
      ty Press, 1984.

Table 1.  Plant Data and Results
-------
                                ahmsa    fundidora  sicartsa     hylsa     hylsap

CAPACITY (metric tons)
  blast furnaces                 3.25       1.40       1.10      0.00       0.00
  open hearth furnaces           1.50       0.85       0.00      0.00       0.00
```

```
  basic oxygen converters        2.07       1.50       1.30       0.00       0.00
  direct reduction units         0.00       0.00       0.00       0.98       1.00
  electric arc furnaces          0.00       0.00       0.00       1.13       0.56

UNUSED CAPACITY (metric tons)
  blast furnaces                 0.13       0.00       0.00       0.00       0.00
  open hearth furnaces           0.00       0.00       0.00       0.00       0.00
  basic oxygen converters        0.00       0.72       0.14       0.00       0.00
  direct reduction units         0.00       0.00       0.00       0.00       0.39
  electric arc furnaces          0.00       0.00       0.00       0.23       0.00

MARGINAL VALUE OF CAPACITY
  (US$/ton)
  blast furnaces                 0.00      69.62      71.69       0.00       0.00
  open hearth furnaces          53.76       1.72       2.09     138.03     145.02
  basic oxygen converters       64.57       0.00       0.00     138.03     145.02
  direct reduction units         0.00       0.00       0.00      80.08       0.00
  electric arc furnaces        136.46     138.03     140.00       0.00      94.28
```

Assume we need the data reported in the first subtable above in a delimited file format in order to import it to other applications, like spreadsheets or databases. Consider the following code:

```
file out2 / 'out2.csv' /;
out2.pc=5;
put out2 'capacity (metric tons)';
loop(i, put i.tl);
loop(m,
     put / m.te(m);
     loop(i, put k(m,i));
);
```

Note that we set the file attribute page control (`.pc`) to 5. This means that non-numeric output items will be quoted and each output item will be delimited with commas. Observe that field widths, alignments and horizontal cursor relocations were completely avoided. The put file `out2.put` will contain the following lines:

```
"capacity (metric tons)","ahmsa","fundidora","sicartsa","hylsa","hylsap"
"blast furnaces",3.25,1.40,1.10,0.00,0.00
"open hearth furnaces",1.50,0.85,0.00,0.00,0.00
"basic oxygen converters",2.07,1.50,1.30,0.00,0.00
"direct reduction units",0.00,0.00,0.00,0.98,1.00
"electric arc furnaces",0.00,0.00,0.00,1.13,0.56
```

While a comma is the most commonly used delimiting character, other delimiters like a blank space (`.pc=4`) and a tab (`.pc=6`) may also be used.

For other examples of code that uses the put writing facility, see the various models in the GAMS Model Library.

4.43 Solver Usage

For the novice GAMS user, solver usage can be very simple: one runs the model and inspects the listing file to see what the solution is. No knowledge of solver options or solver specific return codes is required. While this is enough for some users, most will quickly find they need some basic knowledge of how to control the solver and interpret the results. Section Controlling a Solver via GAMS Options describes how to set the GAMS options that control a solver. Further, most solvers allow the user to set additional, solver-specific options. These can be set via a solver specific options file, which will be discussed in Section The Solver Options File. However, use of generic GAMS options should be preferred, since a GAMS option setting applies to all solvers and is interpreted by the solvers in a consistent way.

A number of solvers can make use of an initialization of variable and equation values. This will be discussed in Starting Point and Initial Basis.

Further solver specific topics, which are more interesting for advanced users, are discussed in the Sections Solve trace and Branch-and-Cut-and-Heuristic Facility (BCH).

For some hints on how to select a solver, see Choosing an appropriate Solver.

4.43.1 Controlling a Solver via GAMS Options

GAMS options can be set on the GAMS command line, e.g.,

```
$ gams trnsport iterlim = 100
```

Additionally, they can be set by an option statement within a GAMS model, e.g.,

```
option iterlim = 100;
```

Finally, a model attribute can set a GAMS option for an individual model:

```
mymodel.iterlim = 100;
```

The model suffix takes precedence over the option statement, which takes precendence over the command line parameters. If none of these methods is used to set an option, default values apply.

Further, one can unset any model-specific option by assigning it the value `NA`:

```
mymodel.iterlim = NA;
```

Unfortunately, not every option can be via as command line parameter, option statement, and model attribute. We refer to

- Solver-Related Options for the list of solve-related options that can be set via the command line,
- Options that Control Solver-Specific Parameters and Options that Control the Choice of Solver for the list of solve-related options that can be set via the option statement, and
- Model Attributes Mainly Used Before Solve for the list of solve-related model attributes.

4.43.2 The Solver Options File

To specify solver-specific options, it is necessary to use a solver option file. Two things are required to do this: one must create an option file having a proper name, and one must tell the solver to read and use this option file.

To tell a solver to use an option file, one can set the `optfile` model attribute or the optfile option to a positive value. For example,

```
model mymodel /all/;
mymodel.optfile = 1;
solve mymodel using nlp maximizing dollars;
```

The option file takes its name from the solver being used: `solvername.XYZ`, where `solvername` is the name of the solver that is specified, and the suffix `XYZ` depends on the value to which `optfile` has been set. If its value is 1, the suffix is `opt`. For example, the option file when calling CONOPT would be called `conopt.opt`. See the documentation on optfile for more information.

The format of the options file can change marginally from solver to solver. The following illustrates some frequent features of the option file format. However, solvers may vary from this format. Thus, the solver-specific documentation should be checked before using an option file.

- Blank lines in an option file are ignored.
- A comment line might begin with an asterisk (∗) in the first column, is not interpreted by either GAMS or the solver, and is used purely for documentation.
- Each non-comment line contains only one option specification.
- The format for specifying options is as follows:

  ```
  keyword(s) [modifier] [value]
  ```

  The keyword may consist of one or more words and is not case sensitive. The value might be an integer, a real, or a string. Real numbers can be expressed in scientific format, e.g., 1e-6. Note that not all options require modifiers or values.
- Any errors in the spelling of keyword(s) or modifiers will lead to that option being misunderstood and therefore ignored. Errors in the value of an option can result in unpredictable behavior. When detected, errors are either ignored or pushed to a default or limiting value, but not all can or will be detected.

Consider the following CPLEX options file,

```
* CPLEX options file
barrier
crossover 2
```

The first line begins with an asterisk and therefore contains comments. The first option specifies the use of the barrier algorithm to solve the linear programming problem, while the second option specifies that the crossover option 2 is to be used. Details of these options can be found in Summary of CPLEX Options.

Options can also be defined by generating an options file within the GAMS source code. Consider the following code fragment for using MINOS options file,

```
Model m /all/;
Option NLP = MINOS;
* MINOS options file
$onecho > minos.opt
scale option 2
completion partial
$offecho
m.OptFile = 1;
Solve m maximizing z using nlp ;
```

The first option sets the scale option to a value of 2. In this case, the keyword 'scale option' consists of two words. In the second line, the 'completion' option is set to 'partial'. Details of these options can be found in Summary of MINOS Options.

4.43.2.1 Dot Options

Dot options in a solver option file allow users to associate values to variables and equations using the GAMS name of the variables and equations. The general syntax of a dot option in the option file is as follows:

```
(variable/equation name).optionname (value)
```

Dot options can be specified for `all`, a `block`, a `slice`, and a `single` variable and equation. Please note that a specific dot option may only apply to variables or equations (e.g. the GAMS/Gurobi dot option prior applies to variables only). The following example makes the use of the dot option clear.

For example, suppose one has a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
Variable v(i,j);
Equation e(i,j);
```

Consider the following lines in an option file with the imaginary option name `dotopt`:

Line in option file	Explanation
`variables.dotopt 1`	Sets the value of all variables to `1`
`equations.dotopt 2`	Sets the value of all equations to `2`
`v.dotopt 3`	Sets the value of the variables in block `v` to `3`
`e.dotopt(*,*) 4`	Sets the value of the equations in block `e` to `4`
`v.dotopt(*,'j2') 5`	Sets the value of the variables v that have `j2` in the second index position (slice) to `5`
`e.dotopt('i3',*) 6`	Sets the value of the equations e that have `i3` in the first index position (slice) to `6`
`w.dotopt('i2') 7`	Sets the value of the single variables `v('i2')` to `7`
`e.dotopt('i3','j3') 8`	Sets the value of the single equations `e('i3','i3')` to `8`

The values of the dot option are applied in correspondence to the sequence in which they appear in the option file. In the current example, the values of `dotopt` for the equation `e` would be as follows:

e.dotopt	i1	i2	i3
j2	4	4	6
j3	4	4	8
j4	4	4	6

4.43.3 Starting Point and Initial Basis

4.43.3.1 Starting Point

NLP solvers that search for a locally optimal solution of a NLP require an initial point to start their search. Further, the closer this initial point is to a local optimum, the less effort the solver may have to spend. The latter can also be true for solvers that search for global optimal solutions, such as most LP or MIP solver or global MINLP solvers.

Because of this immense importance of a starting point, GAMS always passes a starting point to a solver. By default, the point passed on by GAMS is given by the level and marginal attributes of variables and equations. If these values have not been set yet, default values are used. This default value is zero, except for variables whose bounds would forbid this value. In this case, the bound closest to zero is used.

In addition to setting these values explicitly in a GAMS model, a user can also load them from a save file or a GDX point file via execute_loadpoint. The latter may have been generated by running a related model and using option savepoint. Further, in models with several solve statements, the solution from one solve, if any, is used to initialize the starting point for a succeeding solve. This happens automatically since solutions from a solve statements are also stored in the level and marginal values of variables and equations. Finally, note that model attribute defpoint can be used to force sending the default starting point to a solver.

For some solvers, in particular for MIP or MINLP, an option may have to be set to make use of the starting point. Further, some solvers offer the possibility to make use of a partial starting point or use the starting point as a guide for the search. For details, see the specific solver manuals and look for parameters like `mipstart` and the use of the GAMS parameter tryint.

4.43.3.2 Initial Basis

While for some solvers, the values of a starting point are sufficient to initialize the search, active-set algorithms make use of a different form of starting information. An active-set algorithm tries to identify which constraints are active (or binding) in a feasible or optimal solution, that is, which variables are at one of their bounds and for which equations the activity equals the right-hand-side and the marginal is non-zero. For example, the simplex method for linear programs is an active-set algorithm. The classification of constraints as either active or inactive is closely linked to a *basis*. Active constraints are called *nonbasic* and inactive constraints are called *basic*. A basis that specifies the active and inactive constraints in an optimal solution is called an *optimal basis*.

Active-set algorithms may start by guessing an initial basis and then iteratively updating this basis until an optimal basis is found. Solution time may be reduced substantially if a good approximation of the optimal basis can be identified and passed on to the solver. Such a user-provided initial basis is called an *advanced basis*. However, provision of an advanced basis does not always help. For example, the presolving algorithms used in some solvers may cause the advanced basis to be ignored. Further, solvers may perform poorly when the advanced basis provided is worse than what the solver would otherwise have constructed with its own heuristics. Finally, not all algorithms benefit from the provision of an advanced basis: interior-point algorithms are a notable example.

GAMS provides a hint to the solver to suggest whether a basis can or should be extracted from the initial point. The hint is based on the number of rows (aka single equations) with nonzero marginals and the value of the bratio option and is computed internally as:

```
hint := (0 == bRatio) or (rowsWithNonzeroMarg > nRows * bratio)
```

While the setting of the variable level and marginal values is important in specifying an advanced basis, only the *marginal values for the rows* are relevant in computing the basis hint and in choosing a value for bratio. For example, in a problem with 1000 rows and with the default value of bratio (0.25), GAMS would suggest a basis only if at least 250 nonbasic rows exist.

Note that the default starting point - all marginals zero - is usually not sufficient for the construction of an initial basis. If the automatic transfer of a basis from one solve statement to the next leads to poor behavior in the solver, setting the option bratio to 1 will cause the basis hint to be false and suppress the use of an initial basis. Setting the model attribute defpoint to 1 or 2 will achieve the same result. Conversely, setting bratio to 0 will force the basis hint to be true.

Active-set solvers in GAMS typically use the basis hint value to decide whether to extract (and use) the advanced basis available in the starting point. Details can vary by solver, but typically it works as follows:

- Variables with a zero level value are suggested to be nonbasic if and only if they have a non-zero marginal value.
- Variables with a non-zero level value are suggested to be nonbasic if the level value is equal one of the variable bounds. The marginal values may also be used here: nonbasic variables correspond with non-zero marginal values.
- Equations with non-zero marginal are suggested to be nonbasic. Otherwise, they are suggested to be basic.

Thus, a user can attempt to explicitly provide an initial basis by setting a corresponding starting point. That is, one can set a guess for an initial basis by specifying

- non-zero marginals for equations that are predicted to be active in a solution
- non-zero marginals for variables that are predicted to be at their bound in a solution
- non-zero levels for the variables that are predicted to be non-zero in a solution

4.43.4 Trace Features

Sometimes it might be useful to get certain information about a particular solve statement (or GAMS job) in a compact and customizable format.

- The Trace file facility allows to create files containing information about the "end data" of a GAMS job and the contained solve statements.
- The Solve trace facility can provide more detailed information about the solution progress of a particular solve statement (e.g. objective value of the incumbent solution or the best dual bound every five seconds)

4.43.4.1 Trace File

The **trace file** contains information about the "end data" of a GAMS job and the contained solve statements. Creation of a trace file can be activated via command line parameter trace (see example below). The trace feature supports several predefined formatting options, that is differently formatted trace files can be created, depending on what output information is desired. The trace file format option can be set via command line parameter traceOpt. The trace file header defines the contained trace records and the associated trace record fields.

Note

- Trace information is appended to existing trace files **in the format of the existing trace file**. That is, if a previous trace file of the same name already exists, then all new trace data will be appended in the initial format, no matter if the current `traceopt` value actually implies a different format.
- Trace file headers can be modified, i.e. the predefined formats can be customized and trace record fields can be added or removed as needed.

Trace Records

A trace file can contain different types of trace records:

Trace Record Type	Meaning
`GamsStep`	A `GamsStep` refers to a GAMS execution phase (there are potentially multiple phases of GAMS execution in a single GAMS Job). For example, a trace file created with `traceopt=0` for the [**TRNSPORT**] model, which contains a single solve statement, will contain two GamsSteps, one referring top the GAMS execution phase before the solve statement, the other one referring to the execution phase after the solve statement. Note that this may change depending on the setting of solveLink.
`GamsExit`	`GamsExit` describes the final `GamsStep`.
`GamsSolve`	`GamsSolve` describes a trace record referring to a solve statement. If a file has multiple solve statements, the corresponding trace file can have multiple `GamsSolve` trace records.

Trace Record Fields

For every trace record, the trace file can contain multiple fields from the following list.

Name of Field	Meaning
`CNS`	CNS solver.
`ComputerName`	Computer name.
`Direction`	Direction of optimization: `0=min`, `1=max`.
`DNLP`	DNLP solver.
`EMP`	EMP solver.
`ETAlg`	Elapsed time it took to execute the solve algorithm (see corresponding model attribute etAlg).
`ETSolve`	Elapsed time it took to execute a solve statement in total (see corresponding model attribute etSolve).

Name of Field	Meaning
ETSolver	Elapsed time taken by the solver only (see corresponding model attribute etSolver).
GamsCloseDownTime	The time it takes to close down GAMS (which partly depends on command line parameters) including the time to write the file summary, a GDX file, a (obfuscated) save file, a parameter file.
GamsCompTime	Time of the GAMS compilation phase.
GamsElapsedTime	Elapsed time since the start of a GAMS run in seconds.
GamsElements	Number of labels.
GamsErrorCount	Number of compilation and execution errors.
GamsExecTime	GAMS execution time.
GamsLineNumber	Number of lines. This corresponds to the number of lines in the echo print of the input file.
GamsReturnCode	GAMS return code.
GamsStartupTime	The time it takes to start up GAMS including the time to check and dump command line parameters, initialize certain internal data structures, loading a work file, reading a license file.
GamsSymbols	Number of symbols (also called identifiers) including names of intrinsic functions and predefined symbols.
GamsTotalTime	Total time of the corresponding trace record. Does only apply for trace records of type GamsStep and GamsExit.
GamsVersionID	String that contains a GAMS version ID, e.g. WEX282-282 for the Windows 64bit version of GAMS 28.2.
InputFileName	GAMS model filename.
JobDate	Day when the job started.
JobTime	Time when the Job started.
JulianDate	Julian date number with start day/time of job.
LP	LP solver.
Marginals	Indicates availability of marginals: 0=no, 1=yes.
MCP	MCP solver.
MINLP	MINLP solver.
MIP	MIP solver.
MIQCP	MIQCP solver.
ModelGenerationTime	Model generation time. Refers to the last model in the part of the program that corresponds to the trace record.
ModelName	Model name. Refers to the last model in the part of the program that corresponds to the trace record.
ModelStatus	Model status. Refers to the last model in the part of the program that corresponds to the trace record.
ModelType	Model type. Refers to the last model in the part of the program that corresponds to the trace record.
MPEC	MPEC solver.
NLP	NLP solve.
NumberOfDiscreteVariables	Number of discrete variables. Refers to the last model in the part of the program that corresponds to the trace record.
NumberOfDomainViolations	Number of domain violations (see also model attribute domUsd).
NumberOfEquations	Number of equations. Refers to the last model in the part of the program that corresponds to the trace record.
NumberOfInstructions	Length of non-linear code.
NumberOfIterations	Number of iterations. Refers to the solve of the last model in the part of the program that corresponds to the trace record.

Name of Field	Meaning
NumberOfNodes	Number of nodes. Refers to the solve of the last model in the part of the program that corresponds to the trace record. Only relevant if some tree search algorithm (e.g. branch-and-bound was used).
NumberOfNonlinearNonZeros	Number of non-zeroes. Refers to the last model in the part of the program that corresponds to the trace record.
NumberOfNonZeros	Number of variables. Refers to the last model in the part of the program that corresponds to the trace record.
NumberOfVariables	Number of variables. Refers to the last model in the part of the program that corresponds to the trace record.
ObjectiveValue	Objective value. Refers to the solve of the last model in the part of the program that corresponds to the trace record.
ObjectiveValueEstimate	Estimate of the best possible solution for a mixed-integer model (aka best bound). Refers to the solve of the last model in the part of the program that corresponds to the trace record.
OptionFile	Solver option file number. Refers to the solve of the last model in the part of the program that corresponds to the trace record.
Platform	Platform ID, e.g. `WEX` for the Windows 64bit.
QCP	QCP solver.
RMINLP	RMINLP solver.
RMIP	RMIP solver.
RMIQCP	RMIQCP solver.
RMPEC	RMPEC solver.
SolveLine	Line number of the last solve statement in the part of the program that corresponds to the trace record. This corresponds to the line number in the echo print of the input file.
SolveNumber	Number of solve statement for a particular model. For example, `solve myModelA...; solve myModelB...; solve myModelA...;` results in solve numbers `1, 1, 2`.
SolverCalcTime	Time spent in function and derivative calculations (deprecated, see also model attribute resCalc).
SolverElapsedTime	Elapsed time taken by the solver when solveLink=0 is used (almost identical to model attribute etSolver).
SolverID	Solver ID number.
SolverName	Name of the solver. Refers to the solve of the last model in the part of the program that corresponds to the trace record.
SolverReadTime	Time to import model (deprecated, see also model attribute resIn).
SolverRealTime	Elapsed time taken by the solver when solveLink=0 is used (almost identical to model attribute etSolver).
SolverSignature	String containing a solver signature, e.g. `IBM ILOG CPLEX 28.2.0 r750fa45 Released Aug 19, 2019 WEI x86 64bit/MS Window`. Refers to the solver used to solve the last model in the part of the program that corresponds to the trace record.
SolverStatus	Solver Status. Refers to the solve of the last model in the part of the program that corresponds to the trace record.
SolverTime	Time used to solve the model in seconds reported by the solver (see also model attribute resUsd).
SolverVersion	Solver Version (see also model attribute sysVer).
SolverWriteTime	Time to export solution (deprecated, see also model attribute resOut).
User1	Content of user1 string.
User2	Content of user2 string.
User3	Content of user3 string.

Name of Field	Meaning
User4	Content of user4 string.
User5	Content of user5 string.
UserName	User name.

Trace Report

GAMS can create **trace reports** from trace files, if started with command line parameter action=gt. The following sequence of commands loads model [**TRNSPORT**] from the GAMS model library, runs trnsport.gms and creates a tracefile trc.txt, and produces a trace report plus a trace summary from the trace file.

```
$ gamslib trnsport
$ gams trnsport trace=trc.txt
$ gams trc.txt a=gt
```

The **trace file** trc.txt contains the default trace record fields for the GamsStep and GamsSolve trace records:

```
* Trace Record Definition
* GamsStep
* JobDate JobTime InputFileName GAMS GamsVersionID GamsReturnCode GamsErrorCount GamsStartupTime Gams
* GamsSolve
* JobDate JobTime InputFileName ModelType SolverName SolverStatus ModelStatus SolveNumber SolveLine S
*  NumberOfIterations ModelGenerationTime SolverReadTime SolverCalcTime SolverWriteTime ObjectiveValu
*
09/25/19 07:04:00 trnsport.gms GAMS WEX282-282 1 0 0.015 0 0 0.016 0.031 ""
09/25/19 07:04:00 trnsport.gms LP CPLEX 1 1 1 64 23 NA 6 7 19 0 0 4 0 NA NA NA 153.675 ""
09/25/19 07:04:00 trnsport.gms GAMS WEX282-282 0 0 0 0 0 0 0 ""
```

The **trace summary** trc.sum contains condensed information about the trace records:

```
Trace Summary with TL=0 for [...]\trc.txt
Trace Records = 3, Error Records = 0, First Date = 09/25/19 07:04:00
```

The **trace report** is created in trc.lst and contains detailed information about the trace records from the underlying trace file including a ModelSolveStat matrix that assigns a score from 0 to 9 to all potential combinations of model status and solver status:

```
[...]
Trace Report for File: [...]\trc.txt

Using ModelSolveStat for TL=0

     1  2  3  4  5  6  7  8  9 10 11 12 13
  1  9  .  .  .  .  .  .  .  .  .  .  .  .

  total      1    0    0    0    0    0    0    0    0    0    0    0    0    0    0    0    0    0

GTRACE      TIME     =        0.000 SECONDS        VERID WEX282-282
[...]
```

The trace report may be particularly interesting, if the underlying trace file contains multiple trace records from different solve statements. In combination with command line parameter traceLevel, it is easy to filter for `GamsSolve` trace records with a low `ModelSolveStat` score, i.e. undesirable combinations of model status and solver status. If we run [**TRNSPORT**] again with an iteration limit of 0 (remember that the trace information will be appended to the trace file from the example above) and recreate the trace report as follows

```
$ gams trnsport trace=trc.txt iterlim=0
$ gams trc.txt a=gt
```

the trace report shows two solve records and the obtained statuses:

```
Total SOLVE records =     2  all return codes

      solvestatus         1  RC= 1  1 Normal Completion
      solvestatus         1  RC= 2  2 Iteration Interrupt

      modelstatus         1  RC= 1  1 Optimal
      modelstatus         1  RC= 6  6 Intermediate Infeasible
```

A look at the `ModelSolveStat` matrix from the initial example, tells us that a combination of model status 6 (Intermediate Infeasible) in combination with solve status 2 (Iteration Interrupt) results in a score of 5. If we increase the traceLevel to a value greater than or equal to 5 and recreate the trace report again, e.g. via

```
$ gams trc.txt a=gt tracelevel=5
```

the ModelSolveStat matrix at the beginning of the trace report changes such that only the scores greater than 5 for accepted combinations of model and solver status are shown

```
Using ModelSolveStat for TL=5

     1  2  3  4  5  6  7  8  9 10 11 12 13
  1  9  .  .  .  .  .  .  .  .  .  .  .  .
  2  9  9  9  9  9  .  .  9  .  .  .  .  .
  3  9  .  .  .  .  .  .  .  .  .  .  .  .
  4  9  .  .  .  .  .  .  .  .  .  .  .  .
  5  9  .  .  .  .  .  .  .  .  .  .  .  .
  6  .  .  .  .  .  .  .  .  .  .  .  .  .
  7  9  9  9  9  9  .  .  9  .  .  .  .  .
  8  9  9  9  9  9  .  .  9  .  .  .  .  .
  9  .  .  .  .  .  .  .  .  .  .  .  .  .
 10  9  .  .  .  .  .  .  .  .  .  .  .  .
 11  .  .  .  .  .  .  .  .  .  .  .  .  .
 12  .  .  .  .  .  .  .  .  .  .  .  .  .
 13  .  .  .  .  .  .  .  .  .  .  .  .  .
 14  .  .  .  .  .  6  .  .  .  .  .  .  .
 15  9  .  .  .  .  .  .  .  .  .  .  .  .
 16  9  .  .  .  .  .  .  .  .  .  .  .  .
 17  9  .  .  .  .  .  .  .  .  .  .  .  .
 18  9  .  .  .  .  .  .  .  .  .  .  .  .
 19  9  .  .  .  .  .  .  .  .  .  .  .  .
```

and GAMS throws an execution error

```
--- Starting trace report generation
*** Status: Execution error(s)
```

The trace file facility in combination with the trace report can be particularly useful for automated quality assurance tests where certain expected outcomes should be audited.

4.43.4.2 Solve trace

In order to do accurate performance evaluations it may be useful to obtain more detailed information about a solve than the "end data" that the trace file provides. E.g., for a branch-and-bound based solver, one may want to have intermediate information about the values of primal and dual bounds at the root node and subsequent nodes within the search.

The **solve trace** option that is implemented in some of the GAMS solver interfaces allows users to output solve information, e.g., primal and dual bounds, for every n nodes or at every time step. For example, the user may be interested in the objective value of the incumbent solution or the best dual bound on the optimal value every 50 nodes and every five seconds of the solve.

Note

The solve trace file format and options may change in a future GAMS release.

The solve trace option is invoked via a GAMS solver options file. Usually, options to specify a filename of the trace file to be created and options to specify time and node intervals are available. Please refer to the GAMS solver manuals for the exact names of these options (search for solvetrace or miptrace).

The solve trace file is written in comma-separated-value (CSV) format, where the entries in each line have the following meaning:

Column Name	Meaning
lineNum	a line index
seriesID	indicator why the line was written: S = start of search, N = node frequency, T = time frequency, E = end of search
node	number of enumerated branch-and-bound nodes
seconds	time since the solving started
bestFound	primal bound, i.e., objective value of incumbent solution
bestBound	dual bound, i.e., bound on optimal value

A sample solve trace file including statistics of a GAMS run using the MIP model [**DICE**] and the solver XPRESS looks as follows:

```
* miptrace file miptrace.mtr: ID = XPRESS.1 Instance = dice
* fields are lineNum, seriesID, node, seconds, bestFound, bestBound
1, S, 1, 0.078, na, na
2, N, 101, 0.781, 21, 23.9369
3, N, 201, 0.875, 21, 23.5564
4, N, 304, 1.031, 21, 23.5564
5, E, 399, 1.094, 21, 21
* miptrace file miptrace.mtr closed
```

See also the slides for the presentation Advanced Use of GAMS Solver Links (2013) and the accompanying scripts for some ideas on what to do with the solve trace functionality.

4.43.5 Branch-and-Cut-and-Heuristic Facility (BCH)

Global search algorithms can sometimes significantly benefit from user supplied routines that support the solution process of an hard optimization problem. For example, branch-and-cut solvers (e.g., CPLEX, Gurobi, SCIP, Xpress) can profit from user-supplied *cutting planes* or *good feasible solutions*. GAMS users could supply these as part of the model given to the solver, by adding a set of constraints representing likely to be violated cuts and an initial solution (possibly in combination with GAMS parameters like tryint and solver-specific options like mipstart in CPLEX). However, this does not allow a dynamic interaction between a running solver and user supplied routines that, for example, use a current relaxation solution to construct cutting planes or feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) facility attempts to automate all major steps necessary to make callbacks that certain solvers provide for such usage available to the GAMS user. This allows GAMS users to apply complex solution strategies without having to have intimate knowledge about the inner workings of a specific solver.

Currently, only two solvers support the BCH facility: CPLEX and SBB. With GAMS/CPLEX, user supplied GAMS programs that implement primal heuristics and cut generation can be used. With SBB, only primal heuristics are possible.

As the name indicates, the BCH facility has been designed with the solving process of a branch-and-cut solver (e.g., CPLEX, Gurobi, SCIP, Xpress) in mind. Such solvers often allow to call a user supplied routine after a node in the branch-and-bound (B&B) tree has been processed. Within that routine, available information like the solution of a relaxation (often an LP or NLP) at that node and the current incumbent, if any, is exported by the BCH facility into a GDX file using the original GAMS namespace. Next, different user supplied GAMS programs can be called, e.g., for finding cuts which are violated by the relaxation solution (cut generator) or to find new incumbents (primal heuristic). These GAMS programs should import the information from the GDX file and do their computations. After termination, the BCH facility resumes control, reads the findings from the GAMS program and passes them to the solver.

A relaxation solution may be exported into a file `bchout.gdx` by the BCH facility. This GDX file does not only contain the variable values as level values (`.l`), but also variable bounds (`.lo` and `.up`). For a B&B solver, these are the local bounds at this node. Hence, they reflect branching decisions made in the B&B tree and bound tightenings that were deduced by the solver. In a similar way, the BCH facility may export an incumbent solution to the GDX file `bchout_i.gdx`. The bounds for the incumbent solution reflect global bounds, i.e., the original bounds, possibly tightened by the solver. GDX files can be imported by the GAMS program using the compile time $load or run time execute_load.

The BCH facility is activated and controlled by setting certain options in the solvers options file. The precise names and meanings of the options may vary from one solver to another. Therefore, also the corresponding GAMS solver manual should be checked. The options that come with the BCH facility can be used to define the calls of the users GAMS programs, to determine when they should be called, and to overwrite the filenames for the GDX files (to avoid name clashes). General BCH related options are the following:

Name	Description	Default
`UserGDXIn`	The name of the GDX file read back into the solver.	`bchin.gdx`
`UserGDXName`	The name of the GDX file exported from the solver with the solution at the node.	`bchout.gdx`
`UserGDXNameInc`	The name of the GDX file exported from the solver with the incumbent solution.	`bchout_i.gdx`
`UserGDXPrefix`	Prefix to add to `UserGDXIn`, `UserGDXName`, and `UserGDXNameInc`	*empty*
`UserJobID`	Postfix to add to listing and log filenames and to `UserGDXIn`, `UserGDXName`, and `UserGDXNameInc`. Further, `--UserJobID` is added to calls to users GAMS programs.	*empty*
`UserKeep`	Calls users GAMS programs with `gamskeep` instead of `gams`. The use of `gamskeep` will preserve the scratch directory similar to the command line option keep	0

In the following, the interface for the available callbacks are explained in more detail and corresponding options are listed.

4.43.5.1 Primal Heuristics

In the primal heuristic callback, the user can provide a GAMS program which tries to construct a feasible solution based on the information provided by the solver, e.g., a current relaxation solution and the current incumbent. Thus, the GAMS program could attempt to repair infeasibilities in the relaxation solution or try to improve the incumbent from the solver.

If the GAMS program finds a new solution, it should store it in the level values of variables that correspond to the original variables. For example, if the original model uses binary variable `open(i,t)`, then at the end of the GAMS program `open.l(i,t)` should contain a 0 (zero) or a 1 (one). The BCH facility calls the GAMS program and instructs GAMS to store the results in a GDX file at termination. This GDX file is then read in again by the BCH facility and the solution is passed back to the solver. The solver checks this solution for infeasibilities and in case this check is passed and the solution is better than the best known solution, the solver updates it's incumbent.

If the GAMS program cannot find a feasible solution, it can terminate with an execution error triggered by an abort statement to prevent the BCH facility from reading the results from the heuristic run.

BCH parameters to control the primal heuristic call are typically the following:

Name	Description	Default
`UserHeurFreq`	Determines the frequency of the heuristic call.	10

Name	Description	Default
UserHeurMult	Determines the multiplier for the frequency of the heuristic call.	2
UserHeurInterval	Determines the interval when to apply the multiplier for the frequency of the heuristic call. For example, for the first 100 (UserHeurInterval) nodes, the solver calls the heuristic every 10th (UserHeurFreq) node. After 100 nodes, the frequency gets multiplied by 10 (UserHeurMult), so that for the next 100 nodes the solver calls the heuristic every 20th node. For nodes 200-300, the heuristic get called every 40th node, for nodes 300-400 every 80th node and after node 400 every 100th node.	100
UserHeurFirst	For how many of the first nodes the heuristic should be called.	10
UserHeurObjFirst	Similar to UserHeurFirst, but specifices for how many of the first nodes the heuristic should be called if the optimal value of the current nodes relaxation promises a significant improvement of the current incumbent, i.e., the optimal value of the relaxation at the node has to be closer to the current dual bound than the current primal bound.	*solver dependent*
UserHeurNewInt	Whether to calls the heuristic when the solver found a new feasible solution.	no
UserHeurCall	Arguments to the GAMS call to invoke the heuristic GAMS program.	*empty*

As an example, for the Oil Pipeline Network Design problem, the BCH options to invoke the primal heuristic in the GAMS program bchoil_h.inc when using GAMS/CPLEX could be

```
userheurcall     bchoil_h.inc mip cplex optcr 0 reslim 10
userheurfirst    5
userheurfreq     20
userheurinterval 1000
```

4.43.5.2 Cutting Planes

In the cut generator callback, the user can provide a GAMS program which tries to find a linear cut (that is, a linear inequality) that is violated by the relaxation solution. The solver would then add these cuts to it's *cut pool*. Typically, it then resolves the relaxation at the node and calls the cut generator again. If no cutting planes are found, the solver will continue, e.g., by processing the next node. Please note that the solver cannot perform validity checks on the provided cuts. Hence, it is possible to cut off areas of the feasible region, including optimal solutions.

Exporting cuts is a little more complicated than a solution because next to the cut coefficients, also the sense and the right-hand-side of the cut inequality needs to be exported. Further, exporting several cuts with one call should be possible. For this purpose, the GAMS program has to define and fill a set cc and parameters numcuts, rhs_c(cc), and sense_c(cc) appropriately. The set cc is used as a cut index. It can be larger than the number of actually generated cuts.

Note

The elements of the cut index set must form a series of integers starting at 1 (1, 2, 3,...).

Parameter numcuts should specify the number of added cuts. rhs_c(cc) should store the right-hand-side of each cut. Finally, sense_c(cc) should store the sense of each cut, which must be 1 for lower-equal ($\leq$), 2 for equal ($=$, rather unusual for cuts), and 3 for greater-equal ($\geq$). The corresponding declaration in GAMS code may be

```
$set MaxCuts 100
Set        cc          'cuts'  / 1 * %MaxCuts% /;
Parameters numcuts     'number of cuts to be added' / 0 /
           rhs_c(cc)   'cut rhs'
           sense_c(cc) 'the sense of the cuts';
```

The only thing missing are the cut coefficients. As it should be possible to return more than one cut, using variable attributes like level values is not sufficient. Therefore, for each variable that is part of a cut, a new parameter must be added in the GAMS program. The name of the parameter must be the name of the corresponding variable with an additional `_c` at the end. Further, the parameter must be indexed like the variable, but with the cut index set cc added at the beginning. For example, assume variable `open(i,t)` should be part of a cut. Then the cut coefficients should be stored in a parameter `open_c(cc,i,t)`, e.g.,

```
Parameter  open_c(cc,i,t) 'coefficients of variable open(i,t) in cut cc';
```

The BCH facility reads all parameters that end in `_c`, takes the base name and looks for a variable with that name and indices and builds up the cut matrix. A cut cannot introduce a new variable into the model. All cuts added to the model are assumed to be *global cuts*, that is, they need to be valid for the entire problem, not just for the current node.

BCH parameters to control the cut generation call are typically the following:

Name	Description	Default
`UserCutFreq`	Determines the frequency of the cut generator call.	10
`UserCutMult`	Determines the multiplier for the frequency of the cut generator call.	2
`UserCutInterval`	Determines the interval when to apply the multiplier for the frequency of the cut generator call. See UserHeurInterval for details.	100
`UserCutFirst`	Calls the cut generator for the first n nodes.	10
`UserCutNewInt`	Whether to call the cut generator if the solver found a new integer feasible solution.	no
`UserCutCall`	Arguments to the GAMS call to invoke the cut generator GAMS program.	*empty*

As an example, for the Oil Pipeline Network Design problem, the BCH options to invoke the cut generator in the GAMS program `bchoil_c.inc` when using GAMS/CPLEX could be

```
usercutcall   bchoil_c.inc mip cplex
usercutfirst  0
usercutfreq   0
usercutnewint yes
```

4.43.5.3 Incumbent Callbacks

The incumbent callbacks can be used to execute a GAMS program when the solver found a new feasible solution that improves the incumbent. Additionally, the incumbent check callback `UserIncbCall` can be used to notify the solver whether the given feasible solution should be accepted by the solver. This allows to implement a filtering mechanism that forces a solver to search for additional solutions even though an optimal solution might have been found already. Furthermore, the callback `UserLazyConCall` allows to add lazy constraints after an incumbent has been found.

The following parameters control the incumbent callbacks:

Name	Description	Default
UserIncbCall	Arguments to the GAMS call to invoke the incumbent checking GAMS program. The incumbent is rejected if the GAMS program terminates normally. In case of a compilation or execution error, the incumbent is accepted.	*empty*
UserIncbICall	Arguments to the GAMS call to invoke the incumbent reporting GAMS program.	*empty*
UserLazyConCall	Arguments to the GAMS call to invoke the lazy constraint adding GAMS program. Lazy constraints that cut off the incumbent are expected (in a format similar to UserCutCall) if the GAMS program terminates normally. In case of a compilation or execution error, the incumbent is accepted.	*empty*

4.43.5.4 Examples

The GAMS model library contains a few examples to show to use the BCH facility:

- **bchtlbas.gms : Trim Loss Minimization with Heuristic using BCH Facility** This model implements a very simple LP/MIP based primal heuristic for the trimloss minimization problem.
- **bchfcnet.gms : Fixed Cost Network Flow Problem with Cuts using BCH Facility** This model implements simple but difficult to separate cuts for a network design problem. The global solver BARON is used to find violated cuts by solving a non-convex MINLP.
- **bchmknap.gms : Multi knapsack problem using BCH Facility** This model implements simple cover inequalities for the multi-knapsack problem.
- **bchoil.gms : Oil Pipeline Design Problem using BCH Facility** This is the most complex example. It implements three different primal heuristics: an initial heuristic based on a simplified cost structure, a rounding heuristic, and a local branching heuristic. In addition, complex cuts are generated by solving regionalized versions of the original problem.
- **dicegrid.gms : MIP Decomposition and Parallel Grid Submission - DICE Example** This example uses many of the UserJobID option to rename files, since running multiple jobs in parallel requires the use of different filenames. This example also uses the incumbent reporting call UserIncbICall.
- **solnpool.gms : Cplex Solution Pool for a Simple Facility Location Problem** This example uses the incumbent checking call UserIncbCall as an advanced filter for accepting or rejecting solutions found by CPLEX.

4.43.6 Choosing an appropriate Solver

For any of the GAMS problem classes (LP, MCP, MINLP, ...), there is no solver that is best on every problem instance. Below, we provide some links to rules of thumb on choosing a solver or solver comparisons.

4.43.6.1 Relative Merits of MINOS and CONOPT

How to choose between MINOS and CONOPT

It is almost impossible to predict how difficult it is to solve a particular model. The best and most reliable way to find out which solver to use is to try out both. However, there are a few rules of thumb:

CONOPT 3 is well suited for models with very non-linear constraints. If you experience that MINOS has problems achieving feasibility during the optimization, you should try CONOPT. On the other hand, if your model has few nonlinearities outside the objective function, MINOS and QUADMINOS is probably the best solver.

CONOPT is has a fast method for finding a first feasible solution that is particularly well suited for models with few degrees of freedom (this means: the number of variables is approximately the same as the number of constraints - in other words, models that are almost square). In these cases CONOPT is likely to outperform MINOS while for models with many more variables than equations MINOS is probably more suited.

CONOPT has a preprocessing step in which recursive equations and variables are solved and removed from the model. If you have a model where many equations can be solved one by one, CONOPT will take advantage of this property. Similarly, intermediate variables only used to define objective function terms are eliminated from the model and the constraints are moved into the objective function.

CONOPT has many built-in tests (e.g. tests for detecting poor scaling). Many models that can be improved by the modeler are rejected with a constructive message. CONOPT is therefore a useful diagnostic tool during model development even if another solver is used for the production runs.

Why serious NLP modelers should have both MINOS and CONOPT

It is almost impossible to predict how difficult it is to solve a particular model. However, if you have two solvers, you can try both. The overall reliability is increased and the expected solution time will be reduced.

On a test set of 196 large and difficult models, many poorly scaled or without initial values, both MINOS and CONOPT failed on 14 models. However only 4 failed on both MINOS and CONOPT. So the reliability of the combined set of solvers is much better than any individual solver.

Many examples of poorly formulated models were observed on which MINOS failed. CONOPT rejected many of the models, but with diagnostic messages pinpointing the cause of the problem. After incorporating the changes suggested by CONOPT, both MINOS and CONOPT could solve the model. Switching between the two solvers during the initial model building and debugging phase can often provide useful information for improving the model formulation.

Special Offer for two NLP Solvers

In order to encourage modelers to have two NLP solvers, GAMS offers a 50% discount on the second solver when both MINOS and CONOPT are purchased together.

4.43.6.2 PATH versus MILES

This document describes some of the differences between the MCP solvers PATH and MILES. MILES is a free solver, that comes with the GAMS/BASE module, while PATH is an optional solver, that is charged for separately.

PATH and MILES are two GAMS solvers capable of solving mixed nonlinear complementarity problems (MCP). Both solvers are based on the sequential linear complementarity algorithm, i.e., they both solve a sequence of linear mixed complementarity problems whose solutions typically converge to the solution of the MCP. To solve each of the linear subproblems (major iterations), both codes use a generalization of an algorithm due to Lemke that is based on a sequence of pivots (minor iterations) similar to those generated by the simplex method for linear programming. To do these pivots efficiently, both codes use the same sparse linear algebra package.

As a result of the above similarities, the performance of the two codes is comparable for many "easy" models. Viewed over a broad range of problems, however, PATH is typically faster and more robust than MILES. While both codes solve all the MCP and MPSGE models in GAMSLIB, PATH significantly outperforms MILES on the MCPLIB test collection found at CPNET.

Most sophisticated MCP and MPSGE modelers prefer to use PATH over MILES. PATH has a crashing scheme that allows it to quickly improve the user given starting point before starting to solve the linear subproblems. This frequently speeds up solution time. PATH automatically attempts to fix "singular" models using a technique based on proximal perturbations. In many cases, this enables the linear subproblems to be solved, leading to a model solution. This typically helps modelers at model development time.

PATH has many more solution options to enable it solve difficult models. The code automatically tries useful options on difficult problems using a restart procedure. PATH has a much more sophisticated "globalization" procedure that typically improves speed and robustness. PATH implements a nonmonotone watchdog technique. Stalling is frequently circumvented by allowing larger steps to be taken toward solutions.

PATH has many more diagnostic features that help uncover problems in a model. In particular, singularities in the model, zero rows and columns and several measures of optimality are returned to the user. Theoretically, PATH has better convergence properties than MILES. In particular, new merit functions are known to allow more reliable and faster convergence.

4.44 The Save and Restart Feature

GAMS saves the information provided in input files in intermediate - mostly binary - files, called *work files* or *scratch files*. Some of these files are used to exchange information between GAMS and the solvers. They are usually deleted just before a GAMS run is complete. However, these intermediate files may be used to process an input file, save the result and later reload this file and continue with processing another input file. Thus, input files may be processed sequentially through the use of the intermediate files. This is a useful feature that can help to reduce the required time when, e.g., several runs of similar models are being made, all of them sharing an equal large initialization part.

The same process may be described in a different way. Assume a large GAMS program is run and an output file is generated, as usual. Suppose the large program is split in two parts. The first part is run and the resulting work file is saved along with the resulting listing file. Then the second part is run after reading in the data from the work file saved previously and a new listing file is generated for the second part. The content of the two listing files will be the same as the content of the output from the very first run when the large program was processed without interruption. Only the arrangement of the content will slightly differ. Splitting the files makes it possible to interrupt a GAMS task and restart it later without loss of information. Furthermore, changes could be made or errors corrected in the later parts.

Note

- The work file preserves all information (including declarations, values, option settings and dollar control options) known to GAMS at the end of the run.
- The work file is not machine specific and thus is portable between platforms. However, a work file that has been generated with one version of GAMS cannot be used for a restart with an older GAMS version (unless command line parameter forceWork is set).
- Absolute or relative path names (e.g. for put files) that do not exist or have the wrong directory separator may cause execution errors. Moreover, if the code in the work file executes a program that might not exist on another platform (e.g. gdxxrw on Linux) the GAMS execution might also result in execution errors.

This chapter illustrates the basics of the save and restart feature in Section Basic Usage and presents some use cases in Section Use Cases. Preventing unauthorized access to and obfuscating the content of work files is discussed in Sections Secure Work Files and Obfuscated Work Files, respectively. An overview of all command line parameters for saving and restarting in GAMS is given in Section Save and Restart Options (chapter The GAMS Call and Command Line Parameters).

4.44.1 Basic Usage

The mechanism to break up the compilation of a large input file into many components and stages is provided by the command line parameters save and restart.

The following demonstrates saves and restarts with the well known transportation model [**TRNSPORT**]. First, the code is split into three parts, resulting in the files `tranmodel.gms`, `transolve.gms`, and `tranreport.gms`. The file `tranmodel.gms` contains the first part of the model up to and including the model statement:

```
Sets
   i   "canning plants"   / seattle, san-diego /
   j   "markets"          / new-york, chicago, topeka / ;

Parameters
   a(i)  "capacity of plant i in cases"
      /    seattle     350
           san-diego   600  /

   b(j)  "demand at market j in cases"
      /    new-york    325
           chicago     300
           topeka      275  / ;

Table d(i,j)  "distance in 1000 miles"
                  new-york       chicago      topeka
   seattle          2.5           1.7          1.8
   san-diego        2.5           1.8          1.4  ;

Scalar f  "freight in dollars/case per 1000 miles" /90/ ;

Parameter c(i,j)  "transport cost in $1000/case" ;
c(i,j) = f * d(i,j) / 1000 ;

Variables
    x(i,j)  "shipment quantities in cases"
    z       "total transportation costs in 1000$" ;
```

```
Positive Variable x ;

Equations
    cost        "define objective function"
    supply(i)   "observe supply limit at plant i"
    demand(j)   "satisfy demand at market j" ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;
```

The file `transolve.gms` contains the solve statement:

```
solve transport using lp minimizing z;
```

And the third file, `tranreport.gms`, contains the display statement:

```
display x.l, x.m ;
```

Observe that concatenating the three files (in the right order) results in the original model [**TRNSPORT**].

4.44.1.1 Saving The Work File

The information in `tranmodel.gms` may be stored by using the following call to GAMS:

```
> gams tranmodel save=s1
```

This command line statement creates the output file `tranmodel.lst` and the work file `s1.g00` in the current working directory.

Note that the command line parameter `s` is a synonym to save.

4.44.1.2 Restarting from the Work File

Consider the following call:

```
> gams transolve restart=s1
```

GAMS reads the work file named `s1.g00` and regenerates the information stored in `tranmodel.gms`. Then `transolve.gms` is run and the result is as if the a concatenation of `tranmodel.gms` and `transolve.gms` had been executed. Note, that the output file `tranmodel.lst` will contain the echo print of the model and `transolve.lst` will contain the echo print of the solve statement and all the output generated by the solve.

Note that the command line parameter `r` is a synonym of restart.

Observe that a restarted run always requires a GAMS input file to continue with. The restart does not alter work files. They may be used repeatedly to continue a particular run many times, possibly with many different continuation input files.

4.44.1.3 A Sequence of Saves and Restarts

In case there are more than two files that should be run sequentially, the second and any other non-final run will have to generate input files for a following restart. Therefore, their workfiles need to be saved.

Following the splitup of model [**TRNSPORT**] into the three files `tranmodel.gms`, `transolve.gms`, and `tranreport.gms`, a sequence of GAMS calls that would run the whole `trnsport` model could be as follows:

```
> gams tranmodel       s=s1
> gams transolve  r=s1 s=s2
> gams tranreport r=s2
```

The listing file of `tranreport.gms` will contain the compilation output with the echo print of the display statement, the final execution summary with the output generated from the display statement and the file summary. The listing files of all three input files together will have the same content as `trnsport.lst` (generated by a run of `trnsport.gms`).

Observe that the three files could also have been processed with a sequence of $include file statements. The advantages of using the `save` and `restart` feature instead are given in section Use Cases below.

4.44.1.4 Avoiding Common Mistakes

A common mistake that occurs when using the save and restart feature is running GAMS on the same file twice, e.g.,

```
> gams trnsport s=trans
> gams trnsport r=trans
```

In this case all the data and equation definitions are repeated, which will cause compilation errors for the second run as in GAMS each data item may be defined only once.

Further, it is the responsibility of the modeler to ensure that the contents of the input file matches that of the work file, although the compiler will issue errors if it detects any inconsistencies, such as references to symbols not previously declared.

4.44.1.5 Prefixing Symbols in the Work File

Assume writing some reporting code that works off a restart file and new symbol names that have not been used in the previous program are required. GAMS offers a convenient and systematic way to achieve this by prefixing all symbols in the work file with a specified string. Consider the following example, again using the transportation model [**TRNSPORT**]:

```
> gams trnsport s=prefixed symPrefix=aa_
```

This solves the model and saves the work file `prefixed.g00`. The command line parameter symPrefix has the effect that all symbols in the work file are prefixed with `aa_`. For the next step, consider the following simple reporting code, saved in a file called `report.gms`:

```
Scalar i / 0 /;
loop(aa_i, i = i+1);
display 'number of canning plants', i;
```

Note that this code will be run with a restart from the work file `prefixed.g00`. Therefore, the looping set `aa_i` is identical to the set `i` in the model [**TRANSPORT**]. Since all symbols from the original model have been prefixed, convenient symbol names can be used for reporting purposes. The run of `report.gms` is achieved by the following call:

```
> gams report r=prefixed
```

The resulting listing file contains the following output:

```
----     76 number of canning plants
           PARAMETER i                   =        2.000
```

4.44.2 Use Cases

The basic function of a work file is to preserve information that has been expensive to produce. The following discusses several use cases for work files.

4.44.2.1 Separation of Model and Data

The separation of model and data is one of the core principles of the GAMS modeling paradigm. Using the save and restart feature helps to exploit this separation.

Separation of model and data will be illustrated on the transportation model [**TRNSPORT**]. First, consider a GAMS file `transportmodel.gms` which contains only the algebraic representation of the transportation problem, obtained by removing all data and execution statements from [**TRNSPORT**]:

```
Sets i   canning plants
     j   markets ;

Parameters  a(i)    "capacity of plant i in cases"
            b(j)    "demand at market j in cases"
            c(i,j)  "transport cost in 1000$/case"
            d(i,j)  "distance in 1000 miles"  ;

Scalar f  "freight in $/case per 1000 miles"  ;

Variables   x(i,j)  "shipment quantities in cases"
            z       "total transportation costs in 1000$"  ;
Positive Variable x ;

Equations  cost        "define objective function"
           supply(i)   "observe supply limit at plant i"
           demand(j)   "satisfy demand at market j" ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;
```

Second, consider a GAMS file `transportdata.gms` that contains the data of the model as well as the solve and display statements:

```
Sets   i   / seattle, san-diego /
       j   / new-york, chicago, topeka / ;

Parameters  a(i)  / seattle     350
                    san-diego   600  /
            b(j)  / new-york    325
                    chicago     300
                    topeka      275  / ;

Table d(i,j)
                  new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;

Scalar f / 90 / ;

c(i,j) = f * d(i,j) / 1000 ;

Solve transport using lp minimizing z ;
Display x.l, x.m ;
```

The second file (`transportdata.gms`) cannot be run alone as the definition of model `transport` is missing. However, one may first run the first file (`transportmodel.gms`) and save its work file. Then one can restart from this work file to run the second file:

```
> gams transportmodel.gms s=transmod
> gams transportdata.gms  r=transmod
```

4.44.2.2 Advanced Separation of Model and Data

In the previous example some execution time statements namely the assignment of `c`, the `solve`, and the `display` where performed in the data file. If the model execution logic is more complex we do not want to add this to the data file. Hence we create in this example a restart file from this first file but will only compile, but not execute (see difference between compile and execute phases in section GAMS Compile Time and Execution Time Phase):

```
$onEmpty
Sets i(*)   canning plants / /
     j(*)   markets        / / ;

Parameters  a(i)    "capacity of plant i in cases" / /
            b(j)    "demand at market j in cases"  / /
            c(i,j)  "transport cost in 1000$/case"
            d(i,j)  "distance in 1000 miles"       / /;

Scalar f  "freight in $/case per 1000 miles" / 0 /;

c(i,j) = f * d(i,j) / 1000 ;

Variables   x(i,j)  "shipment quantities in cases"
            z       "total transportation costs in 1000$"  ;
```

```
Positive Variable x ;

Equations  cost        "define objective function"
           supply(i)   "observe supply limit at plant i"
           demand(j)   "satisfy demand at market j" ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;
Display x.l, x.m ;
```

Second, we consider a file that contains the data of the model but no other execution time statements. Because we already have empty data statements (`/ /`) for the data items in the first file, we need to instruct the compiler to allow a second data statement with the real data using $onMulti:

```
$onMulti
Sets   i   / seattle, san-diego /
       j   / new-york, chicago, topeka / ;

Parameters  a(i)  / seattle     350
                    san-diego   600  /
            b(j)  / new-york    325
                    chicago     300
                    topeka      275  / ;

Table d(i,j)
                  new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;

Scalar f / 90 / ;
$offMulti
```

In order to run the model we first compile, but not execute the first model (see command line parameter action=c) and create a save file. Next, we run the second model. This does a continued compilation, it compiles the data statements from the second files and then executes the execution time statements from the first (`c(i,j)=...`, `solve ...`, and `display ...`) and second (here there are none).

```
> gams transportmodel.gms action=c s=transmod
> gams transportdata.gms  r=transmod
```

4.44.2.3 Generating Concise Listing Files

By default a GAMS listing file has many components, see chapter GAMS Output for details. In case a more concise listing file is needed, the save and restart feature may be used to generate such a file.

Recall the reorganization of the transportation model [**TRNSPORT**] into a model file `trnsportmodel.gms` and a data-and-solve file `trnsportdata.gms` from the previous section. Now consider the addition of two further files. The first one, called `trnsportreport.gms`, contains post-solution computations for reporting:

```
Parameter m(*,*) 'movement of commodities in cases';
m(i,j)             = x.l(i,j);
m('total',j)       = sum(i, x.l(i,j));
m(i,'total')       = sum(j, x.l(i,j));
m('total','total') = sum(j, m('total',j));
```

The second one, called `trnsportdisplay.gms`, contains only a display statement:

```
Option decimals = 0;
Display m;
```

Using these four files, the following save and restart sequence can be called:

```
> gams trnsportmodel            s=trans1
> gams trnsportdata    r=trans1 s=trans2
> gams trnsportreport  r=trans2 s=trans3
> gams trnsportdisplay r=trans3
```

The output file `trnsportdisplay.lst` is brief. Apart from the echo print, the execution time and the file summary, it contains only the output generated by the display statement:

```
----     52 PARAMETER m  movement of commodities in cases

             new-york     chicago      topeka       total

seattle            50         300                     350
san-diego         275                     275         550
total             325         300         275         900
```

In this way it is possible to create output files that are concise and contain only the information needed, while at the same time the more detailed output is stored in other listing files and may be inspected if needed.

4.44.2.4 Incremental Program Development

GAMS programs are often developed in stages. A typical approach is to start with set statements, tables and data manipulations, then equations are declared and defined, followed by model and solve statements and finally assignments for generating reports. As each piece of the model is built, it should be run and checked for errors by inserting diagnostic display and abort statements. As confidence grows that the parts of the model are correct, it is useful to save the completed parts in a work file. Subsequently, it is possible to work only on the piece under active development by restarting from the saved work file and thus reducing running time and the amount of output produced in each of the development runs.

This approach is especially useful when working on the results report part, since the setup and solution of a model instance is typically dominating the computing time, while the report part has to be run often to get all details of setting up content and layout into a satisfying form. Thus, the model may be generated and solved and the result saved in a work file. One may then restart from the work file while developing the report.

4.44.2.5 Tracking a Sequence of Difficult Solve Statements

In many cases where solves are known to be difficult and expensive, it may be too risky to let GAMS process a job containing many solve statements. The risk is that if one solve does not proceed to normal completion, then the following solve will not be possible or will start from a bad initial point and much time and effort will be wasted.

An alternative is to request one solve at a time and save the work file. By doing so, the output of each solve can be carefully inspected before proceeding. If everything is as expected, the job can be restarted and the next solve be executed. If an error has occurred, the previous solve may be repeated, maybe with a different initial point or modified working limits such as iteration or time limits.

4.44.2.6 What-If Analysis

Many modeling exercises involve a '*what if* ' analysis, in which a *base case* is defined and the point of the study is to see how the system changes when circumstances change, either naturally or by design. Often, the effect of many different changes to the base case are considered separately.

The save and restart feature facilitates such analyses. The base case may be saved using a work file and then all desired scenarios may be run separately by restarting from the same work file. Each scenario probably involves only doing some changes to the data (e.g., coefficients in equations or variable bounds), solving the changed model (the solution of the base case will then automatically be used as a starting point), and reporting.

4.44.3 Secure Work Files

When models are distributed to users other than the original developers or embedded in applications to be deployed by other developers, issues of privacy, security, data integrity and ownership arise. One may have to hide, protect or purge some parts of the model before it can be released. The information to be protected can be of numeric or symbolic nature. Examples include the following:

Privacy

A Social Accounting Matrix supplied by a statistical office is required in a general equilibrium model to be used by the Ministry of Finance. The data from the statistical office needs to be protected for obvious privacy reasons and the model experiments are used to evaluate policy options that are highly confidential. Most of the model structure is public, most of the data however is private and model results need to be transformed in such a way as to prohibit the discovery of the original data.

Security

Components of a model contain proprietary information that describes mathematically a chemical reaction. The associated algebra and some of the data are considered of strategic importance and need to be hidden completely. However, the final model will be used at different locations around the world.

Integrity

Data integrity safeguards are needed to assure the proper functioning of a model. Certain data and symbolic information need to be protected from accidental changes that would compromise the operation of the model.

To address these issues, so called *secure* work files have been introduced to GAMS. Such a work file behaves like any other work file but it is locked to a specific user's license file. The content of a secure work file protected against unauthorized access via the GAMS license mechanism.

Attention

A special GAMS license is required to create secure work file, see also Usage.

The security features of secure work files are not extended to the solver level. As a consequence, full information about a model instance can be extracted on the GAMS solver level by a user that is authorized to solve the model. See Limitations for more information.

4.44.3.1 An Introductory Example

The well-known transportation model [**TRNSPORT**] will be used again to illustrate the creation and deployment of a secure work file. Assume one wants to distribute this model but there are concerns about proprietary formulations and data. In addition, one would like to prevent that the user does unintentional modifications to the model. It is assumed that the objective function and the supply constraints are to be hidden from other users and only the demand figures should be allowed to be changed. Data that is not needed any more will be purged as well.

First, a copy of the model from the model library is created, the model is run and a normal work file `t1` is created:

```
> gamslib trnsport
> gams trnsport s=t1
```

Next, a file `t2.gms` with access control commands is created,

```
$eolcom //
$protect all             // make all symbols read only
$purge   d f             // remove items d and f
$hide    cost supply a   // make objective invisible
$expose  transport b     // allow changes to b
```

and a *secure* work file `t2.g00` is created by executing `t2.gms` with a restart from `t1.g00`:

```
> gams t2 r=t1 s=t2 plicense=target
```

The newly created work file is secure since the access control commands were activated with the privacy GAMS license option PLicense. This command line parameter specifies the name of the target user's license file. The effect is that the work file `t2.g00` can now only be read with the target license file.

The log output will contain the following lines:

```
GAMS Rev 124  Copyright (C) 1987-2001 GAMS Development...
Licensee: Source User Name
          Source Company Name
*** Creating a Secure Restart File for:
***       Target User Name
***       Target Company Name
--- Starting continued compilation
--- T2.GMS(6) 1 Mb
--- Starting execution
*** Status: Normal completion
```

The three lines starting with *** are a recap of the content of the target license file. From now on, the source and the target licenses are 'burned into' this file and all its descendants. One can now send the restart file to the target user or system.

The target user may run the model with new data, add new GAMS statements and create new work files. However, there are two restrictions: some of the symbols are hidden and this model can only be executed using the target license file.

For example, the target user may want to half the demand and compare the original solution with the new one. The following file, called `t3.gms`, will accomplish this:

```
Parameter rep   'summary report';
rep(i,j,'base') = x.l(i,j);
b(j) = b(j)*0.5;

solve transport minimizing z using lp;

rep(i,j,'half') = x.l(i,j);
display rep;
```

This new file may be executed on the target system, restarting from the work file `t2.g00`:

```
> gams t3 r=t2
```

The resulting log file will contain the following lines:

```
GAMS Rev 124 Copyright (C) 1987-2001 GAMS Development...
Licensee: Target User Name
               Target User Company
*** Restarting from a Secure Restart File created by:
***       Source User Name
***       Source Company Name
--- Starting continued compilation
--- T3.GMS(5) 1 Mb
...
```

Note that the originator/owner of the secure work file is mentioned by name. A similar message will be contained in the listing file:

```
...
EXECUTION TIME     =    0.000 SECONDS   1.1 Mb   WIN201-124

**** Secure Save/Restart File Source:
        Source User Name
        Source Company Name
**** Secure Save/Restart File Target:
        Target User Name
        Target User Company
...
```

A more detailed inspection of the listing file shows that the hidden variables and equations do not appear in the usual equation and variable listings and the solution print. The hidden items can only be accessed via a public (exposed) model and a solve statement. However, note that the full model instance may still be accessed by the target user, see Limitations.

In the following, secure work files and the access control commands are described in more detail.

4.44.3.2 Usage

Secure work files control access to symbolic and numeric information and can only be read by a specific GAMS user. The initial creation or additions to access control requires a special GAMS license. Saving secure work files without new access controls does not require a special GAMS license. The creation or addition of access control is signaled by the use of the GAMS command line parameter PLicense, which gives the name of a privacy license file. The shortcut `PLICENSE=LICENSE` sets the privacy license to the current license file. This is convenient when experimenting with access controls.

When a secure work file is written for the first time, the first and second lines of the current license file and the privacy license file are inserted into the work file. This information cannot be changed any more and the original source and the intended target users are locked into the work file.

A secure work file may be used just like any other work file and new work files may be derived from secure files. However, their use is restricted to the `target` user specified with the command line parameter PLicense. The target user can, if licensed, add access controls to an existing secure file by using the parameter `PLICENSE=LICENSE` but cannot change the original information about source and target users.

There are four access control commands (ACCs) that are processed during the compilation phase. These commands can be inserted anywhere in the program. They are processed in chronological order and have the following syntax:

```
$acc ident1 ident2 ...
$acc all
```

Here `ident1` and `ident2` are GAMS identifiers previously defined in the program and `acc` denotes one of the four access control commands:

Dollar Control Option	Description
purge	Removes the objects and all data associated.
hide	Hides the objects but allows them to be used in model calculations.
protect	The objects cannot be modified but they may be used in model calculations.
expose	Removes all privacy restrictions, the symbols will be reverted to their original state.

The keyword `all` applies the ACCs to all identifiers defined up to this point in the GAMS source code. Note that ACCs may be changed and redefined within the same GAMS program. However, identifiers inherited from a restart file cannot be changed.

4.44.3.3 A Practical Example

This section uses the transportation model **[TRNSPORT]** to show how to hide input data and results from the target user. The target user will be allowed to view percentage changes from an unknown base case only. In addition to the original model, a data initialization and a report model will be introduced.

First, a method to calculate input data is defined. As the GAMS language does not offer the definition of methods (or functions), here a model is used to define algebraically the desired correspondence between the input and output of the method we wish to emulate. Execution of the method will then correspond to solving the model. The model is the following:

```
$include trnsport.gms

Variable newc(i,j)    'new tansport data';
Equation defnewc(i,j) 'definition of new transport data';
defnewc(i,j).. newc(i,j) =e= f*d(i,j)/1000;

Model getc            'compute new transport data' / defnewc /;
Solve getc using cns;
```

By solving model `getc` (see Constrained Nonlinear System (CNS) for details on problem type CNS), the variable `newc(i,j)` will obtain the value of `f*d(i,j)/1000` in the variable level attributes. Thus, `newc.l` corresponds to parameter `c` in the original model.

Next, the objective function of the original model is changed to reflect `economies of scale`. Furthermore, a base case value `basex` is computed for later use in the reporting model:

```
Scalar   beta        'scaling exponent' / 1.1 /;
Equation newcost     'economies of scale objective function';
newcost.. z =e= sum((i,j), newc.l(i,j) * x(i,j)**beta);

Model estrans / newcost, supply, demand /;
solve estrans using nlp minimizing z;

Parameter basex(i,j)  'base values of x';
basex(i,j) = x.l(i,j);
```

Finally, a method to transform the results of model `estrans` to the relative change with respect to the base case is defined. As for the computation of the input data (`newc`), a model is used to emulate this method:

```
Variable delta(i,j)      'percentage change from base values';
Equation defdelta(i,j)   'definition of delta';
defdelta(i,j)$basex(i,j).. delta(i,j) =e= 100*(x.l(i,j)-basex(i,j))/basex(i,j);

Model rep / defdelta /;
solve rep using cns;
```

Assume the GAMS code above has been saved in a file `p1.gms`. Running GAMS on this file,

```
> gams p1 s=p1
```

creates a work file with the name `p1.g00`.

In the following, some test runs similar to those that are expected to be defined by the target user are made. Three scenarios to be solved in a loop are defined in file `u1.gms`:

```
Set       s        / one, two, three /;
Parameter sbeta(s) / one 1.25, two 1.5, three 2.0 /
          sf(s)    / one 85,   two 75,  three 50 /;
Parameter report   'summary report';

loop(s,
   beta = sbeta(s);
```

```
   f    = sf(s);
   solve getc using cns;
   solve estrans using nlp minmizing z;
   solve rep using cns;
   report(i,j,s) = delta.l(i,j);
   report('','beta',s) = beta;
   report('','f',s)    = f;
   report('obj','z',s) = z.l
);

display report;
```

File `u1.gms` can be executed with a restart from the work file `p1.g00`:

```
> gams u1 r=p1
```

The display statement generates the following output:

```
----    109 PARAMETER report summary report

                            one         two       three

seattle  .new-york       -4.050      -6.967      -8.083
seattle  .chicago       -18.797     -27.202     -31.550
seattle  .topeka        233.958     348.468     404.187
san-diego.new-york        3.605       6.201       7.194
san-diego.chicago        28.138      40.719      47.228
san-diego.topeka        -15.512     -23.104     -26.799
         .beta            1.250       1.500       2.000
         .f              85.000      75.000      50.000
obj      .z             526.912    1652.963   13988.774
```

Note that all symbols are still completely exposed. Access controls need to be added to the model `p1.gms` before it can be made available to the target client. The information to be protected is the original distance matrix and derived information. A recommended procedure is to first hide everything and then enable access to only selected parts of the model. The access control information is collected in the file `s1.gms`:

```
$hide all
$expose getc estrans rep
$expose i j z delta
$expose f beta a b
```

Using the initial workfile p1, a secure work file `s1.g00` is created by executing

```
> gams s1 r=p1 s=s1 plicense=license
```

To test the system from the target users point of view, the license of the current GAMS system is used also for the target user.

To test the secure work file, problem `u1.gms` is run again, restarting from the work file `s1`:

```
> gams u1 r=s1
```

Inspecting the resulting listing file, one observes that equation, variable and solution listings related to the hidden variables are not shown anymore. Any attempt to reference a hidden variable will cause a compilation error.

4.44.3.4 Limitations

One of the design goals for secure work files has been to minimize the impact on other components of the GAMS system. Solvers used within a secure environment should work as if called within a normal environment. This implies that certain information about a model can easily be recovered by using solvers like CONVERT or solver options like writelp for CPLEX, writemps for CBC, or gams/interactive for SCIP.

For example, consider the secure work file `t2.g00` from Section An Introductory Example. The target user could now reproduce the complete model instance, including the hidden equation `supply` or the objective function `cost` by running the following GAMS code, restarting from `t2.g00`:

```
option mip = scip;
transport.optfile = 1;
$echo gams/interactive = "display prob quit" > scip.opt
solve transport min z using mip;
```

This produces the log output:

```
...
original problem has 6 variables (0 bin, 0 int, 6 cont) and 5 constraints

STATISTICS
  Problem name     : r
  Variables        : 6 (0 binary, 0 integer, 0 implicit integer, 6 continuous)
  Constraints      : 0 initial, 5 maximal
OBJECTIVE
  Sense            : minimize
VARIABLES

  [continuous] <x(seattle,chicago)>: obj=0.153, original bounds=[0,+inf]
  [continuous] <x(seattle,topeka)>: obj=0.162, original bounds=[0,+inf]
  [continuous] <x(san-diego,new-york)>: obj=0.225, original bounds=[0,+inf]
  [continuous] <x(san-diego,chicago)>: obj=0.162, original bounds=[0,+inf]
  [continuous] <x(san-diego,topeka)>: obj=0.126, original bounds=[0,+inf]
CONSTRAINTS
  [linear] <supply(seattle)>: <x(seattle,new-york)>[C] +<x(seattle,chicago)>[C] +<x(seattle,topeka)>
  [linear] <supply(san-diego)>: <x(san-diego,new-york)>[C] +<x(san-diego,chicago)>[C] +<x(san-diego,
  [linear] <demand(new-york)>: <x(seattle,new-york)>[C] +<x(san-diego,new-york)>[C] >= 325;
  [linear] <demand(chicago)>: <x(seattle,chicago)>[C] +<x(san-diego,chicago)>[C] >= 300;
  [linear] <demand(topeka)>: <x(seattle,topeka)>[C] +<x(san-diego,topeka)>[C] >= 275;
END
...
```

Note, that this approach is only possible for the target user, since its license is required to unlock the work file. Further, the original algebra of the model is still protected by GAMS, only the generated model instance (with original variable and equation names) and variable and equation symbols can be made available this way.

A further limitation of secure work files is that the source and target license files are locked to the secure work file and cannot be changed. If the target user receives a new license file (due to a system upgrade, for example), the secure work file cannot be read any more by the target user and must be recreated.

4.44.4 Obfuscated Work Files

GAMS offers a limited set of facilities to change all the names and other documentation related to a specific model run in a work file. This can be useful if the model has to be solved in an untrusted computing environment, e.g., a public cloud facility. When the results are back in the secure environment, the changed names can be transformed back to their original.

A work file that has all strings for symbols, set elements and explanatory text replaced with obfuscated names is called an *obfuscated* work file. GAMS obfuscates by keeping the original length of the symbol name or label name, but replaces them by a sequence of strings. For example, for symbols of length 3 it creates `A00`, `A01`, `A02`, ..., `Z__`. The method used for explanatory text is similar, but here GAMS always uses the single quote character and thus may create many weird looking labels. In addition to item names, labels and explanatory text, titles and subtitles in the listing file are obfuscated. Observe that other strings that have some meaning in the execution of GAMS, e.g., file names, cannot be changed.

Despite of the changes in the string pool, a obfuscated work file has all the capabilities of a normal work file.

Recall from Section Saving The Work File that work files are created with the command line parameter save. Obfuscated work files are created with the variant saveobfuscate. The creation of an obfuscated work file is often combined with the creation of a regular work file, as the latter will be necessary to translate information from an obfuscated work file back to the name space of the original model.

In the following, the intended use of obfuscated work files is illustrated. First, a GAMS model (here [**TRNSPORT**]) is compiled into a regular and an obfuscated work file:

```
> gamslib trnsport
> gams trnsport action=compile s=0named so=0obfuscated
```

Note, that the command line parameter `action=compile` is used to only compile, but not execute, the model. Observe that the name of the regular work file is `0named.g00` and the name of obfuscated work file is `0obfuscated.g00`.

In the next step, the obfuscated work file is moved to a non-secure machine and GAMS is restarted from this work file on an empty GAMS model file. This executes the original model (here `trnsport`), but with all names obfuscated. The outcome of this execution is saved in another, still obfuscated, work file `1obfuscated.g00`.

```
> echo *Empty > empty.gms
> gams empty r=0obfuscated s=1obfuscated
```

The work file `1obfuscated.g00` is now brought back to a trusted machine. To obtain the results, say the marginal values of the `supply` equation, in a non-obfuscated form, GAMS is executed again on a model that writes out values of `supply.m` to a GDX file `supply.gdx`. This model is restarted from the obfuscated work file `1obfuscated.g00`, but additionally the originally created non-obfuscated work file `0named.g00` is passed in via the command line parameter RestartNamed (short: `rn`):

```
> echo "execute_unload 'supply', supply.m;" > unload.gms
> gams unload r=1obfuscated rn=0named
```

Recall, that the work file `0named.g00` resulted from the initial compilation and contains the names from the original namespace. It never left the trusted environment. The effect of combining options `r` and `rn` is that *all* content from the obfuscated work file is taken, except for the names of symbols and labels, the explanatory texts, and the listing file titles and subtitles, which are read from the work file specified via `rn`.

GAMS automatically performs the following three checks to *ensure* that the named and obfuscated work files are consistent:

1. The number of labels and symbols must be identical.
2. The size of the string pool must be identical.
3. The first 10 labels point to the same addresses in the string pool.

The first two checks imply that the execution in the obfuscated name space cannot introduce new symbols or labels or even new strings (e.g., from `display 'this is a new string'`). Therefore, the empty GAMS program that was used to execute from the obfuscated work file above can hardly be replaced by any useful code since the obfuscated symbols and labels are not known.

4.45 Embedded Code Facility

4.45.1 Motivation

GAMS uses relational data tables as a basic data structure. With these, GAMS code for parallel assignment and equation definition is compact, elegant, and efficient. However, traditional data structures (arrays, lists, dictionaries, trees, graphs, ...) are not natively or easily available in GAMS. Though it is possible to represent such data structures in GAMS, the GAMS code working with such structures can easily become unwieldy, obfuscating, or inefficient. Also, in the past it was not easy to connect libraries from other systems for special algorithms (e.g. graph algorithms, matrix operations, ...) to GAMS without some data programming knowledge and a deep understanding of internal representation of GAMS data (e.g. the `GDX API`).

The Embedded Code Facility addresses this need and extends the connectivity of GAMS to other programming languages. It allows the use of external code (e.g. Python) during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary. It utilizes an API (this API can be found in `apifiles/C/api/emblib*.h` together with the code for the Python and Connect embedded code library `apifiles/C/api/embpyoo.c/h`) and additional source code for common tasks so that the user can concentrate on the task at hand and not the mechanics of moving data in and out of GAMS.

4.45.2 Concept

As pointed out in section Motivation, the main idea of the Embedded Code Facility is to enable the use of external code in GAMS and give this code direct in-memory access to the GAMS database (or better: to GAMS symbols, namely sets, parameters, variables, and equations). This can be done by defining sections in the GAMS code which contain code written in a defined external code. These sections can be used at both GAMS compile and execution time (compare section GAMS Compile Time and Execution Time Phase). Details about how to do this can be found in the Syntax section.

Note

> We will continuously extend this feature to different programming languages. At the moment only Python, Connect, and GAMS are supported.

Also, the system provides some help to develop and debug the external code independent of GAMS first. More about this topic can be found in section Troubleshooting Embedded Python Code.

The communication of the data between the GAMS part of the program and the embedded code part was inspired by the existing interface to GDX in many ways. For example, using dollar control options $on/offMulti, $onMultiR, and $on/offFiltered it is possible to decide if data changed in the embedded code should replace the GAMS data or get merged with it and just like loading data from GDX, one can decide if data from embedded code should change the GAMS database filtered or domain checked.

4.45.3 Simple Example

4.45.3.1 Python

In a very first example we look into some Python code that helps to split some label names that are already present in GAMS. We do this at compile time in order to read the broken up pieces as individual sets (`country` and `city`) into GAMS plus some mapping sets (`mccCountry` and `mccCity`) between the original labels and the new labels. The compile-time embedded code starts with a `$onEmbeddedCode` followed by the type of code to expect (`Python:`). The lines between `$onEmbeddedCode` and `$offEmbeddedCode` is Python code. We do not want to go into Python details, but the first few lines initialize some empty Python `list` objects (`mccCountry` and `mccCity`) as well as some empty Python `set` objects. In the Python `for` loop that follows we iterate over all individual labels of the GAMS set `cc`. Python gets access to the GAMS set `cc` via the member function `get` of the implicitly defined Python object `gams`. `get` returns an object that is *iterable* and can be used in a Python `for` loop. The type of the records one gets depend on the dimensionality and type of the GAMS symbol. In the loop body we use the Python `split` function to extract the first (`r[0]` is country) and second (`r[1]` is city) part of the label. The three strings `cc`, `r[0]`, `r[1]` are used to build up the Python `list` objects that store the information for the maps `mccCountry` and `mccCity` and the Python `set` objects that store the labels for the new sets `country` and `city`. The Python `set` has the advantage to store a label just once even if we add it multiple times. Python prepares to send items back to GAMS via the `gams` member function `set` that can deal with both Python `list` and Python `set` objects. The command `$offEmbeddedCode` is followed by a list (without separating commas) of GAMS symbols that instructs the GAMS compiler to read these symbols back. This list is optional and can be left out. GAMS will import all symbols set by the Python code. The GAMS compiler (without executing execution-time embedded code) does not know which symbols will be implicitly loaded, hence it cannot *define* symbols. If such a symbol is referenced further down in the compilation process, the compiler will complain with error `$141: Symbol declared but no values have been assigned.` One can avoid this situation by explicitly list the symbols on the `end/pauseEmbeddedCode` line.

Another caveat with implicit loading is related to aliases. GAMS does not allow to load data into an alias, so the following code will fail with a compilation error `493 Alias cannot receive data`:

```
Set i(*); Alias (i,j);
$onEmbeddedCode Python:
gams.set('j',['i1','i2','i3'])
$offEmbeddedCode j
```

By leaving off the symbol `j` from the `$offEmbeddedCode` line, the code works fine and actually imports the set `i`. The `gams.set` and other write methods in embedded code to an alias symbol, here `j`, actually fills the aliased set, here `i`, and hence the implicit load will load the modified symbol `i` into GAMS.

Implicit loading also needs special consideration in the context of external input. Since embedded code inside an `$on/offExternalInput` section is not executed if the command line parameter IDCGDXInput has been set, there will be no symbols to be loaded implicitly. So make sure the symbols to load are given explicitly in such a situation.

Note that GAMS syntax is case insensitive while Python is case sensitive. Hence, the strings that represent the GAMS symbol names in the Python code can have any casing (e.g. `gams.get("cc")` or `gams.get("CC")`), while the corresponding Python objects need to have consistent casing throughout the Python code.

The following code presents the entire **embeddedSplit** example from the GAMS Data Utilities Library:

```
Set cc      / "France - Paris", "France - Lille", "France - Toulouse"
              "Spain - Madrid", "Spain - Cordoba", "Spain - Seville", "Spain - Bilbao"
              "USA - Washington DC", "USA - Houston", "USA - New York",
              "Germany - Berlin", "Germany - Munich", "Germany - Bonn" /
    country
    city
    mccCountry(cc,country<)  Mapping between country and related elements in set cc
    mccCity(cc,city<)        Mapping between city and related elements in set cc;

$onEmbeddedCode Python:
mccCountry = []
mccCity = []
for cc in gams.get("cc"):
  r = str.split(cc, " - ", 1)
  mccCountry.append((cc,r[0]))
  mccCity.append((cc,r[1]))
gams.set("mccCountry",mccCountry)
gams.set("mccCity",mccCity)
$offEmbeddedCode mccCountry mccCity

Option mccCountry:0:0:1, mccCity:0:0:1;
Display country, city, mccCountry, mccCity;
```

The display in the listing file looks as follows:

```
----     25 SET country
Spain  ,    USA    ,    Germany,    France

----     25 SET city
Berlin       ,    Bilbao       ,    Cordoba      ,    Madrid
New York     ,    Washington DC,    Paris        ,    Houston
Munich       ,    Lille        ,    Seville      ,    Bonn
Toulouse

----     25 SET mccCountry
France - Paris     .France
France - Lille     .France
France - Toulouse  .France
Spain - Madrid     .Spain
Spain - Cordoba    .Spain
Spain - Seville    .Spain
Spain - Bilbao     .Spain
USA - Washington DC.USA
USA - Houston      .USA
USA - New York     .USA
Germany - Berlin   .Germany
Germany - Munich   .Germany
Germany - Bonn     .Germany

----     25 SET mccCity
France - Paris     .Paris
France - Lille     .Lille
France - Toulouse  .Toulouse
Spain - Madrid     .Madrid
Spain - Cordoba    .Cordoba
Spain - Seville    .Seville
Spain - Bilbao     .Bilbao
```

```
USA - Washington DC.Washington DC
USA - Houston       .Houston
USA - New York      .New York
Germany - Berlin    .Berlin
Germany - Munich    .Munich
Germany - Bonn      .Bonn
```

The second example demonstrates the use of embedded code at execution time. The syntax for the execution time embedded code in this example is identical to the compile time variant with the exception of the keywords that start and end the embedded code section: `embeddedCode` and `endEmbeddedCode`. It is important to understand that the execution of the code happens at GAMS execution time, so e.g. no new labels can be produced and send back to GAMS. In this example we use some Python code to generate a random permutation of set elements of set `i` and store this in a two dimensional set `p`. In this example we do not use a loop to iterate through the elements of a GAMS system but make use of the fact that the Python object returned by `gams.get("i")` is iterable and can in its entirety be stored in the Python `list` with name `i` with the short and powerful command `i = list(gams.get("i"))`. The permutation of elements in list `p` which is a copy of list `i` is created by the Python statement `random.shuffle(p)`. The following code presents the entire example:

```
Set i /i1*i10/
    p(i,i) "permutation";

embeddedCode Python:
import random
i = list(gams.get("i"))
p = list(i)
random.shuffle(p)
for idx in range(len(i)):
    p[idx] = (i[idx], p[idx])
gams.set("p", p)
endEmbeddedCode p

option p:0:0:1;
display p;
```

The display in the listing file looks as follows:

```
----     11 SET p  permutation
i1 .i1
i2 .i7
i3 .i5
i4 .i2
i5 .i10
i6 .i6
i7 .i9
i8 .i4
i9 .i8
i10.i3
```

4.45.3.2 Connect

In the following example, we need to process a CSV file that cannot be read directly by GAMS under $onDelim. So we instruct Connect to read the CSV file into the Connect database and then write to GAMS:

```
Set dates, stocks;
Parameter stockprice(dates<,stocks<);

$onText
Read a CSV file that looks as follows:

date;symbol;price
2016/01/04;AAPL;105,35
2016/01/04;AXP;67,59
2016/01/04;BA;140,50
...

and can't be read directly by GAMS under $onDelim because some labels
include '/' and are not quoted, use ';' as field separator, and ',' as
decimal character.
$offText

$onEmbeddedCode Connect:
- CSVReader:
    file: stockprice.csv
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
    fieldSeparator: ';'
    decimalSeparator: ','
- GAMSWriter:
    symbols:
      - name: stockprice
$offEmbeddedCode

display stockprice;
```

We leave the CSV file processing to the CSVReader and then export the `stockprice` symbol to GAMS. Please note that the symbols written to GAMS by the GAMSWriter do not have to be explicitly listed on the `$offEmbeddedCode` line, this is optional. Moreover, the Connect agents GAMSReader and GAMSWriter are only available under embedded code.

We might use the data to calculate an optimal portfolio. The share of each stock in this optimal portfolio is represented by the parameter `share(stocks)` and can be exported to Excel using the ExcelWriter. Before exporting to Excel, the data first needs to be transferred from GAMS to Connect using the GAMSReader:

```
* Continues the code from the previous example

Parameter share(stocks);
* For demonstration we fill share with random numbers
share(stocks) = uniform(0,1);

embeddedCode Connect:
- GAMSReader:
    symbols:
      - name: share
- ExcelWriter:
    file: share.xlsx
    symbols:
      - name: share
endEmbeddedCode
```

4.45.3.3 GAMS

In the following example, we need some execution time GAMS power to create data needed at compilation. We want to solve the bin packing problem. In order to solve this we need the set of bins which is not part of the input data. There are different ways of dealing with this not so uncommon issue and they are all given in the GAMS Model Library model **binpacking**, but we want to concenrate here on a solution that utilizes embedded code GAMS:

```
Set i 'items';
Parameter s(i<) 'item sizes';
Scalar B 'bin capacity';
$gdxLoad data.gdx s B

* Randomize the item sizes:
s(i) = uniform(0.9,1.1)*s(i);

Scalar nj 'number of bins required to pack all items';
$save.keepCode bp

$onEmbeddedCode GAMS: restart=bp
scalar size /0/;
nj = 1; loop(i, size = size+s(i); if (size>B, nj = nj+1; size = s(i)));
$offEmbeddedCode nj

$eval NJ nj
Set j 'bins' / b1*b%NJ% /;

* Simple optimization model to minimize number of bins:
Binary variable y(i,j) 'assignment of item to bin', z(j) 'bin open';
Variable open_bins 'number of open bins';

Equations
    defopen(j) 'allow item in open bins only'
    defone(i)  'assign each item to one bin'
    defobj     'count number of open bins';

defopen(j)..   sum(i, s(i)*y(i,j)) =l= z(j)*B;
defone(i)..    sum(j, y(i,j)) =e= 1;
defobj..       open_bins =e= sum(j, z(j));

model bp 'bin packing' /all/;
solve bp min open_bins using mip;
```

In this example we read the item sizes and the bin capacity from a GDX file and need to create the set of bins `j`. We even randomize the item sizes (at GAMS execution time). In the embedded code GAMS section we utilize a simple way to estimate the number of bins: we pack the items (in data entry order) in a bin and as soon as the bin capacity is exceeded, we open the next bin. Obviously, this is far from being an optimal strategy, but it allows based on the actual sizes to quickly overestimate the number of bins required for the optimization model. The scalar of the number of bin (`nj`) is communicated back to the outer GAMS process and we use this to set a compile time variable `NJ` that is used to build the set of bins `j`. The embedded code GAMS that calculates `nj` can access the items and its sizes without declaration or data statements. This is possible because the embedded code *continues* via embedded code arguments `restart=bp` from a save file created one line above with $save.keepCode bp. Here the save file is created at compile time via `$save` and the execution code compiled so far is kept in the save file due to suffix `.keepCode`. So when the embedded code GAMS section runs, it first executes the code from the save file (here `s(i) = uniform(0.9,1.1)*s(i);`) before it executes its own code (`nj=1; loop(i, ...);`). Without the suffix `.keepCode` the embedded code GAMS would have used the item sizes available at compile time, i.e. the sizes as we find them in the GDX file. The remaining part of the model is a straight forward binary linear model for the bin packing problem.

4.45.4 Syntax

This section explains the GAMS functions/keywords which were introduced to enable the Embedded Code Facility. The first subsection deals with the syntax for compile time, the second with the syntax for execution time (compare section GAMS Compile Time and Execution Time Phase).

4.45.4.1 Compile Time

There are three dollar control options to start an embedded code section at compile time:

```
$onEmbeddedCode[.tag]  [Connect|Python]: [arguments]
$onEmbeddedCodeS[.tag] [Connect|Python]: [arguments]
$onEmbeddedCodeV[.tag] [Connect|Python]: [arguments]
```

Lines following one of the above statements are passed on to the embedded code engine (e.g. Connect or the Python interpreter) until this dollar control option, which ends the embedded code section at compile time, is hit:

```
$offEmbeddedCode[.tag] {symbol[<[=]embSymbol[.dimX]]}
```

These dollar control options are explained here in more detail. The usage of the optional `arguments` by the embedded code is explained in the specific embedded code engine section below.

Note

- The optional `arguments` from the `$onEmbeddedCode[S|V][.tag]` statement can be accessed as `gams.arguments` in the Python code.
- The optional `output symbols` from the `$offEmbeddedCode[.tag]` statement need to be written to by the embedded code.
- More about the specific GAMS Python syntax can be found below.

4.45.4.2 Execution Time

At execution time an embedded code section is started with one of these statements:

```
embeddedCode[.tag]  [Connect|Python]: [arguments]
embeddedCodeS[.tag] [Connect|Python]: [arguments]
embeddedCodeV[.tag] [Connect|Python]: [arguments]
```

Similar to the compile time alternatives $onEmbeddedCode[S|V][.tag], the first two variants are synonyms which allow parameter substitution in the code that follows, while the last variant does not allow this but passes the code verbatim to the embedded code engine. The usage of the optional `arguments` by the embedded code is explained in the specific embedded code engine section below. The arguments passed to the embedded code engine at execution time can be extended by the put_utility command `ECArguments`. For example,

```
put_utility 'ECArguments' / ' world...';
embeddedCode  Python: Hello
gams.printLog(gams.arguments)
endEmbeddedCode
```

prints `Hello world...`.

Lines following one of the statements `embeddedCode[S|V]` are passed on to the embedded code engine (e.g. the Python interpreter) until one of the following two statements, which end the embedded code section at execution time, is hit:

```
endEmbeddedCode[.tag]   {output symbols}
pauseEmbeddedCode[.tag] {output symbols}
```

When the optional `tag` suffix (which can be any string) is used to start an embedded code section, the same one has to be used to end/pause that section. Both statements end the embedded code section and switch back to GAMS syntax in the following lines. Also, both statements can be followed by a GAMS symbol or a list of GAMS symbols which would get updated in the GAMS database after the embedded code got executed. If `output symbols` are specified, they need to be written to (e.g. by `gams.set` for embedded Python code) by the embedded code before.

To continue a previously paused embedded code section one of the following statements is used:

```
continueEmbeddedCode[.tag]  [handle]: [arguments]
continueEmbeddedCodeS[.tag] [handle]: [arguments]
continueEmbeddedCodeV[.tag] [handle]: [arguments]
```

As seen before, the first two variants are synonyms which allow parameter substitution in the embedded code that follows, while the last variant does not allow this but passes the code verbatim to the interpreter. Again, the usage of the optional `arguments` by the embedded code is explained in the specific embedded code engine section below.

New in these statements is the optional `handle`. If omitted, the last code section that was paused will be continued. However, sometimes one might need to maintain different embedded code sections active in parallel and independent of each other. There is a new function to store a handle of the last embedded code section that was executed which could then later be used to continue a specific paused code section:

```
handle = embeddedHandle;
```

What it exactly means to end or pause/continue an embedded code section depends on the embedded code engine and is explained in more detail with the code engine below. Independent of the embedded code engine it is important to note that if GAMS stops and restarts while executing a `solve` statement (with solveLink=0) continuing any embedded code section causes the code to fail with the following error message:

```
    Error executing "continueEmbeddedCode" section
--- (Hint: "Solve" with SolveLink=0 frees previously initialized embedded libraries):
    Error at line 71: No embedded library initialized
```

This happens because under solvelink=0 the GAMS process terminates when the solver starts up. This causes the loss of the state of the embedded code environment that is linked into the GAMS process as a shared library. Under all other settings of solveLink the GAMS process is not stopped and restarted and hence a paused embedded code environment can be continued after the solve statement has carried out.

4.45.5 Python

GAMS and Python complement each other in many different ways. GAMS has a compact but readable syntax for data assignment and equation definition statements. Python is a great scripting language to do more traditional type programming especially string manipulation which is completely missing in GAMS. Moreover, the vast number of packages help solving scientific problems outside the scope of GAMS. In order to open this world to our customers in an easy way, GAMS comes with a Python 3 installation. By default, this installation is used in the Embedded Code Facility for Python and is ready to be used with the GAMS Python API. The Python installation is located in `[GAMS directory]/GMSPython`. In contrast to earlier versions this installation comes without the Python package manager `pip` and therefore is not easily extendable. `GMSPython` comes with a selection of third party packages and modules that are either required by the APIs of the GAMS Python API collection or that are particularly helpful from within embedded Python code. Those packages are located in the `site-packages` directory of `GMSPython`. Running the `GMSPython` interpreter like follows will display all available modules:

```
[GAMS directory]/GMSPython/python -c"help('modules')"
```

The list of redistributed third party packages is subject to constant changes and it is not recommended to rely on their availability. If you need packages that do not come with `GMSPython`, we recommend that you install your own version of Python and follow a few steps to connect GAMS with your Python installation. It is also possible to install `pip` for `GMSPython` using get-pip. While any Python installation should work in combination with GAMS we can recommend the `Anaconda` or `Miniconda` Python distributions. These Python distributions work with environments which allow you to have many different Python installations at the same time that don't get in each other's way.

During the lifetime of the GAMS process a single Python interpreter is used and the code *"lives"* in Python's global scope. This means that objects defined in one embedded Python code section are still there in another embedded Python code section:

```
$onEmbeddedCode Python:
s = 'Hello world'
$offEmbeddedCode
$onEmbeddedCode Python:
gams.printLog(s)
$offEmbeddedCode
```

will produce the following output in the GAMS log:

```
--- Starting compilation
--- main.gms(3) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
--- main.gms(6) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
Hello world
--- main.gms(7) 2 Mb
```

If the GAMS process stops and restarts during execution, e.g. because of a solve with solveLink=0, the Python interpreter will be started new. This can cause complications if GAMS is in a sequence of `pause/continueEmbeddedCode` as discussed above.

Note

> Sometimes it is desirable to move Python code to separate files which get imported from within an embedded Python code section. By default the current working directory is not considered by Pythons `import` statement. In order to achieve this, one can add `sys.path.append(".")` before the actual import.

4.45.5.1 Interface between GAMS and Python

The Python class `ECGamsDatabase` is the interface between GAMS and Python. An instance of this class is automatically created when an embedded code section is entered and can be accessed using the identifier `gams`. The following methods can be used in order to interact with GAMS:

`gams.get(symbolName, keyType=KeyType.STRING, keyFormat=KeyFormat.AUTO, valueFormat=ValueFormat.AUTO,`

This method retrieves an iterable object representing the symbol identified with `symbolName`. Typically there are two possibilities to access the records. Iterating using e.g. a `for` loop provides access to the individual records. By calling `list()` on the iterable object, a list containing all the data is created. Several optional parameters can be used in order to modify the format of the retrieved data:

- `keyType`: Determines the data type of the keys. It can be either `KeyType.STRING` (labels) or `KeyType.INT` (label indexes). The default setting is `KeyType.STRING`.
- `keyFormat`: Specifies the representation of the keys. Possible values are as follows:
  - `KeyFormat.TUPLE`: Encapsulate keys in a tuple
  - `KeyFormat.FLAT`: No encapsulation
  - `KeyFormat.SKIP`: Keys are skipped and do not appear in the retrieved data
  - `KeyFormat.AUTO` (default): Depending on the dimension of the GAMS symbol, a default format is applied:
    - Zero dimensional/scalar: `KeyFormat.SKIP`
      - One dimensional: `KeyFormat.FLAT`
      - Multi dimensional: `KeyFormat.TUPLE`
- `valueFormat`: Specifies the representation of the values. Possible values are as follows:
  - `ValueFormat.TUPLE`: Encapsulate values in a tuple
  - `ValueFormat.FLAT`: No encapsulation
  - `ValueFormat.SKIP`: Values are skipped and do not appear in the retrieved data
  - `ValueFormat.AUTO` (default): Depending on the type of the GAMS symbol, a default formats is applied:
    - Set: `ValueFormat.SKIP`
      - Parameter: `ValueFormat.FLAT`
      - Variable/Equation: `ValueFormat.TUPLE`
- `recordFormat` Specifies the encapsulation of records into tuples. Possible values are as follows:
  - `RecordFormat.TUPLE`: Encapsulates every record in a tuple
  - `RecordFormat.FLAT`: No encapsulation. Throws an exception if it can not be applied. It is guaranteed that the length of a retrieved Python list is equal to the number of records of the corresponding GAMS symbol. This principle leads to an incompatibility of `RecordFormat.FLAT` whenever a record consists of more than one item (e.g. multi dimensional symbols, variables and equations which have five numeric values).
  - `RecordFormat.AUTO` (default): Depending on the number of items that represent a record, a default format is applied. If possible this is always `RecordFormat.FLAT`.

GAMS special values `NA`, `INF`, and `-INF` will be mapped to IEEE special values `float('nan')`, `float('inf')`, and `float('-inf')`. GAMS special value `EPS` will be either mapped to `0` or to the small numeric value `4.94066E-324` depending on the setting of flag gams.epsAsZero.

The following Python code shows some examples of `gams.get` and illustrates the use of different formats:

```
Set i / i1 text 1, i2 text 2 /
    j / j1*j2 /

Scalar p0 /3.14/;
Parameter p1(i)   / #i 3.14 /
          p2(i,j) / i1.#j 3.14 /
Variable v0       / fx 3.14 /;
equation e1(i)    / #i.fx 3.14 /
         e2(i,j)  / i1.#j.fx 3.14 /;

$onEmbeddedCode Python:
# scalar parameter
gams.printLog(f"{list(gams.get('p0'))}")                                    # prints [3.14]
gams.printLog(f"{list(gams.get('p0', recordFormat=RecordFormat.TUPLE))}") # prints [(3.14,)]

# one dimensional parameters:
gams.printLog(f"{list(gams.get('p1'))}")                                    # prints [('i1', 3.14)
gams.printLog(f"{list(gams.get('p1', keyFormat=KeyFormat.TUPLE))}")       # prints [(('i1',), 3.
gams.printLog(f"{list(gams.get('p1', valueFormat=ValueFormat.TUPLE))}")   # prints [('i1', (3.14
gams.printLog(f"{list(gams.get('p1', keyFormat=KeyFormat.TUPLE, valueFormat=ValueFormat.TUPLE))}

# two dimensional parameter:
gams.printLog(f"{list(gams.get('p2'))}")                                    # prints [(('i1', 'j1'
gams.printLog(f"{list(gams.get('p2', keyFormat=KeyFormat.FLAT))}")        # prints [('i1', 'j1',

# one dimensional sets:
gams.printLog(f"{list(gams.get('i'))}")                                     # prints ['i1', 'i2']
gams.printLog(f"{list(gams.get('i',valueFormat=ValueFormat.FLAT))}")      # prints [('i1', 'text

# scalar variables/equations
gams.printLog(f"{list(gams.get('v0'))}")                                    # prints [(3.14, 0.0,

# one dimensional variables/equations:
gams.printLog(f"{list(gams.get('e1'))}")                                    # prints [('i1', (3.14
gams.printLog(f"{list(gams.get('e1', valueFormat=ValueFormat.FLAT))}")    # prints [('i1', 3.14,
gams.printLog(f"{list(gams.get('e1', keyFormat=KeyFormat.TUPLE))}")       # prints [(('i1',), (3

# two dimensional variables/equations:
gams.printLog(f"{list(gams.get('e2'))}")                                    # prints [(('i1', 'j1'
gams.printLog(f"{list(gams.get('e2', keyFormat=KeyFormat.FLAT, valueFormat=ValueFormat.FLAT))}")

# using label indexes instead of labels
gams.printLog(f"{list(gams.get('p1', keyType=KeyType.INT))}")             # prints [(1, 3.14), (
gams.printLog(f"{list(gams.get('i', keyFormat=KeyFormat.TUPLE, valueFormat=ValueFormat.TUPLE, ke
gams.printLog(f"{list(gams.get('e2', keyType=KeyType.INT))}")             # prints [((1, 3), (3.
$offEmbeddedCode

gams.set(symbolName, data, mergeType=MergeType.DEFAULT, domCheck=DomainCheckType.DEFAULT, mapKey
```

This method sets the data for the GAMS symbol identified with `symbolName`. The parameter `data` takes a Python list or set containing items that represent the records of the symbol. It is also possible to pass an instance of a subclass of **_GamsSymbol** (e.g. **GamsParameter** or **GamsSet**) when using the GAMS control API in an embedded code section. In case of a Python list or set, depending on the type and the dimension of the symbol, different formats can be used in order to specify the data. Different formats can not be mixed within one list. In general each record needs to be represented as a tuple containing the keys and the value field(s). Keys and/or values can also be enclosed in a tuple. Keys can be entered as labels (string) or label indexes (int). The argument `mapKeys` allows to pass a callable to remap the

elements of the key (e.g. turn them explicitly into strings via `mapKeys=str`). Value fields depend on the type of the symbol:

- Parameters: One numerical value
- Sets: explanatory text (optional)
- Variable/Equations: Five numerical values: level, marginal, lower bound, upper bound, scale/prior/stage

IEEE special values `float('nan')`, `float('inf')`, and `float('-inf')` will be remapped to GAMS special values `NA`, `INF`, and `-INF`. The small numeric value `4.94066E-324` will be mapped into GAMS special value `EPS`.

The following Python code gives some examples on different valid formats for different symbol types and dimensions:

```
Set i / i1 text 1, i2 text 2 /
    j / j1*j2 /
    ii(i);
Scalar p0;
Parameter p1(i)
          p2(i,j);
equation e1(i)
         e2(i,j);
$onEmbeddedCode Python:
# scalar parameter
gams.set('p0', [3.14])
gams.set('p0', [(3.14,)])

# one dimensional parameters:
gams.set('p1', [("i1", 3.14), ("i2", 3.14)])
gams.set('p1', [(("i1",), 3.14), (("i2",), 3.14)])
gams.set('p1', [("i1", (3.14,)), ("i2", (3.14,))])
gams.set('p1', [(("i1",), (3.14,)), (("i2",), (3.14,))])

# two dimensional parameter:
gams.set('p2', [('i1', 'j1', 3.14), ('i1', 'j2', 3.14)])
gams.set('p2', [(('i1', 'j1'), (3.14,)), (('i1', 'j2'), (3.14,))])

# one dimensional sets:
gams.set('ii', ['i1', 'i2'])
gams.set('ii', [('i1',), ('i2',)])

# one dimensional sets with explanatory text
gams.set('ii', [('i1', "text 1"), ('i2', "text 2")])
gams.set('ii', [(('i1',), ("text 1",)), (('i2',), ("text 2",))])

# one dimensional variables/equations:
gams.set('e1', [("i1", 3.14, 0, 0, 10, 1), ("i2", 3.14, 0, 0, 10, 1)])
gams.set('e1', [("i1", (3.14, 0, 0, 10, 1)), ("i2", (3.14, 0, 0, 10, 1))])
gams.set('e1', [(("i1",), (3.14, 0, 0, 10, 1)), (("i2",), (3.14, 0, 0, 10, 1))])

# two dimensional variables/equations:
gams.set('e2', [("i1", "j1", 3.14, 0, 0, 10, 1), ("i1", "j2", 3.14, 0, 0, 10, 1)])
gams.set('e2', [(("i1", "j1"), (3.14, 0, 0, 10, 1)), (("i1", "j2"), (3.14, 0, 0, 10, 1))])

# using label indexes instead of labels
gams.set('p1', [((1,), (3.14,)), ((2,), (3.14,))]) # one dimensional parameter
gams.set('ii', [((1,), ("text 1",)), ((2,), ("text 2",))]) # one dimensional set
gams.set('e2', [((1, 3), (3.14, 0, 0, 10, 1)), ((1, 4), (3.14, 0, 0, 10, 1))]) # two dimens
$offEmbeddedCode p0 p1 p2 ii e1 e2
```

The optional parameter `mergeType` specifies if data in a GAMS symbol is merged (`MergeType.MERGE`) or replaced (`MergeType.REPLACE`). If left at `MergeType.DEFAULT` it depends on the setting of $on/offMulti[R] if GAMS does a merge, replace, or trigger an error during compile time. During execution time `MergeType.DEFAULT` is the same as `MergeType.MERGE`. The optional parameter `domCheck` specifies if Domain Checking is applied (`DomainCheckType.CHECKED`) or if records that would cause a domain violation are filtered (`DomainCheckType.FILTERED`). If left at `DomainCheckType.DEFAULT` it depends on the setting of $on/offFiltered if GAMS does a filtered load or checks the domains during compile time. During execution time `DomainCheckType.DEFAULT` is the same as `DomainCheckType.FILTERED`.

Note

When calling `gams.set()` in an embedded code section during execution time, new labels that are not known to the current GAMS program can not be added. The attempt will result in an execution error.

`gams.getUel(idx)`

Returns the label corresponding to the label index `idx`

`gams.mergeUel(label)`

Adds `label` to the GAMS universe if it was unknown and returns the corresponding label index.

Note

When calling `gams.mergeUel()` in an embedded code section during execution time, new labels that are not known to the current GAMS program can not be added. The attempt will result in an execution error.

`gams.getUelCount()`

Returns the number of labels.

`gams.printLog(msg)`

Print `msg` to log.

`gams.arguments`

Contains the command line that was passed to the Python interpreter of the embedded code section. The syntax for passing arguments to the Python interpreter can be seen above.

`gams.epsAsZero`

Flag to read GAMS `EPS` as 0 (`True`) or as a small number, `4.94066E-324`, when set to `False`. Default is `True`.

`gams.ws`

Property to retrieve an instance of **GamsWorkspace** that allows to use the GAMS control API. The instance is created when the property is read for the first time using a temporary working directory. A different working directory can be specified using gams.wsWorkingDir. For debug output, the property gams.debug can be set to a value from **DebugLevel**

`gams.wsWorkingDir`

Property that can be specified before accessing gams.ws for the first time in order to set the working directory. Setting the property after the first call to gams.ws will have no effect. of the created GamsWorkspace.

`gams.db`

Property to retrieve an instance of **GamsDatabase**. The instance is created when the property is read for the first time and allows to access the GAMS symbols using the methods of the GAMS control API.

`gams.debug`

Property that can be set to a value from **DebugLevel** for debug output. Default is `DebugLevel.Off` (`0`). The property needs to be changed before accessing gams.ws for the first time in order to take effect in the GAMS control API. Setting the property after the first call to gams.ws will have no effect on the GamsWorkspace.

4.45.5.2 Using the Control API

The ECGamsDatabase class provides mechanisms for using the GAMS control API in an embedded code section. The property `gams.ws` can be used to get an instance of GamsWorkspace. The property `gams.db` allows to access an instance of GamsDatabase that can be used to read and write data from the internal GAMS database like it can be done using `gams.get` and `gams.set` but using the access mechanisms of the GamsDatabase class. In addition to the different reading and writing mechanisms offered by the GAMS control API other classes like *GamsModelInstance* can be used inside embedded Python code. This combination provides programmatic access to a generated model instance and exchange of update parameters and results between Python and GAMS. The GAMS Library model **embmiex1** gives an example of how to combine embedded Python code and a `GamsModelInstance` which utilized the library include `$libInclude pyEmbMI`.

Moreover, the GAMS Transfer Python API can be combine with the GAMS control API in the embedded code context as the following example demonstrates:

```
Set i / i1*i1000 /; alias(i,j);
Parameter a(i,j), aInv(i,j);
a(i,j) = 1 / (ord(i)+ord(j) - 1);
a(i,i) = 1;

embeddedCode Python:
import gams.transfer as gt
import numpy as np

m = gt.Container(gams.db)
A = m.data["a"].toDense()
m.data['aInv'].setRecords(np.linalg.inv(A))
m.write(gams.db, ["aInv"])
endEmbeddedCode aInv
```

4.45.5.3 Exchange via Files and Environment Variables

The Python class ECGamsDatabase provides read and write access to GAMS symbols. There are two other communication methods that can be used at GAMS compile time: *files* and *environment variables*. At compile time the Python code can produce a text file that can be included into GAMS via `$include` as in the following example:

```
$onEmbeddedCode Python: 10
with open('i.txt', 'w') as f:
  for i in range(int(gams.arguments)):
    f.write(f'i{i+1}\n')
$offEmbeddedCode

Set i /
$include i.txt
/;
display i;
```

Here the Python code received the number of elements to write to a text file via the argument after `Python:`. This text file is then included in the data statement of the GAMS set `i`. The display in the listing file looks as follows:

```
----     20 SET i
i1 ,    i2 ,    i3 ,    i4 ,    i5 ,    i6 ,    i7 ,    i8 ,    i9 ,    i10
```

Python provides many packages to read input files for many different formats and hence can be used to transform such formats to a GAMS compatible input format, as an alternative to providing the data via `list` objects and the gams.set functionality.

The second alternative to exchange information at compile time are environment variables. GAMS and Python allow to get and set environment variables and hence can be conveniently used to exchange small pieces of information. The following code provides an example where the maximum value of a parameter `b` is needed to build a set `k`:

```
Set       i    / i1*i5 /;
Parameter b(i) / i1 2, i2 7, i3 59, i4 2, i5 47 /;
$onEmbeddedCode Python:
import os
os.environ["MAXB"] = str(int(max([b for i,b in gams.get("b")])))
gams.printLog(f'max value in b is {os.environ["MAXB"]}')
$offEmbeddedCode

$if x%sysEnv.MAXB%==x $abort MAXB is not set
Set k "from 0 to max(b)" / 0*%sysEnv.MAXB% /;
$eval CARDK card(k)
$log card(k)=%CARDK%
```

It is important to understand that `os.environ` is initialized when Python imports the `os` module. Hence, if we later set an environment variable in GAMS (via `$setEnv ABC abc` or `put_utility "setEnv" / "ABC" / "abc"`) and access this in some embedded code via `os.environ["ABC"]`, this will not provide the expected value "abc". In such a case the environment variable needs to be accessed via `gams.get_env("ABC")` (and can be stored in `os.environ["ABC"]`) as demonstrated by the following code:

```
$onEmbeddedCode Python:
import os
os.environ["TEST"] = 'Hello world'
$offEmbeddedCode
$log TEST=%sysEnv.TEST%
$setEnv ABC abc
$onEmbeddedCode Python:
gams.printLog(f'ABC={os.environ.get("ABC", "ABC not set")}')
gams.printLog(f'ABC={gams.get_env("ABC")}')
$offEmbeddedCode
```

which produces the following output:

```
--- Starting compilation
--- main.gms(4) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
TEST=Hello world
--- main.gms(10) 2 Mb
--- Initialize embedded library embpycclib64.dll
--- Execute embedded library embpycclib64.dll
ABC=ABC not set
ABC=abc
```

Obviously, the set `k` can also be filled directly with data from within Python:

```
Set       i    / i1*i5 /;
Parameter b(i) / i1 2, i2 7, i3 59, i4 2, i5 47 /;
Set       k(*) "from 0 to max(b)";

$onEmbeddedCode Python:
kmax = max([b for i,b in gams.get("b")])
gams.set('k',[str(k) for k in range(int(kmax+1))])
$offEmbeddedCode k
```

In both cases the resulting GAMS symbol `k` is a set with elements `0` to `59`.

Note that the `(*)` in the declaration of `k` is necessary to inform the compiler of dimensionality of the symbol `k`. GAMS symbol declarations can be done without domain list, so a `set k` does not necessarily mean that this is a one dimensional set. The compiler will *learn* the dimensionality from the use of `k`. For example, if `k` shows up as a domain set in a declaration (`parameter p(k)`) it is clear that `k` is a one dimensional set. Without knowing the dimensionality `k` will not be available with embedded code or exported (at compile-time) to GDX and the following code

```
Set k;
$onEmbeddedCode Python:
gams.set('k',['0','1','2'])
$offEmbeddedCode k
```

will fail with compilation error `Cannot load/unload symbol with unknown dimension`.

4.45.5.4 Encodings

Python 3 expects source code to be encoded in `UTF-8` per default. Therefore all embedded Python code has to be encoded in `UTF-8` as well. However, this can be customized by adding a comment in the format `# coding=<encoding name>` or `# -*- coding: <encoding name> -*-` as first line of an Embedded Python Code section. The encoding can be changed from any Embedded Python Code section and will affect all subsequent sections. So in case of a GAMS source file which is encoded using a non-`UTF-8` encoding like `cp1252` or others, it is sufficient to change the encoding only once in the very first Embedded Code section. Note that `UTF-16` encoding is not supported.

Note

Changing the source code encoding has no effect on the default encoding that is used by the `open()` function since it uses whatever `locale.getpreferredencoding(False)` returns. Furthermore the encoding used for `stdin`/`stdout`/`stderr` has to be controlled separately. This can be achieved by setting the environment variable `PYTHONIOENCODING`.

4.45.5.5 Multiple Independent Python Sessions

At execution time the user has the ability to *pause* and *continue* an embedded code segment. As explained at the beginning, the user Python code *lives* in Python's global scope.

4.45.5.6 Troubleshooting Embedded Python Code

The GAMS compiler ensures that the number of errors during execution time is minimized. While the logic of the GAMS program might be flawed there is nothing (with a few exceptions) that the GAMS system cannot execute. This is different if we embed foreign code in a GAMS program. The GAMS compiler does not understand the foreign code syntax and just skips over it. Only when the code is executed we will find out if everything works as expected. If the embedded code contains some (Python) syntax errors the Python parser will inform us about this and the message will appear in the GAMS log. For example, the following Python code using the gams.printLog function two times will generate a syntax error:

```
$onEmbeddedCode Python:
gams.printLog('hello')
 gams.printLog('world...')
$offEmbeddedCode
```

The GAMS log will provide some guidance:

```
--- Execute embedded library libembpycclib64.so
  File "<string>", line 7
    gams.printLog('world...')
    ^
IndentationError: unexpected indent
Python error! Return code from Python execution: -1
*** Error executing embedded code section:
*** Check log above
```

Moreover, if the Python code raises an exception which is not handled within the code this will also lead to a compilation or execution error in GAMS depending at what phase the embedded code is executed.

```
embeddedCode Python:
raise Exception('something is wrong')
endEmbeddedCode
```

will produce the following GAMS log and an execution time error:

```
--- Initialize embedded library libembpycclib64.so
--- Execute embedded library libembpycclib64.so
Exception from Python (line 0): something is wrong
*** Error at line 1: Error executing "embeddedCode" section: Check log above
```

Note

It is good practice to raise a Python exception if an error occurs. In any case using `exit()` needs to be avoided since it terminates the executable in an uncontrolled way.

The Python code is executed as part of the GAMS process and GAMS gives control to the Python interpreter when executing the embedded code. So in the worst case if the Python interpreter crashes, the entire GAMS process will crash. Therefore, it is important to be able to test and debug the embedded Python code independent of GAMS. In the following examples we call the Python interpreter executable as part of a GAMS job. In principle this can be tested and debugged completely independent of GAMS where a GDX file represents the content of the GAMS database.

In the first example we mimic the embedded code facility at compile time by exporting the entire GAMS database to a GDX file `debug.gdx`. With `$on/offEcho` we write the embedded code with a few extra lines at the top and bottom surrounded by a try/except block and execute the Python interpreter via `$call`. One of the extra lines at the end of the embedded code triggers the creation of a GDX result file `debugOut.gdx` which can be imported in subsequent `$gdxin/$load` commands.

```
Set i /i1*i10/
    p(i,i) permutation;

$gdxOut debug.gdx
$unload
$gdxOut

$onEcho > debug.py
from gams.core.embedded import *
gams = ECGAMSDatabase(r'%gams.sysdir% '[:-2], 'debug.gdx')
try:
   import random
   i = list(gams.get("i"))
   p = list(i)
   random.shuffle(p)
   for idx in range(len(i)):
       p[idx] = (i[idx], p[idx])
   gams.set("p", p)
   gmdWriteGDX(gams._gmd,'debugOut.gdx',1);
except Exception as e:
   print(str(e))
$offEcho

$call.checkErrorLevel ="%gams.sysdir%GMSPython/python" debug.py

$gdxIn debugOut.gdx
$loadDC p

Option p:0:0:1;
Display p;
```

In the second example we mimic the embedded code facility at execution time by exporting the entire GAMS database to a GDX file `debug.gdx` via `execute_unload 'debug.gdx';`. We write the embedded code with a few extra lines at the top and bottom surrounded by a try/except block via the `put` facility and execute the Python interpreter via `execute`. Identical to the compile time example, we export the result to the GDX file `debugOut.gdx` which can be imported via the `execute_load` statement.

```
Set i /i1*i10/
    p(i,i) permutation;

execute_unload 'debug.gdx';
file fpy / 'debug.py' /; put fpy;

$onPutS
from gams.core.embedded import *
gams = ECGAMSDatabase(r'%gams.sysdir% '[:-2],'debug.gdx')
try:
   import random
   i = list(gams.get("i"))
   p = list(i)
   random.shuffle(p)
   for idx in range(len(i)):
       p[idx] = (i[idx], p[idx])
   gams.set("p", p)
   gmdWriteGDX(gams._gmd,'debugOut.gdx',1);
except Exception as e:
   print(str(e))
$offPut

putClose fpy;
execute.checkErrorLevel '="%gams.sysdir%GMSPython/python" debug.py';

execute_load 'debugOut.gdx', p;
Option p:0:0:1;
Display p;
```

Automatic Indentation

All embedded Python code is automatically wrapped in a `try-except` block that requires an indentation (two spaces). While this additional indentation makes no difference for most Python code, it does make a difference when it comes to multi-line strings. Therefore, multi-line strings created with triple quotes (either single or double quotes) are excluded from this rule to avoid unintentional spaces, e.g. when writing to a file:

```
$onEmbeddedCode Python:
f = open("file.txt", "w")
f.write('''some
multi
line
string
''')
f.close()
$offEmbeddedCode
```

Still, when using the line continuation character (\) in combination with strings, one has to be aware of the extra spaces that are added automatically:

```
$onEmbeddedCode Python:
s = "some\
multi\
line\
string"
gams.printLog(s)
$offEmbeddedCode
```

This will print `some multi line string` instead of `somemultilinestring` due to the automatically applied indentation.

SSL Certificate Error

When doing HTTPS requests from within Embedded Python code using packages like `urllib` or `urllib3`, one might get an error indicating that no certificate was found:

```
urllib.error.URLError: <urlopen error [SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed: unable to get local
      issuer certificate (_ssl.c:1131)>
```

`GMSPython` comes with the `certifi` package that provides certificates to be used for validating the trustworthiness of SSL certificates. In order to make use of those, one can set the environment variable `SSL_CERT_FILE` at the beginning of the Embedded Code section, before making the actual request:

```
$onEmbeddedCode Python:
import certifi
import os
import urllib.request
os.environ['SSL_CERT_FILE'] = certifi.where()
urllib.request.urlretrieve('<url>', '<file>')
$offEmbeddedCode
```

4.45.5.7 Performance Considerations of Embedded Python Code

If the same embedded code section (e.g. in a loop) is executed many times there are a few considerations to be taken into account in order to get the best performance. For this we will experiment with the example from the introduction. We look for a random permutation of a set `i`. In addition we have a cost matrix `c(i,ii)` and we are looking for the least cost permutation. We should just formulate this as matching in a bi-partite graph but in order to demonstrate some performance considerations we will repeatedly call the Python code that provides a random permutation and we will evaluate the cost of the permutation in GAMS and store the value of the cheapest one. Here is the naive implementation using embedded code:

```
Set i / i1*i50 /
    p(i,i) permutation;
Alias (i,ii);
Parameter c(i,i) cost of permutation;
c(i,ii) = uniform(-50,50);

Set    iter / 1*100 /;
Scalar tcost
       minTCost / +inf /;
loop(iter,
  embeddedCode Python:
  import random
  i = list(gams.get("i"))
```

```
  p = list(i)
  random.shuffle(p)
  gams.set("p", [ (i[idx], p[idx]) for idx in range(len(i)) ])
  endEmbeddedCode p
  tcost = sum(p, c(p));
  if (tcost < minTCost, minTCost = tcost);
);
Display minTCost;
```

Even though the Python interpreter stays alive the fresh start and end of an embedded code section goes together with the setup and initialization of multiple data structure, including the `gams` object of type `ECGAMSDatabase`. We can avoid the repeated setup and initialization by using `pause` and `continue`:

```
Set i / i1*i50 /
    p(i,i) permutation;
Alias (i,ii);
Parameter c(i,i) cost of permutation;
c(i,ii) = uniform(-50,50);

embeddedCode Python:
import random
pauseEmbeddedCode

Set    iter / 1*100 /;
Scalar tcost
       minTCost / +inf /;
loop(iter,
  continueEmbeddedCode:
  i = list(gams.get("i"))
  p = list(i)
  random.shuffle(p)
  gams.set("p", [ (i[idx], p[idx]) for idx in range(len(i)) ])
  pauseEmbeddedCode p
  tcost = sum(p, c(p));
  if (tcost < minTCost, minTCost = tcost);
);
continueEmbeddedCode:
pass
endEmbeddedCode
Display minTCost;
```

The last embedded code execution of the Python `pass` statement is to clean up and terminate the Python session. Since the amount of data is relatively small, there is little difference in the running time between these variants.

There are other performance considerations. We can actually extract the set `i` once before the GAMS loop starts. Moreover, we can work with label indexes rather than the labels itself. Indexes are integers and are often faster than labels that are stored as strings. The only difference to the code above is the extraction method of the Python list `i` by `i = list(gams.get("i",keyType=KeyType.INT))`.

4.45.5.8 Extending GMSPython

While we recommend to use your own Python installation if you need additional packages, there are ways to extend the Python system that comes with GAMS in `GMSPython`. Here are the steps:

1. Get pip via get-pip (https://pip.pypa.io/en/stable/installation/)
2. Update pip
3. Install additional packages

We highly recommend installing pip and additional packages in the user site (use --user when running get-pip and pip). This is especially important for macOS users. Installing files in the GAMS system directory may interfere with the file notarization and may prevent GAMS from starting properly. Here is a typical dialog for Linux/macOS using curl to download get-pip.py. If you don't have curl or wget, use your web browser for downloading.

```
curl https://bootstrap.pypa.io/get-pip.py -o get-pip.py
/path/to/gams/GMSPython/python get-pip.py --user
~/.local/bin/pip install -U pip
~/.local/bin/pip install geocoder --user
```

4.45.5.9 Using an External Python 3 Installation

Let's assume you don't want to work with the GAMS distributed GMSPython but you want to connect GAMS with a Python 3 installation of your liking. In order for the Embedded Code Facility to work, you need to make the alternative Python interpreter aware of the required modules provided by GAMS by following the Getting Started steps in the Python API documentation.

In addition to this you need to do one more step to allow GAMS to find your Python installation when executing Embedded Python code: you need to point to the Python dynamic load library or shared object. On Windows this file is called python3X.dll, on Linux libpython3.X.so, and on macOS libpython3.X.dylib. The X stands for the minor version number of Python 3. While embedded code has been built and tested for Python 3.12, chances are that you can also point to other Python 3 libraries. Since the expert level API is required, the set of versions is limited to what GAMS supports (currently GAMS ships these for Python 3.8 to 3.12). Limited experiments with the embedded code library for Python 3.12 with Python 3.8, 3.9, 3.10, and 3.11 libraries were successful. You need to set the environment variable GMSPYTHONLIB to point GAMS to the Python library:

- Windows:
  ```
  set GMSPYTHONLIB=c:\path\to\python\python312.dll
  ```
- Linux:
  ```
  export GMSPYTHONLIB=/path/to/python/lib/libpython3.12.so
  ```
- macOS:
  ```
  export GMSPYTHONLIB=/path/to/python/lib/libpython3.12.dylib
  ```

GAMS will extract the Python home from the location of the Python library. In case this extraction does not work (because of an unconventional Python installation), you can instruct GAMS to set the Python home via the additional environment variable GMSPYTHONHOME. Please note, that this environment variable only needs to be set for GAMS Embedded Python code, so it is sufficient to add these variables to the GAMS configuration YAML file.

Note

> When using environment-based Python distributions like Anaconda or Miniconda, it is not sufficient to set GMSPYTHONLIB (and GMSPYTHONHOME). The environment to be used needs to be activated properly before (e.g. conda activate myEnv). Packages like numpy which have been installed using conda (conda install numpy) won't work otherwise. In addition to setting GMSPYTHONLIB we therefore recommend to start GAMS itself and also tool like GAMS Studio from an activated conda environment in order to make sure that the environment and all installed packages work as expected.

Although it is recommended to use a self-contained Python installation, it is possible to use a virtual environment instead (e.g. via venv). In this case, GMSPYTHONLIB has to be set to the Python library of the installation from which the environment was derived from. In addition, the PYTHONPATH environment variable needs to be set to the site-packages directory of the virtual environment in order to make its packages available. Note that with this setup the site-packages directory of the original Python installation will also be found by GAMS Embedded Python code.

4.45.5.10 Building your own Embedded Python Code Library

Although the Embedded Code Facility and its binary components are part of the GAMS distribution, it is possible to build it manually from source using the following commands. The exact command line might change depending on the compiler and the operating system in use:

- Windows:

```
cd [GAMS directory]/apifiles/C/api
icl.exe -Feembpycclib64.dll -IC:\path\to\python\include embpyoo.c gmdcc.c gclgms.c -LD -link -no
```

- Linux:

```
cd [GAMS directory]/apifiles/C/api
gcc -o libembpycclib64.so -nostartfiles -shared -Wl,-Bsymbolic -pthread -fPIC -Ipath/to/your/pyt
```

- macOS on x86_64 CPUs:

```
cd [GAMS directory]/apifiles/C/api
gcc -o libembpycclib64.dylib -dynamiclib -shared -install_name @rpath/libembpycclib64.dylib -Ipa
```

- macOS on arm64 CPUs:

```
cd [GAMS directory]/apifiles/C/api
clang -o libembpycclib64.dylib -dynamiclib -shared -install_name @rpath/libembpycclib64.dylib -I
```

4.45.6 Connect

The Connect framework gives unified and platform independent access to data exchange with different formats (e.g. CSV and Excel). The instructions how to access the various data sources are given in YAML syntax. These YAML instructions are the *code* for the embedded *Connect* code. The embedded Connect code engine will parse the YAML instructions and use Connect *agents* to act upon the instructions. The agents GAMSReader and GAMSWriter send data back and forth to GAMS. A simple example is given above.

Embedded code Connect is build on top of embedded code Python. Similar considerations (e.g. Python interpreter is loaded once) carry over from Python to Connect. Moreover, the agent PythonCode has access to the object `gams` of type `ECGamsDatabase` which is used for communication of data with GAMS. In contrast to embedded Python code, the code of the agent `PythonCode` does not execute in the global scope but in a separate block. This means that variables set in the code are not available in another `PythonCode` section. The following code ends up in the except clause and prints `Cannot access my_i`.

```
embeddedCode Connect:
- PythonCode:
    code: |
        my_i = 1
- PythonCode:
    code: |
        try:
          gams.printLog(f'{my_i}')
        except:
          gams.printLog('Cannot access my_i')
endEmbeddedCode
```

Since Python allows to add attributes to an object at runtime, the `my_i` variable can be added to the `gams` object and hence becomes available in different `PythonCode` sections and even in different embedded Connect code parts (when pause/continue is used):

```
embeddedCode Connect:
- PythonCode:
    code: |
        gams.my_i = 1
- PythonCode:
    code: |
        gams.printLog(f'{gams.my_i}')
pauseEmbeddedCode
continueEmbeddedCode:
- PythonCode:
    code: |
        gams.printLog(f'{gams.my_i}')
endEmbeddedCode
```

Even though embedded code Python and Connect share the same basis, they run in different instantiations of the Python interpreter and hence don't share e.g. the same `gams` object.

4.45.6.1 Substitutions in Embedded Connect Code

The GAMS compiler has mechanisms to substitute compile-time variables to parameterize GAMS code including embedded code (unless the `V`, e.g. `$onEmbeddedCodeV`, of embedded code is used). Here is an example how to use double-dash parameters to allow the user to set the CSV file name via the GAMS command line (`gams mymodel.gms --csvfilename=mystockprice.csv`):

```
$if not set CSVFILENAME $set CSVFILENAME stockprice.csv
$onEmbeddedCode Connect:
- CSVReader:
    file: %CSVFILENAME%
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
- GAMSWriter:
    symbols:
      - name: stockprice
$offEmbeddedCode
```

Not only user defined compile-time variables will be substituted, but also all other compile time variables, e.g. `%gams.scrDir%` or `%system.dirSep%`. Another way to pass substitution instructions down to embedded Connect code are the embedded code `arguments`:

```
$if not set MYCSVFILENAME $set MYCSVFILENAME stockprice.csv
$onEmbeddedCodeV Connect: --CSVFILENAME=%MYCSVFILENAME%
- CSVReader:
    file: %CSVFILENAME%
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
- GAMSWriter:
    symbols:
      - name: stockprice
$offEmbeddedCode
```

Together with the put_utility command ECArguments that appends some arbitrary text to the embedded code arguments this can be used to parameterize the embedded Connect code at execution time, e.g. to create files based on label names:

```
Set i /1*5/; Parameter p(i);
loop(i,
   p(i) = uniform(0,1);
   put_utility 'ECArguments' / '--CSVFILENAME=' i.tl:0 '.csv';
   EmbeddedCodeV Connect:
   - GAMSReader:
       symbols:
         - name: p
   - CSVWriter:
       name: p
       file: %CSVFILENAME%
   endEmbeddedCode
);
```

Please note that while the GAMS command line parameters allow various formats to specify double-dash parameters, the embedded code Connect substitution arguments must be in the form `--key=value`, so a `=` character to separate key and value with no spaces. The `value` might be a (double) quoted string though. Please also note that the embedded code arguments set with put_utility command `ECArguments` will be applied to any subsequent embedded code section. So one might want to clear the argument by adding a `put_utility "ECArguments" / "";` after the relevant embedded code section.

4.45.7 GAMS

The embedded code GAMS differs in various ways from the other embedded code *languages*. It's definitely not a *new* language one gets access to or does things not easily possible in GAMS. Moreover, it does the data communication *not* in-memory but via disk files. Mostly it adds some syntactical sugar to methods to call GAMS from within GAMS that are available for a long time. So a compile time embedded code GAMS section

```
$onEmbeddedCode GAMS: args
* ...
$offEmbeddedCode list_of_symbols
```

essentially can be done via some file creation via `$on/offEcho`, spawning of a GAMS process via `$call`, and loading of symbols via `$gdxLoad`:

```
$onEcho > sub.gms
* ...
$offEcho
$call.checkErrorLevel gams sub.gms args gdx=sub.gdx
$gdxLoad sub.gdx list_of_symbols
```

Similar at execution time an embedded code GAMS section

```
embeddedCode GAMS: args
* First part ...
pauseEmbeddedCode list_of_symbols
continueEmbeddedCode GAMS:
* Second part ...
endEmbeddedCode list_of_symbols
```

essentially can be done via some file creation via a put file, spawning of a GAMS process via `execute`, and loading of symbols via `execute_loadpoint`:

```
file fgms / 'sub.gms' /; put fgms;
$onPut
* First part ...
$offPut
putclose;
execute.checkErrorLevel 'gams sub.gms args gdx=sub.gdx save=sub'
execute_loadpoint 'sub.gdx', list_of_symbols;

put fgms;
$onPut
* Second part ...
$offPut
putclose;
execute.checkErrorLevel 'gams sub.gms args gdx=sub.gdx restart=sub'
execute_loadpoint 'sub.gdx', list_of_symbols;
```

In addition to the more readable syntax provided by the embedded code syntax, embedded code GAMS takes care of files (source, log, listing, GDX etc) and options related to these files, e.g. logFile. In case of execution-time `pauseEmbeddedCode`/`continueEmbeddedCode` embedded code handles the management of the save and restart operations which is especially convenient when working with multiple independent embedded code sections in combination with function embeddedHandle. Moreover, the log and listing streams of the embedded code GAMS section become part of the outer GAMS log and listing stream in case the GAMS subprocess returns with an error. For example, the following code with a syntax error (symbol names can't start with _) in the embedded code section:

```
embeddedCode GAMS:
* This produces an error
set _i /1*10/;
endEmbeddedCode
```

results in the following relevant part of the log:

```
...
--- Initialize embedded library embgamscclib64.dll
--- Execute embedded library embgamscclib64.dll
*** Error running gams (return code 2)
--- Start of log file ecgamslog.dat:

```

4.45.7.1 Best Practices

Embedded code GAMS at compile time can be used to build up data, e.g. domain sets, required at compile time inside an embedded code GAMS at execution time. Data from the embedded code GAMS section can be moved via GDX (see example above) or file ASCII input files into the outer GAMS program. The following two examples complements the bin packing example by demonstrating two ways to communicate the data via an ASCII input file.

The following solution creates a global compile time variable for the size of set `j`:

```
...
$save.keepCode bp

$onEmbeddedCode GAMS: restart=bp
scalar size /0/;
nj = 1; loop(i, size = size+s(i); if (size>B, nj = nj+1; size = s(i)));
file fnj / 'nj.gms' /; put fnj '$setGlobal NJ ' nj:0:0;
$offEmbeddedCode
$include nj
Set j 'bins' / b1*b%NJ% /;
...
```

In the next solution the embedded code GAMS writes already the data statement for set `j`:

```
...
$save.keepCode bp

$onEmbeddedCode GAMS: restart=bp
scalar jcnt, size /0/;
nj = 1; loop(i, size = size+s(i); if (size>B, nj = nj+1; size = s(i)));
```

```
file fnj / 'nj.gms' /; put fnj '* Set j:';
* Either as short hand b1*bN or all individual elements
if (1=0,
  put / 'b1*b' nj:0:0;
else
  for (jcnt=1 to nj, put / 'b' jcnt:0:0);
);
$offEmbeddedCode
Set j 'bins' /
$include nj
/;
...
```

Embedded code GAMS works best in combination with restarting from a save file. This makes the embedded code short because it can utilize the symbol declarations and definitions from the restart file. Save files can be created at compile time via $save[.keepCode] fileName and at execution time via put_utility 'save' / 'fileName';.

Execution time embedded code GAMS can be useful if at execution time GAMS needs to deal with new labels as in the following sophisticated example. Here we build on top of the GAMS Model Library **trnsport** model and represent the Jacobian matrix of the LP model utilizing the Convert option dumpGDX in the original name space inside GAMS:

```
...
Model transport / all /;

* Generate the Jacobian (t.gdx) with e1,e2,e3,... and x1,x2,x3,... and a mapping (tdm.gdx) to map the
* scalar elements e1,e2,e3,... and x1,x2,x3,... to the original name space:
$onEcho > convert.opt
dumpGDX t.gdx
dictMap tdm.gdx
$offEcho
transport.optfile = 1; option lp=convert;
solve transport using lp minimizing z;

Sets
    v 'variables block names' / x, z /,
    e 'equation block names' / cost, supply, demand /
    empty 'the empty string' / '' /;
Parameter jac(e,*,*,v,*,*) 'Jacobian of the generated LP model';

embeddedCode GAMS:
$call.checkErrorLevel gdxdump tdm.gdx noData > tdm.gms
$include tdm
Parameter A(i,j) 'Jacobian in e1,e2,.. (set i) and x1,x2,... (set j) space', jac;
$gdxLoad t.gdx A
Alias (*,ti,tii,tj,tjj);
loop((cost_EM(i)      ,x_VM(j,ti,tj)), jac('cost'  ,'' ,'','x',ti,tj) = A(i,j));
loop((cost_EM(i)      ,z_VM(j)      ), jac('cost'  ,'' ,'','z','','') = A(i,j));
loop((supply_EM(i,tii),x_VM(j,ti,tj)), jac('supply',tii,'','x',ti,tj) = A(i,j));
loop((supply_EM(i,tii),z_VM(j)      ), jac('supply',tii,'','z','','') = A(i,j));
loop((supply_EM(i,tjj),x_VM(j,ti,tj)), jac('demand','',tjj,'x',ti,tj) = A(i,j));
loop((supply_EM(i,tjj),z_VM(j)      ), jac('demand','',tjj,'z','','') = A(i,j));
endEmbeddedCode jac

option jac:3:3:3; display jac;
```

The display of the last line in the code provides the following output in the listing file:

```
----     87 PARAMETER jac

                                    x           x           x           x           x           x
                              seattle     seattle     seattle   san-diego   san-diego   san-diego
                             new-york     chicago      topeka    new-york     chicago      topeka

cost   .          .            -0.225      -0.153      -0.162      -0.225      -0.162      -0.126
supply.seattle    .             1.000       1.000       1.000
supply.san-diego.                                                   1.000       1.000       1.000
demand.           .seattle      1.000       1.000       1.000
demand.           .san-diego                                        1.000       1.000       1.000
```

Other embedded code languages allow inside the language to set instructions to either filter/domain check or replace/merge data that comes back into GAMS. At compile time the dollar control options $on/offFiltered and $on/offMulti[R] impact the load of symbols from embedded code sections, including GAMS. At execution time embedded code GAMS *filters* and *merges* the data. If a different behavior is required, the symbols to be loaded should not be listed on the `end/pauseEmbeddedCode` line but should be loaded with the appropriate execute_load*** call like `execute_load`, `execute_loaddc`, or `execute_loadpoint`. The GDX file to load can be set via `put_utility "gdxIn" / gams.scrDir "ecgamsgdx." gams.scrExt;`:

```
Set ii / i0*i10 /, i / i1*i5 /; Parameter p(i) / i1 1, i3 1, i5 1 /;
embeddedCode GAMS:
Parameter p / i2 1, i4 1, i6 1 /;
endEmbeddedCode p
display p;
embeddedCode GAMS:
Parameter p / i2 1, i4 1, i6 1 /;
endEmbeddedCode
put_utility 'gdxIn' / gams.scrDir 'ecgamsgdx.' gams.scrExt;
execute_load p;
display p;
```

GAMS' first load of `p` filters and merges the symbol into the existing `p` resulting in `i1 1, i2 1, i3 1, i4 1, i5 1` while the second load replaces the symbol resulting in `i2 1, i4 1`. An `execute_loaddc p;` would have resulted in a domain violation (`i6`) and would have triggered an execution error.

4.46 GAMS Connect

4.46.1 Concept

GAMS Connect is a framework inspired by the concept of a so-called ETL (extract, transform, load) procedure that allows to integrate data from various data sources. The GAMS Connect framework consists of the Connect database and the Connect agents that operate on the Connect database. Via the available Connect interfaces the user passes instructions to call Connect agents for reading data from various file types into the Connect database, transforming data in the Connect database, and writing data from the Connect database to various file types. Instructions are passed in YAML syntax. Note that in contrast to a typical ETL procedure, read, transform and write operations do not need to be strictly separated.

4.46.2 Usage

GAMS Connect is available via the GAMS command line parameters ConnectIn and ConnectOut, via embedded code Connect, and as a standalone command line utility gamsconnect.

Instructions processed by the GAMS Connect interfaces need to be passed in YAML syntax as follows:

```
- <agent name1>:
    <root option1>: <value>
    <root option2>: <value>
    .
    .
    <root option3>:
      - <option1>: <value>
        <option2>: <value>
        .
        .
      - <option1>: <value>
        <option2>: <value>
        .
        .
      .
      .
- <agent name2>:
    .
    .
.
.
```

The user lists the tasks to be performed successively. All tasks begin at the same indentation level starting with a `-` (a dash and a space) followed by the Connect agent name and a `:` (a colon). Connect agent options are represented in a simple `<option>: <value>` form. Please check the documentation of Connect Agents for available options. Options at the first indentation level are called `root` options and typically define general settings, e.g. the file name. While some agents only have `root` options, others have a more complex options structure, where a root option may be a list of dictionaries containing other options. A common example is the root option `symbols` (see e.g. GDXReader). Via `symbols` many agents allow to define symbol specific options, e.g. the name of the symbol. The option tables of agents with a more complex options structure provide a *Scope* to reflect this structure - options may be allowed at the first indentation level (`root`) and/or are assigned to other root options (e.g. `symbols`).

Note that YAML syntax also supports an abbreviated form for lists and dictionary, e.g. `<root option3>: [ {<option1>: <value>, <option2>: <value>}, {<option1>: <value>, <option2>: <value>} ]`.

Here is an example that uses embedded Connect code to process instructions:

```
$onecho > distance.csv
i;j;distance in miles
seattle;new-york;2,5
seattle;chicago;1,7
seattle;topeka;1,8
san-diego;new-york;2,5
san-diego;chicago;1,8
san-diego;topeka;1,4
$offecho
```

```
$onecho > capacity.csv
i,capacity in cases
seattle,350.0
san-diego,600.0
$offecho

Set i 'Suppliers', j 'Markets';
Parameter d(i<,j<) 'Distance', a(i) 'Capacity';
$onEmbeddedCode Connect:
- CSVReader:
    file: distance.csv
    name: distance
    indexColumns: [1, 2]
    valueColumns: [3]
    fieldSeparator: ';'
    decimalSeparator: ','
- CSVReader:
    file: capacity.csv
    name: capacity
    indexColumns: [1]
    valueColumns: [2]
- GAMSWriter:
    symbols:
      - name: distance
        newName: d
      - name: capacity
        newName: a
$offEmbeddedCode

display i, j, d, a;
```

In this example, we are reading two CSV files `distance.csv` and `capacity.csv` using the CSVReader. Then we directly write to symbols in GAMS using the GAMSWriter.

Note that even though GAMS is case insensitive, GAMS Connect is **case sensitive**, i.e., YAML instructions are treated case sensitive. This also includes, e.g., indices in CSV files. Consider the following example where the index `j2` should be substituted by `ABC` when reading the CSV file `y.csv`:

```
$onecho > y.csv
i1,j1,2.5
i1,J2,1.7
i2,j1,1.8
i2,j2,1.4
$offecho

set i,j;
parameter p(i<,j<);

$onEmbeddedCode Connect:
- CSVReader:
    file: y.csv
    name: p
    indexColumns: [1,2]
    valueColumns: [3]
    header: false
    indexSubstitutions: { j2: ABC }
- GAMSWriter:
```

```
    writeAll: true
$offEmbeddedCode

display i,j,p;
```

Since the YAML instructions are treated case sensitive, the index `J2` will not be substituted.

```
            j1          J2          ABC

i1       2.500       1.700
i2       1.800                   1.400
```

An exception are symbol names in the Connect database. Creating or accessing symbols, e.g. via the `name` option of many agents, is case insensitive.

All instructions provided to the Connect framework are read using `UTF-8` encoding (`utf-8-sig`). This can be customized by adding a comment in the format `# coding=<encoding name>` or `# -*- coding: <encoding name> -*-` as first line in the YAML code. Note that `UTF-16` encoding is not supported.

A note on the **sorting behavior** of Connect agents. All reader and transformer agents do not guarantee a specific order of the created symbol records. However, as the symbol records in the Connect database are saved in *categorical data structures*, the order in the data source is preserved in *ordered categories*. All writer agents guarantee that symbol records are written in the order of the categories. Here is an example:

```
$onecho > ijk_in.csv
i,j,k1,k2
i1,j2,,3
i2,j1,4,
i1,j1,1,2
i2,j2,5,6
$offecho

EmbeddedCode Connect:
- CSVReader:
    file: ijk_in.csv
    name: ijk
    valueColumns: "3:lastCol"
    indexColumns: [1,2]
- PythonCode:
    code: |
        sym = connect.container.data["ijk"]
        print("ijk records in the Connect database after reading:\n", sym.records)

        data_sorted = sym.records.sort_values(sym.records.columns[:-1].tolist())
        print("ijk records sorted according to categories:\n", data_sorted)

        sym.reorderUELs(uels=['j1','j2'], dimensions=1)
        data_sorted = sym.records.sort_values(sym.records.columns[:-1].tolist())
        print("ijk records sorted according to reordered categories:\n", data_sorted)
- CSVWriter:
    file: ijk_out.csv
    name: ijk
    unstack: True
endEmbeddedCode
```

From the data source `ijk_in.csv`, the CSVReader creates the symbol records as shown with the first print:

```
ijk records in the Connect database after reading:
     i   j level_2  value
0  i1  j2      k2    3.0
1  i2  j1      k1    4.0
2  i1  j1      k1    1.0
3  i1  j1      k2    2.0
4  i2  j2      k1    5.0
5  i2  j2      k2    6.0
```

The ordered categories are inferred from the data source, therefore the order for column `i` is `['i1','i2']`, for column `j` `['j2','j1']` and for column `k` the order of the header `['k1','k2']` is preserved. The categories define the order of the symbol records if sorted:

```
ijk records sorted according to categories:
     i   j level_2  value
0  i1  j2      k2    3.0
2  i1  j1      k1    1.0
3  i1  j1      k2    2.0
4  i2  j2      k1    5.0
5  i2  j2      k2    6.0
1  i2  j1      k1    4.0
```

If the order is not as desired, `.reorderUELs()` can be used to change the order of the categories, e.g. to `['j1','j2']` for column `j`:

```
ijk records sorted according to reordered categories:
     i   j level_2  value
2  i1  j1      k1    1.0
3  i1  j1      k2    2.0
0  i1  j2      k2    3.0
1  i2  j1      k1    4.0
4  i2  j2      k1    5.0
5  i2  j2      k2    6.0
```

The CSVWriter automatically sorts the symbol records according to the categories (note that the order of column `j` was changed with the PythonCode agent) and therefore, the content of file `ijk_out.csv` looks as follows:

```
i,j,k1,k2
i1,j1,1.0,2.0
i1,j2,,3.0
i2,j1,4.0,
i2,j2,5.0,6.0
```

4.46.3 Connect Agents Summary

Current Connect agents support the following data source formats: CSV, Excel, GDX and SQL. The following Connect agents are available:

Connect agent	Description	Supported symbol types
Concatenate	Allows concatenating multiple symbols in the Connect database.	Sets and parameters
CSVReader	Allows reading a symbol from a specified CSV file into the Connect database.	Sets and parameters
CSVWriter	Allows writing a symbol in the Connect database to a specified CSV file.	Sets and parameters
DomainWriter	Allows rewriting the domain information of an existing Connect symbol.	Sets, parameters, variables, and equations
ExcelReader	Allows reading symbols from a specified Excel file into the Connect database.	Sets and parameters
ExcelWriter	Allows writing symbols in the Connect database to a specified Excel file.	Sets and parameters
Filter	Allows to reduce symbol data by applying filters on labels and numerical values.	Sets, parameters, variables, and equations
GAMSReader	Allows reading symbols from the GAMS database into the Connect database.	Sets, parameters, variables, and equations
GAMSWriter	Allows writing symbols in the Connect database to the GAMS database.	Sets, parameters, variables, and equations
GDXReader	Allows reading symbols from a specified GDX file into the Connect database.	Sets, parameters, variables, and equations
GDXWriter	Allows writing symbols in the Connect database to a specified GDX file.	Sets, parameters, variables, and equations
LabelManipulator	Allows to modify labels of symbols in the Connect database.	Sets, parameters, variables, and equations
Options	Allows to set more general options that can affect the Connect database and other Connect agents.	-
Projection	Allows index reordering and projection onto a reduced index space of a GAMS symbol.	Sets, parameters, variables, and equations
PythonCode	Allows executing arbitrary Python code.	-
RawCSVReader	Allows reading unstructured data from a specified CSV file into the Connect database.	-
RawExcelReader	Allows reading unstructured data from a specified Excel file into the Connect database.	-
SQLReader	Allows reading symbols from a specified SQL database into the Connect database.	Sets and parameters
SQLWriter	Allows writing symbols in the Connect database to a specified SQL database.	Sets and parameters

4.46.4 Getting Started

We introduce the basic functionalities of GAMS Connect agents on some simple examples. For more examples see section Examples.

4.46.4.1 Simple Connect Example for CSV

The following example (a modified version of the **trnsport** model) shows how to read and write CSV files. The full example is part of DataLib as model **connect03**. Here is a code snippet of the first lines:

```
$onEcho > distance.csv
i,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4
$offEcho

$onEcho > capacity.csv
i,capacity
seattle,350
san-diego,600
$offEcho

$onEcho > demand.csv
j,demand
new-york,325
chicago,300
topeka,275
$offEcho

Set i 'canning plants', j 'markets';

Parameter d(i<,j<) 'Distance', a(i) 'Capacity', b(j) 'Demand';

$onEmbeddedCode Connect:
- CSVReader:
    file: distance.csv
    name: d
    indexColumns: 1
    valueColumns: "2:lastCol"
- CSVReader:
    file: capacity.csv
    name: a
    indexColumns: 1
    valueColumns: 2
- CSVReader:
    file: demand.csv
    name: b
    indexColumns: 1
    valueColumns: 2
- GAMSWriter:
    writeAll: True
$offEmbeddedCode

[...]
```

It starts out with the declaration of sets and parameters. With compile-time embedded Connect code, data for the parameters is read from CSV files using the Connect agent CSVReader. The CSVReader agent, for example, reads the CSV file `distance.csv` and creates the parameter `d` in the Connect database. The name of the parameter must be given by the option name. Column number 1 is specified as the first domain set using option indexColumns. The valueColumns option is used to specify the column numbers 2, 3 and 4 containing the values. Per default, the first row of the columns specified via `valueColumns` will be used as the second domain set. The symbolic constant `lastCol` can be used if the number of index or value columns is unknown. As a last step, all symbols from the Connect database are written to the GAMS database using the Connect agent GAMSWriter. The GAMSWriter agent makes the parameters `d`, `a` and `b` available outside the embedded Connect code. Note that the sets `i` and `j` are defined implicitly through parameter `d`.

Finally, after solving the `transport` model, Connect can be used to export results to a CSV file:

```
[...]

Model transport / all /;
solve transport using lp minimizing z;

EmbeddedCode Connect:
- GAMSReader:
    symbols:
        - name: x
- Projection:
    name: x.l(i,j)
    newName: x_level(i,j)
- CSVWriter:
    file: shipment_quantities.csv
    name: x_level
    unstack: True
endEmbeddedCode
```

This time, we need to use execution-time embedded Connect code. The Connect agent GAMSReader imports variable `x` into the Connect database. With the Connect agent CSVWriter we write the variable level to the CSV file `shipment_quantities.csv`:

```
i_0,new-york,chicago,topeka
seattle,50.0,300.0,0.0
san-diego,275.0,0.0,275.0
```

Setting the option unstack to `True` allows to use the last dimension as the header row.

4.46.4.2 Simple Connect Example for Excel

The following example is part of GAMS Model Library as model **cta** and shows how to read and write Excel spreadsheets. Here is a code snippet of the first lines:

```
Set
   i 'rows'
   j 'columns'
   k 'planes';

Parameter
   dat(k<,i<,j<) 'unprotected data table'
   pro(k,i,j)    'information sensitive cells';

* extract data from Excel workbook
$onEmbeddedCode Connect:
- ExcelReader:
    file: cox3.xlsx
    symbols:
      - name: dat
        range: Sheet1!A1
        rowDimension: 2
        columnDimension: 1
      - name: pro
        range: Sheet2!A1
        rowDimension: 2
```

```
        columnDimension: 1
- GAMSWriter:
    writeAll: True
$offEmbeddedCode

[...]
```

It starts out with the declaration of sets and parameters. With compile-time embedded Connect code, data for the parameters is read from the Excel file `cox3.xlsx` using the Connect agent ExcelReader. The ExcelReader agent allows reading data for multiple symbols that are listed under the keyword `symbols`, here, parameter `dat` and `pro`. For each symbol, the symbol name is given by option name and the Excel range by option range. The option rowDimension defines that the first two columns of the data range will be used for the labels. In addition, the option columnDimension defines that the first row of the data range will be used for the labels. As a last step, all symbols from the Connect database are written to the GAMS database using the Connect agent GAMSWriter. The GAMSWriter agent makes the parameters `dat` and `pro` available outside the embedded Connect code. Note that the sets `i`, `j` and `k` are defined implicitly through parameter `dat`.

Finally, after solving the `cox3c` model with alternative solutions, Connect can be used to export results to Excel:

```
[...]

loop(l$((obj.l - best)/best <= 0.01),
   ll(l) = yes;
   binrep(s,l)             = round(b.l(s));
   binrep('','','Obj',l)   = obj.l;
   binrep('','','mSec',l)  = cox3c.resUsd*1000;
   binrep('','','nodes',l) = cox3c.nodUsd;
   binrep('Comp','Cells','Adjusted',l) = sum((i,j,k)$(not s(i,j,k)), 1$round(adjn.l(i,j,k) + adjp.l(
   solve cox3c min obj using mip;
);

embeddedCode Connect:
- GAMSReader:
    symbols:
      - name: binrep
- ExcelWriter:
    file: results.xlsx
    clearSheet: True
    symbols:
      - name: binrep
endEmbeddedCode
```

This time, we need to use execution-time embedded Connect code. The Connect agent GAMSReader imports the reporting parameter `binrep` into the Connect database. With the Connect agent ExcelWriter we write the parameter into the `binrep` sheet of the Excel file `results.xlsx`.

4.46.4.3 Simple Connect Example for SQL

The following example (a modified version of the **whouse** model) shows how to read from and write to a SQL database (sqlite). The full example is part of DataLib as model **connect04**. Here is a code snippet of the first lines:

```
[...]

Set t 'time in quarters';

Parameter
   price(t)  'selling price ($ per unit)'
   istock(t) 'initial stock      (units)';

Scalar
   storecost 'storage cost  ($ per quarter per unit)'
   storecap  'stocking capacity of warehouse (units)';

$onEmbeddedCode Connect:
- SQLReader:
    connection: {"database": "whouse.db"}
    symbols:
      - name: t
        query: "SELECT * FROM timeTable;"
        type: set
      - name: price
        query: "SELECT * FROM priceTable;"
      - name: istock
        query: "SELECT * FROM iniStockTable;"
      - name: storecost
        query: "SELECT * FROM storeCostTable;"
      - name: storecap
        query: "SELECT * FROM storeCapTable;"
- GAMSWriter:
    writeAll: True
$offEmbeddedCode

[...]
```

It starts out with the declaration of sets and parameters. With compile-time embedded Connect code, data for all the symbols are read from the sqlite database `whouse.db` using the Connect agent SQLReader by passing the connection url through the option connection. The SQLReader agent, for example, queries the table `priceTable` for data and creates the parameter `price` in the Connect database. The SQLReader allows reading data for multiple symbols that are listed under the keyword `symbols` and are fetched through the same connection. For each symbol the name must be given by the option name. The SQL query statement is passed through the option query. The symbol type can be specified using the option type. By default, every symbol is treated as a GAMS parameter. As a last step, all symbols from the Connect database are written to the GAMS database using the Connect agent GAMSWriter. The GAMSWriter agent makes all read in symbols available outside the embedded Connect code.

Further, after solving the warehouse model, Connect can be used to export the results to tables in the SQL database.

```
[...]

Model swp 'simple warehouse problem' / all /;

solve swp minimizing cost using lp;

EmbeddedCode Connect:
- GAMSReader:
    readAll: True
```

```
- Projection:
    name: stock.l(t)
    newName: stock_level(t)
- Projection:
    name: sell.l(t)
    newName: sell_level(t)
- Projection:
    name: buy.l(t)
    newName: buy_level(t)
- SQLWriter:
    connection: {"database": "whouse.db"}
    ifExists: replace
    symbols:
      - name: stock_level
        tableName: stock_level
      - name: sell_level
        tableName: sell_level
      - name: buy_level
        tableName: buy_level
endEmbeddedCode
```

Here, we need to use execution-time embedded Connect code. The Connect agent GAMSReader imports all the variables into the Connect database. The SQLWriter agent then writes each symbol to respective tables in the SQL database `whouse.db`. For example the stock level:

```
|t_0     |level     |
|:-------|:---------|
|q-1     |100.0     |
|q-2     |0.0       |
|q-3     |0.0       |
|q-4     |0.0       |
```

The ifExists option allows to either append to an extending table or replace it with new data. By default, the value for `ifExists` is set to `fails`.

4.46.5 Connect Agents

4.46.5.1 Concatenate

The Concatenate agent allows concatenating multiple symbols (sets or parameters) in the Connect database into a single symbol of the same type. It takes the union of domain sets of all concatenated symbols and uses that as the domain for the output symbol. There are several options to guide this domain finding process which are explained below. The general idea is best explained with an example. Consider three parameters `p1(i,j)`, `p2(k,i)`, and `p3(k,l)`. The union of all domain sets is `i`, `j`, `k`, and `l` and, hence, the output symbol will be `parameterOutput(symbols,i,j,k,l)`. The very first index of `parameterOutput` contains the name of the concatenated symbol followed by the domain sets. If a domain set is not used by a concatenated symbol the corresponding records in `parameterOutput` will feature the emptyUel, a `-` (dash) by default, as the following figures show:

The Concatenate agent is especially useful in combination with UI components that provide a pivot table, like GAMS MIRO, to represent many individual output symbols in a single powerful and configurable table format.

Obviously, there are more complex situations with respect to the domain of the resulting `parameterOutput`. For example, only a subset of domain sets are relevant and the remaining ones should be combined in as few index positions as possible. For this, assume only domain sets `i` and `k` from the above example are relevant and `j` and `l` can be combined in a single index position - a so-called universal domain. The resulting `parameterOutput` would look as follows:

Moreover, the Concatenate agent needs to deal with universe domain sets $*$ and domain sets that are used multiple times in a concatenated symbol. In addition to the `symbols` index (always the first index position of the output symbol), by default the union of domain sets of the concatenated symbols determine the domain of the output symbol. If a domain set (including the universe $*$) appears multiple times in a concatenated symbol domain, these duplicates will be part of the output symbol domain. For example, `q1(*,i,j,*)` and `q2(*,i,i)` will result in the output symbol `parameterOutput(symbols,*,i,j,*,i,)` by default, mapping index positions 1 to 4 of `q1` to positions 2 to 5 of `parameterOutput` and index positions 1 to 3 of `q2` to 2, 3, and 6.

All the described situations can be configured with a few options of the agent. The option outputDimensions allows to control the domain of the output symbol. The default behavior (`outputDimension: all`) gets the domain sets from the concatenated symbols and builds the union with duplicates if required. Alternatively, `outputDimensions` can be a list of the relevant domain sets (including an empty list). In any case, the agent iterates through the concatenated symbols and maps the index positions of a concatenated symbol into the index positions of the output symbol using the domain set names. Names not present in `outputDimensions` will be added as universal domains. Per default, the domain set names of a concatenated symbol will be the original domain set names as stored in the Connect database. There are two ways to adjust the domain set names of concatenated symbols: dimensionMap and an explicitly given domain for a symbol in the name option. The `dimensionMap` which is given once and holds for all symbols allows to map original domain names of concatenated symbols to the desired domain names. The `name` option provides such a map by symbol and via the index position rather than the domain names of the concatenated symbol. In the above example with `p1(i,j)`, `p2(k,i)`, and `p3(k,l)`, we could put indices `i` and `l` as well as `j` and `k` together resulting in the following output symbol:

This can be accomplished in two ways: either we use `dimensionMap: {i: il, l: il, j: jk, k: jk}` or we use `name: p1(il,jk)`, `name: p2(jk,il)`, and `name: p3(jk,il)` to explicitly define the domain names for each symbol. Note that it is not required to set `outputDimensions: [il,jk]` since per default the union of domain sets is built using the mapped domain names. In case a domain set is used more than once in a domain of a concatenated symbol the mapping goes from left to right to find the corresponding output domain. If this is not desired, the Projection agent can be used to reorder index positions in symbols or explicit index naming can be used. In the example with `q1(*,i,j,*)` and `q2(*,i,i)`, the second index position of `q2` will be put together with the second index position of `q1`. If one wants to map the second `i` of `q2` (in the third index position) together with the `i` of `q1` (in second index position), one can, e.g., do with `name: q1(*,i,j,*)`, and `name: q2(*,i2,i)`.

Note

1. The Concatenate agent creates result symbols `parameterOutput` and `setOutput` for parameters and sets separately. Both have the same output domain. If you want different output domains for `parameterOutput` and `setOutput` use two instantiations of the Concatenate agent.
2. Variables and equations need to be turned into parameters with the Projection agent before they can be concatenated.
3. If option `name` is given without an explicit domain for the concatenated symbol, the domain names stored in the Connect container are used and mapped via the `dimensionMap` option, if provided.
4. A domain set of a concatenated symbol that cannot be assigned to an index in `outputDimensions` will be mapped to a so-called universal domain. The Concatenate agent automatically adds as many universal domains as required to the output symbols.

Here is a complete example that uses the Concatenate agent:

```
Sets
   i(i) / i0*i3 "i_text" /
   j(j) / j0*j3 "j_text" /
   k(k) / k0*k3 "k_text" /;

Parameters
   p1(i) / i1 1 /
   p2(k,j) / k1.j0 2, k1.j1 3, k1.j3 4 /
   p3(j,j) / j1.j2 5, j2.j0 6, j3.j1 7, j3.j2 8 /
   s / 5 /;

Positive Variable x(i,j);
x.l(i,j)$(uniform(0,1)>0.8) = uniformint(0,10);

EmbeddedCode Connect:
- GAMSReader:
    readAll: True
- Projection:
    name: x.l(i,j)
    newName: x_level(i,j)
- Concatenate:
    outputDimensions: [j,i]
- GDXWriter:
    file: concat_output.gdx
    symbols:
      - name: setOutput
      - name: parameterOutput
endEmbeddedCode
```

The resulting set and parameter outputs look as follows:

The following options are available for the Concatenate agent.

Option	Scope	Default	Description
concatenateAll	root	`auto`	Indicate if all sets and parameters in the Connect database will be concatenated.
dimensionMap	root	None	Define a mapping for the domain names of concatenated symbols as stored in the Connect database to the desired domain names.
emptyUel	root	`-`	Define a character to use for empty uels.
name	symbols	None	Specify the name of the symbol with potentially index space.
newName	symbols	None	Specify a new name for the symbol in the `symbols` column of the output symbol.
outputDimensions	root	`all`	Define the dimensions of the output symbols.
parameterName	root	`parameterOutput`	Name of the parameter output symbol.
setName	root	`setOutput`	Name of the set output symbol.
skip	root	None	Indicate if sets or parameters should be skipped.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
universalDimension	root	`uni`	Specify the base name of universal dimensions.

Detailed description of the options:

concatenateAll = *boolean or string* (default=`auto`)

If `True` all sets and parameters in the given database are concatenated, symbols will be ignored. Default is `auto` where the Concatenate agent uses `symbols` if specified, otherwise concatenates all sets and parameters in the Connect database.

dimensionMap = *dict* (optional)

Define a mapping for domain names of concatenated symbols as stored in the Connect database to the desired domain names. For example, `dimensionsMap: {i: ij, j: ij}` will map both symbol domains `i` and `j` to `ij`.

emptyUel = *string* (default=`-`)

Define a character to use for empty uels.

name = *string* (required)

Specify the name of the symbol with potentially index space. Requires the format `symName(i1,i2,...,iN)`. The index space may be specified to establish a mapping for the domain names of the symbol as stored in the Connect database to the desired domain names. If no index space is provided, the domain names stored in the Connect data are used and mapped via the `dimensionMap` option if provided.

newName = *string* (optional)

Specify a new name for the symbol in the `symbols` column of the output symbol.

outputDimensions = *list or string* (default=`all`)

Define the dimensions of the output symbols explicitly using a list, e.g., `outputDimensions: [i,j]`. The default `all` gets the domain sets from the concatenated symbols and builds the union with duplicates if required.

parameterName = *string* (default=`parameterOutput`)

Name of the parameter output symbol.

setName = *string* (default=`setOutput`)

Name of the set output symbol.

skip = *string* (optional)

Indicate if sets or parameters should be skipped. Per default the agent takes both sets and parameters into account (if both are available via symbols or concatenateAll) and generates a set and parameter output symbol with the same domain. If `set` is specified, the sets will be skipped, i.e. sets are not taken into account for setting up the domain and no set output symbol will be generated. If `par` is specified, the parameters will be skipped.

symbols = *list* (optional)

A list containing symbol specific options. Allows to concatenate a subset of symbols.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` $>$ `1` some scalar debugging output will be written to the log. For `trace` $>$ `2` the intermediate data frames will be written abbreviated to the log. For `trace` $>$ `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

universalDimension = *string* (default=`uni`)

Specify the base name of universal dimensions.

4.46.5.2 CSVReader

The CSVReader allows reading a symbol (set or parameter) from a specified CSV file into the Connect database. Its implementation is based on the `pandas.DataFrame` class and its I/O API method `read_csv`. See Simple Connect Example for CSV for a simple example that uses the CSVReader.

Option	Default	Description
autoColumn	None	Generate automatic column names.
autoRow	None	Generate automatic row labels.
decimalSeparator	. (period)	Specify a decimal separator.
fieldSeparator	, (comma)	Specify a field separator.
file	None	Specify a CSV file path.
header	inferred	Specify the header(s) used as the column names.
indexColumns	None	Specify columns to use as the row labels.
indexSubstitutions	None	Dictionary used for substitutions in the index columns.
name	None	Specify a symbol name for the Connect database.
names	None	List of column names to use.
quoting	0	Control field quoting behavior.
readCSVArguments	None	Dictionary containing keyword arguments for the `pandas.read_csv` method.
skipRows	None	Specify the rows to skip or the number of rows to skip.
stack	inferred	Stacks the column names to index.
textColumns	None	Specify columns to get the set element text from.
textSubstitutions	None	Dictionary used for substitutions in the text columns.
thousandsSeparator	None	Specify a thousands separator.
trace	inherited	Specify the trace level for debugging output.
valueColumns	None	Specify columns to get the values from.
valueSubstitutions	None	Dictionary used for substitutions in the value columns.

Detailed description of the options:

autoColumn = *string* (optional)

Generate automatic column names. The `autoColumn` string is used as the prefix for the column label numbers. This option overrides the use of a `header` or `names`. However, if there is a header row, one must skip the row by enabling `header` or using `skipRows`.

autoRow = *string* (optional)

Generate automatic row labels. The `autoRow` string is used as the prefix for the row label numbers. The generated unique elements will be used in the first index position shifting other elements to the right. Using `autoRow` can be helpful when there are no labels that can be used as unique elements but also to store entries that would be a duplicate entry without a unique row label.

decimalSeparator = *string* (default=`.`)

Specify a decimal separator. [`.` (period), `,` (comma)]

fieldSeparator = *string* (default=`,`)

Specify a field separator. [`,` (comma), `;` (SemiColon), `\t` (Tab)]

file = *string* (required)

Specify a CSV file path.

header = *boolean, list* (optional)

Specify the header(s) used as the column names. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=True` and column names are inferred from the first line of data, if column names are passed explicitly then the behavior is identical to `header=False`. Explicitly pass `header=True` to be able to replace existing names. Note that missing column names are filled with `Unnamed: n` (where n is the nth column (zero based) in the DataFrame). Hence, reading the CSV file:

```
,j1,
i1,1,2
i2,3,4
,5,6
```

results in the following 2-dimensional parameter:

```
            j1  Unnamed: 2

i1       1.000       2.000
i2       3.000       4.000
```

For a multi-row header, a list of integers can be passed providing the positions of the header rows in the data. Note that reading multi-row header is only supported for parameters. Moreover, the CSVReader can only read all columns and not a subset of columns, wherefore only `indexColumns` can be specified and all other columns will automatically be read as `valueColumns`. Note that `indexColumns` can not be provided as column names together with a multi-row header. `autoRow` and `autoColumn` will be ignored in case of a multi-row header. Here is an example how to read data with a multi-row header:

```
$onecho > multirow_header.csv
j,,j1,j1,j1,j2,j2,j2
k,,k1,k2,k3,k1,k2,k3
h,i,,,,,,
h1,i1,1,2,,4,5,6
h1,i2,,,3,4,5,
$offEcho

$onEmbeddedCode Connect:
- CSVReader:
    file: multirow_header.csv
    name: p
    header: [1,2]
    indexColumns: [1,2]
- PythonCode:
    code: |
        print(connect.container["p"].records)
$offEmbeddedCode
```

The same can be achieved if the data has no index column names:

```
j,,j1,j1,j1,j2,j2,j2
k,,k1,k2,k3,k1,k2,k3
h1,i1,1,2,,4,5,6
h1,i2,,,3,4,5,
```

If the first line of data after the multi-row header has no data in the `valueColumns`, the CSVReader will interpret this line as index column names.

indexColumns = *list or string* (optional)

Specify columns to use as the row labels. The columns can either be given as column positions or column names. Column positions can be represented as an integer, a list of integers or a string. For example: `indexColumns: 1`, `indexColumns: [1, 2, 3, 4, 6]` or `indexColumns: "1:4, 6"`. The symbolic constant `lastCol` can be used with the string representation: `"2:lastCol"`. If no `header` or `names` is provided, `lastCol` will be determined by the first line of data. Column names can be represented as a list of strings. For example: `indexColumns: ["i1","i2"]`. Note that `indexColumns` and `valueColumns`/`textColumns` and must either be given as positions or names not both. Further note that `indexColumns` as column names are not supported together with a multi-row header.

By default the `pandas.read_csv` method interprets the following indices as `NaN`: "", "#N/A", "#N/A N/A", "#NA", "-1.#IND", "-1.#QNAN", "-NaN", "-nan", "1.#IND", "1.#QNAN", "<NA>", "N/A", "NA", "NULL", "NaN", "n/a", "nan", "null". The default can be changed by specifying `pandas.read_csv` arguments `keep_default_na` and `na_value` via readCSVArguments. Rows with indices that are interpreted as `NaN` will be dropped automatically. The indexSubstitutions option allows to remap `NaN` entries in the index columns.

indexSubstitutions = *dictionary* (optional)

Dictionary used for substitutions in the index columns. Each key in `indexSubstitutions` is replaced by its corresponding value. This option allows arbitrary replacements in the index columns of the `DataFrame` including stacked column names. Consider the following CSV file:

```
i1,j1,2.5
i1,,1.7
i2,j1,1.8
i2,,1.4
```

Reading this data into a 2-dimensional parameter results in a parameter with `NaN` entries dropped:

```
            j1

i1       2.500
i2       1.800
```

By specifying `indexSubstitutions: { .nan: j2 }` we can substitute `NaN` entries by `j2`:

```
            j1          j2

i1       2.500       1.700
i2       1.800       1.400
```

name = *string* (required)

Specify a symbol name for the Connect database. Note that each symbol in the Connect database must have a unique name.

names = *list* (optional)

List of column names to use. If the file contains a header row, then you should explicitly pass `header=True` to override the column names. Duplicates in this list are not allowed.

quoting = *integer* (default=0)

Control field quoting behavior. Use QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3). QUOTE_NONNUMERIC (2) instructs the reader to convert all non-quoted fields to type float. QUOTE_NONE (3) instructs reader to perform no special processing of quote characters.

readCSVArguments = *dictionary* (optional)

Dictionary containing keyword arguments for the pandas.read_csv method. Not all arguments of that method are exposed through the YAML interface of the CSVReader agent. By specifying `readCSVArguments`, it is possible to pass arguments directly to the `pandas.read_csv` method that is used by the CSVReader agent. For example, `readCSVArguments: {keep_default_na: False, skip_blank_lines: False}`.

skipRows = *list or integer* (optional)

Specify the rows to skip (list) or the number of rows to skip (integer). For example: `skipRows: [1, 3]` or `skipRows: 5`.

stack = *boolean* (optional)

Stacks the column names to index. Defaults to `True` if there is more than one value/text column, otherwise `False`. Note that missing column names are filled with `Unnamed: n` (where n is the nth column (zero based) in the DataFrame).

textColumns = *list or string* (optional)

Specify columns to get the set element text from. The columns can be given as column positions or column names. Column positions can be represented as a integer, a list of integers or a string. For example: `textColumns: 1`, `textColumns: [1, 2, 3, 4, 6]` or `textColumns: "1:4, 6"`. The symbolic constant `lastCol` can be used with the string representation: `"2:lastCol"`. If no `header` or `names` is provided, `lastCol` will be determined by the first line of data. Column names can be represented as a list of strings. For example: `textColumns: ["i1","i2"]`. Note that `textColumns` and `indexColumns` must either be given as positions or names not both.

By default the `pandas.read_csv` method interprets the following text as `NaN`: "", "#N/A", "#N/A N/A", "#NA", "-1.#IND", "-1.#QNAN", "-NaN", "-nan", "1.#IND", "1.#QNAN", "<NA>", "N/A", "NA", "NULL", "NaN", "n/a", "nan", "null". The default can be changed by specifying `pandas.read_csv` arguments `keep_default_na` and `na_value` via readCSVArguments. Rows with texts that are interpreted as `NaN` will be dropped automatically. The textSubstitutions option allows to remap `NaN` entries in the text columns.

textSubstitutions = *dictionary* (optional)

Dictionary used for substitutions in the text columns. Each key in `textSubstitutions` is replaced by its corresponding value. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading. The default reading behavior is sparse since rows with text that is interpreted as `NaN` are dropped automatically. Consider the following CSV file:

```
i1,text1
i2,
i3,text3
```

thousandsSeparator = *string* (optional)

Specify a thousands separator.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the intermediate data frames will be written abbreviated to the log. For `trace > 3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

valueColumns = *list or string* (optional)

Specify columns to get the values from. The columns can be given as column positions or column names. Column positions can be represented as a integer, a list of integers or a string. For example: `valueColumns: 1`, `valueColumns: [1, 2, 3, 4, 6]` or `valueColumns: "1:4, 6"`. The symbolic constant `lastCol` can be used with the string representation: `"2:lastCol"`. If no `header` or `names` is provided, `lastCol` will be determined by the first line of data. Column names can be represented as a list of strings. For example: `valueColumns: ["i1","i2"]`. Note that `valueColumns` and `indexColumns` must either be given as positions or names not both.

By default the `pandas.read_csv` method interprets the following values as `NaN`: "", "#N/A", "#N/A N/A", "#NA", "-1.#IND", "-1.#QNAN", "-NaN", "-nan", "1.#IND", "1.#QNAN", "<NA>", "N/A", "NA", "NULL", "NaN", "n/a", "nan", "null". The default can be changed by specifying `pandas.read_csv` arguments `keep_default_na` and `na_value` via readCSVArguments. Rows with values that are interpreted as `NaN` will be dropped automatically. Changing the default of values that are interpreted as `NaN` is useful if, e.g., "NA" values should not be dropped but interpreted as GAMS special value `NA`. Moreover, the valueSubstitutions option allows to remap `NaN` entries in the value columns.

valueSubstitutions = *dictionary* (optional)

Dictionary used for substitutions in the value columns. Each key in `valueSubstitutions` is replaced by its corresponding value. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading. All `NaN` entries are removed automatically by default which results in a sparse reading behavior. Consider the following CSV file:

```
i1,j1,
i1,j2,1.7
i2,j1,
i2,j2,1.4
```

Reading this data into a 2-dimensional parameter results in a sparse parameter with all `NaN` entries removed:

```
            j2

i1       1.700
i2       1.400
```

By specifying `valueSubstitutions: { .nan: EPS }` we get a dense representation where all `NaN` entries are replaced by GAMS special value `EPS`:

```
            j1          j2

i1         EPS       1.700
i2         EPS       1.400
```

Beside `EPS` there are the following other GAMS special values that can be used by specifying their string representation: `INF`, `-INF`, `EPS`, `NA`, and `UNDEF`. See the GAMS Transfer documentation for more information.

Reading this data into a 1-dimensional set results in a sparse set in which all `NaN` entries (those that do not have any set element text) are removed:

```
'i1' 'text 1',
'i3' 'text 3'
```

By specifying `textSubstitutions: { .nan: '' }` we get a dense representation:

```
'i1' 'text 1',
'i2',
'i3' 'text 3'
```

It is also possible to use `textSubstitutions` in order to interpret the set element text. Let's assume we have the following CSV file:

```
,j1,j2,j3
i1,Y,Y,Y
i2,Y,Y,N
i3,0,Y,Y
```

Reading this data into a 2-dimensional set results in a dense set:

```
'i1'.'j1' Y,
'i1'.'j2' Y,
'i1'.'j3' Y,
'i2'.'j1' Y,
'i2'.'j2' Y,
'i2'.'j3' N,
'i3'.'j1' 0,
'i3'.'j2' Y,
'i3'.'j3' Y
```

By specifying `textSubstitutions: { 'N': .nan, '0': .nan }` we replace all occurrences of `N` and `0` by `NaN` which gets dropped automatically:

```
'i1'.'j1' Y,
'i1'.'j2' Y,
'i1'.'j3' Y,
'i2'.'j1' Y,
'i2'.'j2' Y,
'i3'.'j2' Y,
'i3'.'j3' Y
```

4.46.5.3 CSVWriter

The CSVWriter allows writing a symbol (set or parameter) in the Connect database to a specified CSV file. Variables and equations need to be turned into parameters with the Projection agent before they can be written. See Simple Connect Example for CSV for a simple example that uses the CSVWriter.

Option	Default	Description
decimalSeparator	`.` (period)	Specify a decimal separator.
file	None	Specify a CSV file path.
fieldSeparator	`,` (comma)	Specify a field separator.
header	`True`	Indicate if the header will be written.
name	None	Specify the name of the symbol in the Connect database.
quoting	`0`	Control field quoting behavior.
setHeader	None	Specify a string that will be used as the header.
skipElementText	`False`	Indicate if the set element text will be skipped.
toCSVArguments	None	Dictionary containing keyword arguments for the `pandas.to_csv` method.
trace	inherited	Specify the trace level for debugging output.
unstack	`False`	Specify the dimensions to be unstacked to the header row(s).

Detailed description of the options:

decimalSeparator = *string* (default=`.`)

Specify a decimal separator. [`.` (period), `,` (comma)]

file = *string* (required)

Specify a CSV file path.

fieldSeparator = *string* (default=`,`)

Specify a field separator. [`,` (comma), `;` (SemiColon), `\t` (Tab)]

header = *boolean* (default=`True`)

Indicate if the header will be written.

name = *string* (required)

Specify the name of the symbol in the Connect database.

quoting = *integer* (default=`0`)

Control field quoting behavior. Use QUOTE_MINIMAL (`0`), QUOTE_ALL (`1`), QUOTE_NONNUMERIC (`2`) or QUOTE_NONE (`3`). QUOTE_MINIMAL (`0`) instructs the writer to only quote those fields which contain special characters such as `fieldSeparator`. QUOTE_ALL (`1`) instructs the writer to quote all fields. QUOTE_NONNUMERIC (`2`) instructs the writer to quote all non-numeric fields. QUOTE_NONE (`3`) instructs the writer to never quote fields.

setHeader = *string* (optional)

Specify a string that will be used as the header. If an empty header is desired, the string can be empty.

skipElementText = *boolean* (default=`False`)

Indicate if the set element text will be skipped. If `False`, the set element text will be written in the last column of the CSV file.

toCSVArguments = *dictionary* (optional)

Dictionary containing keyword arguments for the `pandas.to_csv` method. Not all arguments of that method are exposed through the YAML interface of the CSVWriter agent. By specifying `toCSVArguments`, it is possible to pass arguments directly to the `pandas.to_csv` method that is used by the CSVWriter agent. For example, `toExcelArguments: {index_label: ["index1", "index2", "index3"]}`.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the intermediate data frames will be written abbreviated to the log. For `trace > 3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

unstack = *boolean, list* (default=`False`)

Specify the dimensions to be unstacked to the header row(s). If `False` (default) no dimension will be unstacked to the header row. If `True` the last dimension will be unstacked to the header row. If multiple dimensions should be unstacked to header rows, a list of integers providing the dimension numbers to unstack can be specified.

4.46.5.4 DomainWriter

The DomainWriter agent allows to rewrite domain information for existing Connect symbols and helps dealing with domain violations.

Option	Scope	Default	Description
dropDomainViolations	symbols	`False`	Indicate how to deal with domain violations.
name	symbols	None	Specify the name of the symbol in the Connect database.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
writeAll	root	`auto`	Indicate if all symbols in the Connect database will be treated with the root `dropDomainViolations` setting.

Detailed description of the options:

dropDomainViolations = *boolean (root)/boolean or string (symbols)* (default=`False`)

The Connect symbols might have some domain violations. This agent allows to drop these domain violations so a write to GAMS or GDX works properly. Setting the root option `dropDomainViolations: True` together with `writeAll: True` will drop domain violations from all symbols in the Connect database. The symbols option also allows to drop domain violations. In the `symbols` section the `dropDomainViolations` attribute can be of type boolean (`True` or `False`) or of type string (`before` and `after`). If the attribute has not been set for the symbol, the attribute is inherited from the root attribute. The value `before` means that domain violations are dropped *before* a new domain is applied, see attribute name. The value `after` means that domain violations are dropped *after* a new domain is applied. The value `True` means that domain violations are dropped before and after a new domain is applied. `False` means to not drop domain violations.

name = *string* (required)

Specify a symbol name with index space for the Connect database. `name` requires the format `symName(i1,i2,...,iN)`. The list of indices needs to coincide with the names of the actual GAMS domain sets for a *regular* domain. A *relaxed* domain is set if the index is quoted. For example `name: x(i,'j')` means that for the first index a regular domain with domain set `i` is established, while for the second index the universal domain $*$ is used and a *relaxed domain name* `j` is set.

symbols = *list* (optional)

A list containing symbol specific options. Allows to concatenate a subset of symbols.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` $>$ `1` some scalar debugging output will be written to the log. For `trace` $>$ `2` the intermediate data frames will be written abbreviated to the log. For `trace` $>$ `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

writeAll = *boolean or* ***auto*** (default=`auto`)

Indicate if all symbols in the Connect database will be treated according to root attribute dropDomainViolations. If `True`, treat all symbols according to `dropDomainViolations` and ignore symbols. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`.

4.46.5.5 ExcelReader

The ExcelReader agent allows to read symbols (sets and parameters) from an Excel file into the Connect database. See Simple Connect Example for Excel for a simple example that uses the ExcelReader.

Note

The ExcelReader supports `.xlsx` and `.xlsm` files.

Option	Scope	Default	Description
autoMerge	root/symbols	`False`	Indicate if empty cells in the labels should be merged with previous cells.
columnDimension	root/symbols	`1`	Column dimension of the symbol.
file	root/symbols	None	Specify an Excel file path.
ignoreColumns	symbols	None	Columns to be ignored when reading.
ignoreRows	symbols	None	Rows to be ignored when reading.
ignoreText	root/symbols	`auto`	Indicate if the set element text should be ignored.
index	root	None	Specify the Excel range for reading symbols and options directly from the spreadsheet.
indexSubstitutions	root/symbols	None	Dictionary used for substitutions in the row and column index.
mergedCells	root	`False`	Control the handling of empty cells in the labels and the values that are part of a merged Excel range.
name	symbols	None	Specify the name of the symbol in the Connect database.
range	symbols	`symName!A1`	Specify the Excel range of a symbol.
rowDimension	root/symbols	`1`	Row dimension of the symbol.
skipEmpty	root/symbols	`1`	Number of empty rows or columns to skip before the next empty row or column indicates the end of the block for reading with open ranges.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
type	root/symbols	`par`	Control the symbol type.
valueSubstitutions	root/symbols	None	Dictionary used for mapping in the values.

Detailed description of the options: **autoMerge** = *boolean* (default=`False`)

Indicate if empty cells in the labels should be merged with previous cells. If `True`, each empty cell in the labels will be filled with the value of a previous cell that is not empty. This will resolve merged cells in the labels and will also fill empty cells in the labels that are not part of a merged cell. If the user wants to keep empty cells in the labels that are not part of a merged cell and still resolve merged cells, `autoMerge` needs to be set to `False` and mergedCells needs to be set to `True`.

columnDimension = *integer* (default=`1`)

The number of rows in the data range that will be used to define the labels for columns. The first `columnDimension` rows of the data range will be used for labels.

file = *string* (required)

Specify an Excel file path.

ignoreColumns = *list, integer or string* (optional)

Columns to be ignored when reading. Specify a list of column numbers (integers) or letters (strings) to ignore multiple columns. Specify a column number (integer) ot letter (string) to ignore a single column.

ignoreRows = *list or integer* (optional)

Specify rows to be ignored when reading. Specify a list of row numbers (integers) to ignore multiple rows or specify a row number (integer) to ignore a single row.

ignoreText = *boolean or string* (default=`auto`)

Indicate if the set element text should be ignored. Can be set to `True`/`False` or `auto`. With the default `auto` the set element text will be ignored based on the specification of range and columnDimension/rowDimension. If either `columnDimension` or `rowDimension` is set to `0` and an open range is specified, the set element text will be ignored. If either `columnDimension` or `rowDimension` is set to `0` and a full range is specified, the set element text will be ignored if it is not included in the range specification. In all other cases the set element text will not be ignored.

index = *string* (optional)

Specify the Excel range for reading symbols and options directly from the spreadsheet.

indexSubstitutions = *dictionary* (optional)

Dictionary used for substitutions in the row and column index. Each key in `indexSubstitutions` is replaced by its corresponding value. This option allows arbitrary replacements in the index. Consider the following Excel spreadsheet:

Reading this data into a 2-dimensional parameter results in a parameter with `NaN` entries dropped:

```
            j1

i1       1.000
i2       3.000
```

By specifying `indexSubstitutions: { .nan: j2 }` we can substitute `NaN` entries by `j2`:

```
            j1          j2

i1       1.000       2.000
i2       3.000       4.000
```

mergedCells = *boolean* (default=`False`)

Control the handling of empty cells that are part of a merged Excel range. The option applies to merged cells in the labels and the values, i.e., the numerical values in case of a GAMS parameter and the set element text in case of a GAMS set. If `False`, the cells are left empty. If `True`, the merged label/value is used in all cells. Note that setting this option to `True` has an impact on performance since the Excel file has to be opened in a non-read-only mode that results in non-constant memory consumption (no lazy loading). From the performance perspective, autoMerge should be preferred over `mergedCells` if applicable.

name = *string* (required)

Specify a symbol name for the Connect database. Note that each symbol in the Connect database must have a unique name.

range = *string* (default=`symName!A1`)

Specify the Excel range of a symbol using the format `sheetName!cellRange`. `cellRange` can be either a single cell also known as an *open range* (north-west corner like `B2`) or a *full range* (north-west and south-east corner like `B2:D4`). Per default the ExcelReader uses the range `symName!A1`, where `symName` is the name of the symbol that is read. If only `sheetName!` is specified, the ExcelReader will use an open range starting at cell `A1`. The ExcelReader also allows for named ranges - a named range includes a sheet name and a cell range. Before interpreting the provided `range` attribute, the string will be used to search for a pre-defined Excel range with that name.

rowDimension = *integer* (default=`1`)

The number of columns in the data range that will be used to define the labels for the rows. The first `rowDimension` columns of the data range will be used for the labels.

skipEmpty = *integer* (deault=`1`)

Number of empty rows or columns to skip before the next empty row or column indicates the end of the block for reading with open ranges. If a full range is specified `skipEmpty` will be ignored.

symbols = *list* (optional)

A list containing symbol specific options.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the intermediate data frames will be written abbreviated to the log. For `trace > 3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

type = *string* (default=`par`)

Control the symbol type. Supported symbol types are `par` for parameters and `set` for sets.

valueSubstitutions = *dictionary* (optional)

Dictionary used for mapping in the values. Each key in `valueSubstitutions` is replaced by its corresponding value. The replacement is only performed on the values which is the numerical value in case of a GAMS parameter and the set element text in case of a GAMS set. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading. All `NaN` entries are removed automatically by default which results in a sparse reading behavior. Let's assume we have the following spreadsheet:

Reading this data into a 2-dimensional parameter results in a sparse parameter in which all `NaN` entries are removed:

```
'i1'.'j1' 2.5,
'i1'.'j2' 1.7,
'i2'.'j2' 1.8,
'i2'.'j3' 1.4
```

By specifying `valueSubstitutions: { .nan: EPS }` we get a dense representation in which all `NaN` entries are replaced by GAMS special value `EPS`:

```
'i1'.'j1' 2.5,
'i1'.'j2' 1.7,
'i1'.'j3' Eps,
'i2'.'j1' Eps,
'i2'.'j2' 1.8,
'i2'.'j3' 1.4
```

Beside `EPS` there are the following other GAMS special values that can be used by specifying their string representation: `INF`, `-INF`, `EPS`, `NA`, and `UNDEF`. See the GAMS Transfer documentation for more information.

Let's assume we have data representing a GAMS set:

Reading this data into a 1-dimensional set results in a sparse set in which all `NaN` entries (those that do not have any set element text) are removed:

```
'i1' 'text 1',
'i3' 'text 3'
```

By specifying `valueSubstitutions: { .nan: '' }` we get a dense representation:

```
'i1' 'text 1'
'i2' ''
'i3' 'text 3'
```

It is also possible to use `valueSubstitutions` in order to interpret the set element text. Let's assume we have the following Excel data:

Reading this data into a 2-dimensional set results in a dense set:

```
'i1'.'j1' No,
'i1'.'j2' Y,
'i1'.'j3' Y,
'i2'.'j1' Y,
'i2'.'j2' Y,
'i2'.'j3' Y,
'i3'.'j1' Y,
'i3'.'j2' Y,
'i3'.'j3' N
```

By specifying `valueSubstitutions: { 'N': .nan, 'No': .nan }` we replace all occurrences of `N` and `No` by `NaN` which gets dropped automatically. Note that `No` has to be quotes in order to not be interpreted as `False` by the YAML parser:

```
'i1'.'j2' Y,
'i1'.'j3' Y,
'i2'.'j1' Y,
'i2'.'j2' Y,
'i2'.'j3' Y,
'i3'.'j1' Y,
'i3'.'j2' Y
```

4.46.5.6 ExcelWriter

The ExcelWriter agent allows to write symbols (sets and parameters) from the Connect database to an Excel file. Variables and equations need to be turned into parameters with the Projection agent before they can be written. If the Excel file exists, the ExcelWriter appends to the existing file. See Simple Connect Example for Excel for a simple example that uses the ExcelWriter.

Note

The ExcelWriter only supports `.xlsx` files.

Attention

Please be aware of the following limitation when appending to an Excel file with formulas using the ExcelWriter: Whereas Excel stores formulas and the corresponding values, the ExcelReader and the ExcelWriter read/store either formulas or values, not both. As a consequence, when appending to an Excel file with formulas, all cells with formulas within the Excel file will not have values anymore and a subsequent read by the ExcelReader results into `NaN` for these cells. To avoid this, write to a separate output Excel file. On Windows one can merge the input Excel file with the output Excel file at the end using the tool win32.ExcelMerge (see Connect Example for Excel (executeTool win32.ExcelMerge)). An alternative approach when appending to an Excel file with formulas is to open and save the Excel file before reading it to let Excel evaluate formulas and restore the corresponding values.

Option	Scope	Default	Description
clearSheet	root/symbols	`False`	Indicate if a sheet should be cleared before writing if it exists.
columnDimension	root/symbols	`auto`	Column dimension of the symbol.
file	root	None	Specify an Excel file path.
mergedCells	root/symbols	`False`	Write merged cells.
name	symbols	None	Specify the name of the symbol in the Connect database.
range	symbols	`symName!A1`	Specify the Excel range of a symbol.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
valueSubstitutions	root/symbols	None	Dictionary used for mapping in the `value` column of the `DataFrame`.
writeAll	root	`auto`	Indicate if all set and parameter type symbols in the Connect database will be written to the specified Excel file.

Detailed description of the options:

clearSheet = *boolean* (default=`False`)

Indicate if a sheet should be cleared before writing if it exists. The default is `False` where a sheet will not be cleared if it exists, instead the ExcelWriter overwrites, i.e., writes content to the sheet without removing the existing content.

columnDimension = *integer* (default=`auto`)

The last `columnDimension` index positions of the symbol that will be written to the rows that define the labels of the columns. The first `dim-columnDimension` index positions will be written to the columns that define the labels for the rows. With the default `auto`, `columnDimension` will be set to `1` if `dim`>`0` and otherwise to `0`.

file = *string* (required)

Specify an Excel file path.

mergedCells = *boolean* (default=`False`)

Write merged cells. Please be aware that overwriting already existing merged cells in a sheet may cause problems, in that case consider setting clearSheet to `True`.

name = *string* (required)

Specify a symbol name for the Connect database.

range = *string* (default=`symName!A1`)

Specify the Excel range of a symbol using the format `sheetName!cellRange`. `cellRange` can be either a single cell (north-west corner like `B2`) or a full range (north-west and south-east corner like `B2:D4`). Per default the ExcelWriter uses the range `symName!A1`, where `symName` is the name of the symbol that is written. If only `sheetName!` is specified, the ExcelWriter will use an open range starting at cell `A1`. The ExcelWriter also allows for named ranges - a named range includes a sheet name and a cell range. Before interpreting the provided `range` attribute, the string will be used to search for a pre-defined Excel range with that name.

symbols = *list* (required)

A list containing symbol specific options.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` $>$ `1` some scalar debugging output will be written to the log. For `trace` $>$ `2` the intermediate data frames will be written abbreviated to the log. For `trace` $>$ `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

valueSubstitutions = *dictionary* (optional)

Dictionary used for mapping in the `value` column of the `DataFrame`. Each key in `valueSubstitutions` is replaced by its corresponding value. The replacement is only performed on the `value` column of the `DataFrame` which is the numerical value in case of a GAMS parameter and the set element text in case of a GAMS set. Note that for parameters the ExcelWriter automatically converts numerical GAMS special values to their string representation, i.e., `INF`, `-INF`, `EPS`, `NA`, and `UNDEF`. See the GAMS Transfer documentation for more information on GAMS special values. If the GAMS special values should be replaced by custom values, use the string representation (upper case) in the dictionary. For example, specify {`'EPS': 0`} to replace GAMS special value `EPS` by zero.

writeAll = *boolean or* ***`auto`*** (default=`auto`)

Indicate if all set and parameter type symbols in the Connect database will be written to the specified Excel file. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`. If `True`, the ExcelWriter writes each symbol into a separate sheet using the range `symName!A1`.

4.46.5.7 Filter

The Filter agent allows to reduce symbol data by applying filters on labels and numerical values. Here is a complete example that uses the Filter agent:

```
Set i / seattle, san-diego /
    j / new-york, chicago, topeka /;

Parameter d(i,j) /
seattle.new-york   2.5
seattle.chicago    1.7
seattle.topeka     1.8
san-diego.new-york 2.5
san-diego.chicago  1.8
san-diego.topeka   1.4
/;

$onEmbeddedCode Connect:
- GAMSReader:
    symbols:
      - name: d
- Filter:
    name: d
    newName: d_new
    labelFilters:
      - column: 1
        keep: ['seattle']
      - column: 2
        reject: ['topeka']
    valueFilters:
      - column: value
        rule: x<2.5
- GDXWriter:
    file: report.gdx
    symbols:
      - name: d_new
$offEmbeddedCode
```

The records of the parameter `d` are filtered and stored in a new parameter called `d_new`. Two label filters remove all labels except `seattle` from the first dimension and remove the label `topeka` from the second one. The remaining records are filtered by value where only values less than 2.5 are kept in the data. The resulting parameter `d_new` which is exported into `report.gdx` has only one record (`seattle.chicago 1.7`) left.

The following options are available for the Filter agent:

Option	Scope	Default	Description
column	labelFilters/valueFilters	None	Specify the column to which a filter is applied.
eps	valueFilters	`True`	Used to keep or reject special value `EPS`.
infinity	valueFilters	`True`	Used to keep or reject special value `+INF`.
keep	labelFilters	None	Specify a list of labels to keep.
labelFilters	root	None	Specify filters for index columns of a symbol.
na	valueFilters	`True`	Used to keep or reject special value `NA`.

Option	Scope	Default	Description
name	root	None	Specify a symbol name for the Connect database.
negativeInfinity	valueFilters	`True`	Used to keep or reject special value `-INF`.
newName	root	None	Specify a new name for the symbol in the Connect database.
regex	labelFilters	None	Specify a regular expression to be used for filtering labels.
reject	labelFilters	None	Specify a list of labels to reject.
rule	valueFilters	None	Specify a boolean expression to be used for filtering on numerical columns.
ruleIdentifier	valueFilters	`x`	The identifier used for the value filter rule.
trace	root	inherited	Specify the trace level for debugging output.
undf	valueFilters	`True`	Used to keep or reject special value `UNDF`.
valueFilters	root	None	Specify filters for numerical columns of a symbol.

Detailed description of the options:

column = *integer or string* (optional)

Used to specify the column on which a label filter or a value filter is applied. For label filters the index position can be specified using an integer. For value filters, the following strings are allowed depending on the symbol type:

- Set: not allowed
- Parameter: `value`, `all`
- Variable and Equation: `level`, `marginal`, `upper`, `lower`, `scale`, `all`

Specifying the string `all` will apply the filter on all columns of the current filter (all index columns for labelFilters and all numerical columns for valueFilters).

eps = *boolean* (default=`True`)

Used to keep (`True`) or reject (`False`) special value `EPS`.

infinity = *boolean* (default=`True`)

Used to keep (`True`) or reject (`False`) special value `+INF`.

keep = *list* (optional)

A list of labels to be kept when applying the label filter. For each label filter it is only allowed to specify either keep, reject, or regex at a time.

labelFilters = *list* (optional)

A list containing label filters.

na = *boolean* (default=`True`)

Used to keep (`True`) or reject (`False`) special value `NA`.

name = *string* (required)

Specify the name of the symbol from the Connect database on whose data the filters will be applied.

negativeInfinity = *boolean* (default=`True`)

Used to keep (`True`) or reject (`False`) special value `-INF`.

newName = *string* (required)

Specify a new name for the symbol in the Connect database which will get the data after all filters have been applied. Each symbol in the Connect database must have a unique name.

regex = *string* (optional)

A string containing a regular expression that needs to match in order to keep the corresponding label. Uses a full match paradigm which means that the whole label needs to match the specified regular expression. For each label filter it is only allowed to specify either keep, reject, or regex at a time.

reject = *string* (optional)

A list of labels to be rejected when applying the label filter. For each label filter it is only allowed to specify either keep, reject, or regex at a time.

rule = *string* (optional)

Used to specify a boolean expression for a value filter. Each numerical value of the specified column is tested and the corresponding record is only kept if the expression evaluates to true. The string needs to contain Python syntax that is valid for `pandas.Series`. Comparison operators like >, `>=`, <, `<=`, `==`, or `!=` can be used in combination with boolean operators like `&` or |, but not `and` or `or`. Note that using `&` or | requires the operands to be enclosed in round brackets in order to form a valid expression. As an example, the expression `((x<=10) & (x>=0)) | (x>20)` would keep only those values that are between `0` and `10` (included) or greater than `20`.

ruleIdentifier = *string* (default=`x`)

Specifies the identifier that is used in the rule of a value filter.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` > `1` some scalar debugging output will be written to the log. For `trace` > `2` the intermediate data frames will be written abbreviated to the log. For `trace` > `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

undf = *boolean* (default=`True`)

Used to keep (`True`) or reject (`False`) special value `UNDF`.

valueFilters = *list* (optional)

A list containing value filters.

4.46.5.8 GAMSReader

The GAMSReader allows reading symbols from the GAMS database into the Connect database. Without GAMS context (e.g. when running the `gamsconnect` script from the command line) this agent is not available and its execution will result in an exception.

Option	Scope	Default	Description
name	symbols	None	Specify the name of the symbol in the GAMS database.
newName	symbols	None	Specify a new name for the symbol in the Connect database.
readAll	root	`auto`	Indicate if all symbols in the GAMS database will be read into the Connect database.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.

Detailed description of the options:

name = *string* (required)

Specify the name of the symbol in the GAMS database.

newName = *string* (optional)

Specify a new name for the symbol in the Connect database. Each symbol in the Connect database must have a unique name.

readAll = *boolean or* ***`auto`*** (default=`auto`)

Indicate if all symbols in the GAMS database will be read into the Connect database. If `True`, read all symbols into the Connect database and ignore symbols. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`.

symbols = *list* (optional)

A list containing symbol specific options. Allows to read a subset of symbols.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` > `1` some scalar debugging output will be written to the log. For `trace` > `2` the intermediate data frames will be written abbreviated to the log. For `trace` > `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

4.46.5.9 GAMSWriter

The GAMSWriter allows writing symbols in the Connect database to the GAMS database. Without GAMS context (e.g. when running the `gamsconnect` script from the command line) and as part of the connectOut command line option this agent is not available and its execution will result in an exception.

Option	Scope	Default	Description
domainCheckType	root/symbols	`default`	Specify if domain checking is applied or if records that would cause a domain violation are filtered.
duplicateRecords	root/symbols	`all`	Specify how to deal with duplicate records.
mergeType	root/symbols	`default`	Specify if data in a GAMS symbol is merged or replaced.
name	symbols	None	Specify the name of the symbol in the Connect database.
newName	symbols	None	Specify a new name for the symbol in the GAMS database.
~~symbols~~	~~root~~	~~None~~	~~Specify symbol specific options.~~
trace	root	inherited	Specify the trace level for debugging output.
writeAll	root	`auto`	Indicate if all symbols in the Connect database will be written to the GAMS database.

Detailed description of the options:

domainCheckType = *string* (default=`default`)

Specify if Domain Checking is applied (`checked`) or if records that would cause a domain violation are filtered (`filtered`). If left at `default` it depends on the setting of $on/offFiltered if GAMS does a filtered load or checks the domains during compile time. During execution time `default` is the same as `filtered`.

duplicateRecords = *string* (default=`all`)

The Connect container can hold multiple records even for the same indexes. Such duplicate records are only a problem when exchanging the data with GAMS (and GDX). The attribute determines which record(s) to keep in case of duplicate records. With the default of `all` the GAMSWriter will fail in case duplicate records exist. With `first` the first record will be written to GAMS, with `last` the last record will be written to GAMS. With `none` none of the duplicate records will be written to GAMS. Note that the agent currently deals with duplicate records in a case sensitive way.

mergeType = *string* (default=`default`)

Specify if data in a GAMS symbol is merged (`merge`) or replaced (`replace`). If left at `default` it depends on the setting of $on/offMulti[R] if GAMS does a merge, replace, or triggers an error during compile time. During execution time `default` is the same as `merge`.

name = *string* (required)

Specify the name of the symbol in the Connect database.

newName = *string* (optional)

Specify a new name for the symbol in the GAMS database. Note, each symbol in the GAMS database must have a unique name.

symbols = *list* (optional)

A list containing symbol specific options. Allows to write a subset of symbols.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` $>$ `1` some scalar debugging output will be written to the log. For `trace` $>$ `2` the intermediate data frames will be written abbreviated to the log. For `trace` $>$ `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

writeAll = *boolean or* ***`auto`*** (default=`auto`)

Indicate if all symbols in the Connect database will be written to the GAMS database. If `True`, write all symbols to the GAMS database and ignore symbols. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`.

4.46.5.10 GDXReader

The GDXReader allows reading symbols from a specified GDX file into the Connect database.

Option	Scope	Default	Description
file	root	None	Specify a GDX file path.
name	symbols	None	Specify the name of the symbol in the GDX file.
newName	symbols	None	Specify a new name for the symbol in the Connect database.
readAll	root	`auto`	Indicate if all symbols in the GDX file will be read into the Connect database.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.

Detailed description of the options:

file = *string* (required)

Specify a GDX file path.

name = *string* (required)

Specify the name of the symbol in the GDX file.

newName = *string* (optional)

Specify a new name for the symbol in the Connect database. Each symbol in the Connect database must have a unique name.

readAll = *boolean or* `auto` (default=`auto`)

Indicate if all symbols in the GDX file will be read into the Connect database. If `True`, read all symbols into the Connect database and ignore symbols. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`.

symbols = *list* (optional)

A list containing symbol specific options. Allows to read a subset of symbols.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` > `1` some scalar debugging output will be written to the log. For `trace` > `2` the intermediate data frames will be written abbreviated to the log. For `trace` > `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

4.46.5.11 GDXWriter

The GDXWriter allows writing symbols in the Connect database to a specified GDX file.

Option	Scope	Default	Description
duplicateRecords	root/symbols	`all`	Specify how to deal with duplicate records.
file	root	None	Specify a GDX file path.
name	symbols	None	Specify the name of the symbol in the Connect database.
newName	symbols	None	Specify a new name for the symbol in the GDX file.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
writeAll	root	`auto`	Indicate if all symbols in the Connect database will be written to the GDX file.

Detailed description of the options:

duplicateRecords = *string* (default=`all`)

The Connect container can hold multiple records even for the same indexes. Such duplicate records are only a problem when exchanging the data with GDX (and GAMS). The attribute determines which record(s) to keep in case of duplicate records. With the default of `all` the GDXWriter will fail in case duplicate records exist. With `first` the first record will be written to GDX, with `last` the last record will be written to GDX. With `none` none of the duplicate records will be written to GDX. Note that the agent currently deals with duplicate records in a case sensitive way.

file = *string* (required)

Specify a GDX file path.

name = *string* (required)

Specify the name of the symbol in the Connect database.

newName = *string* (optional)

Specify a new name for the symbol in the GDX file. Note, each symbol in the GDX file must have a unique name.

symbols = *list* (optional)

A list containing symbol specific options. Allows to write a subset of symbols.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` > `1` some scalar debugging output will be written to the log. For `trace` > `2` the intermediate data frames will be written abbreviated to the log. For `trace` > `3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

writeAll = *boolean or* ***`auto`*** (default=`auto`)

Indicate if all symbols in the Connect database will be written to the GDX file. If `True`, write all symbols to the GDX file and ignore symbols. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`.

4.46.5.12 LabelManipulator

The LabelManipulator agent allows to modify labels of symbols in the Connect database. Four different modes are available:

- case: Applies either upper, lower, or capitalize casing to labels.
- code: Replaces labels using a Python code.
- map: Uses a 1-dimensional GAMS set to perform an explicit mapping of labels.
- regex: Performs a replacement based on a regular expression.

Here is a complete example that uses the LabelManipulator agent in all four modes:

```
Set i / seattle, san-diego /
    j / new-york, chicago, topeka /
    map / chicago 'Berlin', san-diego 'Oslo' /;

Parameter d(i,j) /
seattle.new-york   2.5
seattle.chicago    1.7
seattle.topeka     1.8
san-diego.new-york 2.5
san-diego.chicago  1.8
san-diego.topeka   1.4
/;

$onEmbeddedCode Connect:
- GAMSReader:
    readAll: true
- LabelManipulator:
    map:
        setName: map
- LabelManipulator:
    case:
        rule: upper
- LabelManipulator:
    symbols:
      - name: d
    code:
        rule: x.split('-')[-1]
- LabelManipulator:
    symbols:
      - name: d
    regex:
        pattern: '[^O]$'
        replace: '\g<0>X'
- PythonCode:
    code: |
        print("Set i:\n", connect.container["i"].records)
        print("Set j:\n",connect.container["j"].records)
        print("Parameter d:\n",connect.container["d"].records)
$offEmbeddedCode
```

The first LabelManipulator applies a mapping provided by the set `map` to the labels of all symbols in the Connect database. This maps `chicago` to `Berlin` and `san-diego` to `Oslo`. The second LabelManipulator changes the labels of all symbols to upper case. The third LabelManipulator is only applied on symbol `d` and splits labels at `-` into a list and keeps the last entry. This changes `NEW-YORK` to `YORK`. The last LabelManipulator is also only applied on symbol `d` and adds an `X` to the end of all labels that do not end with an `O`. The resulting symbols look as follows:

```
Set i:
        uni element_text
0  SEATTLE
1     OSLO

Set j:
         uni element_text
0  NEW-YORK
1    BERLIN
2    TOPEKA
```

```
Parameter d:
           i         j  value
0  SEATTLEX     YORKX    2.5
1  SEATTLEX   BERLINX    1.7
2  SEATTLEX   TOPEKAX    1.8
3      OSLO     YORKX    2.5
4      OSLO   BERLINX    1.8
5      OSLO   TOPEKAX    1.4
```

The following options are available for the LabelManipulator agent:

Option	Scope	Default	Description
case	root	None	Apply specified casing to labels.
code	root	None	Replace labels using Python code.
invert	map	`False`	Used to invert the mapping direction.
map	root	None	Replace labels using a 1-dimensional GAMS set containing an explicit key-value mapping.
name	symbols	None	Specify a symbol name for the Connect database.
newName	symbols	None	Specify a new name for the symbol in the Connect database.
outputSet	regex/case/code	None	Name of the output set that contains the applied mapping.
pattern	regex	None	The regular expression that needs to match.
regex	root	None	Replace labels using a regular expression.
replace	regex	None	The rule used for replacing labels that match the given pattern.
rule	case/code	None	case: The type of casing to be applied. code: Python function that defines the mapping behavior.
ruleIdentifier	code	`x`	The identifier used for labels in the rule.
setName	map	None	The name of the GAMS set used in map mode.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
writeAll	root	`auto`	Indicate if all symbols in the Connect database will be affected.

Detailed description of the options:

case = *dictionary* (optional)

Used for executing the LabelManipulator in case mode to apply a specified casing to labels. It is only allowed to specify either case, code, map or regex.

code = *dictionary* (optional)

Used for executing the LabelManipulator in code mode to replace labels using a Python function. The given Python function is executed with each label and its return value is used as the replacement. It is only allowed to specify either case, code, map or regex.

invert = *boolean* (default=`False`)

Used for controlling the mapping direction in map mode. If set to `False` (default), the labels that match a label of the provided 1-dimensional GAMS set are replaced by the corresponding set element text. If set to `True` the direction is inverted, meaning all labels that match a set element text of the GAMS set are replaced by the corresponding label.

map = *dictionary* (optional)

Used for executing the LabelManipulator in map mode to replace labels using a 1-dimensional GAMS set containing an explicit key-value mapping. It is only allowed to specify either case, code, map or regex.

name = *string* (optional)

Specify the name of the symbol in the GAMS database. Data of the symbol gets replaced if no newName is specified.

newName = *string* (optional)

Specify a new name for the symbol in the Connect database. The original symbol specified under name remains unchanged. Each symbol in the Connect database must have a unique name.

outputSet = *string* (optional)

Name of the output set that contains mappings that were actually applied on the symbol labels. Per default no output set is written. Providing a name for the output set indicates that an output set should be written to the Connect database. Note that each symbol in the Connect database must have a unique name. Supported by case, code and regex mode.

pattern = *string* (optional)

The regular expression that needs to match for a label to be replaced.

regex = *dictionary* (optional)

Used for executing the LabelManipulator in regex mode to replace labels using a regular expression. It is only allowed to specify either case, code, map or regex.

replace = *string* (optional)

A string that specifies the replacement for all labels for which a given pattern in regex mode matches.

rule = *string* (optional)

Can be specified in case and code mode.

case: The type of casing to be applied. Allowed values are:

- `lower`: Change all labels to lower case.
- `upper`: Change all labels to upper case.
- `capitalize`: Change all labels to a capitalized casing - first letter becomes upper case, all others become lower case.

code: A Python function that defines the mapping behavior.

ruleIdentifier = *string* (default=`x`)

Specifies the identifier that is used in the rule of the code mode.

setName = *string*

Replace labels using a 1-dimensional GAMS set containing an explicit key-value mapping. A 1-dimensional GAMS set that contains an explicit key-value mapping to replace labels. If `invert: False` (default) all labels that match a label of the GAMS set will be replaced by the corresponding set element text.

symbols = *dictionary* (optional)

A list containing symbol specific options. Allows to execute the LabelManipulator on a subset of GAMS symbols in the Connect database.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the intermediate data frames will be written abbreviated to the log. For `trace > 3` the intermediate data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

writeAll = *boolean or* ***auto*** (default=`auto`)

Indicate if the LabelManipulator is applied to all symbols of the database or only a subset of GAMS symbols in the Connect database. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`.

4.46.5.13 Options

The Options agent allows to set more general options that can affect the Connect database and other Connect agents. More specifically, the value of an option set via the Options agent can be inherited as a default value to Connect agents that utilize the considered option.

Option	Default	Description
trace	0	Specify the trace level for debugging output.

Detailed description of the options:

trace = *integer* (default=0)

Specify the trace level for debugging output. A trace level of `0` (default) means no debugging output. For `trace > 0` the Connect database will write some scalar debugging output to the log. The debugging output of Connect agents depends on their implementation of `trace`, please refer to the corresponding documentation.

4.46.5.14 Projection

The Projection agent allows index reordering and projection onto a reduced index space of a GAMS symbol. For variables and equations a suffix (`.l`, `.m`, `.lo`, `.up`, or `.scale`) can be extracted and is written to a parameter. Otherwise, the type of the source symbol determines the type of the new symbol, unless `asSet` is set to `True`. Variables and equations can be turned into parameters with an extra index containing the labels `level`, `marginal`, `lower`, `upper`, and `scale` if the attribute `asParameter` is set to `True`. Moreover, if `name` is a *list* of scalar symbols of the same type (parameters, variables, or equations), they can be stored in a one-dimensional symbols of the same type with the index label being the *name* of the scalar symbol.

Option	Default	Description
aggregationMethod	`first`	Specify the aggregation method for the projection.
asParameter	`False`	Indicate that variable or equation symbols will be turned into a parameter with an extra index that contains the suffix.
asSet	`False`	Indicate that the new symbol is a set independent of the type of the source symbol.
name	None	Specify a symbol name with index space and potentially suffix for the Connect database.
newName	None	Specify a new name with index space for the symbol in the Connect database.
text	None	Element text for resulting sets.
trace	inherited	Specify the trace level for debugging output.

Detailed description of the options:

aggregationMethod = *string* (default=`first`)

Specify the method to aggregate when at least one index position is projected out. The default is `first`, meaning that the first record will be stored in the new symbol. For sets, variables, and equations (without a suffix specified) only `first` and `last` are meaningful. For parameters, variables, and equations with suffix many other aggregation methods are available and meaningful: `max`, `mean`, `median`, `min`, `prod`, `sem` (unbiased standard error of the mean), `sum`, `std` (standard deviation), `nunique` (number of distinct elements), `first`, `last`. The projection agent is based on pandas DataFrames and more detailed explanations of the aggregation method can be found at the `pandas website`.

asParameter = *boolean* (default=`False`)

If the symbol specified by `name` is a variable or equation and `asParameter` is set to `True`, the new symbol (after potential `aggregationMethod` is applied) will be a parameter with an additional index (at the end of the index list) that contains the suffix labels `level`, `marginal`, `lower`, `upper`, and `scale` and the corresponding suffix value.

asSet = *boolean* (default=`False`)

Usually the type of the source symbol and the use of a suffix with variables and equations determine the type of the target symbol. With `asSet` set to `True` the target symbol will be a set.

name = *string* or *list of strings*(required)

One either specifies a single symbol name with index space and potentially suffix for the Connect database or a list of symbol names of scalar symbols. In the prior case, `name` requires the format `symName[.suffix](i1,i2,...,iN)`. The suffix is only allowed on variable and equation symbols and need to be either `l`, `m`, `lo`, `up`, or `scale`. The list of indices does not need to coincide with the names of the actual GAMS domain sets. This index list together with the index list specified for `newName` is solely intended to establish the index order in the symbol specified by `newName`. In the latter case (a list of symbol names) the symbols need to be scalar symbols of the same type (parameter, variable, or equation) and a new one-dimensional symbol (of the same type) is created (using `newName`) that holds the symbol names as labels.

newName = *string* (required)

Specify a new name with index space for the projected or reordered symbol in the Connect database. Note that each symbol in the Connect database must have a unique name. `newName` is given as `symName(i1,i2,...,iN)`. The list of indices does not need to coincide with the names of the actual GAMS domain sets. This index list together with the index list specified for `name` is solely intended to establish the index order. Hence, the names in the index list need to be unique and only names that are part of the index list specified for `name` can be used. For example: `name: p(I,j,k)` and `newName: q(k,i)`.

text = *string* (default=None)

Control the handling of element text if the resulting symbol is a set. If set to `""`, the text will be dropped. When left at default (`None`) and the projected symbol is a set, the element text of the original set will be used. For other symbols types, the text will be dropped. If `text` is a string, this string will be assigned to all elements. The string can contain *place holders* {`i1`} that will be replaced with the content of the matching index position. For example, `text: "{i2} - {i1}: {element_text}"`, where {`i1`} and {`i2`} should be index space names in the symbol name with index space (attribute `name`). {`element_text`} refers to original element text (set) or string representation of a numerical value (parameter or variable/equation with a given suffix) of the source symbol.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` > `1` some scalar debugging output will be written to the log. For `trace` > `2` the intermediate arrays and data frames will be written abbreviated to the log. For `trace` > `3` the intermediate arrays and data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

4.46.5.15 PythonCode

The PythonCode agent allows to execute arbitrary Python code. From within the code, it is possible to access the GAMS database via `gams.db` (if the PythonCode agent is running in a GAMS context) and the Connect database via `connect.container`. The GAMS database is an instance of **GamsDatabase**, whereas the Connect database is a GAMS Transfer `Container` object. Furthermore there is a predefined `instructions` list that can be filled with tasks that are automatically executed.

Option	Default	Description
code	None	Python code to be executed.

Detailed description of the options:

code = *string* (required)

Python code to be executed. The YAML syntax offers the pipe character (|) for specifying multi-line strings:

```
- PythonCode:
    code: |
      print("Print from Python")
      # insert more Python code here
```

It is possible to generate instructions by appending tasks to the Python `instructions` list. A task is specified by using Python data structures that match the schema of a specific Connect agent. At the end of the Python code, all tasks in the `instructions` list are automatically generated and executed. The following example shows how to fill the `instructions` list with three ExcelWriter tasks that write different parameters (`p0`, `p1`, `p2`) into separate Excel workbooks (`data_p0.xlsx`, `data_p1.xlsx`, `data_p2.xlsx`).

```
- GAMSReader:
    readAll: True
- PythonCode:
    code: |
      symbols = [ 'p0', 'p1', 'p2' ]
      for s in symbols:
        instructions.append(
        {
          'ExcelWriter':
          {
            'file': 'data_{}.xlsx'.format(s),
            'symbols': [{'name': s}]
          }
        })
```

Using `connect.container` allows to access the Connect database directly in the Python code. The `connect.container` is a GAMS Transfer Container object and data within the container is stored as Pandas DataFrames. Please refer to the documentation of GAMS Transfer to learn more about GAMS Transfer and its functionalities.

The following complete example shows how to access and modify Connect container data and manually add a new symbol with the modified data to the Connect container:

```
Set i /1, 2, 3/
    i_mod;

$onembeddedCode Connect:
- GAMSReader:
    readAll: True
- PythonCode:
    code: |
        i_mod_records = [ 'i'+n for n in connect.container.data["i"].records.iloc[:,0] ]
        connect.container.addSet("i_mod", ["*"], records=i_mod_records)
- GAMSWriter:
    symbols:
      - name: i_mod
$offembeddedCode

display i, i_mod;
```

The first line takes the data of set `i` and adds an i at the beginning of each uel in the first column of the dataframe. The last line writes the modified dataframe as set `i_mod` to the Connect database.

Here is another complete example modifying Connect container data and adding a new symbol with the modified data:

```
Parameter p;

$onEcho > p_raw.csv
i,j,2000,2001
i1,j1,1,2
i2,j2,3,4
i3,j3,5,6
$offEcho

$onEmbeddedCode Connect:
- CSVReader:
    file: p_raw.csv
```

```
    name: p_raw
    header: True
    indexColumns: "1,2"
    valueColumns: "2:lastCol"
- PythonCode:
    code: |
        p_records = [ [r[0] + '_' + r[1]] + list(r) for i,r in connect.container.data["p_raw"].r
        connect.container.addParameter("p", ["*"]*4, records=p_records)
- GAMSWriter:
    symbols:
      - name: p
$offEmbeddedCode

display p;
```

In this example, we take the data of parameter `p_raw` and insert a column of the concatenated row dimensions into the first column of the dataframe. The modified dataframe is then added to the Connect container as records for the new symbol `p`. Here is a display of GAMS parameter `p`:

```
INDEX 1 = i1_j1

             2000        2001

i1.j1       1.000       2.000

INDEX 1 = i2_j2

             2000        2001

i2.j2       3.000       4.000

INDEX 1 = i3_j3

             2000        2001

i3.j3       5.000       6.000
```

4.46.5.16 RawCSVReader

The RawCSVReader allows reading of unstructured data from a specified CSV file into the Connect database. Due to performance issues this agent is recommended for small to medium sized unstructured CSV only. This reader works similarly compared to the RawExcelReader agent. It reads the entire CSV file and represents its content in a couple of GAMS sets:

- `r / r1, r2, ... /` (rows)
- `c / c1, c2, ... /` (columns)
- `vs(r,c) / s1.r1.c2 "cell text", ... /` (cells with explanatory text)
- `vu(r,c,*) / s1.r1.c1."cell text" "cell text", ...` (cells with potential GAMS label)

and a parameter `vf(r,c) / r2.c2 3.14, ... /` (cells with numerical values). Unlike RawExcelReader cells with a *date* will be not interpreted and stored in `vs` and `vu`. Cells with a string value will be stored in `vs`. If the string length exceeds the maximum length allowed for elements text, it will be truncated.

RawCSVReader will try to represent the cell value as a number and if this succeeds stores the number in `vf`. Strings of GAMS special values `INF`, `-INF`, `EPS`, `NA`, and `UNDEF` as well as `TRUE` and `FALSE` will be also converted to its numerical counterpart. It will also try to represent the cell value as a string and stores this as a label in the third position in `vu`. GAMS labels have a length limitation and hence RawCSVReader automatically shortens the label to fit this limit. RawCSVReader will provide a unique label (ending in ~`n` where `n` is an integer for strings exceeding the label length limit) for each string in the CSV file. The full string (if it fits) will be available as the element text of the `vu` record.

Option	Default	Description
cName	`c`	Symbol name for columns.
columnLabel	`C`	Label for columns.
file	None	Specify a CSV file path.
readAsString	`True`	Control the automatic pandas type conversion of cells.
readCSVArguments	None	Dictionary containing keyword arguments for the `pandas.read_csv` method.
rName	`r`	Symbol name for rows.
rowLabel	`R`	Label for rows.
trace	inherited	Specify the trace level for debugging output.
vfName	`vf`	Symbol name for cells with a numerical value.
vsName	`vs`	Symbol name for cells with an explanatory text.
vuName	`vu`	Symbol name for cells with a potential GAMS label.

Detailed description of the options:

cName = *string* (default=`c`)

Control the name of the set of columns.

columnLabel = *string* (default=`C`)

Control the labels for the set of columns (`c`).

file = *string* (required)

Specify a CSV file path.

readAsString = *boolean* (optional)

Control the type of cells returned by `pandas.read_csv`. If this is set to `True` (default) all cells are returned as string and the agent tries to interpret the string itself. If this is set to `False` pandas will try to infer the type. In such a case the agent can't distinguish between cells with `1` and `1.00` because pandas turned the integer `1` already into a float and the agent has no way for recovering the original cell.

readCSVArguments = *dictionary* (optional)

Dictionary containing keyword arguments for the `pandas.read_csv` method. By specifying `readCSVArguments`, it is possible to pass arguments directly to the `pandas.read_csv` method. For example, `readCSVArguments:` {delimiter: ';'}.

rName = *string* (default=`r`)

Control the name of the set of rows.

rowLabel = *string* (default=`R`)

Control the labels for the set of rows (`r`).

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the cell values and it's processing will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

vfName = *string* (default=`vf`)

Control the name of the parameter for cells with a numerical value.

vsName = *string* (default=`vs`)

Control the name of the set for cells with an explanatory text.

vuName = *string* (default=`vu`)

Control the name of the set for cells with a potential GAMS label.

4.46.5.17 RawExcelReader

The RawExcelReader allows reading of unstructured data from a specified Excel file into the Connect database. Due to performance issues this agent is recommended for small to medium sized unstructured Excel files only. This reader works similarly compared to the xlsdump tool. It reads the entire spreadsheet and represents its content in a couple of GAMS sets:

- `s /s1, s2,.../` (workbook sheets)
- `w / Sheet1, Sheet2, ... /` (workbook sheets by name)
- `ws(s,w) / s1.Sheet1, s2.Sheet2, ... /` (workbook map)
- `r / r1, r2, ... /` (rows)
- `c / c1, c2, ... /` (columns)
- `vs(s,r,c) / s1.r1.c2 "cell text", ... /` (cells with explanatory text)
- `vu(s,r,c,*) / s1.r1.c1."cell text" "cell text", ...` (cells with potential GAMS label)

and a parameter `vf(s,r,c) / s1.r2.c2 3.14, ... /` (cells with numerical values). Cells with a *date* will be stored in it's string representation in `vu` and as a Julian date in `vf`. Cells with a string value will be stored in `vs`. If the string length exceeds the maximum length allowed for elements text, it will be truncated. Excel offers many other cell value types. RawExcelReader will try to represent the cell value as a number and if this succeeds stores the number in `vf`. Strings of GAMS special values `INF`, `-INF`, `EPS`, `NA`, and `UNDEF` will be also converted to its numerical counterpart. It will also try to represent the cell value as a string and stores this as a label in the fourth position in `vu`. GAMS labels have a length limitation and hence RawExcelReader automatically shortens the label to fit this limit. RawExcelReader will provide a unique label (ending in `~n` where n is an integer for strings exceeding the label length limit) for each string in the workbook. The full string (if it fits) will be available as the element text of the `vu` record.

Option	Default	Description
cName	`c`	Symbol name for columns.
columnLabel	`C`	Label for columns.

Option	Default	Description
file	None	Specify an Excel file path.
mergedCells	`False`	Control the handling of empty cells that are part of a merged Excel range.
rName	`r`	Symbol name for rows.
rowLabel	`R`	Label for rows.
sheetLabel	`S`	Label for workbook sheets.
sName	`s`	Symbol name for workbook sheets.
trace	inherited	Specify the trace level for debugging output.
vfName	`vf`	Symbol name for cells with a numerical value.
vsName	`vs`	Symbol name for cells with an explanatory text.
vuName	`vu`	Symbol name for cells with a potential GAMS label.
wName	`w`	Symbol name for workbook sheets by name.
wsName	`ws`	Symbol name for workbook map.

Detailed description of the options:

cName = *string* (default=`c`)

Control the name of the set of columns.

columnLabel = *string* (default=`C`)

Control the labels for the set of columns (`c`).

file = *string* (required)

Specify an Excel file path.

mergedCells = *boolean* (default=`False`)

Control the handling of empty cells that are part of a merged Excel range. If `False`, the cells are left empty. If `True`, the merged value is used in all cells. Note that setting this option to `True` has an impact on performance since the Excel workbook has to be opened in a non-read-only mode that results in non-constant memory consumption (no lazy loading).

rName = *string* (default=`r`)

Control the name of the set of rows.

rowLabel = *string* (default=`R`)

Control the labels for the set of rows (`r`).

sheetLabel = *string* (default=`S`)

Control the labels for the set of workbook sheet (`s`).

sName = *string* (default=`s`)

Control the name of the set of workbook sheets.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the cell values and it's processing will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

vfName = *string* (default=`vf`)

Control the name of the parameter for cells with a numerical value.

vsName = *string* (default=`vs`)

Control the name of the set for cells with an explanatory text.

vuName = *string* (default=`vu`)

Control the name of the set for cells with a potential GAMS label.

wName = *string* (default=`w`)

Control the name of the set of workbook sheets by name.

wsName = *string* (default=`ws`)

Control the name of the set of the workbook map.

4.46.5.18 SQLReader

The SQLReader agent allows to read symbols (sets and parameters) from a specified database management system into the Connect database. It connects to MySQL, Postgres, MS-SQL (SQL-Server), SQLite and PyODBC through their respective python packages to provide native SQL query support. Further, it also utilizes `pandas.DataFrame` class' I/O API method `read_sql` to connect to any other database provided the relevant drivers are present on the system. See Simple Connect Example for SQL for a simple example that uses the SQLReader.

Note

The connectivity to MS-Access databases is available on Windows only and requires a 64-bit MS-Access ODBC driver. See connection for more information.

Option	Scope	Default	Description
connection	root	None	Connection dictionary to specify credentials for the database.
connectionArguments	root	None	Dictionary containing keyword arguments for the `connect` constructor of the respective SQL library or for the `sqlalchemy.create_engine` constructor.
connectionType	root	`sqlite`	Specify the connection type to be used in order to connect to that database.
dTypeMap	root/symbols	None	Dictionary used to specify the dtype of columns.
indexSubstitutions	symbols	None	Dictionary used for substitutions in the index columns.
name	symbols	None	Specify the name of the symbol in the Connect database.
query	symbols	None	Specify the SQL query.
readSQLArguments	symbols	None	Dictionary containing keyword arguments for the
			`pandas.read_sql` method.
symbols	root	None	Specify symbol specific options.
trace	root	inherited	Specify the trace level for debugging output.
type	root/symbols	`par`	Control the symbol type.

Detailed description of the options:

connection = *dict* (required)

Allows to specify the credentials to access the database. Below are examples for connection dictionaries based on the selected `connectionType`.

SQLite:

```
connection: {'database': 'absolute//path//to//datafile.db'}
```

Postgres/MySQL/SQLServer:

```
connection: {'user': <username of the database server>, 'password': <password>, 'host': <hostnam
```

MS-Access:

```
connection: {'DRIVER': 'Microsoft Access Driver (*.mdb, *.accdb)', 'DBQ': 'absolute//path//to//d
```

Note

The connectivity to MS-Access databases is available on Windows only and requires a 64-bit MS-Access ODBC driver. If no MS-Access is installed or a 32-bit version of MS-Access, download and install a 64-bit MS-Access ODBC Driver as a redistributable package from MS (e.g. MS-Access 2013 Runtime_x64).

SQLAlchemy:

Use `connectionType: sqlalchemy` to connect to various databases. Note that the argument `drivername: <dialect+driver>` is required.

For dialect *SQLite*:

```
connection: {'drivername': 'sqlite', 'database': 'absolute//path//to//datafile.db'}
```

For dialect *Postgres*:

```
connection: {'drivername': 'postgresql+psycopg2', 'username': <username of the database server>,
```

For dialect *MySQL*:

```
connection: {'drivername': 'mysql+pymysql', 'username': <username of the database server>, 'pass
```

For dialect *MS-SQL(SQLServer)*:

```
connection: {'drivername': 'mssql+pymssql', 'username': <username of the database server>, 'pass
```

For dialect *MS-Access*:

```
connection: {'drivername': 'access+pyodbc', 'query': {'odbc_connect': 'DRIVER={Microsoft Access
```

Note

Connecting to databases other than SQLite, Postgres, MySQL and MS-SQL through SQLAlchemy would require the respective driver of that database to be present on the system. For example, in the above example `sqlalchemy-access` must be available in order to connect to MS-Access through SQLAlchemy.

PyODBC:

Use `connectionType: pyodbc` to connect to various databases. Therefore, either specify the DSN (Data Source Name):

```
connection: {'DSN': <Data Source Name>}
```

or use:

```
connection: {'user': <username of the database server>, 'password': <password>, 'host': <hostnam
```

connectionArguments = *dict* (optional)

Dictionary containing keyword arguments for the `connect` constructor of the respective SQL library or for the `sqlalchemy.create_engine` constructor.

connectionType = *string* (default=`sqlite`)

Following is the list of valid options for connection type.

1. `sqlite` (default)
2. `postgres`
3. `mysql`
4. `sqlserver`
5. `access`
6. `sqlalchemy`
7. `pyodbc`

A connection using `pyodbc` can be established to any database for which a DSN (Data Source Name) is available on the system. The `pyodbc` connection works readily on windows platform where DSN is already setup. Further, for non-windows platforms, the user is responsible for installing the `pyodbc` package and handling any other dependencies for the local python installation.

dTypeMap = *dict* (optional)

Allows to specify the dtype of columns in a dictionary as `key: value` pairs, i.e. <`column`>: <`dtype`>.

indexSubstitutions = *dict* (optional)

Dictionary used for substitutions in the index columns. Each key in `indexSubstitutions` is replaced by its corresponding value. This option allows arbitrary replacements in the index columns.

name = *string* (required)

Name of the symbol in the Connect database. The name must be unique for each symbol.

query = *string* (required)

Specify the SQL query which will fetch the desired table from the database system.

readSQLArguments = *dict* (optional)

Dictionary containing keyword arguments for the `pandas.read_sql` method. Not all arguments of that method are exposed through the YAML interface of the SQLReader agent. By specifying `readSQLArguments`, it is possible to pass arguments directly to the `pandas.read_sql` method that is used by the SQLReader agent if `connectionType` is `sqlalchemy`. If `connectionType` is not `sqlalchemy`, this option can be used to parameterize the SQL query. A small example showing how this option can be used is given below.

```
query: "SELECT i,j FROM stock_table WHERE value_col > %(value)s"
readSQLArguments: {'value': 10}
```

Note

Different Database management systems use different parameter markers and some do not support named parameter markers, e.g., `PyODBC`.

symbols = *list* (required)

A list containing symbol specific options.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace > 1` some scalar debugging output will be written to the log. For `trace > 2` the intermediate arrays and data frames will be written abbreviated to the log. For `trace > 3` the intermediate arrays and data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

type = *string* (default=`par`)

Control the symbol type. Supported symbol types are `par` for GAMS parameters and `set` for GAMS sets.

valueColumns = *list or string* (optional)

Specify columns to get the values from. The value columns contain numerical values in case of a GAMS parameter and set element text in case of a GAMS set. The columns are given as column names represented as a list of strings. For example: `valueColumns: ["i1", "i2"]`. If there is more than one value column specified, the column names are stacked to index automatically. As string one can specify the symbolic constant `lastCol` (i.e. `valueColumns: "lastCol"`) or an empty string (i.e. `valueColumns: ""`). When `lastCol` is passed the last column will be treated as a value column and all the other columns will be treated as index columns. When an empty string is passed all columns will be treated as index columns. Specifying an empty string is only valid for symbol type `set` since symbol type `par` requires at least one value column. The default for symbol type `par` is `lastCol` and the default for symbol type `set` is an empty string.

valueSubstitutions = *dict* (optional)

Dictionary used for mapping in the value column of the `DataFrame`. Each key in `valueSubstitutions` is replaced by its corresponding value. The replacement is only performed on the value column of the `DataFrame` which is the numerical value in case of a GAMS parameter and the set element text in case of a GAMS set. While it is possible to make arbitrary replacements this is especially useful for controlling sparse/dense reading.

4.46.5.19 SQLWriter

The SQLWriter agent allows to write symbols (sets and parameters) from the Connect database to a specified database management system. Variables and equations need to be turned into parameters with the Projection agent before they can be written. It connects to MySQL, Postgres, MS-SQL (SQL-Server), SQLite and PyODBC through their respective python packages to provide faster write operations. Further, it also utilizes `pandas.DataFrame` class' I/O API method `to_sql` to connect to any other database provided the relevant drivers are present on the system. See Simple Connect Example for SQL for a simple example that uses the SQLWriter.

Note

The connectivity to MS-Access databases is available on Windows only and requires a 64-bit MS-Access ODBC driver. See connection for more information.

Option	Scope	Default	Description
connection	root	None	Connection dictionary to specify credentials for the database.
connectionArguments	root	None	Dictionary containing keyword arguments for the `connect` constructor of the respective SQL library or for the `sqlalchemy.create_engine` constructor.
connectionType	root	None	Specify the connection type to be used in order to connect to that database.
ifExists	root/symbols	`fail`	Specify the behavior when a table with the same name exists in the database/schema.
insertMethod	root/symbols	`default`	Specify the insertion method to be used to write the table in the database.
name	symbols	None	Specify the name of the symbol in the Connect database.
schemaName	root/symbols	None	Specify the schema name.
symbols	root	None	Specify symbol specific options.
tableName	symbols	None	Specify the SQL table/relation in the provided database/schema.
toSQLArguments	root/symbols	None	Dictionary containing keyword arguments for the `pandas.to_sql` method.
trace	root	inherited	Specify the trace level for debugging output.
unstack	root/symbols	`False`	Indicate if the last index column will be used as a header row.
valueSubstitutions	root/symbols	None	Dictionary used for mapping in the value column of the `DataFrame`.
writeAll	root	`auto`	Indicate if all set and parameter type symbols in the Connect database will be written to the specified DBMS.

Detailed description of the options:

connection = *dict* (required)

Allows to specify the credentials to access the database. See SQLReader connection for further details and some examples.

Note

The connectivity to MS-Access databases is available on Windows only and requires a 64-bit MS-Access ODBC driver. If no MS-Access is installed or a 32-bit version of MS-Access, download and install a 64-bit MS-Access ODBC Driver as a redistributable package from MS (e.g. MS-Access 2013 Runtime_x64).

connectionArguments = *dict* (optional)

Dictionary containing keyword arguments for the `connect` constructor of the respective SQL library or for the `sqlalchemy.create_engine` constructor.

connectionType = *string* (default=`sqlite`)

Following is the list of valid options for connection type.

1. `sqlite` (default)
2. `postgres`
3. `mysql`
4. `sqlserver`
5. `access`
6. `sqlalchemy`
7. `pyodbc`

A connection using `pyodbc` can be established to any database for which a DSN (Data Source Name) is available on the system. The `pyodbc` connection works readily on windows platform where DSN is already setup. Further, for non-windows platforms, the user is responsible for installing the pyodbc package and handling any other dependencies for the local python installation.

Note

`pyodbc` provides a simple and consistent API to connect to many different databases using the Open Database Connectivity (ODBC) interface. This introduces the challenge that database specific properties are not taken into consideration. For example, different databases have different escaping syntax in order to escape special characters in column names of a table. Thus, the implementation for connection type `pyodbc` is kept as a general purpose connector to different databases while not escaping the special characters.

ifExists = *string* (default=`fail`)

Specify the behavior when a table with the same name exists in the database/schema. Valid values are `fail`, `replace` and `append`.

insertMethod = *string* (default=`default`)

Specify the insertion method to be used to write the table in the database. Valid values are `bcp`, `bulkInsert`, and `default`.

Note

The options `bulkInsert` and `bcp` is not available with connection type `sqlalchemy`. Further, the option `bcp` is reserved for connection type `sqlserver`. This is useful when the SQL-Server database is available remotely. The `bcp` method uses MS-SQL's command line utility of the same name to insert huge amount of data. In order to use this insertion method, the user must download and install the utility as per the system requirements. The utility is available for `Windows` as well as for `Linux and macOS`. On the other hand, if the SQL-Server database is available locally, then the `bulkInsert` method can be used and the `bcp` utility is not required.

The option `bulkInsert` uses special SQL queries for connection type `mysql`, `postgres`, `sqlserver` and `access`. It creates a temporary csv file and then imports the same in the database. It is to be noted that for MySQL the option `LOCAL_INFILE` must be enabled at the server side for this method to work successfully.

name = *string* (required)

Specify the name of the symbol in the Connect database.

schemaName = *string* (optional)

Specify the schema name for writing the table to the correct location. In Postgres, by default, it writes to a public schema already present in every database.

symbols = *list* (required)

A list containing symbol specific options.

tableName = *string* (required)

Name of the SQL table/relation in the provided database/schema.

toSQLArguments = *dict* (optional)

Dictionary containing keyword arguments for the `pandas.to_sql` method. Not all arguments of that method are exposed through the YAML interface of the SQLWriter agent. By specifying `toSQLArguments`, it is possible to pass arguments directly to the `pandas.to_sql` method that is used by the SQLWriter agent if `connectionType` is `sqlalchemy`.

trace = *integer* (optional)

Specify the trace level for debugging output. For `trace` > `1` some scalar debugging output will be written to the log. For `trace` > `2` the intermediate arrays and data frames will be written abbreviated to the log. For `trace` > `3` the intermediate arrays and data frames will be written entirely to the log (potentially large output). If `trace` has not been set, the `trace` value, set by the Options agent, will be used.

unstack = *boolean* (default=`False`)

Indicate if the last index column will be used as a header row.

valueSubstitutions = *dict* (optional)

Dictionary used for mapping in the value column of the `DataFrame`. Each key in `valueSubstitutions` is replaced by its corresponding value. The replacement is only performed on the value column of the `DataFrame` which is the numerical value in case of a GAMS parameter, variable or equation and the set element text in case of a GAMS set.

writeAll = *boolean or* ***auto*** (default=`auto`)

Indicate if all set and parameter type symbols in the Connect database will be written to the specified DBMS. The default `auto` becomes `True` if there are no symbol options specified, otherwise `False`. If `True`, each symbol is written to a table in the specified DBMS where the table name is defined by the name of the symbol.

4.46.6 Examples

This section provides a collection of more complex examples. For simple examples see section Getting Started.

4.46.6.1 Connect Example for Excel (executeTool win32.ExcelMerge)

The following example shows how to read and write Excel files in Connect. On Windows with Excel installed, the output sheets are merged back into the input workbook using tool win32.ExcelMerge. The entire code is listed at the end of the example. This model is part of DataLib as model **connect05**. First, the original matrix `a` is read using the GAMSReader and is then written to input.xlsx using the ExcelWriter. After clearing symbols `i` and `a` in the GAMS database, the ExcelReader is used to read file input.xlsx back in and create parameter `a` in the Connect database. The Projection agent extracts set `i` from parameter `a`. With the GAMSWriter, symbols `i` and `a` are written to the GAMS database. The tool linalg.invert calculates the inverse `inva` of `a` which is then written to output.xlsx using Connect's GAMSReader and ExcelWriter at execution time. The following lines then check if the code is not executed on a UNIX system and if Excel is available. If both is true, output.xlsx is merged into input.xlsx using tool win32.ExcelMerge and both symbols `inva` and `a` can be read from input.xslx with a single instance of the ExcelReader. If the code is executed on a UNIX system and/or Excel is not available, output.xlsx can not be merged into input.xlsx, and both files need to be read to create the symbols `inva` and `a`. The last part makes sure that `inva` is the inverse of `a`.

```
set i / i1*i3 /; alias (i,j,k);
table a(i,j) 'original matrix'
      i1     i2     i3
i1    1      2      3
i2    1      3      4
i3    1      4      3
;
$onEmbeddedCode Connect:
- GAMSReader:
    symbols:
      - name: a
- ExcelWriter:
    file: input.xlsx
    symbols:
      - name: a
$offEmbeddedCode

$onMultiR
$clear i a

$onEmbeddedCode Connect:
- ExcelReader:
    file: input.xlsx
    symbols:

4.46.6.2 Connect Example for Excel

The following example shows how to read and write Excel files in Connect. The entire code is listed at the end of the example. This model is part of DataLib as model **connect01**. The example (inspired by

the model **herves**) reads a 3-dimensional parameter from a spreadsheet that has one row index (`code`) at the left side of the table and the other row index (`labId`) at the right of the table. A column index (`cut`) is at the top of the table. The column index consists of floating-point numbers. The goal it to read the data into GAMS but modify the labels of some sets: Only the first two decimal digits of the elements in `cut` are significant. Moreover, the `labId` should be prefixed with an `L`. A new spreadsheet with the new labels should be written. The layout of the table should remain with the exception of moving the `labId` column also to the left. Here is a screenshot of the original table:

The following GAMS code uses a separate GAMS program (`getdata.gms`) to get the raw data from the original spreadsheet. Connect runs inside a compile-time embedded code section and uses the Connect agent RawExcelReader to get the raw Excel data. In some subsequent GAMS code the sets `rr` and `cut[Id]` as well as the parameter `raw` are filled knowing the layout of the table (the code is written in a way that the table can grow). This GAMS program gets executed and instructed to create a GDX file. In a compile-time embedded Connect section the relevant symbols (`rr`, `cutId`, and `raw`) are read from this GDX file. The Projection agent extracts the domain `labid` from the set `rr` and some Python code using Connect agent PythonCode makes the label adjustments and sorts the data nicely. The Python code uses the connect.container methods to read from and write to the Connect database. Finally, the GAMSWriter agent sends the data to GAMS. In the main program at execution-time an embedded Connect code section exports the `labdata` parameter in the required form (after reading it from GAMS with the GAMSReader agent). Here is a screenshot of the resulting table:

In the remainder of the GAMS code another execution-time embedded Connect code is used to read the data back from the newly created spreadsheet using Connect agent ExcelReader. The set `rr` is created from parameter `labdata` using the Projection agent and everything is written back to GAMS with Connect agent GAMSWriter. The original data and the data from the newly created spreadsheet are exported to GDX (using execute_unload) and compared to verify that the data is identical by calling gdxdiff.

4.46.6.3 Connect Example for CSV

The following example shows how to read and write CSV files in Connect. The entire code is listed at the end of the example. This model is part of DataLib as model **connect02**. It starts out with defining some data (`stockprice`) in a table statement in GAMS. With compile-time embedded Connect code utilizing the GAMSReader agent to bring this data into Connect and exporting it as a CSV file with agent CSVWriter. The GDXWriter agent also creates a GDX file with the data which is then used in a subsequent call to feed gdxdump that produces the same CSV file as CSVWriter. The text comparison tool `diff` is used to compare the two CSV files. The CSV file look as follows:

```
"date_0","AAPL","GOOG","MMM","MSFT","WMT"
"2012-20-11",12.124061,314.008026,60.966354,21.068886,46.991535
"2112-20-11",12.139372,311.741516,60.731037,20.850344,47.150307
"2212-20-11",12.203673,313.674286,61.467381,20.890808,46.991535
"2312-20-11",12.350039,315.387848,62.401108,21.068886,47.626663
"2712-20-11",12.448025,318.929565,62.461876,21.076981,47.499634
"2812-20-11",12.328911,318.655609,61.604042,20.898905,47.420238
"2912-20-11",12.404848,320.000549,62.332813,21.060795,47.626663
"3012-20-11",12.401172,321.744019,62.044331,21.012224,47.444057
```

In remainder of the example this CSV file is read back via the Connect agent CSVReader. The code also utilizes the tool csv2gdx to read the CSV file into a GDX file. The code compares the results of both methods. Csv2gdx also creates sets with the index elements as `Dim1`, `Dim2`, ... Therefore, Connect utilizes the Projection agent to extract the index sets `date` and `symbol` from the parameter `stockprice` as sets `Dim1` and `Dim2`. The Connect agent GDXWriter creates a GDX file of the Connect database which then can be compared with the GDX file created by csv2gdx. The GDX comparison tool gdxdiff is used to compare the two GDX files.

```
Set date,symbol;
Table stockprice(date<,symbol<)
                AAPL       GOOG       MMM       MSFT       WMT

```

4.46.7 Text Substitutions in YAML File

In many cases one would like to *parameterize* the text in the Connect instruction file. For example, some of the Connect agents require a file name. Instead of hard coding the file name into the YAML instructions, text substitutions allow to have a *place holder* for the attribute that is substituted out before giving the instructions to Connect. The place holder in the YAML file uses the syntax `%SOMETEXT%`, similar to the GAMS compile-time variables. For example:

```
- CSVReader:
    file: %MYFILENAME%
    name: distance
    indexColumns: [1, 2]
    valueColumns: [3]
```

Depending on how Connect runs, the substitution is done in various ways. The section Substitutions in Embedded Connect Code described the substitution mechanisms for embedded Connect code. When Connect is initiated via the command line parameters connectIn or connectOut, the user defined parameter specified by double-dash command line parameters and the given GAMS command line parameters, e.g. `%gams.input%` will be substituted in the YAML file. The list of parameters available for substitution is printed to the GAMS log at the beginning of the job in the section `GAMS Parameters defined`.

When Connect is initiated via the shell command `gamsconnect` all substitutions need to be specified on the command line:

```
gamsconnect myci.yaml key1=val1 key2=val2 ...
```

`key` can be just `MYFILENAME` or be composed like `gams.Input` or `system.dirSep`.

4.46.8 Use Connect Agents in Custom Python Code

Instead of passing instructions via one of the Connect interfaces, users can execute tasks directly in their Python code by creating an instance of `ConnectDatabase` and calling method `.exec_task(task)`. The `task` argument is expected to be a Python dictionary of form:

```
{
   '<agent name>':
   {
      '<root option1>': <value>,
      '<root option2>': <value>,
      ... ,
      '<root option3>':
      [
         {
             '<option1>': <value>,
             '<option2>': <value>,
             ...
         },
         {
             '<option1>': <value>,
             '<option2>': <value>,
             ...
         },
         ...
      ]
   }
}
```

Users can either construct the Python dictionary themselves or let YAML create the dictionary from a YAML script. The following example creates an instance of ConnectDatabase and executes two tasks: First, the CSV file `stockprice.csv` is read into the Connect database and second, the symbol `stockprice` is written to the GAMS database. In this example, the tasks are directly specified as Python dictionaries.

```
Set dates, stocks;
Parameter stockprice(dates<,stocks<);

$onEcho > stockprice.csv
date;symbol;price
2016/01/04;AAPL;105,35
2016/01/04;AXP;67,59
2016/01/04;BA;140,50
$offEcho

$onEmbeddedCode Python:
from gams.connect import ConnectDatabase
cdb = ConnectDatabase(gams._system_directory, ecdb=gams)
cdb.exec_task({'CSVReader': {'file': 'stockprice.csv', 'name': 'stockprice', 'indexColumns': [1, 2],
                             'valueColumns': [3], 'fieldSeparator': ';', 'decimalSeparator': ','}})
cdb.exec_task({'GAMSWriter': {'symbols': [{'name': 'stockprice'}]}})
$offEmbeddedCode

display stockprice;
```

We can also construct the Python dictionaries by using YAML:

```
Set dates, stocks;
Parameter stockprice(dates<,stocks<);

$onEcho > stockprice.csv
date;symbol;price
2016/01/04;AAPL;105,35
2016/01/04;AXP;67,59
2016/01/04;BA;140,50
$offEcho

$onEmbeddedCode Python:
import yaml
from gams.connect import ConnectDatabase
cdb = ConnectDatabase(gams._system_directory, gams)

inst = yaml.safe_load('''
- CSVReader:
    file: stockprice.csv
    name: stockprice
    indexColumns: [1, 2]
    valueColumns: [3]
    fieldSeparator: ';'
    decimalSeparator: ','
- GAMSWriter:
    symbols:
      - name: stockprice
''')
for task in inst:
  cdb.exec_Task(task)
$offEmbeddedCode

display stockprice;
```

Here YAML creates a list of dictionaries (i.e. a list of tasks) from the given YAML script.

4.46.9 Command Line Utility gamsconnect

The GAMS system directory contains the utility `gamsconnect` to run Connect instructions directly from the command line. On Windows the utility has the callable extension `.cmd`. This script wraps the Python script `connectdriver.py` by calling the Python interpreter that ships with GAMS. `gamsconnect` operates as the other Connect drivers on a YAML instruction file. The agents GAMSReader and GAMSWriter are not available from `gamsconnect` and will trigger an exception. Substitutions can be passed to `gamsconnect` via command line arguments as `key=value`, e.g. `filename=myfile.csv` and even `gams.scrdir=/tmp/`. `gamsconnect` is called like this:

```
gamsconnect <YAMLFile> [key1=value1 [key2=value2 [key3=value3 [...]]]]
```

4.47 Extrinsic Functions

4.47.1 Introduction

Mathematical functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and often sophisticated and specialized functions. There is a trade-off between satisfying these requests and avoiding complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, since it allows users to import functions from an external library into a GAMS model. However, these external libraries can currently only provide functionality for the evaluation of functions (incl. their first and second derivatives) in a point. Solvers that need to analyze the algebraic structure of the model instance are therefore not able to work with extrinsic functions. This includes the class of *deterministic* global solvers, see column "Global" in this table, while, for example, *stochastic* global solvers can work with extrinsic functions.

In this chapter we will demonstrate how to access functions from an extrinsic function library in a GAMS model and we will describe the extrinsic function libraries that are included in the GAMS distribution. In addition, we will provide some pointers for users who wish to build their own extrinsic function library.

4.47.2 Using Function Libraries

Function libraries are made available to a model with the following compiler directive:

```
$funcLibIn <InternalLibName> <ExternalLibName>
```

Here `InternalLibName` is a handle that will be used to refer to the library inside the model source code, `ExternalLibName` is the file name of the shared library that implements the extrinsic functions. If no path is given, GAMS will look for the library in the directory `extrinsic_functions` in the GAMS standard locations and in the GAMS system directory. To access a library that does not reside in these standard places, the external name should include a relative or absolute path to the location of the library. GAMS will then search for the specified library using the mechanisms specific to the host operating system. When processing the directive $funcLibIn, GAMS will validate the library, make the included functions available for use and add a table of the included functions to the listing file.

Note

The function library facility gives users complete control over naming so that potential name conflicts between libraries can be avoided.

Before the individual functions may be used, they have to be declared in the following way:

```
Function <InternalFuncName> /<InternalLibName>.<FuncName>/;
```

Here `InternalFuncName` is the name of the individual function that will be used in the GAMS code. The user may choose this internal name freely and thus avoid potential naming conflicts. `InternalLibName` is the name of the function library as defined by the $funcLibIn directive and `FuncName` is the name of the individual function in the external function library. Once functions have been declared in this way they may be used like intrinsic functions.

Consider the following simple example:

```
$funcLibIn myLib tricclib

Function myCos /myLib.Cosine/
         mySin /myLib.Sine/
         myPi  /myLib.Pi/;

Scalar d;
d = myCos(myPi/3);
display d;
```

Note that in the first line the external trigonometric library `tricclib` is activated and the internal name `myLib` is specified for it. Then the functions are declared. Observe that `Cosine`, `Sine` and `Pi` are functions in the trigonometric library. After the library has been loaded and the functions have been declared, the functions may be used as usual. The trigonometric library is discussed in section Example: Trigonometric Library below.

4.47.3 Libraries that are included in the GAMS Distribution

In this section we will present the libraries that are included in the GAMS distribution: the Fitpack Library, the Piecewise Polynomial Library, the Stochastic Library and the LINDO Sampling Library. Note that the LINDO Sampling Library is only available for LINDO license holders. In addition, we will provide details on the Mutex Library.

In the tables that follow, the "Endogenous Classification" (last column) specifies in which models the function may legally appear. In order of least to most restrictive, the choices are *any*, *DNLP*, *NLP*, *none*. See section Classification of Models for details on model types in GAMS. Note well that functions classified as *any* are only permitted with exogenous (constant) arguments.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogenous variables, see section Functions in Equation Definitions. Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.

4.47.3.1 The Fitpack Library

FITPACK by Paul Dierckx [43] is a Fortran-based library for one-dimensional and two-dimensional spline interpolations. This library has been repackaged to work with the GAMS Function Library Facility. The model **[FITLIB01]** from the GAMS Test Library is an example of the use of the library FITPACK inside GAMS.

Note that the supporting points to which the function will be fit need to be stored in a three-dimensional parameter, `fitdata`, in a GDX file `fit.gdx`. The first dimension is a function index, the second dimension is the index of the supporting point and the third dimension takes one of the following four values: `"w"` (weight), `"x"` (x-value), `"y"` (y-value) or `"z"` (z-value).

The FITPACK library is made available with the following directive:

```
$funcLibIn <InternalLibName> fitfclib
```

It provides the following functions:

Function	Description	End. Classif.
`fitFunc(FUNIND,x[,y])`	Evaluate spline	DNLP
`fitParam(FUNIND,PARAM[,VALUE])`	Read or set parameters	none

The function `FitParam` may be used to change certain parameters that are used for the evaluation. The following values are defined:

- 1: Smoothing factor (S)
- 2: Degree of spline in direction x (Kx)
- 3: Degree of spline in direction y (Ky)
- 4: Lower bound of function in direction x (LOx)
- 5: Lower bound of function in direction y (LOy)
- 6: Upper bound of function in direction x (UPx)
- 7: Upper bound of function in direction y (UPy)

4.47.3.2 The Piecewise Polynomial Library

The Piecewise Polynomial Library may be used to evaluate piecewise polynomial functions. An example is given in the model **[PWPLIB01]** in the GAMS Test Library. Note that the functions that are to be evaluated need to be defined and stored in a GDX file. The following code snippet serves as illustration:

```
* Define two piecewise polynomial functions
Table pwpdata(*,*,*) '1st index: function number, 2nd index: segment number, 3rd index: degree'
                 leftBound       0          1         2
       1.1       1               2.4       -2.7       0.3
       1.2       4               5.6       -4.3       0.5

;
* Write pwp data to gdx file, which will be read by external library (pwpcclib)
$gdxout pwp.gdx
$unload pwpdata
$gdxout
```

Observe that on each row of the table `pwpdata` we have the following entries:

```
FuncInd.SegInd    leftBound    Coef0    Coef1    Coef2
```

Here `FuncInd` sets a function index and `SegInd` defines the index of the segment (or interval) which is described. Further, `LeftBound` gives the lower bound of the segment. The upper bound will be taken from the lower bound on the following segment, or set to infinity in case it is the last segment. Finally, `CoefX` defines the `X`-th degree coefficient of the polynomial corresponding to this segment.

The Piecewise Polynomial Library is made available with the following directive:

```
$funcLibIn <InternalLibName> pwpcclib
```

It provides the following function:

Function	Description	End. Classif.
pwpFunc(FUNIND,x)	Piecewise polynomials	DNLP

4.47.3.3 The Stochastic Library

The Stochastic Library provides random deviates, probability density functions, cumulative density functions and inverse cumulative density functions for certain continuous and discrete distributions. This library is made available with the following directive:

```
$funcLibIn <InternalLibName> stodclib
```

The continuous distributions that are available with this library are the following:

Distribution	Description
beta(SHAPE_1,SHAPE_2)	**Beta distribution** with shape parameters SHAPE_1 and SHAPE_2, see MathWorld
cauchy(LOCATION,SCALE)	**Cauchy distribution** with location parameter LOCATION and scale parameter SCALE, see MathWorld
ChiSquare(DF)	**Chi-squared distribution** with degrees of freedom DF, see MathWorld
exponential(LAMBDA)	**Exponential distribution** with rate of change LAMBDA, see MathWorld
f(DF_1,DF_2)	**F-distribution** with degrees of freedom DF_1 and DF_2, see MathWorld
gamma(SHAPE,SCALE)	**Gamma distribution** with shape parameter SHAPE and scale parameter SCALE, see MathWorld
gumbel(LOCATION,SCALE)	**Gumbel distribution** with location parameter LOCATION and scale parameter SCALE, see MathWorld
invGaussian(MEAN,SHAPE)	**Inverse Gaussian distribution** with mean MEAN and scaling parameter SHAPE, see MathWorld
laplace(MEAN,SCALE)	**Laplace distribution** with mean MEAN and scale parameter SCALE, see MathWorld
logistic(LOCATION,SCALE)	**Logistic distribution** with location parameter LOCATION and scale parameter SCALE, see MathWorld
logNormal(LOCATION,SCALE)	**Lognormal distribution** with location parameter LOCATION and scale parameter SCALE, see MathWorld
normal(MEAN,STD_DEV)	**Normal distribution** with mean MEAN and standard deviation STD_DEV, see MathWorld
pareto(SCALE,SHAPE)	**Pareto distribution** with scaling parameter SCALE and shape parameter SHAPE, see MathWorld
rayleigh(SIGMA)	**Rayleigh distribution** with parameter SIGMA, see MathWorld
studentT(DF)	**Student's t-distribution** with degrees of freedom DF, see MathWorld
triangular(LOW,MID,HIGH)	**Triangular distribution** between LOW and HIGH, where MID is the most probable number, see MathWorld
uniform(LOW,HIGH)	**Uniform distribution** between LOW and HIGH, see MathWorld
weibull(SHAPE,SCALE)	**Weibull distribution** with shape parameter SHAPE and scaling parameter SCALE, see MathWorld

Further, the following discrete distributions are available:

Distribution	Description
`binomial(N,P)`	**Binomial distribution** with number of trials `N` and success probability `P` in each trial, see MathWorld
`geometric(P)`	**Geometric distribution** with success probability `P` in each trial, see MathWorld
`hyperGeo(TOTAL,GOOD,TRIALS)`	**Hypergeometric distribution** with total number of elements `TOTAL`, number of good elements `GOOD` and number of trials `TRIALS`, see MathWorld
`logarithmic(P-FACTOR)`	**Logarithmic distribution** with parameter `P-FACTOR`, also called log-series distribution, see MathWorld
`negBinomial(FAILURES,P)`	**Negative Binomial distribution** with `FAILURES` being the number of failures until the experiment is stopped and success probability `P` in each trial. The generated random number describes the number of successes until the defined number of failures is reached, see MathWorld
`poisson(LAMBDA)`	**Poisson distribution** with mean `LAMBDA`, see MathWorld
`uniformInt(LOW,HIGH)`	**Integer Uniform distribution** between `LOW` and `HIGH`, see MathWorld

Note that for each distribution the library offers the following four functions, where `DistributionName` is the name of the distribution as listed in the tables above, `parameters` are the parameters associated with each distribution, and `x` is the point at which the function is to be evaluated. Note that `x` may be an endogenous variable.

Function	Description	End. Classif. for Continuous Distributions	End. Classif. for Discrete Distributions
`d<DistributionName>(parameters)`	Generate a random deviate (sample from the distribution)	none	none
`pdf<DistributionName>(x,parameters)`	Probability density function	DNLP	none
`cdf<DistributionName>(x,parameters)`	Cumulative distribution function	DNLP	none
`icdf<DistributionName>(x,parameters)`	Inverse cumulative distribution function	DNLP	none

For example, the functions for the Normal distribution are

Function	Description	End. Classif.
`dNormal(MEAN,STD_DEV)`	Samples a random number from the Normal distribution	none
`pdfNormal(x,MEAN,STD_DEV)`	Probability density function for Normal distribution	DNLP
`cdfNormal(x,MEAN,STD_DEV)`	Cumulative distribution function for Normal distribution	DNLP
`icdfNormal(x,MEAN,STD_DEV)`	Inverse cumulative distribution function for Normal distribution	DNLP

Finally, the seed for the various random number generators can be set by using the following function:

Function	Description	End. Classif.
SetSeed(SEED)	Defines the seed for random number generator	none

In the following example, a sample of size 20 is generated from the Normal, Binomial, Cauchy, and Lognormal distributions each:

```
$funcLibIn stolib stodclib
Functions randnorm     /stolib.dnormal    /
          randbin      /stolib.dbinomial  /
          randcauchy   /stolib.dcauchy    /
          randlognorm  /stolib.dlognormal /;

Set i / i1*i20 /;
Set j / norm, binomial, cauchy, lognorm /;
Parameter randx(i,j)    "distribution sample";

randx(i,"norm")     = randnorm(5,2);
randx(i,"binomial") = randbin(10,0.5);
randx(i,"cauchy")   = randcauchy(5,1);
randx(i,"lognorm")  = randlognorm(1.2,0.3);
display randx;
```

In the example, first the stochastic library is made available in GAMS, then the functions that will be used from the library are declared, giving them names under which to refer to them in the GAMS model.

The output generated by the display statement is the following:

```
----     15 PARAMETER randx  distribution sample

           norm    binomial      cauchy     lognorm

i1        4.373       4.000       5.520       3.132

i16       3.558       3.000    -112.644       2.092
i17       2.402       4.000       4.078       2.523
i18       2.249       2.000       0.996       2.777
i19       5.639       4.000       3.931       2.678
i20       7.374       4.000       4.671       3.159
```

4.47.3.4 The LINDO Sampling Library

The LINDO Sampling Library provides samples of random numbers for certain distributions.

It is made available by the following directive:

```
$funcLibIn <InternalLibName> lsadclib
```

Observe that a LINDO license is required to use this library.

The following table list the LINDO sampling functions.

Function	Description	End. Classif.
sampleLS<DistributionName>(parameters)	Creates a sample using the distribution DistributionName, according to the distribution parameters, and returns a HANDLE that references the sample, as illustrated in the example below.	none
getSampleValues(HANDLE)	Retrieves sampling created by the function sampleLS. See example below.	none
induceCorrelation(CORTYPE)	Induces the correlation that was set with the function setCorrelation before. CORTYPE describes the correlation type: 0 (Pearson), 1 (Kendall) or 2 (Spearman). See example below.	none
setCorrelation(SAMPLE1,SAMPLE2,COR)	Defines correlation between two samplings. See example below.	none
setSeed(SEED)	Specifies the seed for the random number generator.	none
setRNG(RNG)	Specifies the random number generator that will be used. Possible values are -1 (FREE), 0 (SYSTEM), 1 (LINDO1), 2 (LINDO2), 3 (LIN1), 4 (MULT1), 5 (MULT2), and 6 (MERSENNE).	none

The following tables list the available continuous and discrete distributions, respectively. Note that the parameter SAMSIZE must be specified and describes the size of the sample. However, the parameter VARRED is optional and facilitates choosing a variance reduction method. The values are 0 (meaning "none"), 1 (meaning "Latin Hyper Square") and 2 (meaning "Antithetic"). The default is Latin Hyper Square sampling, it will be used if no variance reduction method is specified.

Continuous Distribution	Description
beta(SHAPE_1,SHAPE_2,SAMSIZE[,VARRED])	**Beta distribution** specified by two shape parameters.
cauchy(LOCATION,SCALE,SAMSIZE[,VARRED])	**Cauchy distribution** specified by the location and the scale parameter.
chisquare(DF,SAMSIZE[,VARRED])	**Chi-Squared** distribution specified by degrees of freedom.
exponential(RATE,SAMSIZE[,VARRED])	**Exponential distribution** specified by rate of change.

Continuous Distribution	Description
f(DF_1,DF_2,SAMSIZE[,VARRED])	**F distribution** specified by degrees of freedom. Note that the function sampleLSf uses another version of the F distribution than the function dF from the Stochastic Library.
gamma(SHAPE,SCALE,SAMSIZE[,VARRED])	**Gamma distribution** specified by shape and scale parameter. Note that the function sampleLSgamma(A,B) is equivalent to the function dGamma(B,A) from the Stochastic Library.
gumbel(LOCATION,SCALE,SAMSIZE[,VARRED])	**Gumbel distribution** specified by location and scale parameter.
laplace(LOCATION,SCALE,SAMSIZE[,VARRED])	**Laplace distribution** specified by location and scale parameter.
logistic(LOCATION,SCALE,SAMSIZE[,VARRED])	**Logistic distribution** specified by location and scale parameter.
lognormal(LOCATION,SCALE,SAMSIZE[,VARRED])	**Log Normal distribution** specified by location and scale parameter.
normal(MEAN,STD_DEV,SAMSIZE[,VARRED])	**Normal distribution** specified by given mean and standard deviation.
pareto(SCALE,SHAPE,SAMSIZE[,VARRED])	**Pareto distribution** specified by shape and scale parameter.
studentt(DF,SAMSIZE[,VARRED])	**Student's t-distribution** specified by degrees of freedom.
triangular(LOW,MID,HIGH,SAMSIZE[,VARRED])	**Triangular distribution** specified by lower and upper limit and mid value.
uniform(LOW,HIGH,SAMSIZE[,VARRED])	**Uniform distribution** specified by the given bounds.
weibull(SCALE,SHAPE,SAMSIZE[,VARRED])	**Weibull distribution** specified by scale and shape parameter. Note that the function sampleLSweibull(A,B) is equivalent to the function dWeibull(B,A) from the Stochastic Library.

Discrete Distribution	Description
binomial(N,P,SAMSIZE[,VARRED])	**Binomial distribution** specified by number of trials N and success probability P in each trial.
hypergeo(TOTAL,GOOD,TRIALS,SAMSIZE[,VARRED])	**Hypergeometric distribution** specified by total number of elements, number of good elements, and number of trials.
logarithmic(P-FACTOR,SAMSIZE[,VARRED])	**Logarithmic distribution** specified by P-Factor. Note that the function sampleLSlogarithmic uses another version of the logarithmic distribution than dLogarithmic from the Stochastic Library.
negbinomial(SUCC,P,SAMSIZE[,VARRED])	**Negative Binomial distribution** specified by the number of successes and the probability of success. The generated random number describes the number of failures until the defined number of successes is reached. Note that the function sampleLSnegbinomial(R,P) is equivalent to the function dNegBinomial(R,P-1) from the Stochastic Library.
poisson(MEAN,SAMSIZE[,VARRED])	**Poisson distribution** specified by mean.

The following example illustrates the use of the sample generator and shows the effect of the functions `setCorrelation` and `induceCorrelation`:

```
$funcLibIn lsalib lsadclib

Functions normalSample   / lsalib.SampleLSnormal    /
          getSampleVal   / lsalib.getSampleValues   /
          setCor         / lsalib.setCorrelation    /
          indCor         / lsalib.induceCorrelation /;

Scalars d "dummy"
        h "handle for first sample"
        k "handle for second sample" ;

Set i "sample index" / i01*i12 /;

Parameters sv_h(i)  "sample values for handle h"
           sv_k(i)  "sample values for handle k";

* generate two handles for 12 samples from normal distribution with mean 5 and std.dev. 2 each
h = normalSample(5,2,12);
k = normalSample(5,2,12);

* retrieve sample values from Lindo library
loop(i, sv_h(i) = getSampleVal(h) );
loop(i, sv_k(i) = getSampleVal(k) );

display sv_h, sv_k;

* set and induce a correlation between samples h and k
d = setCor(h,k,-1);
d = indCor(1);

* retrieve sample values again from correlated distribution
loop(i, sv_h(i) = getSampleVal(h) );
loop(i, sv_k(i) = getSampleVal(k) );

display sv_h, sv_k;
```

The resulting output shows that the values of `sv_k` are reordered according to the desired correlation:

```
----     25 PARAMETER sv_h  sample values for handle h

i01 2.079,    i02 6.454,    i03 4.437,    i04 2.747,    i05 5.339,    i06 4.059,    i07 6.311,    i08

----     25 PARAMETER sv_k  sample values for handle k

i01 5.509,    i02 3.021,    i03 7.550,    i04 6.002,    i05 4.227,    i06 0.704,    i07 3.890,    i08

----     35 PARAMETER sv_h  sample values for handle h

i01 2.079,    i02 6.454,    i03 4.437,    i04 2.747,    i05 5.339,    i06 4.059,    i07 6.311,    i08
```

```
----     35 PARAMETER sv_k  sample values for handle k

i01 7.550,    i02 3.021,    i03 9.474,    i04 6.442,    i05 4.592,    i06 0.704,    i07 3.890,    i08
```

4.47.3.5 The Mutex Library

The Mutex Library allows us to work with a process-level *mutex* - a program object that can be used to synchronize multiple processes. For example, a mutex can be used to coordinate *mutually exclusive* access to a resource shared between processes and, thus, prevent multiple processes from accessing the shared resource at the same time. A mutex object is created with a unique name and can be acquired or locked by only one process at a time. Each process waits to acquire the lock for (i.e. ownership of) the mutex object before executing the code that accesses the shared resource. After accessing the shared resource, the process releases or unlocks the mutex object and other processes waiting for the mutex can acquire the lock and continue execution.

The Mutex Library may be used to prevent simultaneous access to shared resources when running GAMS programs concurrently and the errors and hard-to-explain behavior that result. Such behavior is not unusual or surprising: GAMS even has some language features to spawn programs asynchronously (e.g. Asynchronous Execution), and these concurrent GAMS programs often share files. Consider the following example where we have two GAMS programs A and B concurrently running a common code that writes a GDX file containing a scalar `x`:

```
scalar x;
repeat
  execute_load 'x.gdx', x;
  x = x + 1;
  execute_unload 'x.gdx', x;
until x > 100;
```

To ensure correct execution of the code, we want to ensure that programs A and B have mutually exclusive access to the GDX file. In addition, we want the load-increment-unload sequence to occur atomically (i.e. no other process reads or writes the GDX file during this sequence). The extrinsic function library `mtxcc` provides us with some functions to accomplish this and similar tasks:

- `Create(x)`: Creates a mutex with id `x` in the system. Returns `0` on success and `UNDF` in case of error.
- `Lock(x)`: Request to aquire or lock a mutex with id `x`: it returns immediately if the mutex is available, otherwise it waits until the mutex becomes available. Returns `0` on success and `UNDF` in case of error. Any process waiting in this call will wait forever if the mutex is never unlocked.
- `Unlock(x)`: Unlocks or releases a previously locked mutex with id `x`. Returns `0` on success and `UNDF` in case of error. If processes are waiting to acquire a lock on `x`, one of them will acquire the lock. Note that the lock should be held by the unlocking process: behavior is undefined otherwise.
- `TryLock(x)`: Like `Lock`, but if the mutex is not available, return `1` immediately instead of waiting.
- `TimedLock(x,y)`: Like `Lock`, but instead of waiting forever, return `1` after waiting unsuccessfully for `y` milliseconds.
- `Delete(x)`: Erases a mutex with id `x` from the system. Returns `0` on success and `UNDF` in case of error. Note that a process does not need to own the mutex to erase it. If a mutex is deleted and there are remaining processes queued up waiting for the unlock, these processes will wait forever.

Continuing our previous example, we need to make the functions `Lock` and `Unlock` available so we can use them to protect the entire loop body by enclosing it in `Lock`/`Unlock` calls.

```
$funcLibIn mtxlib mtxcclib
Function lock        / mtxlib.Lock /
         unlock      / mtxlib.Unlock /;
scalar x;
repeat
  abort$lock(12345) 'Problems locking mutex';
  execute_load 'x.gdx', x;
  x = x + 1;
  execute_unload 'x.gdx', x;
  abort$unlock(12345) 'Problems unlocking mutex';
until x > 100;
```

Before we can use the mutex, we first have to create it. Also if both programs are done, we need to make sure that the named mutex is erased at the end of the programs, otherwise named mutexes collect in your system and consume resources (memory or disk depending on the implementation). Because the deletion of a named mutex might be forgotten or a program exits while holding the lock to the mutex or another concurrent system uses the same id, it is a good idea to find a unique mutex name, create it once, and erase it at the end as shown in the following complete example:

```
* generate a unique mutex ID
$eval mtxID round(frac(jnow)*24*60*60*1000)

$onEcho > x.gms
$funcLibIn mtxlib mtxcclib
Function lock        / mtxlib.Lock /
         unlock      / mtxlib.Unlock /;
scalar x;
repeat
  abort$lock(%mtxID%) 'Problems locking mutex';
  execute_load 'x.gdx', x;
  x = x + 1;
  put_utility 'log' / 'Program %prgID% increased x to ' x:0:0;
  execute_unload 'x.gdx', x;
  abort$unlock(%mtxID%) 'Problems unlocking mutex';
until x >= 100;
$offEcho
* Initialize x.gdx
scalar x /1/;
$gdxOut x.gdx
$unload x
$gdxOut

$onEcho > create.gms
$funcLibIn mtxlib mtxcclib
Function create / mtxlib.Create /;
abort$create(%mtxID%) 'problems creating mutex';
$offEcho
* Create the mutex
$call.checkErrorLevel gams create.gms lo=2

* Asynchronously spawn A and B
$call.async 'gams x.gms --prgID=A fileStem=A'
$eval jhA JobHandle
$call.async 'gams x.gms --prgID=B fileStem=B'
$eval jhB JobHandle

* Wait until both jobs are back
```

```
$set statA 0
$set statB 0
$label l1
$eval x sleep(1)
$if not %statA% == 2 $eval statA JobStatus(%jhA%)
$if not %statB% == 2 $eval statB JobStatus(%jhB%)
$if not %statA%%statB% == 22 $goto l1

$onEcho > erase.gms
$funcLibIn mtxlib mtxcclib
Function delete / mtxlib.Delete /;
abort$delete(%mtxID%) 'problems erasing mutex';
$offEcho
* Erase the mutex
$call.checkErrorLevel gams erase.gms lo=2
```

The log indicates which program updated `x` and the GDX file `x.gdx` at what stage:

```
Program B increased x to 20
Program B increased x to 21
Program A increased x to 22
Program A increased x to 23
```

Models **dicegrid** and **asyncincbi** show more realistic uses for the `mtxcc` library.

4.47.4 Build Your Own Library

This section discusses the creation of a custom extrinsic function library. Before attempting to implement such a library, we suggest to study the example libraries for which source code and test models are available. These libraries are studied below.

Attention

> Building extrinsic function libraries requires the knowledge of a regular programming language (like C/C++, Fortran, ...) and experience with handling compilers and linkers to build dynamically linked libraries. In some situation, it may be easier to use the simpler GAMS macros or batinclude files to define own functions.

Note

> Extrinsic functions are limited to 20 scalar arguments and return a scalar value.

An extrinsic function library consists of a specification part and a number of callbacks to evaluate the defined functions at an input point.

The specification part is implemented by a callback `querylibrary`. It returns information about the library itself, available functions, their arguments, endogenous classification, etc. to the GAMS execution system. C, Delphi, or Fortran source code for this callback can be generated automatically by using the Python helper script `ql.py`. The script processes a specification file `*.spec`, which is specified as first argument. The format of this file is documented in the file `tri.spec`. Both `ql.py` and `tri.spec` are contained in the source of the trigonometric library examples in the GAMS test library, obtainable via

```
$ testlib trilib01
$ unzip trisource.zip
```

If an extrinsic function will be used within equations of a GAMS model, next to the function value evaluation callback, also callbacks that compute first and second derivatives with respect to all endogenous arguments at an input point should be provided. Occasionally, this can be inconvenient. Observe that GAMS can use the function values at points close to the input point to estimate the derivate values using finite differences. However, this method is not as accurate as analytic derivatives and requires a number of function evaluations, thus the convenience comes at a price. The attribute `MaxDerivative` in the specification of a function signals GAMS the highest derivatives this function will provide. For higher order derivatives, GAMS will use finite differences to approximate the derivative values. However, a better alternative is often the use of automatic differentiation when implementing the function evaluation. This is demonstrated in the CPP Library Example, see section Automatic Differentiation for more details.

GAMS offers some support to check the implementation of of derivatives for extrinsic functions via the function suffixes `grad`, `gradn`, `hess` and `hessn`. These function suffixes are defined for intrinsic and extrinsic functions. For example, for an extrinsic function `userfunc`, the gradient evaluation that the user implemented may be called with `userfunc.grad`. Further, an approximation of the gradient by finite differences is available by calling `userfunc.gradn`. Comparing the results of these two calls can often help to check the implementation of the gradient. The same principle applies for the Hessian and the function suffixes `.hess` and `.hessn`. The GAMS options FDDelta and FDOpt can be used to influence the finite difference calculations. For more details, see model [**DERIVTST**] in the GAMS Model Library.

4.47.4.1 Example: Trigonometric Library

The Trigonometric Library serves as an example of how to code and build an extrinsic function library. The library is included in the GAMS distribution in binary form. In addition, the source code in C, Delphi, and Fortran is available in the include files of the models [**TRILIB01**], [**TRILIB02**] and [**TRILIB03**] respectively. The library implements the following extrinsic functions:

Function	Description	End. Classif.
`setMode(MODE)`	Sets mode globally. Possible values are `0` for radian and `1` for degree. May be overwritten by the optional argument `MODE` in the functions `cosine` and `sine`.	none
`cosine(x[,MODE])`	Returns the cosine of the argument `x`. Note that the argument `MODE` is optional, default setting: `MODE = 0`.	NLP
`sine(x[,MODE])`	Returns the sine of the argument `x`. Note that the argument `MODE` is optional, default setting: `MODE = 0`.	NLP
`pi`	Value of $\pi = 3.141593...$	any

The C implementation of this extrinsic function library can be found in the files `tricclib.c` and `tricclibql.c`. Together with the API specification file `extrfunc.h`, these files document the callbacks that need to be implemented by a GAMS extrinsic function library. The file `tricclibql.c` implements the `querylibrary` callback, which provides information about the library itself and the extrinsic functions it implements. For example, the information that the function `cosine` has an endogenous required first argument and an exogenous optional second argument is available from the `querylibrary` callback. The file `tricclibql.c` (and also the Delphi and Fortran90 equivalents `tridclibql.inc` and `triifortlibql.f90`) has been generated by the script `ql.py` by processing the specification file `tri.spec`.

4.47.4.2 Example: The CPP Library

The CPP library serves both as an example of how to use C++ to obtain gradients and Hessians "for free" and as a source of functions based on the multivariate Normal distribution. The library is available in

compiled form and as C++ source. Test Library model [**CPPLIB00**] exercises the process of building a shared library from C++ source and doing some basic tests, while models [**CPPLIB01**], [**CPPLIB02**], [**CPPLIB03**], [**CPPLIB04**], and [**CPPLIB05**] are more thorough tests for the CPP library extrinsics shipped with the distribution. These functions are listed and described in the following table. Note that in keeping with the language conventions of statistics, *PDF* is shorthand for "probability density function" and *CDF* is shorthand for "cumulative distribution function".

Function	Description	End. Classif.
`pdfUVN(x)`	PDF of uni-variate Normal distribution, see MathWorld or R	NLP
`cdfUVN(x)`	CDF of uni-variate Normal distribution, see MathWorld or R	NLP
`pdfBVN(x,y,r)`	PDF of bivariate Normal distribution, see MathWorld or R	NLP
`cdfBVN(x,y,r)`	CDF of bivariate Normal distribution, see MathWorld or R	NLP
`pdfTVN(x,y,z,r21,r31,r32)`	PDF of trivariate Normal distribution, see MathWorldor R	NLP

Automatic Differentiation

Often, extrinsic functions are created in order to be used with endogenous arguments. In such cases it is necessary to provide first and second derivatives with respect to these arguments in addition to the function values themselves. One way to compute these derivatives is via automatic differentiation techniques (see the article in Wikipedia for details).

Note that with C++ it is possible to overload the usual arithmetic operators (assignment, addition, multiplication, etc.) so that automatic differentiation occurs with little or no change to the function-only source code. This is the technique used to compute the derivatives in the CPP Library. Observe that the Test Library model [**CPPLIB00**] includes all the source code for the CPP Library and illustrates the steps needed to build the library from this source. The source is a working self-documentation of how the process of automatic differentiation works.

Multi-Variate Normal Distributions

As shown in the table above, the CPP Library implements the PDF and CDF for the univariate, bivariate and trivariate standard Normal distributions. We use the standard Normal (mean of 0, standard deviation of 1) since intrinsic functions are limited to 20 arguments. The functions for the univariate case are included as convenient examples and should give results (nearly) identical to the functions pdfNormal and cdfNormal from the stochastic library. For the multivariate cases, the implementation is based on TVPACK from Alan Genz, with some modifications to allow for proper computation of derivatives. Note that we chose to implement the functions taking correlation coefficients as arguments, not a covariance matrix. The conversion from a covariance matrix to correlation coefficients is straightforward. The following `R` code describes this conversion. Here the package `mnormt` is used that computes the multivariate CDF with similar code to Genz:

```
# start with a mean mu and variance-covariance matrix S1
x <- c(1.0,3.0,3.0)
mu <- c(0.0,1.0,-1.0)
S1 <- matrix(c(1.0,1,1.5, 1,4,1.5,  1.5,1.5,9),3,3)
v1 <- pmnorm(x=x, mean=mu, varcov=S1)
# convert to std normal with 3 correlation coeffs
R <- cov2cor(S1)
sd <- sqrt(diag(S1))
xn <- (x-mu) / sd
v2 <- pmnorm(x=xn, mean=0, varcov=R)
```

Note that for the bivariate case there is one correlation coefficient `r`. The CDF implementation is not quite accurate to machine precision, it has 14 or 15 digits of accuracy. The trivariate case includes 3

correlation coefficients, the 3 off-diagonal elements from the lower triange of `R` above. The accuracy of the CDF depends on the inputs: it is higher when the correlation is nearly zero and lower as the condition number of `R` increases. Typically, an accuracy of 10^{-11} is all that can be achieved. In both multivariate cases, we recommend to avoid evaluating at or near points where the correlation matrix is degenerate. At nearly degenerate points, the accuracy of the distribution and density functions suffers. As the correlation matrix becomes degenerate, the distribution becomes degenerate too.

4.47.4.3 Remark: Stateful Libraries

While GAMS intrinsic functions are *stateless*, users may implement `stateful` extrinsic functions, i.e., functions that have some memory. There are two ways to achieve stateful extrinsic functions:

1. Library initialization (`LibInit`): at initialization time, the function library reads some data that is required to evaluate the provided functions. An example is the Piecewise Polynomial Library.
2. Previous function calls: function calls that alter the execution of successive function calls. An example is the function `SetMode` from the Trigonometric Library.

Attention

> Altering the state of an extrinsic function library by function evaluation calls is problematic, since different parts of the GAMS system potentially use different instances of the function library.

For example, consider that the function `SetMode` of the Trigonometric Library is called via `SetMode(1)` before a solve statement. Unless option solvelink is set to 5, the solver will run in a separate process with a new instance of the function library and therefore will use the default `mode`, which is zero. Further, if `solvelink` is set to zero, the GAMS process will terminate in order to execute the solve statement and will restart a new GAMS process after the solve. The restarted GAMS process will load a fresh instance of the extrinsic function library, which has no memory of the value of `mode` from before the solve statement. This problem is demonstrated in the GAMS Test Library model [**TRILIB04**].

4.47.5 Extrinsic Functions vs. External Equations

In addition to extrinsic functions, GAMS offers another facility to include additional mathematical functions in GAMS: external equations. These equations are denoted by equation type `=x=`. A feasible solution for a model instance must satisfy all internal and external equations. External equations are introduced and discussed in chapter External Equations.

Similar to extrinsic functions, it is the users responsibility to provide routines that evaluates the external equation. Further, both facilities are especially pertinent to nonlinear models.

An overview of some characteristics of extrinsic functions and external equations is given in the following table:

Characteristic	Extrinsic Function	External Equation
Maximum number of arguments	20	No limit
Available in statements	Yes	No
Debugging support	Yes	No
Returns Hessian to solver	Yes	No

Consider the following example, which demonstrates how an equation $z = \int_{x_1}^{x_2} x\,dx$ may be formulated using either an extrinsic function and an external equation:

```
* using an extrinsic function
e1.. integralx(x1,x2) =e= z;

* using an external equation
e1.. 1*x1 + 2*x2 + 3*z =x= 1;
```

Note that the function `integralx` is assumed to be a user-defined extrinsic function, probably implemented as $\texttt{integralx}(x_1, x_2) = \frac{1}{2}(x_2^2 - x_1^2)$.

Note further, that the integers 1 to 3 in the external equation are mapped to indices for variables that are used in external functions inside an external module. The right-hand side of the external equation denotes the external equation number. It is assumed that the user-defined external equation implements the function $(x_1, x_2, z) \mapsto \int_{x_1}^{x_2} x\,dx - z$.

As a simple example for the use of an extrinsic function in a statement, consider the following assignment, which sets the level of variable `y` to the value of $(\int_0^2 x\,dx)^2$:

```
y.l = sqr(integralx(0,2));
```

4.48 External Equations

GAMS provides a number of built-in or intrinsic functions for use in equations. Still, the extremely diverse set of application areas in which GAMS is used can create demand for the addition of new and often sophisticated and specialized functions. There is a trade-off between satisfying these requests and avoiding complexity not needed by most users. The GAMS External Equations Facility provides one means for managing this trade-off, since it allows users to import functions from an external library to define equations in a GAMS model. However, these external libraries can currently only provide functionality for the evaluation of functions (incl. their first derivatives) in a point. Solvers that need to analyze the algebraic structure of the model instance are therefore not able to work with external equations. This includes the class of *deterministic* global solvers, see column "Global" in this table, while, for example, *stochastic* global solvers can work with external equations.

Note

Both external equations and extrinsic functions aim to provide possibilities to extend GAMS by user-provided mathematical functions. However, there are fundamental differences in the use and implementation of both. For most situations, extrinsic functions should be preferred over external equations. See also Extrinsic Functions vs. External Equations.

Attention

Building external equation libraries requires the knowledge of a regular programming language (like C/C++, FORTRAN, ...) and experience with handling compilers and linkers to build dynamically linked libraries.

Note

The external equation interface is not intended as a way to bypass some of the very useful model checking done by GAMS for models that are solved with NLP solvers. External equations are still assumed to be continuous with accurate and smooth first derivatives. The continuity assumption implies that external equations must have very low noise levels, considerably below the feasibility tolerance used by the solver. The assumption about accurate derivatives implies that derivatives must be computed more accurately than can be done with standard finite differences. If these assumptions are not satisfied, then there is no guarantee that the NLP solver can find a solution that has the mathematical properties of a local optimum, i.e., a solution that satisfies the Karush-Kuhn-Tucker conditions within the standard tolerances used by the solver.

In the following, connecting code written in FORTRAN, C, Delphi, or some other programming language to equations and variables in a GAMS model is described. These GAMS equations will be referred to as *external equations* and the compiled version of the programming routines will be referred to as the *external module* that defines the external functions. The form of the external module depends on the operating system that is used. The external module under Windows is a Dynamic Link Library (`.dll`) and the external module under Unix is a shared object (`.so` or `.dylib`). In principle, any language or system may be used to build the DLL or shared object that defines the external module, as long as the interface conventions are not changed.

The GAMS Test Library provides examples of external equations consisting of GAMS models and C, Delphi, Java, and FORTRAN code. For more details, see Section Examples in the GAMS Test Library.

The basic mechanism of external equations is to declare all the equations and variables using the usual GAMS syntax. The interpretation of the external equations is done in a special way. Instead of the usual semantic content, the external equations specify the *mapping* between the equation and variable names used in GAMS and the function and variable indices used in the external module. This mapping is described in Section Model Interface. The external module may be written in C, FORTRAN, or most other programming languages. Section Programming Interface describes the general definitions for an external module for C, Delphi, and FORTRAN from a programming language perspective. Note that the way the program is compiled and converted into an external module is system and compiler specific. The following Section Implementation gives detailed advice on various aspects of the implementation of the external module.

4.48.1 Examples in the GAMS Test Library

Model **[TESTEXEQ]** gives an overview of all examples in the GAMS Test Library and may be used to compile and run them. Note that the remainder of this chapter will reference examples that are listed in this model. Further, model **[COMPLINK]** may be used as a script to compile and link external equation libraries. Note that these models hardcore the path to the Java compiler and libraries and these paths will need to be adapted by the user when running the Java examples.

Observe that regardless of how external libraries are built, the examples (e.g. **[EX1]**) will by default solve a model without using external equations. To solve the example models with all kinds of different external equation libraries, they may be run with the argument

```
--runall=1
```

Alternatively, only selected libraries may be used by using one or more of the following command line parameters:

```
--runC=1
--runC_cb=1
--runD=1
--runD_cb=1
--runF=1
--runF_cb=1
--runJ=1
```

4.48.2 Model Interface

4.48.2.1 External Equation Syntax

External equations that are used to specify the interface to the external module are *declared* in GAMS like any other equation. The syntax for the external equation *definition* statement is as follows:

```
eqn_name(index_list)[$logical_condition(s)].. expression =x= expression ;
```

Note that the only difference to the usual equation definition is the use of the equation type `=x=`.

The equations defined by an external module are always interpreted as equality constraints with zero right-hand sides. Thus inequalities have to be converted to equalities by adding explicit slack variables, which will serve as additional external variables. A nonzero right-hand side need to be taken care of in the external equation implementation.

4.48.2.2 Mapping of external equations and variables to indices

Some mappings must be specified to link an external module to a GAMS model. External equations are assumed to be defined in terms of indices `i = 1...m`. These indices must be mapped to GAMS equation names. Similarly, the variables used inside the external functions are assumed to be defined in terms of indices `j = 1...n`. These indices must be mapped to GAMS variable names. Finally, the name of the external module must be specified. Note that GAMS solvers are typically designed for large models and rely on sparsity. The last part of the specification of a set of external equations is therefore the sparsity pattern of the external equations, i.e., which variables appear in which equations.

The value of the *constant* term of the external equation must be an integer, since the value of the constant maps the row of the GAMS equation to the index (in `1...m`) of the external equation. Several blocks of GAMS equations may be mapped to external equations using the `=x=` notation. The mapping between GAMS equations of type `=x=` and indices `1...m` must be bijective (one-to-one). This means that two GAMS equations may not be mapped into the same external equation index and that there may not be any holes in the list of external equation indices. Although there may be any number of blocks of GAMS external equations, they must all map into and be implemented by one single external module.

The *variable* part of each external equation defines both the sparsity pattern of the external equation and the mapping from GAMS variables to the indices of the external variables. The variable part must be a sum of terms where each term is an integer times a variable. The existence of the term indicates that the variable involved is used in the external equation and that there is a corresponding derivative. The value of the coefficient defines the index of the external variable (in `1...n`) that the GAMS variable is mapped to. For example, the term `5*Y` indicates that the external equation depends on the GAMS variable `Y` and that `Y` is mapped to the 5th element in the vector of external variables. Clearly, if a variable appears in more than one external equation, then the value of its coefficient must be the same in each case.

Note that several blocks of GAMS variables may be used in external equations. In contrast to equations, where all rows in an equation block are either external or not, some columns in a variable block may be external while others are not. The mapping between GAMS variables that appear in equations of type `=x=` and external variable indices `1...n` must be bijective (one-to-one). This means that two GAMS columns may not be mapped into the same external variable index and that there may not be any holes in the list of external variable indices. Although there may be any number of blocks of GAMS variables mapped to external variables, they must all map into one single vector passed to the subroutine in the external module.

Observe that while some GAMS variables are external, there is no syntax provided to mark them as external variables. They may be used in non-external GAMS equations as well as external equations. Indeed, without this capability the model would be separable and the external equations and the functions they map to would be of little use.

Note

- As the coefficients and right-hand sides in the GAMS definition of external equations are interpreted as indices, users are not allowed to scale external equations and variables.
- External equations are treated in a special way, therefore the command line parameter and model attribute HoldFixed will not treat any fixed external variables as constants.

4.48.2.3 Name of external module

The name of the external module in which the external equations are implemented may be defined in a number of ways. By default, the external module is assumed to have the same name as the GAMS model with an extension that is operating system dependent. The extension is `.dll` for Windows, `.dylib` for macOS, and `.so` for any other Unix.

A custom name for the external module may be specified with a file statement. In this case the file name has to be listed as an additional item in the model statement. If the library extension is omitted in the file statement, GAMS will add the system-dependent extension automatically. This helps to make the model portable between different operating systems.

Consider the following simple example:

```
File  myextfile / extern /;
Model mymodel   / all, myextfile /;
```

When model `mymodel` is solved, GAMS will try to load the an external module file named `extern.so`, `extern.dylib`, or `extern.dll`, depending on the current operating system.

By default, the external module is assumed to be located in the directory `external_equations` in the GAMS standard locations or in the directory from which GAMS is called. A different location may be specified with an added path in the file statement.

4.48.3 Programming Interface

This section discusses C, Delphi, and FORTRAN interfaces to the GAMS external equations facility.

The external equation module need to provide a function called `GEFUNC`. The beginning of the external equation module typically looks as follows:

C:

```
#define GE_EXPORT
#include "geheader.h"
GE_API int GE_CALLCONV
gefunc(int* icntr, double* x, double* f, double* d, msgcb_t msgcb)
```

The header file `geheader.h` can be found in the `testlib_ml` subdirectory of the GAMS distribution. It defines `GE_API` and `GE_CALLCONV` and the signature of the function `gefunc`. `GE_API` is used to indicate to the compiler whether the function should be exported or imported. Due to defining `GE_EXPORT` before including `geheader.h`, `GE_API` is defined such that the function will be marked for export (`__declspec(dllexport)` on Windows and `__visibility__("default")` with GCC). Further, `GE_CALLCONV` indicates the calling convention that should be used on Windows. Currently, this is defined to be `__stdcall`. On other operating systems, it is empty.

FORTRAN:

```
      Integer Function gefunc (icntr, x, f, d, msgcb)
C Control Buffer:
      Integer icntr(*)
C Numerical Input and Output:
      Double Precision x(*), f, d(*)
C Message Callback Routine
      External msgcb
```

Delphi:

```
uses
    geheader_d;
Function GeFunc(var Icntr: ticntr;
                var x:     tarray;
                var F:     double;
                var D:     tarray;
                MsgFunc:   tMsgCallBack): integer; stdcall;
```

The unit file `geheader_d.pas` can be found in the `testlib_ml` subdirectory of the GAMS distribution.

In the following, the arguments of `GEFUNC` are described in detail.

4.48.3.1 Control vector icntr

The array `icntr` is a control vector that is used to pack and communicate control information between GAMS and the external module. Some helpful definitions to work with the `icntr` array are provided by the files `geheader.h` (C), `geheader_d.pas` (Delphi), and `gehelper.f90` (Fortran 90). The array elements are the following:

Element	Description
`icntr[I_Length]`	Holds the length of array `icntr` in number of elements. This is provided by GAMS.
`icntr[I_Neq]`	Number of external equation rows seen in the GAMS model. This is provided by GAMS.
`icntr[I_Nvar]`	Number of external variables seen in the GAMS model. This is provided by GAMS.
`icntr[I_Nz]`	Number of nonzero derivatives or Jacobian elements seen in the GAMS model. This is provided by GAMS.
`icntr[I_Mode]`	Current mode of operation. This is provided by GAMS. The following values are possible: `DOINIT`: Initialize. This will be the first call of `GEFUNC`, where initializations needed by the external module may be performed. `DOTERM`: Terminate. This will be the last call of `GEFUNC`, where cleanup tasks needed by the external module may be performed. `DOEVAL`: Function evaluation. External equations should be evaluated. `DOCONSTDERIV`: Constant Derivatives. Information about constant derivatives should be provided. DOHVPROD: Hessian-Vector product. The product between the Hessian of an external equation and a vector should be computed. See Second Derivatives: Hessian times Vector for details.
`icntr[I_Eqno]`	Index of the external equation to be evaluated during this call to `GEFUNC`. This is provided by GAMS in function evaluation mode (`icntr[I_Mode]=DOEVAL`) and is a number between 1 and icntr[I_Neq], inclusive. Note that the external equation interface allows to communicate information about only one function at a time.
`icntr[I_Dofunc]`	Flag whether function value should be computed. `icntr[I_Dofunc]` is provided by GAMS in function evaluation mode (`icntr[I_Mode]=DOEVAL`). If set to 1, then `GEFUNC` must return the numerical value of the function indexed by icntr[I_Eqno] in the scalar `f`.

Element	Description
icntr[I_Dodrv]	Flag whether derivative should be computed. icntr[I_Dodrv] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then GEFUNC must return the numerical values of the derivatives of the function indexed by icntr[I_Eqno] in the array d.
icntr[I_Newpt]	Flag for new point. icntr[I_Newpt] is provided by GAMS in function evaluation mode (icntr[I_Mode]=DOEVAL). If set to 1, then the point x may be different from the previous call of GEFUNC. If set to 0, then x will not have changed since the previous call.
icntr[I_Debug]	If icntr[I_Debug] is set to a nonzero value by the external equation module, then the functions GEstat and GElog will write all strings to a file called debugext.txt and flush the buffer immediately after writing. The string debugger may be used when a shared object crashes before GAMS has had an opportunity to display the messages. In FORTRAN, the string debugger will use FORTRAN unit icntr[I_Debug]. For more details see Section Message Output.
icntr[I_Getfil]	Flag to request the name of a special directory or file from GAMS. The following values are possible: I_Scr: Scratch directory, I_Wrk: Working directory, I_Sys: GAMS system directory, I_Cntr: Control file. For more information, see Section Communicating Data to the External Module via Files.
icntr[I_Smode]	Flag for string mode. This is provided by GAMS. For details see Section Communicating Data to the External Module via Files.
icntr[I_ConstDeriv]	Number of constant derivatives. Specifying this number during intialization is optional. For details see Section Constant Derivatives below.
icntr[I_HVProd]	Indicator for use of Hessian-Vector product for second order derivatives. This entry is optional. For details see Section Second Derivatives: Hessian times Vector below.

Observe that FORTRAN programmers will have to replace the square brackets [] with parentheses ().

4.48.3.2 Evaluation point x

Argument x is an array with icntr[I_Nvar] elements and is provided by GAMS if GEFUNC is called in function evaluation mode (icntr[I_Mode] = DOEVAL). Typically, GAMS and the solvers ensure that the individual elements of x are in between, or very close to, the variable bounds defined in the GAMS model. During initialization and termination calls, x is not defined and the external module must not reference x. C programmers should index this array starting at zero, i.e., the first external variable is referenced as x[0].

4.48.3.3 Function value f

If icntr[I_Mode] = DOEVAL and icntr[I_Dofunc] = 1, then the external module must return the value of the external equation icntr[I_Eqno] in the scalar f. During initialization and termination calls, f must not be referenced.

4.48.3.4 Derivative vector d

If `icntr[I_Mode] = DOEVAL` and `icntr[I_Dodrv] = 1`, then the external module must return the values of the derivatives of external function icntr[I_Eqno] with respect to all variables in the array `d`. The derivative with respect to variable `x[i]` is returned in `d[i]`. It is sufficient to set only those positions in `d` that correspond to variables actually appearing in equation icntr[I_Eqno]. Other positions are not being used by GAMS and may be left undefined. During initialization and termination calls, `d` must not be referenced.

4.48.3.5 Message callback msgcb

This argument is the address of a message callback routine that can be used to write messages to the status and/or log files of the GAMS process. Its type definition in C is as follows:

```
typedef void (GE_CALLCONV * msgcb_t) (const int* mode, const int* nchars, const char* buf, int len);
```

The argument `mode` is used to point to an integer which indicates where messages should be written to. This integer can be set to the following values:

- LOGFILE (1): Write the message to the log file only.
- STAFILE (2): Write the message to the status file only.
- LOGFILE | STAFILE (3): Write the message to both the log file and the status file. Observe that the symbol | denotes the bitwise logical `OR` in C.

The argument `nchars` points to an integer that specifies the number of bytes contained in the message (excluding the \0-terminator if there is one present). Thus, in C, `nchars` is typically set to `strlen(buf)`. The argument `buf` is a pointer to the character array containing the message to be printed. Finally, `len` is the size or length of the string `buf`, thus it is typically the same as `*nchars`.

Calling the message callback msgcb from C is straightforward. Note that the arguments `mode`, `nchars`, and `buf` are all call-by-reference and that addresses, not values, must be used. However, the argument `len` is call-by-value and `*nchars` should be passed as its value.

If the implementation is done in Delphi or Visual Basic, observe that pointers of all types are 4-byte quantities on a 32bit system and 8-byte quantities on a 64bit system. Integers are 4 bytes.

Calling this routine from a FORTRAN environment is a bit more complicated due to the different ways that FORTRAN compilers handle strings. The Unix convention - at least the convention observed on all systems for which GAMS is built - is that strings are passed by reference. In addition, the length of the string is passed by value as a hidden 4-byte quantity appended to the end of the argument list. This is the reason for including `len` as the last argument in `msgcb`. The argument `len` facilitates making FORTRAN callbacks in a Unix environment like the following:

```
character*(*) msgbuf
int nchars, charcount
nchars = charcount(msgbuf)
call MSGCB (mode, nchars, msgbuf)
```

Status Code	Definition

4.48.3.6 Return code

The function GEFUNC must return one of the following status codes:

Status Code	Definition
0	No error occurred.
1	A function evaluation error was encountered. GAMS should not use the content of f and/or d, but GEFUNC has recovered from the error and is ready to be called at a new point. This status code should only be used in function evaluation mode (icntr[I_Mode]=DOEVAL).
2	Fatal error. If this value is returned during the initialization call, then GAMS should abort immediately. It may be returned by GEFUNC during the initial call if some initializations did not work correctly, or if some of the size values in icntr had unexpected values. It may also be returned during function evaluation mode (icntr[I_Mode]=DOEVAL) if the external module has experienced problems from which it cannot recover.

4.48.4 Implementation

After describing the function GEFUNC in Section Programming Interface above, this section offers some practical comments on implementing GEFUNC.

4.48.4.1 Compiling and Linking

The examples for GAMS external equations contain a set of GAMS models for compiling the code on various systems using various compilers. Note that the compiler and linker flags shown in these examples should be used to ensure that the modules conform to the interface standard. In addition, the appropriate include file (geheader.h, geheader_d.pas, gehelper.f90) should be used.

4.48.4.2 Initialization Mode

The initialization mode should always check whether the external equations have the expected size: icntr[I_Neq], icntr[I_Nvar] and icntr[I_Nz] have to be tested against fixed expected values or values derived from some external data set.

The initialization mode may be used for several purposes like allocating memory and initializing numerical information or mapping information needed by the function evaluations that will follow. Data can be computed or read from external data sources or it can be derived from calls to an external database. Note that data that is shared with GAMS may be written to a file from GAMS using the put statement and then read in GEFUNC. Note further, that users must close the put file with a putclose statement before the solve statement. Observe that memory used to hold information from one invocation of GEFUNC to the next should be static. For FORTRAN it should either be in a Common block or it should be included in a Save statement.

4.48.4.3 Termination Mode

The termination mode may be used to perform some clean-up tasks like computing statistics, closing files, and returning memory.

4.48.4.4 Evaluation Mode

The bulk of the computational work will usually be in evaluation mode. Observe that `GEFUNC` only works with one equation at a time. One of the reasons for this choice is that the addressing of derivatives becomes very simple: there is one derivative for each variable and they have the same index in `d` and `x`, respectively.

In some applications several functions are naturally evaluated together, for example, because all functions are computed in some joint integration routine. The icntr[I_Newpt] flag is included for these applications. Using this flag, an implementation could evaluate all functions using a common routine when icntr[I_Newpt] equals 1 and saves the function and derivative values. Additionally, it returns the values corresponding to equation icntr[I_Eqno]. In subsequent calls to `GEFUNC`, `icntr[I_Newpt]` will likely be zero and the function and derivative values can quickly be extracted from the previously computed (and saved) information.

4.48.4.5 Evaluation Errors

It is good modeling practice to add bounds to the variables in such a way that all nonlinear functions are defined for all values of the variables within the bounds. Most solvers will also guarantee that nonlinear functions are called only when all entries of the vector `x` are between the bounds. However, it may not be practical to add all the necessary bounds and the implementation of `GEFUNC` should therefore capture evaluation errors such as division by zero, taking the logarithm of non-positive numbers, overflow in exponentiation, etc. If an equation cannot be evaluated at the given point, function `GEFUNC` should simply let the solver know about this situation by returning the value 1. The solver may then be able to backtrack to a safe point and continue the optimization from there.

Attention

> System-default or user-defined functions that handle evaluation errors (for example, the C library function `matherr()`) will sometimes not work in the same way inside a `DLL` or a shared object as they do in a self-contained program or a static library.

4.48.4.6 Message Output

External modules can send messages to the GAMS status file (usually the listing file) and the GAMS log file (usually the screen). Messages to be included in the GAMS status file can be buffered using the GEstat utility routine described below and messages to be included in the GAMS log file can be buffered using the GElog utility routine. Note that it is not possible to open these files for writing in the external module since GAMS or the solver process controls them.

Moreover, messages may be sent to both the status and log file without buffering, using the message callback msgcb. This removes the limit imposed by the size of the message buffer and may also make debugging somewhat simpler, since there is no need to worry about messages that never got flushed from the buffer. As it may be difficult or impossible to use the message callback from some environments, both the buffered and unbuffered techniques are provided.

Note that the two techniques for sending messages (buffered via `GEstat` and `GElog` and unbuffered via the message callback `msgcb`) are complementary. Either one or the other may be used, but if both are used in the same external module, the buffered messages will be printed after the unbuffered messages.

GEstat: The Utility Routine for Writing Messages to the Status File

GEstat is provided in the appropriate include file (Fortran 90: gehelper.f90, C: geheader.h, Delphi: geheader_d.pas). It is used to communicate messages that should be written to the GAMS status file. The function definition follows:

FORTRAN:
```
      subroutine gestat (icntr, line)
C Control Buffer:
      Integer icntr(*)
C input parameters:
      character*(*) line
```

C:
```
void GEstat(int* icntr, char* line)
```

Delphi:
```
Procedure GeStat(var icntr: ticntr; const s: shortstring);
```

Note that the first argument, icntr, must be passed through from the call of the function GEFUNC. The content of the argument line (or s in Delphi) is packed into the control buffer as one line. When GEFUNC returns, the content of the buffer will be written to the GAMS status file. GEstat may be called several times, each time with one line. Observe that line should not be longer than 132 characters and the overall amount of information written in one call to GEFUNC should not exceed 1000 characters. Further, line should not contain any special characters such as new-line or tab.

In practice, GEstat is often used with calls like the following:

FORTRAN:
```
call GESTAT (icntr, ' ')
call GESTAT (icntr, '**** External module based on abc.for')
```

C:
```
GEstat (icntr, " ")
GEstat (icntr, "**** External module based on abc.c")
```

Delphi:
```
gestat(icntr,' ');
gestat(icntr,'**** External module based on abc.dpr');
```

GElog: The Utility Routine for Writing Messages to the Log File

Like GEstat, GElog is provided in the appropriate include file. It is used to communicate messages that should be written to the GAMS log file. Note that by default, the log file is the screen. Alternatively, log may be written to a file that is specified with the GAMS command line parameter LogFile. The function definition of GElog follows.

FORTRAN:
```
      subroutine gelog( Icntr, line )
C Control Buffer:
      Integer Icntr(*)
C input parameters:
      character*(*) line
```

C:
```
void GElog(int* icntr, char* line)
```

Delphi:
```
Procedure GeLog(var icntr: ticntr; const s: shortstring);
```

Note that GElog behaves exactly like GEstat, with the status file replaced by the log file. The content of line is written to a buffer that in turn is written to the log file when GEFUNC returns.

Observe that it is not possible to write directly to the screen with some combinations of operating system and compiler. This may also depend on the options or flags that are used to build the external module.

Attention

> On some systems writing directly to the screen may cause the external module to crash. Therefore, it is advised not to write to the screen as a method for debugging, unless it is clear that it works. Otherwise the module may continue to crash because of the debugging statements after all other errors have been removed. Writing to a file and flushing the buffer is recommended as a safe alternative.

4.48.4.7 Communicating Data to the External Module via Files

Some external equations will need data from the GAMS program. This data may be passed on via one or more files written using put statements. Usually, such put files will be written in the current directory and the external module will look for them in the current directory. However, if users need to run multiple copies of the same model at the same time, data files should be written in the GAMS scratch directory and the external module should be directed to look for the data files in the scratch directory.

Note that a put file may be defined to be located in the scratch directory with the following file statement in the GAMS model:

```
File f / '%gams.scrdir%filename' /;
```

Observe that if the extension `.dat` is used, GAMS will remove the file from the scratch directory after the run. If another extension is used and the file is not deleted, GAMS will complain about an unexpected file when it cleans up after the run. The external module can receive the name of the scratch directory from GAMS during initialization by setting icntr[I_Getfil] to `I_scr` and returning immediately. GAMS will then store the name of the scratch directory and length of the name in the communication buffer and call `GEFUNC` in initialization mode again. Note that `GEFUNC` will now be called with the sub-mode icntr[I_Smode] set to `I_Scr`. Then the name may be extracted using the following FORTRAN call:

```
call GENAME( Icntr, Scrlen, Scrdir )
```

Here, `Scrdir` (declared as `character*255`) will receive the scratch directory and `Scrlen` (declared as integer) will receive the actual length of `Scrdir`. In C, the call takes the following form:

```
char scratchDir[255];
int scratchDirLen;
scratchDirLen = GEname(icntr, scratchDir, sizeof(scratchDir));
```

Here the routine will return the number or characters transferred to the buffer `scratchDir` if successful and the value -1 otherwise. If there is space, a terminating '\0'-byte will be written to `scratchDir`. If the value returned is equal to `sizeof(scratchDir)`, then the string returned will not be '\0'-terminated and may have been truncated as well.

Observe that it is possible to get other directory or file names by specifying other values in icntr[I_Getfil]. After setting this flag, `GEFUNC` must always return immediately.

For examples, see models **[EX5]** and **[EXMCP3]** and their respective FORTRAN and C source files.

4.48.4.8 Constant Derivatives

Some solvers, like the CONOPT solvers, can take advantage of the knowledge about constant derivatives in equations, which are a result of linear terms. This can be especially useful if an external equation represents an equation like `Y=f(X)`, where `Y` is unbounded, since variable `Y` can then be substituted by `f(X)`.

However, with the external module interface as described so far, the solver cannot know which variables appear linearly in the external equations. An optional extension allows to indicate that some of the relationships are linear. This can be activated by returning the number of constant derivatives in `icntr[I_ConstDeriv]` during the call of `GEFUNC` in initialization mode.

If the solver can use this information (not all solvers will), then `GEFUNC` will be called again repetitively with icntr[I_Mode] set to `DOCONSTDERIV`, once for each external equation, with its index specified as usual in icntr[I_Eqno]. For each of these calls, values of all constant derivatives must be specified in the array d. The remaining elements of `d`, both those corresponding to varying derivatives and to zeros, must be left untouched. These special calls will take place after the initialization call and before the first function evaluation call. Note that in these calls other flags like icntr[I_Dofunc] and icntr[I_Dodrv] and the array x will not be defined.

For an example, see model **[EX4X]** with the corresponding Fortran 90 and C source files `ex4xf_cb.f90` and `ex4xc_cb.c`, respectively. It is instructive to compare these files to the corresponding files without constant derivatives: `ex4f_cb.f90` and `ex4c_cb.c`.

4.48.4.9 Second Derivatives: Hessian times Vector

External modules cannot provide a solver with the Hessian matrix of external equations. However, some solvers have particular options for internally approximating the Hessian. For example, see the hessian_approximation option for IPOPT or hessopt for KNITRO. Further, the solver CONOPT can take advantage of second order information in the form of the product Hessian matrix $\nabla^2 f(x)$ times a vector v. This special form can be used for external equations by setting icntr[I_HVprod] to 1 during the call of `GEFUNC` in initialization mode.

If the solver can use this information (not all solvers will), then `GEFUNC` may be called with icntr[I_Mode] set to DOHVPROD to request this operation. icntr[I_Eqno] will hold the equation number and the array `x` will hold the values of the variables (x) in its first `icntr[I_NVar]` positions and a vector v in the following `icntr[I_Nvar]` positions. `GEFUNC` should evaluate and return $d = \nabla^2 f(x)\, v$ for the particular external equation f at the particular point x. Note that d (which is otherwise used for the derivative vector) will have been initialized to zero by GAMS.

$\nabla^2 f(x)\, v$ will often be needed for several vectors `v` at the same point `x`. Therefore, icntr[I_Newpt] will be used to indicate changes in `x` in the usual way.

Note that model **[EX1X]** with the corresponding Fortran 90 source file shows how to use both constant and second derivatives.

4.48.4.10 Debugging

Implementing external equations brings a number of new potential error sources which GAMS cannot protect against as well as with pure GAMS models. For example, the argument lists in the C or FORTRAN code may be incorrect or the linking process may create an incorrect external module. There is little GAMS can do to help users with this type of errors. It is recommended to carefully follow the examples and output debug messages during the setup calls, for example using the utility routines GEstat and GElog.

Once the overall setup is correct and GAMS can establish proper communication with the external module, there may still be numerical errors where the function values and the derivatives do not match.

Note that the solver CONOPT will by default call its Function and Derivative Debugger in the initial point, if a model has any external equations. The debugger will check that the functions only depend on the variables that are defined in the `sparsity` pattern and that derivatives computed by numerical perturbation are consistent with the derivatives computed by the external module. If an error is found, CONOPT will stop immediately with an appropriate message. For examples, see the GAMS Test Library models **[er1]**, **[er2]**, and **[er3]**, which illustrate different types of errors. The respective error messages will appear if CONOPT is used as the NLP solver. Note that comments about the errors may be found in the C or FORTRAN source code.

Observe that several types of errors cannot be detected. Derivatives that are computed in the external module and are returned in positions that were not defined in the `sparsity` pattern in GAMS will be filtered out by the interface and will therefore not be detected. Similarly, derivatives that should be computed but are forgotten, may inherit values from the same derivatives in another equation computed earlier. Finally, fixed variables cannot be perturbed, thus errors related to these variables will usually not be detected.

4.49 GAMS Return Codes

The most convenient way to embed a GAMS program in a different program (e.g. C#, Java, Python, ...) is the object orient API to GAMS. A much simpler but less powerful way is to make a call to the GAMS executable (`gams.exe` (Windows) or `gams` (Unix)) with appropriate parameters from your program. Different languages and operating systems have different ways of accomplishing such a task. A common way to communicate a small piece of information from the GAMS program to the caller program is the *exit status* or *return code* (see e.g. [https://en.wikipedia.org/wiki/Exit_status] (https://en.wikipedia.org/wiki/Exit_status)). GAMS return codes allow the caller to get some information about the status of the finished GAMS job. Note that return codes do not provide information about a model inside the GAMS job: the model may have been infeasible or may have failed in another way while the return code says all is fine. In fact, there may be multiple solves in a GAMS job, so even conceptually it is not possible to return solution status codes in the return code. The user cannot explicitly set the return code but can trigger action (e.g. `abort 'stop';`) that result in a specific return code (here *execution error* (3)).

Note

In general, the value of zero for return codes denotes success and non-zero values denote failure.

We first demonstrate how to access return codes from within GAMS with a self-explanatory example and then list all return codes. GAMS has the ability to call other programs via the `$call` (compile time) and `execute` (execution time) commands. Naturally, GAMS can call GAMS in a recursive fashion. There are different methods to access the return code of such a sub-GAMS job:

```
$onecho > x.gms
set a /1,2,3/;
$offecho

* Compile time access inside to return values

* Example for non-zero return code
$call gams x.gms lo=0 this_causes_a_parameter_error_with_return_code_6=1 > %system.nullfile%

* Check the return code via if [not] errorlevel n
$if not errorlevel 1 $abort expect a errorlevel >= 1

* Access the return code as function value of function errorLevel
$eval MYERRORLEVEL errorLevel
$log %MYERRORLEVEL%

* Example for zero return code
$call gams x.gms lo=0 > %system.nullfile%

* Check the return code via if [not] errorlevel n
$if errorlevel 1 $abort expect a errorlevel <= 0

* Access the return code as function value of function errorLevel
$eval MYERRORLEVEL errorLevel
$log %MYERRORLEVEL%

* Runtime

* Example for non-zero return code
execute 'gams x.gms lo=0 this_causes_a_parameter_error_with_return_code_6=1 > %system.nullfile%';
```

```
* Access the return code as function value of function errorLevel
scalar myerrorlevel;
myerrorlevel = errorlevel;
display 'should be 6:', myerrorlevel;

* Example for zero return code
execute 'gams x.gms lo=0 > %system.nullfile%';

* Access the return code as function value of function errorLevel
myerrorlevel = errorlevel;
display 'should be 0:', myerrorlevel;
```

Command line interpreters or shells are a powerful way for job control and can naturally also run GAMS jobs. Here are two examples that demonstrate how to access (actually echo) the return code from GAMS in such environments:

Unix shell (e.g. `bash`):

```
$ gams mymodel ...
$ echo $?
```

Here `$?` is the environment variable that stores the return code from the last run.

Windows (`cmd.exe`):

```
C:\tmp> gams mymodel ...
C:\tmp> echo %errorlevel%
```

Here `%errorlevel%` is the environment variable that stores the return code from the last run.

Note

On UNIX, return codes are treated modulo 256, so the return code 400 will be 144 on Unix. The return code modulo 256 is given in parenthesis in the table, if different from the return code.

4.49.1 List of the Error/Return Codes

The following table gives the list of the GAMS return codes:

Return Code	Description
0	Normal return
1	Solver is to be called, the system should never return this number
2	There was a compilation error
3	There was an execution error
4	System limits were reached
5	There was a file error
6	There was a parameter error
7	There was a licensing error
8	There was a GAMS system error
9	GAMS could not be started

Return Code	Description
10	Out of memory
11	Out of disk
109	Could not create process/scratch directory
110	Too many process/scratch directories
112	Could not delete the process/scratch directory
113	Could not write the script `gamsnext`
114	Could not write the `parameter` file
115	Could not read environment variable
400 (144)	Could not spawn the GAMS language compiler (`gamscmex`)
401 (145)	Current directory (`curdir`) does not exist
402 (146)	Cannot set current directory (`curdir`)
404 (148)	Blank in system directory (UNIX only)
405 (149)	Blank in current directory (UNIX only)
406 (150)	Blank in scratch extension (`scrext`)
407 (151)	Unexpected `cmexRC`
408 (152)	Could not find the process directory (`procdir`)
409 (153)	CMEX library not be found (experimental)
410 (154)	Entry point in CMEX library could not be found (experimental)
411 (155)	Blank in process directory (UNIX only)
412 (156)	Blank in scratch directory (UNIX only)
909 (141)	Cannot add path / unknown UNIX environment / cannot set environment variable
1000 (232)	Driver error: incorrect command line parameters for `gams`
2000 (208)	Driver error: internal error: cannot install interrupt handler
3000 (184)	Driver error: problems getting current directory
4000 (160)	Driver error: internal error: GAMS compile and execute module not found
5000 (126)	Driver error: internal error: cannot load option handling library

Note that error 3000 is sometimes caused by specifying the current directory in Microsoft UNC format. The return codes smaller than 100 come from the GAMS compiler and execution system (`gamscmex`) while the codes above 100 come from the GAMS driver program (`gams`).

4.50 GAMS Data eXchange (GDX)

This document describes the **GDX** (**G**AMS **D**ata e**X**change) facilities available in GAMS. The GDX facilities provide basic functionalities for exchanging GAMS data such as read and write. In addition to these facilities, there are a number of GDX Tools for exchanging data between GAMS and other data sources as well as for performing specific operations on a GDX file.

A GDX file is a file that stores the values of one or more GAMS symbols such as sets, parameters variables and equations. GDX files can be used to prepare data for a GAMS model, present results of a GAMS model, store results of the same model using different parameters etc. A GDX file does not store a model formulation or executable statements. Among other usages a GDX file can also be used to prepare data for a GAMS model, pass results of a GAMS model into different programs, and pass results into GAMS from different programs.

GDX files are binary files that are portable between different platforms. They are written using the byte ordering native to the hardware platform they are created on, but can be read on a platform using a different byte ordering. See also General notes on GDX files .

4.50.1 Reading a GDX file

Reading a GDX file into a GAMS model can be done during the compile phase or the execution phase.

4.50.1.1 Compile Phase

During compilation, we can use Dollar Control Options to read data from a GDX file. Reading during the compile phase also allows us to define the elements of a set and the subsequent use of such a set as a domain. For a complete list of available Dollar Control Options for reading data from a GDX file into GAMS during compilation of a GAMS model please refer to Dollar Control Options for GDX Operations.

In addition to the chapters with examples linked from the list you will find further examples below.

4.50.1.2 Execution Phase

When reading data from a GDX file during execution phase the data in the GDX file will be the data present in the GDX file at the time that the statement is executed. The results of all prior calculations and the most recent solve for any model will be reflected. The statements to read data from a GDX file during execution phase are:

- execute_load
- execute_loaddc
- execute_loadpoint
- gdxLoad

execute_load

The `execute_load` statement acts like an assignment statement, except that it does not merge the data read with the current data; it is a full replacement. The same restrictions apply as in an assignment statement: we cannot assign to a set that is used as a domain, or to a set used as a loop control.

Sets defining domains cannot be loaded. However sets that are subsets of existing sets and do not define new elements can be loaded at execution time (Domain defining sets can be loaded at compile time using $load).

The statement with `execute_load` can be used in one of the following forms:

```
execute_load 'file_name', id1[, id2, ..., idn] ;
execute_load 'file_name', id1=gdxid1[, id2=gdxid2, ..., idn=gdxidn] ;
execute_load 'file_name', setid=* ;
```

where

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension `.gdx`; read from the current working directory)
id1, id2, ..., idn	Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional
id1=gdxid1, id2=gdxid2, ..., id2=gdxid2	Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2, ..., gdxidn in the GDX file; note that commas are optional

Note

- Items must be declared with Set, Parameter, Scalar, Variable or Equation statements before the `execute_load` appears.
- When loading data domain checking is not enforced so that when an item is resident in a GDX file for set elements not present in the current file these items are ignored and do not create errors or cause generation of any messages. The execute_loaddc variant checks to see that the domains match.

See [**load11**] and [**qp1x**] from the GAMS Model Library on how to use `execute_load`.

execute_loaddc

With `execute_loaddc` statement any domain violation will be reported and flagged as execution error. In contrast, the `execute_load` statement ignores all domain violations and loads only data that meets the domain restrictions. In addition to loading data for sets, parameters and variables, we can load a field of a variable into a parameter.

Warning: when loading a single field, all other fields are reset to their default value.

The statement with `execute_loaddc` can be used in one of the following forms:

```
execute_loaddc 'file_name', id1[, id2, ..., idn] ;
execute_loaddc 'file_name', id1=gdxid1[, id2=gdxid2, ..., idn=gdxidn] ;
```

where

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension `.gdx`; read from the current working directory)
id1, id2, ..., idn	Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional
id1=gdxid1, id2=gdxid2, ..., idn=gdxidn	Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2, ..., gdxidn in the GDX file; note that commas are optional
setid=*	Allow to load the universe of labels from a GDX file into a set. Note, that only labels known to the GAMS program will be loaded.

See [**load7**] example on how to use `execute_loaddc`.

execute_loadpoint

The `execute_loadpoint` is similar to execute_load, however, the new values are merged with the old values.

If no arguments besides the name of the GDX file are given, all variables and equations that match variables and equations of the calling GAMS programs will be merged with the GDX level and marginal values. Bounds, scales and priorities will remain unchanged. Note that implicitAssign can be particularly useful in this context.

If one or more symbols to be loaded are specified explicitly, values for these symbols will be merged. For variables and equations only the levels and marginals will be merged. To merge other variable or equation attributes like bounds, scales and priorities, they have to be listed explicitly (e.g. `execute_loadpoint 'file_name', x.lo;` to merge the lower bound of variable `x`).

The statement with `execute_loadpoint` can be used in one of the following forms:

```
execute_loadpoint 'file_name'[, id1, id2, ..., idn] ;
execute_loadpoint 'file_name'[, id1=gdxid1, id2=gdxid2, ..., idn=gdxidn] ;
```

where

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension `.gdx`; read from the current working directory)
id1, id2, ..., idn	Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional
id1=gdxid1, id2=gdxid2	Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2 in the GDX file; note that commas are optional

gdxLoad

By default, `gdxLoad` does the same as execute_load. However, while `execute_load` always replaces existing data and loads data filtered (so records with domain violations are ignored), the behavior of `gdxLoad` can be changed using the options replace and filtered.

If no arguments besides the name of the GDX file are given, all symbols that match symbols of the calling GAMS programs will be loaded. Note that implicitAssign can be particularly useful in this context.

The statement with `gdxLoad` can be used in one of the following forms:

```
gdxLoad 'file_name'[, id1, id2, ..., idn] ;
gdxLoad 'file_name'[, id1=gdxid1, id2=gdxid2, ..., idn=gdxidn] ;
```

where

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension `.gdx`; read from the current working directory)
id1, id2, ..., idn	Read GAMS symbols id1, id2, ..., idn from the GDX file; note that commas are optional
id1=gdxid1, id2=gdxid2, ..., idn=gdxidn	Read GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2, ..., gdxidn in the GDX file; note that commas are optional
setid=∗	Allow to load the universe of labels from a GDX file into a set. Note, that only labels known to the GAMS program will be loaded.

4.50.1.3 Example 1 - Reading a GDX File

The file `trnsport.gms` (from [**TRNSPORT**]) has been modified to use the demand data from an external source. Only the relevant declarations are shown.

The parameter `B` is read from the GDX file using the name 'demand', and only those elements that are in the domain `j` will be used. Values for parameter `B` that are outside the domain `j` will be ignored without generating any error messages.

```
* Example 1
Set
   j    markets  / new-york, chicago, topeka / ;
Parameter
   B(j) demand at market j in cases ;
$gdxin demanddata.gdx
$load  b=demand
$gdxin
```

4.50.1.4 Example 2 - Reading a GDX File

In this example, the set `J` is also read from the GDX file, and is used as the domain for parameter `B`. All elements read for the set `J` will be used. Values for the parameter `B` that are outside the domain J will be ignored. Note that the dimension of set `J` is set to one by specifying its domain.

```
* Example 2
$gdxin demanddata.gdx
Set
   J(*)    markets;
$load j=markets
Parameter
   B(j) demand at market j in cases ;
$load  b=demand
$gdxin
```

4.50.1.5 Example 3 - Reading a GDX File

The `$load` command without parameters can read a listing of all symbols in a GDX file. The following:

```
* Example 3
$gdxin trnsport.gdx
$load
```

writes the following to the listing file:

```
Content of GDX C:\XLSFUN\TRNSPORT.GDX

Number Type      Dim  Count  Name

    1 Set         1      2  i         canning plants
    2 Set         1      3  j         markets
    3 Parameter   1      2  a         capacity of plant i in cases
    4 Parameter   1      3  b         demand at market j in cases
    5 Parameter   2      6  d         distance in thousands of miles
    6 Parameter   0      1  f         freight in dollars per case per thousand miles
    7 Parameter   2      6  c         transport cost in thousands of dollars per case
    8 Variable    2      6  x         shipment quantities in cases
    9 Variable    0      1  z         total transportation costs in thousands of dollars
   10 Equation    0      1  cost      define objective function
   11 Equation    1      2  supply    observe supply limit at plant i
   12 Equation    1      3  demand    satisfy demand at market j
```

which lists the items present by `Type`, `Name`, Number of sets the item is defined over(`Dim`), number of elements in the file for this item (`Count`).

4.50.1.6 Example 4 - Reading a GDX File

Sometimes, a set is implicitly given by the elements of a parameter symbol. For example,

```
parameter a(i) / seattle 350, san-diego 600 / ;
```

in `trnsport.gms` implicitly defines the set of plants `i`. GAMS does not allow us to provide domain checked data, if the data for domain sets is unknown. So this code produces a compilation error:

```
Set i plant;
Parameter a(i) capacity / seattle 350, san-diego 600 /;
```

When entering data directly in the GAMS source adding the domain sets before the actual parameter declarations is usually not a problem, but when data comes from external sources (e.g. spreadsheets, databases, etc), this often results in an additional query to the database, spreadsheet etc. Nowadays, such data exchange happens mostly via the GD facility. With the domain load capability of the compile time load instructions ($load, $loadDC, $loadR, $loadM, $loadDCM, and $loadDCR) one can project an index position from a parameter or set symbol in the GDX container and load this slice into a one dimensional set. Here is a simple example:

```
Set i plant;
Parameter a(i) capacity;
$gdxin data
$load i<adata a=adata
```

This will try to load set elements from the GDX parameter symbol `adata` into the set `i` and next load the GDX parameter `adata` into the GAMS parameter `a`. The latter one is no problem anymore, since the data for set `i` is known when loading symbol `a`. GAMS will use the domain information stored in GDX of parameter adata to identify the index position to project on. If no appropriate domain information can be found in GDX, the GAMS compiler will generate an error. In such case the user can explicitly select an index position (here first index position) from the GDX symbol:

```
$load i<adata.dim1 a=adata
```

The automatic index position matching (i.e. no .dimN) using the domain information stored in GDX matches on the name of the set to be loaded and the domain set names stored in GDX for the symbol. The domain in GDX are searched from right to left (start with n=symbol dimension, then n-1, n-2, ...) and stops at the first match. With the projection symbol <=, the domain in GDX is searched from left to right. This follows the style of the GAMS run time projection operation:

```
option sym1<sym2, sym1<=sym2;
```

Here is an example how to load. The network is defined by the capacity parameter cap contained in a GDX container `net.gdx`:

```
parameter cap(n,n) / (1*3).4 5, 4.(5*9) 3 /;
```

The following code loads the entire node set n of the network as well as the nodes with outgoing (`out`) and incoming (`in`) arcs and the capacity `c`.

```
set n nodes, out(n), in(n);
parameter c(n,n) capacity;
$gdxin net
$loadM n<=cap n<cap
$loadDC out<cap.dim1 in<cap.dim2 c=cap
display n, out, in;
```

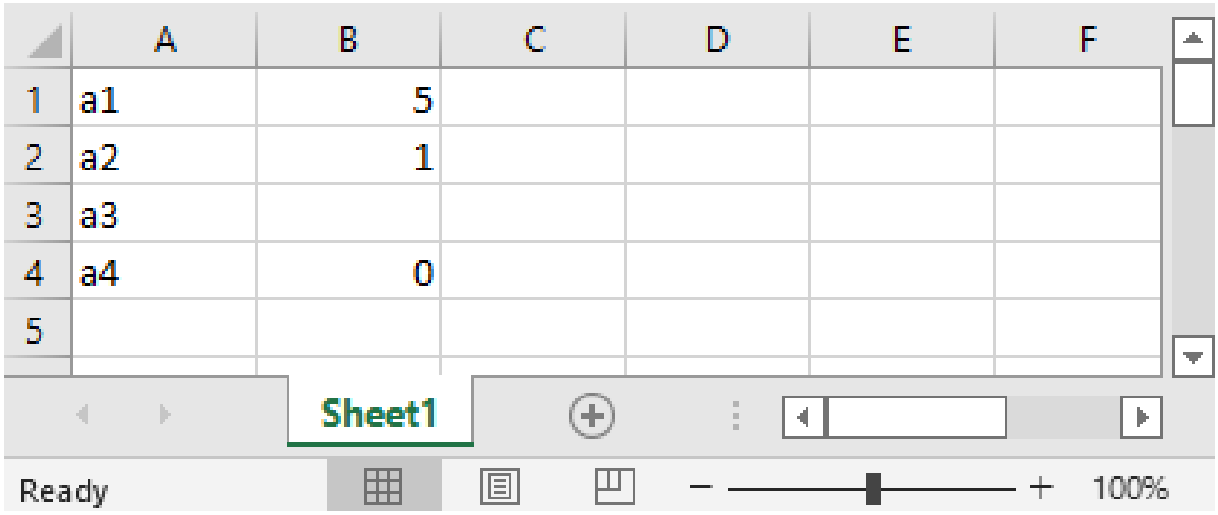
The listing file looks as follows:

```
----      6 SET n  nodes
1,    2,    3,    4,    5,    6,    7,    8,    9

----      6 SET out  Domain loaded from cap position 1
1,    2,    3,    4

----      6 SET in  Domain loaded from cap position 2
4,    5,    6,    7,    8,    9
```

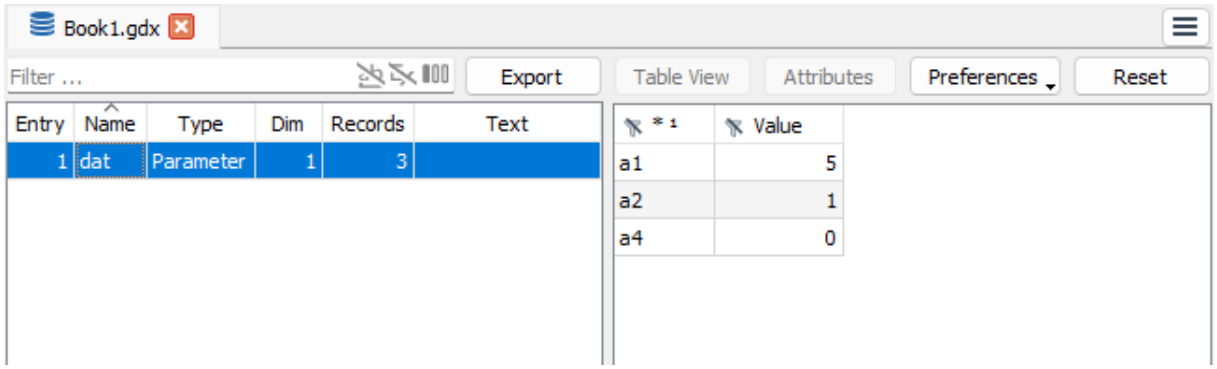
There is a potential issue with loading domains from parameters that have a zero value for some record. Since GAMS works with sparse data, it is sometime difficult to distinguish between a record with value zero (0) and the non-existence of a record. This is usually not a problem since we know the domain of a parameter and hence know all potential records. In case of using a parameter to define the domain this represents a source of confusion. Moreover, GDX has the capability of storing true zeros (most GDX tools like gdxxrw have options (Squeeze=Y or N) to either write a true 0 or squeeze the 0s when writing GDX). So in case GDX has a zero record, a domain load from such a parameter will include this record. Here is an example. The spreadsheet `Book1.xlsx` contains the following data:



The GDX utility GDXXRW with the following command line:

```
gdxxrw Book1.xlsx Squeeze=N par=dat rng=Sheet1!a1 rdim=1
```

reads the Excel data and produces a GDX container Book1.gdx with a one dimensional parameter dat(∗) which can be viewed in the GDX Viewer in GAMS Studio:



Notice that label a4 is present while label a3 is not part of GDX symbol dat. Without the Squeeze=N (the default is Squeeze=Y) we also would not have seen a4. If we load dat to define the domain (remember we need to use $load i<dat.dim1 since gdxxrw does not write domain information to GDX), we will miss out on a3 but have a4 (assuming `Squeeze=N`). Please also note that the zero record disappears on regular loading and is turned into an `EPS` when loading under `$OnEps`:

```
set i;
parameter a(i);
$gdxin Book1
$load i<dat.dim1 a=dat
display i,a;
parameter a0(i);
$OnEps
$load a0=dat
display a0;
```

This results in a listing file

```
----      5 SET i  Domain loaded from dat position 1
a1,    a2,    a4

----      5 PARAMETER a
a1 5.000,    a2 1.000

----      9 PARAMETER a0
a1 5.000,    a2 1.000,    a4   EPS
```

With gdxxrw parameter Squeeze=Y the listing file would look as follows:

```
----      5 SET i  Domain loaded from dat position 1
a1,    a2

----      5 PARAMETER a
a1 5.000,    a2 1.000

----      9 PARAMETER a0
a1 5.000,    a2 1.000
```

4.50.1.7 Example 5 - Reading a GDX File

The following statement reads gams element `k`, `d`, `f`, `a`, `b`, and `x` from file `trans2.gdx` during execution phase:

```
execute_loaddc 'tran2',k=j,d,f,a=sup,b=dem,x,supply;
```

where `k` be renamed from `j`, `a` be renamed from `sup`, and `b` be renamed from `dem` in the GDX file `tran2.gdx`.

Suppose there is one element `topeka` missing from the set definition but the element remains in the GDX file `tran2.gdx`. As a consequences the listing file contains an error message like:

```
**** GDX ERROR AT LINE 45 - Domain violation when loading from GDX file
**** 1 Domain errors for symbol k
     topeka

**** GDX ERROR AT LINE 45 - Domain violation when loading from GDX file
**** 2 Domain errors for symbol d
     seattle.topeka
     san-diego.topeka
```

and the job is aborted with an execution error.

Note

- domain errors occur whenever set element names are not spelled exactly the same as an element specified in the corresponding set in GAMS flagging alternative spellings or missing elements.
- domain errors do not arise when items are not specified with them set to zero (no entry for a set element leaves to a corresponding value of zero)

4.50.2 Writing a GDX file

Writing of GDX files in a GAMS model can be done during the compile phase or the execution phase. A GDX file can also be written after compilation and execution.

4.50.2.1 Compile Phase

During compilation, we can use a group of Dollar Control Options to write data to a GDX file. Writing during the compilation phase also allows us to define the elements of a set and the subsequent use of such a set as a domain. For a complete list of available Dollar Control Options for writing data to a GDX file during compilation of a GAMS model please refer to Dollar Control Options for GDX Operations.

In addition to the chapters with examples linked from the list you will find further examples below. Also see [**unload1**] - [**unload9**] and [**CompTimeWriteTrnsportGDX**] for more examples on how to use `$gdxOut` and `$unLoad`.

4.50.2.2 Execution Phase

When writing data to a GDX file during execution phase the data in the GDX file will be the data present in the GDX file at the time that the statement is executed. The results of all prior calculations and the most recent solve for any model will be reflected. The statements to write data to a GDX file during execution phase are

- execute_unload
- execute_unloaddi
- execute_unloadidx
- savepoint

execute_unload, execute_unloaddi, and execute_unloadidx

The `execute_unload` statement replaces an existing file with that name; it does not add symbols to or replace symbols in an existing GDX file. Without specifying any identifier, all sets, parameters, variables and equations will be written to the GDX file.

The `execute_unloaddi` statement replaces an existing file with that name; it does not add symbols to or replace symbols in an existing GDX file similar to execute_unload, but also writes the domains of all unloaded symbols to the same file.

The `execute_unloadidx` statement requires that each symbol written is a parameter; each parameter must have a domain specified for each index position. These domains have the requirement that they are formed using an integer sequence for the UELs that starts at 1 (one). The domain names are changed to indicate the size of each domain. This information is used when reading the data back from the GDX file using `$LoadIDX` during compilation. Using the special domain names, the UELs for the domains can be recovered without writing the domains to the GDX file; see example below.

The statement with `execute_unload` can be used in one of the following forms:

```
execute_unload  'file_name' , id1, id2, ..., idn ;
execute_unload  'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execute_unload  'file_name' , setid=* ;
```

The statement with execute_unloaddi can be used in one of the following forms:

```
execute_unloaddi 'file_name' , id1, id2, ..., idn ;
execute_unloaddi 'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execute_unloaddi 'file_name' , setid=* ;
```

The statement with execute_unloaddidx can be used in one of the following forms:

```
execute_unloadidx 'file_name' , id1, id2, ..., idn ;
execute_unloadidx 'file_name' , id1=gdxid1, id2=gdxid2, ... ;
execute_unloadidx 'file_name' , setid=* ;
```

where

Parameter(s)	Description
file_name	Specify the name of the GDX file (with or without the extension .gdx; written to from the current working directory)
id1, id2, ..., idn	Write GAMS symbols id1, id2, ..., idn into the GDX file
id1=gdxid1, id2=gdxid2	Write GAMS symbols id1, id2 with corresponding names gdxid1, gdxid2 into the GDX file

Note

- when only file_name is specified without other parameters all GAMS Symbols will be written into the GDX file file_name.
- The GAMS option gdxUELs controls which UELs are registered in file_name. With option gdxUELs = squeezed; (default) only the UELs that are required by the exported symbols are registered while all known UELs are registered if we set option gdxUELs = full;. See also [**unload10**].
- Variables and equations are always exported with all their attributes .l (level), .m (marginal), .lo (lower bound), .up (upper bound), .scale (scale factor). Specifying a suffix for variables or equations when calling execute_unload does not change this behavior. So the following two statements results in the same output:

  ```
  execute_unload 'dataL.gdx', x.L;
  execute_unload 'data.gdx', x;
  ```

See Example 2 - Writing a GDX file and [**qp1x**] on how to use execute_unload. See [**unload10**] on how to use execute_unloaddi. See Example 3 - Writing a GDX file on how to use execute_unloadidx.

Savepoint

A GDX file containing the marginals and levels for all variables and equations at the end of a solve will be created with the command line parameter, model attribute or option statement Savepoint. One can save the solution information from the last solve or from every solve. The points that are saved can be used to provide an advanced basis, integer program starting point or NLP starting point.

The basic command line form is:

```
gams mymodelname Savepoint=number
```

the model attribute form is

```
modelname.savepoint=number;
```

and the option statement form is

```
option savepoint=number
```

where

- when number equals 1/3 a point gdx file is saved from the last solution collected in the GAMS model and the file name will be `modelname_p.gdx` where model name is the name of the model identified in the solve statement.
- when number equals 2/4 a point gdx file is saved from every solve in the GAMS model and the file name will be `modelname_pnn.gdx` where model name is the name of the model identified in the solve statement and nn is the internal number of the solve. Thus if 10 solves occur one will get 10 files named `modelname_p1.gdx` through `modelname_p10.gdx`.

Note

When solving asynchronously, one should keep in mind, that the internal numbers mentioned for `savepoint=2/4` are generated when submitting the model, not when collecting it. And with `savepoint=1/3` it is the last solution collected, not the last model submitted that is written to the savepoint.

The following example:

```
model firm / all /;
firm.savepoint=1;;
solve firm using LP maximizing objfun;
```

saved a point gdx file `firm_p.gdx`.

and:

```
model transport /all/ ;
option savepoint=2;
set newseattle /s1,s2/;
parameter datador(newseattle) /s1 350, s2 450/;

loop(newseattle,
    a("seattle")=datador(newseattle);
    Solve transport using lp minimizing z ;
);
Display x.l, x.m ;
```

saved two point gdx files `transport_p1.gdx` and `transport_p2.gdx`.

4.50.2.3 Example 1 - Writing a GDX file

This example has modified the file `trnsport.gms` from [**TRNSPORT**] by adding the following statements after the last line.

```
...[TRNSPORT]...

d(i,j)=d(i,j)*10;

$gdxout tran
$unload i j
$unload d
$unload f
$unload b=dem a=sup
$gdxout
```

This example creates the GDX file `tran.gdx` containing the data for the sets `i` and `j` as well as the parameters `d`, `f`, `a` and `b` during the compile time, when `a` and `b` have been renamed in the GDX file to `dem` and `sup`. Also note the parameter `d` will not have been multiplied by 10 but rather take on their compile time value.

An `$unload` statement above can specify more than one symbol to be written to a GDX file and the similar result could also be accomplished using:

```
...[TRNSPORT]...

d(i,j)=d(i,j)*10;

$gdxout tran
$unload i j d f b=dem a=sup
$gdxout
```

4.50.2.4 Example 2 - Writing a GDX file

This example has modified from the file `trnsport.gms` (from [**TRNSPORT**]) by adding the following statement right after the solve statement.

```
...[TRNSPORT]...

Solve trnsport using LP minimizing Z;
execute_unload 'results.gdx', i, j, z, x;
```

After solving the model, the sets `i` and `j` and the variables `z` and `x` with all the data available after the solve.

4.50.2.5 Example 3 - Writing a GDX file

This example shows the use of the indexed write and read data during execution phase:

```
Set I /1*100/,
    J /1*50 /;
parameter A(I,J) /1.1=11, 1.9=19, 10.1=101/;

execute_unloadidx 'data.gdx', A;
```

Viewing the file `data.gdx` in GAMS Studio shows the modified domain information:

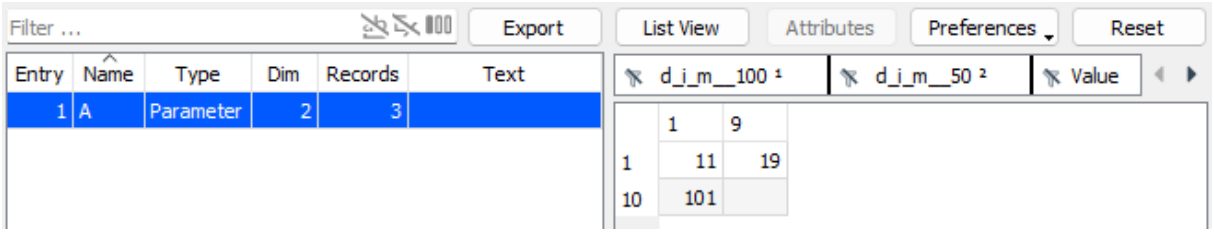


Figure 4.2 GAMS Studio showing data.gdx note the modified domains

To read from `data`.gdx, we use the indexed read:

```
Set I,J;
parameter A(I,J);
* load the data
$gdxin data.gdx
$loadidx A
$gdxin
* write all symbols so we can inspect in GAMS Studio
$gdxout test.gdx
$unload
$gdxout

execute_unloadidx 'data.gdx', A;
```

Viewing the file `test.gdx` in GAMS Studio shows that the domains have been populated:

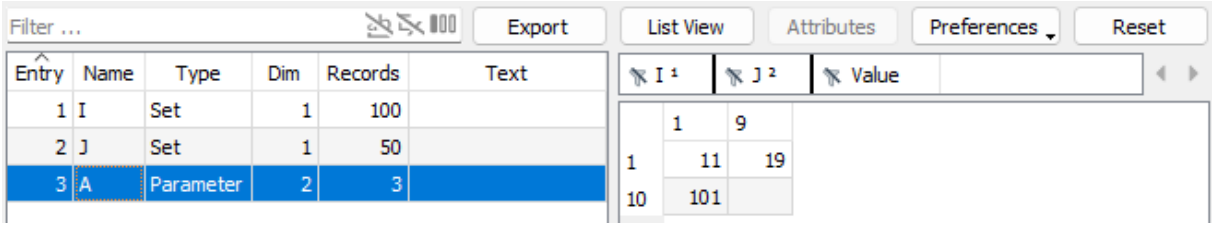

Figure 4.3 View test.gdx in GAMS Studio

4.50.2.6 Writing a GDX file after compilation or execution

A GDX file containing all data items resident at the end of the run of a GAMS code can be created using the gdx command line option either via GAMS call at the command line or via the GAMS Parameter Editor in GAMS Studio. This will cause all sets, parameters, variables and equations to be written to the GDX file.

For example:

```
gams mymodelname gdx=gdxfile_name
```

Or

```
gams mymodelname action=c gdx=gdxfile_name
```

where

- `mymodelname` specifies the name of the GAMS file
- `gdxfile_name` gives the file name and possible path where the GDX file is to be retained. When no path is specified the default directory is the current working directory where the main GAMS file associated with the project is executed via Studio.
- action=c indicates request to write a GDX file after compilation only
- setting GDX to the string "default" (i.e.`gdx=default`) causes GAMS to create a GDX file with the GAMS file root name and a GDX extension. Thus

  ```
  gams trnsport gdx=default
  ```

  will cause GAMS to write the gdx file `trnsport.gdx`.

When GAMS Studio is used, the GDX file creation can be invoked by running the main file with GDX creation.

Note

- When this option is used the GDX file is created just at the end of the GAMS execution so the data written will contain the current values for all sets, parameters, variables and equations that are on hand at the end of the GAMS job.
- The GDX data for the variables and equations contains the levels, marginals, lower bounds, upper bounds and scales for each item.
- This yields a file that is automatically opened in Studio.

Using the gdx command line parameter when running the model via Studio, the process log will show the GDX file name in green indicating that the file can be opened by clicking on the file link. See also Inspecting contents with GAMS Studio.

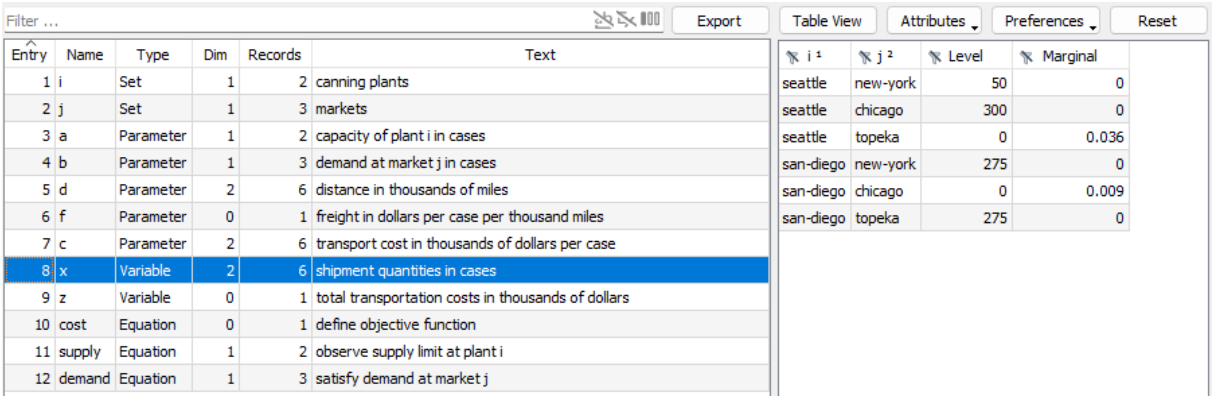
4.50.3 Inspecting contents of a GDX file

In addition to reading data from a GDX file during compile phase or execution phase there are a few ways to examine the contents of a GDX file.

- Inspecting contents with GAMS Studio
- Inspecting contents with $load
- Inspecting contents with GDXDUMP
- Inspecting contents with GDXDIFF

4.50.3.1 Inspecting contents with GAMS Studio

GAMS Studio has a built-in GDX Viewer, which offers extensive possibilities to view the content of a GDX file in a list or in a tabular view. For multidimensional data, you can rearrange the tabular view by simply dragging a column to a different position. You can also filter and sort, and quickly copy data to Excel or other spreadsheet programs. The GDX viewer is fast, which allows analysing big datasets. Learn more about the GDX viewer here.



Entry	Name	Type	Dim	Records	Text
1	i	Set	1	2	canning plants
2	j	Set	1	3	markets
3	a	Parameter	1	2	capacity of plant i in cases
4	b	Parameter	1	3	demand at market j in cases
5	d	Parameter	2	6	distance in thousands of miles
6	f	Parameter	0	1	freight in dollars per case per thousand miles
7	c	Parameter	2	6	transport cost in thousands of dollars per case
8	x	Variable	2	6	shipment quantities in cases
9	z	Variable	0	1	total transportation costs in thousands of dollars
10	cost	Equation	0	1	define objective function
11	supply	Equation	1	2	observe supply limit at plant i
12	demand	Equation	1	3	satisfy demand at market j

i [1]	j [2]	Level	Marginal
seattle	new-york	50	0
seattle	chicago	300	0
seattle	topeka	0	0.036
san-diego	new-york	275	0
san-diego	chicago	0	0.009
san-diego	topeka	275	0

4.50.3.2 Inspecting contents with $load

The $load command without any parameters will show a listing of all symbols in the GDX file. See Example 3 - Reading a GDX File on how to use $load to get a listing of all symbols.

4.50.3.3 Inspecting contents with GDXDUMP

The GDXDUMP utility can list the symbols in the file and it also can write sets and parameters formatted as a GAMS data statement.

```
gdxdump gdxfile_name format=choice symb=optional choice
```

where

- the `gdxfile_name` is the name of the GDX file to write data from.

- the output is created to the screen not to a file. One can also write the GDX file contents into a GAMS file using the command:

```
gdxdump gdxfile_name > filetouse.gms
```

- Data for a selected set, parameter, variable or equation (under all three of the output options when a specific item is named using the SYMB option)
- Data for all sets, parameters, variables and equations (Under normal option when the SYMB is not used)
- Data on solution items (variables and equations) formatted in a fashion suitable for import as a basis in another GAMS program where the marginals and levels are output. All of the scalars, sets and parameters (tables) in a GDX file to standard output formatted as a GAMS program with data statements or in CSV format. It skips information for variables and equations.
- Under the format=CSV choice it only creates output when a symbol is selected using the SYMB syntax.
- Under the format=CSV choice when the requested symbol is a variable or an equation one only gets the level values not the marginal, under the other formats one gets all items.
- Under the format=gamsbas choice one gets all variables and equations when the SYMB syntax is not used.

Suppose we wish to write out the GDX file `tran.gdx`, then we would use the command:

```
gdxdump tran
```

See more Examples on inspecting contents with GDXDUMP.

4.50.3.4 Inspecting contents with GDXDIFF

The GDXDIFF utility can be used to compare two GDX files by creating a third GDX file containing a list of differences between all symbols. In particular for all items with the same name, type and dimension in the two GDX files the differences in numerical values are written to a third GDX file with A summary report written to standard output (ordinarily the LOG file).

Besides the integrated solution in GAMS Studio, this utility can be used either at command line, or by $Call, or execute command.

```
gdxdiff file1 file2 {diffile} {Eps = value} {RelEps = value} {Field = FieldName} {ID=Identifier}
```

GDXDIFF requires the first two file name parameters,

- File1 Name of the first GDX file
- File2 Name of the second GDX file

The remaining parameters are optional

- Diffile An optional third file name that is the name of the GDX file that contains the differences found in the parameters. If that parameter, is absent the file will be named 'diffile.gdx' and placed in the current directory.
- Eps = value A tolerance that is the maximum amount that two numbers may differ by ie given a1 and a2 then abs(a1-a2) is reported as different if it exceeds this tolerance
- RelEps = value A tolerance that is the maximum percentage amount that two numbers may differ by ie given a1 and a2 then abs(a1-a2)/max(abs(a1),abs(a2)) is reported as different if it exceeds this tolerance.
- Field = FieldName A field that if specified limits doen between the information for variables and equations to specific attributes (Lo, L, Up, M, Scale and Prior)
- ID=Identifier Limits the comparisons to selected items; items not specified will be ignored. Multiple items can be specified as: ID=id1 ID=id2 or ID="id1 id2"

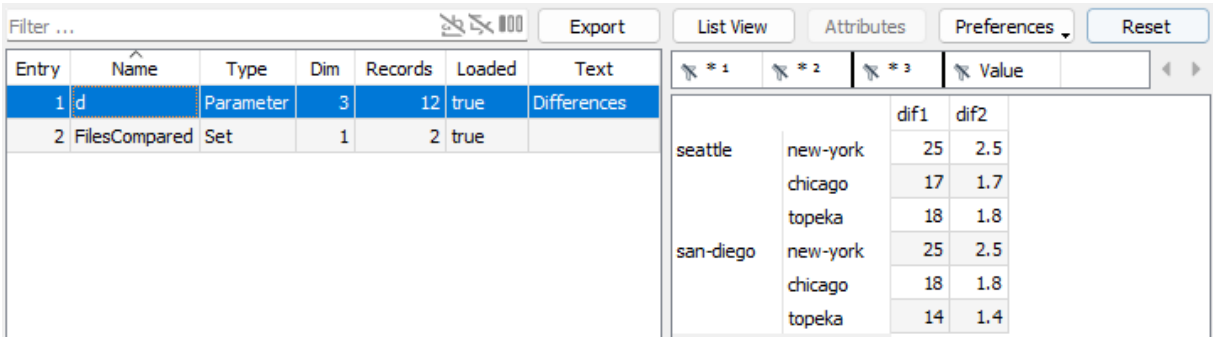
Suppose we wish to compare the GDX files `tran.gdx` and `tran2.gdx`, then we would use the command:

```
gdxdiff tran tran2
```

In turn the output to standard output (nominally the terminal screen) appears as follows:

```
Summary of differences:
     d   Data is different
   dem   Keys are different
   sup   Keys are different
supply   Symbol not found in file 1
     x   Symbol not found in file 1
```

and summarizes the differences found. Simultaneously the file `diffile.gdx` when examined in GAMS Studio contains the following:



which reports on the differences found in the two files.

Note

- Some new coding is introduced in the difference GDX file. Namely a new dimension is added to the parameters being compared which can contain 4 entries
  - dif1 indicates that the entry occurs in both files and shows the value found in the first file.
  - dif2 indicates that the entry occurs in both files and shows the value found in the second file.
  - ins1 indicates that the entry only occurs in the first files and shows the value found.
  - ins2 indicates that the entry only occurs in the second file and shows the value found.
- Only named items with the same name, type and dimension will be compared in the `diffile.gdx` output. Named items that are new or are deleted will only appear in the standard output summary report

See more Examples on inspecting contents with GDXDIFF.

4.50.4 General notes on GDX files

There are several things worth noting about GDX files:

- When working with GDX only one GDX file can be open at a time.
- When reading data from a GDX file, the symbol to be read must be declared before the reading statement appears.
- When the GDX file to be written has the same name as an existing GDX file the existing file will be overwritten. The resultant file will only contain the new data; there is no merge or append option.
- The $unload command to write a GDX during compile time will only write out data defined in the compilation at the point where the command appears. No results of any solves or calculations done within the current GAMS program will be reported with $unload. This is not true when using the execute_unload or execute_unloaddi commands.
- Both execute_unload and execute_unloaddi will write out data defined in the execution sequence at the point where the command appears. The results of the most recent solve command and any parameter calculations occurring before the GDX write will be reported.
- Any subsequent execute_unload or execute_unloaddi to a GDX file written earlier will totally overwrite that file so care must be taken to write all wanted information in the last appearing execute_unload or execute_unloaddi.
- A command line GDX write using the `gdx=file_name` command line parameter will write out data defined at the end of the execution sequence. The results of the most recent solve and any parameter calculations will be reported.
- When loading data domain checking will not be enforced. When items are resident in the GDX file for set elements that are not present in the current file these items will be ignored. GAMS will not generate any message telling you which items are ignored.
- Options Savepoint and execute_Loadpoint provide a GDX way of saving and loading a basis.
- The contents as they differ between GDX files can be examined with GDXMERGE or GDXDIFF.
- Starting with GAMS version 22.3, gdx files can be written in a compressed format unless the environment variable `GDXCOMPRESS` is set to zero. A value of 1 indicates compression.
- GDX files from a different GAMS version can possibly be incompatible due to compression among other changes. A current GAMS system can read all older GDX file formats. GDX files can be converted to a compressed format or an older format using GDXCOPY.
- Users can also write their own programs accessing data in a GDX file via the `expert-level GDX API` using `gdxcclib` library.

4.50.5 GAMS Data eXchange Tools

A number of GDX based tools and GDX related tools are included in the GAMS distribution and maintained by GAMS. See also Tools Manuals.

- The data exchange tools provide functionality to exchange data between GAMS and other data sources.
- The GDX service tools operate directly on GDX containers.
- Some of Data transformation tools perform very specific data transformation tasks that are either awkward or inefficient to implement in GAMS directly.

Some utilities are avaiable only on specific platform. See Supported Platforms for more details.

4.51 Extended Mathematical Programming (EMP)

Extended Mathematical Programming (EMP) is an extension to algebraic modeling languages that facilitates the automatic reformulation of new model types as models in more established mathematical programming classes, allowing them to be solved by mature solver algorithms. A number of important problem classes can be solved, e.g. Nash games and equilibria, bilevel programs, Disjunctive Programs and Stochastic Programs. EMP is independent of the modeling language used but is currently implemented only in GAMS. The new types of problems modeled with EMP are reformulated, using the GAMS solver JAMS, as well established types of problems, and the reformulated models are passed to a suitable GAMS solver to be solved.

EMP models are defined by information taken from two places: the traditional model definition and a text file containing annotations or additional information. The usual model definition contains variables, constraints and/or functions, and perhaps also an objective or matching information. Additional annotations to specify relationships that don't fit within this traditional definition are taken from the EMP info file. For example, the constraints for two optimizing agents in a competitive game can be specified with traditional algebra, while the structure (who owns what variables and constraints) can be specified in the info file. Together, this allows large, complex models to be specified in a convenient, precise, and flexible way.

This chapter is organized as follows.

Note

- At the end of each section we present and discuss the general syntax that EMP provides to write the annotations for that particular problem type. We use the usual GAMS syntax symbols: `[ ]` (the enclosed construct is optional), { } (the enclosed construct may be repeated zero or more times) and | (exclusive `OR`).
- Many EMP model examples are available in the **GAMS EMP Library**.

4.51.1 EMP Annotations: the EMP Info File

EMP models are defined by both the usual content of a GAMS model and annotations found in a simple text file named `emp.info` (aka the EMP info file). It is often most convenient to create this file via the GAMS put writing facility. The annotations primarily serve to *define* the model (e.g. to specify that a variable `u` is really the dual multiplier for a constraint `g`) but can also specify how a solver should process the model. The annotations make use of EMP keywords to do this.

A simple example will serve as illustration. Consider the following NLP:

$$\begin{array}{ll} \text{Min}_{x,y,z} & -3x + xy \\ \text{s.t.} & x + y \leq 1 \\ & x + y - z = 2 \\ & x, y \geq 0 \end{array} \tag{1}$$

We will use EMP annotations to automatically generate the first order conditions (KKT conditions) of this NLP and thus reformulate the NLP as an MCP:

```
Variables          f, z;
Positive Variables x, y;

Equations g, h, defobj;

g..       x + y =l= 1;
h..       x + y - z =e= 2;
defobj..  f =e= -3*x + x*y;

Model comp / defobj, g, h /;

File info / '%emp.info%' /;
putclose info / 'modeltype mcp';

solve comp using EMP minimizing f;
```

Observe that the model is defined in the usual way and the file `emp.info` contains just one line: `modeltype mcp`. The EMP keyword `modeltype` indicates that the value following the keyword is the model type to be used for the reformulation. In this example the model type is `mcp`. Here this specification is required: the sole point of our EMP annotations is to generate an MCP and not (as is usually the case) to define the model. Usually, the model algebra and annotations together imply the type of the reformulated model and so no `modeltype` specification is required or wanted. Finally, note that the model type in the solve statement is `EMP:` this is typical.

The solver JAMS implements the EMP framework. It processes the model and the annotations, automatically reformulates the original EMP model as a model of a different (more easily solved) type, passes the reformulated model on to an appropriate subsolver, and maps the resulting solution back into the original problem space.

In case users wish to inspect the (scalar) reformulated model, the JAMS option `FileName` may be used to specify the name of the file containing this model. Adding the following lines *before* the solve statement in the GAMS code above will cause the MCP reformulation to be saved in the file `myReform.gms`.

```
File empopt / 'jams.opt' /;
comp.optfile = 1;
putclose empopt / 'FileName myReform.gms';
```

The listing file will contain some additional information - the *EMP Summary* - as part of the output for each EMP model solved. We provide details on the EMP summary for each reformulation that we discuss below.

4.51.2 Soft Constraints

In many cases modelers wish to relax certain constraints: violation of these constraints is allowed but is associated with a well-defined penalty. The constraints that are allowed to be violated are called *soft constraints* and the constraints that continue to hold are called *hard constraints*.

In this section we present a mathematical formulation of soft constraints, give an example of how soft constraints can be modeled with GAMS EMP and introduce the EMP annotations specific to soft constraints.

4.51.2.1 Soft Constraints: Mathematical Formulation

A general formulation of a constrained minimization problem is:

$$\begin{array}{ll} \text{Min}_{x\in\mathbb{R}^n} & f(x) \\ \text{s.t.} & c_i(x) \leq 0, \quad \forall i \in \mathcal{I}, \end{array} \tag{2}$$

where f and the functions c_i are smooth, real-valued functions on a subset of $\mathbb{R}^n$ and $\mathcal{I}$ is a finite set of indices. Note that in this problem all feasible solutions must satisfiy all constraints c_i.

Now assume that some constraints are allowed to be violated (i.e. made soft), while the remaining constraints continue to hold for all feasible solutions. The soft constraints are associated with a *penalty function* that is added to the objective function. Since we have a minimization problem, the effect will be a balance or compromise between competing goals: minimizing the objective and minimizing the penalty functions.

Note

> The penalty terms for soft constraints are *added* to the objective function in a minimization problem and *subtracted* in a maximization problem.

Let $\mathcal{L} \in \mathcal{I}$ be the set of indices for the soft constraints: this imples $\mathcal{M} := \mathcal{I} \setminus \mathcal{L}$ is the index set for the hard constraints. Problem (2) becomes:

$$\begin{array}{ll} \text{Min}_{x\in\mathbb{R}^n} & f(x) + \sum_{i\in\mathcal{L}} w_i\, g_i\left(c_i(x)\right) \\ \text{s.t.} & c_i(x) \leq 0, \quad \forall i \in \mathcal{M}, \end{array} \tag{3}$$

where the penalty functions g_i are real-valued functions of $c_i(x)$, $i \in \mathcal{L}$. As we will see later, EMP has implementations of the following penalty functions: absolute value, least squares, and the maximum of a term and zero. Further, w_i is a multiplier associated with each penalty term, also called the *weight*. The weights facilitate prioritizing soft constraints: the weight of more important constraints will be greater than the weight of lesser constraints.

4.51.2.2 Soft Constraints with EMP: A Simple Example

The following simple example is adapted from the JAMS solver manual:

$$\begin{array}{ll} \text{Min}_{x_1,x_2} & -x_1^2 \\ \text{s.t.} & \log(x_1) = 1 \\ & x_2^2 \geq 2 \\ & 3x_1 + x_2 \leq 5 \\ & x_1,\, x_2 \geq 0 \end{array} \tag{4}$$

This problem can be formulated in GAMS as follows:

```
Positive Variables x1, x2;
Variables          obj;

Equations f0 "objective function", f1, f2, f3;

f0..   obj       =e= -sqr(x1);
f1..   log(x1)   =e= 1;
f2..   sqr(x2)   =g= 2;
f3..   3*x1 + x2 =l= 5;

Model m /all/;

x1.l = 1; x2.l = 1;

solve m using NLP min obj;
```

Note that this problem has no feasible solution. Thus we choose to relax the first two constraints by adding a penalty for their violation to the objective function. We also weight the relative importance or priority of the objective and the violations of these two constraints by introducing weights to go with these penalty functions. The resulting problem reads as follows:

$$\begin{array}{ll} \text{Min}_{x_1,x_2} & -x_1^2 + 5\,\|\log(x_1) - 1\|^2 + 2\max(x_2^2 - 2, 0) \\ \text{s.t.} & 3x_1 + x_2 \leq 5 \\ & x_1,\, x_2 \geq 0 \end{array} \tag{5}$$

Note that the first constraint is replaced by a least squares penalty of $(log(x_1) - 1)$ with a weight of 5 and the second constraint by the penalty term $\max(x_2^2 - 2, 0)$ with a weight of 2. However, the "max" penalty makes the objective function non-smooth. To rectify this, we implement the "max" penalty by introducing a new variable v that, due to its bounds and the direction of optimization, will take the value $\max(x_2^2 - 2, 0)$ at the solution. The result is:

$$\begin{array}{ll} \text{Min}_{x_1,x_2,v} & -x_1^2 + 5\,\|\log(x_1) - 1\|^2 + 2v \\ \text{s.t.} & 3x_1 + x_2 \leq 5 \\ & x_1,\, x_2 \geq 0 \\ & v \geq x_2^2 - 2 \\ & v \geq 0 \end{array} \tag{6}$$

This reformulation could of course be implemented directly in GAMS using standard GAMS syntax, but the EMP solution is easier to create and maintain, to read and understand, and to scale upwards as problem size and complexity increase. For the latter, we can simply add the following EMP annotations and updated solve statement (to specify solution as an `EMP`) to the GAMS code above:

```
File soft / '%emp.info%' /;
put soft;
$onput
adjustequ
f1 sqr 5
f2 maxz 2
$offput
putclose;
solve m using EMP min obj;
```

Note that the EMP annotations contain three lines: the first line, containing the EMP keyword `adjustequ` , indicates that the lines that follow specify soft constraints, i.e. equations to be converted to penalty terms; the second line specifies the name of the first soft constraint `f1`, the penalty function to use, and - optionally - the weight; and similarly the third line specifies the name of the second soft constraint `f2`, the penalty function to use, and the weight.

The solver JAMS will use the information in the EMP annotations to automatically reformulate problem (4) as problem (6) and pass it along to an NLP subsolver. The EMP Summary produced by JAMS will contain the following line:

```
--- EMP Summary
    ...
    Adjusted Constraint = 2
    ...
```

This output reflects that indeed two constraints were "adjusted", i.e. converted to penalty terms in the objective function.

4.51.2.3 EMP Syntax for Soft Constraints

The EMP framework provides the following general syntax to specify constraints that are converted to soft constraints:

```
AdjustEqu equ abs|sqr|maxz {weight}
         {equ abs|sqr|maxz {weight}}
```

The EMP keyword `AdjustEqu` indicates that the lines that follow specify equations that are "adjusted": they are moved from constraints to penalty terms in the objective function. `Equ` is the name of the equation to penalize, while the three EMP keywords that follow indicate the penalty function to use. If not specified, the weight used defaults to 1. For an example, see above or the model **[SIMPENLP]** in the GAMS EMP Model Library.

4.51.3 Variational Inequalities (VI)

Variational inequalities provide a general mathematical framework for many problems arising in optimization. For example, constrained optimization problems like LP and NLP are special cases of VI, and systems of equations and complementarity problems can be cast as VI. Thus VI problems have many applications, including those in transportation networks, signal processing, regression analysis, and game theory.

In this section we present a mathematical formulation of VI, give an example of how VI can be modeled with GAMS EMP, and introduce the EMP annotations specific to VI. Note that to fully and properly understand some of this section, the introduction to MCP provides a useful background.

4.51.3.1 Variational Inequalities: Mathematical Formulation

For a given continuous function $F : \mathbb{R}^n \to \mathbb{R}^n$ and a fixed closed convex set $K \subset \mathbb{R}^n$ the variational inequality problem $VI(F, K)$ is to find a point $x^* \in K$ such that:

$$\langle F(x^*), (x - x^*)\rangle \geq 0, \quad \forall x \in K, \tag{7}$$

where $\langle \cdot, \cdot \rangle$ denotes the usual inner product.

Observe that the VI generalizes many problem classes:

- If $F(x) = 0$ and $K \equiv \mathbb{R}^n$, the VI is a system of nonlinear equations.
- If $F(x) = \bigtriangledown f(x)$, the VI is a convex optimization problem.
- If $F(x) = \bigtriangledown f(x)$ and $K = \{x \,|\, Ax = b, Hx \leq h\}$, the VI is an NLP.
- If $F(x) = \bigtriangledown f(x) = p$ and $K = \{x \,|\, Ax = b, Hx \leq h\}$, the VI is an LP.
- If the feasible region is a box $B = \{x \in \mathbb{R}^n | \, l_i \leq x_i \leq u_i, \text{ for } i = 1, \ldots, n\}$, with $l_i \leq u_i,\ l_i \in \mathbb{R} \cup \{-\infty\}$ and $u_i \in \mathbb{R} \cup \{\infty\}$, the VI is an MCP, where $x^* \in B$ is a solution of the respective MCP if for each $i = 1, \ldots, n$ one of the following conditions holds:

$$\begin{array}{lll} F_i(x^*) = 0 & \text{and} & l_i \leq x_i^* \leq u_i, \\ F_i(x^*) > 0 & \text{and} & x_i^* = l_i, \\ F_i(x^*) < 0 & \text{and} & x_i^* = u_i. \end{array} \tag{4.18}$$

Note that the set K is frequently defined in the following way:

$$K = \{x \,|\, x \geq 0,\ h(x) \geq 0\}. \tag{8}$$

Further, note that the $VI(F, K)$ represents a wider range of problems than classical optimization whenever $F(x) \neq \bigtriangledown f(x)$ for some objective function f (or equivalently, the Jacobian of F is not symmetric). For example, problems that can be cast as VI include (generalized) Nash games and Nash equilibrium problems, systems of equations, complementarity problems, and fixed-point problems.

4.51.3.2 Variational Inequalities with EMP: A Simple Example

Consider the following simple three dimensional linear example (adapted from Yashtini & Malek (2007) [207]. Let

$$F(x) = \begin{bmatrix} 22x_1 - 2x_2 + 6x_3 - 4 \\ 2x_1 + 2x_2 \\ 6x_1 + 2x_3 \end{bmatrix}, \; K = \{x \in \mathbb{R}^{\not\models} \,|\, x_1 - x_2 \geq 1,\ -3x_1 - x_3 \geq -4,\ 2x_1 + 2x_2 + x_3 = 0,\ l \leq x \leq u\}, \tag{9}$$

where $l = (-6, -6, -6)^T$, $u = (6, 6, 6)^T$. N.B.: F is not the gradient of any function $\mathbb{R}^3 \to \mathbb{R}$. This $VI(F, K)$ has a unique solution: $x = (2/3, -1/3, -2/3)$. The problem can be implemented in GAMS with EMP as follows:

```
Set      i /1*3/;
Variable x(i);

x.lo(i) = -6;
x.up(i) =  6;

Equations F(i), h1, h2, h3;

F(i)..   (22*x('1') - 2*x('2') + 6*x('3') - 4)$sameas(i,'1')
         + (2*x('1') + 2*x('2'))$sameas(i,'2')
         + (6*x('1') + 3*x('3'))$sameas(i,'3')
         =n= 0;

h1..     x('1') -x('2') =g= 1;

h2..     -3*x('1') - x('3') =g= -4;

h3..     2*x('1') + 2*x('2') + x('3') =e= 0;

Model linVI / F, h1, h2, h3 /;

File annotations /'%emp.info%'/;
put annotations;
putclose 'vi F x h1 h2 h3';

solve linVI using EMP;
```

Observe that the function F and the constraints h are formulated using standard GAMS syntax. F is implemented as an equation of type =n=, which does not imply or enforce any relationship between the left-hand side and the right-hand side. Instead, this relationship is implied by the position of the matching variables (given in the EMP info file) relative to their bounds. The annotations in the EMP info file define the structure of the VI: what functions are matched to what variables, and what constraints serve to define the set K. The EMP keyword `vi` indicates that the model is a VI, that the VI function `F` is matched to the variable `x`, and that the constraints `h1 h2 h3` define the set K.

Alternatively, the EMP annotations could be written as follows:

```
putclose 'vi F x';
```

Here the equations after the equation-variable pair are omitted. This is acceptable, since by default any equations that are part of the model but are not matched with a variable are automatically used to define the set K.

Since VI problems have no objective, the short form of the solve statement is used.

The solver JAMS will reformulate the VI as an MCP and pass this on to an MCP subsolver. The EMP Summary produced by JAMS will contain the following line:

```
--- EMP Summary
    ...
    VI Functions        = 3
    ...
```

This output reflects the fact that there were three VI functions in the model above, one for each member of the set `i`.

Note that there are several VI models in the GAMS EMP Library. For example, the models [**SIMPLEVI**] and [**VI_MCP**] demonstrate how some models can be specified using either MCP or VI syntax. A simple nonlinear VI is given in model [**SIMPLEVI2**]. As the transportation model is so well known, model [**TRANSVI**] demonstrates how it can be cast as a VI.

4.51.3.3 EMP Syntax for Variational Inequalities

The general syntax of the EMP annotations used to specify variational inequalities is as follows:

```
VI [{var|*}] { [-] equ var} [{[-] equ}]
```

The EMP keyword `VI` indicates that this is a variational inequality specification. The core of the VI specification is the (list of) equation-variable pair(s): the other parts are optional. A pair matches the equation `equ` with the variable `var`. This indicates that `equ` defines part of the VI function F, and that these rows of F are perpendicular to columns taken from `var`. Multiple equation-variable pairs are allowed. The optional variables before the pairs are called *preceding variables*. These are variables that appear (and are often defined by) the constraints of the model, but they are not matched explicitly via the VI function F. Instead, they are automatically matched with the zero function. See model **[ZEROFUNC]** for an example and a more detailed discussion. The optional equations after the equation-variable pairs are called *trailing equations*. They define the set K and may be omitted from the VI specification. By default, any equations that are included in the model but are not matched with a variable are automatically used to define the set K. Even though both preceding variables and trailing equations may be omitted from the VI specification, we recommend to explicitly list them, since this clarifies intentions and eliminates ambiguity.

The "-" sign in the syntax above is used to flip (i.e. to reorient or negate) the marked equation, e.g. so that `x**1.5 =L= y` becomes `y =G= x**1.5`. Flipped equations in EMP behave in the same way as flipped equations in MCP.

Note

> More than one VI specification may appear in a model. Often, it makes no difference whether multiple equ-var pairs are part of the same or separate VI specifications, but this is not the case in general. For an example, see model **[SIMPLEVI4]**.

4.51.4 Quasi-Variational Inequalities (QVI)

Quasi-variational inequalities are a generalization of the variational inequality model: in a VI, the feasible set is fixed, while the QVI allows the feasible set to vary with or be a function of the variables in the model. To avoid repetition, we assume you are already familiar with the theory and notation for VI models. In this section, we present a mathematical formulation of QVI, give an example of how QVI can be modeled with GAMS EMP, and introduce the EMP annotations specific to QVI.

4.51.4.1 Quasi-Variational Inequalities: Mathematical Formulation

For a given continuous function $F : \mathbb{R}^n \to \mathbb{R}^n$ and a point-to-set mapping $K(y) : \mathbb{R}^n \to \mathbb{R}^n$, the quasi-variational inequality problem $QVI(F, K)$ is to find a point $y^* \in K$ such that:

$$\langle F(y^*), (y - y^*) \rangle \geq 0, \quad \forall y \in K(y^*), \tag{4.19}$$

where $\langle \cdot, \cdot \rangle$ denotes the usual inner product.

If the point-to-set mapping $K(y) : \mathbb{R}^n \to \mathbb{R}^n$ is constant, then the QVI above reduces to a VI. In order to define $K(x)$ as a function of x it is convenient to introduce a shadow copy x of the variable y. It should be understood that we have only one variable that appears in two forms: the variable of interest y and the parameter variable x. Where y appears, we have a variable in the usual sense, and we take derivatives wrt this variable when deriving optimality conditions. Where x appears, we have a constant variable, i.e. we assume it is fixed when deriving optimality conditions. We can now use a function $g(y, x)$ to define $K(\cdot)$ and express QVI as: find a point $y^* \in K$ (with its associated parameter variable x^*) such that:

$$\langle F(y^*), (y - y^*) \rangle \geq 0, \quad \forall y \text{ s.t. } g(y, x) <= 0. \tag{4.20}$$

4.51.4.2 Quasi-Variational Inequalities with EMP: A Simple Example

Consider the following simple two dimensional linear example. Let y be the variable of interest with its parameter variable x and let

$$F(y) = \begin{bmatrix} 2y_1 + \frac{8}{3}y_2 - \frac{100}{3} \\ 1.25y_1 + 2y_2 - 22.5 \end{bmatrix}, \; K(x) = \{y \in \mathbb{R}^{\not\perp} \mid y_1 + x_2 \leq 15, \; x_1 + y_2 \leq 20, \; 0 \leq y, x \leq 11\}. \quad (4.21)$$

This $QVI(F, K)$ has a solution $y = (10, 5)$. The problem can be implemented in GAMS with EMP as follows:

```
set i / 1*2 /;
alias(i,j);

table A(i,j)
      1       2
1     2     [8/3]
2   [5/4]     2   ;

parameters
  b(i) / 1 [100/3],  2 22.5 /
  Cy(i,j) / 1.1 1,  2.2 1 /
  Cx(i,j) / 1.2 1,  2.1 1 /
  rhs(i) / 1 15, 2 20 /
  ;
positive variables
  y(j)  'variable of interest, aka decision variable'
  x(j)  'parameter variable shadowing y'
  ;
y.up(j) = 11;   x.up(j) = 11;
equations
  F(i)   'FOC for agent optimization models'
  g(i)   'define feasible set K(x) for QVI'
  ;
F(i)..  sum{j, A(i,j)*y(j)} - b(i) =N= 0;

g(i)..  sum{j, Cy(i,j)*y(j)} + sum{j, Cx(i,j)*x(j)} =L= rhs(i);

model m / F, g /;
file annotations / '%emp.info%' /;
putclose annotations  'qvi  F y x  g'  ;
solve m using emp;
```

Observe that the function F and the constraints g are formulated using standard GAMS syntax. F is implemented as an equation of type =n=, which does not imply or enforce any relationship between the left-hand side and the right-hand side. Instead, this relationship is implied by the position of the matching variables (given in the EMP info file) relative to their bounds. The annotations in the EMP info file define the structure of the QVI: what functions are matched to what variables, and what constraints serve to define the mapping $K(x)$. The EMP keyword `qvi` indicates that the model is a QVI, that the QVI function `F` is matched to the variable-of-interest `y` with its parameter variable `x`, and that the constraints `g` define the mapping $K(x)$.

Since QVI problems have no objective, the short form of the solve statement is used.

The solver JAMS will reformulate the QVI as an MCP and pass this on to an MCP subsolver. The EMP Summary produced by JAMS will contain the following lines:

```
--- EMP Summary
    ...
    VI Functions        = 2
    QVI Parameters      = 2
    ...
```

This output reflects the fact that there were two VI functions in the model above, one for each member of the set `i`, and that each of the variables matched to these functions was shadowed by a parameter variable.

Note that there are two QVI models in the GAMS EMP Library, the models [**SIMPLEQVI1**] and [**SIMPLEQVI2**] (an expanded version of the example shown above).

4.51.4.3 EMP Syntax for Quasi-Variational Inequalities

The general syntax of the EMP annotations used to specify quasi-variational inequalities is as follows:

```
QVI {0 var [ parameterVar] | [-] equ var [ parameterVar] } { [-] equ}
```

The EMP keyword `QVI` indicates that this is a quasi-variational inequality specification. All variables and equations included in a QVI must be listed explicitly. First we have the VI functions, their matching variables, and (optionally) the parameter variables shadowing these variables. Note that in a QVI there are no *preceding variables* as we have in a VI spec:: instead, the implied match to the zero function is indicated by the digit `0` appearing where an equation symbol would otherwise appear. After the function/variable pairs have been listed, the *trailing equations* (i.e. the equations/constraints defining the mapping $K(\cdot)$) appear.

4.51.5 Equilibrium Problems

While optimization problems have *one* decision maker that controls all decison variables, equilibrium problems are a collection of optimization problems and variational inequalities, each controlled by a *different agent*. We typically assume that each variable and each equation is controlled by or belongs to exactly one agent. Variables that are controlled by one agent but appear in the equations of a second agent are regarded as fixed or exogenous variables by that second agent: when taking first-order conditions, the second agent won't take derivatives wrt these exogenous variables. Later we will relax this assumption and introduce equilibrium problems with shared constraints and shared variables. Note that in this section we will discuss equilibrium problems of the Nash type, i.e. where all agents are on the same level, each assuming the decisions or strategies of the other agents are known and fixed. Equilibrium problems of the Stackelberg type, where there are leaders and followers, are covered in section Bilevel Programs.

We start with the mathematical formulation of an equilibrium problem, next present two examples, and conclude with a description of the EMP annotations for equilibrium problems.

4.51.5.1 Equilibrium Problems: Mathematical Formulation

Consider the following equilibrium problem with N agents solving minimization problems and one agent solving a variational inequality:

$$\begin{array}{lll} \text{Find} & (x_1^*, \ldots, x_N^*, p^*) \text{ satisfying} & \\ x_i^* & \in \arg\min_{x_i} f_i(x_i, x_{-i}^*) & \\ & \text{s.t.} \quad g_i(x_i, x_{-i}^*) \leq 0, \text{ for } i = 1, \ldots, N, & (10) \\ p^* & \in \text{SOL}\,(H(p, x^*), K(x^*)), & \\ & \text{where } K(x^*) = \{p \,|\, w(p, x^*) \leq 0\}. & \end{array}$$

Note that $f_i(x_i, x_{-i})$ denotes the objective function of the problem of agent i, $g_i(x_i, x_{-i})$ are the constraints relating to this optimization problem and $x_{-i} = (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N)$ denotes the decisions of the other agents. Further, $\text{SOL}\,(H, K)$ represents the solution set of the variational inequality $VI(H, K)$.

This problem can be implemented with EMP as follows:

```
Set  i ;
Variables obj(i), x(i), p;
Equations deff(i), defg(i), defH, defw;

*Definitions of equations are omitted

Model equil / deff, defg, defH, defw /;

File myinfo /'%emp.info%'/;
put myinfo 'equilibrium';
loop(i,
   put / 'min', obj(i), x(i), deff(i), defg(i);
);
put 'vi defH p defw' /;
putclose myinfo;

solve equil using EMP;
```

Note that the GAMS variable `obj(i)` holds the value of $f_i(x)$, `x(i)` represents the variable x_i and `p` denotes the variable p, of course. The equations `deff(i)` and `defg(i)` are closed-form definitions of the objective function $f_i(x)$ and the constraint $g_i(x)$ respectively. The equation `defH` defines the variational inequality function H and the equation `defw` defines the set K. The EMP annotations found in the file `emp.info` specify the equilibrium structure of the model:

```
equilibrium
min obj('1') x('1') deff('1') defg('1')
...
min obj('N') x('N') deff('N') defg('N')
vi defH p defw
```

The EMP keyword `equilibrium` indicates that the annotations are for an equilibrium problem. Each of the EMP keywords `min` begins a new optimization problem (owned by a new agent), where each problem has its own objective variable, decision variables, and equations / constraints. For example, the first agent minimizes `obj('1')`, controls or owns `x('1')`, and is subject to the constraints `deff('1')` and `defg('1')`. If other variables like `x('2')` and `x('3')` appear in `deff('1')` and `defg('1')`, they will be treated as exogenous by the first agent. This specification is consistent with the formulation above in (9). Each agent's optimization problem can be easily (re)constructed given the EMP annotations. Following the optimization problems of the N agents we have the VI specification for agent p. The EMP keyword `vi` is followed by the equation-variable pair `defH p` defining the VI function H and the equation `defw` that defines the feasible set K.

Note that the short form of the solve statement is used for equilibrium problems. Objective variables (if and when they exist) belong to individual agents, not to the model as a whole.

4.51.5.2 Equilibrium Problems with EMP: A Simple Example

Consider the following example from Kim & Ferris (2017) [109]. In this economic equilibrium problem there are three agents: one profit-maximizing producer, one utility-maximizing consumer and a market that determines the price of three commodities based on production and demand. The problem data include a technology matrix A, where the entry $a_{ij} > 0$ denotes the output of the commodity i for each unit of activity of producer j and $a_{ij} < 0$ denotes the respective input. Further, an initial endowment b and the demand function $d(p)$ is given, where p is the price. The consumer maximizes her utility within her budget, which depends on the price p and the initial endowment b. Let y represent the activity of the producer, x represent the demand of the consumer and p represent the prices of commodities. Then (y^*, x^*, p^*) is a general equilibrium if it satisfies the following:

$$\begin{array}{rll} -A^T p^* & \geq 0 & \text{No positive profit for each activity} \\ b + Ay^* - d(p^*) & \geq 0 & \text{No excess demand} \\ p^* \geq 0,\ y^* & \geq 0 & \text{Nonnegativity} \\ -A^T p^* & \perp y^* & \text{No activity for earning negative profit and positive activity implies balanced profit} \\ b + Ay^* - d(p^*) & \perp p^* & \text{Zero price for excess supply and market clearance for positive price} \end{array} \tag{4.22}$$

The code for the respective model is given below. Note that instead of using the consumer demand function $d(p)$ in its explicit form, we introduce a utility-maximizing consumer with demand x.

```
set i 'commodities' / 1*3 /;

variable u 'consumer utility';
positive variables
  y        'activity of the producer'
  x(i)     'Marshallian demand of the consumer'
  p(i)     'prices'
  ;
parameters
  A(i) 'technology matrix'  / 1 1, 2 -1, 3 -1 /
  s(i) 'budget share'       / 1 0.9, 2 0.1, 3 0 /
  b(i) 'endowment'          / 1 0, 2 5, 3 3 /
  ;
equations
  profit   'profit of activity'
  mkt(i)   'constraint on excess demand'
  udef     'Cobb-Douglas utility function'
  budget   'budget constraint'
  ;
profit..   -sum(i, A(i)*p(i)) =g= 0;

mkt(i)..   b(i) + A(i)*y - x(i) =g= 0;

udef..     u =e= sum(i, s(i)*log(x(i)));

budget..   sum(i, p(i)*x(i)) =l= sum(i, p(i)*b(i));

model m / mkt, profit, udef, budget /;

file empinfo /'%emp.info%'/;  putclose empinfo
 'equilibrium' /
 ' max', u, 'x', udef, budget /
 ' vi profit y' /
 ' vi mkt p' /
```

```
 ;
* the second commodity is used as a numeraire
p.fx('2') = 1;
x.l(i) = 1;

solve m using EMP;
```

Observe that in the EMP annotations the problems of the three agents are specified after the EMP keyword `equilibrium:` the consumer solves a maximization problem (where the utility `u` is maximized) and the activities of the producer and the price-setting market are expressed as VI. As there are three commodities, the first VI actually generates three VI functions, one for each commodity. Thus there are three agents and four VI functions in the equilibrium problem. This is reflected in the EMP Summary in the listing file:

```
--- EMP Summary
    ...
    VI Functions        = 4
    Equilibrium Agent   = 3
    ...
```

In the GAMS EMP Library there are several models that have a similar form, e.g. Scarf's activity analysis model [**SCARFEMP-DEM**] and the simple equilibrium problem [**SIMPEQUIL**]. The latter demonstrates that there are equilibrium problems where the optimization problems of the individual agents are solvable, but the overall equilibrium problem does not have a solution.

4.51.5.3 Equilibrium Problems with EMP: Example with Dual Variables

In many applications equilibrium problems come with a twist: the dual variable associated with a constraint in the problem of one agent appears *exogenously* in the problem of another agent. The following simple example with two agents is from model [**DUALVAR**] in the GAMS EMP Library.

$$\begin{array}{lll} \text{Problem of the first agent:} \min_{(v,w)} & z = v + w & \\ \text{s.t.} & \sqrt{v+1} + 2w \geq 2 & (\perp\ u \geq 0) \\ & v, w \geq 0 & \end{array} \tag{11}$$

$$\text{Problem of the second agent:} VI: \quad F(y) := y - 4u + 1 \quad (\perp\ y \text{ free})$$

N.B.: the variable u that appears in the problem of the second agent is the dual multiplier (aka shadow price) of the first agent's constraint. This equilibrium problem can be modeled in GAMS with EMP as follows:

```
positive variables
  v     'belongs to min agent'
  w     'belongs to min agent'
  u     'dual of min constraint'
  ;
free variables
  y     'belongs to VI agent'
  z     'objective var'
  ;
equations
  defz  'objective def'
  g     'constraint for min agent'
```

```
  Fy    'VI function'
  ;
defz..   v + w =e= z;

g..      sqrt(v+1) + 2*w =g= 2;

Fy..     y - 4*u + 1 =n= 0;

Model opt 'min agent and VI agent' / defz, g, Fy /;

File empinfo / '%emp.info%' /;  putclose empinfo
'equilibrium' /
'  min z v w defz g' /
'  vi Fy y' /
'  dualvar u g' /
;
defz.m = -1;
g.m = 0.5;   Fy.m = 1;
v.l = 0;      w.l = 0.5;
y.l = 1;      u.l = 0.5;

solve opt using emp;
```

The EMP info file contains the EMP keyword `equilibrium` followed by the specifications for the two agents: a minimization problem for the first agent and a VI for the second agent. The special relationship between the variable `u` and the equation `g` is declared via the EMP keyword `dualvar` followed by the respective variable-equation pair. Recall our usual assumption that each variable and each equation is owned or controlled by exactly one agent. Since variable `u` is tied to equation `g` and `g` is owned by the first agent, variable `u` is owned by the first agent also.

Besides the number of equilibrium agents and the number of VI functions, the EMP Summary lists the number of dual variable maps:

```
--- EMP Summary
    ...
    Dual Variable Maps  = 1
    ...
    VI Functions        = 1
    Equilibrium Agent   = 2
    ...
```

Note

Although the example above contained an optimizing agent and a VI agent, dual variables most often occur in equilibrium problems with several optimizing agents.

Other examples with dual variables in the GAMS EMP Library include a formulation of the well-known transportation model as an equilibrium problem [**TRANSEQL**], Scarf's activity analysis model [**SCARFEMP-PRIMAL**] and the general equilibrium model [**TWO3EMP**].

4.51.5.4 EMP Syntax for Equilibrium Problems

The EMP framework provides the following general syntax to specify equilibrium problems:

```
Equilibrium
  {VIsol {equ}}
  {Implicit {var equ}}
  {MAX|MIN obj {var|*} {[-] equ}}
  {VI {var|*} {[-] equ var} {[-] equ}}
  {DualVar {var [-] equ}}
```

The EMP keyword `Equilibrium` indicates that the specifications that follow define the structure of an equilibrium problem. The `MAX`, `MIN`, and `VI` keywords specify agents in the problem, while the rest of the keywords are optional modifiers used to adjust the structure of the agent models or the meaning of the equations they contain.

Note

An equilibrium problem must contain at least one agent, i.e must contain one of the keywords `MAX`, `MIN`, or `VI`.

The EMP keyword `VIsol` identifies a shared constraint(s) and specifies the MCP reformulation to use for it: see section Equilibrium Problems with Shared Constraints below for details. The keyword `Implicit` identifies a shared variable and its defining constraint: see section Equilibrium Problems with Shared Variables below for details. The keywords `MAX` and `MIN` each begin the specification of an optimization agent and are followed by the objective variable `obj` and the other variables and equations owned by the agent, as described in the formulation and example above. The keyword `VI` begins the specification of a VI agent: see the section on VI above for details. Finally, the EMP keyword `DualVar` specifies that the variable `var` is the Lagrange multiplier for the equation `equ`. For examples, see sections Equilibrium Problems with EMP: Example with Dual Variables and Embedded Complementarity Systems.

The symbol '*' specifies that the default or automatic assignment of variables to this agent be used, i.e. the set of variables used in the equations owned by this agent but not explicitly or otherwise assigned to another agent. Note that if a variable occurs in equations owned by multiple agents and is not explicitly assigned to any agent, the default assignment is not well defined and using it will be flagged as an error. To avoid confusion and promote clarity, we recommend that modelers use explicit variable lists and avoid the '*' symbol.

The "-" sign in the syntax above is used to flip (i.e. to reorient or negate) the marked equation, e.g. so that `x**1.5 =L= y` becomes `y =G= x**1.5`. Flipped equations in EMP behave in the same way as flipped equations in MCP.

Note

When the EMP keyword `equilibrium` appears in the EMP annotations, the solve statement takes the short form also used for complementarity problems in GAMS.

4.51.6 Embedded Complementarity Systems

Embedded complementarity systems of the following form arise frequently in applications:

$$\begin{array}{lll} \text{Min}_x & f(x,y) & \\ \text{s.t.} & g(x,y) \leq 0 & (\perp\ \lambda \geq 0) \end{array} \tag{12}$$

$$H(x,y,\lambda) = 0 \qquad (\perp\ y \text{ free}) \tag{4.23}$$

Note that the optimization problem is over the variable x and it is parametrized by the variable y. The choice of y is determined by the complementarity relationships represented here by H.

From an EMP perspective, there are two ways to annotate a GAMS model to specify the model above: we will describe both below. These approaches provide equivalent additional information that prompts the EMP tool to automatically create the following MCP:

$$\begin{array}{lll} 0 = \bigtriangledown_x L(x,y,\lambda) & \perp & x \text{ free} \\ 0 \leq -\bigtriangledown_\lambda L(x,y,\lambda) & \perp & \lambda \geq 0 \\ 0 = H(x,y,\lambda) & \perp & y \text{ free}, \end{array} \tag{13}$$

where the Lagrangian is defined as

$$L(x,y,\lambda) = f(x,y) + \lambda^T g(x,y). \tag{4.24}$$

The first approach uses the EMP keywords `dualequ` and `dualvar`, as contained in the model [**FERRIS43**].

```
variables         obj, x, y;
positive variable lambda;

equations defobj, g, H;

* We omit the equation definitions here.

model ecs /defobj, g, H/;

file empinfo / '%emp.info%' /; putclose empinfo
'dualequ H y' /
'dualvar lambda g' / ;

solve ecs using EMP minimizing obj;
```

The external constraint H is expressed as a standard GAMS equation. The long form of the solve statement is used here, which implies the existence of a single optimizing agent that by default owns all equations and variables. The first EMP keyword `dualequ` indicates that the equation `H` and the variable `y` do not belong to the optimizing agent: instead, `y` is treated as an exogenous variable by this agent, and this agent is assumed to know nothing about the functional form of `H`, so that `H` will not appear in any first-order conditions. Instead, a complementarity relationship between the function defined by `H` and the variable `y` is required to exist at optimality. The EMP keyword `dualvar` indicates that the variable `lambda` is the dual of the equation `g`. As a result `lambda` will be treated exogenously wherever it appears. Given the EMP annotations for this model, JAMS will automatically reformulate the problem as the MCP in (12) and pass this model to an MCP subsolver.

The EMP Summary produced by JAMS contains the following lines:

```
--- EMP Summary
    Dual Variable Maps  = 1
    Dual Equation Maps  = 1
```

The second modeling approach recasts the problem above as an equilibrium problem with two agents: the first agent solves a minimization problem and the second agent solves a VI. The algebra in the model remains the same: only the EMP annotations and the solve statement change.

```
putclose empinfo
'equilibrium' /
' min obj x g defobj' /
' vi H y' /
' dualvar lambda g' /

solve ecs using EMP;
```

The EMP keyword `equilibrium` indicates we have an equilibrium problem. The EMP keyword `min` indicates that the first agent solves a minimization problem with the objective variable `obj`, the decison variable `x` and the equations `g` and `defobj`. In contrast to the first approach, where the default (because of the long-form solve statement) is one optimizing agent owning all equations, here we specify the first agent's minimization model explicitly and from the ground up. As a result it doesn't contain the equation `H` and we do not use the `dualequ` keyword to take `H` out. Instead, the EMP keyword `vi` specifies that the second agent solves a VI defined by `H` matched with the variable `y`. The `dualvar` keyword functions here as it did in the previous example.

The EMP Summary produced by JAMS contains the following lines:

```
--- EMP Summary
    ...
    Dual Variable Maps  = 1
    Dual Equation Maps  = 0
    VI Functions        = 1
    Equilibrium Agent   = 2
    ...
```

Other examples of embedded complementarity systems in the GAMS EMP Library include the simple equilibrium problem [**SIMPEQUIL2**], the equilibrium problem formulation of the well-known transportation model [**TRANSECS**], the PIES energy equilibrium problem [**PIES**], the pure exchange model [**NEGISHI**] and the spatial price equilibrium model [**HARK-MONOP**].

It's worthwhile highlighting the differences between the `dualvar` and `dualequ` keywords, as the two are easily and frequently confused. The `dualvar` keyword makes reference to a constraint owned by an optimizing agent. Derivatives of this constraint, multiplied by the variable referenced, appear in the first-order optimality conditions for this agent. The `dualvar` keyword allows us to use this variable or multiplier explicitly (and in a sense exogenously) in the model algebra. In constrast, the `dualequ` keyword indicates that, contrary to what the default is, an equation is not owned by any optimizing agent, so no derivatives of this equation will appear in any FOC or in the reformulated model. The two are similar in that if a variable `x` appears with either `dualvar` or `dualequ`, no derivatives w.r.t. `x` will appear in the model reformulation.

dualvar x F	**dualequ F x**
Variable symbol appears first	Equation symbol appears first
F is owned by an optimizing agent	F is a system constraint
Derivatives of F appear in FOC	No derivatives of F appear in derived model
Does not change ownership of F	F is taken away from an optimizing agent

Table 1: Differences between dualvar and dualequ

4.51.7 Equilibrium Problems with Shared Constraints

In the equilibrium problems we have discussed so far, each variable and each constraint was owned by a single agent. In this section we relax the assumption that each constraint has to be controlled by a single agent and introduce *shared constraints*. Shared constraints are constraints that appear in the problems of several agents. They are mainly used to model resources shared among agents. Note that the examples in this section are from Kim & Ferris (2017) [109].

Consider the following example:

$$\begin{array}{lll} \text{Find} & (x_1^*, \ldots, x_N^*) & \text{satisfying} \\ x_i^* \in & \arg\min_{x_i} & f_i(x_i, x_{-i}^*) \\ & \text{s.t.} & g_i(x_i, x_{-i}^*) \leq 0 \\ & & h(x_i, x_{-i}^*) \leq 0, \qquad \text{for } i = 1, \ldots, N. \end{array} \tag{14}$$

The constraints g_i are owned by agent i, while the constraint h is shared by all agents. This example can be reformulated in two different ways, each with its own EMP annotations and resulting MCP. However, both share the model formulation below:

```
variables obj(i), x(i);
equations deff(i), defg(i), defh;

model sharedc / deff, defg, defh /;
```

Observe that the equation `defh` implementing the shared constraint $h(x) \leq 0$ is not indexed: it is exists once, not once per agent. The first way to write the EMP annotations is as follows:

```
file empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
loop(i,
    put 'min', obj(i), x(i), deff(i), defg(i), defh; /;
);
putclose empinfo;
```

Here the equation `defh` appears in the minimization problem of each agent. As the equation `defh` is not indexed by agent and appears in the problem of each agent, it is easy to see that it is a shared constraint. Given these annotations, the EMP framework aggregates the FOC for each agent to create the following MCP:

$$\begin{array}{lll} F(z) = ((F_i(z)^T)_{i=1}^N)^T, & & z = ((z_i^T)_{i=1}^N)^T, \\ F_i(z) = \begin{bmatrix} \nabla_{x_i} f_i(x) - \nabla_{x_i} g_i(x)\lambda_i - \nabla_{x_i} h(x)\mu_i \\ g_i(x) \\ h(x) \end{bmatrix}, & z_i = \begin{bmatrix} x_i \\ \lambda_i \leq 0 \\ \mu_i \leq 0 \end{bmatrix}, & \text{for } i = 1, \ldots, N. \end{array} \tag{15}$$

Note that the equation $h(\cdot)$ is replicated for each agent and each agent is assigned a separate multiplier μ_i.

Attention

> By default, the solver JAMS does not allow shared constraints. The option `SharedEqu` needs to be specified in the option file `jams.opt` if shared constraints are intended, otherwise an error is reported when they are detected. This cautious default helps minimize the number of surprising results.

A full model including the JAMS option file is given below.

The second way to write the EMP annotations uses the EMP keyword `VIsol` to specify that a *variational equilibrium* be computed, i.e. a solution where the multipliers μ_i are all equal. The `VIsol` keyword should appear *after* the EMP keyword `equilibrium` and *before* the descriptions of agent models.

```
put / 'VIsol defh';
```

The multipliers to make equal (or, equivalently, the constraints not to replicate) are indicated by the equation name(s) following the keyword `VIsol`. These constraints appear once in the resulting MCP, not once per agent. The EMP tool creates the following MCP:

$$\begin{array}{ll} F(z) = ((F_i(z)^T)_{i=1}^N, F_h(z)^T)^T, & z = ((z_i^T)_{i=1}^N, z_h^T)^T, \\ F_i(z) = \begin{bmatrix} \bigtriangledown_{x_i} f_i(x) - \bigtriangledown_{x_i} g_i(x)\lambda_i - \bigtriangledown_{x_i} h(x)\mu \\ g_i(x) \end{bmatrix}, & z_i = \begin{bmatrix} x_i \\ \lambda_i \leq 0 \end{bmatrix}, \quad \text{for } i = 1, \ldots, N, \\ F_h(z) = \big[h(x)\big], & z_h = \big[\mu \leq 0\big]. \end{array} \tag{16}$$

If there are no constraints $g_i(x)$, then - assuming a constraint qualification - the equilibrium problem with the shared constraint corresponds exactly to the variational inequality $VI(F, X)$, where the set $X = \{x \,|\, h(x) \leq 0\}$ and $F(x) = ((\bigtriangledown_{x_i} f_i(x)^T)_{i=1}^N)^T$. This corresponds in turn to the solution of the first MCP (with the replicated shared constraints) in case that solution has the property that the multipliers μ_i are all equal. This is what gives the latter solution its name *variational equilibrium*. If the equilibrium problem with the shared constraint has a unique solution, both MCP reformulations will have the same solution. Otherwise, the two MCPs that correspond to the two different EMP annotations may have different solutions.

An example for shared constraints is the pollution of a river basin in Haurie & Krawczyk (1997) [96] and Krawczyk & Uryasev (2000) [111], where the total amount of pollutants that may be dumped in a river is restricted. This implies that the environmental constraints of some pollutant-producing agents are shared. This example can be formulated as follows, where i is the agent index and m denotes the number of shared constraints.

$$\begin{array}{llll} \text{Find} & (x_1^*, x_2^*, x_3^*) & \text{satisfying} & \\ x_i^* \in & \arg\min_{x_i} & (c_{1i} + c_{2i} x_i)\, x_i - \Big(d_1 - d_2\Big(\sum_{j=1,\, j\neq i}^3 x_j^* + x_i\Big)\Big)\, x_i & \\ & \text{s.t.} & \sum_{j=1,\, j\neq i}^3 x_j^* (u_{jm} e_j x_j^*) + u_{im} e_i x_i \leq K_m, & \\ & & \text{for } i = 1, 2, 3,\ m = 1, 2, & \\ & \text{where} & (c, d, e, u, K) \text{ is the problem data.} & \end{array} \tag{17}$$

Here three agents produce some commodities and aim to maximize their profit. The term $(c_{1i} + c_{2i} x_i)\, x_i$ denotes the total cost for each agent i and the term $(d_1 - d_2(\sum_{j=1,\, j\neq i}^3 x_j^* + x_i))\, x_i$ represents the revenue for each agent. The amount of pollutants each agent dumps in the river is limited by the two shared constraints. This problem can be implemented in GAMS with EMP as follows:

```
Sets i / 1*3 /
     m / 1*2 / ;
alias(i,j) ;

Variable          obj(i) ;
Positive Variable x(i) ;

Parameters K(m) / 1 100, 2 100 /
           d1   / 3 /
           d2   / 0.01 /
           e(i) / 1 0.5, 2 0.25, 3 0.75 / ;

Table c(m,i)
       1      2     3
  1  0.1   0.12  0.15
  2  0.01  0.05  0.01 ;

Table u(i,m)
       1      2
  1  6.5    4.583
  2  5.0    6.250
  3  5.5    3.750 ;

Equations  objdef(i)
           cons(m) ;

objdef(i)..  obj(i) =e= (c('1',i) + c('2',i)*x(i))*x(i) - (d1 - d2*sum(j, x(j)))*x(i);

cons(m)..    sum(i, u(i,m)*e(i)*x(i)) =l= K(m);

Model m_shared / objdef, cons /;

File empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
put 'VIsol cons' /;
loop(i,
    put 'min', obj(i), x(i), objdef(i), 'cons' /;
);
putclose empinfo;

$echo SharedEqu > jams.opt
m_shared.optfile = 1;

solve m_shared using emp;
display x.l, cons.m;
```

Note that the shared environmental constraints are expressed with the equation `cons`. In the EMP annotations, we have chosen the formulation with the EMP keyword `VIsol`. It leads to the solution $x^* = (21.145, 16.028, 2.726)$. Alternatively, we could delete the line with the EMP keyword `VIsol` and thus prompt the framework to compute the MCP in (15), resulting in the solution $x^* = (0, 6.473, 22.281)$.

4.51.8 Equilibrium Problems with Shared Variables

In the last section, we relaxed the restriction that each constraint has to be controlled by a single agent and introduced *shared constraints*. In this section, we go a step further and allow *shared variables*. Note that the content of this section is adapted from Kim & Ferris (2017) [109].

First, we introduce the notion of *implicit variables*. In mathematical terms, a variable y is called an implicit variable if for each value of x there is at most one value of y satisfying $(y, x) \in X$. For such implicit variables there exists one and only one function $g(\cdot)$ such that $(g(x), x) \in X$, where g is defined over the set $\{x \mid \exists\, y \text{ such that } (y, x) \in X\}$. The set X is called the *defining constraint* of the variable y: the value of y is implicitly defined by the value of x via the defining constraint. In the current implementation, the defining constraint may only be represented as a system of equations and implicit variables must be free variables in GAMS.

Shared variables in equilibrium problems are implicit variables that have the same defining constraint for all agents that share the variable. Hence, the defining constraint becomes a shared constraint. Consider the following equilibrium problem with the shared decision variable y and its defining constraint $X = \{(y, x) \mid H(y, x) = 0\}$:

$$\begin{array}{llll} \text{Find} & (y^*, x_1^*, \ldots, x_N^*) & \text{satisfying} & \\ (y^*, x_i^*) \in & \arg\min_{y, x_i} & f_i(y, x_i, x_{-i}^*) & \\ & \text{s.t.} & H(y, x_i, x_{-i}^*) = 0, \quad \text{for } i = 1, \ldots, N, & \\ & \text{where} & H : \mathbb{R}^{m+n} \to \mathbb{R}^m,\ y \in \mathbb{R}^m & \end{array} \tag{18}$$

Note that there are N agents, m is the dimension of the variable y and $n = \sum_i n_i$, where n_i is the dimension of x_i. Assuming we have 4 agents, this example can be implemented in GAMS EMP as follows:

```
Set       i / 1*4/;
Variables obj(i), x(i), y;

Equations deff(i), defH;

Model     sharedv / deff, defH /;

File empinfo / '%emp.info%' /;
put empinfo 'equilibrium' /;
put 'implicit y defH' /;
loop (i,
   put 'min', obj(i), x(i), y, deff(i) /;
);
putclose empinfo;

solve sharedv using EMP;
```

In the EMP annotations, the EMP keyword `implicit` is used to declare the implicit variable `y` and its defining constraint `defH`. Note that the keyword `implicit` must be followed by variable-constraint pairs. If multiple pairs are specified with a single keyword `implicit`, they will be augmented to form a single vector of implicit variables and its defining constraint.

Note

Implicit variables are declared *before* the agent problems are defined.

Observe that the shared variable `y` appears in the problem specification for each agent. However, the defining equation `defH` does not appear in each problem specification, since it is assumed to be part of the implicit variable.

4.51.8.1 Reformulation Strategies for Equilibrium Problems with Shared Variables

Like other equilibrium problems, equilibrium problems with shared variables are reformulated as MCPs by the EMP tool. Users can choose between three different reformulation strategies if shared decision variables are involved. In the first strategy, the shared variables are *replicated* for each agent and the respective KKT conditions are computed, resulting in the following MCP:

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N]^T, & z &= [(z_i^T)_{i=1}^N]^T \\ F_i(z) &= \begin{bmatrix} \bigtriangledown_{x_i} f_i(x,y) - (\bigtriangledown_{x_i} H(y,x))\mu_i \\ \bigtriangledown_{y_i} f_i(x,y) - (\bigtriangledown_{y_i} H(y,x))\mu_i \\ H(y_i,x) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ y_i \\ \mu_i \end{bmatrix}. \end{aligned} \tag{19}$$

Note that in this MCP the constraint H and the variable y are replicated N times. The size of the MCP is $(n + 2mN)$. This reformulation is obtained by specifying the option `ImplVarModel=replication` in the JAMS options file.

The second reformulation strategy involves *switching* each shared variable with the multiplier associated with its defining equation. This technique can be applied if all of the following three conditions are met:

1. The defining constraint is given as an equation.
2. The dimension of the range of the defining constraint equals the dimension of the shared variable.
3. The shared variable is a free (unbounded) variable.

The switching strategy uses the fact that in an MCP, the matching between free variables and equations is somewhat arbitrary: it can be re-assigned without changing the solution. Applying this technique, we obtain the following MCP:

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N, F_h(z)^T]^T, & z &= [(z_i^T)_{i=1}^N, z_h^T]^T \\ F_i(z) &= \begin{bmatrix} \bigtriangledown_{x_i} f_i(x,y) - (\bigtriangledown_{x_i} H(y,x))\mu_i \\ \bigtriangledown_{y_i} f_i(x,y) - (\bigtriangledown_{y_i} H(y,x))\mu_i \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ \mu_i \end{bmatrix} \\ F_h(z) &= \begin{bmatrix} H(y,x) \end{bmatrix}, & z_h &= \begin{bmatrix} y \end{bmatrix}. \end{aligned} \tag{20}$$

Observe that in this MCP, the defining constraint H and the shared variable y appear only once. Thus the size of the problem is reduced to $(n + mN + m)$. The EMP framework will use this reformulation if the option `ImplVarModel=switching` is specified in the JAMS option file. This is currently the default strategy used.

The third strategy is selected by specifying option `ImplVarModel=substitution` in the JAMS option file. It uses the implicit function theorem to *substitute* the multipliers μ_i by new variables Λ_i, where $\Lambda_i = \bigtriangledown_{x_i} H(\bigtriangledown_y H)^{-1}$. This technique may be applied when the three conditions of the switching strategy are satisfied, and in addition, the implicit function theorem holds for the defining constraints. The basic idea is to regard the shared variable y as a function of other non-shared variables and apply the derivative. At each solution to the problem (y^*, x^*), there exists a locally defined implicit function $h_{x^*}(x)$ such that $y^* = h_{x^*}(x^*)$ and $H(h_{x^*}(x), x) = 0$ for each x in some neighborhood of x^*. It can be shown that given the implications of the implicit function theorem and the new variables Λ_i, the equilibrium problem can be reformulated as the MCP that follows. However, we omit a step-by-step mathematical derivation here, it is given in Kim & Ferris (2017) [109].

$$\begin{aligned} F(z) &= [(F_i(z)^T)_{i=1}^N, F_h(z)^T]^T, & z &= [(z_i^T)_{i=1}^N, z_h^T]^T \\ F_i(z) &= \begin{bmatrix} \bigtriangledown_{x_i} f_i(x,y) - (\bigtriangledown_{y_i} f_i(x,y))\Lambda_i \\ \bigtriangledown_y H(y,x)\Lambda_i - (\bigtriangledown_{x_i} H(y,x)) \end{bmatrix}, & z_i &= \begin{bmatrix} x_i \\ \Lambda_i \end{bmatrix} \\ F_h(z) &= \begin{bmatrix} H(y,x) \end{bmatrix}, & z_h &= \begin{bmatrix} y \end{bmatrix}. \end{aligned} \tag{21}$$

The size of this MCP is $(n + mn + m)$. It can be significantly reduced if the shared variable is *explicitly* defined, for example, $H(y, x) = y - h(x)$. In this case, $(\bigtriangledown_y H)^{-1}$ is the identity matrix, therefore it is not neccessary to introduce the variables Λ_i and the MCP takes the following form:

$$\begin{array}{ll} F(z) = [(F_i(z)^T)_{i=1}^N, F_h(z)^T]^T, & z = [(z_i^T)_{i=1}^N, z_h^T]^T \\ F_i(z) = \left[\bigtriangledown_{x_i} f_i(x,y) - \bigtriangledown_{x_i} H(y,x) \bigtriangledown_y f_i(x,y)\right], & z_i = \left[x_i\right] \\ F_h(z) = \left[H(y,x)\right], & z_h = \left[y\right]. \end{array} \tag{22}$$

The size of this MCP is $(n + m)$, which is a huge decrease compared to the other formulations. Note that the EMP framework detects automatically if the shared variable is explicitly defined and exploits this fact. In the following table an overview of the size of the MCP for the different reformulation techniques is given.

Strategy	Size of the MCP
Replication	$(n + 2mN)$
Switching	$(n + mN + m)$
Substitution (implicit)	$(n + mn + m)$
Substitution (explicit)	$(n + m)$

Table 2: Size of the Reformulated MCP For Different Reformulation Techniques

4.51.8.2 Equilibrium Problems with Shared Variables: A Simple Example

The following simple example computes a saddle point of the Lagrangian associated with a minimization over x subject to a single equality constraint with dual multiplier y. The GAMS EMP implementation is from Youngdae Kim. The primal (minimizing) and dual (maximizing) agents share the variable `L` containing the value of the Lagrangian, as well as its defining equation `defL`:

```
set i / 1*2 /;
variables
  L    'Lagrangian function: f(x) - y * h(x)'
  x(i) 'primal variables'
  y    'dual variable'
  ;
equation defL;
defL..
   L =e= sum{i, sqr(x(i)-1)} - y*(sum{i, x(i)} - 4);

model m / defL /;
file empinfo / '%emp.info%' /; putclose empinfo
  'equilibrium' /
  'implicit L defL' /
  '  min L x' /
  '  max L y' /
  ;

solve m using emp;
```

Note that the variable `L` is not indexed and it appears in the optimization problem of each agent. It is declared to be an implicit variable (using the keyword `implicit`) in the first line following the `equilibrium` keyword. Its defining constraint `defL` is listed only once, in this same line: it does not appear in the problem specification of each agent. By modeling the Lagrangian as a shared variable, its defining equation does not have to be replicated for each agent.

For other, more complex examples, both with shared decision variables and with a shared objective variable, see Kim & Ferris 2017 [109] .

4.51.9 Bilevel Programs

Bilevel programs are mathematical programs with optimization problems in their constraints. The main problem is called the *upper-level* problem or the *leader* and the nested problem is called the *lower-level* problem or the *follower*. A simple example is the bilevel programming problem that optimizes an upper-level objective over constraints that include a lower-level optimization problem. A famous example from economics is the Stackelberg game, where there is one leader and many followers. Bilevel programming is used in many areas, for example the design of optimal tax instruments: the tax instrument is modeled in the upper level and the clearing market is modeled in the lower level.

In this section we first present a mathematical formulation of a bilevel program with one follower and introduce the respective EMP annotations. Then we present three examples: a simple first example, an example with a variational inequality as the lower-level problem and an example with multiple followers that form a Nash equilibrium. We conclude the section with a short discussion of the general EMP syntax for bilevel programs.

4.51.9.1 Bilevel Programs: Mathematical Formulation

A bilevel program with one leader and one follower can be expressed as follows:

$$\begin{array}{lllll} \text{Min}_{x\in X,y} & f(x,y) & & & \\ \text{s.t.} & h(x,y) \leq 0 & & & \\ & y \quad \text{solves} & \text{Min}_y & g(x,y) & \\ & & \text{s.t} & k(x,y) \leq 0, & \end{array} \tag{23}$$

where

- $x \in \mathbb{R}^n$ are the upper-level variables,
- $y \in \mathbb{R}^m$ are the lower-level variables,
- $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is the upper-level objective function,
- $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is the lower-level objective function,
- $h : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^u$ are the upper-level constraints, and
- $k : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^l$ are the lower-level constraints.

Note that the upper-level constraints do not bind the lower-level decision maker.

This problem can be implemented with EMP as follows:

```
Sets  i, j ;
Variables x(i), objout, y(i), objin;
Equations deff(x,y), defg(x,y), defh(x,y), defk(x,y);

* Definitions of equations are omitted

Model bilevel / deff, defg, defH, defw /;

$onecho > "%emp.info%"
bilevel x
min objin y defg defk
$offecho

solve bilevel using EMP minimizing objout ;
```

Note that the variables and equations of the program are defined in GAMS in the usual way. The special bilevel structure of the model is specified in the EMP annotations. The EMP keyword `bilevel` indicates that this is a bilevel problem. The name and direction of the leader's objective variable is taken from the solve statement, but the other variables owned by the leader are listed after the `bilevel` keyword. The lower-level problem is specified next via the EMP keyword `min`, followed by the follower's objective variable `objin`. The other variables and the equations of the lower-level problem are listed next. Observe that this is exactly the same syntax that we introduced above for specifying optimization problems in the context of equilibrium problems.

The EMP tool reformulates the bilevel problem as a Mathematical Program with Equilibrium Constraints (MPEC) and passes this on to a subsolver (e.g. NLPEC or KNITRO). The reformulation is obtained by replacing the lower-level optimization problem by its KKT conditions, resulting in the following problem:

$$\begin{array}{lll} \text{Min}_{x\in X,y,\lambda} & f(x,y) & \\ \text{s.t.} & h(x,y) \leq 0 & \\ & k(x,y) \leq 0 & \\ & \lambda_i \leq 0, & i=1,\ldots,l \\ & \lambda_i k_i(x,y) = 0, & i=1,\ldots,l \\ & \bigtriangledown_y \mathcal{L}(x,y,\lambda) = 0, & \end{array} \tag{24}$$

where

$$\mathcal{L}(x,y,\lambda) = g(x,y) + \sum_{i=1}^{l} \lambda_i k_i(x,y) \tag{4.25}$$

is the Lagrangian function associated with the lower-level problem.

Note, however, that this reformulation is potentially problematic. KKT conditions require theoretical assumptions (like convexity) to be necessary and sufficient for *local optimality*. There may be cases where the lower lovel problem has multiple local solutions, but the modeler is interested in the *global* solution. Hence the reformulation above may not lead to the global solution, even if a global subsolver is used within the solver NLPEC.

Observe that there are two variations to problem (23) that the EMP framework is equipped to handle: the lower-level problem may be a variational inequality instead of an optimization problem, and there may be multiple lower-level problems (optimizing and/or VI) each behaving in a Nash manner. Examples follow in sections Bilevel Programs with EMP: A VI as Follower and Bilevel Programs with EMP: Multiple Followers respectively.

4.51.9.2 Bilevel Programs with EMP: A Simple Example

To illustrate, we use model **[BARD851]** from the GAMS EMP Library. Mathematically, the problem is

$$\begin{array}{lll} \text{Min}_{x,y_1,y_2} & (x-1)^2 + 2y_1^2 - 2x & \\ & x \geq 0 & \\ \text{s.t.} & (y_1,y_2) \quad \text{solve} & \begin{array}{ll} \text{Min}_{y_1,y_2} & (2y_1-4)^2 + (2y_2-1)^2 + xy_1 \\ \text{s.t} & 4x + 5y_1 + 4x_2 \leq 12 \\ & -4x + 5y_1 + 4x_2 \leq -4 \\ & 4x - 4y_1 + 5x_2 \leq 4 \\ & -4x + 4y_1 + 4x_2 \leq -4 \\ & y_1, y_2 \geq 0 \end{array} \end{array} \tag{25}$$

Note that this problem does not have any upper-level constraints. The GAMS code follows.

```
Positive Variables x, y1, y2;
Variables          objout, objin;

Equations defout, defin, e1, e2, e3, e4;

defout..  objout =e= sqr(x-1) + 2*sqr(y1) - 2*x;
defin..   objin  =e= sqr(2*y1-4) + sqr(2*y2-1) + x*y1;

e1..      4*x + 5*y1 + 4*y2 =l= 12;
e2..    - 4*x - 5*y1 + 4*y2 =l= -4;
e3..      4*x - 4*y1 + 5*y2 =l=  4;
e4..    - 4*x + 4*y1 + 5*y2 =l=  4;

Model bard / all /;

$echo bilevel x min objin y1 y2 defin e1 e2 e3 e4 > "%emp.info%"

solve bard use emp min objout;
```

The leader minimizes the variable `objout`, as specified in the solve statement. The EMP annotations specify the rest of the bilevel structure: the variable `x` belongs to the upper-level problem, and there is one lower-level agent or problem with `objin` minimized over the variables `y1` and `y2` subject to the constraints or equations `defin`, `e1`, `e2`, `e3` and `e4`.

Alternatively, we could write the EMP annotations as:

```
$echo bilevel x min objin * defin e1 e2 e3 e4 > "%emp.info%"
```

Here the lower-level variables are not listed: instead, the '$*$' indicates that all variables in the GAMS model not explicitly assigned to any agent are to be assigned to the follower.

The EMP Summary produced by JAMS gives the number of followers in the bilevel program:

```
--- EMP Summary
    Bilevel Followers   = 1
```

The GAMS EMP Library contains other bilevel examples, including several models `bard`$*$, the engineering models [**CCMG74**] and [**CCMG153**], and the simple nonconvex model [**MIRRLESS**]. The models [**JOINTC1**] and [**JOINTC2**] illustrate the interplay of the decision variables of the upper-level and lower-level problems.

4.51.9.3 Bilevel Programs with EMP: A VI as Follower

If the lower-level problem is a variational inequality, problem (23) will take the following form:

$$\begin{array}{ll} \text{Min}_{x,y} & f(x,y) \\ \text{s.t.} & h(x,y) \leq 0 \\ & y \text{ solves } \quad VI(F,K(x)), \end{array} \tag{26}$$

where

- $x \in \mathbb{R}^n$ are upper-level variables and $y \in \mathbb{R}^m$ are lower-level variables, and
- $K(x) \subseteq \mathbb{R}^m$ is a closed convex set, parametrized by x.

Consider the following simple example adapted from **[MULTMPEC]**:

$$\begin{array}{ll} \text{Min}_{w,z} & z \\ \text{s.t.} & e^z + w = 2 \\ & z \geq 1 \\ & w \text{ solves the } VI(F,K), \text{ where } K = \mathbb{R} \text{ and } F = w + z + 3 \end{array} \tag{27}$$

This bilevel problem can be modeled with EMP as follows:

```
variables w, z;
equations h, F;

h..  exp(z) + w =e= 2;
F..  w + z =n= -3;

z.lo = 1;

model bpvi / h, F /;

$onecho > %emp.info%
bilevel z
vi F w
$offecho

solve bpvi using emp min z;
```

Note that in the EMP annotations the lower-level problem is specified as a VI with the VI function `F` and the corresponding variable `w:` for details see section EMP Syntax for Variational Inequalities. The count of VI functions is indicated in the EMP Summary:

```
--- EMP Summary
    ...
    VI Functions        = 1
    ...
    Bilevel Followers   = 1
```

4.51.9.4 Bilevel Programs with EMP: Multiple Followers

The EMP framework allows multiple followers in a bilevel program. Taking the leader decisions as fixed, these followers behave as the agents in a Nash equilibrium. Consider the engineering example **[CCMG71]** from the GAMS EMP Library. In this bilevel program there are two followers, both solving minimization problems, specified in the EMP annotations as follows:

```
...
$onecho > %emp.info%
bilevel x1 x2 x3 x4
 min h1 u1 u2 u3 u4 defh1 e1
 min h2 v1 v2 v3 v4 defh2 e2
$offecho
...
```

The variables x1, x2, x3 and x4 are owned or controlled by the leader. The first follower minimizes the variable h1 over the variables u1, u2, u3 and u4 subject to the constraint/equation e1. The second follower is defined in a similar way. More details on how to specify optimization subproblems in the EMP annotations are given in section EMP Syntax for Equilibrium Problems.

Observe that in the EMP annotations of the actual model [**CCMG71**] the following shorthand notation is used:

```
...
$onecho > %emp.info%
bilevel x1 x2 x3 x4
min h1 * defh1 e1
min h2 * defh2 e2
$offecho
...
```

The symbol '∗' in the problem of the first follower indicates that this agent will optimize over all variables appearing in equations defh1 and e1 (i.e. the equations it controls) that are not claimed by another agent. In this case, the respective variables are u1, u2, u3 and u4. N.B.: in this example, if a variable appears in the equations for both followers the problem structure is not well defined and an error will result. To avoid confusion and promote clarity, we recommend that modelers explicitly list all the variables in each agent's problem, as shown in the first version of the EMP annotations above.

The number of followers is indicated in the EMP Summary:

```
--- EMP Summary
    ...
    Bilevel Followers   = 2
```

The **GAMS EMP Library** contains several bilevel problems with several followers, e.g. the well-known transportation model with a variable demand function cast as a bilevel problem with one optimization follower and one VI follower [**TRANSBP**], a simple example with two VI followers [**MULTMPEC**], and the spatial equilibrium Stackelberg model [**HARK-STACK**].

4.51.9.5 EMP Syntax for Bilevel Programs

The general syntax that EMP provides to specify bilevel programs in the EMP annotations file emp.info is as follows:

```
Bilevel {var}
{MAX|MIN obj {var|*} {[-] equ}}
{VI {var|*} {[-] equ var} {[-] equ}}
{Dualvar {var [-] equ}}
```

A bilevel program is declared with the EMP keyword bilevel, followed by the decision variables of the upper-level problem. The other specifications refer to the lower-level problems. These lower-level followers are optional, but at least one follower has to be specified. Optimization problems are defined using the EMP keyword max or min followed by the objective variable obj and the decision variables and the equations that implement the constraints of the problem. Variational inequalities are introduced with the EMP keyword vi: details of the specification are given in section EMP Syntax for Variational Inequalities. The dualvar keyword is used in the same way as it is for equilibrium problems.

Note

> While the EMP framework allows the symbol '∗' to be used to specify an automatically-created list of variables, we recommend against using the '∗' in the annotations file. Instead, list all variables explicitly to make the structure of the model clear and unambiguous to both human and machine readers of the EMP info file.

4.51.10 Disjunctive Programming

Disjunctive programming is an alternative modeling approach to mixed integer programming. Both mathematical programs model optimization problems that involve discrete and continuous variables. The advantage of disjunctive programming is that it retains and exploits the inherent logic structure of problems and thus reduces the combinatorics and improves the relaxations by using Boolean variables and disjunction definitions for modeling discrete choices.

Disjunctive programs have many applications, including ordering of tasks in a production process, organizing complex projects in a time saving manner and choosing the optimal route in a circuit.

In this section we first present the mathematical formulation of Generalized Disjunctive Programs (GDPs) and then demonstrate how disjunctive programs are implemented with GAMS EMP using two simple examples. Note that both examples are adapted from the `LogMIP 2.0 User's Manual`. At the end of the section we introduce and discuss the syntax for EMP annotations for disjunctive programs.

For information on the development of disjunctive programming in GAMS EMP and its connection to the solver LogMIP, see the respective section in the solver manual of the solver JAMS.

4.51.10.1 Generalized Disjunctive Programs (GDPs)

A GDP has Boolean and continuous variables, algebraic constraints that need to be satisfied regardless of the discrete choices, disjunctions that represent the discrete choices, and logic propositions that contain the logic relationships between the Boolean variables. Mathematically, the general structure of a GDP may be expressed as follows:

$$\begin{array}{lll} \text{Min} & f(x) & \text{Objective Function} \\ \text{s.t.} & g(x) \leq 0 & \text{Algebraic Constraints} \\ & \bigvee_{i \in D_k} \begin{bmatrix} Y_{ik} \\ r_{ik}(x) \leq 0 \end{bmatrix}, k \in K & \text{Disjunctions} \\ & \Omega(Y) = \text{True} & \text{Logic Propositions} \\ & L \leq x \leq U,\ x \in \mathbb{R}^n, & \text{Continuous Variables} \\ & Y_{ik} \in \{\text{True, False}\} & \text{Boolean Variables} \end{array} \tag{28}$$

where:

- $f : \mathbb{R}^n \to \mathbb{R}$ is a function, x is a vector of continuous variables with bounds L and U.
- $g : \mathbb{R}^n \to \mathbb{R}^l$ represents the set of global constraints.
- Each disjunction $k \in K$ is composed of a number of terms $i \in D_k$ that are connected by the Boolean operator `OR` ($\bigvee$).
- Each term $i \in D_k$ consists of a Boolean variable Y_{ik} and a set of inequalities $r_{ik}(x) \leq 0$, $r_{ik} : \mathbb{R}^n \to \mathbb{R}^j$. If Y_{ik} is true, then $r_{ik}(x) \leq 0$ is enforced, otherwise these constraints are ignored.
- $\Omega(Y) = \text{True}$ are logic propositions for the Boolean variables Y_{ik} expressed in the Conjunctive Normal Form $\Omega(Y) = \bigwedge_{t=1,2,\ldots,T}[\bigvee_{Y_{jk} \in R_t}(Y_{jk}) \bigvee_{Y_{jk} \in Q_t}(\neg Y_{jk})]$, where for each clause $t \in 1, \ldots, T$, R_t is the subset of Boolean variables that are non-negated and Q_t is the subset of Boolean variables that are negated.

N.B.: we assume that each disjunction is an exclusive-or, so that for each k exactly one variable Y_{ik} is true. Put another way, we assume the logic constraints $\underline{\bigvee}_{i \in D_k} Y_{ik}$ are contained in $\Omega(Y) = \text{True}$.

There are three cases of disjunctive programs: the functions f, g and r are linear, some of them are nonlinear, but convex, and some of them are nonlinear and nonconvex. Note that currently GAMS EMP facilitates modeling only the first two cases.

4.51.10.2 Disjunctive Programming with EMP: Example with No Algebraic Constraints

Consider the following simple example, that has no algebraic constraints which must be satisfied regardless of the disjunctive choices:

$$
\begin{array}{lll}
\text{Minimize} & c + 2x_1 + x_2 & \text{Objective Function} \\
\text{subject to} & & \\
& \begin{bmatrix} Y_1 \\ -x_1 + x_2 + 2 \leq 0 \\ c \leq 5 \end{bmatrix} \vee \begin{bmatrix} Y_2 \\ 2 - x_2 \leq 0 \\ c \leq 7 \end{bmatrix} & \text{Disjunctions} \\
& \begin{bmatrix} Y_3 \\ x_1 - x_2 \leq 0 \end{bmatrix} \vee \begin{bmatrix} \neg Y_3 \\ x_1 \leq 1 \end{bmatrix} & \\
& Y_1 \wedge \neg Y_2 \Rightarrow \neg Y_3 & \text{Logic Propositions} \\
& Y_2 \Rightarrow \neg Y_3 & \\
& Y_3 \Rightarrow \neg Y_2 & \\
& 0 \leq x_1 \leq 5 & \text{Continuous Variables} \\
& 0 \leq x_2 \leq 5 & \\
& c \geq 0 & \\
& Y_j \in \{\text{True, False}\},\ j = 1, 2, 3 & \text{Boolean Variables}
\end{array}
\tag{29}
$$

Observe that there are two disjunctions, each with two terms. In the first disjunction, each term is governed by a different Boolean variable: the first term is active if Y_1 is true and the second term is active if Y_2 is true. In the second disjunction, both terms are governed by the Boolean variable Y_3: the first term applies if Y_3 is true and the second term applies if Y_3 is false.

Note that the logic propositions imply that if Y_1 is true and Y_2 is false , then Y_3 must be false, and that Y_2 and Y_3 cannot both be true.

This example can be implemented in GAMS EMP as follows:

```
Set i / 1*2 /
    j / 1*3 /;

Positive Variables x(i), c;
Variable           z;
Binary Variables   y(j);

x.up(i) = 5;
c.up    = 7;

Equations Obj, Eq1, Eq2, Eq3, Eq4, Eq5, Eq6;

Obj..   z =e= c + 2*x('1') + x('2');

* Equations for Disjunctions
Eq1..   x('2') - x('1') =l=  - 2;
Eq2..   c =l= 5;
Eq3..   x('2') =g= 2;
Eq4..   c =l= 7;
Eq5..   x('1') - x('2') =l= 1 ;
Eq6..   x('1') =l= 1;
```

```
* Equations for Logic Propositions
Logic Equations  LEq1, LEq2, LEq3;

LEq1..   y('1') and not y('2') -> not y('3');
LEq2..   y('2') -> not y('3');
LEq3..   y('3') -> not y('2');

Model small1 / all /;

File emp / '%emp.info%' /;
put emp;
$onput
disjunction y('1') Eq1 Eq2 elseif y('2') Eq3 Eq4
disjunction y('3') Eq5 else Eq6
$offput
putclose;

Option optcr = 0.0;

solve small1 using EMP minimize z;
```

Note that in this model the Boolean variables Y_j are implemented as GAMS binary variables, the inequalities in the terms of the disjunctions are formulated as GAMS equations, and the logic propositions are expressed as GAMS logic equations. The disjunctive structure of the model is specified in the EMP annotations file `emp.info`. This file contains two lines (one per disjunction), each starting with the EMP keyword `disjunction` and specifying the structure and content of its disjunction. In the first line or disjunction, the binary variable `y('1')` that governs the first term is followed by the two equations contained in this term. The EMP keyword `elseif` denotes the start of a new term, here governed by the binary variable `y('2')` listed next and containing the two equations `Eq3` and `Eq4`. Similarly, in the second line, the binary variable `y('3')` that governs the first term of the second disjunction is followed by the equation `Eq5` contained in that term. As the binary variable governing the second term is just the negation of `y('3')`, the keyword `else` is enough to specify this and is followed by the equation `Eq6` of the second term.

Note

> Much more complex logical constructs for disjunctions are possible. For details, see section EMP Syntax for Disjunctive Programming below.

Finally, note that the model type in the solve statement is `EMP`.

Given the annotations in the file `emp.info`, the solver JAMS reformulates the model as a MIP (Mixed Integer Programming) model and passes it to a subsolver. By default, the convex hull relaxation is used for the reformulation, but users may choose reformulations that use big M or indicator constraints: see section EMP Syntax for Disjunctive Programming for details.

Observe that the listing file will contain some additional information if the model type EMP is used. The *EMP Summary* and the *Disjunction Summary* may be particularly useful. The respective listings for our example model follow:

```
--- EMP Summary
    Logical Constraints = 3
    Disjunctions        = 2
...
...
--- Disjunction Summary
    Disjunction 1 Term 2 is active
    Disjunction 2 Term 2 is active
```

Note that the EMP summary lists the number of logic constraints and disjunctions and the disjunction summary reports which terms of the disjunctions are active in the optimal solution.

4.51.10.3 Disjunctive Programming with EMP: Example with No Logic Propositions

Consider the following simple example:

$$
\begin{array}{lll}
\text{Min} & t & \text{Objective Function} \\
\text{s.t.} & t \geq x_A + 8 & \text{Algebraic Constraints} \\
 & t \geq x_B + 5 & \\
 & t \geq x_C + 6 & \\
 & \begin{bmatrix} Y_1 \\ x_A - x_C + 5 \leq 0 \end{bmatrix} \vee \begin{bmatrix} \neg Y_1 \\ x_C - x_A + 2 \leq 0 \end{bmatrix} & \text{Disjunctions} \\
 & \begin{bmatrix} Y_2 \\ x_B - x_C + 1 \leq 0 \end{bmatrix} \vee \begin{bmatrix} \neg Y_2 \\ x_C - x_B + 6 \leq 0 \end{bmatrix} & \\
 & \begin{bmatrix} Y_3 \\ x_A - x_B + 5 \leq 0 \end{bmatrix} \vee \begin{bmatrix} \neg Y_3 \\ x_B - x_A \leq 0 \end{bmatrix} & \\
 & t, x_A, x_B, x_C \geq 0 & \text{Continuous Variables} \\
 & Y_j \in \{\text{True, False}\},\ j = 1,2,3 & \text{Boolean Variables}
\end{array}
\tag{30}
$$

As this example has no logic propositions, the binary variables would not appear in any equations of a GAMS formulation like the one above. As a result, the binary variables would not be part of the model and any EMP annotations file that mentions these variables would be rejected by the EMP solver. To avoid this problem, we can introduce a dummy equation and include it in the EMP model: this ensures that the binary variables will be part of the GAMS model. The respective code follows:

```
set i / A, B, C /
    j / 1*3 /
    ;
positive variables x(i), t;
binary variables   y(j);
variable           z;

equations obj,  alg1, alg2, alg3,
          d1t1, d1t2, d2t1, d2t2, d3t1, d3t2
          dummy;

obj..  z =e= t;

* common algebraic equations
alg1..  t =g= x('A') + 8;
alg2..  t =g= x('B') + 5;
alg3..  t =g= x('C') + 6;

* equations for disjunctions
d1t1..  x('A') - x('C') + 5 =l= 0;
d1t2..  x('C') - x('A') + 2 =l= 0;
d2t1..  x('B') - x('C') + 1 =l= 0;
d2t2..  x('C') - x('B') + 6 =l= 0;
d3t1..  x('A') - x('C') + 5 =l= 0;
d3t2..  x('B') - x('C')     =l= 0;

* dummy equation
dummy..   sum(j, y(j)) =g= 0;
```

```
model small2 / all /;
file emp / '%emp.info%' /;

putclose emp
"disjunction y('1') d1t1 else d1t2" /
"disjunction y('2') d2t1 else d2t2" /
"disjunction y('3') d3t1 else d3t2" /
;
option optcr = 0.0;
solve small2 using EMP minimize z;
```

Apart from the dummy equation, this formulation is very similar to the formulation in the first example above.

EMP also supports an alternative formulation for models that have no logic equations, a formulation using *implicit default binary variables*. These variables are denoted in the EMP annonations with the star symbol '∗', which is internally replaced by a default binary variable. Note that this alternative model does not contain any explicit binary variables `Y(j)` and hence the dummy equation may be omitted, as in the following GAMS code which can be added to the model above:

```
model small3  'no dummy equation needed' / small2 - dummy /;

putclose emp
"disjunction * d1t1 else d1t2" /
"disjunction * d2t1 else d2t2" /
"disjunction * d3t1 else d3t2" /
;
solve small3 using EMP minimize z;
```

4.51.10.4 EMP Syntax for Disjunctive Programming

The general syntax that EMP provides to write disjunctions to the EMP annotations file `emp.info` is as follows:

```
Disjunction [chull [chull eps] | bigM [big M value] | indic]
            [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]
```

The EMP keyword `Disjunction` is mandatory, it indicates that what follows is a disjunction. The three constructs that follow are optional and relate to the three possible reformulations: convex hull (`chull`), big M method (`bigM`) or indicator constraints (`indic`). Note that in the the sequencing model **[SEQUENCE]** all three options are implemented. Note further, that currently, indicator constraints can only be handled by the solvers CPLEX, SCIP and XPRESS.

Note

- By default, the convex hull reformulation method is used.
- A different reformulation method may be used for each disjunction.

Observe that for the convex hull reformulation, the value of the parameter `epsilon` may optionally be specified. This parameter is an upper bound to check for constraint satisfaction, the default value is 0.0001.

Note that for the big M method, the value of `M` may optionally be specified. The value of `M` should be large enough to relax the constraint, but it should not be too large, to avoid infeasible solutions. The default value is 10000.

Following the EMP keyword `disjunction`, the first mandatory entry is a specification of the variable that governs the disjunction: `[NOT] var|*`. This may be either a binary variable, a negated binary variable or the symbol '*', that is internally replaced by default binary variables. For an example and more details on the symbol '*' in this context, see section Disjunctive Programming with EMP: Example with No Logic Propositions. Further, {`equ`} denotes a set of GAMS equation names that must be satisfied if the first disjunction term is selected. The remainder of the syntax is self-explanatory.

Alternatively, the following syntax may be used:

```
Default [chull [chull eps] | bigM [big M value] | indic]
Disjunction  [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]
```

Note that the first line is optional and serves to specify the reformulation method. The second line is identical to the first formulation of the general syntax where the specification of the reformulation method is omitted. Some users find this alternative syntax clearer, since the specification of the reformulation method and the disjunction are separated.

In addition to the sequencing model [**SEQUENCE**] that was already mentioned, the GAMS EMP Library has two other models for disjunctive programming: the manufacturing problem [**FOODEMP**] and the job scheduling problem [**MAKESPAN**]

4.51.11 Stochastic Programming

Stochastic programs are mathematical programs that involve data that is not known with certainty. Deterministic programs are formulated with fixed parameters, whereas real world problems frequently include some uncertain parameters. Often these uncertain parameters follow a probability distribution that is known or can be estimated. Thus stochastic programs approximate unknown data by probability distributions. The goal is to find some policy that is feasible for all (or almost all) the possible data instances and that maximizes the expectation of some function of the decision variables and the random variables. The EMP framework includes an extension for stochastic programming that allows users to model various stochastic problems as deterministic models, while information about the stochastic structure of the problem, like probability distributions for some data, is specified in the EMP annotations. Thus formulating stochastic programs becomes straightforward.

In the remainder of this chapter we discuss the stochastic programming extension of GAMS EMP. We introduce the basics of stochastic programming with EMP using a two-stage stochastic model and then show how the logic can be extended to multi-stage stochastic problems. In most stochastic problems the expected value of the objective is optimized. The EMP framework facilitates optimizing two additional risk measures: Value at Risk (VaR) and Conditional Value at Risk (CVaR). These alternative risk measures are discussed next. Another type of stochastic programming includes constraints that hold only with certain probabilities. These constrains are called chance constraints (or *probabilistic constraints*), they are the topic of the last section on stochastic programming. At the end of each section we give an overview of the EMP annotations that are specific to each topic: stochastic programming with recourse, additional risk measures, and chance constraints. A summary of all EMP keywords for stochastic programming is given in section GAMS EMP Keywords for Stochastic Programming.

4.51.11.1 Stochastic Programming with Recourse

One way to think about stochastic problems is to require the decision maker to make a decision now and then to minimize the expected costs of the consequences of that decision. This paradigm is called the *recourse* model. The simplest form of the recourse model has two stages: a decision is made in the first stage, then the realization of the uncertain parameters is revealed at the start of the second stage and recourse actions can be taken given this new information. This simple model can be extended to include more stages. In a *multistage* problem, a decision is made in the first stage, then some uncertainty is resolved in the second stage and another decision is made based on this new knowledge, then some other uncertainty is resolved and so on. The objective is to minimize the expected costs of the decisions in all stages.

This section is organized as follows. We start with a mathematical formulation of the two-stage stochastic problem with recourse, then show how such problems can be modeled with EMP using a simple example. The uncertain data in this first example follows a discrete distribution, there are just three different scenarios. Continuous distributions are more complex to model. Mostly, they are approximated to discrete distributions by sampling, which is discussed next. The second example illustrates how the modeling approach for a simple two-stage problem can be extended to solve a multi-stage problem. We conclude this section with a description of the EMP annotations for stochastic programs with recourse.

Two-Stage Stochastic Programs: Mathematical Formulation

The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^m$ be two variables and let the set of all realizations of the unknown data be given by Ω, $\Omega = \{\omega_1, \ldots, \omega_S\} \subseteq \mathbb{R}^r$, where r is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

$$\begin{array}{lllllllll} & \text{Min}_x & z = & c^T x & + & \mathbb{E}[Q(x,\omega)] & & & \\ & \text{s.t.} & & Ax & & & = & b, & x \geq 0, \\ \text{where} \quad Q(x,\omega) = & \text{Min}_y & & & & q_\omega^T y(\omega) & & & \\ & \text{s.t.} & & T_\omega x & + & W_\omega y(\omega) & = & h_\omega, & y(\omega) \geq 0, \quad \forall \omega \in \Omega. \end{array} \tag{31}$$

The first two lines define the *first-stage* problem and the last two lines define the *second-stage* problem. In the first stage, x is the decision variable, c^T represents the cost coefficients of the objective function and $\mathbb{E}[Q(x,\omega)]$ denotes the expected value of the optimal solution of the second stage problem. In addition, A denotes the coefficients and b the right-hand side of the first stage constraints. In the second stage, y is the decision variable, T represents the transition matrix, W the recourse matrix (cost of recourse) and h the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on the specific realization of the stochastic data ω. The objective variable z is also a random variable, since it is a function of ω. As a random variable cannot be optimized, stochastic solvers automatically optimize the *expected value* of the objective variable z. Note that the EMP framework allows other risk measures to be optimized in addition to the expected value. This is discussed below.

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then it will become known which values the uncertain parameters will take. Given the fixed solution of the first stage and the new data, recourse action can be taken in the second stage and the optimal solution determined. Each possible realization of the uncertain data is represented by $\omega_s \in \Omega$ and is called a *scenario*. The objective is to find a feasible solution x that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the *deterministic equivalent*. Assume that the uncertain parameters follow a (finite) discrete distribution and that each

scenario ω_s occurs with probability $P(\omega_s) = p_s$ for all $s = 1, \ldots, S$ and $\sum_s p_s = 1$. Thus $\mathbb{E}[Q(x,\omega)] = \sum_s p_s q^T y_s$, where y_s denotes the optimal second-stage decision for the scenario ω_s. Then the deterministic equivalent can be expressed as follows:

$$\begin{array}{lllllllllll} c^T x & + & p_1 q^T y_1 & + & p_2 q^T y_2 & + & \ldots & + & p_S q^T y_S & & \\ \text{s.t.} & & & & & & & & & & \\ Ax & & & & & & & & & = & b \\ T_1 x & + & W_1 y_1 & & & & & & & = & h_1 \\ T_2 x & & & + & W_2 y_2 & & & & & = & h_2 \\ \vdots & & & + & & & \ddots & & & & \vdots \\ T_S x & & & & & & & + & W_S y_S & = & h_S \\ x \in \mathbb{R}^n & & y_1 \in \mathbb{R}^m & & y_2 \in \mathbb{R}^m & & & & y_S \in \mathbb{R}^m & & \end{array} \tag{32}$$

Note that for stochastic linear programs the deterministic equivalent is just another (potentially very large) linear program.

A GAMS EMP stochastic model has three parts: the *core model*, EMP annotations and the *dictionary*, which contains output-handling information. The *core model* is a deterministic model, where the uncertain data is given as fixed parameters. Often, the expected value of the probability distribution is chosen.

The *annotations* contain information about the stochastic features of the model: a specification of the random variables and their distributions, details about the stages and possibly directions concerning sampling.

Given the probability distributions of the random variables, the solvers of stochastic programming models create various scenarios and evaluate them. In the *dictionary* users specify which results from each scenario are to be stored in standard parameters in order to be accessed later. These three parts of a GAMS EMP stochastic model will become much clearer as they are illustrated in the next subsection.

A Simple Example: The News Vendor Problem

Consider the following simple example adapted from the news vendor model **[NBSIMPLE]**. A news vendor has to decide early in the morning how many newspapers to buy from a distributor on a particular day in order to sell them to his customers. He knows from experience that the demand will be 45 in 70% of all cases, 40 with a probability of 20% and 50 with a probability of 10%. If the demand is less than the number of newspapers he bought in the morning, the left-over newspapers will be stored in an inventory at a cost per unit. If the demand exceeds his expectations and there are more customers than newspapers, then he will have to pay a penalty. He aims to maximize his profit by selling the newspapers at a higher price than he has bought them. Mathematically, the problem can be expressed as follows:

$$\begin{array}{lllll} & \text{Max}_x & Z(x,D) = -cx + \mathbb{E}[Q(x,D)], & x \geq 0, & \\ \text{where} \quad Q(x,D) = & \text{Max}_{s,i,l} & vs_D - hi_D - pl_D & & \\ & \text{s.t.} & x - s_D - i_D = 0 & & \\ & & s_D + l_D = D, & s_D, i_D, l_D \geq 0 & \end{array} \tag{33}$$

where

- the variable x denotes the number of newspaper bought in the morning,
- c is the cost per newspaper,
- D is a random variable that denotes the uncertain demand; the set of all realizations of D is given by $\Omega = \{d_1, d_2, d_3\}$, with $d_1 = 45$, $d_2 = 40$ and $d_3 = 50$, and the respective probabilities $p_1 = 0.7$, $p_2 = 0.2$ and $p_3 = 0.1$,

- the variable s denotes the number of newspapers that are sold,
- v is the selling price,
- the variable i denotes the number of newspapers that could not be sold, in case the demand turned out to be less than expected,
- h is the holding cost in the inventory per unit,
- the variable l denotes the unsatisfied demand, in case the demand turned out to be higher than expected,
- p is the penalty per unit of unsatisfied demand.

Note that x is the first-stage decision variable and the variables s, i and l are the second-stage decision variables. The second-stage decision variables are dependent on D. An overview of the stages in this problem is given in the following table:

1st Stage Decision Variable	**2nd Stage Decision Variable;** $\Omega = \{d_1, d_2, d_3\}$	**Probabilities**
x	$y_{d_1} = (s_{d_1}, l_{d_1}, i_{d_1})$	Scenario 1: $p_1 = 0.7$
x	$y_{d_2} = (s_{d_2}, l_{d_2}, i_{d_2})$	Scenario 2: $p_2 = 0.2$
x	$y_{d_3} = (s_{d_3}, l_{d_3}, i_{d_3})$	Scenario 3: $p_3 = 0.1$

Table 3: Two stages in the News Vendor Problem

Observe that the decision x has to be made before the realization of the demand D is known. Given the uncertainty of the demand, we aim to maximize the *expected value* of the profit, denoted by $\mathbb{E}[Z(x, D)]$. The expected value of the profit is the profit *on average*. Note that as we have a finite number of scenarios and their probabilities are known, the expected value of the profit $\mathbb{E}[Z(x, D)]$ can be expressed as a weighted sum:

$$\begin{aligned} \mathbb{E}[Z(x,D)] = \quad & -cx + \mathbb{E}[Q(x,D)] \\ & -cx + \textstyle\sum_{k=1}^{3} p_k Q(x, d_k). \end{aligned} \tag{34}$$

Note that in this example there are no first stage equations $Ax = b$.

The *core model* is the first part of the respective GAMS EMP model:

```
Variable  z      "profit";
Positive Variables
          x      "units bought"
          i      "inventory"
          l      "lost sales"
          s      "units sold";

Scalars   c      "purchase costs per unit"          / 30 /
          p      "penalty shortage cost per unit"   /  5 /
          h      "holding cost per leftover unit"   / 10 /
          v      "revenue per unit sold"            / 60 /
          d      "demand, random parameter"         / 45 /;

Equations profit "profit to be maximized"
          row1   "demand = UnitsSold + LostSales"
          row2   "inventory = UnitsBought - UnitsSold";
```

```
profit..  z =e= v*s - c*x - h*i - p*l;
row1..    d =e= s + l;
row2..    i =e= x - s;

Model nv / all /;
```

Observe that the model is defined in the usual way. In particular, the demand `d` is modeled as a fixed parameter.

The EMP annotations are the second part. Here we specify the stochastic structure:

```
File emp / '%emp.info%' /;
put emp '* problem %gams.i%'/;
$onput
randvar d discrete 0.7 45 0.2 40 0.1 50
stage 2 i l s d
stage 2 Row1 Row2
$offput
putclose emp;
```

First, we define the parameter `d` to be a random variable using the EMP keyword `randvar` and we specify the probability distribution. The EMP keyword `discrete` indicates that `d` follows a discrete distribution: with probability 0.7 it takes a value of 45, with probability 0.2 it takes a value of 40, and with probability 0.1 it takes a value of 50.

Note

> If the sum of the probabilities of a discrete distribution is smaller or larger than 1, the EMP framework will automatically normalize the probabilities so that the sum equals 1 and a corresponding remark will appear in the log and listing file.

Observe that continuous distributions are also possible, see section Random Variables with Continuous Distributions below for details.

Secondly, we specify which variables and equations belong to stage 2 using the EMP keyword `stage`. Note that the variables and equations that are not listed in the annotations are automatically assigned to a stage, by default stage 1 (this could be changed using the EMP keyword stageDefault). Only the objective variable (in this case `Z`) and the objective equation (`profit`) are assigned to the highest stage specified instead (stage 2 in this example). Observe that Z is in fact a random variable since it is a function of the random variable D. As such it cannot be optimized directly, EMP implicitly maximizes the *expected value* of Z. This might lead to some confusion since the expected value of Z belongs to `stage 1`. We show in section Expected Value Revisited how to specify more clearly the fact that we are maximizing $\mathbb{E}(Z)$.

All keywords that can be used in EMP annotations in the context of stochastic programming are introduced in subsequent examples and they are summarized in section GAMS EMP Keywords for Stochastic Programming.

The dictionary with output-handling information and the solve statement are the third part of the model. After solving a stochastic programming model, only the solution of the expected value problem may be accessed via the regular `.l` and `.m` fields. The results of the scenarios that were created and evaluated by the stochastic solvers may be stored in standard parameters in the following way:

```
Set scen           "scenarios" / s1*s3 /;
Parameter
     s_d(scen)     "demand realization by scenario"
     s_x(scen)     "units bought by scenario"
     s_s(scen)     "units sold by scenario"
     s_rep(scen,*) "scenario probability"   / #scen.prob 0/;

Set dict / scen .scenario.''
           d    .randvar .s_d
           s    .level   .s_s
           x    .level   .s_x
           ''   .opt     .s_rep /;

solve nv max z use EMP scenario dict;
display s_d, s_x, s_s, s_rep;
```

The size of the set `scen` defines the maximal number of scenarios we are willing to store results for. It does not have to match the number of scenarios that are actually generated in the solution process. Assume that the size of the set `scen` is n and n is smaller than the number of generated scenarios. In this case only the results for the first n scenarios will be stored. On the other hand, if the size of `scen` is larger than the number of generated scenarios, then the positions of the surplus elements of `scen` will be empty in the parameters (e.g. `s_d`).

The elements of the three-dimensional set `dict` determine which scenario-dependent values will be stored. The set contains mapping information between the symbols in the model in the first position and the symbols in which scenario solution information is stored in the third position. The type of storing is specified in the second position. The following entries are allowed:

Label	Description
`level`	Stores the level values of a scenario solution of a variable or equation.
`marginal`	Stores the marginal values of a scenario solution of a variable or equation.
`randvar`	Stores the realization of a random variable.
`opt`	Stores the probability of each scenario.
`scenario`	The symbol in the first position of the tuple is used as the scenario index.

Table 4 Entries in the second position of the tuples in the scenario dictionary

Attention

> The first two tuples in the set `dict` are mandatory, all other elements of the set are optional. If one of the first two tuples is missing, the stochastic model cannot be solved and an error will be generated.

In the example above, we store the realization for each scenario of the random variable `d` in the parameter `s_d`, the level values of the variables `s` and `x` in the parameters `s_s` and `s_x` respectively and the actual probability of each scenario in the parameter `s_rep`.

Note

> Storing and retrieving the actual probabilities of the scenarios may be particularly relevant if the probabilities have been normalized such that their sum equals 1.

Finally, the solve statement needs to be adjusted: we use the model type `EMP` and add `scenario dict` to indicate that a stochastic problem is to be solved.

Random Variables with Continuous Distributions

Now we assume that the random variable D in the example above has a continuous distribution, say a Normal distribution with mean 45 and standard deviation 10. The structure of the problem remains unchanged, the only difference is that the set Ω, that is the set of all realizations of D, contains an infinite number of scenarios. There are various ways of modeling this. For example, a sampling procedure implemented in the solver can be used: a finite number of scenarios is generated to approximate Ω and thus the problem is converted to a problem with a finite discrete distribution.

We can model a continuous distribution of the random variable in GAMS EMP by changing the annotations in the following way:

```
randvar d normal 45 10
```

Note that currently only the solver LINDO has implemented a sampling procedure for parametric distributions so that it can solve such a problem directly. If the solver DE is used, the sampling can be performed by the LINDO system behind the scenes. More details about sampling are given in the next section. All parametric distributions that can be modeled are listed in Table 5 .

Distribution	Parameter 1	Parameter 2	Parameter 3
Beta	shape 1	shape 2	
Cauchy	location	scale	
Chi_Square	deg. of freedom		
Exponential	lambda		
F	deg. of freedom 1	deg. of freedom 2	
Gamma	shape	scale	
Gumbel	location	scale	
Laplace	mean	scale	
Logistic	location	scale	
LogNormal	mean	std dev	
Normal	mean	std dev	
Pareto	scale	shape	
StudentT	deg. of freedom		
Triangular	low	mid	high
Uniform	low	high	
Weibull	shape	scale	
Binomial	n	p	
Geometric	p		
Hyper_Geometric	total	good	trials
Logarithmic	p-factor		
Negative_Binomial	failures	p	
Poisson	lambda		

Table 5: Parametric distributions supported by LINDO

Recall that there are two ways to specify that a specific solver should be used (that is not the default solver for the problem type): with a command line parameter (e.g. `emp=lindo`) and with an option statement (e.g. `option emp = lindo;`).

Examples with random variables that follow parametric distributions include the multistage example below (three random variables with Gamma distributions) and the production model [**PRODSP3**] in

the GAMS EMP Model Library (one random variable that follows a Normal distribution and one random variable that is uniformly distributed).

Sampling

Currently, only the solver LINDO has the ability to perform sampling for parametric distributions directly. Note that LINDO generates 6 samples by default and users need a LINDO license for sample sizes larger than 10 (smaller sample sizes are included in the demo version, but just for certain distributions). Also, changing the default variance reduction method requires a valid LINDO license. There are three ways to customize sampling: including additional information in the EMP annotations, generating a sample with the LINDO library `lsadclib` (these two options allow to pass on the samples to other solvers with EMP SP capabilities) and setting various options in the solver LINDO. We discuss each method in more detail in the next three subsections.

Customizing Sampling in the EMP Annotations

The EMP framework provides two keywords to facilitate sampling: `sample` and `setSeed`. The keyword `sample` allows users to specify the size of the sample in the EMP annotations. Consider the following example:

```
randvar d normal 45 10
sample d 9
```

The second line specifies that the size of the sample of the distribution of the random variable D is 9. Note that currently the LINDO Sampling Library is used for this sampling. If the solver DE is used and a parametric distribution for the random variable is specified, the second line with the keyword `sample` is *mandatory*. Otherwise the following error message will appear:

```
*** Only random variables with sampled continuous distributions supported.
```

In addition to specifying the size of the sample, information about a mathematical variance reduction method may be added in the line that starts with the keyword `sample`. Variance reduction is a procedure used to increase the precision of the estimated values from the distribution. LINDO provides three methods for reducing the variance: Monte Carlo sampling, Latin Square sampling and Antithetic sampling. We illustrate with an example.

Consider a stochastic model with four random variables: E, F, G and H. Assume that E follows a Normal distribution with mean 23 and standard deviation 5, F follows a Normal distribution with mean 37 and standard deviation 8, G is uniformly distributed on the interval $[0, 1]$ and H is binomially distributed with $n = 100$ and $p = 0.55$. We wish that three variance reduction methods are applied: Antithetic sampling is to be used for E and F, Monte Carlo sampling for G and Latin Square sampling for H. We insert the following lines in the EMP annotations:

```
randvar e normal 23 5
randvar f normal 37 8
randvar g uniform 0 1
randvar h binomial 100 0.55
sample e f 10 method1
sample g 12 method2
sample h 8 method3
```

First, the random variables and their distributions are defined. Next, details about the sampling procedures are given. Note that the keyword `sample` can take more than one random variable if the sample size and the variance reduction method for these random variables are identical. We need to add the following lines before the solve statement to specify the content of `method1`, `method2` and `method3` (we assume that the name of the model is `nv`):

```
$onecho > lindo.opt
SVR_LS_ANTITHETIC=method1
SVR_LS_MONTECARLO=method2
SVR_LS_LATINSQUARE=method3
$offecho
nv.optfile=1;
```

If Latin Square sampling should also be used for E and F, we would simply change the EMP annotations to replace the label `method1` with the label `method3`. For more details on variance reduction methods, please consult the LINDO manual.

In addition, the EMP keyword `setSeed` may be used to further customize the sampling procedure:

```
setSeed <seed>
```

This line sets the seed (an integer number) for the random number generator of the sampling routines. If `setSeed` is used in the EMP annotations, the seed will be set once before all samples are generated. Please note that `setSeed` only works with a valid LINDO license.

Separating Sampling and Solving

Users may want to sample from a distribution with the LINDO system and solve the model with another solver, say DE. This is possible with the sampling routines from the LINDO Sampling Library `lsadclib`. We could solve the news vendor model by first drawing a sample from a Normal distribution with mean 45 and standard deviation 10 and then using the sample in the EMP annotations. The GAMS code for sampling from a Normal distribution where the sample size is 9 follows:

```
$funclibin msllib lsadclib

Function setSeed         / msllib.setSeed /
         sampleNormal    / msllib.sampleLSNormal /
         getSampleValues / msllib.getSampleValues /;

Scalar k;
k = sampleNormal(45,10,9);

Set g /1*9/; parameter sv1(g);
loop(g,
   sv1(g) = getSampleValues(k);
);
display sv1;
```

The directive in the first line makes the LINDO sampling library available, `msllib` is the internal library name (see also $funcLibIn for more information). For further details and a list of the available probability distributions, see section The LINDO Sampling Library.

In the following lines we demonstrate how the sample is used in the EMP annotations:

```
File emp / '%emp.info%' /;
put emp;
put 'randvar d discrete '; loop(g, put (1/card(g)) ' ' sv1(g) ' ');
$onput
stage 2 I L S d
stage 2 Row1 Row2
$offput
putclose emp;
```

Note that the third line states that the random variable D follows a discrete distribution and the probabilities and values are taken from the previously generated sample. The other lines of the annotations remain unchanged.

Sampling Options for the Solver LINDO

There are some customizable sampling options in LINDO. Users could control the number of sampled scenarios by setting any of the following LINDO/SP options in the file LINDO options file `lindo.opt`:

```
STOC_NSAMPLE_PER_STAGE      - list of sample sizes per stage (starting at stage 2)
STOC_NSAMPLE_SPAR           - common sample size per stochastic parameter
STOC_NSAMPLE_STAGE          - common sample size per stage
```

For example, we could insert the following three lines before the solve statement:

```
option emp = lindo;
$echo STOC_NSAMPLE_STAGE = 100 > lindo.opt
nv.optfile = 1;
```

The first line directs GAMS to solve models of the type `emp` with the LINDO solver. The second line writes `STOC_NSAMPLE_STAGE = 100` to the file `lindo.opt`, it communicates to the solver to generate 100 samples per stage. The third line informs GAMS to use the solver option file (i.e. `lindo.opt`).

The following example shows how to use large samples and instruct LINDO to use a Benders decomposition algorithm to tackle the problem:

```
$onecho > lindo.opt
STOC_MAX_NUMSCENS = 1000000
STOC_NSAMPLE_STAGE = 40
STOC_METHOD = 1
$offecho
```

In the second line we ensure that the maximum number of scenarios is large enough. The options in the following lines state the sample size and determine the stochastic method to be used (1 means Nested Benders Decomposition). For further details on LINDO options, please consult the LINDO user manual.

Multistage Stochastic Programming Example

The modeling principles for two-stage stochastic models can be easily extended to multistage stochastic models. At the beginning of each stage some uncertainty is resolved and recourse decisions or adjustments are made after this information has become available. At the point where decisions are made only outcomes of the current stage and previous stages are available. This logic can be pictured schematically as follows:

$$\begin{aligned}\underbrace{\text{Make decision}}_{\text{Stage 1}} \rightarrow \underbrace{\text{Random Variable is realized} \rightarrow \text{Make decision}}_{\text{Stage 2}} \\ \rightarrow \cdots \rightarrow \underbrace{\text{Random Variable is realized} \rightarrow \text{Make decision}}_{\text{Stage n}}\end{aligned} \tag{4.26}$$

Observe that random variables which are realized in stage k are fixed parameters in stage $k+1$ and following; stage 1 random variables are in fact simply given deterministic values and will create a warning or an error dependent on the solver selected.

Consider an inventory problem. At the end of each week the decision how many hats should be bought in order to satisfy the stochastic demand in the following week must be made. The aim is to maximize the profit. We assume that the stochastic demand can be modeled using a Gamma distribution. The planning horizon is 3 weeks. *Before* the first week starts an initial purchase decision has to be made and the goods are stored in the inventory for use in week 1. At this point only the *distribution* of the demand of the first week is known. During the first week the *actual* demand is revealed and some items that were stored in the inventory are sold. Some items may be left over; they are stored as the inventory for the second week. In addition, a purchase decision for the second week has to be made given the size of the inventory and the *distribution* of the demand in the second week. Again, the *actual* demand is revealed in the course of the second week. The same holds for the third week.

We will model the problem with 4 stages, where the first stage corresponds to the preparation time before the first week, the second stage corresponds to decisions made in the first week, the third stage corresponds to decisions made in the second week and the fourth stage corresponds to decisions made in the third week. Let t denote the stages. Note that while the stages range from $t = 1$ to $t = 4$, demand variables are realized only at $t = 2$ to $t = 4$. Let y_t be the amount bought and i_t the amount stored at the end of each stage and let D_t denote the demand in each week and s_t the amount sold each week. Note that we denote the demand with a capital D since it is a random variable. Let $\alpha = 10$ be the cost per hat bought, $\beta = 20$ the revenue per hat sold and $\delta = 4$ the storage cost per unit. Further, in the storage facility a maximum of $\kappa = 5000$ hats can be stored.

Mathematically, this problem can be expressed as follows:

$$\begin{array}{ll}\text{Max}_{s_t,y_t,i_t} & z = -\alpha y_1 - \gamma i_1 + \mathbb{E}[\text{Max} \quad \beta s_2(D_2) - \alpha y_2(D_2) - \delta i_2(D_2) + \cdots + \\ & \mathbb{E}[\text{Max} \quad \beta s_4(D_4) + -\alpha y_4(D_4) - \delta i_4(D_4)] \dots] \\ \text{s.t.} & i_1 = y_1 \\ & i_{t-1} + y_t = s_t + i_t \\ & s_t \leq i_{t-1} \\ & s_t \leq D_t \\ & i_t \leq \kappa \\ & y_1, i_1, s_t, y_t, i_t \geq 0,\end{array} \tag{35}$$

where $t = 2, \dots, 4$ and D_t follows a Gamma distribution. Note that s_t, y_t and i_t depend on the realization of D_t.

As discussed above, the solvers use a sampling procedure to approximate a problem with a continuous random variable by a problem with a discrete distribution. Figure 1 illustrates the stages assuming a sample size of 6 (per stage). Note that this results in a total of $6^3 = 216$ scenarios.

The problem can be modeled with GAMS EMP as follows:

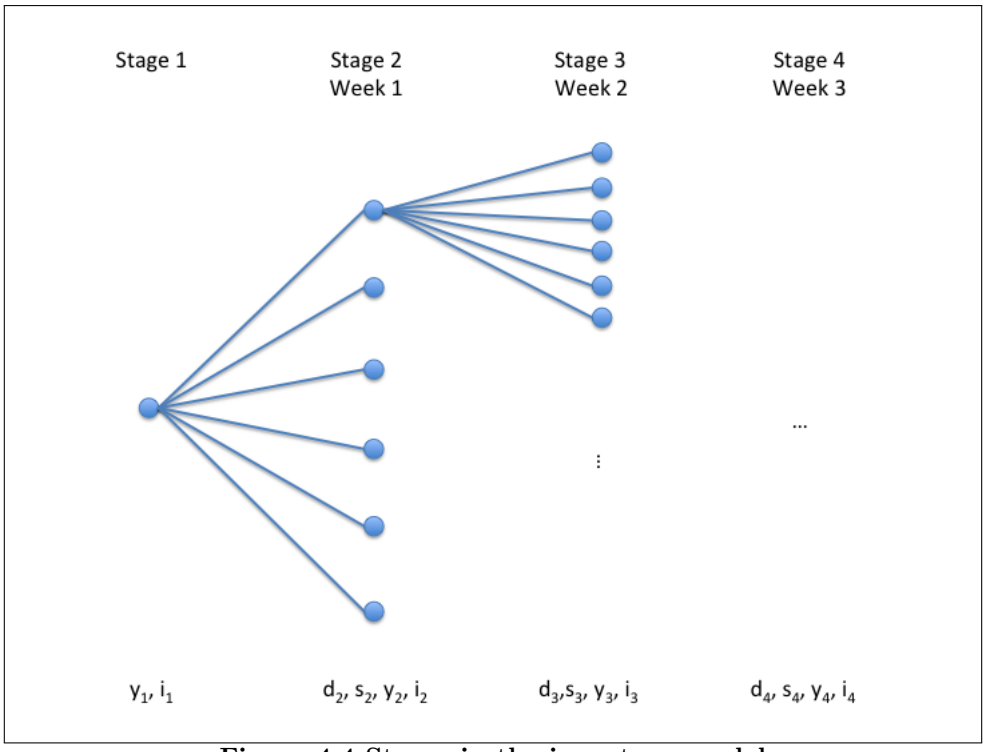


Figure 4.4 Stages in the inventory model

```
* Core Model
Set t             "stages" / 1*4 /;
Set st(t)         "stages where sales occur" / 2*4 / ;

Positive Variables
     y(t)         "units to be bought in time period t"
     i(t)         "ending inventory in period t"
     s(t)         "units sold in time period t" ;
Free Variable
     profit ;

Scalars
    kappa         "capacity of storage building"                    / 5000 /
    alpha         "cost per unit bought"                            /   10 /
    beta          "revenue per unit sold"                           /   20 /
    delta         "cost per unit stored at the end of time period" /    4 / ;

Parameters
     k            "shape of demand (1st parameter of gamma distribution)" / 16         /
     d_theta(st)  "scale of demand (2nd parameter of gamma distribution)" / 2 208.3125
                                                                            3 312.5
                                                                            4 125      /
     d(st)        "demand" ;

d(st) = k * d_theta(st);

Equations
     defprofit    "definition of profit"
     balance(t)   "balance equation"
     sales1(st)   "sales cannot exceed demand"
     sales2(t)    "sales cannot exceed inventory of previous time period" ;
```

```
defprofit..        profit =e= sum(t, beta * s(t)$st(t) - alpha * y(t) - delta * i(t));
balance(t)..       i(t-1) + y(t) =e= s(t)$st(t) + i(t) ;
sales1(st)..       s(st) =l= d(st);
sales2(t)$st(t)..  s(t) =l= i(t-1);

i.up(t) = kappa;
Model inventory /all/;

* EMP Annotations
File emp / '%emp.info%' /;
put emp; emp.nd=6;
put "randvar d('2') gamma ", k d_theta('2') /;
put "randvar d('3') gamma ", k d_theta('3') /;
put "randvar d('4') gamma ", k d_theta('4') /;
$onput
stage 1 y('1') i('1') balance('1')
stage 2 y('2') d('2') s('2') i('2') balance('2') sales1('2') sales2('2')
stage 3 y('3') d('3') s('3') i('3') balance('3') sales1('3') sales2('3')
stage 4 y('4') d('4') s('4') i('4') balance('4') sales1('4') sales2('4')
$offput
putclose emp;

* Dictionary
Set scen          "scenarios" / s1*s216 /;
Parameters
     s_d(scen,st) "demand realization by scenario"
     s_y(scen,t)  "units bought by scenario"
     s_s(scen,t)  "units sold by scenario"
     s_i(scen,t)  "units stored by scenario" ;

Set dict /
   scen .scenario.''
   d    .randvar .s_d
   s    .level   .s_s
   y    .level   .s_y
   i    .level   .s_i  /;

option emp=lindo;
solve inventory max profit using emp scenario dict;
display s_d, s_s, s_y, s_i;
```

Observe that in the core problem the values of the demand `d(t)` are replaced by the expected values of the random variable D_t which follows a Gamma distribution. Note that as expected, in stage 1 we have only the variables `y` and `i`, but no variables `s` and `d`. Recall that currently only the solver LINDO can solve models with parametric distributions, see sections Random Variables with Continuous Distributions and Sampling for more information.

EMP Syntax for Stochastic Programs with Recourse

The general syntax of the EMP annotations used to specify stochastic problems with recourse is as follows:

```
[randvar rv discrete prob val {prob val}]
[randvar rv distr par {par}]
[jrandvar rv rv {rv} prob val val {val} {prob val val {val}}]
```

```
[setSeed number]
[sample  rv1 [rv2 ... rvn] sampleSize [varRedMethod]]
stage stageNo rv | equ | var {rv | equ | var}
{stage stageNo rv | equ | var {rv | equ | var}}
[stageDefault stageNo]
```

The first three lines present three ways to specify random variables: a single random variable with a discrete distribution, a single random variable with a parametric distribution and joint random variables with discrete distributions. Note that `randvar`, `jrandvar` and `discrete` are EMP keywords. The distribution of single discrete random variables is defined by pairs of the probability `prob` of an outcome and the corresponding realization `val`, see example above. The distribution of parametric random variables is defined by the name of the distribution `dist` and the respective parameter(s) `par`. An overview of all supported parametric distributions can be found in Table 5. All possible values for `distr` and the related parameters `par` are listed there. The keyword `jrandvar` is used to define discrete random variables that are *jointly* distributed. At least two random variables must be named. For an example, see the news vendor model [**NBDISCJOINT**].

Note

At least one random variable must be defined and all three ways to define random variables may appear in the EMP annotations. See the scheduling model [**AIRLIFT**] for an example with both, a discrete random variable and a continuous random variable.

The keywords `setSeed` and `sample` are optional. The seed for the random number generator may be set with `setSeed`. The random number generator is used for the sampling routines that are called with the keyword `sample`. If `setSeed` is used, the seed will be set once before all samples will be generated. The keyword `sample` is followed by the name of the respective random variable, the sample size (a number) and - optionally - a variance reduction method. Note that the random variable must have been previously declared to follow a parametric distribution. Note further, that the sample size of more than one random variable may be customized simultaneously. Observe that the default sample size is 6. For details on available variance reduction methods, see section Customizing Sampling in the EMP Annotations.

Note

- A valid LINDO license is required to use the keywords `setSeed` and `sample`. The keyword `sample` may be used with a demo or community version of the LINDO license, but it is limited to the Normal and Binomial distributions with a maximum sample size of 10 and the variance reduction method cannot be changed.
- If a parametric distribution is used with any solver but LINDO, the keyword `sample` is mandatory, see above for details.

With the keyword `stage` random variables, variables and equations are assigned to their respective stages, where `StageNo` defines the stage number. Note that the default stage for all random variables, equations and variables is 1, except for the objective equation and variable. The default for those is the highest stage in the problem.

With the keyword `stageDefault` one can change the default stage to which symbols get assigned if they are not listed with a `stage` keyword explicitly.

4.51.11.2 Risk Measures with EMP

The literature on stochastic programming usually assumes that the expected value of the objective is optimized. The EMP tool follows this trend and implicitly optimizes the expected value. However, there are other risk measures that could be taken into consideration and that are frequently used in practice, particularly in finance. For example, a fund manager might be more interested in the expected value of the 10% worst cases of the projected wins than in the expected value of the overall distribution. The expected value of a partition of the distribution at one tail is called *Conditional Value at Risk*. The EMP framework provides special keywords to facilitate optimizing this risk measure. On a more abstract level, risk measures can be understood as mechanisms to evaluate the effects of uncertainty in the underlying system on the outcomes of interest. They can be used to modify the distribution of outcomes.

Using the example of an investor who wishes to balance expected rewards and the risk of loss when she decides how to allocate assets in a portfolio, we explore how stochastic optimization problems involving risk measures can be modeled with EMP. Note that this example is adapted from the stochastic portfolio model **[PORTFOLIO]**. For simplicity of exposition, we only describe two-stage models here. In the examples that follow, the period $(0, T)$ is the period between investing in a portfolio of assets and return from this portfolio.

We first present the example problem and introduce a new EMP keyword to model the expected value explicitly. Then we introduce and discuss Value at Risk (VaR) and Conditional Value at Risk (CVaR). At the end of this section, we give a summary of the EMP annotations that are specific to risk measures.

Note

The stochastic extension of EMP facilitates the optimization of a single risk measure or a combination of risk measures (for example, the weighted sum of Expected Value and CVaR). In addition, the modeler can choose to trade off risk measures.

Expected Value Revisited

Suppose an investor has the opportunity to invest a certain amount in three assets. She is given the probability distribution in Table 6 that links each asset with a possible return at time T. The question arises how she should allocate her funds between the three assets at time 0 in order to maximize her *expected* return at time T.

Scenario	Probability	ATT	GMC	USX
s1	1/12	1.300	1.225	1.149
s2	1/12	1.103	1.290	1.260
s3	1/12	1.216	1.216	1.419
s4	1/12	0.954	0.728	0.922
s5	1/12	0.929	1.144	1.169
s6	1/12	1.056	1.107	0.965
s7	1/12	1.038	1.321	1.133
s8	1/12	1.089	1.305	1.732
s9	1/12	1.090	1.195	1.021
s10	1/12	1.083	1.390	1.131
s11	1/12	1.035	0.928	1.006
s12	1/12	1.176	1.715	1.908

Table 6: Return by scenario

Mathematically, the problem can be expressed as follows:

$$\begin{array}{ll} \text{Max} & \mathbb{E}[R] \\ \text{s.t} & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{array} \tag{36}$$

where the variable R denotes the return and is a function of the random variable v, $\mathbb{E}[R]$ is the expected return, w_j is the weight associated with each asset j, and v_j is the return of each asset j. The weights can also be interpreted as proportions of the amount to be invested, their sum must equal 1. Note that w_j is the decision variable in this problem. Note further, that v_j is a random variable that depends on which scenario is realized.

We present two different ways to model this problem in GAMS EMP: in the first version the expected value of the return is modeled *implicitly* and in the second version it is modeled *explicitly*. Both models have two stages, in the first stage the weights are chosen without knowing which scenario will be realized, in the second stage the 12 scenarios are taken into account. We start with the part of the code where the data is given. It is named `data.gms` and it will be included in all models in this section.

```
Sets   j       "assets"     / att, gmc, usx /
       s       "scenarios"  / s1*s12 / ;

Table vs(s,j) "scenario returns from assets"
     att     gmc     usx
 s1  1.300   1.225   1.149
 s2  1.103   1.290   1.260
 s3  1.216   1.216   1.419
 s4  0.954   0.728   0.922
 s5  0.929   1.144   1.169
 s6  1.056   1.107   0.965
 s7  1.038   1.321   1.133
 s8  1.089   1.305   1.732
 s9  1.090   1.195   1.021
s10  1.083   1.390   1.131
s11  1.035   0.928   1.006
s12  1.176   1.715   1.908 ;

Parameters
      v(j)    "return from assets "
      p(s)    "probability" / #s [1/card(s)] / ;

v(j) =  sum(s, vs(s,j))/card(s);
```

The first model is similar to the two-stage example model above, the fact that the *expected* return is being maximized is not stated explicitly but is only implied:

```
* Core Model
$include data.gms
Variables
      r       "value of portfolio under each scenario"
      w(j)    "portfolio selection" ;
Positive Variables
      w ;

Equations
```

```
      defr    "return of portfolio"
      budget  "budget constraint" ;

defr..     r =e= sum(j, v(j)*w(j));
budget..   sum(j, w(j)) =e= 1;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /;
emp.nd=4;
put emp '* problem %gams.i%'
    / 'stage 2 v r defr'
    / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
      s_v(s,j) "return from assets by scenario"
      s_r(s)   "return from portfolio by scenario" ;

Set   dict / s  .scenario.''
             v  .randvar .s_v
             r  .level   .s_r /;

solve portfolio using emp max r scenario dict;
display s_v, s_r;
```

As usual, the core model is defined first and the specifications relating to the stochastic structure of the model are written to the file `emp.info`. Note that the statement `emp.nd=4` ensures that 4 decimal places are used for the values of the parameter `vs`. In the first line of the EMP annotations, the variables `v` and `r` and the equation `defr` are assigned to the second stage. Note that the other variables and equations (in this case, the variable `w` and the equation `budget`) are automatically assigned to the first stage. In the second line of the annotations, the EMP keyword `jrandvar` is used to declare that `v('att')`, `v('gmc')` and `v('usx')` are *joint* random variables, i.e. they are jointly distributed (thus we have 12 scenarios and not 12∗12∗12=1728 scenarios). The respective probabilities and values are specified with a loop statement. Observe that the syntax of the solve statement suggests that the return `r` is maximized. However, `r` is in fact a random variable, since it is a function of random variables, so actually the *expected* return is maximized.

In the second model we introduce a new variable for the expected return, `evr`. This new variable is linked to the EMP keyword `ExpectedValue` in the annotations, thus it is made explicit that the expected value of the return is optimized.

```
* Core Model
$include data.gms
Variables
      r       "value of portfolio under each scenario"
      w(j)    "portfolio selection"
      evr     "expected value of r"
      obj     "objective variable" ;
Positive Variables
      w ;

Equations
```

```
      defr    "return of portfolio"
      budget  "budget constraint"
      defobj  "objective equation" ;

defr..     r =e= sum(j, v(j)*w(j));
budget..   sum(j, w(j)) =e= 1;
defobj..   obj =e= evr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /;
emp.nd=4;
put emp '* problem %gams.i%'
    / 'ExpectedValue r evr'
    / 'stage 1 obj defobj evr'
    / 'stage 2 v defr r'
    / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
      s_v(s,j) "return from assets by scenario"
      s_r(s)   "return from portfolio by scenario" ;

Set   dict / s  .scenario.''
             v  .randvar .s_v
             r  .level   .s_r /;

solve portfolio using emp max obj scenario dict;
```

In the EMP annotations, the EMP keyword `ExpectedValue` is followed by the variable `r` and the variable `evr`. In this way the variable `evr` is declared to be the expected value of the (random) variable `r`. Note that the new variables `evr` and `obj` belong to stage 1 and the variable `evr` is maximized (via `obj`). The remainder of the annotations and the code referring to the output-handling information in the dictionary are the same like in the first model. Both models have the same solution. We prefer the second model since the syntax is more explicit and clearer.

Observe that the keyword `ExpectedValue` is particularly useful if users wish to model an objective that is the weighted sum of several risk measures, thus trading-off different risk measures. An example with the weighted sum of the expected value and Value at Risk as objective and an example with the weighted sum of the expected value and Conditional Value at Risk as objective are given below.

Value at Risk (VaR)

The Value at Risk (VaR) is the value of the distribution at a given cut-off point; for example, the value of the standard Normal distribution at the point x such that 95% of the distribution is to the left. In this subsection we introduce the notion of VaR in more detail by developing a mathematical formulation, demonstrating how VaR can be modeled with GAMS EMP using a simple example and showing how to optimize the weighted sum of the expected value and VaR.

VaR: Mathematical Formulation

Suppose $G(x,\xi)$ is a real valued function of the decision vector x and a random data vector ξ and that it denotes the *loss* function of a portfolio of assets. We aim to restrict potential losses and so we choose a portfolio composition such that the loss only exceeds a certain threshold γ ($\gamma \in \mathbb{R}$) with a probability smaller or equal to α, $\alpha \in (0,1)$, where α is small. This condition can be modeled as a chance constraint and has the following form:

$$P(G(x,\xi) > \gamma) \leq \alpha \tag{37}$$

It is easy to see that this can be written in the following way:

$$P(G(x,\xi) - \gamma \leq 0) \geq 1 - \alpha. \tag{38}$$

Consider the random variable $Z_x := G(x,\xi) - \gamma$. For a given value of x, let $F_Z(z) := P(Z \leq z)$ be the cumulative distribution function of Z. Now, the point x satisfies the constraint (37) if and only if $F_Z(0) \geq 1-\alpha$. This is equivalent to saying that x satisfies the constraint (39) if and only if $F_Z^{-1}(1-\alpha) \leq 0$.

The (left-side) quantile $F_Z^{-1}(\theta)$ is called *Value at Risk*. It is denoted by $VaR_\theta(Z)$, i.e.

$$VaR_\theta(Z) = \inf\{t : F_Z(t) \geq \theta\}. \tag{39}$$

Hence constraint (38) can be written in the following equivalent form:

$$VaR_{1-\alpha}(G(x,\xi)) \leq \gamma. \tag{40}$$

Value at Risk as introduced in equation (39) refers to a percentile on the *left* tail of a distribution. From now on it will be denoted by $\underline{VaR}_\theta(Z)$. When considering the Value at Risk at the *right* tail of the distribution, θ typically equals 0.9 or 0.95, it is denoted by $\overline{VaR}_\theta(Z)$.

Figure 2 illustrates $\underline{VaR}_{0.05}(Z)$, where Z is normally distributed with mean $\mu = 0.645$ and standard deviation $\sigma = 1$.

The EMP framework provides the EMP keywords `varlo` and `varup` as a convenient alternative to chance constraints to model Value at Risk.

VaR with EMP: A Simple Example

We continue to illustrate with the stochastic portfolio model that we have already used above. Consider that the investor might be interested in a strategy that maximizes the threshold at a certain cutoff, say at 10% on the left tail of the return curve. Mathematically, the problem can be expressed as follows:

$$\begin{array}{ll} \text{Max} & \underline{VaR}_\theta[R] \\ \text{s.t} & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{array} \tag{41}$$

where $\underline{VaR}_\theta$ is the Value at Risk at the lower θth percentile.

In the EMP annotations of the corresponding GAMS model we introduce a new variable for VaR (`varr`), a scalar to specify the percentile we are interested in (`theta`) and the EMP keyword `varlo`:

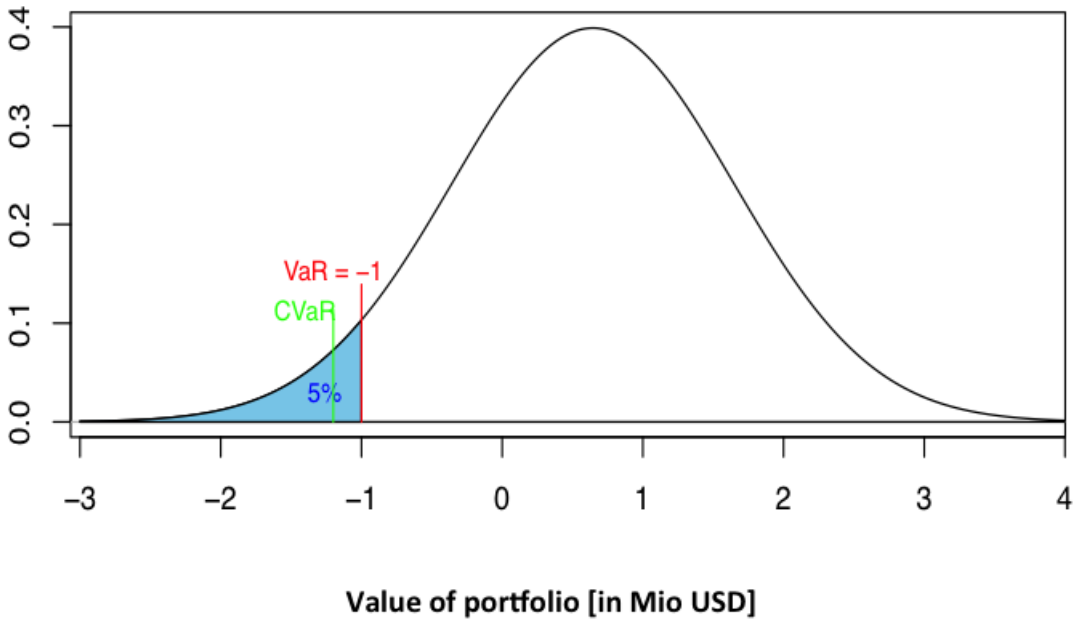

Figure 4.5 VaR and CVaR

```
* Core Model
$include data.gms
Variables
      r       "value of portfolio under each scenario"
      w(j)    "portfolio selection"
      varr    "value at risk of r"
      obj     "objective variable" ;
Positive Variables
      w ;

Scalar
      theta   "relative volume" / 0.1 /;

Equations
      defr    "return of portfolio"
      budget  "budget constraint"
      defobj  "objective equation" ;

defr..     r =e= sum(j, v(j)*w(j));
budget..   sum(j, w(j)) =e= 1;
defobj..   obj =e= varr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
```

```
      / 'varlo r varr ' theta
      / 'stage 1 obj defobj varr'
      / 'stage 2 r defr v'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
      s_v(s,j) "return from assets by scenario"
      s_r(s)   "return from portfolio by scenario" ;

Set   dict / s  .scenario.''
             v  .randvar .s_v
             r  .level   .s_r /;

solve portfolio using emp max obj scenario dict;
```

The first line in the EMP annotations begins with the EMP keyword `varlo`. This line specifies that the variable `varr` is the Value at Risk relating to the random variable `r` and the scalar `theta` is the percentile (in range 0 to 1) we consider. The other lines in the annotations are similar to the second model above. Note that the objective equals the Value at Risk at the left tail, denoted by $\underline{VaR}$.

Observe that the EMP keyword `varlo` specifies VaR at the *left* tail of the probability distribution. For the `right` tail of the distribution, the EMP keyword to be used is `varup`.

Note

- The keyword `var` is identical to `varup` which refers to the right tail of the distribution.
- Currently only the solver DE supports the keywords for VaR.

Note further, that it is only appropriate to maximize $\underline{VaR}_\alpha$ and minimize $\overline{VaR_\alpha}$.

The implementation of the keywords `varlo` and `varup` is based on a mixed integer program similar to that described in section Example with a Single Chance Constraint. Observe that these implementations are likely to be hard and/or time consuming to solve. There is an option that allows users to customize the big M value (default is 1000) in the same manner that we outline below:

```
$onecho > de.opt
VaRBigM = 500
$offecho
portfolio.optfile=1;
```

Observe that the EMP framework offers an alternative, shorter way to model VaR. There is no additional variable for VaR, hence in the EMP annotations, the EMP keyword `varlo` is only followed by `theta` and the objective variable in the solve statement is `r`. As `varlo` is specified in the annotations, the risk measure is applied to the objective variable implicitly. The modified EMP annotations and the new solve statement follow.

```
File emp / '%emp.info%' /;
put emp '* problem %gams.i%'
      / 'varlo ' theta
      / 'stage 2 r defr v'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,   put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;
...
solve portfolio using emp max r scenario dict;
```

Note that this alternative notation is shorter, but it is also opaque, therefore we recommend the first way.

Combining VaR and Expected Value

In a variation of the example above, consider an investor who aims to take into account both, the expected return and the Value at Risk of the return at a certain threshold θ. She combines the two risk measures and uses a scalar (λ) as a weight. A mathematical formulation of the problem reads as follows:

$$\begin{array}{ll} \text{Max} & \lambda\mathbb{E}[R] + (1-\lambda)\underline{VaR}_\theta[R] \\ \text{s.t} & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{array} \tag{42}$$

where $\mathbb{E}[R]$ is the expected value of the return and $\underline{VaR}_\theta$ is the Value at Risk at the θth percentile.

This problem can be modeled in GAMS EMP as follows:

```
* Core Model
$include data.gms
Variables
      r       "value of portfolio under each scenario"
      w(j)    "portfolio selection"
      varr    "value at risk of r"
      evr     "expected value of r"
      obj     "objective variable" ;
Positive Variables
      w ;

Scalars
      theta   "relative volume" / 0.1 /
      lambda  "weight EV versus VaR"  / 0.2 /;

Equations
      defr    "return of portfolio"
      budget  "budget constraint"
      defobj  "convex combination of both risk measures" ;

defr..      r =e= sum(j, v(j)*w(j));
budget..    sum(j, w(j)) =e= 1;
defobj..    obj =e= lambda*evr + (1-lambda)*varr;

Model portfolio_ext / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
      / 'ExpectedValue r evr'
      / 'varlo r varr ' theta
      / 'stage 2 r defr v'
      / 'stage 1 defobj obj'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
      s_v(s,j) "return from assets by scenario /s1.att 1/"
```

```
      s_r(s)   "return from portfolio by scenario" ;

Set   dict / s  .scenario.''
             v  .randvar .s_v
             r  .level   .s_r /;

solve portfolio_ext using EMP max obj scenario dict;
```

Note that we introduced a variable for the expected value of the return like in the example above where we modeled the expected return explicitly. Note further, that we added the parameter `lambda` and we defined the variable `obj` to be the weighted sum of the expected value of the return `evr` and the lower VaR `varr`. Observe that in the EMP annotations both keywords `ExpectedValue` and `varlo` are used. The other parts of the model remain unchanged.

Conditional Value at Risk (CVaR)

The Conditional Value at Risk (CVaR) is the expected value of the left or right tail of the distribution; for example, the expected value of the left 5% of the standard Normal distribution. Note that CVaR is also called *expected shortfall*. In this subsection we introduce and discuss CVaR in more detail by presenting a mathematical formulation, demonstrating how CVaR can be modeled with GAMS EMP using a simple example and showing how to optimize the weighted sum of the expected value and CVaR.

CVaR: Mathematical Formulation

$\underline{CVaR}_\alpha$ is the expected average return (in a given time period) given that we are in the $(\alpha \times 100)\%$ *left tail* of the return distribution, where $\alpha \in (0,1)$. In other words, $\underline{CVaR}_\alpha$ is a mean of the left tail. For example, if we are interested in the 5% worst cases, i.e. $\alpha = 0.05$, $\underline{CVaR}_\alpha$ is the conditional expectation of the return, given the return is no greater than VaR.

Let ξ be a random variable with probability density function $p(\xi)$, let $G(\xi)$ be a function of the random variable ξ denoting the *return* of a portfolio of assets and let $\alpha \in (0,1)$ be a probability. Then the conditional value at risk of $G(\xi)$ is defined as

$$\underline{CVaR}_\alpha(G(\xi)) = \frac{1}{\alpha}\int_{-\infty}^{VaR_\alpha} G(\xi)\cdot p(\xi)d\xi, \tag{43}$$

where VaR_α is the value at risk.

CVaR with EMP: A Simple Example

In the stochastic portfolio example that we have used throughout this section, the investor might be interested to make sure that in the worst cases she loses as little as possible. Thus she could consider only the worst 10% of possible cases and allocate her funds such that the expected mean return in these cases is maximized. Mathematically, the problem can be expressed as follows:

$$\begin{array}{ll} \text{Max} & \underline{CVaR}_\theta[R] \\ \text{s.t} & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{array} \tag{44}$$

where $\underline{CVaR}_\theta$ is the CVaR at the confidence level θ at the *left* tail of the distribution.

Like in the case of Value at Risk above, we introduce a new variable for CVaR (`cvarr`), a scalar to specify the percentile we are interested in (`theta`) and the EMP keyword `cvarlo` in the EMP annotations:

```
* Core Model
$include data.gms
Variables
      r       "value of portfolio under each scenario"
      w(j)    "portfolio selection"
      cvarr   "conditional value at risk of r"
      obj     "objective variable" ;
Positive Variables
      w ;

Scalar
      theta   "relative volume" / 0.1 /;

Equations
      defr    "return of portfolio"
      budget  "budget constraint"
      defobj  "objective equation" ;

defr..     r =e= sum(j, v(j)*w(j));
budget..   sum(j, w(j)) =e= 1;
defobj..   obj =e= cvarr;

Model portfolio / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
      / 'cvarlo r cvarr' theta
      / 'stage 1 obj defobj cvarr'
      / 'stage 2 r defr v'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
      s_v(s,j) "return from assets by scenario"
      s_r(s)   "return from portfolio by scenario" ;

Set   dict / s  .scenario.''
             v  .randvar .s_v
             r  .level   .s_r /;

solve portfolio using emp max obj scenario dict;
```

In the EMP annotations, the first line starts with the EMP keyword `cvarlo`. This line specifies that the variable cvarr is the left-tail CVaR relating to the random variable `r` and the scalar `theta` is the fraction (in range 0 to 1) we consider. Like in the previous section, the objective variable, the objective equation and the variable in the objective equation belong to the first stage while the equation that handles the random data and all its variables belong to the second stage. Observe that the objective equals the Conditional Value at Risk.

Note that the keyword `cvarlo` specifies CVaR at the *left* tail of the probability distribution. For the *right* tail of the distribution the keyword to be used is `cvarup`.

Note

- The EMP keyword `cvar` is identical to the keyword `cvarup`.
- Currently only the solver DE supports the keywords for CVaR.

The conditional value at risk denoting the mean of the *right* tail of the distribution can be denoted by $\overline{CVaR}$ and is defined as:

$$\overline{CVaR}_\alpha(G(\xi)) = \frac{1}{1-\alpha}\int_{VaR_\alpha}^{\infty} G(\xi)\cdot p(\xi)d\xi. \tag{45}$$

Observe that it is only appropriate to maximize $\underline{CVaR}_\alpha$ and minimize $\overline{CVaR_\alpha}$. Furthermore, $\underline{CVaR}_\alpha$ is a concave function and so should only be constrained using e.g.

$$\underline{CVaR}_\alpha \geq \gamma$$

and $\overline{CVaR_\alpha}$ is convex, so should only appear in constraints like

$$\overline{CVaR_\alpha} \leq \gamma.$$

The EMP framework offers an alternative way to model CVaR. In this alternative formulation, there is no additional variable for CVaR, hence in the EMP annotations, the EMP keyword `cvarlo` is only followed by `theta` and the objective variable in the solve statement is `r`. As `cvarlo` is specified in the annotations, the risk measure is applied to the objective variable implicitly. The modified EMP annotations and the new solve statement follow.

```
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
      / 'cvarlo ' theta
      / 'stage 2 r defr v'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,   put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;
...
solve portfolio using emp max r scenario dict;
```

Note that this alternative notation is shorter, but it is considerably less clear, therefore we recommend the explicit notation of the first model.

Combining CVaR and Expected Value

In a final variation on the portfolio example, we consider an investor who aims to take into account both, the expected return and the Conditional Value at Risk of the return at a certain threshold θ. She combines the two risk measures and uses a scalar (λ) to weigh the two summands. A mathematical formulation of the problem reads as follows:

$$\begin{array}{ll} \text{Max} & \lambda\mathbb{E}[R] + (1-\lambda)\underline{CVaR}_\theta[R] \\ \text{s.t} & R = \sum_j w_j v_j \\ & \sum_j w_j = 1 \\ & w_j \geq 0, \end{array} \tag{46}$$

where $\mathbb{E}[R]$ is the expected value of the return and $\underline{CVaR}_\theta$ is the CVaR at the confidence level θ.

This problem can be modeled with GAMS EMP as follows:

```
* Core Model
$include data.gms
Variables
      r       "value of portfolio under each scenario"
      w(j)    "portfolio selection"
      cvarr   "conditional value at risk of r"
      evr     "expected value of r"
      obj     "objective variable" ;
Positive Variables
      w ;

Scalars
      theta   "relative volume" / 0.1 /
      lambda  "weight EV versus CVaR"  / 0.2 /;

Equations
      defr    "return of portfolio"
      budget  "budget constraint"
      defobj  "convex combination of both risk measures" ;

defr..     r =e= sum(j, v(j)*w(j));
budget..   sum(j, w(j)) =e= 1;
defobj..   obj =e= lambda*evr + (1-lambda)*cvarr;

Model portfolio_ext / all /;

* EMP Annotations
File emp / '%emp.info%' /
put emp '* problem %gams.i%'
      / 'ExpectedValue r evr'
      / 'cvarlo r cvarr ' theta
      / 'stage 2 r defr v'
      / 'stage 1 defobj obj'
      / "jrandvar v('att') v('gmc') v('usx')"
loop(s,
  put / p(s) vs(s,"att") vs(s,"gmc") vs(s,"usx"));
putclose emp;

* Dictionary
Parameters
      s_v(s,j) "return from assets by scenario"
      s_r(s)   "return from portfolio by scenario" ;

Set   dict / s  .scenario.''
             v  .randvar .s_v
             r  .level   .s_r /;

solve portfolio_ext using emp max obj scenario dict;
```

Note that apart from the EMP keyword `varlo` being replaced by `cvarlo`, the code is identical to the code above, where we maximized the weigthed sum of the expected value and VaR. Observe that by decreasing the value of λ from 1 to 0 we can explore the results of an increasingly risk averse behavior.

EMP Syntax for Risk Measures

The EMP annotations where risk measures are used have the same general syntax like stochastic models with recourse. In addition, the following keywords may be used:

```
ExpectedValue rv var
varlo [rv var] scalar
varup [rv var] scalar
cvarlo [rv var] scalar
cvarup [rv var] scalar
```

The EMP keyword `Expected Value` is used to state that the variable `var` is the expected value of the random variable `rv`. Note that the random variable `rv` must be defined to be a random variable in the EMP annotations.

The EMP keywords `varlo`, `varup`, `cvarlo` and `cvarup` refer to VaR at the left tail of the distribution ($\underline{VaR}_\alpha$), VaR at the right tail of the distribution ($\overline{VaR}_\alpha$), CVaR at the left tail of the distribution ($\underline{CVaR}_\alpha$) and CVaR at the right tail of the distribution ($\overline{CVaR}_\alpha$) respectively.

Note

The EMP keyword `var` is a synonym to `varup` and `cvar` is a synonym to `cvarup`.

The specifications that follow all four keywords have a long and a short version. In the long version, the random variable `rv` and the variable that is assigned to be the respective risk measure (VaR or CVaR) are named explicitly. The scalar is a number in the interval $(0, 1)$, it defines the percentile in VaR and confidence level in CVaR. In the short version, only the scalar is specified. In this case the risk measure will applied to the objective variable implicitly.

Note

These five keywords are only supported by the solver DE.

4.51.11.3 Chance Constraints with EMP

In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints (or some of them) to be violated with a certain probability. Note that chance constraints are also called *probabilistic constraints*.

This section is organized as follows. After introducing a mathematical formulation of chance constraints, we show how such problems can be modeled with GAMS EMP using a simple example with only one chance constraint. Then we extend the model to include multiple chance constraints. We discuss the two ways to model problems with multiple chance constraints: using *joint chance constraints* and using *individual chance constraints*. Joint chance constraints require that all constraints are satisfied simultaneously with a given probability. Individual chance constraints require each constraint to be satisfied with a given probability independently of other constraints. Further, the EMP framework offers the option to penalize the violation of chance constraints. This is the topic of subsection Penalizing Violations of Chance Constraints. We conclude this section with an overview of the EMP annotations that are specific to chance constraints.

Chance Constraints: Mathematical Formulation

Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

$$\begin{array}{ll} \text{Min}_x & c^T x \\ \text{s.t.} & P(Ax \leq b) \geq p \\ & x \geq 0, \end{array} \tag{47}$$

where $x \in \mathbb{R}^n$ is the decision variable and c^T denotes the coefficients of the objective function, $A \in \mathbb{R}^{m \times n}$ is a random matrix and represents the coefficients and $b \in \mathbb{R}^m$ is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability $\epsilon = 1 - p$, where $0 < p \leq 1$. Note that ϵ is sometimes called the *risk tolerance*.

One way to solve a stochastic problem with chance constraints is to convert it to a mixed-integer problem (MIP) first and then solve the MIP equivalent. The idea is to introduce a set of scenarios S and a vector with binary variables, say $y_k \in \mathbb{R}^m$, for each scenario $k \in S$. The binary variables take value 1 if the corresponding constraint is satisfied in a scenario and 0 otherwise. A scenario-based formulation of the chance-constrained stochastic linear program above can be written as:

$$\begin{array}{ll} \text{Min}_x & c^T x \\ \text{s.t.} & A^k x \leq b^k + M^k(1 - y_k) \\ & \sum_{k \in S} y_k \geq p \times |S| \\ & x \geq 0, \quad y \in (0,1)^{|S|}, \end{array} \tag{48}$$

where $M^k \in \mathbb{R}^m$ is a chosen big-M vector. The entries of the vector M^k should be chosen such that it does not cut off any feasible solution if $y_k = 0$.

Example with a Single Chance Constraint

We start with the simplest case, where the random matrix A consists of just one random vector a, resulting in a problem with a single chance constraint. The following example is adapted from model [**SIMPLECHANCE**].

$$\begin{array}{lll} \text{Min} & x_1 + x_2 & \\ \text{s.t.} & P(\omega x_1 + x_2 \geq 7) \geq 0.75, & \omega \in \Omega = \{1,2,3,4\} \\ & x_1, x_2 \geq 0. & \end{array} \tag{49}$$

Here the random parameter ω has four possible realizations. Thus we have four scenarios and we assume that each scenario is equally likely to be realized, i.e. $\pi^k = \frac{1}{4}$, where π^k denotes the probability that scenario k is realized. Note that in this example b is fixed at 7. As $p = 0.75$ and each scenario is equally likely to be realized, we need to choose x_1 and x_2 such that the inequality is satisfied in at least 3 scenarios. For clarity, we spell out the inequalities for the scenarios:

$$\begin{array}{llll} k = 1: & \omega_1 = 1 & \omega_1 x_1 + x_2 \geq 7 \\ k = 2: & \omega_2 = 2 & \omega_2 x_1 + x_2 \geq 7 \\ k = 3: & \omega_3 = 3 & \omega_3 x_1 + x_2 \geq 7 \\ k = 4: & \omega_4 = 4 & \omega_4 x_1 + x_2 \geq 7. \end{array} \tag{50}$$

The MIP equivalent of problem (49) is given below:

$$
\begin{array}{ll}
\text{Min} & x_1 + x_2 \\
\text{s.t.} & 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
& 2x_1 + x_2 \geq 7 - M(1 - y_2) \\
& 3x_1 + x_2 \geq 7 - M(1 - y_3) \\
& 4x_1 + x_2 \geq 7 - M(1 - y_4) \\
& \\
& cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 4,\ \pi^k = \frac{1}{4} \\
& \\
& x_1, x_2 \geq 0 \\
& 0 \leq cc_1 \leq (1 - 0.75) \\
& y_k \in (0, 1).
\end{array}
\tag{51}
$$

Observe that the first four constraints cover the four possible scenarios with ω taking the values 1, 2, 3 and 4 respectively. On the right-hand side we introduce a big-M factor and y_k, a binary indicator variable. y_k takes the value 1 if the constraint is satisfied and zero otherwise. The new variable cc_1 represents the probability that the constraint is violated. If cc_1 equals zero, the sum will equal 1, indicating that the constraint is satisfied in all four scenarios. If $cc_1 = 0.25$, the constraint will be unsatisfied in one scenario out of four (for this scenario $y_k = 0$).

The problem can be modeled in GAMS EMP as follows:

```
* Core Model
Positive Variables x1, x2;
Variables          z;

Scalar om  / 1 /;

Equations obj, e1;

obj..   z =e= x1 + x2;
e1..    om*x1 + x2 =g=  7;

Model sc / all /;

* EMP Annotations
File emp / '%emp.info%' /;
put emp;
$onput
randvar om discrete 0.25 1  0.25 2   0.25 3   0.25 4
chance e1 0.75
$offput
putclose emp;

* Dictionary
Set scen "scenarios" / s1*s4 /;
Parameter  s_om(scen)
       x1_l (scen)
       x2_l (scen)
       e1_l (scen);

Set dict / scen .scenario.''
            om  .randvar .s_om
            x1  .level   .x1_l
            x2  .level   .x2_l
```

```
            e1  .level   .e1_l/;

solve sc min z use EMP scenario dict;
display s_om, x1_l, x2_l, e1_l;
```

Like other EMP stochastic programming models, the model consists of three parts: the core model, the EMP annotations and the dictionary with output-handling information. As usual, the core model is defined as a deterministic model and the specifications relating to the stochastic structure of the problem are written to the file `emp.info`. In the EMP annotations, the EMP keyword `randvar` is used to declare a parameter from the core model as a random variable. The keyword is followed by `om`, the random variable, and the distribution. The EMP keyword `discrete` indicates that we have a discrete distribution. The discrete distribution is specified via probability-numerical value pairs. Note that continuous distributions are also possible. See section Random Variables with Continuous Distributions for more information. The second line in the EMP annotations starts with the EMP keyword `chance` followed by the equation `e1` and a probability. The specification means that the constraints `e1` must hold for at least 75% of all scenarios. We can verify that this requirement has been enforced by checking in the listing file the level value of the constraint `e1_l`. We will see that in the first scenario the constraint was violated, but is was satisfied in all other scenarios.

Observe that the EMP keyword `chance` allows for an optional specification that is related to a penalization factor for constraints that are violated. This topic is discussed in section Penalizing Violations of Chance Constraints below.

Note

> Currently, there are no stages in stochastic problems with chance constraints, unlike in stochastic problems with recourse.

As the problem is solved as a MIP, it is important that the options OptCA and OptCR are assigned appropriate values.

Note that the default value of M is 1e7 for the solver Lindo. To customize this and set it to, e.g., 1000 instead, one could insert the following five lines before the solve statement:

```
option emp = lindo;
$onecho > lindo.opt
STOC_BIGM 1e3
$offecho
sc.optfile = 1;
```

For DE the default value of M is 10000 and it could be changed to 1000 in a similar way as seen above for Lindo:

```
option emp = de;
$onecho > de.opt
ccreform bigM 1e3
$offecho
sc.optfile = 1;
```

Note that `ccreform` is a DE option. This option allows to specify two alternative solution strategies: a reformulation using a convex hull and a reformulation using indicator variables and indicator constraints. The following line indicates that a convex hull with $M = 1000$ and $\epsilon = 0.00001$ is to be used:

```
ccreform cHull 1e3 1e-6
```

For indicator variables and constraints, the following line is used:

```
ccreform indic
```

Note that currently only the solver CPLEX supports indicator variables, so the resulting reformulated problem has to be solved with CPLEX.

Examples with Multiple Chance Constraints

Stochastic problems with multiple chance constraints have two different forms: problems with *joint* chance constraints and problems with *multiple individual* chance constraints. In problems with joint chance constraints the constraints all have to be satisfied simultaneously with probability p. In problems with multiple individual chance constraints each constraint carries its own risk tolerance. We illustrate with two examples.

Joint Chance Constraints

We illustrate joint chance constraints by extending the example above by one constraint resulting in a problem with two chance constraints:

$$\begin{array}{ll} \text{Min} & x_1 + x_2 \\ \text{s.t.} & P(\omega_1 x_1 + x_2 \geq 7;\ \omega_2 x_1 + 3x_2 \geq 12) \geq 0.6, \qquad (\omega_1, \omega_2) \in \Omega \\ & x_1, x_2 \geq 0, \end{array} \tag{52}$$

where

$$\Omega = \{(1,1),(1,2),(1,3),(2,1),(2,2),(2,3),(3,1),(3,2),(3,3),(4,1),(4,2),(4,3)\} \tag{4.27}$$

and

$$\pi^k = \pi(\omega_1, \omega_2) = \frac{1}{12} \quad \text{for all} \quad (\omega_1, \omega_2) \in \Omega. \tag{4.28}$$

Note that both random variables follow discrete uniform distributions, ω_1 has four realizations and ω_2 has three realizations. Thus we have 12 scenarios that are all equally likely. The MIP equivalent takes the following form:

$$\begin{array}{ll} \text{Min} & x_1 + x_2 \\ \\ \text{s.t.} & 1x_1 + x_2 \geq 7 - M(1 - y_1) \\ & 1x_1 + 3x_2 \geq 12 - M(1 - y_1) \\ & 2x_1 + x_2 \geq 7 - M(1 - y_2) \\ & 1x_1 + 3x_2 \geq 12 - M(1 - y_2) \\ & \vdots \\ & 4x_1 + x_2 \geq 7 - M(1 - y_{12}) \\ & 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}) \\ \\ & cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 12,\ \pi^k = \frac{1}{12} \\ & x_1, x_2 \geq 0 \\ & 0 \leq cc_1 \leq (1 - 0.6) \\ & y_k \in (0,1). \end{array} \tag{53}$$

Note that the first set of constraints covers the 12 scenarios, where each scenario has two constraints. The other constraints are similar to those introduced in the previous model.

The problem can be modeled with GAMS EMP as follows:

```
* Core Model
Positive Variables x1, x2;
Variables          z;

Scalars om1, om2;
om1 = 1;
om2 = 1;

Equations obj, e1, e2;

obj..   z =e= x1 + x2;
e1..    om1*x1 +   x2 =g=  7;
e2..    om2*x1 + 3*x2 =g= 12;

Model sc / all /;

* EMP Annotations
File emp / '%emp.info%' /;
put emp '* problem %gams.i%'/;
$onput
randvar om1 discrete 0.25 1  0.25 2  0.25 3  0.25 4
randvar om2 discrete 0.3333 1  0.3334 2  0.3333 3
chance e1 e2 0.6
$offput
putclose emp;

* Dictionary
Set scen "scenarios" / s1*s12 /;
Parameters  s_om1(scen)
            s_om2(scen)
            x1_l (scen)
            x2_l (scen)
            e1_l (scen)
            e2_l (scen);

Set dict / scen .scenario.''
           om1  .randvar .s_om1
           om2  .randvar .s_om2
           x1   .level   .x1_l
           x2   .level   .x2_l
           e1   .level   .e1_l
           e2   .level   .e2_l/;

solve sc min z use emp scenario dict;
display s_om1, s_om2, x1_l, x2_l, e1_l, e2_l;
```

In the EMP annotations, the line `chance e1 e2 0.6` specifies that in at least 60% of all scenarios both constraints `e1` and `e2` must be satisfied at the same time. There are a total of 12 scenarios, hence both constraints must be satisfied in at least 8 scenarios (i.e. $12 \times 0.6 = 7.2 \leq 8$). We can verify that this requirement has been enforced by checking in the listing file the level values of the constraints, `e1_l` and `e2_l`. Indeed, in the optimal solution both constraints hold in scenarios 4 to 12, meaning that there are 9 scenarios that satisfy both inequalities.

Individual Chance Constraints

In stochastic problems with individual chance constraints there is no correlation between the probabilities of the rows of the matrix A. Hence problem (47) takes the following form:

$$\begin{array}{ll} \text{Min}_x & c^T x \\ \text{s.t.} & P(A_i x \leq b_i) \geq p_i, \quad i = 1, \ldots, m \\ & x \geq 0. \end{array} \tag{54}$$

To illustrate, we use an extended version of the the example from the previous section and replace the joint chance constraints by individual chance constraints:

$$\begin{array}{lll} \text{Min} & x_1 + x_2 & \\ \text{s.t.} & P(\omega_1 x_1 + x_2 \geq 7) \geq 0.75, & \omega_1 \in \Omega_1 = \{1, 2, 3, 4\} \\ & P(\omega_2 x_1 + 3x_2 \geq 12) \geq 0.6, & \omega_2 \in \Omega_2 = \{1, 2, 3\} \\ & P(\omega_1 x_1 + \omega_2 x_2 \geq 10) \geq 0.5, & (\omega_1, \omega_2) \in \Omega_1 \times \Omega_2 = \Omega \\ & x_1, x_2 \geq 0. & \end{array} \tag{55}$$

Note that Ω is defined as in (52) above, we have again 12 scenarios, each with probability $\pi^k = \frac{1}{12}$. However, in this example, the first inequality must hold in 9 out of 12 scenarios ($0.75 \times 12 = 9$), the second inequality must hold in 8 out of 12 inequalities ($0.6 \times 12 = 7.2 \leq 8$) and the third inequality must hold in 6 out of 12 scenarios. Note further, that we may have four types of scenarios: scenarios where all constraints are violated, scenarios where two constraints are violated, scenarios where one constraint is violated and scenarios where all three constraints are satisfied. The only condition is that for each constraint there is the respective number of scenarios where the constraint is satisfied. Observe that the random data in the third inequality is a combination of the random data of the first two inequalities. The inequalities for the scenarios are given below:

$$\begin{array}{lll} k = 1: & \omega_1^1 = 1,\ \omega_2^1 = 1 & \omega_1^1 x_1 + x_2 \geq 7 \\ & & \omega_2^1 x_1 + 3x_2 \geq 12 \\ & & \omega_1^1 x_1 + \omega_2^1 x_2 \geq 10 \\ k = 2: & \omega_1^2 = 1,\ \omega_2^2 = 2 & \omega_1^2 x_1 + x_2 \geq 7 \\ & & \omega_2^2 x_1 + 3x_2 \geq 12 \\ & & \omega_1^2 x_1 + \omega_2^2 x_2 \geq 10 \\ \vdots & & \\ k = 12: & \omega_1^{12} = 4,\ \omega_2^{12} = 3 & \omega_1^{12} x_1 + x_2 \geq 7 \\ & & \omega_2^{12} x_1 + 3x_2 \geq 12 \\ & & \omega_1^{12} x_1 + \omega_2^{12} x_2 \geq 10 \end{array} \tag{56}$$

The MIP equivalent follows:

$$
\begin{array}{ll}
\text{Min} & x_1 + x_2 \\
\\
\text{s.t.} & 1x_1 + x_2 \geq 7 - M(1 - y_1^1) \\
& 1x_1 + 3x_2 \geq 12 - M(1 - y_1^2) \\
& 1x_1 + 1x_2 \geq 10 - M(1 - y_1^3) \\
& 2x_1 + x_2 \geq 7 - M(1 - y_2^1) \\
& 1x_1 + 3x_2 \geq 12 - M(1 - y_2^2) \\
& 2x_1 + 1x_2 \geq 10 - M(1 - y_2^3) \\
& \vdots \\
& 4x_1 + x_2 \geq 7 - M(1 - y_{12}^1) \\
& 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}^2) \\
& 4x_1 + 3x_2 \geq 10 - M(1 - y_{12}^3) \\
\\
& cc_1 = 1 - \sum_k \pi^k y_k^1, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& cc_2 = 1 - \sum_k \pi^k y_k^2, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& cc_3 = 1 - \sum_k \pi^k y_k^3, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
\\
& x_1, x_2 \geq 0 \\
& 0 \leq cc_1 \leq (1 - 0.75) \\
& 0 \leq cc_2 \leq (1 - 0.6) \\
& 0 \leq cc_3 \leq (1 - 0.5) \\
& y_k^j \in (0, 1).
\end{array}
\tag{57}
$$

As expected, there are three constraints for every scenario. Note that we introduced three new variables, cc_1, cc_2 and cc_3 and three corresponding constraints. Each of the variables has a different range reflecting the different probabilities with which a constraint may be violated.

The core model of the GAMS code is very similar to the core model with joint chance constraints. We just add the third inequality:

```
Equations obj, e1, e2, e3;

obj..   z =e= x1 + x2;
e1..    om1*x1 +   x2 =g=  7;
e2..    om2*x1 + 3*x2 =g= 12;
e3..    om1*x1 + om2*x2 =g= 10;
```

There is a slight modification in the annotations:

```
File emp / '%emp.info%' /;
put emp '* problem %gams.i%'/;
$onput
randvar om1 discrete 0.25 1   0.25 2  0.25 3  0.25 4
randvar om2 discrete 0.3333 1  0.3334 2  0.3333 3
chance e1 0.75
chance e2 0.6
chance e3 0.5
$offput
putclose emp;
```

Observe that we have three lines that start with the EMP keyword `chance:` every constraint is listed separately with its respective probability.

Note

In case one constraint has to be satisfied in all scenarios (so it is strictly speaking not a chance constraint), then it has to be listed with probability 1.0.

An overview of which constraints are satisfied in which scenarios in the optimal solution is given in the following table:

Scenarios	1	2	3	4	5	6	7	8	9	10	11	12
Scenarios where `e1` is satisfied				x	x	x	x	x	x	x	x	x
Scenarios where `e1` is satisfied		x	x		x	x		x	x		x	x
Scenarios where `e1` is satisfied						x	x	x	x	x	x	x

Table 7: Overview of constraint satisfaction per scenario

Observe that all constraints are satisfied in as many scenarios as required and there are scenarios where all three constraints are satisfied ($k = 6, 8, 9, 11, 12$), scenarios where only two constraints are satisfied ($k = 5, 7, 10$), scenarios where only one constraint is satisfied ($k = 2, 3, 4$) and one scenario where all constraints are violated ($k = 1$).

The choice whether joint or individual chance constraints should be used depends on the system being modeled. Both approaches have their own advantages. Individual chance constraints are weaker since not all constraints have to be satisfied at the same time. This can be clearly observed in the optimal solution for example (55). The objective value is 5.20 in the model with joint chance constraints and 4.75 in the model with individual chance constraints (assuming that each constraint is satisfied in 60% of all scenarios). As it is a minimizing problem, the model with individual chance constraints yields the better result. However, in this solution we have only 6 scenarios where both constraints are simultaneously satisfied while each constraint is satisfied in eight scenarios in total for the joint chance constraint formulation, as required.

Penalizing Violations of Chance Constraints

The EMP framework provides the syntax for a penalty factor for each scenario that violates one or more constraints. In the example with joint constraints above, the EMP annotations could be modified in the following way:

```
$onput
randvar om1 discrete 0.25 1  0.25 2  0.25 3  0.25 4
randvar om2 discrete 0.3333 1  0.3334 2  0.3333 3
chance e1 e2 0.6 3
$offput
```

Note that we added the number 3 at the end of the last line. This new entry represents a penalty factor. Recall that the MIP equivalent (53) takes the following form:

$$
\begin{array}{ll}
\text{Min} & z = x_1 + x_2 \\
\text{s.t.} & 1x_1 + x_2 \geq 7 - M(1 - y_1) \\
& 1x_1 + 3x_2 \geq 12 - M(1 - y_1) \\
& \vdots \\
& 4x_1 + x_2 \geq 7 - M(1 - y_{12}) \\
& 3x_1 + 3x_2 \geq 12 - M(1 - y_{12}) \\
& cc_1 = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12} \\
& x_1, x_2 \geq 0 \\
& 0 \leq cc_1 \leq (1 - 0.6) \\
& y_k \in (0, 1).
\end{array}
\tag{58}
$$

Observe that the probability with which the constraints are allowed to be violated is stored in the variable cc_1. Introducing a penalty factor or weight w has the effect that the term $(w \times cc_1)$ is added to the objective function:

$$z = x_1 + x_2 + w \times cc_1 = x_1 + x_2 + 3\,cc_1 \tag{4.29}$$

Similarly, we could add weights in the example with individual chance constraints:

```
chance E1 0.75 5
chance E2 0.6 6
chance E3 0.5 7
```

Given these annotations, we obtain the following objective function in the MIP equivalent:

$$z = x_1 + x_2 + 5\,cc_1 + 6\,cc_2 + 7\,cc_3. \tag{4.30}$$

Penalty terms can be useful to explore sensitivities to slight changes.

Note

> Like in the context of soft constraints, the penalty term is *added* in *minimization* problems and *subtracted* in *maximization* problems.

Moreover, the probability expression cc_1 in the MIP equivalent may be used as a variable in the original model. For example, in the joint chance constraints problem above, we could introduce a new variable, *viol*, in the objective function:

$$\text{Min} \quad z = x_1 + x_2 + 3 * viol \tag{4.31}$$

Then we write the chance constraint specification in the EMP annotations as follows:

```
chance E1 E2 0.6 viol
```

The addition of the variable `viol` as penalty factor causes cc_1 to be replaced by *viol* in the MIP equivalent. Thus we have:

$$viol = 1 - \sum_k \pi^k y_k, \quad k = 1, \ldots, 12, \quad \pi^k = \frac{1}{12}, \quad viol \in [0, 0.4]. \tag{4.32}$$

Note that the corresponding model is equivalent to the joint chance constraints model with penalty factor 3 with which we started this subsection.

EMP Syntax for Chance Constraints

The general syntax of the EMP annotations used to specify stochastic problems with chance constraints is as follows:

```
[randvar rv discrete prob val {prob val}]
[randvar rv distr par {par}]
[jrandvar rv rv {rv} prob val val {val} {prob val val {val}}]
chance equ {equ} [holds] minRatio [weight|var]
{chance equ {equ} [holds] minRatio [weight|var]}
```

The first three lines present three ways to specify random variables. The syntax and logic is the same as in stochastic problems with recourse, see above for details. Note that at least one random variable has to be specified. The EMP keyword `chance` is used to define the constraint(s) that only have to hold for a certain ratio of the possible outcomes. This ratio is given with the number `minRatio` ($0 \leq$ minRatio ≤ 1). The keyword `holds` is optional and does not affect the solver. The remaining specifications are optional and relate to the penalization of chance constraints that are violated. If `weight` is defined, the violation of a chance constraint will be penalized in the objective function (weight $\times$ violationRatio). Alternatively, if the name of a variable of the model (`var`) is specified, the violation will be multiplied by the value of this variable instead of the fixed multiplier `weight`.

In this section we have introduced various versions of problems with chance constraints with simple examples. For a more complex example, see the farming model [**KILOSAFARM**] in the GAMS EMP Model Library.

4.51.12 EMP Keywords

Some words act as keywords in the context of the EMP annotations in the file `emp.info`, but they are *not* GAMS reserved words, i.e. they are not keywords in the GAMS code apart from the EMP annotations. In this section we present an overview of all GAMS EMP keywords, ordered according to the type of programming where they are used.

4.51.12.1 GAMS EMP Keywords for Soft Constraints

EMP Keyword	Description
`abs`	Penalty function: absolute value of the equation.
`adjustequ`	Indicates that the specification(s) that follow relate to equations that are converted from constraints to penalty terms in the objective function.
`maxz`	Penalty function: the maximum of the equation and zero. An example is given above.
`sqr`	Penalty function: least squares applied to the equation. An example is given above.

4.51.12.2 GAMS EMP Keywords for Variational Inequalities

EMP Keyword	Description
`VI`	Indicates that the specifications that follow are a variational inequality. See the discussion of EMP specifications for VI and the example above.
`QVI`	Indicates that the specifications that follow are a quasi-variational inequality. See the discussion of EMP specifications for QVI and the example above.

4.51.12.3 GAMS EMP Keywords for Equilibrium Problems

EMP Keyword	Description
`dualvar`	See below.
`Equilibrium`	Indicates that the specifications that follow define the structure of an equilibrium problem. For examples, see sections Equilibrium Problems with EMP: A Simple Example and Equilibrium Problems with EMP: Example with Dual Variables. The general syntax of EMP annotations for equilibrium problems is introduced in section EMP Syntax for Equilibrium Problems.
`implicit`	Specifies a shared variable and its defining constraint. For details, see section Equilibrium Problems with Shared Variables.
`max`	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the *maximization* problem of one agent.
`min`	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the *minimization* problem of one agent.
`VI`	Indicates that the specifications that follow define a VI, as in this example.
`VIsol`	Specifies that the equation that follows is a shared constraint and prompts the EMP framework to use the MCP reformulation where a variational inequality is associated with the shared constraint. For more information and an example, see section Equilibrium Problems with Shared Constraints.

4.51.12.4 GAMS EMP Keywords for Embedded Complementarity Systems

EMP Keyword	Description
`DualEqu`	This keyword is followed by an equation-variable pair. It establishes a complementarity relationship between an external equation and the named variable of the model. An example is given above. See also the spatial price equilibrium model [**HARK-MONOP**].
`DualVar`	This keyword is followed by a variable-equation pair. It specifies that the variable is the dual of the equation. Examples are discussed in sections Equilibrium Problems with EMP: Example with Dual Variables and Embedded Complementarity Systems.

Note that problems with embedded complementarity systems can be recast as equilibrium problems. Details are given in section Embedded Complementarity Systems.

4.51.12.5 GAMS EMP Keywords for Bilevel Programming

EMP Keyword	Description
`bilevel`	Indicates that the specifications that follow relate to a bilevel programming problem. The keyword is follwed by the decision variable(s) of the upper-level problem and the definitins(s) of the lower-level problem(s). For examples and more details, see section Bilevel Programs.
`dualvar`	See above.
`max`	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the *maximization* problem of one agent.
`min`	This keyword is followed by the objective variable, the decision variable(s) and the equation(s) of the *minimization* problem of one agent, as in this example.
`VI`	Indicates that the specifications that follow define a VI, as in this example.

4.51.12.6 GAMS EMP Keywords for Disjunctive Programming

EMP Keyword	Description
`bigM`	Indicates that the big M reformulation method shall be used.
`chull`	Indicates that a convex hull shall be used for the reformulation. Note that this is the default method.
`default`	Indicates that the specification that follows is the reformulation method.
`disjunction`	Indicates that the specification that follows is a disjunction. For a discussion of the general syntax following this keyword, see above.
`indic`	Indicates that indicator constraints shall be used as reformulation method.
`star (*)`	The symbol $*$ will be replaced by internal default binary variables, thus explicit binary variables that model the Boolean variables are not needed. Note that default binary variables may only be used if there are no logic equations in the model. For an example and more details, see above.

4.51.12.7 GAMS EMP Keywords for Stochastic Programming

EMP Keyword	Description
`chance`	Defines individual or joint chance constraints.
`cvar`	Synonym to cvarup.
`cvarlo`	This keyword assigns a variable to have the value $\underline{CVaR}_\alpha$, where α is a scalar that represents the confidence level for the Conditional Value at Risk. Note that `cvarlo` refers to the left tail of the distribution. For more details and examples, see section Conditional Value at Risk (CVaR).
`cvarup`	This keyword assigns a variable to have the value $\overline{CVaR}_\alpha$. α is a scalar that represents the confidence level for the Conditional Value at Risk. Note that `cvarup` refers to the right tail of the distribution.
`discrete`	Indicates that the specification that follows is the discrete distribution of one or more random variables.
`ExpectedValue`	This keyword is used to state that a variable is the expected value of a random variable.
`jrandvar`	This keyword is used to define discrete random variables that are *jointly* distributed. At least two random variables must be named. For an example, see the news vendor model [**NBDISCJOINT**].
`randvar`	This keyword declares that a parameter of the model is in fact a stochastic random variable. The keyword is followed by the name of the parameter and details about the probability distribution (discrete or parameteric). A list of all supported parametric distributions is given in Table 4.
`sample`	This keyword allows users to customize the size of the sample of one or more random variables from a continuous distribution and - optionally - to determine the variance reduction method to be used. An example and further details are given above. Note that without a valid LINDO license this is limited to the Normal and Binomial distributions with a maximum sample size of 10.
`setSeed`	This keyword sets the seed for the random number generator of the sampling routines that are called via the keyword sample. If `setSeed` is used in EMP annotations, the seed will be set once before all samples will be generated. Note that a valid LINDO license is required to use this keyword.
`stage`	This keyword is followed by a number and the names of the random variables, variables and equations that are assigned to the respective stage. Stage 1 is the default stage for all random variables, variables and equations that are not assigned a stage explicitly except for objective equation and variable. Their default stage is the highest stage in the model.

EMP Keyword	Description
`stageDefault`	This keyword is followed by a number. This specifies the default stage for all random variables, variables and equations that are not assigned a stage explicitly (except for objective equation and variable). If this keyword is not used explicitly, the default is 1.
`var`	Synonym to varup.
`varlo`	This keyword assigns a variable to have the value $\underline{VaR}_\alpha$, where α is a scalar that represents the percentile of the Value at Risk. Note that `varlo` refers to the left tail of the distribution. For more details and examples, see section Value at Risk (VaR).
`varup`	This keyword assigns a variable to have the value $\overline{VaR}_\alpha$, where α is a scalar that represents the percentile of the Value at Risk. Note that `varup` refers to the right tail of the distribution and α typically equals 0.95 or 0.9. For further information, see section Value at Risk (VaR).

Currently, two GAMS solvers can be used to solve stochastic programming models with EMP: DE and LINDO. Not all keywords mentioned above are supported by both solvers. The following table specifies which keywords can be used with which solvers. The keywords not mentioned in the table are supported by all solvers mentioned.

	DE	LINDO
`chance`	√	√
`jrandvar`	√	√
`randvar`(discrete)	√	√
`randvar`(parametric)	√	√
`sample`	√	√
`setSeed`		√
`var`	√	
`cvar`	√	
`ExpectedValue`	√	

Table 8: Solver capabilities

Note

In general, JAMS is the default solver for models of type `EMP`. However, since `JAMS` cannot handle stochastic EMP models, GAMS switches the solver to DE automatically when, a stochastic EMP model is tried to be solved with `JAMS`.

Further information about these solvers can be found in the corresponding solver manuals. The stochastic programming options for the solver LINDO might be of particular interest.

4.52 Accessing Model Libraries

Professor Paul Samuelson is fond of saying that he hopes each generation of economists will be able to `"stand on the shoulders"` of the previous generation. The library of models included with the GAMS system is a reflection of this desire. We believe that the quality of modeling will be greatly improved and the productivity of modelers enhanced if each generation can stand on the shoulders of the previous generation by beginning with the previous models and enhancing and improving them. The Model Libraries includes a large number of models, collectively organized as

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.
- **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.
- **GAMS Data Utilities Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.
- **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.
- **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.
- **FIN Library** - includes GAMS practical financial optimization models described in the book `Practical Financial Optimization: Decision Making for Financial Engineers` by Consiglio, Nielsen and Zenios,
- **NOA Library** - includes GAMS nonlinear optimization applications models based on the book `Nonlinear Optimization Applications Using the GAMS Technology` by Neculai Andrei.
- **PSOPT Library** - includes GAMS optimization models based on the book `Power System Optimization Modelling in GAMS` by Alireza Soroudi.

The models included have been selected not only because they collectively provide strong shoulders for new users to stand on, but also because they represent interesting and sometimes classic problems. For example the trade-off between consumption and investment is richly illustrated in the Ramsey problem, which can be solved using nonlinear programming methods. Examples of other problems included in the library are production and shipment by firms, investment planning in time and space, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and relational databases.

Another criterion for including models in the library is that they illustrate the modeling capabilities GAMS offers. For example, the mathematical specification of cropping patterns can be represented handily in GAMS. Another example of the system's capability is the style for specifying initial solutions as staring points in the search for the optimal solution of dynamic nonlinear optimization problems.

Finally, some models have been selected for inclusion because they have been used in other modeling systems. Examples are network problems and production planning models. These models permit the user to compare how problems are set up and solved in different modeling systems.

Most of the models have been contributed by GAMS users. The submission of new models is encouraged. If you would like to see your model in a future release of the library, please send the model and associated documents and reports to GAMS Development Corporation.

4.52.1 Usage

4.52.1.1 Command Line Approach

One way to access the library is through command line. The following commands copy a model from the library directory into the current directory.

Command	Library to access
gamslib	**GAMS Model Library**
testlib	**GAMS Test Library**
datalib	**GAMS Data Library**
emplib	**GAMS EMP Library**
apilib	**GAMS API Library**
finlib	**FIN Library**
noalib	**NOA Library**
psoptlib	**PSOPT Library**

Take the command gamslib for an example, if you enter gamslib without any parameters, the command syntax will be displayed as shown below:

```
> gamslib modelname [target]
```

or

```
> gamslib modelnum [target]
```

where

- modelname is the modelname
- modelnum is the model sequence number, and
- target is the target file name.

If the target file name is not provided, the default is modelname.gms. The file will be automatically copied into the current working directory. For example, the [**TRNSPORT**] model from the **GAMS Model library** has sequence number 1 and could be copied in any of the following ways.

To copy [**TRNSPORT**] model file to target file trnsport.gms under the current directory:

```
> gamslib trnsport
```

```
> gamslib 1
```

To copy [**TRNSPORT**] model file to target file myname.gms under the current directory:

```
> gamslib trnsport myname
```

```
> gamslib 1 myname
```

The other commands have similar usage to gamslib command.

4.52.1.2 IDE Approach

A convenient way to access the model library on the major platforms is the "Model Library Explorer" from GAMS Studio. It is described in detail in the GAMS Studio documentation.

Users may define their own library by using a GLB file. These libraries can also be accessed through Studio.

4.53 Mathematical Programming System for General Equilibrium analysis (MPSGE)

- Introduction to MPSGE
- MPSGE Models in GAMS
- Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE
- Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae
- `A Library of Small Examples for Self-Study`
- `Linking Implan Social Accounts to MPSGE`
- The MPSGE guide is also available as `PDF`.

4.53.1 Introduction to MPSGE

MPSGE is a language used for formulating and solving Arrow–Debreu economic equilibrium models and exists as a subsystem within GAMS. The name stands for 'mathematical programming system for general equilibrium'. MPSGE provides a short-hand non-algebraic representation for the systems of nonlinear inequalities which underly general equilibrium models. The MPSGE framework is based on nested constant elasticity of substitution utility and production functions. The data requirements for a model include share and elasticity parameters, endowments, and tax rates for all the consumers and production sectors in the model. These may or may not be calibrated from a consistent benchmark equilibrium dataset.

The main benefit of using MPSGE is that modelers are released from having to write the equations of the model and the calibrated demand and supply functions. Experience shows that even computing the parameters of the functions is error-prone. The tabular input format of MPSGE facilitates a compact, non-algebraic representation of the equations of a model. Thus algebraic tedium and the scope for programming errors are reduced, and more attention can be paid to economic interpretation and testing of alternative formulations.

This chapter offers an introduction to MPSGE for users who are familiar with GAMS. For more information on MPSGE and details on more advanced features, see [156] and

[130]. In addition, a library of small examples for self-study is available `here` .

This chapter is organized as follows. We start with an overview of some basic economic ideas and general remarks on specifying an MPSGE model. Next, we introduce a first simple example. Then we demonstrate how intermediate demand and joint production are modeled with MPSGE. We follow with a third model that features a small open economy and also includes taxes on inputs and outputs, labor-leisure choice, classical unemployment, and nested demand functions. We conclude the chapter with an overview of MPSGE keywords and the syntax for specifying functions, some other features like domain restrictions on variable declarations, and a few brief comments on MPSGE-specific output in the GAMS listing file. Note that a full version of all MPSGE models that are discussed, including standard GAMS versions, are given in the Appendix.

4.53.1.1 Some Basic Economic Ideas

MPSGE models are based on the following economic ideas. In each model there are multiple interacting agents, where each agent solves an optimization problem. For example, consumers maximize utility subject to their budget constraint, and producers minimize their cost given available technology. Agent interactions are mediated by markets and prices and the optimal solution is an equilibrium where prices and activity levels have adjusted so that markets for produced goods and input factors clear. In equilibrium, each agent cannot do better by altering their behavior (given the constraints they face). In this section we give more details on these basic economic ideas. In particular, we offer brief introductions to consumer demand theory, producer supply theory and general economic equilibrium.

Consumer Demand Theory

Consumer choice is modeled using an optimization paradigm: consumers form a consumption bundle which maximizes welfare subject to a budget constraint. As an abstract notion, this seems plausible, but certain details must be dealt with to provide an operational application of the idea.

Consider the following example. Thomas lives in Ann Arbor where he spends 30% on housing and the rest of his income on other goods. This information is essentially an observation of a *benchmark equilibrium*, consisting of the prevailing prices and quantities of goods demanded. Now, Thomas has an employment offer in Berlin which pays 50% more than he currently earns, but he is hesitant to take the job since rental rates in Berlin are three times higher than in Ann Arbor. The question is: On purely economic grounds, should he move?

Thomas' choices are illustrated below. Point a represents the benchmark point, where he spends the amount H_a on housing in Ann Arbor. Point b represents a potential trade-off between housing and other goods in Berlin, where he spends a lower percentage of his income on housing and more on other goods.

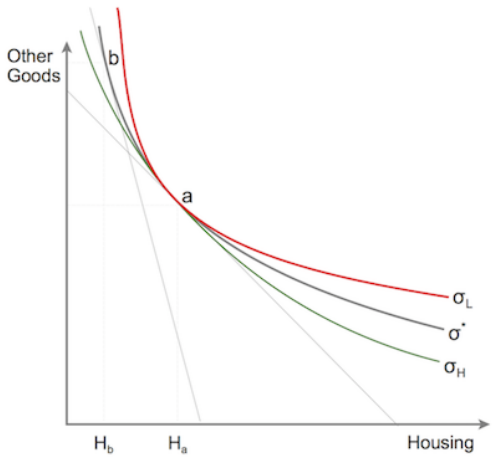

Figure 4.6 Thomas' Choices

Whether Thomas derives the same welfare from the choices represented by point b like those represented by point a depends on the *elasticity of substitution*. The elasticity of substitution is the willingness to exchange some amount of one good for more of the other good. The three curves in the figure above represent three elasticities of substitution. Note that the less convex (flatter) the curve is, the higher is the elasticity, i.e. the more willing is Thomas to substitue housing for other goods.

If the elasticity of substitution equals $\sigma^\star$, Thomas is *indifferent* between choices a and b, since both points lie on the respective *indifference curve*. However, if the elasticity of substitution is lower, say is equals σ_L, or higher, say it equals σ_H, then b will be worse than a and Thomas will not choose it. Hence, the

elasticity of substitution is crucial in determining whether Thomas should move on economic grounds. Note that the elasticity of substitution is a measure for Thomas' preferences.

The utility function can be deduced if prices and the associated choices are observed and the elasticity of substitition is given. Thus, in MPSGE, a utility function is represented by benchmark (or observed) quantities, benchmark prices and the associated elasticity of substitution. Benchmark quantities determine an anchor point for the set of indifference curves. Benchmark prices fix the slope of the indifference curve at that point. The elasticity of substitution is a measure of the curvature of the indifference curve and specifies the utility function unambiguously.

Producer Supply Theory

While consumers aim to maximize their utility subject to a budget, producers aim to reduce their cost of production given available technology. The activity of a firm is modeled as a *production function* that maps inputs into outputs. Inputs are primary factors like labor, capital, land, raw materials etc. and outputs are goods and services. Similarly to utility functions, in MPSGE, a production function is represented by reference quantities of reference prices of inputs and outputs, elasticities of substitution and elasticities of transformation.

Summarizing, the main principle for both, consumers and producers, is choice. Consumers choose quantities of goods given their preferences, prices and budgets. Producers choose quantities of primary factors and output levels given available technology. Available technology is modeled via elasticities of substitution between inputs and elasticities of transformation between outputs.

General Economic Equilibrium

As mentioned above, MPSGE is a system for modeling general economic equilibria. General economic equilibrium analysis studies the working of an economic system as a whole. The basic assumption is that there are two types of agents in the economy: producers and consumers. Producers are assumed to operate with constant return to scale and to be perfectly competitive price-taking firms. Further, they are assumed to select factor inputs and output levels in order to maximize their profits given available technology. Consumers are assumed to maximize their welfare subject to budget constraints (incomes and endowments). An economy is in economic equilibrium if all consumers spend their given incomes such that they gain maximum satisfaction, all firms in each sector minimize their costs given availabe technology, and prices (for primary factors and commodities) and activity levels have adjusted such that all agents cannot do better by altering their behavior given the constraints they face. In equilibrium, all markets have cleared: in both, goods and factors markets, total demand equals total supply.

Mathematically, such an economy is modeled as a system of weak inequalities, where each inequality is associated with a non-negative variable denoting a price or a quantity. If a particular weak inequality holds as an equation, then the associated variable is strictly positive. If it holds as a strict inequality, then the associated variable equals zero. This is a mixed complemantarity problem that can be formulated and solved with standard GAMS syntax. For details see section Mixed Complementarity Problems (MCPs). As we will demonstrate, MPSGE models can be translated to standard GAMS MCP models. However, the framework that MPSGE offers is much more user-friendly, since modelers do not have to input the complex equations manually.

4.53.1.2 Specifying an MPSGE Model

In this section we give an overview of the MPSGE model specification, a simple introductory example follows in the next section. Like any standard GAMS program, a program with an embedded MPSGE model begins with set and parameter definitions that will later be used in the model. The MPSGE model is specified within an $ontext / $offtext block.

First, the name of the model must be defined:

```
$MODEL:mymodel
```

Here `$MODEL` is an MPSGE keyword and the model name `mymodel` is a GAMS identifier.

In a GAMS program lines within $on/offtext are are treated as a block comment. However, if the preprocessor encounters the MPSGE model definition statement, it will recognize that an MPSGE model specification follows and will process the code accordingly.

Note

Like GAMS, MPSGE is not case sensitive.

Secondly, the variables for an MPSGE model are declared. In every model, there are three classes *central variables:*

- `$SECTORS:` variables for activity levels associated with constant returns to scale production sectors in the economy, which are non-negative,
- `$COMMODITIES:` variables for commodity prices including all final goods, intermediate goods and primary factors of production, which are also non-negative, and
- `$CONSUMERS:` variables for income levels, one for each "household" in the model, including any government entities.

In addition, models may include *auxiliary* variables (`$AUXILIARY`) that are used to introduce endogenous tax instruments or endogenous endowment quantities to a model.

Note

Unlike GAMS models, variables in an MPSGE model must be declared over an explicit domain. Only variables that have been declared as one of the four MPSGE variable types may be used in the MPSGE model. Error messages are generated for variables which are declared but not referenced.

Thirdly, the parameters for functions are specified in a structured manner. The general syntax for all possible entries is given is section Syntax for Production and Demand Functions below. The MPSGE framework uses these specifications to automatically generate the respective market-clearing and income-balance equations. There are two types of functions:

- `$PROD:` This block defines a production function, specifying inputs, outputs and elasticities of substitution and transformation. A production function must be given for each sector in the model. Note that most of the power and subtleties of the MPSGE framework center on the `$PROD` tables.
- `$DEMAND:` This block defines a demand function. This function represents preferences (using reference demands), initial factor endowments and elasticities of substitution. A demand function must be specified for each consumer in the model.

Finally, any auxiliary variable has an associated equilibrium condition that is defined by the user with conventional GAMS algebraic syntax and placed in a block called `$CONSTRAINT`.

These four parts - model definition, variable declarations, function specifications and possibly side constraints for auxiliary variables - are the core of the MPSGE model specification. The model specification is followed by the dollar control option `$offtext` and the following compiler directive:

```
$sysinclude mpsgeset mymodel
```

This compiler directive instructs MPSGE to compile the functions and generates an external file called MYMODEL.GEN. This external file is then loaded to the GAMS file with the following directive:

```
$include MYMODEL.GEN
```

Finally, a standard GAMS solve statement follows and the model will be handed for solution to one of the MCP solvers:

```
solve mymodel using mcp;
```

Observe that the appropriate GAMS model type is MCP.

Most often the model is first evaluated at the benchmark point to test whether it is peoperly calibrated and everything works as expected. This is achieved by setting the option iterlim to zero. Then one or more counterfactuals are solved: first some parameter is modified using standard GAMS syntax, then the $include statement is repeated and the model is solved again.

Note

"$sysInclude mpsgeset" allows for an optional argument -mt=0 or 1 after the model name. The default value for the argument mt can be controlled via the double dash option --MPSGEMT=0 or 1. If the mt option is set to 1 the MODEL.GEN file is created in the GAMS scratch directory. Hence the $include before the solve needs to read $include "%gams.scrdir%MODEL.GEN". This allows to run multiple MPSGE jobs with the same model in the same working directory. The default of this option is 0. The model **hansmge** demonstrates the use.

4.53.1.3 An Introductory Example: Two Goods and Two Factors in a Closed Economy

In the canonical 2x2 model, two final goods, X and Y, are produced with two primary factors, labor L and capital K, and there is a single representative agent (consumer) RA. The model is defined by technology, preferences and endowments. We can describe prefrences by a utility function which provides an ordinal ranking of consumption levels for X and Y. We assume that both factors are in fixed supply, thus in equilibrium, factor endowments equal factor demands, and the supply of the two goods equal their demand.

The problem can be cast as consisting of three production activities, X, Y and U, and five markets X, Y, U, K and L. The initial data for the model are given by the following matrix.

	Production Sectors			Consumers	
Markets	X	Y	U	RA	Row Sums
PX	100		-100		0
PY		50	-50		0
PU			150	-150	0
PK	-50	-20		70	0
PL	-50	-30		80	0
Column Sums	0	0	0	0	

The data describes a representative equilibrium. Rows correspond to markets, where PX, PY, PU, PK and PL are the prices for the commodity X, the commodity Y, the utility U, and capital and labor respectively. Positive entries denote the value of commodity flows *into* the economy (sales or factor supplies) and negative entries represent the value of commodity flows *out* of the economy (factor demands and good demands). Observe that the sum of a row will equal zero if the market clears, i.e. the total amount of commodity that flows into the economy equals the total amount of this commodity that flows out of the economy. The matrix is called *balanced* if all rows and columns sum to zero.

Note that the layout of the matrix ensures that a complete list of the transactions associated with an activity is given in each production column. The sum of a production sector column is zero if the value of the outputs equals the costs of the inputs. A consumer column is balanced if the sum of primary factor sales equals the value of final demands. Hence columns that sum to zero indicate zero profits. This type of matrix is related to the concept of a *social accounting matrix* (or short: *SAM*).

The problem can be modeled with GAMS MPSGE as follows:

```
Parameter   endow     index of labour endowment     / 1.0 /;

*       MPSGE model declaration follows

$ontext
$MODEL:twobytwo

$SECTORS:
    X   ! Activity level for sector X -- benchmark=1
    Y   ! Activity level for sector Y -- benchmark=1
    U   ! Activity level for sector U -- benchmark=1

$COMMODITIES:
    PX  ! Relative price index for commodity X -- benchmark=1
    PY  ! Relative price index for commodity Y -- benchmark=1
    PU  ! Relative price index for commodity U -- benchmark=1
    PL  ! Relative price index for labor -- benchmark=1
    PK  ! Relative price index for capital -- benchmark=1

$CONSUMERS:
    RA  ! Income level for representative agent -- benchmark=150;

$PROD:X s:1
        O:PX   Q:100
        I:PL   Q: 50    ! Variable LX in the algebraic model
        I:PK   Q: 50    ! Variable KX in the algebraic model

$PROD:Y s:1
        O:PY   Q: 50
        I:PL   Q: 20    ! Variable LY in the algebraic model
        I:PK   Q: 30    ! Variable KY in the algebraic model

$PROD:U s:1
        O:PU   Q:150
        I:PX   Q:100    ! Variable DX in the algebraic model
        I:PY   Q: 50    ! Variable DY in the algebraic model

$DEMAND:RA
        D:PU
        E:PL   Q: (70*endow)
        E:PK   Q: 80
```

```
$offtext

* Compiler directive instructing MPSGE to compile the functions

$sysinclude mpsgeset twobytwo

* Benchmark replication

twobytwo.iterlim = 0;
$include TWOBYTWO.GEN
solve twobytwo using mcp;
abort$(abs(twobytwo.objval) gt 1e-7) "*** twobytwo does not calibrate ! ***";
twobytwo.iterlim = 1000;

*   Counterfactual : 10% increase in labor endowment

endow = 1.1;

*   Solve the model with the default normalization of prices which
*   fixes the income level of the representative agent.  The RA
*   income level at the initial prices equals 80 + 1.1*70 = 157.

$include TWOBYTWO.GEN
solve twobytwo using mcp;
```

Note that an algebraic version of this model using standard GAMS syntax is given in the Appendix.

After the model statement where the model is named, variables are declared in each of the three central variable classes. Unlike conventional GAMS syntax, in MPSGE, trailing comments in variable declarations (starting with the symbol `!`) are interpreted as variable descriptors that will appear in the listing file.

Then three production blocks `$PROD` - one for each sector - follow. Output parameters are specified in the line starting with the label `O` and input parameters are given in the line starting with the label `I`, the respective quantities are listed in the field `Q`. Note that the first input in the production block for sector `X` represents labor demand in sector X and the second input represents capital demand in sector `X`. Similarly, the inputs in the production block for sector `Y` represent labor and capital demand for sector `Y`. In the production block for sector `U`, the inputs represent demand for `X` and `Y` in sector `U`. In the field `s:` next to the name of the sector the elasticity of substitution between the inpiuts is specified.

A demand block `$DEMAND` for the consumer `RA` completes the model specification. Demand parameters are specified in the line starting with the label `D` and endowment parameters are given in the line starting with the label `E` . Note that all possible entries for production and demand blocks are discussed in section Syntax for Production and Demand Functions. Observe that there is no algebraic formulation of equations, only parameter specifications. Given this input, the MPGSGE frameworks generates the respective equations automatically.

Note that it is not necessary to fix a numeraire. If a numeraire is not specified, the normalization of prices is arbitrary. For example, in the model above, `RA` is used as a numeraire and the following remark appears in the listing file:

```
Default price normalization using income for RA
```

Note that the version of this model in the Appendix includes two additional counterfactual scenarios, where first sector `X` is used as numeraire commodity and then the wage rate `PL` is fixed as numeraire. In the Appendix, there are also two alternative versions of the model above: a model in standard GAMS syntax where the equations that are automatically generated by the MPSGE framework are given explicitly, and an MPSGE model that uses vector notation instead of scalars.

4.53.1.4 Modeling Intermediate Demand and Joint Production

In this section we extend the two by two model above in the following three ways:

1. We distinguish between production sectors and produced goods.
2. Each sector produces both goods, so we have *joint production*.
3. In addition to primary factors like labor and capital, goods enter the production process as inputs. Thus we have *intermediate demand*.

The full MPSGE model and MCP and NLP versions of the model are given in the Appendix. Here we reproduce and discuss only selected code snippets. The main difference to the simple model above is the specification of the production block:

```
$PROD:X(j)   s:1    t:1
      O:P(i)    Q:make0(i,j)    ! S(i,j) in the MCP and NLP models
      I:P(i)    Q:use0(i,j)     ! D(i,j) in the MCP and NLP models
      I:PF(f)   Q:fd0(f,j)      ! FD(f,j) in the MCP and NLP models
```

Note that the supply is specified in the output line, the intermediate demand is given in the first input line and the factor demand is listed in the second input line. Thus each sector `j` produces the goods `i` using the intermediate goods `i` and the primary factors `f`. Consider the fully spelled-out production block for sector `s1`:

```
$PROD:X("s1")   s:1    t:1
      O:P("g1")        Q:6.0
      O:P("g2")        Q:2.0
      I:P("g1")        Q:4.0
      I:P("g2")        Q:2.0
      I:PF("labor")    Q:1.0
      I:PF("capital")  Q:1.0
```

At benchmark, sector `s1` produces 6 units of good `g1` and 2 units of good `g2`. The input for this output is 4 units of the good `g1`, 2 units of the good `g2` and labor (one unit) and capital (one unit).

Note

> *Double* quotes have to be used if a singleton set element is referenced in an MPSGE model. Single quotes are not recognized.

Observe that the technology used to combine these four production factors is based on a Cobb-Douglas production function, i.e. the elasticity of substitution equals 1, as indicated by the value in field `s`. In addition, the curvature of the production possibility frontier (the constant elasticity of transformation function) is given in field `t`.

4.53.1.5 Modeling a Small Open Economy

An open economy is one in which goods are traded on international markets, typically at fixed international prices, i.e. there are imports and exports. One class of models for small open economies are known as "123 models" [42]. In the original 123 model, there was one small country, two producing sectors and three goods (one domestic good, one import good and one export good). The 123 model we present and discuss in this section has exogenously given world prices for imports and exports, taxes, labor-leisure choice, classical unemployment and joint production. The programming language keeps track of tax revenue flows, equations which are otherwise tedious to program. The model is a tiny version of the open economy GTAP model [115]. It follows the canonical microecomic optimization framework: (i) consumers maximize welfare subject to a budget constraint with fixed levels of investment and public expenditure, and (ii) producers combine intermediate inputs and primary factors at least cost for given technology.

Note that the full MPSGE model `mge123` and an algebraic version are given in the Appendix. In addition, we introduce and discuss a version of the model that includes nesting. Note further, that the data for the model and its variants are included in a separate GAMS file. Observe that the input-output matrix in the data file provides data on value flows for primary production factors, intermediate goods and final consumption products. In the following, we comment on selected code snippets and thereby discuss the most important features of the model.

Consider the production block for the entire production of the small economy:

```
$PROD:Y  t:etadx s:esubkl
        O:PD    Q:d0    P:1                              ! YD
        O:PX    Q:x0    P:px0   A:GOVT  T:tx             ! YX
        I:RK    Q:kd0   P:rr0   A:GOVT  T:tk             ! KD
        I:PL    Q:ly0   P:pl0   A:GOVT  T:tl N:TAU_TL    ! LY
```

Note that the first output line represents production for the domestic market, which is denoted by the variable `YD` in the algebraic version of the model. The reference price at benchmark is given in the new field `P`.

Note

The default value for both P and Q fields is 1.0

The second output line represents production for the export market (variable `YX` in the algebraic version). Observe that taxes are specified in the two new fields `A` and `T:` the tax recipient is specified in field `A` and the tax rate is listed in field `T`. Note that the tax recipient must reference a `$CONSUMER` variable and the tax rate `tx` (tax rate on exports) is given *exogenously*.

Attention

In MPSGE, the way exogneous taxes are computed depends on whether they are imposed on outputs or inputs. Taxes on *outputs* are specified on a *gross* basis. Hence, if a tax on outputs has proportional rate t, the producer price will be $p(1-t)$, where p is the market price. However, taxes on *inputs* are specified on a *net* basis. Hence, if a tax on inputs has ad valorem rate t , the user cost will be $p(1+t)$, where p is the market price.

The first input line represents capital demand (variable `KD` in the algebraic version). The model includes investment by the private (domestic) households, thus the variable `RK` denotes a rental price index. Observe that capital is taxed exogenously at the capital tax rate `tk`.

The second input line represents labor demand (variable `LY` in the algebraic version). In addition to an exogenous labor tax `tl`, an *endogenous* tax is imposed on this input. The endogenous tax rate is determined by the auxiliary variable `TAU_TL`, which is the entry in the field `N` at the end of the line. Note that an equation associated with the auxiliary variable is specified in the following block:

```
$CONSTRAINT:TAU_TL
        GOVT =e= PA * g0;
```

Note

When an auxiliary variable is fixed no constraint is required. When the lower bound of the auxiliary variable is less than the upper bound, a constraint is required.

Note further, that the variable TAU_TL is a wage replacement tax and at benchmark, it is fixed at zero. It is positive in two of the four counterfactual scenarios.

Domestic demand is modeled using the Armington assumption: consumers demand one single good which is an aggregation of *composite goods* consisting of the goods produced domestically and the imported versions, where imports and domesctic goods in the same sector are imperfect substitutes. The aggregated composite good is given by a constant elasticity of substitution aggregation function of the domestic goods and the imported goods with elasticity of substitution sigmadm. In our model, sigmadm equals 4 (domestic versus imported goods). The production of the Armington good is specified in the following block:

```
$PROD:A  s:sigmadm
        O:PA    Q:a0    A:GOVT  t:ta
        I:PD    Q:d0                        ! DA
        I:PM    Q:m0    p:pm0 A:GOVT t:tm   ! MA
```

Note that both inputs are intermediate goods. The first input line represents domestic absorption (variable DA in the algebraic version of the model) and the second input line represents imports (variable MA in the algebraic version). Imports are taxed with the import tariff rate tm and the composite good is taxed with the excise and sales tax rate ta. Both taxes are exogenous.

In addition, the model contains production blocks for imports and exports. Foreign exchange (denoted by the MPSGE variable PFX) is used in these two production blocks. It is the input in the production block for imports and the output in the production block for exports.

The two consumers in the model are the government (MPSGE variable GOVT) and aggregated private households (MPSGE variable HH). The demand block for the government agent is as follows:

```
$DEMAND:GOVT
        E:PFX   Q:bopdef
        E:PA    Q:dtax
        E:PA    Q:g0            R:TAU_LS
        D:PA
```

Note that the first endowment line represents the balance of payment in the current account (denoted by the $COMMODITIES variable PFX). In our model, exports exceed imports resulting in the deficit bopdef. If imports are larger than exports there will be a surplus. The other two endowment lines represent taxes that are paid by the households: a direct tax dtax and a lumpsum labor replacement tax that is specified as an auxiliary variable and determined by the respective complementarity equation. In this model the labor replacement tax is either a lumpsum tax (TAU_LS) or it is levied on labor at a tax rate of TAU_TL (see above). Note that the direct tax and the lumpsum tax feature in the demand block for HH as *negative* endowments. Negative endowments represent payments to be made. The demand block for HH follows:

```
$DEMAND:HH  s:sigma
        E:PA    Q:(-g0)         R:TAU_LS
        E:PA    Q:(-dtax)
        E:RK    Q:kd0
        E:PA    Q:(-i0)
        E:PL    Q:(ly0+l0)      ! Labor endowment = ly0+l0 - UR * (ly0+l0)
        E:PL    Q:(-(ly0+l0))   R:UR
        D:PA    Q:c0
        D:PL    Q:l0
```

Households demand two goods: the Armington composite good PA (first demand line) and leisure (second demand line). Note that the first two endowment lines represent taxes as discussed above. The third and and fourth endowment line relate to capital: the third line represents the income generated by capital investment and the fourth line represents capital investments. The last two endowment lines refer to labor. Labor endowment for the aggregated households equals the sum of labor and leisure minus the percentage of unemployment. Note that at benchmark, the unemployment rate UG is fixed at zero, other scenarios are explored in the counterfactuals.

In model mge123, the rate of substitution for domestic and imported goods that constitute the Armington good PA is fixed at sigmadm = 4. Suppose that we want more control over substitution possibilities. For example, we may wish to model a substitution rate in final demand that is different than for other uses of the Armington good. MPSGE facilitates modeling this additional degree of freedom through *nesting*. Consider the following demand block for HH from model mgenested, a variant of model mge123:

```
$DEMAND:HH  s:sigma    c:sigmac
        E:PA    Q:(-g0)          R:TAU_LS
        E:PA    Q:(-dtax)
        E:RK    Q:kd0
        E:PA    Q:(-i0)
        E:PL    Q:(ly0+l0)           ! Labor endowment = ly0+l0 - UR * (ly0+l0)
        E:PL    Q:(-(ly0+l0))   R:UR
        D:PD    Q:cd0    c:
        D:PM    Q:cm0    c:
        D:PL    Q:l0
```

Note that in this formulation the endowment lines are unchanged and we have three demand lines. The first two demand lines have an additional field (c:). This tag indicates that these two goods are part of a nest: they are combined to an intermediate good called C. The rate of substitution for the goods in the nest is given in the first line of the demand block: c:sigmac. Observe that except for the substitution rate, C equals PA. The structure of the final demand can be presented graphically using the followong nesting diagram:

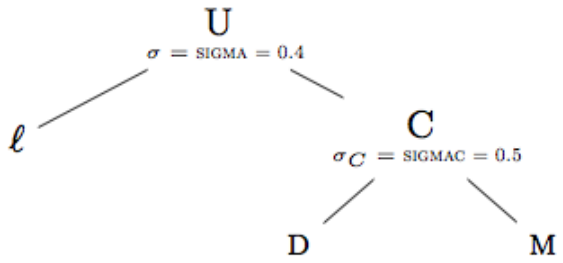

Figure 4.7 Structure of nested demand for HH

The nested utility function, expressed as a *unit function* is:

$$U = \left[\theta\left(\frac{\ell}{\bar{\ell}}\right)^{1-1/\sigma} + (1-\theta)\left(\alpha\left(\frac{D}{\bar{D}}\right)^{1-1/\sigma_C} + (1-\alpha)\left(\frac{M}{\bar{M}}\right)^{1-1/\sigma_C}\right)^{\frac{1-1/\sigma}{1-1/\sigma_C}}\right]^{1/1-1/\sigma}$$

in which θ is the budget share of leisure (ℓ) in aggregate expenditure, and α is the budget share of domestic goods (D) in commodity expenditure, both evaluated at the benchmark point:

$$\theta = \frac{\bar{\ell}}{\bar{\ell} + \bar{D} + \bar{M}}$$

and

$$\alpha = \frac{\bar{D}}{\bar{D} + \bar{M}}$$

The demand for leisure is a function of extended income (HH):

$$\ell = \bar{\ell} \left(\frac{p_U}{p_\ell} \right)^{\sigma} \frac{HH}{p_U \left(\bar{\ell} + \bar{D} + \bar{M} \right)}$$

The demand for domestic and imported goods is a function of both the top-level elasticity of substitution, σ, as well as the elasticity of substitution between consumption goods, σ_C:

$$D = \bar{D} \left(\frac{p_U}{p_C} \right)^{\sigma} \left(\frac{p_C}{p_D} \right)^{\sigma_C} \frac{HH}{p_U \left(\bar{\ell} + \bar{D} + \bar{M} \right)}$$

and

$$M = \bar{M} \left(\frac{p_U}{p_C} \right)^{\sigma} \left(\frac{p_C}{p_M} \right)^{\sigma_C} \frac{HH}{p_H (\bar{\ell} + \bar{D} + \bar{M})}$$

The graph illustrates the two-level nesting structure. Domestic goods and imports are combined in the second-level nest with an elasticity of substitution of `sigmac`. Here we use the identifier `C`.

Note

> The name space of nesting assignments is segmented from that of sets, parameters and variables in the GAMS code. Two set idenifiers are predefined: `s:` and `t:`. All other identifiers are accepted provided they have four or fewer characters.

The full model `mgenested` is given in the Appendix. Observe that as the substitution rate of the Armington good in final demand has changed, some parameters are modified at the beginning of the program in order to recalibrate the model.

A tariff reform is similar to a tax reform, it has a major influence on the structure of the budget of a government. Suppose we wish to keep government expenditure constant and experiment with different scenarios that represent different combinations of tax instruments. For example, at benchmark, in our model the unemployment rate `UR` and the endogenous wage tax `TAU_TL` are fixed at zero. Four alternative closures are explored in the counterfactuals. They depend on revenue replacement (lumpsum versus wage tax) and labor market (flexible versus fixed wages). An overview of the outcomes are given in the following table:

```
----   1914 PARAMETER report  Tariff Remove with Revenue Replacement (% impact)

          Lump Sum    Lump Sum    Wage Tax    Wage Tax
          Flexible  Rigid Wage    Flexible  Rigid Wage

PFX            4.6         4.6        13.0         9.4

UR                                                10.0
```

Note that the classical unemployment part in this model provides a good way to motivate the usefulness of the modeling framework. We easily produce a model which illustrates the importance of the labor market formulation. When the real wage is downward rigid, replacement of tariffs with wage taxes reduces welfare (denoted by `W`) by 7.9%, output by 6.6% and employment by 10%. If the wage is flexible, replacement of tariffs by wage taxes leads to a 0.1% decrease in welfare.

4.53.1.6 MPSGE Keywords and Syntax

In the presentation of the general syntax in this section, we use the usual GAMS syntax symbols: `[ ]` (the enclosed construct is optional), { } (the enclosed construct may be repeated zero or more times) and | (exclusive `OR`). `EOL` means "end-of-line" and `num_expr` denotes a number or GAMS numerical expression that may include a dollar condition for exception handling.

MPSGE Keywords

MPSGE provides nine keywords that are used to specify an MPSGE model. They are given in Table 1. Note that these keywords are *not* GAMS reserved words, i.e. they are not keywords in the GAMS code apart from the MPSGE model specification.

MPSGE Keyword and Syntax	Description
`$MODEL:model_name`	This keyword is used to assign the identifier `model_name` to the model. `Model_name` must be a valid file name, since it is used to form `model_name.GEN`. This must be the first statement within the `$ontext - $offtext` block containing the MPSGE code; all lines in an `$ontext - $offtext` block before this keyword are treated as comments.

`$SECTORS:`
`sect1 ! Description1`
`sect2 ! Description2`
...
	This keyword is used to declare one or more variables for sectors that are used in the model.

`$COMMODITIES:`
`com1 ! Description1`
`com2 ! Description2`
...
	This keyword is used to declare one or more variables for commodities that are used in the model.

`$CONSUMERS:`
`cons1 ! Description1`
`cons2 ! Description2`
...
	This keyword is used to declare one or more variables for consumers that are used in the model.

`$AUXILIARY:`
`aux1 ! Description1`
`aux2 ! Description2`
...
	This keyword is used to declare one or more auxiliary variables. It is only used in models with side constraints and endogenous taxes or rationed endowments.

`$PROD:sector`	This keyword is used to specify a production function. A production function must be specified for each sector in the model. Note that `sector` must have been previously declared with a `$SECTORS` statement.
`$DEMAND:consumer`	This keyword is used to define a demand function. A demand function must be specified for each consumer in the model. Note that `consumer` must have been previously declared with a `$CONSUMERS` statement.
`$CONSTRAINT:auxiliary`	This keyword is used to specify a side constraint to be associated with the auxiliary variable `auxiliary`. Note that `auxiliary` must have been previously declared with an `$AUXILIARY` statement.
`$REPORT:`	This keyword identifies the set of additional variables to be calculated. These variables are used for reports and include outputs and inputs by sector, and demands and welfare by individual consumers. The variables declared in `$REPORT` blocks may not be used in model equations. Note that we did not discuss report blocks in this chapter. For details see [130] .

Table 1: MPSGE Keywords

Syntax for Production and Demand Functions

In addition to the keywords above, MPSGE provides a fixed structure for specifying production and demand functions. This structure has a tabular format with pre-specified fields (or labels). The names of most fields are single letters that are reserved words in MPSGE. The exception are nest identifiers: they are arbitray names with up to four characters.

The syntax for the definition of a production function is as follows.

```
$PROD:sector    [s:num_expr]   [t:num_expr]   [a:num_expr {b:num_expr}]
O:commodity1    [Q:num_expr]   [P:num_expr]   [A:consumer]   [T:num_expr  {T:num_expr}]  [N:auxiliary
I:commodity2    [Q:num_expr]   [P:num_expr]   [A:consumer]   [T:num_expr  {T:num_expr}]  [N:auxiliary
```

Note that the numerical expression num_expr may be a parameter or a value.

Each production function block starts with the MPSGE keyword $PROD and the respective sector. Note that the variable sector must have been previously defined in the $SECTORS block. The labels that follow are optional. They include the following:

- s: Top level elasticity of substitution between inputs. The default value is zero.
- t: Elasticity of transformation between outputs in production. Can be zero, but not infinity.
- a:,b:,... Elasticities of substitution in individual input nests. Here a and b are nest identifiers.

Each production block has at least one output line O and one input line I. The value in the fields O and I is a commodity that has been previously declared in the $COMMODITIES block. Note that only this first field is mandatory, all other entries are optional and depend on the model. The valid labels for both lines include the following:

- Q: Reference quantity. Default value is 1. When specified, it must be the second entry.
- P: Reference price. Default value is 1.
- A: Tax revenue agent, the entry must be a consumer that has been previously defined in the $CONSUMERS block. This field must appear *before* the corresponding T or N field.
- T: Tax rate of the *exogenous* tax rate. Note that more that one tax rate may be listed in one line.
- N: *Endogenous* tax, the entry is an auxiliary variable that has been previously defined in the $AUXILIARY block.
- M: Endogenous tax multiplier. The ad valorem tax rate is the product of the value of the endogenous tax and this multiplier. Note that if the M field is omitted in a line with an N field, M:1 will be assumed. Observe that the M field cannot be included in the absence of an N field.
- a:,b:,.. Nesting assignments. Only one such label may appear per line.

The syntax for the specification of a demand function is as follows.

```
$DEMAND:consumer    [s:num_expr]   [a:num_expr {b:num_expr}]
D:commodity1        [Q:num_expr]   [P:num_expr]                          [a: | b:]
E:commodity2        [Q:num_expr]   [R:auxiliary]
```

Each demand function block starts with the MPSGE keyword $DEMAND and the respective consumer. Note that the variable consumer must have been previously declared in the $CONSUMERS block. The labels that follow are optional. They include the following:

- s: Top level elasticity of substitution between demands.
- a:,b:,... Elasticities of substitution in individual demand nests.

Each demand block has at least one demand line D and it may have one or more endowment lines E. The value in the fields D and E is a commodity that has been previously declared in the $COMMODITIES block. Note that only this first field is mandatory, all other entries are optional and depend on the model. The valid labels in a D line include the following:

- Q: Reference quantity. Default value is 1. When specified, it must be the second entry.
- P: Reference price. Default value is 1.

- `a:,b:,..` Nesting assignments. Only one such label may appear per line.

The valid labels in an `E` line include the following:

- `Q:` Reference quantity. Default value is 1. When specified, it must be the second entry.
- `R:` Rationing instrument, the entry is an `auxiliary` variable that has been previously defined in the `$AUXILIARY` block.

Auxiliary constraints in MPSGE models conform to standard GAMS equation syntax. They may refer to any of the four classes of variables, `$SECTORS`, `$COMMODITIES`, `$CONSUMERS` and `$AUXILIARY`, but they may not reference variables names declared within a `$REPORT` block. Complementarity conditions apply to upper and lower bounds on auxiliary variables and the associated constraints. For this reason, the orientation of the equation is important. When an auxiliary variable is designated `POSITIVE` (the default), the auxiliary constraint should be expressed as an equation of the type `=g=`. If an auxiliary variable is designated `FREE`, the associated constraint must be expressed as an equality (`=e=`).

Domain Restrictions on Variable Declarations

Domain restrictions on variable declarations are a crucial difference between models formulated in GAMS and those formulated in MPSGE. In GAMS, variables are defined over a domain, but the explicit domain used in the model is determined by CMEX at the point when the model is generated. In an MPSGE model, users are required to declare the explicit domain for every variable. If they include variables which are not referenced in the model, they will get a "No source" or "No sink" error message. If a variable is referenced which is not declared, an error message will be generated by the MPSGE function evaluator.

Consider the following example of a sector declaration in MPSGE:

```
$SECTORS:
   Y(i)$y0(i)
   M(i)$m0(i)
...
```

The corresponding production blocks need to have the corresponding exception operators:

```
$PROD:Y(i)$y0(i)
   ...

$PROD:M(i)$m0(i)
   ...
```

For more information on exception handling in GAMS, see chapter Conditional Expressions, Assignments and Equations.

The Nest Labor Operator and the Spanning Operator

The nest labor operator (`.tl`) is used to create a set of nests. The following example serves as illustraton and is self-explanatory:

```
$PROD:Y     s:0.5    m:0   i.tl(m):esubdm(i)   va:1
   O:PY     Q:y0
   I:PD(i)  Q:d0(i)        i.tl:
   I:PM(i)  Q:m0(i)        i.tl:
   I:PK     Q:k0                               va:
   I:PL     Q:l0                               va:
```

The spanning operator (`#`) is a way to provide multiple inputs of one commodity. For example, a commodity with price `PM` is a wholesale/retail trade margin. The benchmark value of margins on commodity `i` is `md0(i)`, and the net of margin (wholesale) value of commodity `i` sales is `d0(i)`. If goods trade off in a Cobb-Douglas nest at the gross of margin price, we can represent this in an MPSGE model as:

```
$PROD:A       s:1         i.tl:0
   O:PA       Q:a0
   I:P(i)     Q:d0(i)     i.tl:
   I:PM#(i)   Q:md0(i)    i.tl:
```

4.53.1.7 MPSGE-Specific Output

The output in the listing file of an MPSGE model has some distinctive features. Note that the MPSGE model specification is reproduced in the echo print. After the directive `$offtext`, the echo print is interrupted and a symbol reference map is inserted. In this map, both, the identifiers defined using standard GAMS syntax and MPSGE variables are listed. In addition to the standard GAMS data types, the following MPSGE shorthand symbols may appear in this listing:

Shorthand Symbol	MPSGE Data Type
`ACTIV`	sector variable
`AUXIL`	auxiliary variable
`CONSU`	consumer variable
`PRICE`	commodity variable

Table 2: Shorthand Symbols for MPSGE Data Types

For example, the symbol reference map for the first simple model in vector notation reads as follows:

```
Symbol Listing

      Symbol      Type       References
      ==========  =====      ==================================================
      CONS        PARAM          19   23
      DEMAND      PARAM          20
      ENDOW       PARAM          24
      F           SET             9   16   16   24   24
      FACTOR      PARAM          16
      I           SET             3   14   15   15   16   20   20
```

```
      PC          PRICE          8   15   20
      PF          PRICE          9   16   24
      PU          PRICE          7   19   23
      RA          CONSU         12   22
      SUPPLY      PARAM         15
      U           ACTIV          4   18
      Y           ACTIV          3   14
```

Note that if the normalization was done automatically, a comment will appear after the solve summary detailing which variable was used as a numeraire. For example,

```
Default price normalization using income for RA
```

Observe that the lower, level, upper and marginal values of the MPSGE variables are given in the solution listing like for any other GAMS variable. For more information on standard GAMS output, see chapter GAMS Output.

4.53.1.8 Appendix

Three Versions of Model TWOBYTWO

Model TWOBYTWO: Algebraic Version in GAMS MCP

```
$title  A two by two general equilibrium model -- scalar GAMS/MCP

parameter   endow     index of labour endowment     / 1.0 /;

*   =====================================================
*   Variables which appear explicitly in the MPSGE model:

Nonnegative Variables
    X   Activity level for sector X -- benchmark=1
    Y   Activity level for sector Y -- benchmark=1
    U   Activity level for sector U -- benchmark=1

    PU  Relative price index for commodity U -- benchmark=1,
    PX  Relative price index for commodity X -- benchmark=1,
    PY  Relative price index for commodity Y -- benchmark=1
    PL  Relative price index for labor -- benchmark=1
    PK  Relative price index for capital -- benchmark=1;

Free Variable
    RA  Income level for representative agent -- benchmark=150;

*   Assign default prices and activity levels:

X.L = 1; Y.L = 1; U.L = 1; PX.L = 1; PY.L = 1; PK.L = 1; PU.L = 1; RA.L = 150;

*   Insert lower bounds to avoid bad function calls:

PX.LO = 0.001; PY.LO = 0.001; PU.LO = 0.001; PL.LO = 0.001; PK.LO = 0.001;

*   =====================================================
*   Variables that enter the MPSGE model implicitly:

variables
   LX   'compensated labor demand in sector x'
   LY   'compensated labor demand in sector y'
   KX   'compensated capital demand in sector x'
   KY   'compensated capital demand in sector y'
   DX   'compensated demand for x in sector u'
   DY   'compensated demand for y in sector u';

*   Equations for the implicit variables:

Equations

   lxdef    'compensated labor demand in sector x'
   lydef    'compensated labor demand in sector y'
   kxdef    'compensated capital demand in sector x'
   kydef    'compensated capital demand in sector y'
   dxdef    'compensated demand for x in sector u'
   dydef    'compensated demand for y in sector u';

lxdef..     LX =e= 50 * (PL**0.5 * PK**0.5)/PL;
lydef..     LY =e= 20 * (PL**0.4 * PK**0.6)/PL;
kxdef..     KX =e= 50 * (PL**0.5 * PK**0.5)/PK;
```

```
kydef..     KY =e= 30 * (PL**0.4 * PK**0.6)/PK;
dxdef..     DX =e= 100 * (PX**(2/3) * PY**(1/3))/PX;
dydef..     DY =e= 50  * (PX**(2/3) * PY**(1/3))/PY;

*   Initial values:

LX.L = 50; LY.L = 20; KX.L = 50; KY.L = 30; DX.L = 100; DY.L = 50;

*   ===================================================

Equations
   prf_x    'zero profit for sector x'
   prf_y    'zero profit for sector y'
   prf_u    'zero profit for sector u (Hicksian welfare index)'

   mkt_x    'supply-demand balance for commodity x'
   mkt_y    'supply-demand balance for commodity y'
   mkt_l    'supply-demand balance for primary factor l'
   mkt_k    'supply-demand balance for primary factor k'
   mkt_u    'supply-demand balance for aggregate demand'

   i_ra     'income definition for consumer (ra)';

*   Zero profit:

prf_x..     PL*LX + PK*KX  =e= 100 * PX;
prf_y..     PL*LY + PK*KY  =E= 50 * PY;
prf_u..     PX*DX + PY*DY =E= 150*PU;

*   Market clearance:

mkt_x..         100 * X =e= DX*U;
mkt_y..         50 * Y =e= DY*U;
mkt_u..         150 * U =E= RA / PU;
mkt_l..         70 * endow =e= LX*X + LY*Y;
mkt_k..         80 =e= KX*X + KY*Y;

*   Income balance:

i_ra..      RA =e= (70*endow)*PL + 80*PK;

* We declare the model using the mixed complementarity syntax
* in which equation identifiers are associated with variables.

model algebraic / prf_x.X, prf_y.Y, prf_u.U, mkt_x.PX, mkt_y.PY, mkt_l.PL,

Model MCP123: Algebraic Version in GAMS MCP

This GAMS model is the model `mge123` translated verbatim into GAMS/MCP (algebraic) format. This is the way the model will look in the MPSGEv2 framework.

```
$title  Static 123 Model Ala Devarjan -- GAMS/MCP Format

$include 123data

*   ====================================================
*   Variables which appear explicitly in the MPSGE model:

Nonnegative Variables

*$SECTORS:
        Y        Production
        A        Armington composite
        M        Imports
        X        Exports

*$COMMODITIES:
        PD       Domestic price index
        PX       Export price index
        PM       Import price index
        PA       Armington price index
        PL       Wage rate index
        RK       Rental price index
        PFX      Foreign exchange

*$CONSUMERS:
        HH       Private households
        GOVT     Government

*$AUXILIARY:
        TAU_TL   Wage replacement tax,
        TAU_LS   Lump sum replacement tax
        UR       Unemployment rate;

*   Assign default prices and activity levels:

Y.L = 1; A.L = 1; M.L = 1; X.L = 1;
PD.L = 1; PX.L = 1; PM.L = 1; PA.L = 1; PL.L = 1; RK.L = 1; PFX.L = 1;
HH.L = c0+l0; GOVT.L=g0;
TAU_TL.L = 0; TAU_LS.L = 0; UR.L = 0;

*   Insert lower bounds to avoid bad function calls:

PD.LO = 1e-4; PX.LO = 1e-4; PM.LO = 1e-4; PA.LO = 1e-4; PL.LO = 1e-4; RK.LO = 1e-4; PFX.LO = 1e-4;

*   ====================================================
*   Variables enter the MPSGE model implicitly:

Variable
    YD  Production for the domestic market,
    YX  Production for the export market,
    KD  Capital demand,
    LY  Labor demand,
```

```
    DA  Domestic absorption,
    MA  Imports,
    C   Consumption of goods (uncompensated),
    LD  Leisure demand (uncompensated);

*   Equations for the implicit variables:

Equations YDdef, YXdef, KDdef, LYdef, DAdef, MAdef, Cdef, LDdef;

*   Macros defining composite prices (unit cost and unit revenue):

Parameter thetal  Labor share in cost function,
          thetac  Consumption share in expenditure function,
          thetam  Share parameter in Armington function
          thetaz  Share parameter in transformation function  ;

thetal = ly0*pl0 /(kd0*rr0+ly0*pl0);
thetaz = x0 *px0 /(d0+x0*px0);
thetam = m0 *pm0 /(d0+m0*pm0);
thetac = c0/(c0+l0);

$macro CY   ((PL*(1+tl+TAU_TL)/pl0)**thetal * (RK*(1+tk)/rr0)**(1-thetal))
$macro RY   ((thetaz * (PX*(1-tx)/px0)**(1+etadx) + (1-thetaz) * PD**(1+etadx)) **(1/(1+etadx)))
$macro CA   ((thetam *(PM*(1+tm)/pm0)**(1-sigmadm) + (1-thetam)*PD**(1-sigmadm))**(1/(1-sigmadm)))
$macro CU   ((thetac*PA**(1-sigma) + (1-thetac)*PL**(1-sigma))**(1/(1-sigma)))
$macro W    (HH.L/((c0+l0)*CU))

*   Definitions of demand and supply functions:

YDdef..     YD =e= d0  * (PD/RY)**etadx;
YXdef..     YX =e= x0  * (PX*(1-tx)/(px0*RY))**etadx;

4.53.2 MPSGE Models in GAMS

MPSGE is a *mathematical programming system for general equilibrium analysis* which operates as a subsystem within GAMS. MPSGE is essentially a library of function and Jacobian evaluation routines which facilitates the formulation and analysis of AGE models. MPSGE simplifies the modeling process and makes AGE modeling accessible to any economist who is interested in the application of these models. In addition to solving specific modeling problems, the system serves a didactic role as a structured framework in which to think about general equilibrium systems.

MPSGE requires the GAMS/BASE Module including the MILES MCP solver. Optionally it can use the PATH MCP solver.

4.53.2.1 Introduction

This paper introduces a programming language for economic equilibrium modeling. The paper presents the motivation for the system, the programming syntax, and three small scale examples. A library of larger models are provided with the program. The purpose of the paper is to provide a concise introduction to the modeling environment.

MPSGE is a modeling language specially designed for solving Arrow-Debreu economic equilibrium models. (See Rutherford (1987, 1989).) The name stands for "mathematical programming system for general equilibrium". The idea of the *MPSGE* program is to provide a transparent and relatively painless way to write down and analyze complicated systems of nonlinear inequalities. The language is based on nested constant elasticity of substitution utility functions and production functions. The data requirements for a model include share and elasticity parameters for all the consumers and production sectors included in the model. These may or may not be calibrated from a consistent benchmark equilibrium dataset.

GAMS, the "Generalized Algebraic Modeling System", is a modeling language which was originally developed for linear, nonlinear and integer programming. This language was developed over 15 years ago by Alex Meeraus when he was working at the World Bank. (See Brooke, Kendrick and Meeraus (1988).)

Since that time, *GAMS* has been widely applied for large-scale economic and operations research modeling projects.

MPSGE and *GAMS* embody different philosophies in their designs. *MPSGE* is appropriate for a specific class of nonlinear equations, while *GAMS* is capable of representing any system of algebraic equations. While *GAMS* is applicable in several disciplines, *MPSGE* is only applicable in the analysis of economic models within a particular domain. The expert knowledge embodied in *MPSGE* is of particular use to economists who are interested in the insights provided by formal models but who are unable to devote many hours to programming. *MPSGE* provides a structured framework for novice modellers. When used by experts, *MPSGE* reduces the setup cost of producing an operational model and the cost of testing alternative specifications.

Prior to the connection with *GAMS*, the "achilles heel" of *MPSGE* had been the process by which input data was translated into the tabular format of the *MPSGE* input file. For small models, this translation was not difficult. Given a calibrated "benchmark equilibrium dataset", a couple of hours with a word processor is usually enough time to generate and investigate a moderately large model. If, however, a model involves several classes of sectors and agents, a wide range of tax instruments and large tables of input data, the word- processor approach is impossible. When there are many numbers, there are many opportunities for oversights and typographical errors.

In contrast, the *GAMS* modeling language is designed for managing large datasets. The use of sets and detached-coefficient matrix notation makes the *GAMS* environment very nice for both developing balanced benchmark datasets and for writing solution reports. For large complicated models, a shortcoming of the *GAMS* modeling environment lies in the specification of the nonlinear equations. Economic equilibrium models, particularly those based on complicated functions such as nested CES, are easier to understand at an abstract level than they are to specify in detail, and the translation of a model from input data into algebraic relations can be a tedious and error- prone undertaking.

The interface between *GAMS* and *MPSGE* combines the strengths of both programs. The system uses *GAMS* as the "front end" and "back end" to *MPSGE* facilitating data handling and report writing. The language employs an extended *MPSGE* syntax based on *GAMS* sets, so that model specification is very concise. In addition, the system includes two large-scale solvers, MILES (Rutherford (1993)) and PATH (Ferris and Dirkse (1993)), which may be used interchangeably. The availability of two algorithms greatly enhances robustness and reliability.

The remainder of this paper is organized as follows. Section 2 introduces *MPSGE* input syntax and the *GAMS* interface using a small two-sector model of taxation. Section 3 extends the 2x2 model to illustrate how the software is used to perform equal-yield (differential) tax policy analysis and to analyze tax reform in a model with endogenous taxation. Section 4 provides a brief summary and conclusion. The paper introduces language features largely through example. Details on language syntax and program structure are provided in two appendices. Appendix A provides a complete statement of *MPSGE* syntax and a summary of differences with the original (1989) language. Appendix B provides an overview of the modeling environment and the structure of *GAMS* input files which employ *MPSGE*.

Before proceeding, both to placate impatient readers and to provide some hands-on experience for novices, I recommend that readers install the *GAMS* system, then retrieve and process the library file THREEMGE which contains three *MPSGE* models (`HARBERGER`, `SHOVEN` and `SAMUELSON`). Two commands to retrieve and run these models:

```
gamslib threemge
gams threemge
```

After having processed this file, print the listing files (`THREEMGE.LST`) for reference.

4.53.2.2 A Mathematical Introduction

Mathiesen (1985) demonstrated that an Arrow-Debreu general economic equilibrium model could be formulated and efficiently solved as a complementarity problem. Mathiesen's formulation may be posed in terms of three sets of "central variables":

p = a non-negative n-vector of commodity prices including all final goods, intermediate goods and primary factors of production;

y = a non-negative m-vector of activity levels for constant returns to scale production sectors in the economy; and

M = an h-vector of income levels, one for each "household" in the model, including any government entities.

An equilibrium in these variables satisfies a system of three classes of nonlinear inequalities.

Zero Profit

The first class of constraint requires that in equilibrium no producer earns an "excess" profit, i.e. the value of inputs per unit activity must be equal to or greater than the value of outputs. This can be written in compact form as:

$$-\prod_j(p) = C_j(p) - R_j(p) \geq 0 \quad \forall j$$

where $\prod_j(p)$ is the unit profit function, the difference between unit revenue and unit cost, defined as:

$$C_j(p) = \min\{\sum_i p_i x_i | f_j(x) = 1\}$$

and

$$R_j(p) = \max\{\sum_i p_i y_i | g_j(y) = 1\}$$

where f and g are the associated production functions characterizing feasible input and output. For example, if we have:

$$f(x) = \phi \prod_i x_i^{\alpha_i} \quad \sum_i \alpha_i = 1, \quad \alpha_i \geq 0$$

and

$$g(y) = \psi \max_i \frac{y_i}{\beta_i} \quad \beta_i \geq 0$$

then the dual functions will be:

$$C(p) = \frac{1}{\phi} \prod_i (\frac{p_i}{\alpha_i})^{\alpha_i}$$

and

$$R(p) = \sum_i \beta_i p_i$$

Market Clearance

The second class of equilibrium conditions is that at equilibrium prices and activity levels, the supply of any commodity must balance or exceed excess demand by consumers. We can express these conditions as:

$$\sum_j y_i \frac{\delta \Pi_j(p)}{\delta p_i} + \sum_h \omega_{ih} \geq \sum_h d_{ih}(p, M_h)$$

in which the first sum, by Shepard's lemma, represents the net supply of good i by the constant-returns to scale production sectors, the second sum represents the aggregate initial endowment of good i by households, and the sum on the right-hand-side represents aggregate final demand for good i by households, given market prices p and household income levels M. Final demand are derived from budget-constrained utility maximization:

$$d_{ih}(p, M_h) = argmax\{U_h(x) | \sum_i p_i x_i = M_h\}$$

in which U_h is the utility function for household h.

Income Balance

The third condition is that at an equilibrium, the value of each agent's income must equal the value of factor endowments:

$$M_h = \sum_i p_i \omega_{ih}$$

We always work with utility functions which exhibit non-satiation, so Walras' law will always hold:

$$\sum_i p_i d_{ih} = M_h = \sum_i p_i \omega_{ih}$$

Aggregating market clearance conditions using equilibrium prices and the zero profit conditions using equilibrium activity levels, it then follows that:

$$\sum_j y_j \Pi_j(p) = 0$$

or

$$y_j \Pi_j(p) = 0 \quad \forall_j$$

Furthermore, it follows that:

$$p_i \left(\sum_j y_i \frac{\delta \Pi_j(p)}{\delta p_i} + \sum_h \omega_{ih} - \sum_h d_{ih}(p, M_h) \right) = 0 \quad \forall_i$$

In other words, complementary slackness is a feature of the equilibrium allocation even though it is not imposed as an equilibrium condition, per-se. This means that in equilibrium, an production activity which is operated makes zero profit and any production activity which earns a negative net return is idle. Likewise, any commodity which commands a positive price has a balance between aggregate supply and demand, and any commodity in excess supply has an equilibrium price of zero.

4.53.2.3 A small example: Harberger

This section of the paper introduces *MPSGE* model building using a two- good, two-factor (2x2) example. This is addressed to readers who may be unfamiliar with *GAMS* and/or the original (scalar) *MPSGE* syntax. The discussion provides some details on the formulation and specification of one small model from the *MPSGE* library. Subsequently, two extensions are presented, one which illustrates equal yield constraints and another which introduces a pure public good. These examples are by no means exhaustive of the classes of equilibrium structures which can be investigated using the software, but they do provide a starting point for new users.

The structure of *MPSGE* model `HARBERGER` is "generic" Arrow-Debreu with taxes. Households obtain income by supplying factors of production to industry or collecting tax revenue. This income is then allocated between alternative goods in order to maximize welfare subject to the budget constraint.

Firms operate subject to constant returns to scale, selecting factor inputs in order to minimize cost subject to technological constraints. For an algebraic description of a model closely related to this one, see Shoven and Whalley (1984). The present model differs in two respects from the Shoven-Whalley example. First, in this model there are intermediate inputs to production while in the Shoven-Whalley model goods are produced using only value-added. Second, this model incorporates a labor-leisure choice so that the excess burden of factor taxes here incorporates the disincentive to work associated with a lower net wage.

Benchmark Data

Table 1 presents most of the input data for a two good, two factor, closed economy model. This is an economy in which, initially, taxes are levied only on capital inputs to production. We treat tax revenue as though it were returned lump-sum to the households.

	Sectors		Consumers		
	X	Y	OWNERS	WORKERS	GOVT
PX	100	-20	-30	-50	
PY	-10	80	-40	-30	
PK	-20	-40	60		
PL	-50	-10		100	-40
TRNS			10	20	-30
TK	-20	-10			30

The input data is presented in the form of a balanced matrix, the entries in which represent the value of economic transactions in a given period (typically one year). Social accounting matrices (SAMs) can be quite detailed in their representation of an economy, and they are also quite flexible. All sorts of inter-account taxes, subsidies and transfers can be represented through an appropriate definition of the accounts.

Traditionally, a SAM is square with an exact correspondence between rows and columns. (For an introduction, see Pyatt and Round, "Social Accounting Matrices: A Basis for Planning", The World Bank, 1985.) The numbers which appear in a conventional SAM are typically positive, apart from very special circumstances, whereas the rectangular SAM displayed in Table 1 follows a sign convention wherein supplies or receipts are represented by positive numbers and demands or payments are represented by negative numbers. Internal consistency of a rectangular SAM implies that row sums and column sums are zero. This means that supply equals demand for all goods and factors, tax payments equal tax receipts, there are no excess profits in production, the value of each household expenditure equals the value of factor income plus transfers, and the value of government tax revenue equals the value of transfers to households.

With simple *MPSGE* models, it is convenient to use a *rectangular* SAM format. This format emphasizes how the *MPSGE* program structure is connected to the benchmark data. In the rectangular SAM, we have one row for every market (traded commodity). In the present model, there are four markets, for goods X and Y and factors L and K.

There are two types of columns in the rectangular SAM, corresponding to production sectors and consumers. In the present model, there are two production sectors (X and Y) and three consumers (`OWNERS`, `WORKERS` and `GOVT`).

Data Entry in *GAMS*

Consider a generalized version of the model in which the set of production sectors be denoted S (here, $S = \{X, Y\}$). Let the set of goods be G. Production sectors are mapped one-to-one with the goods, so we see that sets S and G are in fact the same set. Let F denote the set of primary factors (here, $F = L, K$), and let H denote the set of households (here `H={OWNER,WORKER}`). Now that we have identified the underlying sets, we may interpret the input matrix as a set of parameters with which we can easily specify the benchmark equilibrium. (See Table 2.) It is quite common to begin a general equilibrium modeling project with a large input-output table or social accounting matrix which may then be mapped onto a number of submatrices, each of which is dimensioned according to the underlying sets used in the model.

```
                     Sectors        Consumers
                     ----------------------------------------
                        (S)         Households(H)   Government
                     ----------------------------------------
Goods Markets (G):   A(G,S)-B(G,S)   -C(G,H)
Factor Markets (F): -FD(F,S)        E(F,H)-D(F,H)
Capital taxes:      -T("K",S)                          GREV
Transfers:                            TRN(H)          -GREV
```

The *GAMS* specification of benchmark data is presented in Table 3 which begins with a statement of the underlying sets (G, F, H). The statement `"ALIAS (S,G)"`; simply says that S and G both reference X, Y. Thereafter follows the social accounting data table and declarations for the various submatrices. The parameters `ELAS()` and `ESUB()` are elasticities ("free parameters") which can be chosen independently from the benchmark accounts. The parameters $TF$and PF are calibrated tax and reference price arrays which are computed given benchmark factor and tax payments. (In this model, average and marginal tax rates are not distinguished, so the benchmark marginal tax rate is simply the tax payment divided by the net factor income.)

A general equilibrium model determines only relative prices. For purposes of reporting or constructing value-indices, we use Laspeyres quantity index, `THETA(G)`, the elements of which correspond to shares of aggregate consumer expenditure in the benchmark period.

*       INSTALL FUNCTIONS OF BENCHMARK VALUES:

GREV     = SUM(H, TRN(H));
TF(F,S) = T(F,S) / FD(F,S);
PF(F,S) = 1 + TF(F,S);
THETA(G) = SUM(H, C(G,H));
THETA(G) = THETA(G) / SUM(S, THETA(S));
WBAR(H) = SUM(G, C(G,H)) + SUM(F, D(F,H));
```

Model Specification

The *MPSGE* description of this model is shown in Table 4. Declarations following the `$MODEL` statement indicate that the model involves one class of production activities ($AL(S)$), three classes of commodities ($P(G)$, $W(F)$ and PT), and two types of consumers, private consumers ($RA(H)$), and a government "consumer" (`GOVT`).

One `$PROD:` block describes the single class of production activities, and two `$DEMAND:` blocks characterize endowments and preferences for the two classes of consumers.

Consider the records associated with production sector $AL(S)$. The entries on the first line of a `$PROD:` block are elasticity values. The "s:0" field indicates that the top-level elasticity of substitution between inputs is zero (Leontief). The entry `"a:ELAS(S)"` indicates that inputs identified as belonging to the `"a:"` aggregate trade off with an elasticity of substitution `ELAS(S)` (at the second level of the production function). In these production functions, the primary factors ($W(F)$) are identified as entering in the $a : aggregate$.

The records within a `$PROD:` block begin with `"O:"` or `"I:"`. An `"O:"` indicates an output and an `"I:"` represents an input. In both types of records, `"Q:"` is a "quantity field" indicating a reference input or output level of the named commodity. A `"P:"` signifies a reference price field. This price is measured as a user cost, gross of applicable taxes. The default values for reference price and reference quantity are both unity (i.e., a value of 1 is installed if a `P:` or `Q:` field is missing).

The `A:` and `T:` fields in a `$PROD:` block indicate tax agent and ad-valorem tax rate, respectively. The tax agent is specified before the tax rate. A single input or output coefficient may have two or more taxes applied. Consumers are treated symmetrically, and there is thus no restriction on the consumer to whom the tax is paid. Typically, however, one consumer is associated with the government.

To better understand the relationship between reference prices and tax rate specification, consider inputs of $W.K$ to sector $AL.X$ in this model. The benchmark payment to capital in the X sector is 20 and the tax payment is 20. Hence the ad-valorem tax rate in the benchmark equilibrium is 100% ($T:1$), and the reference price of capital, market price of unity times $(1 + 100\%)$, is 2 ($P:2$). If in a counterfactual experiment the tax rate on capital inputs to sector X is altered, this will change the $T:$ field but it will not change the $P:$ field. $Q:$ and $P:$ characterize a reference equilibrium point, and these are therefore unaffected by subsequent changes in the exogenous parameters.

It is important to remember that the `$PROD:AL(S)` block represents as many individual production functions as there are elements in set S (two in this case). Within the `$PROD:AL(S)` block, inputs refer to sets G and F , while the output coefficient, $O : P(S)$, refers only to set S. Sets referenced within a commodity name in an $I:$ or $O:$ field may be sets which are "controlled" by the sets referenced in the function itself, in which case only a scalar entry is produced. In `$PROD:AL(S)` there are only outputs of commodity S in sector S.

The first line of a `$DEMAND` block also contains fields (e.g.,`s:, a:, b:` etc.) which represent elasticities of substitution. The subsequent records may begin with either an $E:$ field or a $D:$ field. These, respectively, represent commodity endowments and demands. In the demand fields, the $P:$ and $Q:$ entries are interpreted as reference price and reference quantity, analogous to the input fields in a `$PROD` block. Ad-valorem taxes may not be applied on final demands, so that if consumption taxes are to be applied in a model they must be levied on production activities upstream of the final demand.

The benchmark values for all activity levels and prices are equal to the default value of unity, and therefore we are able to specify values in the $Q:$ fields directly from the benchmark data. An equivalent model could be specified in which the benchmark activity levels for `AL(S)` equal, for example, `A(S,S)`. This would then require rescaling the input and output coefficients for those sectors, and it would not necessarily be helpful, because in a scaled model it is more difficult to verify consistency of the benchmark accounts and MPSGE input file. Furthermore, for numerical reasons it is advisable to scale equilibrium values for the central variables to be close to unity.

Government transfers to households are accomplished through the use of an "artificial commodity" `(PT)`. The government is identified as the agent who receives all tax revenue (see the `A:GOVT` entry in both of the `$PROD:` blocks). Commodity PT is the only commodity on which `GOVT` spends this income, hence government tax revenue is divided between the two households in proportion to their endowments of the artificial good. In order to scale units so that the benchmark price of `PT` is unity, the $30 of government tax revenue chases 10 units of PT assigned to OWNER and 20 units assigned to WORKER. (See values for `TRN(H)` in Table 3.)

The `$REPORT` section of the input file requests the solution system to return values for inputs, outputs, final demands or welfare indices at the equilibrium. Only those items which are requested will be written to the solution file. Each record in the report block begins with a $V:$ (variable name) field. These names must be distinct from all other names in the model. The second field of the report record must have one of the labels $I:$, $O:$ or $D:$ followed by a commodity name, or the label $W:$ followed by a consumer name.

The third field's label must be `"PROD:"` in an I : or O : record, and it must be `"DEMAND:"` if it is a `D:` record.

An Algebraic Formulation of Harberger Model

The unit cost of production in sector $A_h s$ is given by a nested Leontief-CES function defined over the cost of intermediate inputs and primary factors with ad-valorem taxes on factor demands. In equilibrium, the unit cost must be no less than the market price of output:

Zero Net Profit

$$-\prod_s = \sum_g p_g B_{bs} \quad + \quad \phi_s \left(\sum_f \alpha_{fs} (\omega_f (1 + t_{fs}))^{1-\sigma_s} \right)^{\frac{1}{1-\sigma_s}} \quad - \quad p_s \geq 0 \quad \forall s | \sigma_s \neq 1$$

and

$$-\prod_s = \sum_g p_g B_{bs} \quad + \quad \phi_s \left(\prod_f (\omega_f (1 + t_{fs}))^{\alpha_{fs}} \right) \quad - \quad p_s \geq 0 \quad \forall s | \sigma_s = 1$$

Income Balance for Government

Government tax income (PT) is determined by the value of tax revenue, calculated using activity levels, compensated demands, market prices and ad-valorem tax rates:

$$PT = \sum_s \frac{\partial \prod_s}{\partial (\omega_f (1 + t_{fs}))} \quad AL_s \omega_f t_{fs}$$

Income Balance for Households

Household income is determined by the net of tax return to primary factors plus the household share of government revenue:

$$M_h = \sum_f \omega_f E_{fh} + s_h PT$$

Market Clearance for Goods

Producer output is equal to the sum of intermediate plus final demand:

$$AL_g \geq \sum_s AL_s B_{gs} + \sum_h \frac{\gamma h M_h}{e_h(p)} \left(\frac{e_h(p)}{p_g} \right)^{\sigma_h}$$

where γ_h is the household budget share devoted to the consumption of goods, and $e_h h$ is the "unit expenditure function" which may be written:

$$e_h(p) \equiv \left(\sum_i \beta_{ih} p_i^{1-\sigma_h} \right)^{\frac{1}{1-\sigma_h}}$$

Market Clearance for Factors

The aggregate supply of factors equals the sum of producer and consumer demand. Producers pay taxes on factor inputs, consumers do not because we consider these demands to be "leisure" or "household production". Consumer demands for factors are specified as Cobb-Douglas (constant budget shares):

$$\sum_h E_{fh} = \sum_s AL_s \frac{\partial \prod_s}{\partial (\omega_f (1 + t_{fs}))} + \sum_h \frac{\mu_{fh} M_h}{\omega_f}$$

***MPSGE* Formulation: Key Ideas**

There are two points regarding the MPSGE function format which are important yet easily misunderstood by new users:

1. *The elasticities together with the reference quantities and reference prices of inputs and outputs completely characterize the underlying nested CES functions.* No other data fields in the `$PROD:` block alters the technology. If, for example, a tax rate changes as part of a counter-factual experiment, this has no effect on the reference price. The value in the $P:$ field depends on the benchmark value of the $T:$ field if the model has been calibrated, but subsequent changes in $T:$ do not change the underlying technology.

2. *Tax rates are interpreted differently for inputs and outputs.* The tax rate on inputs is specified on a net basis, while the tax rate on outputs is specified on a gross basis. That is, the user cost of an input with market price p subject to an ad-valorem tax at rate t is $p(1+t)$, while the user cost of an output subject to an ad-valorem tax at rate t is $p(1-t)$. (A tax increases the producer cost of inputs and decreases the producer value of outputs.)

MPSGE provides a limited number of economic components with which complex models can be constructed. There are some models which lie outside the *MPSGE* domain, but in many cases it is possible to recast the equilibrium structure in order to produce an *MPSGE* model which is logically equivalent to the original model - usually after having introduced some sort of artificial commodity or consumer. In the present model, the use of commodity PT to allocate government revenue between households provides a fairly typical example of how this can be done. In the process of making such a transformation, one often gains a meaningful economic insight.

The Solution Listing

The detailed solution listing for model HARBERGER is shown in Table 5. The standard *GAMS* report facilities display solution values. Central variables are always either fixed (upper = lower), or they are non-negative (lower bound = 0, upper bound = `+INF`). The MARGINAL column in the solution report returns the value of the associated slack variable. Complementarity implies that in equilibrium, either the level value of a variable will be positive or the marginal value will be positive, but not both.

The output file (not shown) also provides details on the computational process. For an explanation of these statistics, see Rutherford (1993).

Computing Counter-factual Scenarios

Table 6 presents the *GAMS* code for specification and solution of three counterfactual equilibria. In these experiments, the nonuniform system of capital taxes from the benchmark is replaced by three alternative uniform factor tax structures: a tax on labor, a tax on capital, and a tax on both labor and capital. In each case, the tax rate is chosen to replace the benchmark tax revenue at benchmark prices and demand (ignoring induced substitution effects). Following each solution, the equilibrium values for tax revenue, welfare (Hicksian equivalent variation), employment, prices and output are stored in parameter `REPORT`.

4.53.2.4 Alternative models: Shoven and Samuelson

The "standard" *MPSGE* model is based on fixed endowments and tax rates, but many empirical models do not fit into this structure. For example, in the model HARBERGER, the level of each replacement tax was specified to be consistent with "equal yield", but as a result of the endogenous response of prices and quantities, the resulting tax revenues differed significantly from the benchmark levels. For example, when the capital tax is replaced by a uniform labor tax at a rate which, in the absence of labor supply response, produces "equal yield", we find that tax revenue in fact declines by 39%. In order to perform differential (equal yield) tax policy analysis, it is therefore necessary to accommodate the endogenous determination of tax rates as part of the equilibrium computation. This is one of many possible uses of "auxiliary variables" in *MPSGE*.

Tax Analysis with Equal Yield

Table 7 presents the *MPSGE* model definition for test problem SHOVEN. This model is equivalent to the HARBERGER, apart from the addition of an auxiliary variable TAU. Within *MPSGE*, auxiliary variables

can either represent price-adjustment instruments (endogenous taxes) or they can represent a quantity-adjustment instruments (endowment rations). In model SHOVEN, TAU is used to proportionally scale factor taxes in order to achieve a target level of government revenue. The auxiliary variable first appears in the $PROD:AL(S) block, following the declaration of a tax agent. There are two fields associated with an endogenous tax. The first field (N:) gives the name of the auxiliary variable which will scale the tax rate. The second field (M:) specifies the multiplier. If the M : field is omitted, the multiplier assumes a default value of unity. If the value in the M : field is zero, the tax does not apply.

The auxiliary variable TAU also appears at the bottom of the file where it labels an associated inequality constraint. This constraint exhibits complementary slackness with the associated non-negative auxiliary variable (i.e., if TAU is positive, the constraint must hold with an equality, whereas if the constraint is non-binding TAU must be zero). An auxiliary variable may or may not appear in its associated constraint.

The constraint associated with TAU is based on a price index defined by THETA(G). The constraint assures a level of tax revenue such that the value of transfers to households is held constant. (Endowments of the commodity PT are fixed, so when the value of PT is fixed, then so too are the value of transfers from GOVT to each of the households.)

SHOVEN illustrates how an auxiliary variable can be interpreted as a tax instrument. In the *MPSGE* syntax, auxiliary variables may also be employed to endogenously determine commodity endowments. There is no restrictions on how a particular auxiliary variable is to be interpreted. A single variable could conceivably serve simultaneously as an endogenous tax as well as a endowment ratio, although this would be rather unusual.

An Algebraic Formulation of Shoven Model

Zero Net Profit

The unit cost of production in sector $A_h s$ is given by a nested Leontief-CES function defined over the cost of intermediate inputs and primary factors with ad-valorem taxes on factor demands. Unlike the Harberger models, tax rates in this model are determined endogenously. In equilibrium, the unit cost must be no less than the market price of output:

$$-\prod_s = \sum_g p_g B_{bs} \quad + \quad \phi_s\left(\sum_f \alpha_{fs}(\omega_f(1+\tau t_{fs}))^{1-\sigma_s}\right)^{\frac{1}{1-\sigma_s}} \quad - \quad p_s \geq 0 \quad \forall s|\sigma_s \neq 1$$

and

$$-\prod_s = \sum_g p_g B_{bs} \quad + \quad \phi_s\left(\prod_f(\omega_f(1+\tau t_{fs}))^{\alpha f_s}\right) \quad - \quad p_s \geq 0 \quad \forall s|\sigma_s = 1$$

Income Balance for Government

Government tax income (PT) is determined by the value of tax revenue, calculated using activity levels, compensated demands, market prices and ad-valorem tax rates:

$$PT = \sum_s \frac{\partial \prod_s}{\partial(\omega_f(1+\tau t_{fs}))} \quad AL_s \omega_f \tau t_{fs}$$

Equal Yield

In equilibrium, tax rates are multiplicatively adjusted to achieve a target level of government revenue:

$$PT = \sum_g \theta_g p_g$$

Income Balance for Households

Household income is determined by the net of tax return to primary factors plus the household share of government revenue:

$$M_h = \sum_f \omega_f E_{fh} + s_h PT$$

Market Clearance for Goods

Producer output is equal to the sum of intermediate plus final demand:

$$AL_g \geq \sum_s AL_s B_{gs} + \sum_h \frac{\gamma h M_h}{e_h(p)} \left(\frac{e_h(p)}{p_g} \right)^{\sigma_h}$$

where γ_h is the household budget share devoted to the consumption of goods, and $e_h h$ is the "unit expenditure function" which may be written:

$$e_h(p) \equiv \left(\sum_i \beta_{ih} p_i^{1-\sigma_h} \right)^{\frac{1}{1-\sigma_h}}$$

Market Clearance for Factors

The aggregate supply of factors equals the sum of producer and consumer demand. Producers pay taxes on factor inputs, consumers do not because we consider these demands to be "leisure" or "household production". Consumer demands for factors are specified as Cobb-Douglas (constant budget shares):

$$\sum_h E_{fh} = \sum_s AL_s \frac{\partial \prod_s}{\partial(\omega_f(1+\tau t_{fs}))} + \sum_h \frac{\mu_{fh} M_h}{\omega_f}$$

Public Goods and Endogenous Taxation

Consider a final extension of the 2x2 model in which tax revenue funds a pure public good. Model SAMUELSON presented in Table 8. This model illustrates one of several ways that public goods can be modelled in *MPSGE*. Here the level of public provision is determined by a Samuelson-condition equating the sum of individual marginal rates of substitution (marginal benefit) with the marginal rate of transformation (marginal cost). Unlike the equal yield formulation, the tax revenues collected by `GOVT`are not returned lump-sum but are instead used to finance provision of a pure public good. This representation of government has not been widely adopted in the CGE literature, perhaps because of the difficulties involved in specifying preferences for public goods.

The relevant characteristic of a pure public good entering final demand is that each consumer "owns" the same quantity. Agents' attitudes toward public goods differ, and because there is no market, agents' valuations of the public good will also differ. In an *MPSGE* model, the separate valuations are accommodated through the introduction of "personalized" markets for public good - one market for each consumer. In the model, consumer expenditure encompasses both private and public "purchases", and consumer income encompasses both private and public "endowments". An individual is endowed with a quantity of her own version of the public good determined by the level of public expenditures. An increase in taxes, to the extent that it increases tax revenue, will increase the level of public provision.

In this model, the structure of relative factor taxes is exogenous but the aggregate level of taxes is not. Tax rates are scaled up or down so that the sum of individual valuations of the public good (the marginal benefit) equals the cost of supply of the public good (the direct marginal cost).

Consider features of model `SAMUELSON` which do not appear in `SHOVEN`:

1. There are new commodities `PG` and `VG(H)`. The first of these represents the direct marginal cost of public output from sector `GP`, a Leontief technology which converts private goods inputs into the public good. For the `SAMUELSON` structure, all government revenues apply to purchases of the public good (observe that the only good demanded by consumer `GOVT`is `PG`). The prices `VG(H)` represent the individual consumer valuations of the public good. Commodity `VG(H)` appears only in the endowments and demands of consumer `RA(H)`. The endowment record for `VG(H)` includes a quantity `V(H)` which is the benchmark valuation of the public good by agent `H`.
2. There are two auxiliary variables. `TAU` has the same interpretation as in the `SHOVEN`, determining the aggregate tax level. Auxiliary variable `LGP` is a rationing instrument representing an index of the "level of public goods provision", scale to equal 1 in the benchmark. Consumer `RA(H)` thus is endowed with a quantity of `VG(H)` given by `V(H) * LGP` .

3. The constraint for TAU in SAMUELSON differs from the TAU constraint in SHOVEN. Here the constraint represents the Samuelson condition, equating the marginal cost (PG*GREV) and the sum of individuals' marginal benefit (SUM(H,VG(H)*V(H))). The constraint for LGP simply assigns LGP equal to the sector GP activity level. (The LGP variable and constraint are only needed because the R: field only accepts auxiliary variables.)

An Algebraic Formulation of Samuelson Model

Zero Net Profit for Private Production

The unit cost of production in sector $A_h s$ is given by a nested Leontief - Cobb-Douglas function defined over the cost of intermediate inputs and primary factors with ad-valorem taxes on factor demands. Unlike the Harberger models, tax rates in this model are determined endogenously. In equilibrium, the unit cost must be no less than the market price of output:

$$-\prod_s = \sum_g p_g B_{bs} \quad + \quad \phi_s \left(\prod_f (\omega_f (1 + \tau t_{fs}))^{\alpha f_s} \right) \quad - \quad p_s \geq 0 \quad \forall s$$

Zero Net Profit for Public Sector Contractors

The unit cost of public provision is determined by the market price of commodity inputs to the Leontief activity. Input requirements are defined by a vector of public sector input coefficients, $A_h g$. In equilibrium, the price paid by the government equals the cost of market inputs:

$$\sum_g p_g a_g \quad - \quad p_G \geq 0$$

Income Balance for Government

Government tax income (PT) is determined by the value of tax revenue, calculated using activity levels, compensated demands, market prices and ad-valorem tax rates. In equilibrium, the value of tax revenue equals the market cost of public sector output:

$$PT = \sum_s \frac{\partial \prod_s}{\partial(\omega_f (1+\tau t_{fs}))} \quad AL_s \omega_f \tau t_{fs} = p_G G$$

Income Balance for Households

Household income is determined by the net of tax return to primary factors plus the imputed value of public provision:

$$M_h = \sum_f \omega_f E_{fh} + v_h G$$

Market Clearance for Private Goods

Producer output is equal to the sum of intermediate plus final demand:

$$AL_g \geq \sum_s AL_s B_{gs} + \sum_h \frac{\gamma h M_h}{e_h(p)} \left(\frac{e_h(p)}{p_g} \right)^{\sigma_h}$$

where γ_h is the household budget share devoted to the consumption of goods, and $e_h h$ is the "unit expenditure function" which may be written:

$$e_h(p) \equiv \left(\sum_i \beta_{ih} p_i^{1-\sigma_h} \right)^{\frac{1}{1-\sigma_h}}$$

Personalized Markets for Public Goods

We assume a "pure" public good in this model, hence each household may attach a different marginal valuation to public provision in an equilibrium. In order to compute these marginal values, we include a separate public good "market" for each houshold which balances the level of provision with the household "demand":

$$G = \frac{\mu_{Gh} M_h}{v_h}$$

in which μ_{Gh} is the budget share of public goods in the top-level Cobb-Douglas preferences of household h.

Market Clearance for Factors

The aggregate supply of factors equals the sum of producer and consumer demand. Producers pay taxes on factor inputs, consumers do not because we consider these demands to be "leisure" or "household production". Consumer demands for factors are specified as Cobb-Douglas (constant budget shares):

$$\sum_h E_{fh} = \sum_s AL_s \frac{\partial \prod_s}{\partial(\omega_f(1+\tau t_{fs}))} + \sum_h \frac{\mu_{fh} M_h}{\omega_f}$$

Samuelson Rule for "Optimal" Provision of Public Goods

The tax rate multiplier is adjusted to balance the marginal cost of public provision with the summation across households of marginal willingness to pay. Due to the existence of household factor demand, factor taxes are necessarily distortionary and there will be an excess social cost of public funds. For this reason, the Samuelson rule is neither necessary nor sufficient for optimal provision. We apply the rule here merely to illustrate the programming methodology, even though the resulting equilibrium may be "suboptimal":

$$PG = \sum_h v_h$$

Comparing Model Results

Although the foregoing discussion has focused on the nuances of *MPSGE* model syntax, but there are many interesting economic questions which can be addressed using even small-scale models such as tho ones described here. Consider the output listing from parameter REPORT is displayed in Table 9. It is perhaps surprising to note that none of the uniform tax structures represents a Pareto-superior choice compared to the benchmark tax structure. Furthermore, from the standpoint of aggregate welfare (`"WELFARE.TOTAL"` = income-weighted sum of individual EV's), only the uniform capital tax represents an improvement.

4.53.2.5 Summary

This paper has provided an introduction to a new *GAMS* subsystem for applied general modeling. This extension of *GAMS* accomodates a tabular representation of highly nonlinear cost and expenditure functions through which model specification is concise and transparent. The paper has presented three small examples which illustrate the programming environment and its application to traditional economic issues in public finance for which applied general equilibrium analysis is a standard tool. Further work is underway in the development and evaluation of solution algorithms for applied general equilibrium models implemented within *GAMS/MPSGE*. In addition to providing a convenient framework for model-builders, the new *GAMS/MPSGE* system also simplifies the implementation and testing of algorithms for complementarity problems. Information on the relative effectiveness of different solution strategies should prove quite helpful to users who are using the system to solve very large systems of nonlinear equations.

4.53.2.7 Appendix A: Language Syntax

General syntax rules

- All input is free format (spaces and tabs are ignored) except keywords for which "$" must appeatr in column 1.
- End-of-line is significant. Continuation lines are indicated by a "+" in column 1.
- In general, input is not case sensitive, except in the specification of sub-nests for production and demand functions.
- Numeric expression involving GAMS parameters or constants must be enclosed in parentheses.

Keywords

Keywords typically appear in the following order:

Keywords	Description
`$ONTEXT`	Indicate the beginning of a GAMS comment block containing an MPSGE model.
`$MODEL:model_name`	*model_name* must be a legitimate file name. This name is subsequently used to form `MODEL_NAME.GEN` (this file name must be upper case when running under UNIX).
`$SECTORS:`, `$COMMODITIES:`, `$AUXILIARY:`, `$CONSUMERS:`	Four keywords define variables which are used in the model. Entries in these blocks share the same syntax. The `$AUXILIARY` block is only used in models with side constraints and endogenous taxes or rationed endowments.
`$PROD:sector`	Production functions must be specified for each production sector in the model.
`$DEMAND:consumer`	Demand functions must be specified for every consumer in the model. General structure is the same as for production functions above.
`$CONSTRAINT:auxiliary`	Specifies a side constraint to be associated with a specified auxiliary variable.
`$REPORT:`	Identifies the set of additional variables to be calculated. These include outputs and inputs by sector and demands by individual consumers.
`$OFFTEXT`	Indicates the end of model specification.

Variable Declarations

There are four classes of variables within an *MPSGE* model: activity levels for production sectors, prices for commodities, income levels for consumers and level values for auxiliary variables. These classes of variables are distinguished in order to permit additional semantic checking by the *MPSGE* preprocessor. For example, if `P` has been declared as a price (within the `$COMMODITIES:` block), then the preprocessor would report an error if it encountered `"$PROD:P"`. |

The `$SECTORS:`, `$COMMODITIES:`, `$CONSUMERS:` and `$AUXILIARY:` blocks contain implicit *GAMS* variable declarations in which the index sets must be specified in the *GAMS* program above and the variable names must be distinct from all other symbols in the *GAMS* program. One or more variables may be declared per line separated by one or more spaces.

```
$SECTORS:
          Y(R,T)      ! Output in region R in period T
          K(T)        ! "Aggregate capital stock, period T"
```

In these declarations, the trailing comments (signified by "!") are interpreted as variable name descriptors which subsequently appear in the solution listing.

The equivalent *GAMS* declaration for these variables would be:

```
 VARIABLES   Y(R,T)  Output in region R in period T
             K(T)    "Aggregate capital stock, period T";
```

As with the usual *GAMS* syntax, when a variable descriptor contains a punctuation symbol such as ",", it is required to enclosed in quotes.

```
$SECTORS:
        X(R,T)$(X0(R) GT 0)
```

Here, the *GAMS* conditional operator "$" is used to restrict the domain of the variable X. The expression following the dollar sign is passed through to the *GAMS* compiler and must conform to *GAMS* syntax rules.

```
$SECTORS:
          X Y(R)$Y0(R) Z    !  Descriptor for Z
          W(G,R,T)          !  Descriptor for W
```

More than one symbol may appear on a single line. The descriptor only applies to the last one.

All *MPSGE* variables must be declared. When multidimensional variables are specified, they must be declared explicitly - declarations like `X(*)` are not permitted. Two further restrictions are that the sets used in the declaration must be static rather than dynamic, and any variable which is declared must be used in the model. There is a simple way to work around these restrictions. Let me illustrate with an example. Suppose that in a model the set of production sectors AL is employed for all elements of a static set S which satisfy a particular condition, for example `BMX(S)` not equal to 0. This would require that AL be declared as follows:

```
$SECTORS:
    AL(S)$BMX(S)
```

In this context, the symbol "$" is used as an "exception operator" which should be read as "such that". In this case, we have generated one AL sector for each element of the set S for which BMX(S) is nonzero.

Function Declarations

Functional declarations characterize nested CES functions which characterize both preferences and technology. The former are written within a $DEMAND: block and the latter within a $PROD: block. Tax entries may appear within a $PROD: block but not within a $DEMAND: block, otherwise the syntax is nearly identical. The syntax for these blocks will be described through a sequence of examples:

```
$PROD:Y(R)  s:1
O:P(R)      Q:YO(R)
I:W(F,R)    Q:FDO(F,R)
```

This block characterizes a Cobb-Douglas production function in which the elasticity of substitution between inputs is one - "s:1" in the first line which sets a top level substitution elasticity equal to unity. Variable Y(R) is an activity level declared within the $SECTORS: block. Variables P(R) and W(F,R) are prices declared within the $COMMODITIES: block. The O: label indicates an output, and the I: prefix indicates an input. The Q: fields in both records represent "reference quantities". YO(R) and FDO(F,R) must be GAMS parameters defined previously in the program.

```
$PROD:X(R)  s:ESUB(R)  a:0  b:(ESUB(R)*0.2)
O:PX        Q:XO(R)
I:PY(G)     Q:YXO(G,R)  a:
I:PL        Q:LXO(R)  b:
I:PK        Q:KXO(R)  b:
```

The keyword line specifies three separate elasticities related to this function. ESUB(R) is the top level elasticity of substitution. There are two sub-nests in the function. Nest a: is a Leontief nest (in which the compensated elasticity is zero). The elasticity of subtitution in nest b: is one-fifth of the top level elasticity.

In the function specification, commodities PY(G) (one input for each element of set G) enter in fixed proportions. Commodities PL and PK enter in nest b.

If this function has been specified using a balance benchmark dataset with reference prices equal to unity, then the following identity should be satisfied:

```
XO(R) = SUM(G, YXO(G,R)) + LXO(R) + KXO(R)
```

```
$PROD:AL(S)  s:0  a:ELAS(S)
O:P(G)    Q:A(G,S)
I:P(G)    Q:B(G,S)
I:W(F)    Q:FD(F,S)  P:PF(F,S)  A:GOVT  T:TF(F,S)  a:
```

In this function, we have two new ideas. The first is the use of a reference price denoted by "P:". This entry indicates that the function should be calibrate to a reference point where individual input prices (gross of tax) equal PF(F,S). If P: does not appear, prices of one are assumed.

The second new idea here is that taxes may be levied on production inputs. The A: label identifies the name of the tax agent (a $CONSUMER:). The T: label identifies the ad-valorem tax rate.

```
$DEMAND:RA(R)$RAO(R)   s:1
E:PL                   Q:LE(R)
D:P(G)$DG(G)           Q:DO(G,R)$DD(G,R) P:PO(G,R)
```

This function specification demonstrates the use of conditionals. This function is only generated when `RAO(R)` is nonzero. The demands D: for a particular element of set G are suppressed entirely when `DG(G)` equals 0. The `Q:` field also has an exception operator, so that the default value for `Q:` (unity) is applied when `DD(G,R)` equals zero.

This example is somewhat artificial, but it illustrates the distinction between how exception operators affect lead entries (`I:`, `O:`, `D:` and `E:`) and subsequent entries. When an exception is encountered on the lead entry, the entire record may be suppressed. Exceptions on subsequent entries only applied to a single field.

The valid labels in a function declaration (`$PROD:` or `$DEMAND:`) line include:

`s:` Top level elasticity of substitution between inputs or demands.

`t:` Elasticity of transformation between outputs in production. (valid only in `$PROD` blocks)

`a:,b:,...` Elasticities of substitution in individual input nests.

The recognized labels in an `I:` or `O:` line include:

`Q:` Reference quantity. Default value is 1. When specified, it must be the second entry.

`P:` Reference price. Default value is 1.

`A:` Tax revenue agent. Must be followed by a consumer name.

`T:` Tax rate field identifier. (More than one tax may apply to a single entry.)

`N:` Endogenous tax. This label must be followed by the name of an auxiliary variable.

`M:` Endogenous tax multiplier. The advalorem tax rate is the product of the value of the endogenous tax and this multiplier.

`a:,b:,..` Nesting assignments. Only one such label may appear per line.

The valid labels in an `E:` line include:

`Q:` Reference quantity

`R:` Rationing instrument indicating an auxiliary variable.

The valid labels in a `D:` line include:

`Q:` Reference quantity

`P:` Reference price

`a:,b:...` Nesting assignment

Constraints

Auxiliary constraints in *MPSGE* models conform to standard *GAMS* equation syntax. The may refer to any of the four classes of variables, `$SECTORS`, `$COMMODITIES`, `$CONSUMERS` and `$AUXILIARY`, but they may not reference variables names declared within a `$REPORT` block. Complementarity conditions apply to upper and lower bounds on auxiliary variables and the associated constraints. For this reason, the orientation of the equation is important. When an auxiliary variable is designated POSITIVE (the default), the auxiliary constraint should be expressed as a "greater or equal" inequality (`=G=`). If an auxiliary variable is designated FREE, the associated constraint must be expressed as an equality (`=E=`).

```
$CONSTRAINT:TAU
                  G =G= X * Y;
$CONSTRAINT:MU(I)$MU0(I)

            MU(I) * P(I) * Q(I) =G= SUM(J, THETA(I,J) * PX(J));
```

The exception applied in this example restricts the equation only to those elements of set `I` for which `MU0(I)` is not zero.

Report Declaration

The GAMS interface to MPSGE normally returns level values only for the central variables - those declared within `$SECTORS:`, `$COMMODITIES:`, `$CONSUMERS:` and `$AUXILIARY:` sections. An equilibrium determines not only these values, but also levels of demand and supply by individual sectors and consumers. Given benchmark information, elasticities and the equilibrium values, all such demands can be computed, but this can be tedious to do by hand. In order to have these values returned by MPSGE, it is necessary to indicate the name of the variable into which the value is to be returned. The general form is as follows:

```
$REPORT:
      V:variable name   I:commodity       PROD:sector
      V:variable name   O:commodity       PROD:sector
      V:variable name   D:commodity       DEMAND:consumer
      V:variable name   W:consumer
```

The first row returns an input quantity, the second row returns an output quantity, the third returns a demand quantity, and the fourth row returns a consumer welfare index. (Note: the level value returned for a "consumer variable" is an income level, not a welfare index.)

```
$REPORT:
      V:DL(S)                 I:PF("L")         PROD:Y(S)
      V:DK(S)                 I:PF("K")         PROD:Y(S)
      V:SX(G,S)$SX0(G,S)      O:PX(G)           PROD:X(S)
      V:D(G,H)                D:P(G)            DEMAND:RA(H)
      V:W(H)                  W:RA(H)
```

Note that the "$" exception is only meaningful on the first entry. Also notice that the domain of the report variable must conform to the domain of the subsequent two entries.

Differences between Scalar and Vector *MPSGE Syntax*

1. `$MODEL:` statement The `$MODEL` statement is required in the vector format and it must precede all other statements. A name which is an acceptable file name prefix must be used. The preprocessor does not begin translation of an*MPSGE* model until it encounters a `$MODEL` statement following an `$ONTEXT` record. The preprocessor continues to translate until it reaches an $OFFTEXT statement, skipping blank lines and comment lines identified by a "$*$" in column 1.

2. Case folding: In the vector syntax, upper and lower case letters are not distinguished. The entire file is processed as though it were written in upper case. This is not compatible with the earlier version of*MPSGE* in which "P" and "p" were distinct.

3. Distinct names: Names used for variables in the*MPSGE* model must be distinct from each other as well as from all other symbols in the *GAMS* program. If there is a *GAMS* set or parameter or model named X, then X may not be used to identify an*MPSGE* sector or commodity.

4. Tabs:*MPSGE* fields are free format and tabs are translated to spaces by the preprocessor. Tabs are permitted in *GAMS* provided that the compiler is properly configured (under DOS, "TABIN 8" must be inserted in file *GAMS*PARM.TXT in the *GAMS* system directory).

Exception Handling

The *GAMS* exception operator can be used on virtually any entry in the*MPSGE* input file. For example, if you want to have sector X(S) have one production structure for elements S in a subset T(S), you can provide separate production function declarations as follows:

```
$PROD:X(S)$T(S)
...         ! sector X described for S in T

$PROD:X(S)$(NOT T(S))
...         ! sector X described for S not in T.
```

The preprocessor does not require one and exactly one declaration for each sector. If multiple declarations appear, the later set of coefficients overwrites the earlier set.

Switches and Debug Output

Run-time tolerances and output switches may be specified within the vector-syntax model specification or using the PUT facility, they can be written directly to the MPS input file. Output switches control the level of debug output written by the*MPSGE* subsystem to the solver status file. Reports provided by $ECHOP, $FUNLOG and $DATECH can be returned to the listing file by specifying "OPTION SYSOUT=ON;" within the *GAMS* program prior to the SOLVE statement. The recognized*MPSGE* parameters are:

```
$ECHOP: logical         Default=.FALSE.
```

is a switch for returning all or part of the scalar*MPSGE* file to the solver status file. In order to have this output printed in the listing file, enter the *GAMS* statement "OPTION SYSOUT=ON;" prior to solving the model.

```
$PEPS:  real            Default=1.0E-6
```

is the smallest price for which price-responsive demand and supply functions are evaluated. If a price is below PEPS, it is perturbed (set equal to PEPS) prior to the evaluation.

```
$EULCHK:    logical     Default=.TRUE.
```

is a switch for evaluating Euler's identity for homogeneous equations. The output is useful for monitoring the numerical precision of a Jacobian evaluation. When a price or income level is perturbed in a function, the Euler check may fail.

```
$WALCHK:    logical     Default=.TRUE.
```

is a switch for checking Walras's law. Like EULCHK, this switch is provided primarily to monitor numerical precision. When an income level is perturbed, the Walras check may fail.

```
$FUNLOG:    logical     Default=.FALSE.
```

is a switch to generate a detailed listing of function evaluations for all production sectors and consumers.

FUNLOG triggers a function evaluation report which provides detailed output describing the evaluation of supply and demand coefficients. The information provide is sufficient that an industrious graduate student should be able to reproduce the results (given a pencil, paper and slide rule).

The evaluation report has the following headings:

Heading	Description
T	Coefficient "type" with the following interpretation: IA Input aggregate OA Output aggregate I Input O Output D Demand E Endowment
N	Name (either nest identifier or commodity name)
PBAR	Benchmark price (the P: field value)
P	Current price (gross of tax)
QBAR	Benchmark quantitity (the Q: field value)
Q	Current quantity
KP	Identifier for parent entry in nesting structure.
ELAS	Associated elasticity (input or output aggregates only)

When $FUNLOG:.TRUE is specified, a complete report of demand and supply coefficients for every production and demand function in every iteration. Be warned that with large models this can produce an enrmous amount of output!

The following two function evaluation reports are generated in the first iteration in solving case "L" for model HARBERGER:

```
Function Evaluation for: AL.X

$DATECH:    logical     Default=.FALSE.
```

is a switch to generate a annotated listing of the function and Jacobian evaluation including a complete listing of all the nonzero coefficients.

MPSGE generates an analytic full first-order Taylor series expansion of the nonlinear equations in every iteration. Nonzero elements of the Jacobian matrix are passed to the system solver (*MILES* or *PATH*) which uses this information in the direction-finding step of the Newton algorithm. Coefficients are produced with codes which help interpret where they came from. The following codes are used:

- `W0` indicates an element from the orthogonal part of F().
- `W1` indicates an element from the non-orthogonal part of F().
- `B` indicates a linear term from F.
- `E0` indicates a homogeneous Jacobian entry.
- `E1` indicates a non-homogeneous Jacobian entry.

The Euler checksum examines elements from the linearization which are type `"E0"`. The Walras check sum examines elements from the function evaluation which are type `"W0"`.

Needless to say, the `$DATECH:.TRUE.` switch produces a very big status file for large models. It is not something which is very useful for the casual user.

Here is a partial listing of nonzeros generated during the first linearization for scenario `"L"` in model `HARBERGER:`

```
---------------------------------------- Coefficients for sector:AL.X
P.X             AL.X              1.0000E+02    B
AL.X            P.X              -1.0000E+02    B
P.Y             AL.X             -1.0000E+01    B
AL.X            P.Y               1.0000E+01    B
W.K             AL.X             -2.3466E+01    B
AL.X            W.K               3.5199E+01    B
W.L             AL.X             -4.3999E+01    B
AL.X            W.L               4.3999E+01    B
W.K             W.K               1.3037E+01   E0      1.3037E+01

4.53.2.8 Appendix B: File Structure

This appendix provides an overview of the structure of *GAMS* input files which include*MPSGE* models. The text of the paper presents many of these ideas by way of example, but it may also be helpful for some users to have a "template" for constructing*MPSGE* models. The discussion in this section focuses on a "generic" input file, the schematic form of which is presented in Table 10. This section first presents a "top down" view of program organization, and then it discusses aspects of the new syntax for model specification.

Flow of Control

When a model is developed using *GAMS* as a front-end to*MPSGE*, the input file generally has five sections as identified in Table 10. Section (i), the benchmarking section, contains standard *GAMS* statements. This includes *GAMS* `SET` declarations, input data (`SCALARS`, `PARAMETERS` and `TABLES`), and `PARAMETER` declarations for intermediate arrays used in benchmarking or model specification. In complex models, this section of the file will typically contain some algebraic derivations, the result of which is a calibrated benchmark equilibrium dataset.

Users who are unfamiliar with *GAMS* can consult the manual. Beginning *GAMS* programmers should remember that the*MPSGE* interface to *GAMS* is unlike other solution subsystems. "Level values" are passed between the *GAMS* program and*MPSGE* in the usual fashion, but*MPSGE* models do not require the explicit use of the `VARIABLE` or `EQUATION` statements.)

The second section of the file consists of a *GAMS* comment range, beginning with an $ONTEXT record and ending with an $OFFTEXT record, followed by an invocation of the preprocessor. The preprocessor writes operates on statements in the*MPSGE* model declaration which are "invisible" to the *GAMS* compiler. This program reads the*MPSGE* model statements and generates *GAMS*-readable code, including a model_name.gen file. Additional *GAMS* code produced by the preprocessor includes declarations for each of the central variables and report variables in the*MPSGE* model.

The third section of the generic input file performs a "benchmark replication" and may not be present in all applications. There are four statements required for benchmark validation. The first statement sets the iteration limit to be zero; the second statement causes the*MPSGE* model to be "generated", and the third statement causes the*MPSGE* solver to read the model and return the deviations. In this call, the level values passed to the solver are unaltered because the iteration limit is zero. Market excess supplies and zero profit checks are returned in the "marginals" of the associated commodity prices and activity levels, respectively. The final statement in this section resets the iteration limit to 1000 (the default value) for subsequent counter-factual computations.

Section (iv) defines and then computes a counter-factual equilibrium. A counter-factual equilibrium is defined by parameter values such as tax rates or endowments which take on values different from those in the benchmark equilibrium. Within the *GAMS* interface to*MPSGE*, it is also possible to fix one or more central variables. When any variable is fixed, the associated equation is omitted from the equilibrium system during the solution process but the resulting imbalance is then reported in the solution returned through the marginal.

The final section of the file represents the *GAMS* algebra required for comparing counter-factual equilibria. It would be possible, for example, to construct welfare measures or to report percentage changes in certain values. All of these calculations are quite easy because the equilibrium values are returned as level values in the associated variables.

The final section of the file represents the *GAMS* algebra required for comparing counter-factual equilibria. It would be possible, for example, to construct welfare measures or to report percentage changes in certain values. All of these calculations are quite easy because the equilibrium values are returned as level values in the associated variables.

For large models, the advantage of the vector format is that by using appropriately defined *GAMS* sets, the number of individual functions which need to be defined is reduced only to the number of "classes" of functions. This makes it possible to represent large dimensional models using only a few lines of code.

To summarize, here are the basic features of a program which uses *GAMS* as a front-end to *MPSGE*:

1. An *MPSGE* model is defined within a *GAMS* comment range followed by

   ```
   $sysinclude mpsgeset model_name
   ```

2. Every `SOLVE` statement for a particular model is preceded by `$INCLUDE MODEL.GEN`. The GEN file is written by the preprocessor based on the model structure.

3. Solution values for the cental variables in the *MPSGE* model and any declared "report variables" are returned in *GAMS* variable level values. Level values for slacks are returned as "marginals" for the associated variables.

4. The model description follows a format which is a direct extension of the scalar data format. Certain aspects of the new language, such as case folding, are incompatible with the original *MPSGE* syntax.

GAMS Code Generated by the Preprocessor: the GEN File

Most novice users will find it easiest to treat the preprocessor output files as "black boxes". These files contain *GAMS* source code required for declaring and generating the *MPSGE* input file. Table 11 contains portions of the GEN file for the same model. Table 12 shows the preprocessor-generated listing and symbol table which are always appended to the bottom of the GEN file. If a preprocessor error occurs, it can be helpful to consult the symbol table to track down the bug. Finally, Table 13 shows the first page of scalar format *MPSGE* input file produced by HARBERGER.GEN. Normally, this file is written and then erased in the course of a *GAMS* run, although all or part of the file may be retained using the `$ECHOP:` switch.

4.53.3 Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE

This research was supported by the *GAMS* Applied General Equilibrium Research Fund. The author remains responsible for any bugs which exist in this software.

4.53.3.1 An Overview

This document describes a mathematical programming system for general equilibrium analysis named *MPSGE* which operates as a subsystem to the mathematical programming language *GAMS*. *MPSGE* is library of function and Jacobian evaluation routines which facilitates the formulation and analysis of AGE models. *MPSGE* simplifies the modeling process and makes AGE modeling accessible to any economist who is interested in the application of these models. In addition to solving specific modeling problems, the system serves a didactic role as a structured framework in which to think about general equilibrium systems.

MPSGE separates the tasks of model formulation and model solution, thereby freeing model builders from the tedious task of writing model-specific function evaluation subroutines. All features of a particular model are communicated to *GAMS*/*MPSGE* through a tabular input format. To use *MPSGE*, a user must learn the syntax and conventions of this model definition language.

The present paper is intended for students who have completed two semesters of study in microeconomics. The purpose of this presentation is to give students a practical perspective on microeconomic theory. The diligent student who works through all of the examples provided here should be capable of building small models "from scratch" to illustrate basic theory. This is a first step to acquiring a set of useable tools for applied work.

The remainder of this paper is organized as follows. Section The Theory of Consumer Demand review the theory of consumer demand; section Getting Started provides guidance on how to verify that the *GAMS/MPSGE* software is operational; section Modeling Consumer Demand introduces the modeling framework with three models illustrating the representation of consumer demand within the *MPSGE* language. Section The Pure Exchange Model reviews the pure exchange model, and section Modeling Pure Exchange with MPSGE presents two *MPSGE* models of exchange. Each of the model-oriented sections present exercises based on the models which give students a chance to work through the material on their own. Additional introductory examples for self-study can be found in the `Markusen library` as well as in the **GAMS Model Library** (look for models with names ending in "MGE").

The level of presentation and diagrammatic exposition adopted here is based on Hal Varian's undergraduate microeconomics textbook (*Intermediate Microeconomics: A Modern Approach*, Third Edition, W. W. Norton & Company, Inc., 1993).

The ultimate objective of this piece is to remind students of some theory which they have already seen and illustrate how these ideas can be used to build numerical models using *GAMS* with *MPSGE*. It is not my intention to provide a graduate level presentation of this material. So far as possible, I have avoided calculus and even algebra. The objective here is to demonstrate that what matters are economic ideas. With the proper tools, it is possible to do concrete economic modeling without a lot of mathematical formalism.

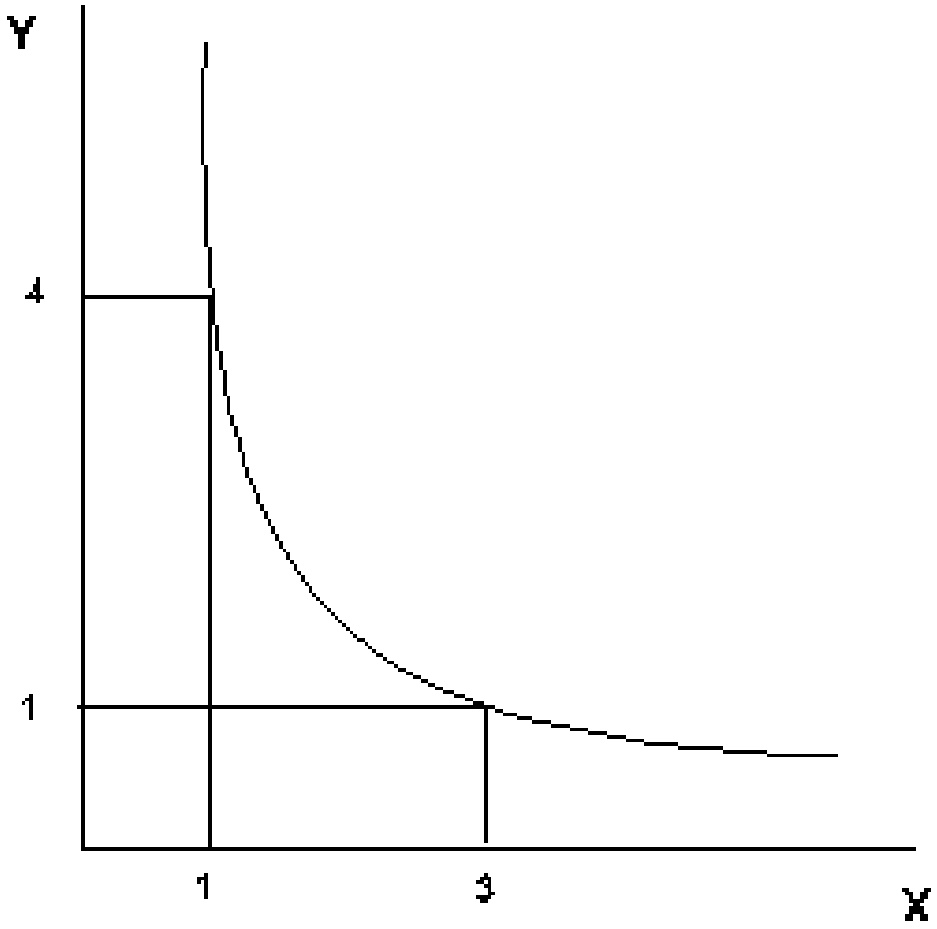
4.53.3.2 The Theory of Consumer Demand

A central idea underlying most microeconomic theory is that agents optimize subject to constraints. The optimizing principle applied to consumer choice begins from the notion that agents have preferences over consumption bundles and will always choose the most preferred bundle subject to applicable constraints. To operationalize this theory, three issues which must be addressed:

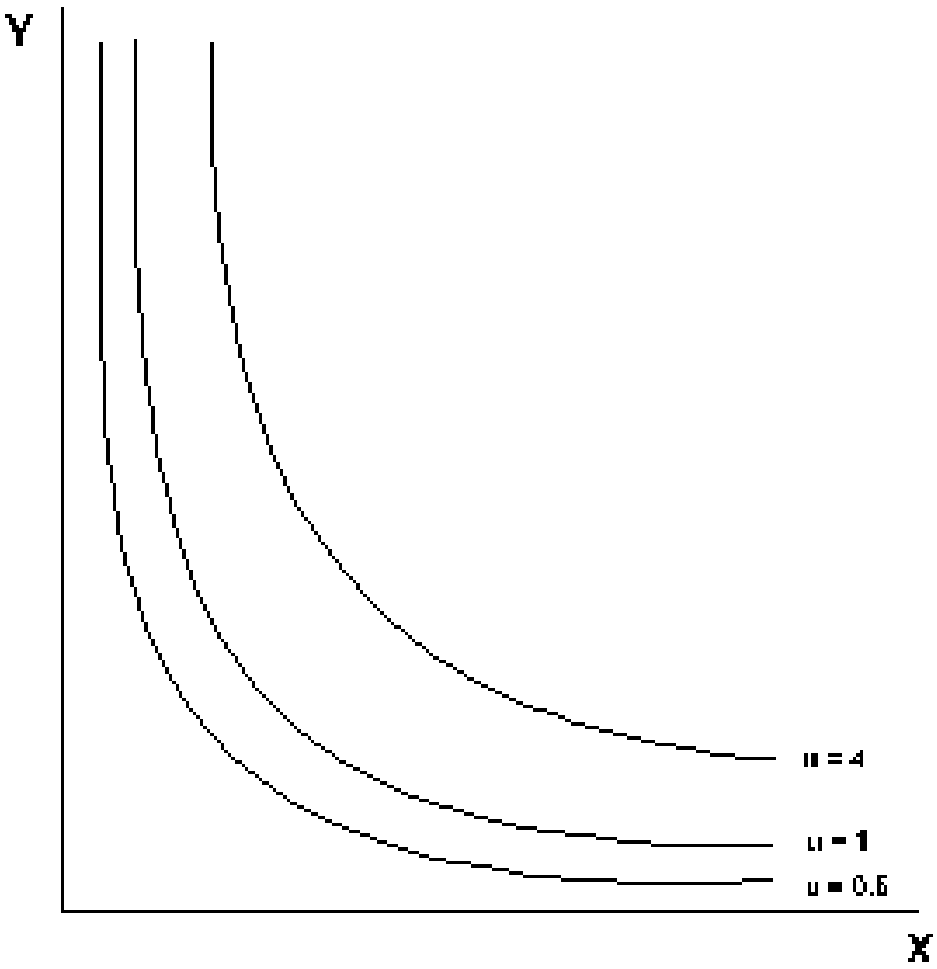
1. How can we represent preferences?
2. What is the nature of constraints on consumer choice? and
3. How can the choice be modelled?

Preferences are relationships between alternative consumption "bundles". These can be represented graphically using "indifference curves", as illustrated in Figure 1. Focusing now on the preferences of a single consumer, the indifference curve is a line which connects all combinations of two goods `x` and `y` between which our consumer is indifferent. As this curve is drawn, we have represented an agent with "well-behaved preferences": at any allocation, more is better (monotonicity), and averages are preferred to extremes (convexity). Exactly one such indifference curve goes through each positive combination of `x` and `y`. Higher indifference curves lie to the "north-east".

Figure 1: An Indifference Curve



Y
4
1
1
3
X



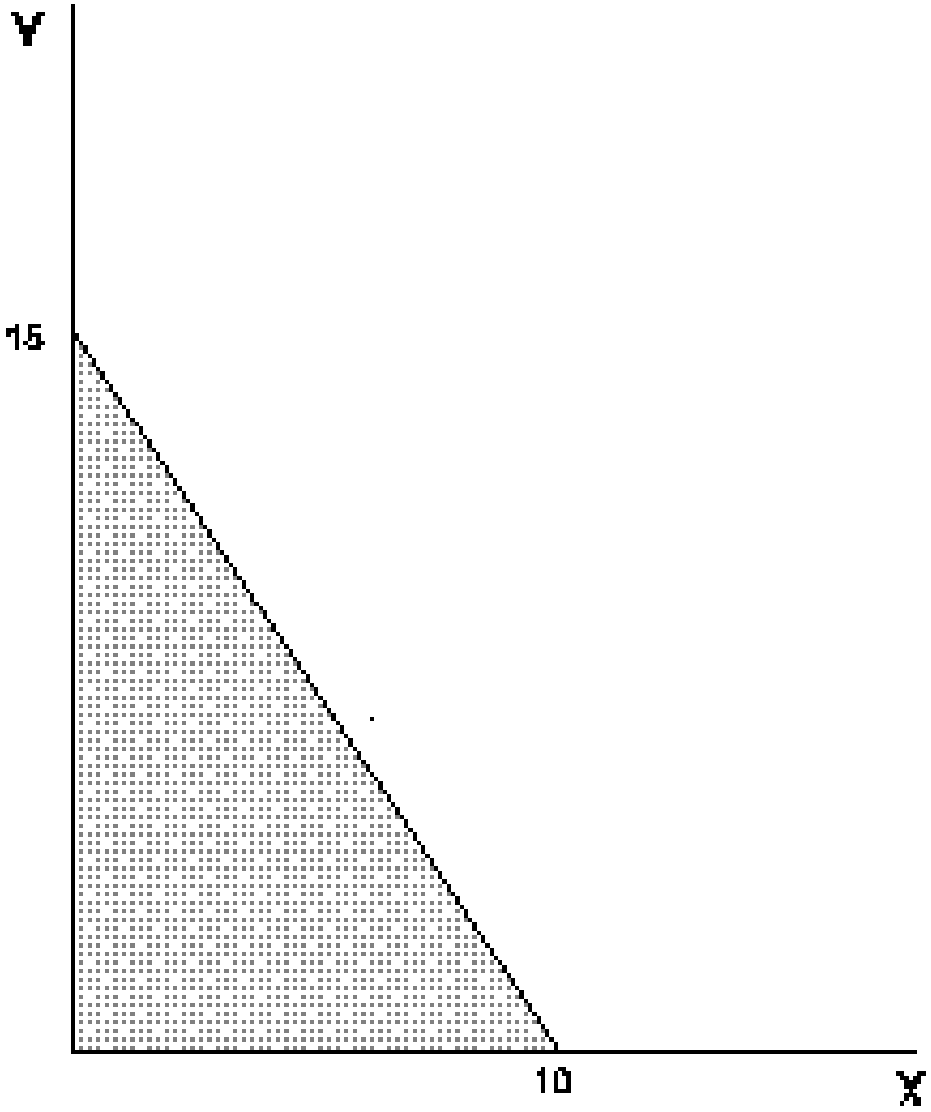
If we wish to characterize an agent's preferences, the "marginal rate of substitution" (MRS) is a useful point of reference. At a given combination of `x` and `y`, the marginal rate of substitution is the slope of the associated indifference curve. As drawn, the MRS increases in magnitude as we move to the northwest and the MRS decreases as we move to the south east. The intuitive understanding is that the MRS measures the willingness of the consumer to trade off one good for the other. As the consumer has greater amounts of `x`, she will be willing to trade more units of `x` for each additional unit of `y` – this results from convexity.

An "ordinal" utility function $U(x, y)$ provides a helpful tool for representing preferences. This is a function which associates a number with each indifference curve. These numbers increase as we move to the northeast, with each successive indifference curve representing bundles which are preferred over the last. The particular number assigned to an indifference curve has no intrinsic meaning. All we know is that if $U(x1, y1) > U(x2, y2)$, then the consumer prefers bundle 1 to bundle 2.

Figure 2 illustrates how it is possible to use a utility function to generate a diagram with the associated indifference curves. This figure illustrates Cobb-Douglas well-behaved preferences which are commonly employed in applied work.

Figure 2: Indifference Curves and Utility Levels

Up to this point, we have we have focused exclusively on the characterization of preferences. Let us now consider the other side of the consumer model – the budget constraint. The simplest approach to



characterizing consumer income is to assume that the consumer has a fixed money income which she may spend on any goods. The only constraint on this choice is that the value of the expenditure may not exceed the money income. This is the standard budget constraint:

$$Px\ x + Py\ y = M.$$

Graphically, this equation defines the line depicted in Figure 3. All points inside the budget line are affordable. The consumer faces a choice of which affordable bundle to select.

Figure 3: The Budget Set

Within the framework of our theory, the answer is straightforward – the consumer will choose the one combination of x and y from the set of affordable bundles which maximizes her utility. This combination of x and y will be at the point where the indifference curve is tangent the budget line. This point is called the optimal choice. We see this illustrated in Figure 4.

Figure 4: Utility Maximization on the Budget Set

The standard model of consumer behavior provides a starting point for learning *MPSGE*. This introduction is "hands on" – I will discuss issues as they arise, assuming that you have access to a computer and can invoke the program and read the output file. You may wish to learn the rudiments of *GAMS* syntax before starting out, although you may be able to pick up these ideas as they come, depending on your aptitude for computer languages.

4.53.3.3 Getting Started

For running MPSGE models, the GAMS/BASE module is required along with a suitable MCP solver such as MILES or PATH. To verify that the system is operational, run one of the *MPSGE* library models, e.g. SCARFMGE. This can be done easily via GAMS Studio (search for *SCARFMGE* in the Model Library Explorer). Alternatively, from a command prompt, connect to a working directory (never run models from the *GAMS* system directory!). Then, extract and run the model:

```
C:\>MKDIR WORK

C:\>CD WORK

C:\WORK>GAMSLIB SCARFMGE

C:\WORK>GAMS SCARFMGE
```

If the *GAMS* system is properly installed, these commands will cause *GAMS* to solve a sequence of models from the `SCARFMGE` sample problem. The output from this process is written to file `SCARFMGE.LST` . If you search for the word "STATUS", you can verify that all the cases are processed.
There are a number of *MPSGE* models included in the **GAMS Model Library**. If you are using a *GAMS* demo license, you will be able to process most but not all of the library models. The demo license limits the number of variables in the model to 1000.
Assuming that you have successfully installed the software, let us now proceed to some examples which illustrate both the computing syntax and the underlying economics.

4.53.3.4 Modeling Consumer Demand

Example 1: Evaluating a Demand Function

Consider a standard consumer choice problem, one which might appear on a midterm examination in intermediate microeconomics:

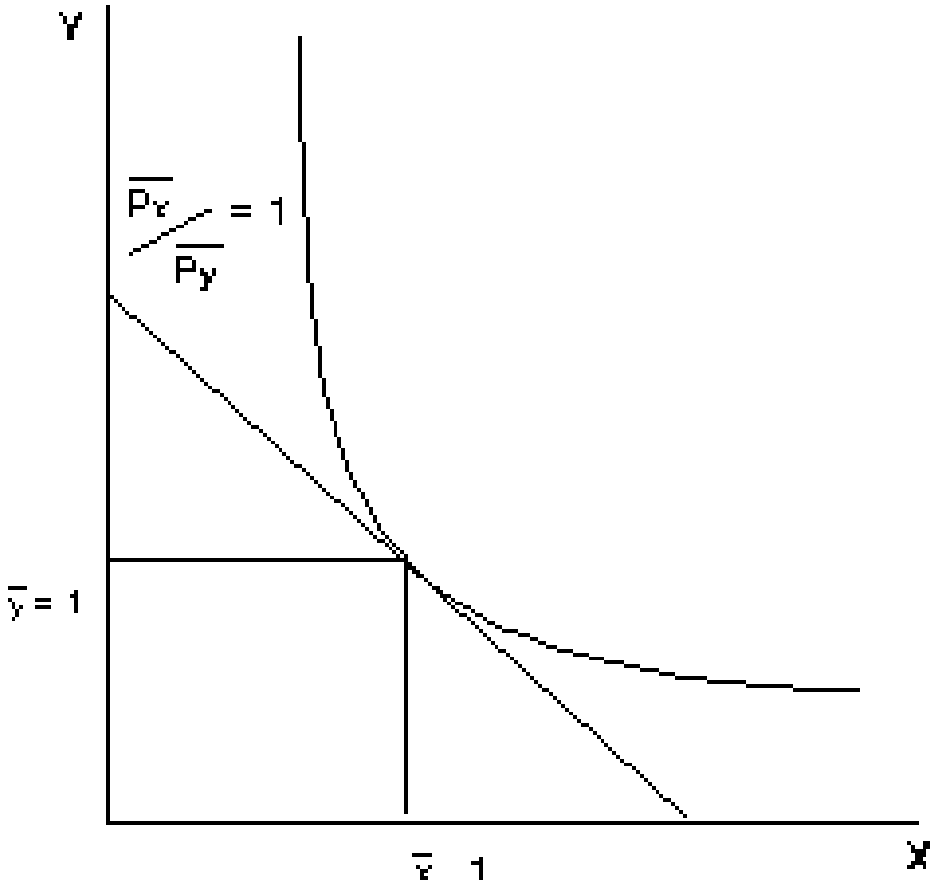
$$\begin{aligned} &\max U(x,y) = \ln(x) + 2\ln(y) \\ &\text{subject to:} \\ &1x + 2y = 120 \end{aligned}$$

where 1 is the exogenous price of `x` and `2` is the price of `y`.

This type of problem is solved easily using GAMS/MINOS (as a nonlinear program). Strictly speaking, it is not the sort of model for which you would need to use *MPSGE*. At the same time, this can be an instructive example.

The key issue in this example is learning how to represent utility functions. *MPSGE* is "non-algebraic" – so function specification depends on an intuitive understanding of the underlying economic structure.

Consider Figure 5 and focus on a single point, $x = 1$, $y = 1$. There is an indifference curve through this point, and the marginal rate of substitution (MRS) at this point is simply the slope of this curve. The benchmark MRS does not uniquely determine the underlying preferences.



Y
$\frac{\overline{P_x}}{\overline{P_y}} = 1$
$\bar{y} = 1$
$\bar{x}$ 1
X

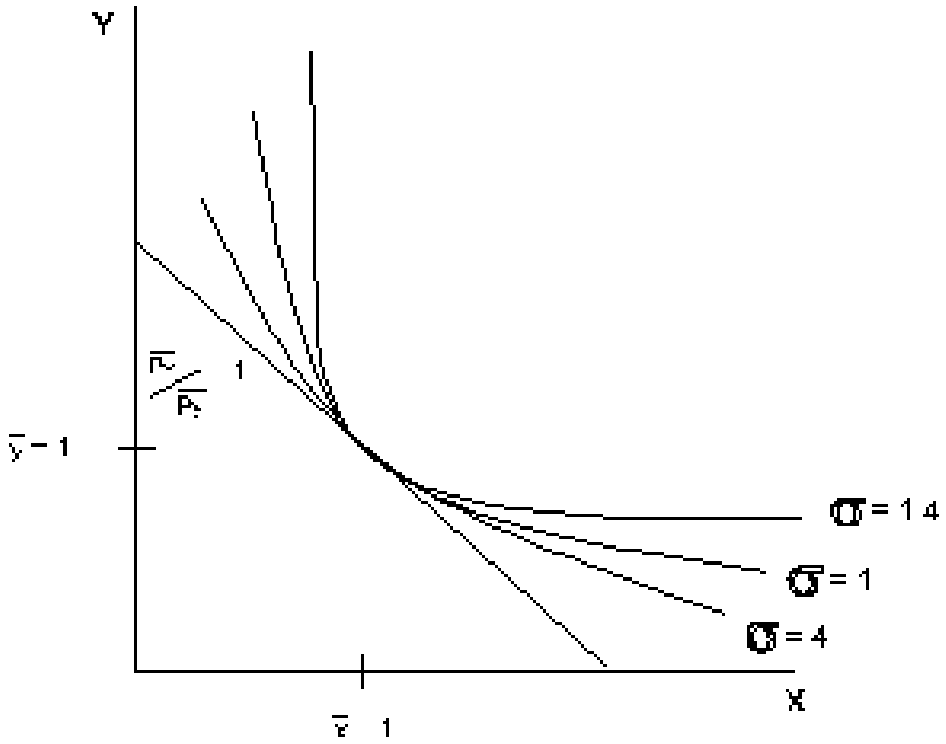


Figure 5: A Calibrated Benchmark

A utility function is represented in *MPSGE* by the specification of: (i) benchmark demand quantities, (ii) benchmark demand prices (iii) an elasticity of substitution at the benchmark point. Benchmark quantities determine an anchor point for the set of indifference curves. Benchmark prices fix the slope of the indifference curve at that point, and the elasticity describes the curvature of the indifference curve. Speaking formally, elasticities provide a "second order approximation" of the utility function. To understand the importance of the benchmark elasticity of substitution, consider Figure 6. This figure shows three indifference curves all of which share the same benchmark quantities and benchmark prices. They differ only in the elasticities of substitution. The least convex (flattest) curve has the highest elasticity, the most convex curve has the lowest elasticity. (When the elasticity of substitution is 0, the indifference curve is L-shaped with the corner at the benchmark point.)

Figure 6:The Elasticity of Substitution

Let us now consider how the consumer optimization problem can be cast as a general equilibrium model. We do this by adding a single factor of production and two "production" sectors. For concreteness, let the factor of production be called labor with a price PL. One production function converts one unit of labor into one unit of `x`, the other sector converts 2 units of labor into one unit of`y`. Setting the labor endowment equal 120, the market clearance condition for labor reads:

$$1x + 2y = 120$$

which is precisely the budget constraint for the consumer's problem.

We will now present the program code, a few lines at a time. As part of working through the example, the student should type these lines into a file.

A *MPSGE* model specification is always listed between `$ONTEXT` and `$OFFTEXT` statements. The first statement within an *MPSGE* model-description assigns a name to the model. The model name must begin with a letter and must have 10 or fewer characters.

```
$ONTEXT

$MODEL:DEMAND
```

The model specification begins by declaring variables for the model. In a standard model, there are three types of variables: commodity prices, sectoral activity levels, and consumer incomes. The end of each line may include "! variable description ".

N.B. The variables associated with commodities are prices, not quantities. (In this and subsequent models, I use P as the first letter for each of the commodity variables to remind us that these variables are prices.)

N.B. The variable associated with a consumer is an income level, not a welfare index.

```
$SECTORS:
        X       ! ACTIVITY LEVEL FOR X = DEMAND FOR GOOD X
        Y       ! ACTIVITY LEVEL FOR Y = DEMAND FOR GOOD Y

$COMMODITIES:
        PX      ! PRICE OF X WHICH WILL EQUAL PL
        PY      ! PRICE OF Y WHICH WILL EQUAL 2 PL
        PL      ! PRICE OF THE ARTIFICIAL FACTOR L

$CONSUMERS:
        RA      ! REPRESENTATIVE AGENT INCOME
```

Function specifications follow the variable declarations. In this model, our first declarations correspond to the two production sectors. In this model, the production structures are particularly simple. Each of the sectors has one input and one output. In the *MPSGE* syntax, `I:` denotes an input and `O:` denotes an output. The output quantity coefficients for both sectors are unity `(Q:1)`. This means that the level values for `x` and `y` correspond to the actual quantities produced. The final function specified in the model represents the utility function and endowments for our single consumer. In this function, the `E:` entries correspond to endowments and the `D:` entries are demands. Reference demands, reference prices and the substitution elasticity `(s:1)` characterize preferences.

The demand entries shown here are consistent with a Cobb-Douglas utility function in which the budget share for y is twice the budget share for x (i.e. the MRS at `(1,1)` equals `1/2`):

```
$PROD:X
      O:PX  Q:1
      I:PL  Q:1

$PROD:Y
      O:PY  Q:1
      I:PL  Q:2

$DEMAND:RA  s:1
      E:PL  Q:120
      D:PX  Q:1   P:(1/2)
      D:PY  Q:1   P:1

$OFFTEXT
```

The final three statements in this file invoke the *MPSGE* preprocessor, "generate" and solve the model:

```
$SYSINCLUDE mpsgeset DEMAND

$INCLUDE DEMAND.GEN
SOLVE DEMAND USING MCP;
```

The preprocessor invocation (`$SYSINCLUDE mpsgeset`) should be placed immediately following the `$OFFTEXT` block containing the model description. The model generator code, `DEMAND.GEN`, is produced by the previous statement and must be referenced immediately before each subsequent SOLVE statement.

At this point, the reader should take the time to type the example into a file and execute the program with GAMS/*MPSGE*.

This is possibly the first GAMS model which some readers have solved, so it is worth looking through the listing file in some detail. After running the solver, we examine the listing file. I typically begin my assessment of a model's solution by searching for "STATUS". For this model, we have the following:

```
               S O L V E      S U M M A R Y

     MODEL   DEMAND
     TYPE    MCP
     SOLVER  PATH                FROM LINE  263

**** SOLVER STATUS     1 NORMAL COMPLETION
**** MODEL STATUS      1 OPTIMAL

 RESOURCE USAGE, LIMIT          1.432     1000.000
 ITERATION COUNT, LIMIT         5         1000
 EVALUATION ERRORS              0            0

 Work space allocated           --    4.86 Mb

Default price normalization using income for RA
```

This information is largely self-explanatory. The most important items are the `SOLVER STATUS` and `MODEL STATUS` indicators. When the solver status is 1 and the model status is 1, the system has returned an equilibrium.

For small models such as this, the limits on resource usage (time) and solver iterations have no effect. (You can modify these values with the statements:

```
 model.RESLIM  =  number of cpu seconds ;

 model.ITERLIM =  number of iterations ;
```

entered into the program before the SOLVE statement.)

The work space allocation for *MPSGE* models is determined by the number of variables in the model. It is possible to exogenously specify the work space allocation by assigning

```
model.WORKSPACE = xx ;
```

where `xx` is the desired number of megabytes.

The final message, `"Default price normalization..."`, is significant. It reminds the user that an Arrow-Debreu general equilibrium model determines only relative prices. In such an equilibrium, the absolute scaling of prices is indeterminant. (I.e., if `(p*,M*)` are a set of equilibrium prices and income levels, then `(2 p*,2 M*)` is also a solution, etc.)

It is common practice in economics to address the normalization issue through the specification of a numeraire commodity. You can do this for an *MPSGE* model by "fixing" a price, with a statement like:

```
PX.FX = 1;
```

entered following the model declaration (`$SYSINCLUDE mpsgeset`) but prior to the solver invocation. When any price or income level is fixed, *MPSGE* recognizes that a numeraire has been specified and does no automatic normalization.

Following some output from the solver (`PATH` in this case), the listing file provides a complete report of equilibrium values. With *MPSGE* models, the equation listings are superfluous. The variable listings provide all the relevant information.

For this model, the solution listing appears as follows:

```
                          LOWER     LEVEL     UPPER    MARGINAL
---- VAR X                  .       40.000     +INF       .
---- VAR Y                  .       40.000     +INF       .
---- VAR PX                 .        1.000     +INF       .
---- VAR PY                 .        2.000     +INF       .
---- VAR PL                 .        1.000     +INF       .
---- VAR RA                 .      120.000     +INF       .

  X           SUPPLY AND DEMAND OF GOOD X
  Y           SUPPLY AND DEMAND OF GOOD Y
  PX          PRICE OF X WHICH WILL EQUAL CX * PL
  PY          PRICE OF Y WHICH WILL EQUAL CY * PL
  PL          PRICE OF THE ARTIFICIAL FACTOR L
  RA          REPRESENTATIVE AGENT INCOME
```

The LOWER and UPPER columns report variable bounds applied in the model. In these columns, zero is represented by "." and infinity is represented by `"+INF"`. The LEVEL column reports the solution value returned by the algorithm. Here we see that the equilibrium price of `x` is 1 and the price of `y` is 2, as determined by the specification of labor inputs.

Exercises 1

(a) The utility function calibration point is arbitrary. Here, we have selected $x = y = 1$ as the reference quantity. Revise the program to use a different calibration point where $x = 2$ and $y = 1$, where $MRS(2, 1) = 1/4$. (Remember to modify both the $Q:$ and $P:$ fields.) Rerun the model to demonstrate that this does not change the result.

(b) Increase the price of x from 1 to 2 by changing the `Q:` coefficient for `PL` in sector X from 1 to 2. What happens to the demand for x? Explain why a change in the price of x is represented by a change in the `Q:` field for sector X.

(c) Compute an equilibrium in which commodity y is defined as the numeraire.

Example 2: Evaluating the MRS

This example further explores the representation of demand functions with *MPSGE*. It sets up a trivial equilibrium model with two goods and one consumer which returns the marginal rate of substitution of good x for good y at a given level of demand. The underlying utility function is:

$$U(x, y) = \ln(x) + 4\ln(y)$$

When $x = y = 1$, the marginal rate of substitution of x for y is $1/4$. We use this information to calibrate the demand function, specifying the ratio of the reference prices of x to y equal to $1/4$.

In an equilibrium, final demand always equals endowments for both goods, because these are the only sources of demand and supply. The model as parameterized demonstrates that if we set endowments for this model equal to the demand function calibration point, the model equilibrium price ratio equals the benchmark MRS.

This program begins with some GAMS statements in which three scalar parameters are declared. These parameters will be used in the place of numbers within the *MPSGE* model. The syntax for these GAMS statements is introduced in Chapter 2 of the *GAMS* manual. In short, we declare x, y and MRS as scalar parameters and initialize the first two of these to unity. The MRS parameter is assigned a value following the solution of the model.

```
SCALAR
      X     QUANTITY OF X FOR WHICH THE MRS IS TO BE EVALUATED /1/
      Y     QUANTITY OF Y FOR WHICH THE MRS IS TO BE EVALUATED /1/
      MRS   COMPUTED MARGINAL RATE OF SUBSTITUTION;
The remainder of the <em>MPSGE</em> program is, in fact, simpler than Example 1.

$ONTEXT

$INCLUDE MRSCAL.GEN
SOLVE MRSCAL USING MCP;
```

Following the solution, we compute a function of the solution values, the ratio of the price of x to the price of y. We do this using the GAMS syntax which references the equilibrium level values of the `PX` and `PY` and storing this result in the scalar MRS. This scalar value is then displayed in the listing file with 8 digits:

```
MRS = PX.L / PY.L;
OPTION MRS:8;
DISPLAY MRS;
```

Exercises 2

(a) Show that the demand function is homothetic by uniform scaling of the x and y endowments. The resulting MRS should remain unchanged.

(b)Modify the demand function calibration point so that the reference prices of both x and y equal unity (hint: the marginal rate of substitution is:

$$MRS = x/(4y).$$

Example 3: Leisure Demand and Labor Supply

This model investigates the labor-leisure decision. A single consumer is endowed with labor which is either supplied to the market or "repurchased" as leisure. The consumer utility function over market goods (x and y) and leisure is Cobb-Douglas:

$$U(x, y, L) = \ln(x) + \ln(y) + \ln(L)$$

Goods x and y may only be purchased using funds obtained from labor sales. This constraint is written:

$$x + y = \text{LPROD LS}$$

where goods x and y both have a price of unity at base year productivity and `LPROD` is an index of labor productivity. An increase in productivity is equivalent to a proportional decrease in the prices of x and y.

The model declaration is as follows:

```
SCALAR          LPROD   AGGREGATE LABOR PRODUCTIVITY /1/,
                CX      COST OF X AT BASE YEAR PRODUCTIVITY /1/,
                CY      COST OF Y AT BASE YEAR PRODUCTIVITY /1/;

```

We can use this model to evaluate the wage elasticity of labor supply. In the initial equilibrium (computed in the last statement) the demands for x, y and L all equal 40. A subsequent assignment to `LPROD` (below) increases labor productivity. After computing a new equilibrium, we can use the change in labor supply to determine the wage elasticity of labor supply, an important parameter in labor market studies. It should be emphasized that the elasticity of labor supply should be an input rather than an output of a general equilibrium model – this is a parameter for which econometric estimates can be obtained.

Here is how the programming works. First, we declare some scalar parameters which we will use for reporting, then save the "benchmark" labor supply in `LS0`:

```
SCALAR
      LS0   REFERENCE LEVEL OF LABOR SUPPLY
      ELS   ELASTICITY OF LABOR SUPPLY WRT REAL WAGE;

LS0 = LS.L;
```

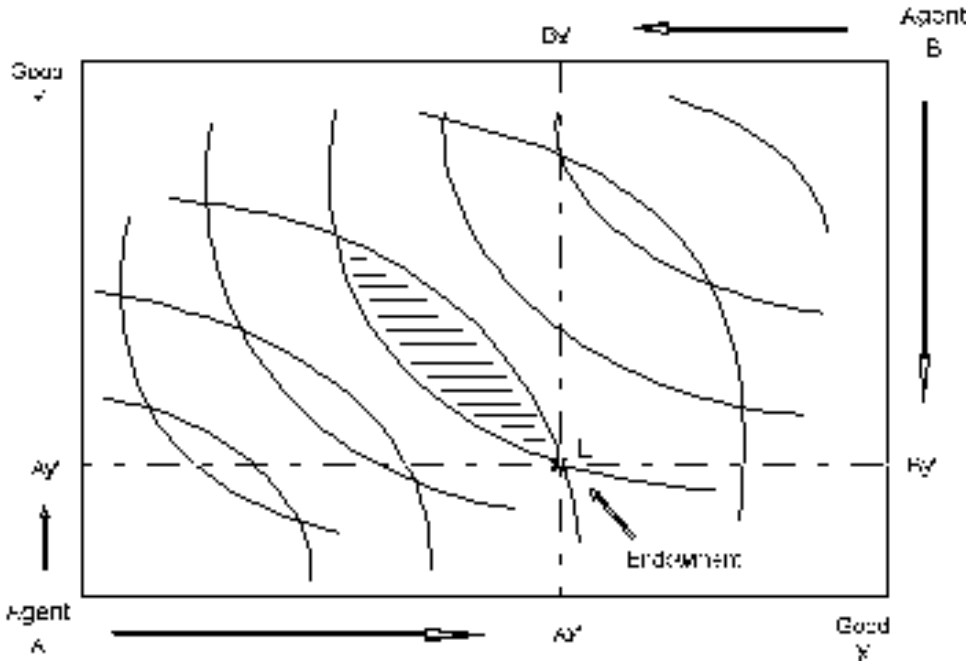
Next, we modify the value of scalar `LPROD`, increasing labor productivity by 1%. Because this is a neoclassical model, this change is equivalent to increasing the real wage by 1%. We need to recompute equilibrium prices after having changed the LPROD value:

```
LPROD = 1.01;
$INCLUDE LSUPPLY.GEN
SOLVE LSUPPLY USING MCP;
```

We use this solution to compute and report the elasticity of labor supply as the percentage change in the LS activity:

```
ELS = 100 * (LS.L - LS0) / LS0;
DISPLAY ELS;
```

As the model is currently constructed, the wage elasticity of labor supply equals zero. This is because the utility function is Cobb-Douglas over goods and leisure, and the consumer's only source of income is labor. As the real wage rises, this increases both the demand for goods (labor supply) and the demand for leisure. These effect exactly balance out and the supply of labor is unchanged.



Exercises 3

(a) One way in which the labor supply elasticity might differ from zero in a model with Cobb-Douglas final demand is if there were income from some other source. Let the consumer be endowed with good x in addition to labor. What x endowment is consistent with a labor supply elasticity equal to 0.15?

(b) A second way to "calibrate" the labor supply elasticity is to change the utility function. We can do this by changing the `s:1` to `s:SIGMA`, where `SIGMA` is a scalar value representing the benchmark elasticity of substitution between x, y and L in final demand. Modify the program to include SIGMA as a scalar, and find the value for `SIGMA` consistent with a labor supply elasticity equal to 0.15.

4.53.3.5 The Pure Exchange Model

Partial equilibrium analysis forms the basis of most economics courses at the undergraduate level. In these models we focus on price, supply and demand for a single commodity. The partial equilibrium approach neglects indirect effects, through which changes in the market for one good may influence the market for another good.

In the previous section, we focused on the choices of a single consumer. In the present section, we will explore the implications of interactions between many consumers with heterogeneous preferences. Furthermore, the analysis will explore the potentially important interaction between market prices and income which are determined jointly in a general equilibrium.

The most widely-used graphical framework for multi-agent exchange equilibrium analysis is the Edgeworth-Bowley box as illustrated in Figure 7. In this diagram we model the following economy:

Figure 7: The Edgeworth-Bowley Box

- Two types of consumers, denoted A and B. We consider A and B to each represent multiple consumers, each with the same endowments and preferences. This assumption is helpful for justifying our assumption of perfectly competitive, price-taking behavior.

- Two commodities, denoted x and y
- Fixed endowments of both goods. The horizontal axis measures the total world endowment of good X. The vertical axis measure the total world endowment of good Y. Any point in the box then represents an allocation of goods between the two agents. The agent H allocation is measured with respect to the lower left origin. The agent F allocation is measured with respect to the upper right origin.

Each agent has a given initial endowment, here denoted point E. Furthermore, we assume that there is no possibility for trade. The indifference curves through point E therefore represent autarchy welfare levels.

The key idea in this model is that trade can improve both agents' welfare. One agent gives some amount good x to the other in return for an amount of good y. The "terms of trade", the rate of exchange between x and y, is determined by the model. The model illustrates a number of important properties of market economies:

- Trade is mutually beneficial. So long as the transactions are voluntary, neither H nor F will be hurt by engaging in trade.
- Market prices can be used to guide the economy to a Pareto-efficient allocation, a state of affairs in which further mutually-beneficial trades are not possible.
- There is no guarantee that the gains from trade will be "fairly distributed" across consumers. A competitive equilibrium may produce a significant welfare increase for one consumer while have negligible impact on the other.
- There are multiple Pareto-efficient allocations, typically only one of which is a competitive equilibrium. We can use this model to demonstrate that the issues of efficiency and equity can be separated when there is the possibility of lump-sum income transfers between agents.

4.53.3.6 Modeling Pure Exchange with MPSGE

Example 4: A 2x2 Exchange Model

In this program, we examine the simple two good, two agent model of exchange equilibrium. The world endowments for goods x and y are both equal to 1. Six parameters are used to parameterize the model. These are declared as scalars at the top of the program:

```
SCALAR  XA              AGENT A ENDOWMENT OF X ( 0 < XA < 1)    /0.2/
        YA              AGENT A ENDOWMENT OF Y ( 0 < YA < 1)    /0.8/
        THETA_A         AGENT A DEMAND SHARE PARAMETER FOR X    /0.5/
        THETA_B         AGENT B DEMAND SHARE PARAMETER FOR X    /0.8/
        SIGMA_A         AGENT A ELASTICITY PARAMETER            /2.0/
        SIGMA_B         AGENT B ELASTICITY PARAMETER            /0.5/;
```

This model is actually simpler than the models presented above because we have no need for production. There are simply two commodities and two consumers. The consumers differ in terms of commodity endowments and preferences. The competitive equilibrium prices are such that supply equals demand for both goods and both agents spend an amount equal to their endowment income.

This model illustrates how to use computed function coefficients. See, for example, `Q:(1-THETA_A)` in the `$DEMAND:A` block. Any numeric input field in an MPSGE model may be "computed", provided that the algebraic expression is enclosed within parentheses and legitimate *GAMS* code.

This model specification uses the default values for reference prices in the demand function blocks. When P:value is not specified in a `D:`,`I:` or `O:` record, `P:1` is assumed.

This model uses the more general constant-elasticity-of-substitution utility function.

```

$SYSINCLUDE mpsgeset EXCHANGE

$INCLUDE EXCHANGE.GEN
SOLVE EXCHANGE USING MCP;

SCALAR
      PRATIO  EQUILIBRIUM PRICE OF X IN TERMS OF Y,
      IRATIO  EQUILIBRIUM RATIO OF CONSUMER A INCOME TO CONSUMER B INCOME;

PRATIO = PX.L / PY.L;
IRATIO = A.L  / B.L;

DISPLAY IRATIO, PRATIO;
```

The foregoing sets up the model and computes the competitive equilibrium. After *GAMS* returns from the solver, we declare and compute some report values.

Absolute levels of income and price returned from a general equilibrium model are not meaningful because a model determines only relative prices. For this reason, we report equilibrium income and price levels in relative terms.

In the final step, we compute an alternative efficient equilibrium, one in which the income levels for A and B are equal. The purpose of this exercise is to demonstrate the second welfare theorem. When incomes are both fixed, the equilibrium remains efficient, but the connection between market prices and endowment income is eliminated.

In *GAMS/MPSGE*, a variable may be fixed using the *GAMS* syntax

```
variable.fx= value;
```

as illustrated in this model:

```
A.FX = 1;
B.FX = 1;
$INCLUDE EXCHANGE.GEN
SOLVE EXCHANGE USING MCP;

SCALAR      TRANSFER  IMPLIED TRANSFER FROM A TO B AS A PERCENTAGE OF INCOME;

TRANSFER = 100 * ( A.L - PX.L * XA - PY.L * YA ); PRATIO = PX.L / PY.L;
IRATIO = A.L  / B.L;

DISPLAY TRANSFER, PRATIO, IRATIO;
```

Exercises 4

(a) Set up a separate models which computes the autarchy price ratios for consumers A and B. (You can use one of the earlier models as a starting point.)

(b) Determine parameter values for which the endowment point is the equilibrium point.

(c) Set up a series of computations from which you can sketch the efficiency locus. Draw the Edgeworth box diagram which is consistent with these values.

Example 5: Import Tariffs and Market Power

The exchange model provides a remarkably useful tool for analyzing issues related to international trade. Formal trade theory is more complicated with the inclusion of separate production technologies. We will present some of those models below. Before going forward, however, we will consider a slight generalization of the 2x2 model exchange model. In this extension, we introduce independent markets for consumers A and B and trade activities which deliver goods from one market to the other.

The set of input parameters largely the same as in the previous example. Two new parameters are ad-valorem tariffs which apply on imports to each of the regions.

```
SCALAR  XA              AGENT A ENDOWMENT OF X ( 0 le XA le 1)    /0.2/
        YA              AGENT A ENDOWMENT OF Y ( 0 le YA le 1)    /0.8/
        THETA_A         AGENT A DEMAND SHARE PARAMETER FOR X    /0.4/
        THETA_B         AGENT B DEMAND SHARE PARAMETER FOR X    /0.6/
        SIGMA_A         AGENT A ELASTICITY PARAMETER            /1.0/
        SIGMA_B         AGENT B ELASTICITY PARAMETER            /1.0/,
        T_A             AD-VALOREM TARIFF ON IMPORTS TO AGENT A /0.10/
        T_B             AD-VALOREM TARIFF ON IMPORTS TO AGENT B /0.10/;
```

The program differs from the previous example in several respects. First, we introduce a separate commodity price for each agent. In the absence of tariffs, these prices are identical.

A second difference is that in this model trade activities deliver goods from one agent to the other. These are denoted `M{good}{agent}` for imports of `{good}` to `{agent}`. There are four flows which may be operated in only one direction (the activity levels are non-negative). In terms of initial endowments and preferences, this model has exactly the same economic structure as the previous model.

```
$ONTEXT

$MODEL:TARIFFS

        D:PXB   Q:THETA_B
        D:PYB   Q:(1-THETA_B)
```

The trade activities each have one input and one output. They simply deliver a good (X or Y) from one agent to the other. The new syntax presented here is specification of an ad-valorem tax. Adding a tax requires two new fields. The first is `"A:"` which specifies the tax agent, a consumer who collects the tax revenue as part of income. The second is `"T:"` which specifies the ad- valorem tax rate.

MPSGE permits taxes to applied on production inputs and outputs but it does not permit taxes on final demand.

The tax applies on a net basis on inputs. For example, if we consider the MXA sector, the price of one unit of input is given by:

$$Px\_B * (1 + Ta)$$

where Px_B is the net of tax price of a unit of x in the agent B market and Ta is the ad-valorem tariff rate.

```
$PROD:MXA
      O:PXA Q:1
      I:PXB Q:1   A:A  T:T_A

$PROD:MXB
      O:PXB Q:1
      I:PXA Q:1   A:B  T:T_B
```

```
$PROD:MYA
      O:PYA Q:1

$PROD:MYB
      O:PYB Q:1
      I:PYA Q:1   A:B  T:T_B
```

The final portions of the file introduces one use of "MPSGE report variables". In this case, report variables are used to recover a Hicksian money-metric welfare index for each of the agents. We compute the initial, tariff-ridden equilibrium in order to compute the benchmark welfare levels. We then set all tariffs to zero and compute the free-trade equilibrium. Using the final welfare indices and the saved values of the benchmark welfare levels, we are able to report the change in welfare from removing tariff distortions.

Exercises 5

(a) Find the "optimal tariff" in this model for agent A, assuming that agent B does not retaliate and leaves her tariff rate at the benchmark level.

(b) Insert the endowment and preference parameters from the previous problem, retaining the same "benchmark" tariff rates. Does free trade benefit both countries? If not, why not?

4.53.4 Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae

Notes prepared for GAMS General Equilibrium Workshop held December, 1995 in Boulder Colorado.

Author

Thomas F. Rutherford, Department of Economics, University of Colorado

Date

December, 1995

4.53.4.1 The Basics

In many economic textbooks the constant elasticity of substitution (CES) utility function is defined as:

$$U(x,y) = (\alpha x^\rho + (1-\alpha)y^\rho)^{\frac{1}{\rho}},$$

It is a fairly routine but tedious calculus excercise to demonstrate that the associated demand functions are:

$$x(p_x,p_y,M) = \left(\frac{\alpha}{p_x}\right)^\sigma = \frac{M}{\alpha^\sigma p_x^{1-\sigma} + (1-\alpha)^\sigma p_y^{1-\sigma}},$$

and

$$y(p_x,p_y,M) = \left(\frac{1-\alpha}{p_y}\right)^\sigma \frac{M}{\alpha^\sigma p_x^{1-\sigma} + (1-\alpha)^\sigma p_y^{1-\sigma}},$$

The corresponding indirect utility function has is:

$$V(p_x,p_y,M) = M\left(\alpha^\sigma p_x^{1-\sigma} + (1-\alpha)^\sigma p_y^{1-\sigma}\right)^{\frac{1}{\sigma-1}},$$

Note that U(x,y) is linearly homogeneous:

$$U(\lambda_x,\lambda_y) = \lambda U(x,y)$$

This is a convenient cardinalization of utility, because percentage changes in U are equivalent to percentage Hicksian equivalent variations in income.

Because U is linearly homogeneous, V is homogeneous of degree one in M and degree -1 in p.

In the representation of technology, we have an analogous set of relationships, based on the cost and compensated demand functions. If we have a CES production function of the form:

$$y(K,L) = \gamma\left(\alpha K^\rho + (1-\alpha)L^\rho\right)^{\frac{1}{\rho}},$$

the unit cost function then has the form:

$$c(p_K, p_L) = (\frac{1}{\gamma})\left(\alpha^\sigma p_K^{1-\sigma} + (1-\alpha)^\sigma p_L^{1-\sigma}\right)^{\frac{1}{1-\sigma}},$$

and associated demand functions are:

$$K(p_K, p_L) = \left(\frac{y}{\gamma}\right)\left(\frac{\alpha\gamma c(p_K, p_L)}{p_K}\right)^\sigma,$$

and

$$L(p_K, p_L) = \left(\frac{y}{\gamma}\right)\left(\frac{(1-\alpha)\gamma c(p_K, p_L)}{p_L}\right)^\sigma.$$

In most large-scale applied general equilibrium models, we have many function parameters to specify with relative ly few observations. The conventional approach is to *calibrate* functional parameters to a single benchmark equilibrium. For example, if we have benchmark estimates for output, labor, capital inputs and factor prices , we calibrate function coefficients by inverting the factor demand functions:

$$\theta = \frac{\bar{p}_k \bar{K}}{\bar{p}_k \bar{K} + \bar{P}_L \bar{L}}, \quad \rho = \frac{\sigma - 1}{\sigma}, \quad \alpha = \theta \bar{K}^{\frac{-1}{\rho}},$$

and

$$\gamma = \bar{y}\left[\alpha \bar{K}^\rho + (1-\alpha)\bar{L}^\rho\right]^{\frac{-1}{\rho}}.$$

4.53.4.2 The Calibrated Share Form

Calibration formulae for CES functions are messy and difficult to remember. Consequently, the specification of function coefficients is complicated and error-prone. For applied work using calibrated functions, it is much easier to use the "calibrated share form" of the CES function. In the calibrated form, the cost and demand functions explicitly incorporate

- benchmark factor demands
- benchmark factor prices
- the elasticity of substitution
- benchmark cost
- benchmark output
- benchmark value shares

In this form, the production function is written:

$$y = \bar{y}\left[\theta\left(\frac{K}{\bar{K}}\right)^\rho + (1-\theta)\left(\frac{L}{\bar{L}}\right)^\rho\right]^{\frac{1}{\rho}}$$

The only calibrated parameter, θ , represents the value share of capital at the benchmark point. The corresponding cost functions in the calibrated form is written:

$$c(p_K, p_L) = \bar{c}\left[\theta\left(\frac{p_K}{\bar{p}_k}\right)^{1-\sigma} + (1-\theta)\left(\frac{p_L}{\bar{p}_L}\right)^{1-\sigma}\right]^{\frac{1}{1-\sigma}}$$

where $\bar{c} = \bar{p}_L\bar{L} + \bar{p}_K\bar{K}$and the compensated demand functions are:

$$K(p_K, p_L, y) = \bar{K}\frac{y}{\bar{y}}\left(\frac{\bar{p}_K}{p_K}\frac{c}{\bar{c}}\right)^{\sigma}$$

and

$$L(p_K, p_L, y) = \bar{L}\frac{y}{\bar{y}}\left(\frac{c}{\bar{c}}\frac{\bar{p}_L}{p_K}\right)^{\sigma}.$$

Normalizing the benchmark utility index to unity, the utility function in calibrated share form is written:

$$U(x, y) = \left[\theta\left(\frac{x}{\bar{x}}\right)^{\rho} + (1-\theta)\left(\frac{y}{\bar{y}}^{\rho}\right)\right]^{\frac{1}{\rho}}$$

Defining the unit expenditure function as:

$$e(p_x, p_y) = \left[\theta\left(\frac{p_x}{\bar{p}_x}\right)^{1-\sigma} + (1-\theta)\left(\frac{p_y}{\bar{p}_y}\right)\right]^{\frac{1}{1-\sigma}}$$

the indirect utility function is:

$$V(p_x, p_y, M) = \frac{M}{\bar{M}e(p_x, p_y)}$$

and the demand functions are:

$$x(p_x, p_y, M) = \bar{x}\ V(p_x, p_y, M)\left(\frac{e(p_x, p_y)\bar{p}_x}{p_x}\right)^{\sigma}$$

and

$$y(p_x, p_y, M) = \bar{y}\ V(p_x, p_y, M)\left(\frac{e(p_x, p_y)\bar{p}_y}{p_y}\right)^{\sigma}$$

The calibrated form extends directly to the n-factor case. An n-factor production function is written:

$$y = f(x) = \bar{y}\left[\sum_i \theta_i\left(\frac{x_i}{\bar{x}_i}\right)^{\rho}\right]^{\frac{1}{\rho}}$$

and has unit cost function:

$$C(p) = \bar{C}\left[\sum_i \theta_i\left(\frac{p_i}{\bar{p}_i}\right)^{1-\sigma}\right]^{\frac{1}{1-\sigma}}$$

and compensated factor demands:

$$x_i = \bar{x}_i\frac{y}{\bar{y}}\left(\frac{C\bar{p}_i}{\bar{C}p_i}\right)^{\sigma}$$

4.53.4.3 Excercises

(i) Show that given a generic CES utility function:

$$U(x,y) = (\alpha^\rho + (1-\alpha)y^\rho)^{\frac{1}{\rho}}$$

can be represented in share form using:

$$\bar{x} = 1,\ \bar{y} = 1,\ \bar{p}_x = t\alpha,\ \ \bar{p}_y = t(1-\alpha),\ \bar{M} = t.$$

for any value of $t > 0$.

(ii) Consider the utility function defined:

$$U(x,y) = (x-a)^\alpha (y-b)^{1-\alpha}$$

A benchmark demand point with both prices equal and demand for y equal to twice the demand for x. Find values for which are consistent with optimal choice at the benchmark. Select these parameters so that the income elasticity of demand for x at the benchmark point equals 1.1.

(iii) Consider the utility function:

$$U(x,L) = (\alpha L^\rho + (1-\alpha)x^\rho)^{\frac{1}{\rho}}$$

which is maximized subject to the budget constraint:

$$p_x x = M + \omega(\bar{L} - L)$$

in which M is interpreted as non-wage income, ω is the market wage rate. Assume a benchmark equilibrium in which prices for x and L are equal, demands for x and L are equal, and non-wage income equals one-half of expenditure on x. Find values of α and ρ consistent with these choices and for which the price elasticity of labor supply equals 0.2.

(iv) Consider a consumer with CES preferences over two goods. A price change makes the benchmark consumption bundle unaffordable, yet the consumer is indifferent. Graph the choice. Find an equation which determines the elasticity of substitution as a function of the benchmark value shares. (You can write down the equation, but it cannot be solved in closed form.)

(v) Consider a model with three commodities, x, y, and z. Preferences are CES. Benchmark demands and prices are equal for all goods. Find demands for x, y and z for a doubling in the price of x as a function of the elasticity of substitution.

(iv) Consider the same model in the immediately preceeding question, except assume that preferences are instead given by:

$$U(x,y,z) = (\beta \min(x,y)^\rho + (1-\beta)z^\rho)^{\frac{1}{\rho}}$$

Determine $\beta$from the benchmark, and find demands for x, y and z if the price of x doubles.

4.53.4.4 Flexibility and Non-Separable CES functions

We let π_i denote the user price of the ith input, and let $x_i(\pi)$ be the cost-minizing demand for the ith input. The reference price and quantities are $\bar{\pi}_i$ and $\bar{x}_i$. One can think of set i as $\{K, L, E, M\}$ but the methods we employ may be applied to any number of inputs. Define the reference cost, and reference value share for ith input by $\bar{C}$ and θ_i , where

$$\bar{C} \equiv \sum_i \bar{\pi}_i \bar{x}_i$$

and

$$\theta_i \equiv \frac{\pi_i \bar{x}_i}{\bar{C}}.$$

The single-level constant elasticity of substitution cost function in "calibrated share form" is written:

$$C(\pi) = \bar{C}\left(\sum_i \theta_i \left(\frac{\pi_i}{\bar{\pi}_i}\right)^{1-\sigma} \right)^{\frac{1}{1-\sigma}}$$

Compensated demands may be obtained from Shephard's lemma:

$$x_i(\pi) = \frac{\delta C}{\delta \pi_i} \equiv C_i = \bar{x}_i \left(\frac{C(\pi)}{\bar{C}} \frac{\bar{\pi}_i}{\pi_i} \right)^{\sigma}$$

Cross-price Allen-Uzawa elasticities of substitution (AUES) are defined as:

$$\sigma_{ij} \equiv \frac{C_{ij} C}{C_i C_j}$$

where

$$C_{ij} = \frac{\delta^2 C(\pi)}{\delta \pi_i \, \delta \pi_j} = \frac{\delta x_i}{\delta \pi_j} = \frac{\delta x_j}{\delta \pi_i}$$

For single-level CES functions:

$$\sigma_{ij} = \sigma \quad \forall_{i \neq j} \quad .$$

The CES cost function exibits homogeneity of degree one, hence Euler's condition applies to the second derivatives of the cost function (the Slutsky matrix):

$$\sum_j C_{ij}(\pi)(\pi_j) = 0$$

or, equivalently:

$$\sum_j \sigma_{ij}(\theta_j) = 0$$

The Euler condition provides a simple formula for the diagonal AUES values:

$$\sigma_{ii} = \frac{-\sum_{j \neq i} \sigma_{ij} \theta_j}{\theta_i}$$

As an aside, note that convexity of the cost function implies that all minors of order 1 are negative, i.e. $\sigma_{ii} < 0 \; \forall_i$. Hence, there must be at least one positive off-diagonal element in each row of the AUES or Slutsky matrices. When there are only two factors, then the off-diagonals must be negative. When there are three factors, then only one pair of negative goods may be complements.

Let:

k be the reference the index of second-level nest

s_{ik} denote the fraction of good i inputs assigned to the kth nest

ω_k denote the benchmark value share of total cost which enters through the kth nest

γ denote the top-level elasticity of substitution

σ^k denote the elasticity of substitution in the kth aggregate

$p_k(\pi)$ denote the price index associated with aggregate k, normalized to equal unity in the benchmark, i.e.:

$$p_k(\pi) = \left[\frac{\sum_i s_{ik}\theta_i}{\omega_k \left(\frac{\pi_i}{\bar{\Pi}_i}\right)^{1-\sigma^k}} \right]^{\frac{1}{1-\sigma^k}}$$

The two-level nested, nonseparable constant-elasticity-of-substitution (NNCES) cost function is then defined as:

$$C(\pi) = \bar{C}\left(\sum_k \omega_k p_k(\pi)^{1-\gamma} \right)^{\frac{1}{1-\gamma}}$$

Demand indices for second-level aggregates are needed to express demand functions in a compact form. Let $z_k(\pi)$ denote the demand index for aggregate k, normalized to unity in the benchmark; i.e.

$$z_k(\pi) = \left(\frac{C(\pi)}{\bar{C}} \; \frac{1}{p_k(\pi)} \right)^{\gamma}$$

Compensated demand functions are obtained by differentiating $C(\pi)$. In this derivative, one term arise for each nest in which the commodity enters, so:

$$x_i(\pi) = \bar{x}_i \sum_K z_k(\pi) \left(\frac{p_k(\pi)\bar{\pi}_i}{\pi_i} \right)^{\sigma^k} = \bar{x}_i \sum_k \left(\frac{C(\pi)}{\bar{C}} \; \frac{1}{p_k(\pi)} \right)^{\gamma} \left(\frac{p_k(\pi)\bar{\pi}_i}{\pi_i} \right)^{\sigma^k}$$

Simple differentiation shows that benchmark cross-elasticities of substitution have the form:

$$\sigma_{ij} = \gamma + \sum_k \frac{(\sigma^k - \gamma) s_{ik} s_{jk}}{\omega_k}$$

Given the benchmark value shares θ_i and the benchmark cross-price elasticities of substitution, σ_{ij} , we can solve for values of , s_{ik} , ω_k, σ^k and γ . We compute these parameters using a constrained nonlinear programming algorithm, CONOPT, which is available through GAMS, the same programming environment in which the equilibrium model is specified. Perroni and Rutherford (EER, 1994) prove that calibration of the NNCES form is possible for arbitrary dimensions whenever the given Slutsky matrix is negative semi-definite. The two-level (NxN) function is flexible for three inputs; and although we have not proven that it is flexible for 4 inputs, the only difficulties we have encountered have resulted from indefinite calibration data points.

Two GAMS programs are listed below. The first illustrates two analytic calibrations of the three-factor cost function. The second illustrates the use of numerical methods to calibrate a four-factor cost function.

4.53.4.5 Two NNCES calibrations for a 3-input cost functions

4.53.4.8 Calibrating Labor Supply and Savings Demand

This material was published in the MUG newsletter, 8/95.

Following Ballard, Fullerton, Shoven and Whalley (BFSW), we consider a representative agent whose utility is based upon current consumption, future consumption and current leisure. Changes in "future

consumption" in this static framework are associated with changes in the level of savings. There are three prices which jointly determine the price index for future consumption. These are:

P_I the composite price index for investment goods

P_K the composite rental price for capital services

P_C the composite price of current consumption.

All of these prices equal unity in the benchmark equilibrium.

Capital income in each future year finances future consumption, which is expected to cost the same as in the current period, PC (static expectations). The consumer demand for savings therefore depends not only on P_I, but also on P_K and P_C, namely:

$$P_S = \frac{P_I P_C}{P_K}$$

The price index for savings is unity in the benchmark period. In a counter-factual equilibrium, however, we would expect generally that $P_S \neq P_I$. When these price indices are not equal, there is a "virtual tax payment" associated with savings demand.

Following BFSW, we adopt a nested constant-elasticity-of-substitution function to represent preferences. In this function, at the top level demand for savings (future consumption) trades off with a second CES aggregate of leisure and current consumption. These preferences can be summarized with the following expenditure function:

$$P_U = \left[\alpha P_H^{1-\sigma_S} + (1-\alpha) P_H^{1-\sigma_S}\right]^{\frac{1}{1-\sigma_S}}$$

Preferences are homothetic, so we have defined P_U as a linearly homogeneous cost index for a unit of utility. We conveniently scale this price index to equal unity in the benchmark. In this definition, α is the benchmark value share for current consumption (goods and leisure). P_H is a compositive price for current consumption defined as:

$$P_H = \left[\beta P_l^{1-\sigma_L} + (1-\beta) P_C^{1-\sigma_L}\right]^{\frac{1}{1-\sigma_L}}$$

in which β is the benchmark value share for leisure within current consumption. Demand functions can be written as follows:

$$S = S_0 \left(\frac{P_U}{P_F}\right)^{\sigma_S} \quad \frac{I}{I_0 P_U},$$

$$C = C_0 \left(\frac{P_H}{P_C}\right)^{\sigma_L} \quad \left(\frac{P_U}{P_H}\right)^{\sigma_S} \quad \frac{I}{I_0 P_U},$$

and

$$\ell = \ell_0 \left(\frac{P_H}{P_L}\right)^{\sigma_L} \quad \left(\frac{P_U}{P_H}\right)^{\sigma_S} \quad \frac{I}{I_0 P_U},$$

Demands are written here in terms of their benchmark values (S_0, C_0 and ℓ_0) and current and benchmark income (I and I_0).

There are four components in income. The first is the value of labor endowment (E), defined inclusive of leisure. The second is the value of capital endowment (K). The third is all other income (M). The fourth is the value of "virtual tax revenue" associated with differences between the shadow price of savings and the cost of investment.

$$I = P_L E + P_K K + M + (P_S - P_I) S$$

The following parameter values are specified exogenously:

1. $\zeta = 1.75$ is the ratio of labor endowment:

$$\zeta \equiv E/L_0$$

where L_0 is the benchmark labor supply. Given ζ and L_0 we have:

$$\ell_0 = L_0(\zeta - 1)$$

2. $\xi = 0.15$ is the uncompensated elasticity of labor supply with respect to the net of tax wage, i.e.

$$\xi = \frac{\delta L}{\delta P_L}\frac{P_L}{L} = \frac{\delta(E-\ell)}{\delta P_L}\frac{P_L}{L} = -\frac{\delta \ell}{\delta P_L}\frac{P_L}{L}$$

3. $\eta = 0.4$ is the elasticity of savings with respect to the return to capital:

$$\eta \equiv \frac{\delta S}{\delta P_K}\frac{S}{P_K}$$

Shephard's lemma applied at benchmark prices provides the following identities which are helpful in deriving expressions for η and ξ :

$$\frac{\delta P_U}{\delta P_H} = \alpha, \frac{\delta P_U}{\delta P_S} = 1-\alpha, \frac{\delta P_H}{\delta P_L} = \beta, \frac{\delta P_H}{\delta P_C} = 1-\beta,$$

It is then a relatively routine application of the chain rule to show that:

$$\xi = (\zeta - 1)\left[\sigma_L + \beta(\sigma_S - \sigma_L) - \alpha\beta(\sigma_S - 1) - \frac{E}{I_0}\right]$$

and

$$\eta = \sigma_S\alpha + \frac{K}{I_0}$$

The expression for *eta* does not involve σ_L , so we may first solve for σ_S and use this value in determining σ_L :

$$\sigma_S = \frac{\eta - \frac{K}{I_0}}{\alpha}$$

and

$$\alpha_L = \frac{\frac{\xi}{\xi-1} - \sigma_S\beta(1-\alpha) - \alpha\beta + \frac{E}{I_0}}{1-\beta}$$

$INCLUDE CHKCAL.GEN
SOLVE CHKCAL USING MCP;

*       CHECK THE LABOR SUPPLY ELASTICITY:

PL.L = 1.001;

CHKCAL.ITERLIM = 0;
$INCLUDE CHKCAL.GEN
SOLVE CHKCAL USING MCP;
*       Compute induced changes in labor supply using the labor market
*       "marginal", PL.M.  This marginal returns the net excess supply of
*       labor at the given prices.  We started from a balanced benchmark,
*       with no change in labor demand (the iteration limit was zero).
*       Hence, PL.M returns the magnitude of the change in labor supply.
*       We multiply by the benchmark wage (1) and divide by the benchmark
*       labor supply (LS0) to produce a finite difference approximation
*       of the elasticity:

DISPLAY "CALIBRATION CHECK -- THE FOLLOWING VALUES SHOULD BE IDENTICAL:", XI;
XI = (PL.M / 0.001) * (1 / LS0);
```

```
DISPLAY XI;

PL.L = 1.0;

*       CHECK THE ELASTICITY OF SAVINGS WRT RENTAL RATE OF CAPITAL:

PK.L = 1.001;
PS.L = 1 / 1.001;
TS   = 1 / 1.001 - 1;

CHKCAL.ITERLIM = 0;

*       Compute elasticity of savings with respect to the rental rate of
*       capital.  This requires some recursion in order to account for the
*       effect of changes in savings on effective income.  When PK increases,
*       PS declines -- there is an effective "subsidy" for saving, paid from
*       consumer income.  In order to obtain a difference approximation for
*       the elasticity of savings response, we need to make sure the virtual
*       tax payments are properly handled.  In the MPSGE model, this means
*       that the level value for S must be adjusted so that it exactly equals
*       the savings.  We do this recursively:

SET ITER /IT1*IT5/;

PS.M = 1;
LOOP(ITER$(ABS(PS.M) GT 1.0E-8),

$INCLUDE CHKCAL.GEN
        SOLVE CHKCAL USING MCP;
        S.L = S.L - PS.M;
);

DISPLAY "CALIBRATION CHECK -- THE FOLLOWING VALUES SHOULD BE IDENTICAL:", ETA;
ETA = ((S.L - S0) / 0.001) * (1 / S0);
DISPLAY ETA;
```

Chapter 5

Solver Manuals

A large number of solvers for mathematical programming models have been hooked up to GAMS. The tables below provide a brief description of each solver, the `model types` each solver is cabable of solving, and the `platforms` supported by each solver. For general information on using GAMS solvers, see Solver Usage.

Solver	Vendor	Description
ALPHAECP 2.11	Abo University	MINLP solver based on the extended cutting plane (ECP) method
ANTIGONE 1.1	Princeton University	Deterministic global optimization for MINLP
BARON	The Optimization Firm, LLC	Branch-And-Reduce Optimization Navigator for proven global solutions
CBC 2.10	COIN-OR Foundation	High-performance LP/MIP solver
CONOPT 3	ARKI Consulting and Development	Large scale NLP solver
CONOPT 4	ARKI Consulting and Development	Large scale NLP solver
CONVERT	GAMS Development Corp	Framework for translating modes into scalar models of other languages
COPT 7.0	Cardinal Operations	High-performance LP/MIP solver
CPLEX 22.1	IBM ILOG	High-performance LP/MIP solver
DE	GAMS Development Corp	Generates and solves the deterministic equivalent of a stochastic program, included in EMP/SP
DECIS	G. Infanger, Inc.	Large scale stochastic programming solver
DICOPT 2	GAMS Development Corp	Framework for solving MINLP models
EXAMINER	GAMS Development Corp	A tool for examining solution points and assessing their merit
GAMSCHK	Bruce McCarl	A System for Examining the Structure and Solution Properties of Linear Programming Problems Solved using GAMS
GUROBI 11.0	Gurobi Optimization	High performance LP/MIP solver
GUSS	GAMS Development Corp	A framework for solving many instances of related models efficiently (Gather-Update-Solver-Scatter)
HiGHS 1.6	ERGO	High performance LP/MIP solver

Solver	Vendor	Description
IPOPT 3.14	COIN-OR Foundation	Interior Point Optimizer for large scale nonlinear programming
JAMS	GAMS Development Corp	Solver to reformulate extended mathematical programs (incl. LogMIP)
KESTREL	NEOS	Framework for using remote NEOS solvers with a local GAMS system
KNITRO 14.0	Artelys	Large scale NLP and MINLP solver
LINDO 14.0	Lindo Systems Inc.	A stochastic solver from Lindo Systems, Inc. Includes an unrestricted version of LINDOGLOBAL
LINDOGLOBAL 14.0	Lindo Systems Inc.	MINLP solver for proven global solutions
MILES	University of Colorado at Boulder	MCP solver
MINOS 5.6	Stanford University	NLP solver
MOSEK 10	MOSEK ApS	Large scale mixed-integer conic programming solver
NLPEC	GAMS Development Corp	MPEC to NLP translator that uses other GAMS NLP solvers
ODHCPLEX 7	Optimization Direct Inc	ODHeuristic on top of Cplex
PATHNLP	University of Wisconsin - Madison	Large scale NLP solver for convex problems
PATH	University of Wisconsin - Madison	Large scale MCP solver
QUADMINOS 5.6	Stanford University	Quad-precision NLP solver
SBB	ARKI Consulting and Development	Branch-and-Bound algorithm for solving MINLP models
SCIP 8.1	Zuse Institute Berlin et.al.	High-performance Constraint Integer Programming solver
SHOT 1.1	Abo Akademi University	MINLP solver based on the extended supporting hyperplane (ESH) method
SNOPT 7.7	Stanford University	Large scale SQP based NLP solver
SOPLEX 6.0	Zuse Institute Berlin	High-performance LP solver
XPRESS 41.01	FICO	High performance LP/MIP and SLP based MINLP solver

5.1 Model Types

GAMS is able to formulate models in many different types of problem classes or model types. Typically, a solver will be capable of solving (i.e. will accept as input) more than one model type. The solver/model type matrix shows which solver is capable of which model type:

∗ deterministic global solver

When choosing a solver, some judgement should be applied when considering the listed model type capabilities for the solver - the same capability "check boxes" does not imply equality in capacity or suitability. For example, take a hypothetical solver WeOpt designed to solve MINLP models. Since the problem class MINLP includes NLP, MIP, and LP as subclasses, solver WeOpt could include these capabilities also. If WeOpt is also a good performer on NLP models, it would include that capability. But if it does not shine at all as a MIP or LP solver, we would choose not to include MIP and LP in the capability list for WeOpt. In such a case one can always solve using a more general model type (e.g. solve an LP model as NLP so WeOpt can be used), but WeOpt will not advertise itself as an LP solver. Since the WeOpt solver does not even recognize MCP or MPEC models, we don't include those capabilities.

There are two types of non-linear solvers: local and global. A local solver can find a local optimum but generally cannot comment on global optimality of the solution. A local optimum is a point where the objective value is better than its neighboring points but could be worse than a distant point. On the other hand, a global solver can find and prove that the obtained solution is a global optimum i.e., there is no feasible solution that would result in a better objective value. It is worth noting that a local solver can solve a model to global optimality in some special cases. In the table shown, the entries with ∗ in the column Global indicate solvers that can solve a model to global optimality.

There are other differences in solvers that are difficult to quantify or cannot be captured by a capability table like the one shown. For example, for nonconvex NLP or QCP models, one solver could look only for first-order stationary points, another for local solutions, a third for local solutions using a scatter search or similar search heuristic, and a fourth could do a true global search for the global optimum. The relative merits (measured typically by speed alone) of solvers is the subject of considerable benchmarking activity and discussion.

The GAMS sales team can help answer questions you may have about solver capability. We also offer free evaluation licenses to help you decide what solvers are most suitable for your models.

5.2 Supported Platforms

The solver/platform matrix shows which platforms each solver is supported on. In addition, where a vendor has discontinued solver support for a particular platform and we continue to ship the last available supported version, this version number is indicated as well.

5.3 AlphaECP

Author

Tapio Westerlund (twesterl@abo.fi) and Toni Lastusilta. Åbo Akademi University, Finland
Ville-Pekka Eronen. University of Turku, Finland

5.3.1 Introduction

AlphaECP is a Mixed-Integer Non-Linear Programming (MINLP) solver based on the extended cutting plane (ECP) method. The solver can be applied to general MINLP problems and it can ensure global

optimal solutions for pseudo-convex MINLP problems. The documentation is written as if the considered problem is a minimization problem, if not otherwise denoted.

The ECP method is an extension of Kelley's cutting plane method, which was originally given for convex NLP problems [105] . The method only requires the solution of a MIP sub-problem in each iteration. The MIP sub-problems can be solved to optimality, to feasibility, or only to an integer relaxed solution in intermediate iterations. This makes the ECP algorithm efficient and easy to implement. Further information about the underlying algorithm can be found in [200] and [145] [174] [199] [201] .

Further developments of the GAMS/AlphaECP algorithm have introduced additional functionality. A NLP solver can now be called at MIP solutions. This improves AlphaECP's ability to find feasible and accurate solutions, especially for MINLP problems which mainly contain continuous variables. Furthermore, a heuristic that reselects cutting planes during the iteration procedure can be used to improve the capability of solving non-convex problems. In addition to the termination based on constraint tolerance the algorithm can terminate also if relative objective gap termination criterion is satisfied. This is only supported for convex problems.

5.3.1.1 Licensing and software requirements

Users need to have a GAMS/AlphaECP license in order to use GAMS/AlphaECP. In addition, a licensed MIP solver is required for solving the mixed integer sub-problem, and a licensed NLP solver is required if the NLP option is used.

5.3.1.2 Running AlphaECP

AlphaECP solves MINLP models. If AlphaECP is not specified as the default solver for these models it can be invoked by issuing the following command before the solve statement:

```
option minlp=alphaecp, miqcp=alphaecp;
```

In principle AlphaECP can also handle NLP models, but it is more suitable for MINLP problems. However, when combined with an NLP solver it can find solutions the NLP solver cannot find by itself. In this case it acts as a good starting point generator. If you want to solve NLPs with AlphaECP you need to *trick* the GAMS system by solving your NLP as an MINLP:

```
solve mynlpmodel minimizing obj using minlp;
```

Constraint violations are reported throughout the progress of AlphaECP and at the end of the algorithm. The violation is reported for the non-linear constraints only. The violation of the linear constraints is subject to the feasibility tolerance of the MIP/NLP solver.

5.3.2 GAMS/AlphaECP Output

The log output below is obtained for the MINLP model fuel.gms from the GAMS model library:

```
--------------------------------------------------------------------------------
                  Welcome to AlphaECP v2.11.01

```

In every iteration, information about the MIP problem and modifications to it is given in 10 columns. Here is a description of the different columns:

Iteration: Iteration identifier.

Stepcode, Problems: Letter for what actions were taken in this iteration, i.e. MIP problem modifications before the next iteration.

A: MIP solver feasible.

B: MIP solver feasible after moving cutting planes, i.e. alpha update.

C: MIP solver feasible after moving cutting planes close to their generation point. The movement is done to make it easier to satisfy nonlinear equality constraints.

D: Line search was successful (in ECPstrategy `3`).

E: Line search failed (in ECPstrategy `3`).

F: A NLP solver was called.

G: Found a MINLP solution.

H: Added linearization(s) to the next MIP problem.

I: Updated alpha values and possibly added linearizations.

J: All cutting planes are valid underestimators for the pseudo-convex constraints, except for the nonlinear objective function constraint.

K: The nonlinear objective function constraint value and MIP solution value differ more than ϵ_f. A linearization was done to reduce the difference (in ECPstrategy `3`).

L: Removed all temporal linearizations.

M: Domain violation(s), some of the constraint could not be evaluated.

N: Some cutting plane(s) could not be generated because of gradient problems.

O: No cutting planes could be generated.

P: Reselecting cuts because cutting planes are repeatedly moved close to their generation point.

Q: Added temporal linearization(s).

R: Failed to add temporal linearization(s).

S: MIP solver strategy to find encountered solutions selected.

T: MIP solver strategy to require MIPnrsols solutions selected.

U: MIP solver strategy to require MIPnrsols solutions with a MIPoptcr <= `0.2` selected.

Number of Cuts: The number of cutting planes the solved MIP problem had.

Point usage: Number of points used to generate the cuts in the solved MIP problem.

Alpha Upd.: The number of times the alpha values has been increased.

OPTCR: Relative MIP gap. Note that this is different from TOLoptcr.

Movement Norm: The Euclidean norm of the current and previous MIP solution.

Viol Cons: Number of unsatisfied (violating) nonlinear constraints.

Maximum Violation: The most violating nonlinear constraint value.

MIPobjval/NLobjval: MIP or nonlinear objective variable value depending on ECPstrategy setting.

The cut reselection heuristic is called in the following cases:

1. If the MIP solver would otherwise return infeasible.
2. When the violation is not reducing, but the cutting planes are repeatedly moved close to their generation point.
3. When the violation is not reducing and domain violations are repeatedly encountered.

The heuristic reselects cutting planes in different ways, but always ensures that the same point cannot be found twice.

```
Pointusage     6/90     Cutusage     15/341    (    0,135  )
```

`Pointusage` informs how many points of all usable points have been used to generate the cutting planes. `Cutusage` tells how many cuts of all usable cuts have been used. The first number in `( 0,135 )` tells how many cuts is required by the user, see CUTnrcuts and the second number gives the sum of added and removed cuts, i.e. a measure of how much the MIP problem has been modified. AlphaECP may fix some cuts and remove points and cuts during the cut reselection procedure in order to save memory.

At the end of each solve AlphaECP gives a summary which includes Problem, Solver Status, Model Status, etc. Note the following lines:

- **Exit comment** may give further information than solverstatus on why the solution procedure stopped.
- **Domain violations** (function evaluation failed) or **Gradients unusable** (all gradients < TOLgrad) might be caused by poor variable bounds.
- **Alphamax bound violations** inform the user how many times an alphamax value was calculated to be $> 10^{154}$ and was reset to 10^{154}.

5.3.3 Notes about Options

To instruct AlphaECP to read an option file you may use **ModelName.OptFile = 1**. The name of the option file is in this case `alphaecp.opt`. For further information, see The Solver Options File. AlphaECP supports the GAMS parameters reslim and optCR, however, other GAMS parameters are passed on to the sub-solvers. Note that optCR is transferred to option TOLoptcr. Furthermore, you may also pass additional sub-solver specific options to the sub-solvers. For example, if you want to use all available threads and sub-solver CPLEX in opportunistic parallel search mode, then you may specify this in a GAMS model, in a similar way, as follows:

```
Model m / all /;
Option threads=0;
m.optfile=1;
$echo MIPsolver cplex.1 > alphaecp.opt
$echo parallelmode -1 > cplex.opt
Solve m using MINLP minimizing objvar;
```

The following information is worth noting when you are interested in AlphaECP options. A linearization of a nonlinear constraint is called a cutting plane or cut. Here a point refers to the variable levels. Global optimality can be guaranteed for pseudo-convex problems. However, if the objective variable is in a nonlinear constraint and pseudo-convex, then ECPstrategy >= 3 needs to be used to guarantee global optimality (because one non-linear equality constraint makes a problem non-pseudo-convex, and hence also non-convex). The basic options might significantly impact the solution procedure, and the best values are likely to be problem specific. The user is therefore encouraged to try different values for the basic options.

5.3.4 Summary of AlphaECP Options

5.3.4.1 Basic options

Option	Description	Default
CUTnrcuts	Cut generation pace	0
ECPmaster	Master strategy (0=User 1=Convex)	0
MIPnrsols	Upper limit of considered MIP solutions per MIP call	50
MIPsolstrat	MIP solution collection strategy	1
MIPsolver	MIP solver for sub-problems and . option file number	GAMS MIP solver
NLPsolver	NLP solver for sub-problems and . option file number	GAMS NLP solver
reslim	Time limit for AlphaECP (in seconds)	GAMS reslim

5.3.4.2 Algorithmic options for advanced users

Option	Description	Default
CUTdelcrit	Cutting plane strategy	3
ECPbeta	Updating multiplier if MIP is infeasible	1.3
ECPdumpsol	Write encountered solutions to gdx files	0
ECPgamma	Updating multiplier when verifying solution	2.0
ECPiterlim	Maximum number of AlphaECP iterations	-1
ECPloglevel	Level of AlphaECP output to statusfile	0
ECPpcostrategy	Pseudo-convex objective function strategy	3
ECPretsol	Return solution (1.MIP/2.NLP/3.QUALITY/4.PERFORMANCE)	2
ECPstart	User specified start-point	3
ECPstrategy	AlphaECP strategy	2
ECPtoltype	AlphaECP termination criterion	1
solvelink	Solvelink for NLP and MIP sub-solver	5
solvetrace	Filename of solvetrace file	
solvetracetime	Time interval when a trace record is written	1
TOLepsf	Pseudo-convex objective function termination tolerance	1e-3
TOLepsg	Constraint tolerance	1e-3
TOLepsz	Distance tolerance for a new linearization	1e-1
TOLgrad	Gradient tolerance	1e-6
TOLinfbnd	Infinity bound (MIP variable bound)	1e10
TOLoptcr	Relative termination tolerance for MINLP	GAMS optCR

5.3.4.3 MIP Solver related options

Option	Description	Default
MIPloglevel	Level of MIP solver output	0
MIPoptcr	Relative MIP gap in intermediate sub-problems	1.0
MIPoptcrlim	Initial iteration limit when MIPoptcr is reduced	200
MIPoptcrlimtype	Strategy to increase MIPoptcrlim	0
MIPoptimaliter	MIP is solved to optimality with this frequency	0

5.3.4.4 NLP Solver related options

Option	Description	Default
NLPcall	NLP strategy	5
NLPcalliter	NLP solver call at next (incremental) iteration	0
NLPlimsameint	NLP call after a number of recurring integer solutions	5
NLPloglevel	Level of NLP solver output	0
NLPreslim	NLP time limit per call	0

5.3.5 Detailed Descriptions of AlphaECP Options

CUTdelcrit *(integer)*: Cutting plane strategy ↩

Default: 3

value	meaning
0	Do not remove any valid cuts.
1	As 0 and allow temporary cuts at semirandom points if normal cuts can not be made.
2	Allow temporary cuts and cut reselection, and use memory to save points and cuts.
3	As 2 and call the reselection heuristic before termination to improve the solution.

CUTnrcuts *(real)*: Cut generation pace ↩

The number of linearizations that are generated during an iteration can be chosen by AlphaECP, proportional to the number of violating constraints, or can be determined by a fixed amount. Furthermore, the cut reselection CUTdelcrit >=2 adds cuts to the problem so that the requested cut generation pace is taken into consideration.

Default: 0

value	meaning
0	Let AlphaECP decide.
0<n<1	Number of linearizations = n∗ the number of linearizations that is possible to generate.
>1	Specifies the number of linearizations to generate.

ECPbeta *(real)*: Updating multiplier if MIP is infeasible ↩

In case of an infeasible MIP solution, the invalid cuts are updated with the ECPbeta multiplier.

Range: [1.001, ∞]

Default: 1.3

ECPdumpsol *(integer)*: Write encountered solutions to gdx files ↩

Default: 0

value	meaning
0	No.
1	Solutions that the NLP solver found.
2	Solutions that the NLP or MIP solver found.

ECPgamma *(real)*: Updating multiplier when verifying solution ↩

If a MINLP solution is obtained but some cuts are not valid underestimators they are updated with the ECPgamma multiplier in order to make them into valid underestimators.

Range: [1.001, ∞]

Default: 2.0

ECPiterlim *(integer)*: Maximum number of AlphaECP iterations ↩

This is the maximum number of iterations given to AlphaECP to perform the optimization. Value -1 deactivates the AlphaECP iteration limit.

Default: -1

value	meaning
-1	No limit.
>=0	Specifies an iteration limit.

ECPloglevel *(integer)*: Level of AlphaECP output to statusfile ↩

Default: 0

value	meaning
0	No additional output to statusfile.
1	Report solutions. Report all encountered solutions with their corresponding variable levels.
2	Report main actions at iteration level (available for minimization problems).
3	Report main actions at linearization level (available for minimization problems).
4	Full reporting. Report the main actions taken, the linearizations, function values, and solution points for every iteration and line search details (available for minimization problems).

ECPmaster *(integer)*: Master strategy (0=User 1=Convex) ↩

The master strategy sets some options in order to solve a model with specific characteristics more efficiently. The affected options are noted in the log output. The set options takes precedence over the value set by the user for the affected options.

Default: `0`

value	meaning
0	Use only user defined options.
1	The model is convex. Set option ECPstrategy, CUTdelcrit and ECPtoltype.

ECPpcostrategy *(integer)*: Pseudo-convex objective function strategy ↩

Default: `3`

value	meaning
1	Remove support. Remove old support planes when a new pseudo-convex problem is formed.
2	Replace support. Replace old support planes with linearizations of the reduction constraint when a new pseudo-convex problem is formed.
3	Remove support and line search. Remove old support planes when a new pseudo-convex problem is formed and perform a line search when it is possible.
4	Replace support and line search. Replace old support planes with linearizations of the reduction constraint when a new pseudo-convex problem is formed and perform a line search when it is possible.

ECPretsol *(integer)*: Return solution (1.MIP/2.NLP/3.QUALITY/4.PERFORMANCE) ↩

The reported solution can be extracted from either the MIP or NLP solver result. If the MIP solution is returned only the primal values are available.

Default: `2`

value	meaning
1	Choose MIP solution if it is available.
2	Choose NLP solution if it is available.
3	Choose the solution with the best tolerance.
4	Choose the solution with the best objective value.

ECPstart *(integer)*: User specified start-point ↩

Define which variable levels are used when the optimization is started.

Default: `3`

value	meaning
0	Do not use a start-point; start the algorithm by solving the linear part (MIP) of the problem.

value	meaning
1	Use the user specified startpoint, but adjust the variable levels with a small value.
2	Use the exact start-point set by the user.
3	Use the exact start-point if linearly feasible; else adjust variable levels with a small value.

ECPstrategy *(integer)*: AlphaECP strategy ↩

Default: 2

value	meaning
1	Convex strategy. Ensures global optimality for problems with convex objective function and convex constraints.
2	Pseudo-convex constraints. Ensures global optimality for problems with convex objective function and pseudo-convex constraints.
3	Pseudo-convex objective. Ensures global optimality for problems with pseudo-convex objective function and pseudo-convex constraints. The reformulation of a non-linear objective function into a constraint must be done in a specific way. The requirement is that the objective variable must be in a linear part of the non-linear function. Assuming that the minimized or maximized variable is called objvar, the reformulation can be done as follows: (objective function expression) - objvar =E= 0. Furthermore, this strategy can effectively use a feasible start-point.
4	Pseudo-convex objective, but first complete with ECPstrategy 2. (Only the necessary linearizations are removed when the ECPstrategy is changed.)
5	Pseudo-convex objective, but find the first solution with ECPstrategy 2. (Only the necessary linearizations are removed when the ECPstrategy is changed.)

ECPtoltype *(integer)*: AlphaECP termination criterion ↩

Default: 1

value	meaning
1	Use termination based on tolerances TOLepsg and TOLepsf.
2	Terminate also if relative objective gap is satisfied according to TOLoptcr. The relative objective gap termination criterion also called relative termination criterion is only supported for convex problems when using ECPstrategy=1. The relative termination criterion can be used for non-convex problems, as well as, with ECPstrategy=2, however, in this case it may not work properly because the lower bound may be invalid.

MIPloglevel *(boolean)*: Level of MIP solver output ↩

By default the detailed log of the MIP solver is suppressed in the AlphaECP log stream. If this option is turned on the MIP log will be merged into the AlphaECP log.

Default: 0

value	meaning
0	No output.
1	MIP solver log goes to GAMS log.

MIPnrsols *(integer)*: Upper limit of considered MIP solutions per MIP call ↩

When the MIP solver returns several solutions the most suitable solution is chosen. Many times the solutions from the MIP solver are similar and a larger number might help to find a feasible MINLP solution if the constraints are almost satisfied. See MIPsolstrat to change the solution collection strategy.

Range: {1, ..., ∞}

Default: 50

MIPoptcr *(real)*: Relative MIP gap in intermediate sub-problems ↩

The relative stopping tolerance sent to the MIP solver for intermediate MIP problems. Note that the MIPoptcr value is decreased automatically to zero during the optimization.

Range: [0, 1]

Default: 1.0

MIPoptcrlim *(integer)*: Initial iteration limit when MIPoptcr is reduced ↩

The MIPoptcr parameter is reduced in steps: From 1 to 0.5 to 0.3 to 0.2 to 0.1 to 0.0. The first reduction is at iteration `MIPoptcrlim`. The following reductions occur also at iteration `MIPoptcrlim` but it is updated with a strategy defined by parameter MIPoptcrlimtype. Note that a step reduction may happen for other reasons.

Range: {1, ..., ∞}

Default: 200

MIPoptcrlimtype *(integer)*: Strategy to increase MIPoptcrlim ↩

Default: 0

value	meaning
0	Exponential increase of MIPoptcrlim. The parameter MIPoptcrlim is increased by multiplying it by 2. The increase occurs at iteration "MIPoptcrlim". If MIPoptcrlim=200 it will have values 200,400,800 etc.
1	Linear increase of MIPoptcrlim. The parameter MIPoptcrlim is increased by adding the original value of MIPoptcrlim to it. If MIPoptcrlim=200 it will have values 200,400,600 etc.

MIPoptimaliter *(integer)*: MIP is solved to optimality with this frequency ↩

Defines the frequency to solve the MIP problem to optimum before the algorithm sets MIPoptcr=0 and, hence, solves MIP problems to optimum. For example if `MIPoptimaliter`=n, then at least every nth iteration the MIP problem is solved to the optimum. Solving MIP problem to optimum yields a lower bound for a convex MINLP problem which can help to terminate the algorithm faster if ECPtoltype=2 is used. Non-default value is not recommended for non-convex problems nor if ECPstrategy >1.

Default: 0

value	meaning
0	Never.
n>0	Every nth iteration, where n is the given value.

MIPsolstrat *(integer)*: MIP solution collection strategy ↩

Default: 1

value	meaning
0	Instruct MIP solver to return only one solution.
1	Instruct MIP solver to return any solutions encountered during MIP procedure.
2	Instruct MIP solver to search for solutions to obtain requested number MIPnrsols solutions.
3	As 2, but also require the solutions to fulfill MIPoptcr >= 0.2.
4	Let AlphaECP decide.

MIPsolver *(string)*: MIP solver for sub-problems and . option file number ↩

`solver[.n]` Solver is the name of the GAMS MIP solver and `n` is the integer corresponding to optfile. The option file is appended to the option file, that is written by AlphaECP. Hence, the specified options take precedence over the options set by AlphaECP. If `.n` is missing, the optfile is treated as zero i.e. the MIP solver will not look for a options file specified by the user. This option can be used to overwrite the default that uses the MIP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: `GAMS MIP solver`

NLPcall *(integer)*: NLP strategy ↩

Determine when the NLP solver is called.

Default: 5

value	meaning
0	No output.
1	Call the NLP solver at end of AlphaECP algorithm.
2	As 1 and when a better solution is found.
3	As 2 and when the same integer solution is encountered NLPlimsameint times.
4	Let AlphaECP decide.
5	Let AlphaECP decide and add noise to the variable levels before call.

NLPcalliter *(integer)*: NLP solver call at next (incremental) iteration ↩

Specify an iteration interval for the NLP solver calls.

Default: 0

NLPlimsameint *(integer)*: NLP call after a number of recurring integer solutions ↩

If the same integer solution is encountered `NLPlimsameint` times in a row then the NLP solver is called. The counter is reset after the NLP solver is called.

Range: {1, ..., ∞}

Default: 5

NLPloglevel *(boolean)*: Level of NLP solver output ↩

By default the detailed log of the NLP solver is suppressed in the AlphaECP log stream. If this option is turned on the NLP log will be merged into the AlphaECP log.

Default: `0`

value	meaning
`0`	No output.
`1`	NLP solver log goes to GAMS log.

NLPreslim *(real)*: NLP time limit per call ↩

The time limit (in seconds) given to the chosen NLP solver at each NLP solver call. Setting this option to 0 calculates a time limit which is relative to the problem size.

Default: `0`

NLPsolver *(string)*: NLP solver for sub-problems and . option file number ↩

`solver[.n]` Solver is the name of the GAMS NLP solver that should be used in the root node, and `n` is the integer corresponding to optfile. If `.n` is missing, the optfile is treated as zero, i.e., the NLP solver will not look for an options file. This option can be used to overwrite the default that uses the NLP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: `GAMS NLP solver`

reslim *(real)*: Time limit for AlphaECP (in seconds) ↩

Default: `GAMS reslim`

solvelink *(integer)*: Solvelink for NLP and MIP sub-solver ↩

Default: `5`

value	meaning
`1`	Call NLP and MIP solver via script.
`2`	Call NLP and MIP solver via module.
`5`	Call NLP and MIP solver in memory.

solvetrace *(string)*: Filename of solvetrace file ↩

solvetracetime *(real)*: Time interval when a trace record is written ↩

Default: `1`

TOLepsf *(real)*: Pseudo-convex objective function termination tolerance ↩

Maximum allowed absolute difference between the nonlinear and the MIP objective function value (used only in ECPstrategy 3).

Range: [`1e-20`, `1`]

Default: `1e-3`

TOLepsg *(real)*: Constraint tolerance ↩

The nonlinear constraint tolerance defines the maximum value that a nonlinear constraint may violate. For example, a constraint required to be zero may hold a value +/- `TOLepsg` at a solution.

Range: [`1e-20`, `1`]

Default: `1e-3`

TOLepsz *(real)*: Distance tolerance for a new linearization ↩

The maximum perpendicular distance between a valid cutting plane and its generation point (MIP solution).

Range: [`1e-20`, `1`]

Default: `1e-1`

TOLgrad *(real)*: Gradient tolerance ↩

The absolute value of a gradient's partial derivative must be above `TOLgrad` value in order for it to be considered nonzero.

Range: [`1e-20`, `1`]

Default: `1e-6`

TOLinfbnd *(real)*: Infinity bound (MIP variable bound) ↩

All variables must have a positive and a negative finite bound in order to ensure a bounded MIP problem. The finite bound value `TOLinfbnd` will be applied to single or double unbounded variables.

Default: `1e10`

TOLoptcr *(real)*: Relative termination tolerance for MINLP ↩

The relative objective gap termination criterion is satisfied if |UB-LB|/ (10E-12+max(|LB|,|UB|)) < `TOLoptcr`, where UB is the current best upper bound and LB is the current best lower bound. Upper bounds are obtained from solving NLP problems and lower bounds are obtained from lower bounds of MIP problems. If the inequality holds true and ECPtoltype=2, the algorithm terminates.

Range: [`1e-20`, ∞]

Default: `GAMS optCR`

5.3.6 FAQ

- What are good settings to solve a convex problem?

  Use ECPmaster `1`.

- What are good settings if the solution speed is essential?

  Try ECPstrategy `1` and CUTdelcrit `1` to see if using multiple threads for the MIP solver improves the solution speed. However, there is considerable chance that a feasible solution for a non-convex problem with nonlinear equality constraints cannot be found.

- What are good settings when the solution quality is essential?

  Use NLPcalliter `1` and MIPsolstrat `4` or `3`, and also try different values, for CUTnrcuts option, for example `0.1`.

- The objective function is non-linear, should the default ECPstrategy be used?

  If the objective function constraint can be written in the required form of ECPstrategy `3` then this strategy may find a better solution. If the constraints and the objective function are pseudo-convex the global optimal solution will be found.

5.4.1 Introduction

ANTIGONE, Algorithms for coNTinuous / Integer Global Optimization of Nonlinear Equations, is a deterministic general mixed-integer nonlinear global optimization framework [134] [135] [137] [136] [138] .

MINLP is defined:

$$\begin{aligned} \min \quad & f_0(\boldsymbol{x},\, \boldsymbol{y},\, \boldsymbol{z}) \\ \text{s.t.} \quad & b_m^{\text{LO}} \leq f_m(\boldsymbol{x},\, \boldsymbol{y},\, \boldsymbol{z}) \leq b_m^{\text{UP}} \quad \forall\, m \in \{1,\, \ldots,\, M\} \\ & \boldsymbol{x} \in \mathbb{R}^C;\; \boldsymbol{y} \in \{0,\, 1\}^B;\; \boldsymbol{z} \in \mathbb{Z}^I \end{aligned} \tag{MINLP}$$

where C, B, I, and M represent the number of continuous variables, binary variables, integer variables, and constraints, respectively. Parameters vectors $\boldsymbol{b_m^{\text{LO}}}$ and $\boldsymbol{b_m^{\text{UP}}}$ bound the constraints. We assume that it is possible to infer finite bounds $\left[x_i^L,\, x_i^U\right]$ on the variables participating in nonlinear terms f_m and that the image of f_m is finite on $\boldsymbol{x}$. Typical expressions for $f_0(\boldsymbol{x},\, \boldsymbol{y},\, \boldsymbol{z})$ and $f_m(\boldsymbol{x},\, \boldsymbol{y},\, \boldsymbol{z})$ are:

$$\begin{aligned} f_m(\boldsymbol{x},\, \boldsymbol{y},\, \boldsymbol{z}) = c_m + a_m^T\, [\boldsymbol{x};\; \boldsymbol{y};\; \boldsymbol{z}] + [\boldsymbol{x};\; \boldsymbol{y};\; \boldsymbol{z}]^T\, Q_m\, [\boldsymbol{x};\; \boldsymbol{y};\; \boldsymbol{z}] \\ + \sum_{s=1}^{S_m} c_{s_m} \cdot \prod_{c=1}^{C} x_c^{p_{s_m,\,c}} + \sum_{e=1}^{E_m} c_{e_m} \cdot e^x + \sum_{\ell=1}^{L_m} c_{\ell_m} \cdot \log x \end{aligned}$$

where the powers $p_{s_m,\,c}$ are constant reals; c_m, a_m, Q_m, c_{s_m}, c_{e_m}, c_{ℓ_m} are constant coefficients; S_m, E_m, L_m are the number of signomial, exponential, and logarithmic terms, respectively.

As illustrated in Figure 5.1, ANTIGONE responds dynamically to exploit special structure within (MINLP). ANTIGONE falls broadly into the category of branch-and-bound global optimization because it: generates and solves convex relaxations of the nonconvex MINLP that rigorously bound the global solution; finds feasible solutions via local optimization; divides and conquers the feasible set to generate a sequence of convex relaxations converging to the global optimum [68] [67] .

5.4.1.1 Licensing and software requirements

Using GAMS/ANTIGONE requires

1. an ANTIGONE license,
2. a CPLEX license, and
3. a CONOPT or SNOPT license.

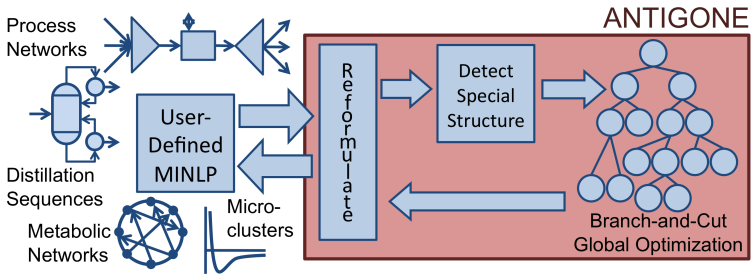

Figure 5.1 Given an MINLP optimization problem, ANTIGONE reformulates the model, detects special structure in the reformulated MINLP, solves the optimization problem, and returns the model with respect to the original problem variables

5.4.1.2 Running GAMS/ANTIGONE

GAMS/ANTIGONE solves: `NLP`; `MINLP`; `RMINLP`; `QCP`; `MIQCP`; `RMIQCP`; `CNS`. If GAMS/ANTIGONE is not the default solver for these models, it can be called using the following command before the `solve` statement:

```
option nlp=antigone, minlp=antigone, rminlp=antigone;
```

5.4.2 GAMS/ANTIGONE Output

The log output shown below is generated using the MINLP model `cecil_13` from the MINLPLib.

```

5.4.3 Summary of ANTIGONE Options

5.4.3.1 General Options

Option	Description	Default
abs_opt_tol	absolute stopping tolerance	GAMS optca
dumpsolutions	name of solutions index gdx file for writing alternate solutions	
max_number_nodes	node limit	GAMS nodlim
max_time	resource limit	GAMS reslim
readparams	read secondary option file in ANTIGONE syntax	
rel_opt_tol	relative stopping tolerance	GAMS optcr
trydual	call CONOPT or SNOPT to produce duals	5

5.4.3.2 Options for Solving the MILP Relaxations

Option	Description	Default
cplex_optfile	read a secondary GAMS/CPLEX options file that will be applied to every LP and MILP subsolve	
cut_generation_epsilon	absolute violation threshold for separating hyperplanes	1e-4
nominal_time_limit	nominal time limit for solving MILP subproblems	100
populate_solution_pool	emphasis on generating starting points	3

5.4.3.3 Options for Finding Feasible Solutions

Option	Description	Default
conopt_optfile	read a secondary GAMS/CONOPT options file that will be applied to every NLP subsolve	
feas_soln_time_limit	time limit (s) for an NLP solve	30
feas_tolerance	absolute feasibility tolerance	1e-6
nlp_solver	use CONOPT or SNOPT to find feasible solutions	conopt

5.4.3.4 Options for Branching

Option	Description	Default
branching_bounds_push_away	branch a minimum fraction away from the variable bounds	0.1
branching_weight	branch on a convex combination of midpoint and solution	0.25
num_reliability_tests	number of strong branching initialization tests	8
reliability_branching	heuristic choice for building reliable pseudocosts	error
reliability_branching_mu	score parameter for building reliability	0.15
use_reliability_branching	use reliability branching?	1

5.4.3.5 Options for Bounding

Option	Description	Default
fbbt_improvement_bound	bounds reduction improvement threshold needed to exit FBBT loop	0.999
max_fbbt_iterations	maximum number of FBBT iterations	50
max_obbt_iterations	maximum number of OBBT iterations	30
max_time_each_obbt	time limit (s) for each OBBT LP	10
obbt_improvement_bound	bounds reduction improvement threshold	0.95
use_obbt	use optimality-based bounds tightening?	1

5.4.3.6 Options for Logging to the Console

Option	Description	Default
logging_freq	how often should we log progress to the console?	5
logging_level	logging information level	-1
print_options	print the option parameter choices used in a single run?	1

5.4.3.7 Options for Addressing Special Structure

Option	Description	Default
adaptive_add_rlt	use the dynamic approach to adaptively determine deep RLT cuts?	1
adaptive_add_rlt_tree_depth	tree depth for heuristic that adaptively determines deep RLT cuts	3
add_bilinear_terms	allow addition of nonconvex bilinear terms to generate deep RLT cuts	1
convexity_cuts	derive convexity-based separating cuts for multivariable terms?	1
dominant_ec_only	add only the low-dimension edge-concave aggregations introducing dominant cuts into relaxations?	1
eigenvector_projections	use eigenvector projections as additional cuts?	1
eigenvector_projection_partitioning	allow partitioning on eigenvector projections?	1
low_dim_edge_concave_agg	use low-dimension edge-concave aggregations?	1
max_partitioned_quantities	number of partitioned quantities	0
max_rlt_cuts	maximum number of violated RLT cuts to add before resolving the relaxation?	100
naive_add_ec	naively integrate all low-dimension edge-concave aggregations into relaxations?	0
naive_add_rlt	naively add all RLT cuts to the relaxations?	0
number_of_partitions	how many partitions per variable?	1

Option	Description	Default
partitioning_scheme	Partitioning scheme can be linear or logarithmic	linear
piecewise_linear_partitions	use piecewise-linear partitioning?	0
rlt	find RLT variable/equation and equation/equation pairs?	1
use_alpha_bb	apply globally-valid alphaBB cuts to tighten a node relaxation	1
use_edge_concave_dynamic	apply locally-valid edge-concave cuts to tighten a node relaxation	1

In addition, GAMS option threads specifies the number of processors to use for linear algebra routines, e.g., when computing eigenvalues of a quadratic coefficients matrix. By default, all available processors are used.

5.4.4 Detailed Descriptions of ANTIGONE Options

abs_opt_tol *(real)*: absolute stopping tolerance ↩

Default: `GAMS optca`

adaptive_add_rlt *(boolean)*: use the dynamic approach to adaptively determine deep RLT cuts? ↩

In the first few levels of the branch-and-bound tree, query the RLT equations after solving an initial relaxation. Add violated equations to the relaxation and resolve. Track the most commonly-violated equations and include those cuts in later nodes.

Default: `1`

adaptive_add_rlt_tree_depth *(integer)*: tree depth for heuristic that adaptively determines deep RLT cuts ↩

To the specified tree depth, solve the relaxation of a node twice if RLT equations are violated. After this depth, automatically add the most commonly violated cuts to the solution of each node

Range: {`1`, ..., `100`}

Default: `3`

add_bilinear_terms *(boolean)*: allow addition of nonconvex bilinear terms to generate deep RLT cuts ↩

Default: `1`

branching_bounds_push_away *(real)*: branch a minimum fraction away from the variable bounds ↩

Range: [`0`, `0.5`]

Default: `0.1`

branching_weight *(real)*: branch on a convex combination of midpoint and solution ↩

The branching weight specifies the emphasis on the midpoint of a variable, so larger branching weights imply branching closer to the center of a variable range.

Range: [0, 1]

Default: 0.25

conopt_optfile *(string)*: read a secondary GAMS/CONOPT options file that will be applied to every NLP subsolve ↩

Gain direct access to the GAMS/CONOPT options. The value of the string should match the name of the GAMS/CONOPT options file.

convexity_cuts *(boolean)*: derive convexity-based separating cuts for multivariable terms? ↩

Default: 1

cplex_optfile *(string)*: read a secondary GAMS/CPLEX options file that will be applied to every LP and MILP subsolve ↩

Gain direct access to the GAMS/CPLEX options. Specifying an options file allows, for example, the possibility of running the CPLEX subsolver with multiple threads. The value of the string should match the name of the GAMS/CPLEX options file.

cut_generation_epsilon *(real)*: absolute violation threshold for separating hyperplanes ↩

Absolute violation threshold to generate separating hyperplanes for convex multivariable terms

Range: [1e-7, 10]

Default: 1e-4

dominant_ec_only *(boolean)*: add only the low-dimension edge-concave aggregations introducing dominant cuts into relaxations? ↩

Default: 1

dumpsolutions *(string)*: name of solutions index gdx file for writing alternate solutions ↩

The GDX file specified by this option will contain a set call `index` that contains the names of GDX files with the individual solutions. For details see example model **dumpsol** in the GAMS Test Library.

eigenvector_projections *(boolean)*: use eigenvector projections as additional cuts? ↩

Default: 1

eigenvector_projection_partitioning *(boolean)*: allow partitioning on eigenvector projections? ↩

Default: 1

fbbt_improvement_bound *(real)*: bounds reduction improvement threshold needed to exit FBBT loop ↩

Range: [0, 1]

Default: 0.999

feas_soln_time_limit *(real)*: time limit (s) for an NLP solve ↩

Range: [1, ∞]

Default: `30`

feas_tolerance *(real)*: absolute feasibility tolerance ↩

Default: `1e-6`

logging_freq *(real)*: how often should we log progress to the console? ↩

Wait at least the specified time in seconds before next output to the console

Range: [1, ∞]

Default: `5`

logging_level *(integer)*: logging information level ↩

Log to the console at the specified level (-1: default; 0: minimal logging; 3: extensive logging)

Default: `-1`

value	meaning
-1	minimal plus warnings
0	minimal
1	entering info
2	updating info
3	includes Cplex updates

low_dim_edge_concave_agg *(boolean)*: use low-dimension edge-concave aggregations? ↩

Default: 1

max_fbbt_iterations *(integer)*: maximum number of FBBT iterations ↩

Range: {1, ..., 100}

Default: 50

max_number_nodes *(integer)*: node limit ↩

Default: GAMS nodlim

max_obbt_iterations *(integer)*: maximum number of OBBT iterations ↩

Range: {1, ..., 100}

Default: 30

max_partitioned_quantities *(integer)*: number of partitioned quantities ↩

Range: {0, ..., 50}

Default: 0

max_rlt_cuts *(integer)*: maximum number of violated RLT cuts to add before resolving the relaxation? ↩

Range: {1, ..., 1000}

Default: 100

max_time *(real)*: resource limit ↩

Default: GAMS reslim

max_time_each_obbt *(real)*: time limit (s) for each OBBT LP ↩

Range: [1, 100]

Default: 10

naive_add_ec *(boolean)*: naively integrate all low-dimension edge-concave aggregations into relaxations? ↩

Default: 0

naive_add_rlt *(boolean)*: naively add all RLT cuts to the relaxations? ↩

Default: 0

nlp_solver *(string)*: use CONOPT or SNOPT to find feasible solutions ↩

Note, that independent of the setting for this option, for the initial NLP solve from the user provided starting point, always CONOPT is used, if available. Further, for the final NLP solve (see trydual), always CONOPT is used, if available, otherwise SNOPT is used.

Default: conopt

value	meaning
conopt	Conopt
snopt	Snopt

nominal_time_limit *(real)*: nominal time limit for solving MILP subproblems ↩

Nominal time limit for solving MILP subproblems. Terminate long-running MILP subproblems over this time limit once they reach an integer feasible point

Range: [0.1, 1000]

Default: 100

number_of_partitions *(integer)*: how many partitions per variable? ↩

Range: {0, ..., 16}

Default: 1

num_reliability_tests *(integer)*: number of strong branching initialization tests ↩

Range: {1, ..., 100}

Default: 8

obbt_improvement_bound *(real)*: bounds reduction improvement threshold ↩

Bounds reduction improvement threshold needed to exit OBBT loop This parameter also determines whether to continue obbt in child; if the parent bound improvement is less than this threshold, then child node won't try OBBT

Range: [0, 1]

Default: 0.95

partitioning_scheme *(string)*: Partitioning scheme can be linear or logarithmic ↩

Linear partitioning uses a number of binary variables linear in the number of partitions while logarithmic partitioning uses a number of binary variables logarithmic in the number of breakpoints. Linear partitioning tends to be numerically favorable for a few breakpoints while logarithmic partitioning is better for a larger number of breakpoints.

Default: linear

value	meaning
linear	Linear partitioning
logarithmic	Logarithmic partitioning

piecewise_linear_partitions *(boolean)*: use piecewise-linear partitioning? ↩

Default: 0

populate_solution_pool *(integer)*: emphasis on generating starting points ↩

Emphasis on generating many starting points for NLP solves using the CPLEX solution pool feature. Larger number implies more starting points.

Range: {0, ..., 4}

Default: 3

print_options *(boolean)*: print the option parameter choices used in a single run? ↩

Default: 1

readparams *(string)*: read secondary option file in ANTIGONE syntax ↩

reliability_branching *(string)*: heuristic choice for building reliable pseudocosts ↩

Default: error

value	meaning
error	Max Error Branching
forward	Forward branching
reverse	Reverse branching

reliability_branching_mu *(real)*: score parameter for building reliability ↩

Range: [0, 1]

Default: 0.15

rel_opt_tol *(real)*: relative stopping tolerance ↩

Default: GAMS optcr

rlt *(boolean)*: find RLT variable/equation and equation/equation pairs? ↩

Default: 1

trydual *(real)*: call CONOPT or SNOPT to produce duals ↩

Spend the specified amount of time in seconds or less in producing a dual solution by calling CONOPT or SNOPT.

Range: [0, ∞]

Default: 5

use_alpha_bb *(boolean)*: apply globally-valid alphaBB cuts to tighten a node relaxation ↩

Default: 1

use_edge_concave_dynamic *(boolean)*: apply locally-valid edge-concave cuts to tighten a node relaxation ↩

Default: 1

use_obbt *(boolean)*: use optimality-based bounds tightening? ↩

Default: 1

use_reliability_branching *(boolean)*: use reliability branching? ↩

Default: 1

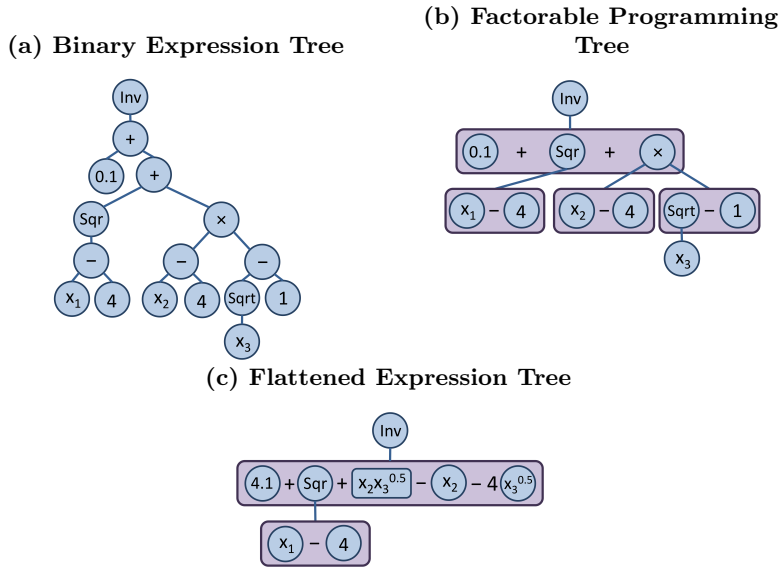

Figure 5.2 (a) A binary tree represents algebraic expressions; (b) A factorable programming tree employs operator-based relaxations; (c) The ANTIGONE transformation to a flattened expression tree allows access to term-based underestimators; Convex form $(x_1 - 4)^2$ is not expanded.

5.4.5 ANTIGONE Algorithmic Features

As illustrated in Figure 5.1, the primary algorithmic features in ANTIGONE are reformulating model input, elucidating special structure, and branch-and-bound global optimization [134] [135] [137] [136] [138] .

5.4.5.1 Reformulating Model Input

As illustrated in Figure 5.2, ANTIGONE transforms a factorable programming tree into a flattened expression tree to capitalize on the development of tight convex underestimators for specific classes of nonlinear terms. ANTIGONE extends the efficacy of hybrid strategies by meaningfully integrating mutually reinforcing operator- and term-based strategies [27] [76] [136] . This approach reformulates towards multivariable terms with specialized underestimators while maintaining a tree-like representation of powers that cannot be distributed and convex operators that can be exploited by dynamic cut generation.

5.4.5.2 Elucidating Special Structure

After reformulating the user-defined MINLP, ANTIGONE detects special mathematical structure that it will exploit in the branch-and-cut phase (Section Branch-and-Bound Global Optimization). The types of special structure that ANTIGONE considers are: reformulation-linearization technique (RLT) equations; convexity/concavity; edge-convexity/edge-concavity; αBB relaxations; term-specific underestimators [134] [135] [137] [136] [138] .

- **RLT** multiplies every pairwise combination of: variables; nonlinear terms; equations [11] [119] [135] [136] [138] [169] [170] [171] [172] [173] . ANTIGONE saves the combinations that do *not* introduce new terms into the model formulation and updates these equations at every node of the branch-and-cut tree. Special RLT equations are added directly to the model formulation; other RLT equations are used as cutting planes and integrated into the feasibility-based bounds tightening routines.

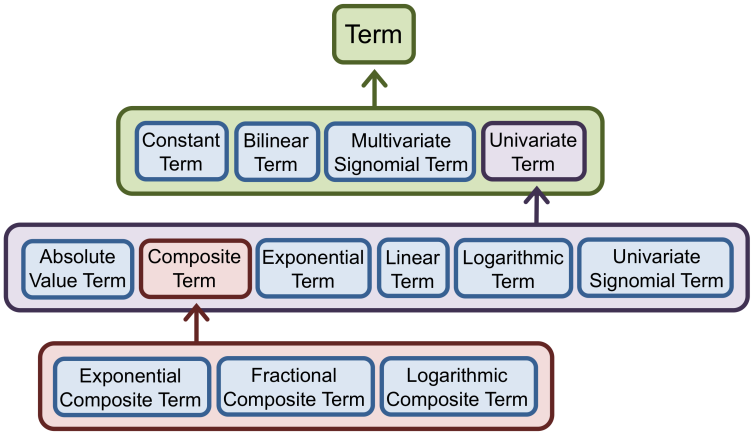

Figure 5.3 Inheritance Structure of Base Class Term

- **Convexity/Concavity** permits the easy generation of a cutting plane at a point $\hat{x}$:

$$f(x) \geq f(\hat{x}) + f'(x) \cdot (x - \hat{x}) \quad \text{(convex)}$$
$$f(x) \leq f(\hat{x}) + f'(x) \cdot (x - \hat{x}) \quad \text{(concave)}$$

  Based on interval arithmetic, terms and multi-term expressions are labeled as always/sometimes/never convex/ concave; this information is used in the branch-and-cut phase.

- **Edge-Convexity/Edge-Concavity** implies a vertex polyhedral envelope; ANTIGONE labels terms and multi-term expressions as always/sometimes/never edge-convex/edge-concave with a simple interval arithmetic test [133] [175] [176] [177] .

- **αBB** underestimators convexify an expression with univariate quadratics [5] [6] [10] [66] [128]; ANTIGONE uses αBB to relax aggregates of bilinear terms.

- **Term-Specific Underestimators** are diagrammed in Figure 5.3; their implementation is based on work available in the open literature [53] [52] [65] [77] [118] [125] [123] [124] [129] [133] [134] [146] [175] [176] [178] .

5.4.5.3 Branch-and-Bound Global Optimization

After the reformulation and special structure detection phases, ANTIGONE initiates a branch-and-cut global optimization algorithm that generates tight convex underestimators, dynamically generates separating hyperplanes, bounds the variables [6] [10] [5] [11] [18] [49] [50] [116] [157] [158] [172] [173] [191]; branches on the search space [3] [18], and finds feasible solutions.

5.5.1 Introduction

The Branch-And-Reduce Optimization Navigator (BARON) is a GAMS solver for the *global solution* of nonlinear (NLP) and mixed-integer nonlinear programs (MINLP).

While traditional NLP and MINLP algorithms are guaranteed to converge only under certain convexity assumptions, BARON implements deterministic global optimization algorithms of the branch-and-bound type that are *guaranteed to provide global optima* under fairly general assumptions. These include the existence of finite lower and upper bounds on nonlinear expressions in the NLP or MINLP to be solved.

BARON implements algorithms of the branch-and-bound type enhanced with a variety of constraint propagation, interval analysis, and duality techniques for reducing ranges of variables in the course of the algorithm. Rigorous relaxations are constructed by enlarging the feasible region and/or underestimating the objective function.

Parts of the BARON software were created at the University of Illinois at Urbana-Champaign. The algorithms implemented in the software, the theory behind them, and some related applications are (partly) described in [157] [51] [158] [161] [93] [120] [78] [187] [168] [188] [163] [79] [159] [178] [179] [180] [183] [184] [165] [160] [162] [7] [181] [164] [182] [36] [12] [149] [13] [106] [107] [208] [209] [108] [210] [14] .

5.5.1.1 Licensing and software requirements

In order to use GAMS/BARON, users will need to have a GAMS/BARON license. BARON comes with several embedded LP/MIP/QP and NLP solvers (CBC; IPOPT, FilterSD, FilterSQP). Additionally, GAMS/BARON users can expedite convergence by accessing CPLEX and XPRESS to solve BARON's LP/MIP/QP subproblems and MINOS, SNOPT, and any GAMS NLP solver, such as CONOPT, to solve BARON's NLP subproblems. These solvers need to be licensed with GAMS separately.

By default, GAMS/BARON will attempt to use CPLEX as the LP solver and select an NLP solver automatically. The user can use the options LPSol and NLPSol to specify the LP/MIP/QP and NLP solver, respectively. If the user does not have a license for the user-specified solver, BARON will automatically select a licensed one and may default to CLP/CBC and IPOPT if no other LP/MIP and NLP solver is available, respectively. BARON can be used without a local NLP solver by setting DoLocal and NumLoc to 0.

5.5.1.2 Running GAMS/BARON

BARON is capable of solving models of the following types: LP, MIP, RMIP, NLP, DNLP, RMINLP, and MINLP. If BARON is not specified as the default solver for these models, it can be invoked by issuing the following command before the solve statement:

```
option <modeltype>=baron;
```

where <`modeltype`> stands for `LP`, `MIP`, `RMIP`, `QCP`, `MIQCP`, `RMIQCP`, `CNS`, `NLP`, `DNLP`, `MINLP`, or `RMINLP`.

5.5.2 Model requirements

In order to achieve convergence to global optimality, additional model constraints may be required. The additional constraints may speed up solver time and increase the probability of success.

5.5.2.1 Variable and expression bounds

All nonlinear expressions in the mathematical program to be solved must be bounded below and/or above. It is important that finite lower and upper bounds be provided by the user on all problem variables. Note that providing finite bounds on variables alone may not suffice to guarantee finite bounds on nonlinear expressions arising in the model.

For example, consider the term `1/x` for $\texttt{x} \in \texttt{[0,1]}$, which has finite variable bounds, but is unbounded. It is important to provide bounds for problem variables that guarantee that the problem functions are finitely-valued. If the user model does not include variable bounds that guarantee that all nonlinear expressions are finitely-valued, BARON will attempt to infer appropriate bounds from problem constraints. If this step fails, global optimality of the solutions provided is not guaranteed. Occasionally, because of the lack of bounds no numerically stable lower bounding problems can be constructed, in which case BARON may terminate.

See section Some BARON features on how to specify variable bounds.

5.5.2.2 Allowable nonlinear functions

In addition to multiplication and division, GAMS/BARON can handle nonlinear functions that involve `exp(x)`, `ln(x)`, $\texttt{x}^{\alpha}$ for real α, $\beta^{\texttt{x}}$ for real β, $\texttt{x}^{\texttt{y}}$, and $|\texttt{x}|$. Currently, there is no support for other functions, including the trigonometric functions `sin(x)`, `cos(x)`, etc.

5.5.3 BARON output

5.5.3.1 BARON log output

The log output below is obtained for the MINLP model `gear.gms` from the GAMS model library using absolute and relative optimality tolerances of 1e-6.

==============================================================================
```

The solver first tests feasibility of the user-supplied starting point. This point is found to be feasible with an objective function value of 36.1767610000. BARON subsequently performs a randomized local search procedure and, eventually, finds a feasible solution with an objective of 4.23791612465. Then, the iteration log provides information every 1,000,000 branch-and-bound iterations and every 30 seconds. Additionally, information is printed at the end of the root node, whenever the value of the incumbent is improved by at least 10^{-5}, and at the end of the search. A star ($*$) in the first position of a line indicates that a better feasible solution was found that improves the value of previous best known solution by at least 10^{-5}. The log fields include the iteration number, number of open branch-and-bound nodes, the CPU time taken thus far, the lower bound, and the upper bound for the problem. The log output fields are summarized below:

Field	Description
`Itn. no.`	The number of the current iteration. A plus (`+`) following the iteration number denotes reporting while solving a probing (as opposed to a relaxation) subproblem of the corresponding node.
`Open Nodes`	Number of open nodes in branch-and-reduce tree.
`Time`	Current computational time in seconds. CPU time is reported for single-threaded jobs and wall clock time is reported for multi-threaded jobs.
`Lower Bound`	Current lower bound on the model.
`Upper Bound`	Current upper bound on the model.

Once the branch-and-reduce tree is searched, the best solution is isolated and a corresponding dual solution is calculated. Finally, the total number of branch-and-reduce iterations (number of search tree nodes) is reported, followed by the node where the best solution was identified (a `-1` indicates preprocessing as explained in the next section on termination messages).

5.5.3.2 Termination messages, model and solver statuses

Upon normal termination, BARON will report the node where the optimal solution was found. We refer to this node as `nodeopt`. Associated with this node is a return code indicating the status of the solution found at `nodeopt`. The return code is given in the log line:

```
Best solution found at node:  (return code)
```

The return codes have the following interpretation:

-3 : no feasible solution found

-2 : the best solution found was the user-supplied

-1 : the best solution was found during preprocessing

`i` : the best solution was found in the `i`-th node of the tree

In addition to reporting `nodeopt`, upon termination, BARON will issue one of the following statements:

`*** Normal completion ***`

This is the most desirable termination status. The problem has been solved within tolerances in this case. If BARON returns a code of `-3`, then no feasible solution exists.

`*** Heuristic termination ***`

While global optimality is not guaranteed in this case, BARON will terminate with this message when (a) a feasible solution has been found and (b) the progress of lower/upper bounds satisfies the heuristic termination criterion set by the user through BARON's DeltaTerm option.

`*** User did not provide appropriate variable bounds ***`

The user will need to read the BARON output (in file `sum.dat` in the scratch directory, use GAMS parameter `keep=1` to prevent the automatic removal of this directory) for pointers to variables and expressions with missing bounds. The model should be modified in order to provide bounds for variables and intermediate expressions that make it possible for BARON to construct reliable relaxations. Even though relaxation bounds are printed on the screen to give the user a feeling for convergence, these bounds may not be valid for the problem at hand. This message is followed by one of the following two messages:

`***Infeasibility is therefore not guaranteed ***`

This indicates that, because of missing bounds, no feasible solution was found, but model infeasibility was not proven.

`*** Globality is therefore not guaranteed ***`

This indicates that, because of missing bounds, a feasible solution was found, but global optimality was not proven.

`*** Max.  allowable nodes in memory reached ***`

The user will need to increase the physical memory of the computer or change algorithmic options, such as branching and node selection rules, to reduce the size of the search tree and memory required for storage.

*** Max. allowable BaR iterations reached ***

The user will need to increase the maximum number of allowable iterations. The BARON option is MaxIter. To specify this in GAMS, one can use the NodLim option. We remark that the BARON option MaxIter overrides NodLim.

*** Max. allowable CPU time exceeded ***

The user will need to increase the maximum of allowable CPU time. The BARON option is MaxTime. To specify this in GAMS, one can use the ResLim option. We remark that the BARON option MaxTime overrides ResLim.

*** Problem is numerically sensitive ***

BARON is designed to automatically handle problems with numerical difficulties. However, for certain problems, the global optimum is numerically sensitive. This occurs, for instance, when the objective function value varies significantly over small neighborhoods of points that are strictly outside the feasible region but nonetheless feasible within numerical tolerances. When BARON returns this message, the "Best possible" reported on the objective is likely correct.

*** Search interrupted by user ***

The run was interrupted by the user (Ctrl-C).

*** Insufficient memory for data structures ***

More memory is needed to set up the problem data structures. The user will need to increase the physical memory available on the computer in order to accommodate problems of this size.

*** A potentially catastrophic access violation just took place ***

In the unlikely event of a memory access violation, BARON will terminate the search and return the best known solution. Please report problems that lead to this condition to Nick Sahinidis (niksah@minlp.com).

5.5.4 Some BARON features

The features described in this section rely on options that are further detailed in the next section. For details of the algorithmic implementations, the user may wish to consult publications cited at the end of this document.

5.5.4.1 No starting point is required

In contrast to many NLP algorithms that require a feasible starting point, a starting point is not required for BARON. A user may optionally provide a starting point for all or even some of the problem variables. BARON will judiciously initialize any variables that are not initialized by the user. Even when the problem functions cannot be evaluated at a user-provided starting point, BARON is still capable of carrying out its global search.

For problems for which GAMS compilation is aborted because the nonlinear functions cannot be evaluated at the starting point, the user can use the following commands before the SOLVE statement:

```
MaxExecError = 100000;
option sys12 = 1;
```

The first command asks GAMS to continue compilation for as many as MaxExecError execution errors. The sys12 option will pass the model to the BARON despite the execution errors. Even though the starting point is bad in this case, BARON is capable of carrying out its global search.

5.5.4.2 Finding a few of the best or all feasible solutions

BARON offers a facility, through its NumSol option, to find the best few, or even all feasible, solutions to a model. The development of this facility was motivated by combinatorial optimization problems but the facility is applicable to continuous problems as well. Even for combinatorial problems, BARON does not rely on integer cuts to find multiple solutions. Instead, it utilizes a single search tree, thus providing a computationally efficient method for finding multiple solutions. Furthermore, because BARON's approach applies to integer as well as continuous programs, it can be used to find *all* feasible solutions to a system of nonlinear equality and inequality constraints.

Once a model is solved by BARON with the NumSol option, the solutions found can be recovered using the GAMS GDX facility. An example is provided below.

```
$eolcom !
$Ontext
  Purpose: demonstrate use of BARON option 'numsol' to obtain the best
  numsol solutions of an optimization problem in a single branch-and-bound
  search tree.

  The model solved here is a linear general integer problem with 18 feasible
  solutions.  BARON is run with a request to find up to 20 solutions.  The
  model solved is the same as the one solved in gamslib/icut.gms.

5.5.4.3 Using BARON as a multi-start heuristic solver

To gain insight into the difficulty of a nonlinear program, especially with regard to existence of multiple local solutions, modelers often make use of multiple local searches from randomly generated starting points. This can be easily done with BARON's NumLoc option, which determines the number of local searches to be done by BARON's preprocessor. BARON can be forced to terminate after preprocessing by setting the number of iterations to 0 through the MaxIter option. In addition to local search, BARON's preprocessor performs extensive reduction of variable ranges. To sample the search space for local minima without range reduction, one would have to set to 0 the range reduction options TDo, MDo, LBTTDo, and OBTTDo. On the other hand, leaving these options to their default values increases the likelihood of finding high quality local optima during preprocessing. If NumLoc is set to -1, local searches in preprocessing will be done from randomly generated starting points until global optimality is proved or MaxTime seconds have elapsed.

5.5.4.4 Systematic treatment of unbounded problems

If BARON declares a problem as unbounded, it will search for and may report a vertex and direction of an unbounded ray. In addition, BARON will report the best solution found. This will be a feasible point that is as far as possible along an unbounded ray while avoiding numerical errors due to floating point arithmetic.

5.5.4.5 Systematic treatment of infeasible problems

If BARON declares a problem as infeasible, it has the capability to identify a subset of the constraints that are infeasible and become feasible once any one of them is eliminated. This, so-called, *irreducibly inconsistent system* (IIS) can be obtained by BARON for all types of problems handled by BARON, including linear and nonlinear, continuous and integer, convex and nonconvex, and problems with complementarity constraints. BARON's CompIIS option can be used to identify an IIS.

As an example, consider the problem of minimizing the nonconvex function x_1x_3 over the following nonconvex constrained set:

$$
\begin{aligned}
e_1: \quad & 85 + 0.006x_2x_5 + 0.0006x_1x_4 - 0.002x_3x_5 <= 92 \\
e_2: \quad & 0.8x_2x_5 + 0.003x_1x_2 + 0.002x_3^2 = 110 \\
e_3: \quad & 9 + 0.005x_3x_5 + 0.001x_1x_3 + 0.002x_3x_4 <= 25 \\
& 78 \leq x_1 \leq 102 \\
& 33 \leq x_2 \leq 45 \\
& 27 \leq x_i \leq 45, \quad i = 3, \ldots, 5
\end{aligned}
$$

When this problem is solved with CompIIS equal to 1, BARON provides the following result in the listing file:

```
Number of equations in the IIS: 1.
Upper: e_2 <= 110

Number of variables in the IIS: 3.
Lower: x_1 >= 78
Lower: x_2 >= 33
Lower: x_5 >= 27
```

The IIS consists of the lower bounds of variables x_1, x_2, and x_5, along with the $\leq$ part of the equality constraint e_2. This suggests that constraint e_2 and the entire model can be made feasible by lowering the lower bound of any of the three variables that are part of the IIS, whereas modifying the bounds of x_3 would not make the model feasible.

If a problem is known to be infeasible and the user desires to identify an IIS, it may be beneficial to set BARON's NumLoc option to zero. Doing so will deactivate BARON's initial upper bounding search, which involves multiple local searches. On the other hand, DoLocal should be nonzero in order to permit local search during the solution of certain subproblems that BARON solves while searching for an IIS.

5.5.4.6 Handling of complementarity constraints

Complementarity relationships of the type `f(x)g(x) = 0` are automatically recognized and exploited algorithmically by BARON. The functions `f` and `g` may be univariate or multivariate, linear or nonlinear, convex or nonconvex, in terms of continuous and/or integer variables, and may be subject to additional constraints in the model. These complementarity relationships can be inferred by BARON even when implied by problem constraints and variable bounds. As a result, BARON can solve general mathematical programs with equilibrium constraints (MPECs). This class of problems includes the classical linear complementarity problem

(LCP): Find $z \geq 0$ and q such that

$$\begin{aligned} Mz + q &\geq 0, \\ z^t(Mz + q) &= 0 \end{aligned}$$

as well as the more general mixed complementarity problem

(MCP): Given a function $f : \mathbb{R}^n \to \mathbb{R}^n$ and bounds $l, u \in \mathbb{R}^n$ with $\overline{\mathbb{R}} = \mathbb{R} \cup \{-\infty, +\infty\}$, find $z \in \mathbb{R}^n$ and $w, v \in \mathbb{R}^n_+$ such that

$$\begin{aligned} f(z) &= w - v, \\ l \leq z &\leq u, \\ (z - l)^t w &= 0, \\ (u - z)^t v &= 0. \end{aligned}$$

Both problems are automatically recognized and exploited by BARON without the user having to mark complementarities in any special way. In GAMS, all these problems can be solved by BARON when declared as NLP or MINLP models.

5.5.4.7 Parallel capabilities

For difficult problems with integer variables, most of BARON's time is spent on solving MIP relaxations. Hence, considerable speedups may be obtained via parallel solution of the MIP subproblems. For this purpose, the option threads may be used to specify the number of cores that BARON's MIP subsolver is allowed to use. By default, this option has the value of 1, meaning that a single core will be utilized.

5.5.5 The BARON options

The BARON options allow the user to control termination tolerances, branching and relaxation strategies, heuristic local search options, and output options as detailed in this section.

Many options can also be set in the GAMS model. The most relevant GAMS options are ResLim, NodLim, OptCA, OptCR, OptFile, and CutOff. The IterLim option is not implemented. specify BARON iterations, the user can set the MaxIter option, which is equivalent to the GAMS option NodLim.

Additionally, a BARON Options file can be provided. See section The Solver Options File for general use of solver option files.

For branching, users can specify separate branching priorities for any discrete and continuous variables using Dot Options. To specify variable branching priorities, one specifies

(variable).`prior` *(value)*

in the BARON options file, where *(value)* can be any non-negative real value. The lower the value, the higher the priority for branching, see also Setting Priorities for Branching. Specifying `maxdouble` for *(value)* translates to passing 0 as branching priority for *(variable)*.

5.5.5.1 Termination options

Option	Description	Default
AbsConFeasTol	Absolute constraint feasibility tolerance This tolerance is used for general constraints and variable bounds. `AbsConFeasTol` must be $\geq$ 1e-12. A point is considered feasible for a constraint/bound if the absolute or relative constraint feasibility tolerance is satisfied. Range: [`1e-12`, ∞]	`1e-5`
AbsIntFeasTol	Absolute integer feasibility tolerance All integer variable values must satisfy this tolerance. `AbsIntFeasTol` must be $\geq$ 1e-12. A point is considered integer feasible for a variable if integrality is satisfied using the absolute or relative integer feasibility tolerance. Range: [`1e-12`, ∞]	`1e-5`
BoxTol	Box elimination tolerance. Boxes will be eliminated if smaller than this tolerance. `BoxTol` must be $\geq$ 1e-12.	`1e-8`
CutOff	Eliminate solutions that are no better than this value Can also be used with the GAMS model attribute option CutOff.	`GAMS CutOff`
DeltaA	Absolute improvement for insufficient progress termination `DeltaA` (δ_a) must be $\geq$ 1e-12. Range: [`1e-12`, ∞]	∞

Option	Description	Default
DeltaR	Relative improvement for insufficient progress termination `DeltaR` (δ_r) must be $\geq$ 1e-12. Range: [`1e-12`, ∞]	`1`
DeltaT	Time interval for insufficient progress termination If DeltaTerm is set to 1, BARON will terminate if insufficient progress is made over `DeltaT` (δ_t) consecutive seconds. If δ_t is set to a non-positive quantity, BARON will automatically set δ_t equal to -δ_t times the CPU time taken till the end of root node processing. `DeltaT` can take any real value. Range: [-∞, ∞]	`-100`
DeltaTerm	Indicates whether insufficient progress termination is on or off Users have the option to request BARON to terminate if insufficient progress is made over DeltaT (δ_t) consecutive seconds. Progress is measured using the absolute and relative improvement thresholds DeltaA (δ_a) and DeltaR (δ_r). Termination will occur if, over a period of δ_t consecutive seconds, the value of the best solution found by BARON is not improved by at least an absolute amount δ_a or an amount equal to δ_r times the value of the incumbent at time `t`-δ_t. This termination condition is enforced after processing the root node and only after a feasible solution has been obtained. Because it relies on CPU time measurements, which may depend on machine load, this option may result in nondeterministic behavior. `0`: do not enforce this termination condition `1`: terminate if progress is insufficient	`0`
EpsA	Absolute termination tolerance. BARON terminates if |`U-L`| $\leq$ `EpsA`, where `U` and `L` are the upper and lower bound, respectively, on the optimal value of the optimization problem at the current iteration. `EpsA` must be $\geq$ 1e-12.	GAMS OptCA
EpsR	Relative termination tolerance. BARON terminates if |`U-L`| $\leq$ `EpsR`|`U`|, where `U` and `L` are the objective function value of the incumbent and the lower bound (if minimizing, otherwise upper bound) on the optimal value, respectively, for the optimization problem at the current iteration.	GAMS OptCR
FirstFeas	Changes the search for first numsol solutions If set to 1, BARON will terminate once it finds NumSol feasible solutions, irrespective of solution quality. `0`: search for the *best* NumSol feasible solutions `1`: find NumSol solutions irrespective of solution quality	`0`
FirstLoc	Terminate the search as soon as a local optimum is found	`0`
ISolTol	Solution Distance Separation distance between solutions. This option is used in conjunction with NumSol. For combinatorial optimization problems, feasible solutions are isolated. For continuous problems, feasible solution points within an l_∞ distance that does not exceed `IsolTol` will be treated as identical by BARON. `IsolTol` must be $\geq$ 1e-12.	`1e-4`
MaxIter	Maximum number of branch-and-reduce iterations allowed Setting `MaxIter` to 0 will force BARON to terminate after root node preprocessing. Setting `MaxIter` to 1 will result in termination after the solution of the root node. `MaxIter` must be $\geq$ -1, where -1 implies unlimited. Range: {`-1`, ..., ∞}	GAMS NodeLim

Option	Description	Default
MaxTime	Maximum time allowed (sec) `MaxTime` must be -1 or > 0, where -1 implies unlimited. For single-threaded jobs, i.e., when threads equals 1, this limit is enforced on CPU time consumed by the job. For multi-threaded jobs, the limit is enforced on wall clock time.	GAMS ResLim
NumSol	Number of feasible solutions to be found Solutions found will be listed in the `results` file. As long as `NumSol` ≠ -1, these solutions will be sorted from best to worse. If `NumSol` is set to -1, BARON will search for all feasible solutions to the given model and print them, in the order in which they are found, in the `results` file. `NumSol` must be ≥ -1. Range: {-1, ..., ∞}	1
RelConFeasTol	Relative constraint feasibility tolerance This tolerance is used for general constraints and variable bounds. `RelConFeasTol` must be ≥ 0. A point is considered feasible for a constraint/bound if the absolute or relative constraint feasibility tolerance is satisfied. Range: [0, 0.1]	0
RelIntFeasTol	Relative integer feasibility tolerance All integer variable values must satisfy this tolerance. `RelIntFeasTol` must be ≥ 0. A point is considered integer feasible for a variable if integrality is satisfied using the absolute or relative integer feasibility tolerance. Range: [0, 0.1]	0

5.5.5.2 Relaxation options

Option	Description	Default
Nouter1	Number of outer approximators of convex univariant functions `NOuter1` must be ≥ 0.	4
NoutIter	Number of rounds of cutting plane generation at node relaxation `NOutIter` must be a ≥ 0.	4
NoutPerVar	Number of outer approximations per variable for convex multivariate functions `NOutPerVar` must be ≥ 0.	4
OutGrid	Number of grid points per variable for convex multivariate approximators of BARON's `CONVEX_EQUATIONS`. `OutGrid` must be a ≥ 0.	20
Threads	Number of cores used for solution of MIP subproblems The value of this option is passed to CBC, CPLEX, and XPRESS. GAMS option threads set to 0 corresponds to `Threads=1`. Range: {1, ..., ∞}	GAMS Threads

5.5.5.3 Range reduction options

Option	Description	Default
LBTTDo	Linear-feasibility-based range reduction option (poor man's LPs) `0`: no range reduction based on feasibility. `1`: range reduction done based on feasibility.	1
MDo	Marginals-based reduction option `0`: no range reduction based on marginals. `1`: range reduction done based on marginals.	1

Option	Description	Default
OBTTDo	Optimality based tightening option 0: no range reduction based on optimality. 1: range reduction done based on optimality.	1
PDo	Number of probing problems allowed -2: automatically decided by BARON. -1: probing on all variables. 0: no range reduction by probing. n: probing on n variables.	-2
TDo	Nonlinear-feasibility-based range reduction option (poor man's NLPs) 0: no bounds tightening is performed. 1: bounds tightening is performed.	1

5.5.5.4 Tree management options

Option	Description	Default
BrPtStra	Branching point selection strategy 0: BARONs dynamic strategy 1: w-branching 2: bisection-branching 3: convex combination of 1 and 2	0
BrVarStra	Branching variable selection strategy 0: BARONs dynamic strategy 1: largest violation 2: longest edge	0
NodeSel	Specifies the node selection rule to be used for exploring the search tree 0: BARONs mixed selection scheme 1: best bound 2: last in first out [LIFO] 3: minimum infeasibility	0

5.5.5.5 Local search options

Option	Description	Default
DoLocal	Local search option for upper bounding 0: no local search is done during upper bounding 1: BARON's dynamic local search decision rule	1
NumLoc	Number of local searches done in preprocessing The first local search begins with the user-specified starting point. Subsequent local searches are done from judiciously chosen starting points. If NumLoc is set to -1, local searches in preprocessing will be done until proof of globality or MaxTime is reached. If NumLoc is set to -2, BARON decides the number of local searches in preprocessing based on problem and NLP solver characteristics. NumLoc must be $\geq$ -2. Range: {-2, ..., ∞}	-2

5.5.5.6 Output Options

Option	Description	Default
LocRes	Option to control output from local search 0: no local search output 1: detailed results from local search will be printed to res.dat file	0
prfreq	Log output frequency in number of nodes	1000000
prlevel	Defines the level of log output printed. 0: all log output is suppressed 1: print log output	1
prtimefreq	Log output frequency in number of seconds	30

5.5.5.7 Subsolver Options

Option	Description	Default
AllowCbc	Indicator for use of CLP/CBC with automatic LP/MIP/QP solver selection	1
AllowCplex	Indicator for use of CPLEX with automatic LP/MIP/QP solver selection	1
AllowExternal	Indicator for use of External NLP solver with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of external GAMS NLP solver as an NLP subsolver. 0: do not use the GAMS external NLP solver for local search 1: consider the GAMS external NLP solver for local search	1
AllowFilterSD	Indicator for use of FILTERSD with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of FILTERSD as an NLP subsolver. 0: do not use FILTERSD for local search 1: consider FILTERSD for local search	1
AllowFilterSQP	Indicator for use of FILTERSQP with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of FILTERSQP as an NLP subsolver. 0: do not use FILTERSQP for local search 1: consider FILTERSQP for local search	1
AllowHsl	Indicator for use of HSL LA04 with automatic LP solver selection	1
AllowIpopt	Indicator for use of IPOPT with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of IPOPT as an NLP subsolver. 0: do not use IPOPT for local search 1: consider IPOPT for local search	0 on macOS/ARM64, 1 otherwise

Option	Description	Default
AllowMinos	Indicator for use of MINOS with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of MINOS as an NLP subsolver. 0: do not use MINOS for local search 1: consider MINOS for local search	1
AllowSnopt	Indicator for use of SNOPT with automatic NLP solver selection In case of automatic NLP solver selection, this option can be used to selectively permit or disallow the use of SNOPT as an NLP subsolver. 0: do not use SNOPT for local search 1: consider SNOPT for local search	1
AllowXpress	Indicator for use of FICO XPRESS with automatic LP/MIP/QP solver selection	0 on macOS/ARM64, 1 otherwise
ExtNLPsolver	External GAMS NLP solver and option file (e.g. conopt.1) Specifies the GAMS NLP solver to be used when NLPSol is set to -1 or 6. All GAMS NLP solvers are available through this option. If a non-existing solver is specified or the solver chosen cannot solve NLPs, NLPSol will be reset to its default. A GAMS solver options file can be specified for the GAMS NLP solver by adding a dot followed by the options file number to the solver name, e.g., setting ExtNLPSolver to CONOPT.42 would instruct GAMS/CONOPT to use options file conopt.o42.	conopt
LPAlg	Specifies the LP algorithm to be used (available only with CPLEX as the LP solver) 0: automatic selection of LP algorithm 1: primal simplex 2: dual simplex 3: barrier	0
LPSol	Specifies the LP/MIP/QP Solver to be used By default, BARON will select the LP solver and may switch between different LP solvers during the search according to problem characteristics and solver performance. The solvers CPLEX, if available, and CBC will be used for this purpose. A single specific LP solver can be specified by setting this option to a value other than the default. If the specified solver is not licensed, BARON will default to automatic solver selection. -1: Automatic LP/MIP/QP solver selection and switching strategy 3: CPLEX 7: XPRESS 8: CLP/CBC 15: HSL LA04	-1

Option	Description	Default
NLPSol	Specifies the NLP solver to be used By default, BARON will select the NLP solver and may switch between different NLP solvers during the search, based on problem characteristics and solver performance. Any combination of licensed NLP solvers may be used in that case. A single specific NLP solver can be specified by setting this option to a value other than the default. If the specified solver is not licensed, BARON will default to automatic solver selection. -1: Automatic NLP solver selection and switching strategy 0: Local search based on function evaluations alone with no calls to local solvers 2: MINOS 4: SNOPT 6: GAMS NLP solver (see ExtNLPsolver) 9: IPOPT 10: FILTERSD 14: FILTERSQP	-1

5.5.5.8 Other Options

Option	Description	Default
CompIIS	Request the computation of an Irreducible Inconsistent Set (IIS) In case of an infeasible problem, this option can be used to search for an IIS. Setting this option 1, works very well for most problems. 0: do not search for an IIS 1: the search for an IIS is based on a fast heuristic 2: an IIS is obtained using a deletion filtering algorithm 3: an IIS is obtained using an addition filtering algorithm 4: an IIS is obtained using an addition-deletion filtering algorithm 5: an IIS is obtained using a depth-first search algorithm	0
IISInt	Indicates whether general integers should be considered as potential members of the IIS When search for an IIS is requested through CompIIS, BARON assumes that the model is unlikely to include an error in terms of binaries, i.e., the binary definitions are assumed correct and the IIS output should be interpreted with respect to binary definitions. General integer bounds may be assumed as correct or can be questioned using the option `IISint`. Integrality is enforced in both cases. 0: do not consider general integers as part of an IIS, assume them to be correct 1: consider general integers (but not binaries) as part of an IIS	0
IISOrder	Order in which constraints are considered in the search for an IIS -1: auto set to aim for a small IIS depending on the value of CompIIS 1: arrange constraints in problem order 2: arrange constraints in ascending order of degree 3: arrange constraints in descending order of degree >3: random order using `IISorder` as seed	-1
WantDual	whether to try to provide dual solution values 0: BARON may or may not return a dual solution. 1: BARON will return a dual solution using an inexpensive technique to solve a KKT system corresponding to the best primal solution identified	1

5.5.5.9 Interface and Conversion

Option	Description	Default
BarName	Name of BARON problem file to be written	225a/mybaron.dat
ClockType	Type of clock to use when reporting solving time back to GAMS wall: report time according to "clock on the wall" (as used by most GAMS solver links) cpu: report time used by CPU (summed up over all cores) baron: report same time as used by BARON ("cpu" if one thread, "wall" if multiple threads)	wall
.EquClass	Equation Classification Specifies nature of named constraint in the users model. This is a Dot Option. Slices like supply.EquClass("new-york") 1 are allowed. 0: Regular constraint. 1: Relaxation-only constraint. These constraints are provided to BARON as RELAXATION_ONLY_EQUATIONS and used to help strengthen the relaxation bound but are not considered as part of the user model and thus not used for feasibility testing of solutions or local search. Adding, for instance, the first-order optimality conditions as relaxation-only constraints often expedites convergence. 2: Convex constraint. These constraints are provided to BARON as CONVEX_EQUATIONS and used to generate cutting planes from the set of outer approximating supporting hyperplanes of the convex constraint set. 3: Convex constraint that is relaxation-only.	0
GDXOut	Prefix for GDX file names for multiple solutions if NumSol > 1.	
InfBnd	infinity value to be used on bounds If set to 0, then no bounds are used.	0

5.6 CBC

CBC (COIN-OR Branch and Cut) is an open-source mixed integer programming solver working with the COIN-OR LP solver CLP and the COIN-OR Cut generator library Cgl. The code has been written primarily by John J. Forrest. Most of the CBC documentation in the section was copied from the help in the CBC standalone version.

The CBC link in GAMS supports continuous, binary, integer, semicontinuous, semiinteger variables, special ordered sets of type 1 and 2, and branching priorities.

5.6.1 Usage

The following statement can be used inside your GAMS program to specify using CBC

```
Option LP = CBC;      { or MIP or RMIP }
```

The above statement should appear before the Solve statement. If CBC was specified as the default solver during GAMS installation, the above statement is not necessary.

For usage and syntax of solver options file, see Section The Solver Option File. Following is an example options file cbc.opt.

```
cuts root
perturbation off
```

It will cause CBC to use cut generators only in the root node and turns off the perturbation of the LP relaxation.

GAMS/CBC currently does not support the GAMS Branch-and-Cut-and-Heuristic (BCH) Facility. If you need to use GAMS/CBC with BCH, please consider to use a GAMS system of version $\leq$ 23.3.

The following GAMS parameters are currently supported by GAMS/CBC: reslim, iterlim, nodlim, optca, optcr, cheat, cutoff, and threads.

5.6.2 List of Options

There are many parameters which can affect the performance the CBCs Branch and Cut Algorithm. First just try with default settings and look carefully at the log file. Did cuts help? Did they take too long? Look at the output to see which cuts were effective and then do some tuning (see the option cuts). If the preprocessing reduced the size of the problem or strengthened many coefficients then it is probably wise to leave it on. Switch off heuristics which did not provide solutions. The other major area to look at is the search. Hopefully good solutions were obtained fairly early in the search so the important point is to select the best variable to branch on. See whether strong branching did a good job – or did it just take a lot of iterations? Adjust the options strongBranching and trustpseudocosts.

In the following, we summarize all available CBC options.

5.6.2.1 General Options

Option	Description	Default
clocktype	type of clock for time measurement	wall
reslim	maximum seconds	GAMS reslim
special	options passed unseen to CBC	
writemps	create MPS file for problem	

5.6.2.2 LP Options

Option	Description	Default
autoScale	Whether to scale objective, rhs and bounds of problem if they look odd (experimental)	0
biasLU	Whether factorization biased towards U	LX
bscale	Whether to scale in barrier (and ordering speed)	off
crash	Whether to create basis for problem	off
crossover	Whether to get a basic solution with the simplex algorithm after the barrier algorithm finished	on
denseThreshold	Threshold for using dense factorization	-1
dualPivot	Dual pivot choice algorithm	automatic

Option	Description	Default
factorization	Which factorization to use	normal
gamma	Whether to regularize barrier	off
idiotCrash	Whether to try idiot crash	-1
iterlim	Maximum number of iterations before stopping	GAMS iterlim
KKT	Whether to use KKT factorization in barrier	0
maxFactor	Maximum number of iterations between refactorizations	200
passPresolve	How many passes in presolve	5
perturbation	Whether to perturb the problem	1
presolve	Whether to presolve problem	on
primalPivot	Primal pivot choice algorithm	automatic
primalWeight	Initially algorithm acts as if it costs this much to be infeasible	1e+10
psi	Two-dimension pricing factor for Positive Edge criterion	-0.5
randomSeedClp	Random seed for Clp	1234567
scaling	Whether to scale problem	automatic
smallFactorization	Threshold for using small factorization	-1
sparseFactor	Whether factorization treated as sparse	1
sprintCrash	Whether to try sprint crash	-1
startalg	LP solver for root node	dual
substitution	How long a column to substitute for in presolve	3
tol_dual	For an optimal solution no dual infeasibility may exceed this value	1e-07
tol_presolve	Tolerance to use in presolve	1e-08
tol_primal	For a feasible solution no primal infeasibility, i.e., constraint violation, may exceed this value	1e-07

5.6.2.3 MIP Options

Option	Description	Default
costStrategy	How to use costs for branching priorities	off
cutoff	Bound on the objective value for all solutions	GAMS cutoff
cutoffConstraint	Whether to use cutoff as constraint	off
dumpsolutions	name of solutions index gdx file for writing alternate solutions	
dumpsolutionsmerged	name of gdx file for writing all alternate solutions	
expensiveStrong	Whether to do even more strong branching	0
extraVariables	Allow creation of extra integer variables	0

Option	Description	Default
fixOnDj	Try heuristic based on fixing variables with reduced costs greater than this	-1
increment	A valid solution must be at least this much better than last integer solution	GAMS cheat
infeasibilityWeight	Each integer infeasibility is expected to cost this much	0
loglevel	amount of output printed by CBC	1
maxsol	Maximum number of solutions to save	100
mipstart	whether it should be tried to use the initial variable levels as initial MIP solution	0
multipleRootPasses	Do multiple root passes to collect cuts and solutions	0
nodeStrategy	What strategy to use to select the next node from the branch and cut tree	fewest
nodlim	node limit	GAMS nodlim
optca	Stop when gap between best possible and best less than this	GAMS optca
optcr	Stop when gap between best possible and best known is less than this fraction of larger of two	GAMS optcr
OrbitalBranching	Whether to try orbital branching	off
parallelmode	whether to run opportunistic or deterministic	deterministic
preprocess	Whether to use integer preprocessing	sos
printfrequency	frequency of status prints	0
randomSeedCbc	Random seed for Cbc	-1
sollim	Maximum number of feasible solutions to get	∞
solvefinal	final solve of MIP with fixed discrete variables	1
solvetrace	name of trace file for solving information	
solvetracenodefreq	frequency in number of nodes for writing to solve trace file	100
solvetracetimefreq	frequency in seconds for writing to solve trace file	5
sosPrioritize	How to deal with SOS priorities	off
strategy	Switches on groups of features	1
strongBranching	Number of variables to look at in strong branching	5
threads	Number of threads to try and use	GAMS threads
tol_integer	For a feasible solution no integer variable may be more than this away from an integer value	1e-07
trustPseudoCosts	Number of branches before we trust pseudocosts	10

5.6.2.4 MIP Options for Cutting Plane Generators

Option	Description	Default
cliqueCuts	Whether to use Clique cuts	ifmove
conflictcuts	Conflict Cuts	0

Option	Description	Default
cut_passes_root	Number of rounds that cut generators are applied in the root node	20 or 100
cut_passes_slow	Maximum number of rounds for slower cut generators	10
cut_passes_tree	Number of rounds that cut generators are applied in the tree	10
cutDepth	Depth in tree at which to do cuts	-1
cutLength	Length of a cut	-1
cuts	Switches all cut generators on or off	on
flowCoverCuts	Whether to use Flow Cover cuts	ifmove
gomoryCuts	Whether to use Gomory cuts	ifmove
gomorycuts2	Whether to use alternative Gomory cuts	off
knapsackCuts	Whether to use Knapsack cuts	ifmove
lagomoryCuts	Whether to use Lagrangean Gomory cuts	off
latwomirCuts	Whether to use Lagrangean TwoMir cuts	off
liftAndProjectCuts	Whether to use Lift and Project cuts	off
mirCuts	Whether to use Mixed Integer Rounding cuts	ifmove
probingCuts	Whether to use Probing cuts	ifmove
reduceAndSplitCuts	Whether to use Reduce-and-Split cuts	off
reduceAndSplitCuts2	Whether to use Reduce-and-Split cuts - style 2	off
residualCapacityCuts	Whether to use Residual Capacity cuts	off
twoMirCuts	Whether to use Two phase Mixed Integer Rounding cuts	root
zeroHalfCuts	Whether to use zero half cuts	ifmove

5.6.2.5 MIP Options for Primal Heuristics

Option	Description	Default
combine2Solutions	Whether to use crossover solution heuristic	off
combineSolutions	Whether to use combine solution heuristic	off
Dins	Whether to try Distance Induced Neighborhood Search	off
diveSolves	Diving solve option	100
DivingCoefficient	Whether to try Coefficient diving heuristic	off
DivingFractional	Whether to try Fractional diving heuristic	off
DivingGuided	Whether to try Guided diving heuristic	off
DivingLineSearch	Whether to try Linesearch diving heuristic	off
DivingPseudoCost	Whether to try Pseudocost diving heuristic	off
DivingRandom	Whether to try Diving heuristics	off

Option	Description	Default
DivingVectorLength	Whether to try Vectorlength diving heuristic	off
dwHeuristic	Whether to try Dantzig Wolfe heuristic	off
feaspump	Whether to try the Feasibility Pump heuristic	on
feaspump_artcost	Costs ≥ this treated as artificials in feasibility pump	0
feaspump_cutoff	Fake cutoff for use in feasibility pump	0
feaspump_fracbab	Fraction in feasibility pump	0.5
feaspump_increment	Fake increment for use in feasibility pump	0
feaspump_passes	How many passes to do in the Feasibility Pump heuristic	20
greedyHeuristic	Whether to use a greedy heuristic	on
heuristics	Switches most primal heuristics on or off	1
hOptions	Heuristic options	0
localTreeSearch	Whether to use local tree search when a solution is found	0
naiveHeuristics	Whether to try some stupid heuristic	off
pivotAndComplement	Whether to try Pivot and Complement heuristic	off
pivotAndFix	Whether to try Pivot and Fix heuristic	off
proximitySearch	Whether to do proximity search heuristic	off
randomizedRounding	Whether to try randomized rounding heuristic	off
Rens	Whether to try Relaxation Enforced Neighborhood Search	off
Rins	Whether to try Relaxed Induced Neighborhood Search	off
roundingHeuristic	Whether to use simple (but effective) Rounding heuristic	on
VndVariableNeighborhoodSearch	Whether to try Variable Neighborhood Search	off
vubheuristic	Type of VUB heuristic	-1

5.6.3 Detailed Options Description

In the following, we give a detailed description of all available CBC options.

autoScale: Whether to scale objective, rhs and bounds of problem if they look odd (experimental) ↩

Range: boolean

Default: 0

biasLU: Whether factorization biased towards U ↩

Range: UU, UX, LX, LL

Default: LX

bscale: Whether to scale in barrier (and ordering speed) ↩

Range: off, on, off1, on1, off2, on2

Default: off

cliqueCuts: Whether to use Clique cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglClique

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

clocktype: type of clock for time measurement ↩

value	meaning
cpu	CPU clock
wall	Wall clock

Default: wall

combine2Solutions: Whether to use crossover solution heuristic ↩

This heuristic does branch and cut on the problem given by fixing variables which have the same value in two or more solutions. It obviously only tries after two or more solutions. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: off

combineSolutions: Whether to use combine solution heuristic ↩

This heuristic does branch and cut on given problem by just using variables which have appeared in one or more solutions. It is obviously only tried after two or more solutions have been found. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
onquick	
bothquick	
beforequick	
~~0~~	~~Same as off. This is a deprecated setting.~~
1	Same as on. This is a deprecated setting.

Default: off

conflictcuts: Conflict Cuts ↩

Equivalent to setting cutoffconstraint=conflict

Range: boolean

Default: 0

costStrategy: How to use costs for branching priorities ↩

Value 'priorities' assigns highest priority to variables with largest absolute cost. This primitive strategy can be surprisingly effective. Value 'columnorder' assigns the priorities 1, 2, 3, ... with respect to the column ordering. Value '01first' ('01last') assignes two sets of priorities such that binary variables get high (low) priority. Value 'length' assigns high priority to variables that occur in many equations.

value	meaning
off	
priorities	
columnOrder	
01first	
binaryfirst	This is a deprecated setting. Please use 01first.
01last	
binarylast	This is a deprecated setting. Please use 01last.
length	
singletons	
nonzero	
generalForce	

Default: off

crash: Whether to create basis for problem ↩

If crash is set to 'on' and there is an all slack basis then Clp will flip or put structural variables into the basis with the aim of getting dual feasible. On average, dual simplex seems to perform better without it and there are alternative types of 'crash' for primal simplex, e.g. 'idiot' or 'sprint'. A variant due to Solow and Halim which is as 'on' but just flips is also available.

Range: off, on, solow_halim, lots, idiot1, idiot2, idiot3, idiot4, idiot5, idiot6, idiot7

Default: off

crossover: Whether to get a basic solution with the simplex algorithm after the barrier algorithm finished ↩

Interior point algorithms do not obtain a basic solution. This option will crossover to a basic solution suitable for ranging or branch and cut.

value	meaning
on	
off	
presolve	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: on

cut_passes_root: Number of rounds that cut generators are applied in the root node ↩

The default is to do 100 passes if the problem has less than 500 columns, 100 passes (but stop if the drop in the objective function value is small) if the problem has less than 5000 columns, and 20 passes otherwise. A negative value -n means that n passes are also applied if the objective does not drop.

Range: {-∞, ..., ∞}

Default: 20 or 100

Synonym: passCuts

cut_passes_slow: Maximum number of rounds for slower cut generators ↩

Some cut generators are fairly slow - this limits the number of times they are tried. The cut generators identified as 'may be slow' at present are Lift and project cuts and both versions of Reduce and Split cuts.

Range: {-1, ..., ∞}

Default: 10

Synonym: slowcutpasses

cut_passes_tree: Number of rounds that cut generators are applied in the tree ↩

The default is to do one pass. A negative value -n means that n passes are also applied if the objective does not drop.

Range: {-∞, ..., ∞}

Default: 10

Synonym: passTreeCuts

cutDepth: Depth in tree at which to do cuts ↩

Cut generators may be off, on, on only at the root node, or on if they look useful. Setting this option to a positive value K let CBC call a cutgenerator on a node whenever the depth in the tree is a multiple of K. The default of -1 lets CBC decide.

Range: {-1, ..., ∞}

Default: -1

cutLength: Length of a cut ↩

At present this only applies to Gomory cuts. -1 (default) leaves as is. Any value >0 says that all cuts ≤ this length can be generated both at root node and in tree. 0 says to use some dynamic lengths. If value ≥10,000,000 then the length in tree is value%10000000 - so 10000100 means unlimited length at root and 100 in tree.

Range: {-1, ..., ∞}

Default: -1

cutoff: Bound on the objective value for all solutions ↩

All solutions must have a better objective value than the value of this option. CBC also updates this value whenever it obtains a solution to the value of the objective function of the solution minus the cutoff increment.

Range: real

Default: GAMS cutoff

cutoffConstraint: Whether to use cutoff as constraint ↩

For some problems, cut generators and general branching work better if the problem would be infeasible if the cost is too high. If this option is enabled, the objective function is added as a constraint which right hand side is set to the current cutoff value (objective value of best known solution)

value	meaning
off	
on	
variable	
forcevariable	
conflict	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

Synonym: constraintfromCutoff

cuts: Switches all cut generators on or off ↩

This can be used to switch on or off all cut generators (apart from Reduce and Split). Then one can turn individual ones off or on. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node.

Range: off, on, root, ifmove, forceOn

Default: on

Synonym: cutsOnOff

denseThreshold: Threshold for using dense factorization ↩

If processed problem $\leq$ this use dense factorization

Range: {-1, ..., 10000}

Default: -1

Dins: Whether to try Distance Induced Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
often	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

diveSolves: Diving solve option ↩

If >0 then do up to this many solves. However, the last digit is ignored and used for extra options: 1-3 enables fixing of satisfied integer variables (but not at bound), where 1 switches this off for that dive if the dive goes infeasible, and 2 switches it off permanently if the dive goes infeasible.

Range: {-1, ..., 200000}

Default: 100

DivingCoefficient: Whether to try Coefficient diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

DivingFractional: Whether to try Fractional diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

DivingGuided: Whether to try Guided diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

DivingLineSearch: Whether to try Linesearch diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

DivingPseudoCost: Whether to try Pseudocost diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

DivingRandom: Whether to try Diving heuristics ↩

This switches on a random diving heuristic at various times. One may prefer to individually turn diving heuristics on or off. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

Synonym: DivingSome

DivingVectorLength: Whether to try Vectorlength diving heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

dualPivot: Dual pivot choice algorithm ↩

The Dantzig method is simple but its use is deprecated. Steepest is the method of choice and there are two variants which keep all weights updated but only scan a subset each iteration. Partial switches this on while automatic decides at each iteration based on information about the factorization. The PE variants add the Positive Edge criterion. This selects incoming variables to try to avoid degenerate moves. See also option psi.

value	meaning
automatic	
dantzig	
partial	
steepest	
PEsteepest	
PEdantzig	
auto	Same as automatic. This is a deprecated setting.

Default: automatic

dumpsolutions: name of solutions index gdx file for writing alternate solutions ↩

The name of a solutions index gdx file for writing alternate solutions found by CBC. The GDX file specified by this option will contain a set called index that contains the names of GDX files with the individual solutions.

Range: string

Default: *empty*

dumpsolutionsmerged: name of gdx file for writing all alternate solutions ↩

Range: string

Default: *empty*

dwHeuristic: Whether to try Dantzig Wolfe heuristic ↩

This heuristic is very very compute intensive. It tries to find a Dantzig Wolfe structure and use that. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: off

expensiveStrong: Whether to do even more strong branching ↩

Strategy for extra strong branching. 0 is normal strong branching. 1, 2, 4, and 6 does strong branching on all fractional variables if at the root node (1), at depth less than modifier (2), objective equals best possible (4), or at depth less than modifier and objective equals best possible (6). 11, 12, 14, and 16 are like 1, 2, 4, and 6, respecitively, but do strong branching on all integer (incl. non-fractional) variables. Values ≥ 100 are used to specify a depth limit (value/100), otherwise 5 is used. If the values ≥ 100, then above rules are applied to value%100.

Range: {0, ..., ∞}

Default: 0

extraVariables: Allow creation of extra integer variables ↩

Switches on a trivial re-formulation that introduces extra integer variables to group together variables with same cost.

Range: {-∞, ..., ∞}

Default: 0

factorization: Which factorization to use ↩

The default is to use the normal CoinFactorization, but other choices are a dense one, OSL's, or one designed for small problems.

Range: normal, dense, simple, osl

Default: normal

feaspump: Whether to try the Feasibility Pump heuristic ↩

This heuristic is due to Fischetti, Glover, and Lodi and uses a sequence of LPs to try and get an integer feasible solution. Some fine tuning is available by options passFeasibilityPump and pumpTune. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: on

Synonym: feasibilityPump

feaspump_artcost: Costs ≥ this treated as artificials in feasibility pump ↩

A value of 0.0 means off. Otherwise, variables with costs ≥ this are treated as artificial variables and fixed to lower bound in feasibility pump.

Range: [0, ∞]

Default: 0

Synonym: artificialCost

feaspump_cutoff: Fake cutoff for use in feasibility pump ↩

A value of 0.0 means off. Otherwise, add a constraint forcing objective below this value in feasibility pump

Range: real

Default: 0

Synonym: pumpCutoff

feaspump_fracbab: Fraction in feasibility pump ↩

After a pass in the feasibility pump, variables which have not moved about are fixed and if the preprocessed model is smaller than this fraction of the original problem, a few nodes of branch and bound are done on the reduced problem.

Range: [1e-05, 1.1]

Default: 0.5

Synonym: fractionforBAB

feaspump_increment: Fake increment for use in feasibility pump ↩

A value of 0.0 means off. Otherwise use as absolute increment to cutoff when solution found in feasibility pump

Range: real

Default: 0

Synonym: pumpIncrement

feaspump_passes: How many passes to do in the Feasibility Pump heuristic ↩

Range: {0, ..., 10000}

Default: 20

Synonym: passFeasibilityPump

fixOnDj: Try heuristic based on fixing variables with reduced costs greater than this ↩

If this is set integer variables with reduced costs greater than this will be fixed before branch and bound - use with extreme caution!

Range: real

Default: -1

flowCoverCuts: Whether to use Flow Cover cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglFlowCover

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

gamma: Whether to regularize barrier ↩

Range: off, on, gamma, delta, onstrong, gammastrong, deltastrong

Default: off

gomoryCuts: Whether to use Gomory cuts ↩

The original cuts - beware of imitations! Having gone out of favor, they are now more fashionable as LP solvers are more robust and they interact well with other cuts. They will almost always give cuts (although in this executable they are limited as to number of variables in cut). However the cuts may be dense so it is worth experimenting (Long allows any length). Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglGomory

Range: off, on, root, ifmove, forceOn, onglobal, forceandglobal, forceLongOn, long

Default: ifmove

gomorycuts2: Whether to use alternative Gomory cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. This version is by Giacomo Nannicini and may be more robust than gomoryCuts.

Range: off, on, root, ifmove, forceOn, endonly, long, longroot, longifmove, forceLongOn, longendonly

Default: off

Synonym: GMICuts

greedyHeuristic: Whether to use a greedy heuristic ↩

This heuristic tries to obtain a feasible solution by just fixing a percentage of variables and then try a small branch and cut run. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: on

heuristics: Switches most primal heuristics on or off ↩

This option can be used to switch on or off all heuristics that search for feasible solutions, except for the local tree search, as it dramatically alters the search. Then individual heuristics can be turned off or on.

Range: boolean

Default: 1

Synonym: heuristicsOnOff

hOptions: Heuristic options ↩

Value 1 stops heuristics immediately if the allowable gap has been reached. Other values are for the feasibility pump - 2 says do exact number of passes given, 4 only applies if an initial cutoff has been given and says relax after 50 passes, while 8 will adapt the cutoff rhs after the first solution if it looks as if the code is stalling.

Range: {-∞, ..., ∞}

Default: 0

idiotCrash: Whether to try idiot crash ↩

This is a type of 'crash' which works well on some homogeneous problems. It works best on problems with unit elements and rhs but will do something to any model. It should only be used before the primal simplex algorithm. It can be set to -1 when the code decides for itself whether to use it, 0 to switch off, or n > 0 to do n passes.

Range: {-1, ..., ∞}

Default: -1

increment: A valid solution must be at least this much better than last integer solution ↩

Whenever a solution is found the bound on the objective value for new solutions is set to the objective function of the found solution (in a minimization sense) plus this. If it is not set then CBC will try and work one out, e.g. if all objective coefficients are multiples of 0.01 and only integer variables have entries in the objective function, then the increment can be set to 0.01. Be careful if setting this to a negative value!

Range: real

Default: GAMS cheat

infeasibilityWeight: Each integer infeasibility is expected to cost this much ↩

A primitive way of deciding which node to explore next. Satisfying each integer infeasibility is expected to cost this much.

Range: [0, ∞]

Default: 0

iterlim: Maximum number of iterations before stopping ↩

For an LP, this is the maximum number of iterations to solve the LP. For a MIP, this option is ignored.

Range: {0, ..., ∞}

Default: GAMS iterlim

Synonym: maxIterations

KKT: Whether to use KKT factorization in barrier ↩

Range: boolean

Default: 0

knapsackCuts: Whether to use Knapsack cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglKnapsackCover

Range: off, on, root, ifmove, forceOn, onglobal, forceandglobal

Default: ifmove

lagomoryCuts: Whether to use Lagrangean Gomory cuts ↩

This is a gross simplification of 'A Relax-and-Cut Framework for Gomory's Mixed-Integer Cuts' by Matteo Fischetti & Domenico Salvagnin. This simplification just uses original constraints while modifying objective using other cuts. So you don't use messy constraints generated by Gomory etc. A variant is to allow non messy cuts e.g. clique cuts. So 'only' does this while 'clean' also allows integral valued cuts. 'End' is recommended and waits until other cuts have finished before it does a few passes. The length options for gomory cuts are used.

Range: off, endonlyroot, endcleanroot, root, endonly, endclean, endboth, onlyaswell, cleanaswell, bothaswell, onlyinstead, cleaninstead, bothinstead, onlyaswellroot, cleanaswellroot, bothaswellroot

Default: off

latwomirCuts: Whether to use Lagrangean TwoMir cuts ↩

This is a Lagrangean relaxation for TwoMir cuts. See lagomoryCuts for description of options.

Range: off, endonlyroot, endcleanroot, endbothroot, endonly, endclean, endboth, onlyaswell, cleanaswell, bothaswell, onlyinstead, cleaninstead, bothinstead

Default: off

liftAndProjectCuts: Whether to use Lift and Project cuts ↩

These cuts may be expensive to compute. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglLandP

Range: off, on, root, ifmove, forceOn

Default: off

localTreeSearch: Whether to use local tree search when a solution is found ↩

The heuristic is from Fischetti and Lodi and is not really a heuristic although it can be used as one (with limited functionality). It is not switched on when heuristics are switched on.

Range: boolean

Default: 0

loglevel: amount of output printed by CBC ↩

Range: {0, ..., ∞}

Default: 1

maxFactor: Maximum number of iterations between refactorizations ↩

If this is left at its default value of 200 then CLP will guess a value to use. CLP may decide to re-factorize earlier for accuracy.

Range: {1, ..., ∞}

Default: 200

maxsol: Maximum number of solutions to save ↩

Maximal number of solutions to store during search and to dump into gdx files if dumpsolutions options is set.

Range: {0, ..., ∞}

Default: 100

Synonym: maxSavedSolutions

mipstart: whether it should be tried to use the initial variable levels as initial MIP solution ↩

This option controls the use of advanced starting values for mixed integer programs. A setting of 1 indicates that the variable level values should be checked to see if they provide an integer feasible solution before starting optimization.

Range: boolean

Default: 0

mirCuts: Whether to use Mixed Integer Rounding cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglMixedIntegerRounding2

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

Synonym: mixedIntegerRoundingCuts

multipleRootPasses: Do multiple root passes to collect cuts and solutions ↩

Solve (in parallel, if enabled) the root phase this number of times, each with its own different seed, and collect all solutions and cuts generated. The actual format is aabbcc where aa is the number of extra passes; if bb is non zero, then it is number of threads to use (otherwise uses threads setting); and cc is the number of times to do root phase. The solvers do not interact with each other. However if extra passes are specified then cuts are collected and used in later passes - so there is interaction there. Some parts of this implementation have their origin in idea of Andrea Lodi, Matteo Fischetti, Michele Monaci, Domenico Salvagnin, and Andrea Tramontani.

Range: {0, ..., ∞}

Default: 0

naiveHeuristics: Whether to try some stupid heuristic ↩

This is naive heuristics which, e.g., fix all integers with costs to zero!. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

nodeStrategy: What strategy to use to select the next node from the branch and cut tree ↩

Normally before a feasible solution is found, CBC will choose a node with fewest infeasibilities. Alternatively, one may choose tree-depth as the criterion. This requires the minimal amount of memory, but may take a long time to find the best solution. Additionally, one may specify whether up or down branches must be selected first (the up-down choice will carry on after a first solution has been bound). The default choice 'hybrid' does breadth first on small depth nodes and then switches to 'fewest'.

Range: hybrid, fewest, depth, upfewest, downfewest, updepth, downdepth

Default: fewest

nodlim: node limit ↩

Maximum number of nodes that are enumerated in the Branch and Bound tree search.

Range: {-1, ..., ∞}

Default: GAMS nodlim

Synonyms: maxNodes nodelim

optca: Stop when gap between best possible and best less than this ↩

If the gap between best known solution and the best possible solution is less than this value, then the search will be terminated. Also see ratioGap.

Range: [0, ∞]

Default: GAMS optca

Synonym: allowableGap

optcr: Stop when gap between best possible and best known is less than this fraction of larger of two ↩

If the gap between the best known solution and the best possible solution is less than this fraction of the objective value at the root node then the search will terminate. See 'allowableGap' for a way of using absolute value rather than fraction.

Range: [0, ∞]

Default: GAMS optcr

Synonym: ratioGap

OrbitalBranching: Whether to try orbital branching ↩

This switches on Orbital branching. Value 'on' just adds orbital, 'strong' tries extra fixing in strong branching. 'cuts' just adds global cuts to break symmetry. 'fastish' only computes symmetry at root. 'lightweight' is as on where computation seems cheap

Range: off, on, strong, force, simple, fastish, lightweight, moreprinting, cuts, cutslight

Default: off

parallelmode: whether to run opportunistic or deterministic ↩

Determines whether a parallel MIP search (threads > 1) should be done in a deterministic (i.e., reproducible) way or in a possibly faster but not necessarily reproducible way

Range: opportunistic, deterministic

Default: deterministic

passPresolve: How many passes in presolve ↩

Normally Presolve does 10 passes but you may want to do less to make it more lightweight or do more if improvements are still being made. As Presolve will return if nothing is being taken out, you should not normally need to use this fine tuning.

Range: {-200, ..., 100}

Default: 5

perturbation: Whether to perturb the problem ↩

Perturbation helps to stop cycling, but CLP uses other measures for this. However, large problems and especially ones with unit elements and unit right hand sides or costs benefit from perturbation. Normally CLP tries to be intelligent, but one can switch this off.

Range: boolean

Default: 1

pivotAndComplement: Whether to try Pivot and Complement heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before

Default: off

pivotAndFix: Whether to try Pivot and Fix heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

preprocess: Whether to use integer preprocessing ↩

This tries to reduce size of model in a similar way to presolve and it also tries to strengthen the model - this can be very useful and is worth trying. Value 'save' saves the presolved problem to a file presolved.mps. Value 'equal' will turn inequality-cliques into equalities. Value 'sos' lets CBC search for rows with upper bound 1 and where all nonzero coefficients are 1 and creates special ordered sets if the sets are not overlapping and all integer variables (except for at most one) are in the sets. Value 'trysos' is same as 'sos', but allows any number of integer variables outside of sets. Value 'equalall' lets CBC turn all valid inequalities into equalities by adding integer slack variables.

Range: off, on, save, equal, sos, trysos, equalall, strategy, aggregate, forcesos, stopaftersaving

Default: sos

presolve: Whether to presolve problem ↩

Presolve analyzes the model to find such things as redundant equations, equations which fix some variables, equations which can be transformed into bounds, etc. For the initial solve of any problem this is worth doing unless one knows that it will have no effect. Option 'on' will normally do 5 passes, while using 'more' will do 10.

value	meaning
on	
off	
more	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: on

primalPivot: Primal pivot choice algorithm ↩

The Dantzig method is simple but its use is deprecated. Exact devex is the method of choice and there are two variants which keep all weights updated but only scan a subset each iteration. Partial switches this on while 'change' initially does 'dantzig' until the factorization becomes denser. This is still a work in progress. The PE variants add the Positive Edge criterion. This selects incoming variables to try to avoid degenerate moves. See also Towhidi, M., Desrosiers, J., Soumis, F., The positive edge criterion within COIN-OR's CLP; Omer, J., Towhidi, M., Soumis, F., The positive edge pricing rule for the dual simplex.

value	meaning
automatic	
exact	
dantzig	
partial	
steepest	
change	
sprint	
PEsteepest	
PEdantzig	
auto	Same as automatic. This is a deprecated setting.

Default: automatic

primalWeight: Initially algorithm acts as if it costs this much to be infeasible ↩

The primal algorithm in Clp is a single phase algorithm as opposed to a two phase algorithm where you first get feasible then optimal. So Clp is minimizing this weight times the sum of primal infeasibilities plus the true objective function (in minimization sense). Too high a value may mean more iterations, while too low a value means the algorithm may iterate into the wrong directory for long and then has to increase the weight in order to get feasible.

Range: [1e-20, ∞]

Default: 1e+10

printfrequency: frequency of status prints ↩

Controls the number of nodes that are evaluated between status prints.

Range: {0, ..., ∞}

Default: 0

probingCuts: Whether to use Probing cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Value 'forceOnBut' turns on probing and forces CBC to do probing at every node, but does only probing, not strengthening etc. Value 'strong' forces CBC to strongly do probing at every node, that is, also when CBC would usually turn it off because it hasn't found something. Value 'forceonbutstrong' is like 'forceonstrong', but does only probing (column fixing) and turns off row strengthening, so the matrix will not change inside the branch and bound. Reference: https://github.com/coin-or/Cgl/wiki/CglProbing

Range: off, on, root, ifmove, forceOn, onglobal, forceonglobal, forceOnBut, forceOnStrong, forceOnButStrong, strongRoot

Default: ifmove

proximitySearch: Whether to do proximity search heuristic ↩

This heuristic looks for a solution close to the incumbent solution (Fischetti and Monaci, 2012). The idea is to define a sub-MIP without additional constraints but with a modified objective function intended to attract the search in the proximity of the incumbent. The approach works well for 0-1 MIPs whose solution landscape is not too irregular (meaning the there is reasonable probability of finding an improved solution by flipping a small number of binary variables), in particular when it is applied to the first heuristic solutions found at the root node. Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
10	
100	
300	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

psi: Two-dimension pricing factor for Positive Edge criterion ↩

The Positive Edge criterion has been added to select incoming variables to try and avoid degenerate moves. Variables not in the promising set have their infeasibility weight multiplied by psi, so 0.01 would mean that if there were any promising variables, then they would always be chosen, while 1.0 effectively switches the algorithm off. There are two ways of switching this feature on. One way is to set psi to a positive value and then the Positive Edge criterion will be used for both primal and dual simplex. The other way is to select PEsteepest in dualpivot choice (for example), then the absolute value of psi is used. Code donated by Jeremy Omer. See Towhidi, M., Desrosiers, J., Soumis, F., The positive edge criterion within COIN-OR's CLP; Omer, J., Towhidi, M., Soumis, F., The positive edge pricing rule for the dual simplex.

Range: [-1.1, 1.1]

Default: -0.5

randomizedRounding: Whether to try randomized rounding heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

randomSeedCbc: Random seed for Cbc ↩

Allows initialization of the random seed for pseudo-random numbers used in heuristics such as the Feasibility Pump to decide whether to round up or down. The special value of 0 lets Cbc use the time of the day for the initial seed.

Range: {-1, ..., ∞}

Default: -1

Synonym: randomCbcSeed

randomSeedClp: Random seed for Clp ↩

Initialization of the random seed for pseudo-random numbers used to break ties in degenerate problems. This may yield a different continuous optimum and, in the context of Cbc, different cuts and heuristic solutions. The special value of 0 lets CLP use the time of the day for the initial seed.

Range: {0, ..., ∞}

Default: 1234567

Synonym: randomSeed

reduceAndSplitCuts: Whether to use Reduce-and-Split cuts ↩

These cuts may be expensive to generate. Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglRedSplit

Range: off, on, root, ifmove, forceOn

Default: off

reduceAndSplitCuts2: Whether to use Reduce-and-Split cuts - style 2 ↩

This switches on reduce and split cuts (either at root or in entire tree). This version is by Giacomo Nannicini based on Francois Margot's version. Standard setting only uses rows in tableau ≤ 256, long uses all. These cuts may be expensive to generate. See option cuts for more information on the possible values.

Range: off, on, root, longOn, longRoot

Default: off

Synonym: reduce2AndSplitCuts

Rens: Whether to try Relaxation Enforced Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve. Value 'on' just does 50 nodes. 200, 1000, and 10000 does that many nodes.

value	meaning
off	
on	
both	
before	
200	
1000	
10000	
dj	
djbefore	
usesolution	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

residualCapacityCuts: Whether to use Residual Capacity cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglResidualCapacity

Range: off, on, root, ifmove, forceOn

Default: off

reslim: maximum seconds ↩

Range: [-1, ∞]

Default: GAMS reslim

Synonym: seconds

Rins: Whether to try Relaxed Induced Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
often	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: off

roundingHeuristic: Whether to use simple (but effective) Rounding heuristic ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

value	meaning
off	
on	
both	
before	
0	Same as off. This is a deprecated setting.
1	Same as on. This is a deprecated setting.

Default: on

scaling: Whether to scale problem ↩

Scaling can help in solving problems which might otherwise fail because of lack of accuracy. It can also reduce the number of iterations. It is not applied if the range of elements is small. When the solution is evaluated in the unscaled problem, it is possible that small primal and/or dual infeasibilities occur. Option 'equilibrium' uses the largest element for scaling. Option 'geometric' uses the squareroot of the product of largest and smallest element. Option 'auto' let CLP choose a method that gives the best ratio of the largest element to the smallest one.

value	meaning
off	
equilibrium	
geometric	
automatic	
dynamic	
rowsonly	
auto	Same as automatic. This is a deprecated setting.

Default: automatic

smallFactorization: Threshold for using small factorization ↩

If processed problem $\leq$ this use small factorization

Range: {-1, ..., 10000}

Default: -1

sollim: Maximum number of feasible solutions to get ↩

Range: {1, ..., ∞}

Default: ∞

Synonym: maxSolutions

solvefinal: final solve of MIP with fixed discrete variables ↩

Whether the MIP with discrete variables fixed to solution values should be solved after CBC finished.

Range: boolean

Default: 1

solvetrace: name of trace file for solving information ↩

Name of file for writing solving progress information during solve.

Range: string

Default: *empty*

solvetracenodefreq: frequency in number of nodes for writing to solve trace file ↩

Range: {0, ..., ∞}

Default: 100

solvetracetimefreq: frequency in seconds for writing to solve trace file ↩

Range: [0, ∞]

Default: 5

sosPrioritize: How to deal with SOS priorities ↩

This sets priorities for SOS. Values 'high' and 'low' just set a priority relative to the for integer variables. Value 'orderhigh' gives first highest priority to the first SOS and integer variables a low priority. Value 'orderlow' gives integer variables a high priority then SOS in order.

Range: off, high, low, orderhigh, orderlow

Default: off

sparseFactor: Whether factorization treated as sparse ↩

Range: boolean

Default: 1

special: options passed unseen to CBC ↩

This parameter let you specify CBC options which are not supported by the GAMS/CBC interface. The string value given to this parameter is split up into parts at each space and added to the array of parameters given to CBC (in front of the -solve command). Hence, you can use it like the command line parameters for the CBC standalone version.

Range: string

Default: *empty*

sprintCrash: Whether to try sprint crash ↩

For long and thin problems this method may solve a series of small problems created by taking a subset of the columns. The idea as 'Sprint' was introduced by J. Forrest after an LP code of that name of the 60's which tried the same tactic (not totally successfully). CPLEX calls it 'sifting'. -1 lets CLP automatically choose the number of passes, 0 is off, n is number of passes

Range: {-1, ..., ∞}

Default: -1

Synonym: sifting

startalg: LP solver for root node ↩

Determines the algorithm to use for an LP or the initial LP relaxation if the problem is a MIP.

value	meaning
primal	Primal Simplex algorithm
dual	Dual Simplex algorithm
barrier	Primal-dual predictor-corrector algorithm

Default: dual

strategy: Switches on groups of features ↩

This turns on newer features. Use 0 for easy problems, 1 is default, 2 is aggressive. 1 uses Gomory cuts with a tolerance of 0.01 at the root node, does a possible restart after 100 nodes if many variables could be fixed, activates a diving and RINS heuristic, and makes the feasibility pump more aggressive.

Range: {0, ..., 2}

Default: 1

strongBranching: Number of variables to look at in strong branching ↩

In order to decide which variable to branch on, the code will choose up to this number of unsatisfied variables to try minimal up and down branches on. Then the most effective one is chosen. If a variable is branched on many times then the previous average up and down costs may be used - see also option trustPseudoCosts.

Range: {0, ..., ∞}

Default: 5

substitution: How long a column to substitute for in presolve ↩

Normally Presolve gets rid of 'free' variables when there are no more than 3 coefficients in a row. If you increase this, the number of rows may decrease but the number of coefficients may increase.

Range: {0, ..., 10000}

Default: 3

threads: Number of threads to try and use ↩

If set to 0, then multithreading of Cbc itself is disabled, but all available processors are made available for linear algebra subroutines.

Range: {0, ..., 99}

Default: GAMS threads

tol_dual: For an optimal solution no dual infeasibility may exceed this value ↩

Normally the default tolerance is fine, but one may want to increase it a bit if the dual simplex algorithm seems to be having a hard time. One method which can be faster is to use a large tolerance e.g. 1.0e-4 and the dual simplex algorithm and then to clean up the problem using the primal simplex algorithm with the correct tolerance (remembering to switch off presolve for this final short clean up phase).

Range: [1e-20, ∞]

Default: 1e-07

Synonym: dualTolerance

tol_integer: For a feasible solution no integer variable may be more than this away from an integer value ↩

Beware of setting this smaller than the primal feasibility tolerance.

Range: [1e-20, 0.5]

Default: 1e-07

Synonym: integerTolerance

tol_presolve: Tolerance to use in presolve ↩

One may want to increase this tolerance if presolve says the problem is infeasible and one has awkward numbers and is sure that the problem is really feasible.

Range: [1e-20, ∞]

Default: 1e-08

Synonym: preTolerance

tol_primal: For a feasible solution no primal infeasibility, i.e., constraint violation, may exceed this value ↩

Normally the default tolerance is fine, but one may want to increase it a bit if the primal simplex algorithm seems to be having a hard time.

Range: [1e-20, ∞]

Default: 1e-07

Synonym: primalTolerance

trustPseudoCosts: Number of branches before we trust pseudocosts ↩

Using strong branching computes pseudo-costs. This parameter determines after how many branches for a variable we just trust the pseudo costs and do not do any more strong branching.

Range: {-3, ..., ∞}

Default: 10

twoMirCuts: Whether to use Two phase Mixed Integer Rounding cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. Reference: https://github.com/coin-or/Cgl/wiki/CglTwomir

Range: off, on, root, ifmove, forceOn, onglobal, forceandglobal, forceLongOn

Default: root

VndVariableNeighborhoodSearch: Whether to try Variable Neighborhood Search ↩

Value 'on' means to use the heuristic in each node of the tree, i.e. after preprocessing. Value 'before' means use the heuristic only if option doHeuristics is used. Value 'both' means to use the heuristic if option doHeuristics is used and during solve.

Range: off, on, both, before, intree

Default: off

vubheuristic: Type of VUB heuristic ↩

This heuristic tries and fix some integer variables.

Range: {-2, ..., 20}

Default: -1

writemps: create MPS file for problem ↩

Write the problem formulation in MPS format. The parameter value is the name of the MPS file.

Range: string

Default: *empty*

zeroHalfCuts: Whether to use zero half cuts ↩

Value 'on' enables the cut generator and CBC will try it in the branch and cut tree (see cutDepth on how to fine tune the behavior). Value 'root' lets CBC run the cut generator generate only at the root node. Value 'ifmove' lets CBC use the cut generator in the tree if it looks as if it is doing some good and moves the objective value. Value 'forceon' turns on the cut generator and forces CBC to use it at every node. This implementation was written by Alberto Caprara.

Range: off, on, root, ifmove, forceOn, onglobal

Default: ifmove

5.7 CONOPT 3

Author

Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.7.1 Introduction

This documentation is for CONOPT3. We will refer to CONOPT3 as CONOPT in the following. Note that there is also the improved version CONOPT4.

Nonlinear models created with GAMS must be solved with a nonlinear programming (NLP) algorithm. Currently, there is a large number of different solvers available and the number is growing.

The most important distinction between the solvers is whether they attempt to find a local or a global solution. Solvers that attempt to find a global solution (so called Global Solvers) can usually not solve very large models. As a contrast most Local Solvers can work with much larger models, and models with over 10,000 variables and constraints are not unusual. If the model has the right mathematical properties, e.g. is convex, then Local Solvers will find a global optimum. Unfortunately, the mathematical machinery for testing whether a general NLP model is convex or not has not yet been developed (and is expected to be in the class or hard problems).

It is almost impossible to predict how difficult it is to solve a particular model with a particular algorithm, especially for NLP models, so GAMS cannot select the best algorithm for you automatically. When GAMS is installed you must select one of the nonlinear programming algorithms as the default solver for NLP models. If you want to switch between algorithms for a particular model you may add the statement `Option NLP = <solvername>`, in your GAMS source file before the `Solve` statement, you may add `NLP = <solvername>` on the GAMS command line or by rerunning the `gamsinst` program.

The only reliable way to find which solver to use for a particular class of models is so far to experiment. However, there are a few rules of thumb:

CONOPT is well suited for models with very nonlinear constraints. If you experience that a solver has problems maintaining feasibility during the optimization you should try CONOPT. On the other hand, if you have a model with few nonlinearities outside the objective function then other solvers could be the best solver.

CONOPT has a fast method for finding a first feasible solution that is particularly well suited for models with few degrees of freedom. If you have a model with roughly the same number of constraints as variable you should try CONOPT. CONOPT can also be used to solve square systems of equations without an objective function corresponding to the GAMS model class CNS - Constrained Nonlinear System.

CONOPT can use second derivatives. If the number of variables is much larger than the number of constraints CONOPT will use second derivatives and overall progress can be considerably faster than for MINOS or SNOPT. IPOPT and KNITRO will also use second derivatives, but the method is very different and it is not possible to predict which solver will be better.

CONOPT has a preprocessing step in which recursive equations and variables are solved and removed from the model. If you have a model where many equations can be solved one by one then CONOPT will take advantage of this property. Similarly, intermediate variables only used to define objective terms are eliminated from the model and the constraints are moved into the objective function.

CONOPT has many built-in tests and messages, and many models that can and should be improved by the modeler are rejected with a constructive message. CONOPT is therefore also a helpful debugging tool during model development. The best solver for the final, debugged model may or may not be CONOPT.

CONOPT has been designed for large and sparse models. This means that both the number of variables and equations can be large. Indeed, NLP models with over 100,000 equations and variables have been solved successfully, and CNS models with over 1,000,000 equations and variables have also been solved. The components used to build CONOPT have been selected under the assumptions that the model is sparse, i.e. that most functions only depend on a small number of variables. CONOPT can also be used for denser models, but the performance will suffer significantly.

CONOPT is designed for models with smooth functions, but it can also be applied to models that do not have differentiable functions, in GAMS called DNLP models. However, CONOPT will use the same algorithm used for a real NLP model and it will search for a point that satisfies standard first-order optimality conditions without taking into account that parts of the model could be non-smooth or non-differentiable. The lack of smoothness may confuse the algorithm in CONOPT causing slow convergence, and a point that satisfies standard first-order optimality conditions may not even exist. There are therefore no guaranties whatsoever for this class of models. If CONOPT terminates with a locally optimal solution then the solution will indeed be locally optimal. However, you will sometimes get termination messages like "Convergence too slow" or "No change in objective although the reduced gradient is greater than the tolerance" that indicate unsuccessful termination. The final point may or may not be locally optimal. If possible, you should try to reformulate a DNLP model to an equivalent or approximately equivalent form as described in section NLP and DNLP Models .

Most modelers should not be concerned with algorithmic details such as choice of algorithmic sub-components or tolerances. CONOPT has considerable build-in logic that selects a solution approach that seems to be best suited for the type of model at hand, and the approach is adjusted dynamically as information about the behavior of the model is collected and updated. The description of the CONOPT algorithm has therefore been moved to an appendix (Appendix A) and most modelers can skip it. However, if you are solving very large or complex models or if you are experiencing solution difficulties you may benefit from using non-standard tolerances or options, in which case you will need some understanding of what CONOPT is doing to your model. Some guidelines for selecting options can be found at the end of Appendix A and a list of all options and tolerances is shown in Appendix B.

The main text of this User's Guide will give a short overview over the iteration output you will see on the screen (section Iteration Output), and explain the termination messages (section CONOPT Termination Messages). We will then discuss function evaluation errors (section Function Evaluation Errors), the use of options (section The CONOPT Options File), and give a CONOPT perspective on good model formulation including topics such as initial values and bounds, simplification of expressions, and scaling (section Hints on Good Model Formulation). Finally, we will discuss the difference between NLP and DNLP models (section NLP and DNLP Models).

5.7.2 Iteration Output

On most machines you will by default get a logline on your screen or terminal at regular intervals. The iteration log may look something like this:

```

   247   4        1.0128171043E+00 5.7E-08    13

 ** Optimal solution. Reduced gradient less than tolerance.
```

The first few lines identify the version of CONOPT you use.

The first iterations have a special interpretation: iteration 0 represents the initial point exactly as received from GAMS, iteration 1 represent the point that is the result of CONOPT's pre-processing, and iteration 2 represents the same point after scaling (even if scaling is turned off).

The remaining iterations are characterized by the value of "Phase" in column 2. The model is infeasible during Phase 0, 1, and 2 and the Sum of Infeasibilities in column 4 (labeled "Infeasibility") is being minimized; the model is feasible during Phase 3 and 4 and the actual objective function, also shown in column 4 (now labeled "Objective"), is minimized or maximized. Phase 0 iterations are Newton-like iterations. They are very cheap so you should not be concerned if there are many of these Phase 0 iterations. During Phase 1 and 3 the model behaves almost linearly and CONOPT applies special linear iterations that take advantage of the linearity. These iterations are sometimes augmented with some inner "Sequential Linear Programming" (SLP) iterations, indicated by a number of inner SLP iterations in the "InItr" column. During Phase 2 and 4 the model behaves more nonlinear and most aspects of the

iterations are therefore changed: the line search is more elaborate, and CONOPT needs second order information to improve the convergence. For small and simple models CONOPT will approximate second order information as a byproduct of the line searches. For larger and more complex models CONOPT will use some inner "Sequential Quadratic Programming" (SQP) iterations based on exact second derivatives. These SQP iterations are identified by the number of inner SQP iterations in the "InItr" column.

The column "NSB" for Number of SuperBasics defines the degree of freedom or the dimension of the current search space, and "rgmax" measures the largest reduced gradient among the non-optimal variables. Rgmax should eventually converge towards zero, but convergence is not expected to be monotone. The last two columns labeled "MX" and "OK" gives information about the line search: OK = T means that the line search was well-behaved, and OK = F means that the line search was terminated before an optimal step length was found because it was not possible to find a feasible solution for large step lengths. MX = T means that the line search was terminated by a variable reaching a bound (always combined with OK = T), and MX = F means that the step length was determined by nonlinearities. If OK = T then the step length was optimal; if OK = F then the constraints were too nonlinear to allow CONOPT to make a full optimal step.

5.7.3 CONOPT Termination Messages

CONOPT may terminate in a number of ways. This section will show most of the termination messages and explain their meaning. It will also show the Model Status returned to GAMS in <model>.modelStat, where <model> represents the name of the GAMS model. The Solver Status returned in <model>.solveStat will be given if it is different from 1 (Normal Completion). We will in all cases first show the message from CONOPT followed by a short explanation. The first 4 messages are used for optimal solutions and CONOPT will return modelStat = 2 (Locally Optimal), except as noted below:

```
** Optimal solution. There are no superbasic variables.
```

The solution is a locally optimal corner solution. The solution is determined by constraints only, and it is usually very accurate. In some cases CONOPT can determine that the solution is globally optimal and it will return modelStat = 1 (Optimal).

```
** Optimal solution. Reduced gradient less than tolerance.
```

The solution is a locally optimal interior solution. The largest component of the reduced gradient is less than the tolerance `rtredg` with default value 1.e-7. The value of the objective function is very accurate while the values of the variables are less accurate due to a flat objective function in the interior of the feasible area.

```
** Optimal solution. The error on the optimal objective function
   value estimated from the reduced gradient and the estimated
   Hessian is less than the minimal tolerance on the objective.
```

The solution is a locally optimal interior solution. The largest component of the reduced gradient is larger than the tolerance `rtredg`. However, when the reduced gradient is scaled with information from the estimated Hessian of the reduced objective function the solution seems optimal. For this to happen the objective must be large or the reduced objective must have large second derivatives so it is advisable to scale the model. See the sections on "Scaling" and "Using the Scale Option in GAMS" for details on how to scale a model.

```
** Optimal solution. Convergence too slow. The change in
   objective has been less than xx.xx for xx consecutive
   iterations.
```

CONOPT stops with a solution that seems optimal. The solution process is stopped because of slow progress. The largest component of the reduced gradient is greater than the optimality tolerance `rtredg`, but less than `rtredg` multiplied by the largest Jacobian element divided by 100. The model must have large derivatives so it is advisable to scale it.

The four messages above all exist in versions where "Optimal" is replaced by "Infeasible" and modelStat will be 5 (Locally Infeasible) or 4 (Infeasible). The infeasible messages indicate that a Sum of Infeasibility objective function is locally minimal, but positive. If the model is convex it does not have a feasible solution; if the model is non-convex it may have a feasible solution in a different region. See the section on "Initial Values" for hints on what to do.

```
** Feasible solution. Convergence too slow. The change in
   objective has been less than xx.xx for xx consecutive
   iterations.

** Feasible solution. The tolerances are minimal and
   there is no change in objective although the reduced
   gradient is greater than the tolerance.
```

The two messages above tell that CONOPT stops with a feasible solution. In the first case the solution process is very slow and in the second there is no progress at all. However, the optimality criteria have not been satisfied. These messages are accompanied by modelStat = 7 (Feasible Solution) and solveStat = 4 (Terminated by Solver). The problem can be caused by discontinuities if the model is of type DNLP; in this case you should consider alternative, smooth formulations as discussed in section NLP and DNLP Models . The problem can also be caused by a poorly scaled model. See section Scaling for hints on model scaling. Finally, it can be caused by stalling as described in section Stalling in Appendix A. The two messages also exist in a version where "Feasible" is replaced by "Infeasible". modelStat is in this case 6 (Intermediate Infeasible) and solveStat is still 4 (Terminated by Solver); these versions tell that CONOPT cannot make progress towards feasibility, but the Sum of Infeasibility objective function does not have a well defined local minimum.

```
   <var>: The variable has reached infinity

** Unbounded solution. A variable has reached 'infinity'.
   Largest legal value (Rtmaxv) is xx.xx
```

CONOPT considers a solution to be unbounded if a variable exceeds the indicated value of `rtmaxv` (default 1.e10) and it returns with modelStat = 3 (Unbounded). The check for unboundedness is done at every iteration which means that CONOPT will stop if an intermediate solution has a variable that is very large, even if none of the variables in the optimal solution have large values. Check whether the solution appears unbounded or the problem is caused by the scaling of the unbounded variable "<var>" mentioned in the first line of the message. If the model seems correct you are advised to scale it. There is also a lazy solution: you can increase the largest legal value, `rtmaxv`, as mentioned in the section on options. However, you will pay through reduced reliability or increased solution times. Unlike LP models, where an unbounded model is recognized by an unbounded ray and the iterations are stopped far from "infinity", CONOPT will actually have to make a line search and move to a region with large values of the variables. This may lead to bad scaling and to many different kinds of tolerance and roundoff problems, including problems of determining whether a solution is feasible or not.

The message above exists in a version where "Unbounded" is replaced by "Infeasible" and modelStat is 5 (Locally Infeasible). You may also see a message like

```
   <var>: Free variable becomes too large

** Infeasible solution. A free variable exceeds the allowable
   range.  Current value is 1.02E+10 and current upper bound
   (Rtmaxv) is 1.00E+10
```

These two messages indicate that some variables become very large before a feasible solution has been found. You should again check whether the problem is caused by the scaling of the unbounded variable "<var>" mentioned in the first line of the message. If the model seems correct you should scale it.

```
** The time limit has been reached.
```

The time or resource limit defined in GAMS, either by default (usually 1000 seconds) or by `Option ResLim = xx;` or `<model>.ResLim = xx;` statements, has been reached. CONOPT will return with solveStat = 3 (Resource Interrupt) and modelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

```
** The iteration limit has been reached.
```

The iteration limit defined in GAMS, either by default (usually 2000000000 iterations) or by `Option IterLim = xx;` or `<model>.IterLim = xx;` statements, has been reached. CONOPT will return with solveStat = 2 (Iteration Interrupt) and modelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

```
** Domain errors in nonlinear functions.
   Check bounds on variables.
```

The number of function evaluation errors has reached the limit defined in GAMS by `Option DomLim = xx;` or `<model>.DomLim = xx;` statements or the default limit of 0 function evaluation errors. CONOPT will return with solveStat = 5 (Evaluation Error Limit) and modelStat either 6 (Locally Infeasible) or 7 (Feasible Solution). See more details in section Function Evaluation Errors .

```
** An initial derivative is too large (larger than Rtmaxj= xx.xx)
   Scale the variables and/or equations or add bounds.

   <var> appearing in
   <equ>: Initial Jacobian element too large = xx.xx
```

and

```
** A derivative is too large (larger than Rtmaxj= xx.xx).
   Scale the variables and/or equations or add bounds.

   <var> appearing in
   <equ>: Jacobian element too large = xx.xx
```

These two messages appear if a derivative or Jacobian element is very large, either in the initial point or in a later intermediate point. The relevant variable and equation pair(s) will show you where to look. A large derivative means that the function changes very rapidly even after a very small change in the variable and it will most likely create numerical problems for many parts of the optimization algorithm. Instead of attempting to solve a model that most likely will fail, CONOPT will stop and you are advised to adjust the model if at all possible.

If the offending derivative is associated with a Log(x) or 1/x term you may try to increase the lower bound on x. If the offending derivative is associated with an Exp(x) term you must decrease the upper bound on x. You may also try to scale the model, either manually or using the variable.Scale and/or equation.Scale option in GAMS as described in section Scaling There is also in this case a lazy solution: increase the limit on Jacobian elements, `rtmaxj`; however, you will pay through reduced reliability or longer solution times.

In addition to the messages shown above you may see messages like

```
** An equation in the pre-triangular part of the model cannot be
   solved because the critical variable is at a bound.

** An equation in the pre-triangular part of the model cannot be
   solved because of too small pivot.
```

or

```
** An equation is inconsistent with other equations in the
   pre-triangular part of the model.
```

These messages containing the word "Pre-triangular" are all related to infeasibilities identified by CONOPT's pre-processing stage and they are explained in detail in section Iteration 1: Preprocessing in Appendix A.

Usually, CONOPT will be able to estimate the amount of memory needed for the model based on statistics provided by GAMS. However, in some cases with unusual models, e.g. very dense models or very large models, the estimate will be too small and you must request more memory yourself using a statement like <model>.WorkFactor = x.x; or <model>.WorkSpace = xx; in GAMS or by adding WorkFactor=xx to the command line call of GAMS. The message you will see is similar to the following:

```
** FATAL ERROR **  Insufficient memory to continue the
                   optimization.

                   You must request more memory.
                   Current   CONOPT space =  0.29 Mbytes
                   Estimated CONOPT space =  0.64 Mbytes
                   Minimum   CONOPT space =  0.33 Mbytes

CONOPT time Total                          0.109 seconds
  of which: Function evaluations           0.000 =  0.0%
            1st derivative evaluations     0.000 =  0.0%
```

The text after "Insufficient memory to" may be different; it says something about where CONOPT ran out of memory. If the memory problem appears during model setup the message will be accompanied by solveStat = 13 (System Failure) and modelStat = 13 (Error No Solution) and CONOPT will not return any values. If the memory problem appears later during the optimization solveStat will be 11 (Internal Solver Failure) and modelStat will be either 6 (Intermediate Infeasible) or 7 (Feasible Solution) and CONOPT will return primal solution values. The marginals of both equations and variables will be zero or EPS.

It is recommended that you use the WorkFactor option if you must change the amount of memory. The same number will usually work for a whole family of models. If you prefer to use WorkSpace, the GAMS WorkSpace option corresponds to the amount of memory, measured in Mbytes.

A new termination message has been added from version 3.16C:

```
** Feasible solution. The solution process has been terminated
   because intermediate results have become NaN (Not A Number).
```

and similar with Infeasible. To prevent non-sensible results and/or infinite loops in special degenerate cases CONOPT has added checks for internal intermediate results being NaN (Not A Number) or very large. If this happens CONOPT will try to change some tolerances and try to continue the optimization. If this attempt fails CONOPT will stop and return the message above. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible." Section Overflow and NaN (Not A Number) in Appendix A has more details on the sources of NaN and the actions that can be taken by the user and by CONOPT.

5.7.4 Function Evaluation Errors

Many of the nonlinear functions available with GAMS are not defined for all values of their arguments. Log is not defined for negative arguments, Exp overflows for large arguments, and division by zero is illegal. To avoid evaluating functions outside their domain of definition you should add reasonable variable bounds. CONOPT will in return guarantee that the nonlinear functions never are evaluated with variables outside their bounds.

In some cases bounds are not sufficient, e.g. in the expression Log(Sum(i, x(i))): in some models each individual x should be allowed to become zero, but the Sum should not. In this case you should introduce an intermediate variable and an extra equation, e.g. xSumDef .. xSum =E= sum(i,x(i)); add a lower bound on xSum; and use xSum as the argument to the Log function. See section Simple Expressions for additional comments on this topic.

Whenever a nonlinear function is called outside its domain of definition, GAMS' function evaluator will intercept the function evaluation error and prevent the system to crash. GAMS will replace the undefined result by some appropriate real number, and it will make sure the error is reported to the modeler as part of the standard solution output in the GAMS listing file. GAMS will also report the error to CONOPT, so CONOPT can try to correct the problem by backtracking to a safe point. Finally, CONOPT will be instructed to stop after `DomLim` errors.

During Phase 0, 1, and 3 CONOPT will often use large steps as the initial step in a line search and functions will very likely be called with some of the variables at their lower or upper bound. You are therefore likely to get a division-by-zero error if your model contains a division by x and x has a lower bound of zero. And you are likely to get an exponentiation overflow error if your model contains Exp(x) and x has no upper bound. However, CONOPT will usually not get trapped in a point outside the domain of definition for the model. When GAMS' function evaluator reports that a point is "bad", CONOPT will decrease the step length, and it will for most models be able to recover and continue to an optimal solution. It is therefore safe to use a large value for `DomLim` instead of GAMS default value of 0.

CONOPT may get stuck in some cases, for example because there is no previous point to backtrack to, because "bad" points are very close to "reasonable" feasible points, or because the derivatives are not defined in a feasible point. The more common messages are:

```
** Fatal Error **  Function error in initial point in Phase 0
                   procedure.

** Fatal Error **  Function error after small step in Phase 0
                   procedure.

** Fatal Error **  Function error very close to a feasible point.

** Fatal Error **  Function error while reducing tolerances.

** Fatal Error **  Function error in Pre-triangular equations.

** Fatal Error **  Function error after Preprocessing.

** Fatal Error **  Function error in Post-triangular equation.
```

In the first four cases you must either add better bounds or define better initial values. If the problem is related to a pre- or post-triangular equation as shown by the last three messages then you can turn part of the pre-processing off as described in section Iteration 1: Preprocessing . in Appendix A. However, this may make the model harder to solve, so it is usually better to add bounds and/or initial values.

5.7.5 The CONOPT Options File

CONOPT has been designed to be self-tuning. Most tolerances are dynamic. As an example: The feasibility of a constraint is always judged relative to the dual variable on the constraint and relative to the expected change in objective in the coming iteration. If the dual variable is large then the constraint must be satisfied with a small tolerance, and if the dual variable is small then the tolerance is larger. When the expected change in objective in the first iterations is large then the feasibility tolerances are also large. And when we approach the optimum and the expected change in objective becomes smaller then the feasibility tolerances become smaller.

Because of the self-tuning nature of CONOPT you should in most cases be well off with default tolerances. If you do need to change some tolerances, possibly following the advice in Appendix A, it can be done in the CONOPT Options file. The name of the CONOPT Options file is on most systems "conopt.opt". You must tell the solver that you want to use an options file with the statement `<model>.OptFile = 1` in your GAMS source file before the Solve statement or with `OptFile = 1` on the command line.

The format of the CONOPT Options file consists in its simplest form of a number of lines like these:

```
rtmaxv = 1.e12
lfnsup = 500
```

The value must be written using legal GAMS format, i.e. a real number may contain an optional E exponent, but a number may not contain blanks. The value must have the same type as the option, i.e. real options must be assigned real values, integer options must be assigned integer values, and logical options must be assigned logical values. The logical value representing true are `true, t, yes`, or `1`, and the logical values representing false are `false, f, no`, or `0`.

In previous versions of CONOPT you could add "SET" in front of the option assignment. This is no longer supported. You can still replace the equal sign with `:=` and you can add end of line comments after a `#` or `!` character. Lines starting with $*$ in column 1 are treated as comment lines.

5.7.6 Hints on Good Model Formulation

This section will contain some comments on how to formulate a nonlinear model so it becomes easier to solve with CONOPT. Most of the recommendations will be useful for any nonlinear solver, but not all. We will try to mention when a recommendation is CONOPT specific.

5.7.6.1 Initial Values

Good initial values are important for many reasons. Initial values that satisfy or closely satisfy many of the constraints reduces the work involved in finding a first feasible solution. Initial values that in addition are close to the optimal ones also reduce the distance to the final point and therefore indirectly the computational effort. The progress of the optimization algorithm is based on good directional information and therefore on good derivatives. The derivatives in a nonlinear model depend on the current point, and the initial point in which the initial derivatives are computed is therefore again important. Finally, non-convex models may have multiple solutions, but the modeler is looking for one in a particular part of the search space; an initial point in the right neighborhood is more likely to return the desired solution.

The initial values used by CONOPT are all coming from GAMS. The initial values used by GAMS are by default the value zero projected on the bounds. I.e. if a variable is free or has a lower bound of zero, then its default initial value is zero. Unfortunately, zero is in many cases a bad initial value for a nonlinear variable. An initial value of zero is especially bad if the variable appears in a product term since the initial derivative becomes zero, and it appears as if the function does not depend on the variable. CONOPT will

warn you and ask you to supply better initial values if the number of derivatives equal to zero is larger than 20 percent.

If a variable has a small positive lower bound, for example because it appears as an argument to the Log function or as a denominator, then the default initial value is this small lower bound and it is also bad since this point will have very large first and second derivatives.

You should therefore supply as many sensible initial values as possible by making assignment to the level value, var.L, in GAMS. An easy possibility is to initialize all variables to 1, or to the scale factor if you use GAMS' scaling option. A better possibility is to select reasonable values for some variables that from the context are known to be important, and then use some of the equations of the model to derive values for other variables. A model may contain the following equation:

```
pmDef(it) .. pm(it) =e= pwm(it)*er*(1 + tm(it)) ;
```

where pm, pwm, and er are variables and tm is a parameter. The following assignment statements use the equation to derive consistent initial values for PM from sensible initial values for pwm and er:

```
er.l = 1; pwm.l(it) = 1;
pm.l(it) = pwm.l(it)*er.l*(1 + tm(it)) ;
```

With these assignments equation pmDef will be feasible in the initial point, and since CONOPT uses a feasible path method it will remain feasible throughout the optimization (unless the pre-processor destroys it, see section Iteration 1: Preprocessing in Appendix A).

If CONOPT has difficulties finding a feasible solution for your model you should try to use this technique to create an initial point in which as many equations as possible are satisfied. You may also try the optional Crash procedure described in section Preprocessing: The Optional Crash Procedure in Appendix A by adding the line `lstcrs=t` to the CONOPT options file. The crash procedure tries to identify equations with a mixture of uninitialized variables and variables with initial values, and it solves the equations with respect to the uninitialized variables; the effect is similar to the manual procedure shown above.

5.7.6.2 Bounds

Bounds have two purposes in nonlinear models. Some bounds represent constraints on the reality that is being modeled, e.g. a variable must be positive. These bounds are called model bounds. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called algorithmic bounds.

Model bounds have natural roots and do not cause any problems. Algorithmic bounds require a closer look at the functional form of the model. The content of a Log should be greater than say 1.e-3, the content of an Exp should be less than 5 to 8, and a denominator should be greater than say 1.e-2. These recommended lower bounds of 1.e-3 and 1.e-2 may appear to be unreasonably large. However, both Log(x) and 1/x are extremely nonlinear for small arguments. The first and second derivatives of Log(x) at x=1.e-3 are 1.e+3 and -1.e6, respectively, and the first and second derivatives of 1/x at x=1.e-2 are -1.e+4 and 2.e+6, respectively.

If the content of a Log or Exp function or a denominator is an expression then it may be advantageous to introduce a bounded intermediate variable as discussed in the next section.

Note that bounds in some cases can slow the solution process down. Too many bounds may for example introduce degeneracy. If you have constraints of the following type

```
vub(i) .. x(i) =l= y;
```

or

```
ysum   .. y =e= sum( i, x(i) );
```

and x is a `Positive Variable` then you should in general not declare y a `Positive Variable` or add a lower bound of zero on y. If y appears in a nonlinear function you may need a strictly positive bound. Otherwise, you should declare y a free variable; CONOPT will then make y basic in the initial point and y will remain basic throughout the optimization. New logic in CONOPT tries to remove this problem by detecting when a harmful bound is redundant so it can be removed, but it is not yet a fool proof procedure.

Section Iteration 1: Preprocessing in Appendix A gives another example of bounds that can be counter productive.

5.7.6.3 Simple Expressions

The following model component

```
Parameter mu(i);
Variable  x(i), s(i), obj;
Equation  objDef;
objDef .. obj =e= Exp( Sum( i, Sqr( x(i) - mu(i) ) / s(i) ) );
```

can be re-written in the slightly longer but simpler form

```
Parameter mu(i);
Pariable  x(i), s(i), obj, inTerm;
Equation  intDef, objDef;
intDef .. inTerm =e= Sum( i, Sqr( x(i) - mu(i) ) / s(i) );
objDef .. obj    =e= Exp( inTerm );
```

The first formulation has very complex derivatives because Exp is taken of a long expression. The second formulation has much simpler derivatives; Exp is taken of a single variable, and the variables in intDef appear in a sum of simple independent terms.

In general, try to avoid nonlinear functions of expressions, divisions by expressions, and products of expressions, especially if the expressions depend on many variables. Define intermediate variables that are equal to the expressions and apply the nonlinear function, division, or product to the intermediate variable. The model will become larger, but the increased size is taken care of by CONOPT's sparse matrix routines, and it is compensated by the reduced complexity. If the model is solved with CONOPT using explicit second derivatives then simple expressions will result in sparser second derivatives that are both faster to compute and to use.

The reduction in complexity can be significant if an intermediate expression is linear. The following model fragment:

```
Variable x(i), y;
Equation yDef;
yDef ..  y =e= 1 / Sum(i, x(i) );
```

should be written as

```
Variable x(i), xSum, y;
Equation xSumDef, yDef;
xSumDef .. xSum =e= Sum(i, x(i) );
yDef    .. y =e= 1 / xSum;
xSum.lo = 1.e-2;
```

for three reasons. First, because the number of nonlinear derivatives is reduced in number and complexity. Second, because the lower bound on the intermediate result will bound the search away from the singularity at xSum = 0. And third, because the matrix of second derivatives for the last model only depend on xSum while it depends on all x in the first model.

The last example shows an added potential saving by expanding functions of linear expressions. A constraint depends in a nonlinear fashion on the accumulated investments, inv, like

```
con(i) .. f( Sum( j$(ord(j) le ord(i)), inv(j) ) ) =l= b(i);
```

A new intermediate variable, cap(i), that is equal to the content of the Sum can be defined recursively with the constraints

```
cDef(i) .. cap(i) =e= inv(i) + cap(i-1);
```

and the original constraints become

```
con(i) .. f( cap(i) ) =l= b(i);
```

The reformulated model has n additional variables and n additional linear constraints. In return, the original n complex nonlinear constraints have been changed into n simpler nonlinear constraints. And the number of Jacobian elements, that has a direct influence on much of the computational work both in GAMS and in CONOPT, has been reduced from n∗(n+1)/2 nonlinear elements to 3∗n-1 linear elements and only n nonlinear element. If f is an invertible increasing function you may even rewrite the last constraint as a simple bound:

```
cap.lo(i) = finv(b(i));
```

Some NLP solvers encourage you to move as many nonlinearities as possible into the objective which may make the objective very complex. This is neither recommended nor necessary with CONOPT. A special pre-processing step (discussed in section Iteration 1: Preprocessing in Appendix A) will aggregate parts of the model if it is useful for CONOPT without increasing the complexity in GAMS.

5.7.6.4 Scaling

Nonlinear as well as Linear Programming Algorithms use the derivatives of the objective function and the constraints to determine good search directions, and they use function values to determine if constraints are satisfied or not. The scaling of the variables and constraints, i.e. the units of measurement used for the variables and constraints, determine the relative size of the derivatives and of the function values and thereby also the search path taken by the algorithm.

Assume for example that two goods of equal importance both cost $1 per kg. The first is measured in gram, the second in tons. The coefficients in the cost function will be $1000/g and $0.001/ton, respectively. If cost is measured in $1000 units then the coefficients will be 1 and 1.e-6, and the smaller may be ignored by the algorithm since it is comparable to some of the zero tolerances.

CONOPT assumes implicitly that the model to be solved is well scaled. In this context well scaled means:

- Basic and superbasic solution values are expected to be around 1, e.g. from 0.01 to 100. Nonbasic variables will be at a bound, and the bound values should not be larger than say 100.
- Dual variables (or marginals) on active constraints are expected to be around 1, e.g. from 0.01 to 100. Dual variables on non-binding constraints will of course be zero.
- Derivatives (or Jacobian elements) are expected to be around 1, e.g. from 0.01 to 100.

Variables become well scaled if they are measured in appropriate units. In most cases you should select the unit of measurement for the variables so their expected value is around unity. Of course there will always be some variation. Assume x(i) is the production at location i. In most cases you should select the same unit of measurement for all components of x, for example a value around the average capacity.

Equations become well scaled if the individual terms are measured in appropriate units. After you have selected units for the variables you should select the unit of measurement for the equations so the expected values of the individual terms are around one. If you follow these rules, material balance equations will usually have coefficients of plus and minus one.

Derivatives will usually be well scaled whenever the variables and equations are well scaled. To see if the derivatives are well scaled, run your model with a positive Option LimRow and look for very large or very small coefficients in the equation listing in the GAMS output file.

CONOPT computes a measure of the scaling of the Jacobian, both in the initial and in the final point, and if it seems large it will be printed. The message looks like:

```
** WARNING **  The variance of the derivatives in the initial
               point is large (= 4.1 ). A better initial
               point, a better scaling, or better bounds on the
               variables will probably help the optimization.
```

The variance is computed as Sqrt(Sum(Log(Abs(jac(i)))**2)/nz) where jac(i) represents the nz nonzero derivatives (Jacobian elements) in the model. A variance of 4.1 corresponds to an average value of Log(jac)**2 of 4.1**2, which means that Jacobian values outside the range Exp(-4.1)=0.017 to Exp(+4.1)=60.4 are about as common at values inside. This range is for most models acceptable, while a variance of 5, corresponding to about half the derivatives outside the range Exp(-5)=0.0067 to Exp(+5)=148, can be dangerous.

Scaling of Intermediate Variables

Many models have a set of variables with a real economic or physical interpretation plus a set of intermediate or helping variables that are used to simplify the model. We have seen some of these in section Simple Expressions on Simple Expressions. It is usually rather easy to select good scaling units for the real variables since we know their order of magnitude from economic or physical considerations. However, the intermediate variables and their defining equations should preferably also be well scaled, even if they do not have an immediate interpretation. Consider the following model fragment where x, y, and z are variables and y is the intermediate variable:

```
Set p / p0*p4 /
Parameter a(p) / p0 211, p1 103, p2 42, p3 31, p4 6 /
yDef .. y =e= Sum(p, a(p)*Power(x,Ord(p)-1));
zDef .. z =e= Log(y);
```

x lies in the interval 1 to 10 which means that y will be between 211 and 96441 and Z will be between 5.35 and 11.47. Both x and z are reasonably scaled while y and the terms and derivatives in yDef are about a factor 1.e4 too large. Scaling y by 1.e4 and renaming it ys gives the following scaled version of the model fragment:

```
yDefs1 .. ys =e= Sum(p, a(p)*Power(x,Ord(p)-1))*1.e-4;
zDefs1 .. z  =e= Log(ys*1.e4);
```

The z equation can also be written as

```
zDefs2 .. z  =e= Log(ys) + Log(1.e4);
```

Note that the scale factor 1.e-4 in the yDefs1 equation has been placed on the right hand side. The mathematically equivalent equation

```
yDefs2 .. ys*1.e4 =e= Sum(p, a(p)*Power(x,Ord(p)-1));
```

will give a well scaled YS, but the right hand side terms of the equation and their derivatives have not changed from the original equation yDef and they are still far too large.

Using the Scale Option in GAMS

The rules for good scaling mentioned above are exclusively based on algorithmic needs. GAMS has been developed to improve the effectiveness of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as "natural" as possible. The units of measurement is one part of this natural notation, and there is unfortunately often a conflict between what the modeler thinks is a good unit and what constitutes a well scaled model.

To facilitate the translation between a natural model and a well scaled model GAMS has introduced the concept of a scale factor, both for variables and equations. The notation and the definitions are quite simple. First of all, scaling is by default turned off. To turn it on, enter the statement <model>`.ScaleOpt = 1;` in your GAMS program somewhere after the `Model` statement and before the `Solve` statement. <model> is the name of the model to be solved. If you want to turn scaling off again, enter the statement <model>`.ScaleOpt = 0;` somewhere before the next `Solve`.

The scale factor of a variable or an equation is referenced with the suffix ".Scale", i.e. the scale factor of variable x(i) is referenced as x.Scale(i). Note that there is one scale value for each individual component of a multidimensional variable or equation. Scale factors can be defined in assignment statements with x.Scale(i) on the left hand side, and scale factors, both from variables and equations, can be used on the right hand side, for example to define other scale factors. The default scale factor is always 1, and a scale factor must be positive; GAMS will generate an execution time error if the scale factor is less than 1.e-20.

The mathematical definition of scale factors is a follows: The scale factor on a variable, V^s is used to related the variable as seen by the modeler, V^m, to the variable as seen by the algorithm, V^a, as follows:

$$V^m = V^a * V^s$$

This means, that if the variable scale, V^s, is chosen to represent the order of magnitude of the modeler's variable, V^m, then the variable seen by the algorithm, V^a, will be around 1. The scale factor on an equation, G^s, is used to related the equation as seen by the modeler, G^m, to the equation as seen by the algorithm, G^a, as follows:

$$G^m = G^a * G^s$$

This means, that if the equation scale, G^s, is chosen to represent the order of magnitude of the individual terms in the modelers version of the equation, G^m, then the terms seen by the algorithm, G^a, will be around 1.

The derivatives in the scaled model seen by the algorithm, i.e. dG^a/dV^a, are related to the derivatives in the modelers model, dG^m/dV^m, through the formula:

$$dG^a/dV^a = dG^m/dV^m * V^s/G^s$$

i.e. the modelers derivative is multiplied by the scale factor of the variable and divided by the scale factor of the equation. Note, that the derivative is unchanged if $V^s = G^s$. Therefore, if you have a GAMS equation like

```
G .. V =e= expression;
```

and you select $G^s = V^s$ then the derivative of V will remain 1. If we apply these rules to the example above with an intermediate variable we can get the following automatic scale calculation, based on an "average" reference value for x:

```
Scalar xRef; xRef = 6;
y.Scale = Sum(p, a(p)*Power(xRef,Ord(p)-1));
yDef.Scale = y.Scale;
```

or we could scale y using values at the end of the x interval and add safeguards as follows:

```
y.Scale = Max( Abs(Sum(p, a(p)*Power(x.Lo,Ord(p)-1))),
               Abs(Sum(p, a(p)*Power(x.Up,Ord(p)-1))),
               0.01 );
```

Lower and upper bounds on variables are automatically scaled in the same way as the variable itself. Integer and binary variables cannot be scaled.

GAMS' scaling is in most respects hidden for the modeler. The solution values reported back from a solution algorithm, both primal and dual, are always reported in the user's notation. The algorithm's versions of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if `Option LimRow` and/or `LimCol` are positive, and in debugging output from the solution algorithm, generated with `Option SysOut = On`. In addition, the numbers in the algorithms iteration log will represent the scaled model: the infeasibilities and reduced gradients will correspond to the scaled model, and if the objective variable is scaled, the value of the objective function will be the scaled value.

A final warning about scaling of multidimensional variables is appropriate. Assume variable x(i,j,k) only appears in the model when the parameter ijk(i,j,k) is nonzero, and assume that Card(i) = Card(j) = Card(k) = 100 while Card(ijk) is much smaller than 100**2 = 1.e6. Then you should only scale the variables that appear in the model, i.e.

```
x.Scale(i,j,k)$ijk(i,j,k) = expression;
```

The statement

```
x.Scale(i,j,k) = expression;
```

will generate records for x in the GAMS database for all combinations of i, j, and k for which the expression is different from 1, i.e. up to 1.e6 records, and apart from spending a lot of time you will very likely run out of memory. Note that this warning also applies to non-default lower and upper bounds.

5.7.7 NLP and DNLP Models

GAMS has two classes of nonlinear model, NLP and DNLP. NLP models are defined as models in which all functions that appear with endogenous arguments, i.e. arguments that depend on model variables, are smooth with smooth derivatives. DNLP models can in addition use functions that are smooth but have discontinuous derivatives. The usual arithmetic operators (+, -, ∗, /, and ∗∗) can appear on both model classes.

The functions that can be used with endogenous arguments in a DNLP model and not in an NLP model are Abs, Min, and Max and as a consequence the indexed operators SMin and SMax.

Note that the offending functions can be applied to expressions that only involve constants such as parameters, var.l, and equ.m. Fixed variables are in principle constants, but GAMS makes its tests based on the functional form of a model, ignoring numerical parameter values and numerical bound values, and terms involving fixed variables can therefore not be used with Abs, Min, or Max in an NLP model.

The NLP solvers used by GAMS can also be applied to DNLP models. However, it is important to know that the NLP solvers attempt to solve the DNLP model as if it was an NLP model. The solver uses the derivatives of the constraints with respect to the variables to guide the search, and it ignores the fact that some of the derivatives may change discontinuously. There are at the moment no GAMS solvers designed specifically for DNLP models and no solvers that take into account the discontinuous nature of the derivatives in a DNLP model.

5.7.7.1 DNLP Models: What Can Go Wrong?

Solvers for NLP Models are all based on making marginal improvements to some initial solution until some optimality conditions ensure no direction with marginal improvements exist. A point with no marginally improving direction is called a Local Optimum.

The theory about marginal improvements is based on the assumption that the derivatives of the constraints with respect to the variables are a good approximations to the marginal changes in some neighborhood around the current point.

Consider the simple NLP model, Min Sqr(x), where x is a free variable. The marginal change in the objective is the derivative of Sqr(x) with respect to x, which is 2∗x. At x = 0, the marginal change in all directions is zero and x = 0 is therefore a Local Optimum.

Next consider the simple DNLP model, Min Abs(x), where x again is a free variable. The marginal change in the objective is still the derivative, which is +1 if x > 0 and -1 if x < 0. When x = 0, the derivative depends on whether we are going to increase or decrease x. Internally in the DNLP solver, we cannot be sure whether the derivative at 0 will be -1 or +1; it can depend on rounding tolerances. An NLP solver will start in some initial point, say x = 1, and look at the derivative, here +1. Since the derivative is positive, x is reduced to reduce the objective. After some iterations, x will be zero or very close to zero. The derivative will be +1 or -1, so the solver will try to change x. however, even small changes will not lead to a better objective function. The point x = 0 does not look like a Local Optimum, even though it is a Local Optimum. The result is that the NLP solver will muddle around for some time and then stop with a message saying something like: "The solution cannot be improved, but it does not appear to be optimal."

In this first case we got the optimal solution so we can just ignore the message. However, consider the following simple two-dimensional DNLP model: Min Abs(x1+x2) + 5∗Abs(x1-x2) with x1 and x2 free variables. Start the optimization from x1 = x2 = 1. Small increases in x1 will increase both terms and small decreases in x1 (by dx) will decrease the first term by dx but it will increase the second term by 5∗dx. Any change in x1 only is therefore bad, and it is easy to see that any change in x2 only also is bad. An NLP solver may therefore be stuck in the point x1 = x2 = 1, even though it is not a local solution: the direction (dx1,dx2) = (-1,-1) will lead to the optimum in x1 = x2 = 0. However, the NLP solver cannot distinguish what happens with this model from what happened in the previous model; the message will be of the same type: "The solution cannot be improved, but it does not appear to be optimal."

5.7.7.2 Reformulation from DNLP to NLP

The only reliable way to solve a DNLP model is to reformulate it as an equivalent smooth NLP model. Unfortunately, it may not always be possible. In this section we will give some examples of reformulations.

The standard reformulation approach for the ABS function is to introduce positive and negative deviations as extra variables: The term z = Abs(f(x)) is replaced by z = fPlus + fMinus, fPlus and fMinus are declared as positive variables and they are defined with the identity: f(x) =e= fPlus - fMinus. The discontinuous derivative from the Abs function has disappeared and the part of the model shown here is smooth. The discontinuity has been converted into lower bounds on the new variables, but bounds are handled routinely by any NLP solver. The feasible space is larger than before; f(x) = 5 can be obtained both with fPlus = 5, fMinus = 0, and z = 5, and with fPlus = 1000, fMinus = 995, and z = 1995. Provided the objective function has some term that tries to minimize z, either fPlus or fMinus will become zero and z will end with its proper value.

You may think that adding the smooth constraint fPlus $*$ fMinus =e= 0 would ensure that either fPlus or fMinus is zero. However, this type of so-called complementarity constraint is "bad" in any NLP model. The feasible space consists of the two half lines: (fPlus = 0 and fMinus $\geq$ 0) and (fPlus $\geq$ 0 and fMinus = 0). Unfortunately, the marginal change methods used by most NLP solvers cannot move from one half line to the other, and the solution is stuck at the half line it happens to reach first.

There is also a standard reformulation approach for the Max function. The equation z =e= Max(f(x),g(y)) is replace by the two inequalities, z =g= f(x) and z =g= g(y). Provided the objective function has some term that tries to minimize z, one of the constraints will become binding as equality and z will indeed be the maximum of the two terms.

The reformulation for the Min function is similar. The equation z =E= Min(f(x),g(y)) is replaced by the two inequalities, z =l= f(x) and z =l= g(y). Provided the objective function has some term that tries to maximize z, one of the constraints will become binding as equality and z is indeed the minimum of the two terms.

Max and Min can have more than two arguments and the extension should be obvious.

The non-smooth indexed operators, SMax and SMin can be handled using a similar technique: for example, z =E= SMax(i, f(x,i)) is replaced by the indexed inequality: inEq(i) .. z =l= f(x,i);

The reformulations that are suggested here all enlarge the feasible space. They require the objective function to move the final solution to the intersection of this larger space with the original feasible space. Unfortunately, the objective function is not always so helpful. If it is not, you may try using one of the smooth approximations described next. However, you should realize, that if the objective function cannot help the "good" approximations described here, then your overall model is definitely non-convex and it is likely to have multiple local optima.

5.7.7.3 Smooth Approximations

Smooth approximations to the non-smooth functions ABS, MAX, and MIN are approximations that have function values close to the original functions, but have smooth derivatives.

A smooth GAMS approximation for Abs(f(x)) is

```
Sqrt( Sqr(f(x)) + Sqr(delta) )
```

where delta is a small scalar. The value of delta can be used to control the accuracy of the approximation and the curvature around f(x) = 0. The approximation error is largest when f(x) is zero, in which case the error is delta. The error is reduced to approximately Sqr(delta)/2 for f(x) = 1. The second derivative is 1/delta at f(x) = 0 (excluding terms related to the second derivative of f(x)). A delta value between 1.e-3 and 1.e-4 should in most cases be appropriate. It is possible to use a larger value in an initial optimization, reduce it and solve the model again. You should note, that if you reduce delta below 1.e-4 then large second order terms might lead to slow convergence or even prevent convergence.

The approximation shown above has its largest error when f(x) = 0 and smaller errors when f(x) is far from zero. If it is important to get accurate values of Abs exactly when f(x) = 0, then you may use the alternative approximation

```
Sqrt( Sqr(f(x)) + Sqr(delta) ) - delta
```

instead. The only difference is the constant term. The error is zero when f(x) is zero and the error grows to -delta when f(x) is far from zero.

Some theoretical work uses the Huber, H(∗), function as an approximation for Abs. The Huber function is defined as

```
H(x) =  x for x  >   delta,
H(x) = -x for x  <  -delta and
H(x) = Sqr(x)/2/delta + delta/2 for -delta  <  x  <  delta.
```

Although the Huber function has some nice properties, it is for example accurate when Abs(x) > delta, it is not so useful for GAMS work because it is defined with different formula for the three pieces.

A smooth GAMS approximation for Max(f(x),g(y)) is

```
( f(x) + g(y) + Sqrt( Sqr(f(x)-g(y)) + Sqr(delta) ) )/2
```

where delta again is a small scalar. The approximation error is delta/2 when f(x) = g(y) and decreases with the difference between the two terms. As before, you may subtract a constant term to shift the approximation error from the area f(x) = g(y) to areas where the difference is large. The resulting approximation becomes

```
( f(x) + g(y) + Sqrt( Sqr(f(x)-g(y)) + Sqr(delta) ) - delta )/2
```

Similar smooth GAMS approximations for Min(f(x),g(y)) are

```
( f(x) + g(y) - Sqrt( Sqr(f(x)-g(y)) + Sqr(delta) ) )/2
```

and

```
( f(x) + g(y) - Sqrt( Sqr(f(x)-g(y)) + Sqr(delta) ) + delta )/2
```

Appropriate delta values are the same as for the Abs approximation: in the range from 1.e-2 to 1.e-4.

It appears that there are no simple symmetric extensions for Max and Min of three or more arguments or for indexed SMax and SMin.

5.7.7.4 Are DNLP Models Always Non-smooth?

A DNLP model is defined as a model that has an equation with an Abs, Max, or Min function with endogenous arguments. The non-smooth properties of DNLP models are derived from the non-smooth properties of these functions through the use of the chain rule. However, composite expressions involving Abs, Max, or Min can in some cases have smooth derivatives and the model can therefore in some cases be smooth.

One example of a smooth expression involving an Abs function is common in water systems modeling. The pressure loss over a pipe, dH, is proportional to the flow, Q, to some power, P. P is usually around +2. The sign of the loss depend on the direction of the flow so dH is positive if Q is positive and negative if Q is negative. Although GAMS has a Sign function, it cannot be used in a model because of its discontinuous nature. Instead, the pressure loss can be modeled with the equation dH =E= const * Q * Abs(Q)**(P-1), where the sign of the Q-term takes care of the sign of dH, and the Abs function guaranties that the real power ** is applied to a non-negative number. Although the expression involves the Abs function, the derivatives are smooth as long as P is greater than 1. The derivative with respect to Q is const * (P-1) * Abs(Q)**(P-1) for $Q > 0$ and -const * (P-1) * Abs(Q)**(P-1) for $Q < 0$. The limit for Q going to zero from both right and left is 0, so the derivative is smooth in the critical point $Q = 0$ and the overall model is therefore smooth.

Another example of a smooth expression is the following terribly looking Sigmoid expression:

```
Sigmoid(x) = Exp( Min(x,0) ) / (1+Exp(-Abs(x)))
```

The standard definition of the sigmoid function is

```
Sigmoid(x) = Exp(x) / ( 1+Exp(x) )
```

This definition is well behaved for negative and small positive x, but it not well behaved for large positive x since Exp overflows. The alternative definition:

```
Sigmoid(x) = 1 / ( 1+Exp(-x) )
```

is well behaved for positive and slightly negative x, but it overflows for very negative x. Ideally, we would like to select the first expression when x is negative and the second when x is positive, i.e.

```
Sigmoid(x) = (Exp(x)/(1+Exp(x)))$(x < 0) + (1/(1+Exp(-x)))$(x > 0)
```

but a $ -control that depends on an endogenous variable is illegal. The first expression above solves this problem. When x is negative, the nominator becomes Exp(x) and the denominator becomes 1+Exp(x). And when x is positive, the nominator becomes Exp(0) = 1 and the denominator becomes 1+Exp(-x). Since the two expressions are mathematically identical, the combined expression is of course smooth, and the Exp function is never evaluated for a positive argument.

Unfortunately, GAMS cannot recognize this and similar special cases so you must always solve models with endogenous Abs, Max, or Min as DNLP models, even in the cases where the model is smooth.

5.7.7.5 Are NLP Models Always Smooth?

NLP models are defined as models in which all operators and functions are smooth. The derivatives of composite functions, that can be derived using the chain rule, will therefore in general be smooth. However, it is not always the case. The following simple composite function is not smooth: y = Sqrt(Sqr(x)). The composite function is equivalent to y = Abs(x), one of the non-smooth DNLP functions.

What went wrong? The chain rule for computing derivatives of a composite function assumes that all intermediate expressions are well defined. However, the derivative of Sqrt grows without bound when the argument approaches zero, violating the assumption.

There are not many cases that can lead to non-smooth composite functions, and they are all related to the case above: The real power, x**y, for $0 < y < 1$ and x approaching zero. The Sqrt function is a special case since it is equivalent to x**y for y = 0.5.

If you have expressions involving a real power with an exponent between 0 and 1 or a Sqrt, you should in most cases add bounds to your variables to ensure that the derivative or any intermediate terms used in their calculation become undefined. In the example above, Sqrt(Sqr(x)), a bound on x is not possible since x should be allowed to be both positive and negative. Instead, changing the expression to Sqrt(Sqr(x) + Sqr(delta)) may lead to an appropriate smooth formulation.

Again, GAMS cannot recognize the potential danger in an expression involving a real power, and the presence of a real power operator is not considered enough to flag a model as a DNLP model. During the solution process, the NLP solver will compute constraint values and derivatives in various points within the bounds defined by the modeler. If these calculations result in undefined intermediate or final values, a function evaluation error is reported, an error counter is incremented, and the point is flagged as a bad point. The following action will then depend on the solver. The solver may try to continue, but only if the modeler has allowed it with an `Option DomLim = xxx;`. The problem of detecting discontinuities is changed from a structural test at the GAMS model generation stage to a dynamic test during the solution process.

You may have a perfectly nice model in which intermediate terms become undefined. The composite function Sqrt(Power(x,3)) is mathematically well defined around x = 0, but the computation will involve the derivative of Sqrt at zero, that is undefined. It is the modeler's responsibility to write expressions in a way that avoids undefined intermediate terms in the function and derivatives computations. In this case, you may either add a small strictly positive lower bound on x or rewrite the function as x**1.5

5.7.8 APPENDIX A: Algorithmic Information

The objective of this Appendix is to give technically oriented users some understanding of what CONOPT is doing so they can get more information out of the iteration log. This information can be used to prevent or circumvent algorithmic difficulties or to make informed guesses about which options to experiment with to improve CONOPT's performance on particular model classes.

5.7.8.1 Overview of CONOPT

CONOPT is a GRG-based algorithm specifically designed for large nonlinear programming problems expressed in the following form

```
min or max      f(x)            (1)
subject to      g(x) = b        (2)
lo < x < up                     (3)
```

where x is the vector of optimization variables, lo and up are vectors of lower and upper bounds, some of which may be minus or plus infinity, b is a vector of right hand sides, and f and g are differentiable nonlinear functions that define the model. n will in the following denote the number of variables and m the number of equations. (2) will be referred to as the (general) constraints and (3) as the bounds.

The relationship between the mathematical model in (1)-(3) above and the GAMS model is simple: The inequalities defined in GAMS with `=l=` or `=g=` are converted into equalities by addition of properly bounded slacks. Slacks with lower and upper bound of zero are added to all GAMS equalities to ensure that the Jacobian matrix, i.e. the matrix of derivatives of the functions g with respect to the variables x, has full row rank. All these slacks are together with the normal GAMS variables included in x. lo represent the lower bounds defined in GAMS, either implicitly with the Positive Variable declaration, or explicitly with the Var.Lo notation, as well as any bounds on the slacks. Similarly, up represent upper bounds defined in GAMS, e.g. with the Var.Up notation, as well as any bounds on the slacks. g represent the non-constant terms of the GAMS equations themselves; non-constant terms appearing on the right hand side are by GAMS moved to the left hand side and constant terms on the left hand side are moved to the right. The objective function f is simply the GAMS variable to be minimized or maximized.

Additional comments on assumptions and design criteria can be found in the Introduction to the main text.

5.7.8.2 The CONOPT Algorithm

The algorithm used in CONOPT is based on the GRG algorithm first suggested by Abadie and Carpentier (1969). The actual implementation has many modifications to make it efficient for large models and for models written in the GAMS language. Details on the algorithm can be found in Drud (1985 and 1992). Here we will just give a short verbal description of the major steps in a generic GRG algorithm. The later sections in this Appendix will discuss some of the enhancements in CONOPT that make it possible to solve large models.

The key steps in any GRG algorithm are:

1. Initialize and Find a feasible solution.
2. Compute the Jacobian of the constraints, J.
3. Select a set of n basic variables, x_b, such that B, the sub- matrix of basic column from J, is nonsingular. Factorize B. The remaining variables, x_n, are called nonbasic.
4. Solve $B^T u = df/dx_b$ for the multipliers u.
5. Compute the reduced gradient, $r = df/dx - J^T u$. r will by definition be zero for the basic variables.
6. If r projected on the bounds is small, then stop. The current point is close to optimal.
7. Select the set of superbasic variables, x_s, as a subset of the nonbasic variables that profitably can be changed, and find a search direction, d_s, for the superbasic variables based on r_s and possibly on some second order information.
8. Perform a line search along the direction d. For each step, x_s is changed in the direction d_s and x_b is subsequently adjusted to satisfy $g(x_b, x_s) = b$ in a pseudo-Newton process using the factored B from step 3.
9. Go to 2.

The individual steps are of course much more detailed in a practical implementation like CONOPT. Step 1 consists of several pre-processing steps as well as a special Phase 0 and a scaling procedure as described in the following sections Iteration 0: The Initial Point to Finding a Feasible Solution: Phase 0 . The optimizing steps are specialized in several versions according to the whether the model appears to be almost linear or not. For "almost" linear models some of the linear algebra work involving the matrices J and B can be avoided or done using cheap LP-type updating techniques, second order information is not relevant in step 7, and the line search in step 8 can be improved by observing that the optimal step as in LP almost always will be determined by the first variable that reaches a bound. Similarly, when the model appears to be fairly nonlinear other aspects can be optimized: the set of basic variables will often remain constant over several iterations, and other parts of the sparse matrix algebra will take advantage of this (section Finding a Feasible Solution: Phase 1 and 2 and Linear and Nonlinear Mode: Phase 1 to 4). If the model is "very" linear an improved search direction (step 7) can be computed using specialized inner LP-like iterations (section Linear Mode: The SLP Procedure) and a steepest edge procedure can be useful for certain models that needs very many iterations (section Linear Mode: The Steepest Edge Procedure). If the model is "very" nonlinear and has many degrees of freedom an improved search direction (step 7) can be computed using specialized inner SQP-like iterations based on exact second derivatives for the model (section Nonlinear Mode: The SQP Procedure).

The remaining two sections give some short guidelines for selecting non-default options (section How to Select Non-default Options), and discuss miscellaneous topics (section Miscellaneous Topics) such as CONOPT's facilities for strictly triangular models (section Triangular Models) and for square systems of equations, in GAMS represented by the model class called CNS or Constrained Nonlinear System (section Constrained Nonlinear System or Square Systems of Equations), as well as numerical difficulties due to loss of feasibility (section Loss of Feasibility) and slow or no progress due to stalling (section Stalling).

5.7.8.3 Iteration 0: The Initial Point

The first few "iterations" in the iteration log (See section Iteration Output), in the main text for an example) are special initialization iterations, but they have been counted as real iterations to allow the user to interrupt at various stages during initialization. Iteration 0 corresponds to the input point exactly as it was received from GAMS. The sum of infeasibilities in the column labeled "Infeasibility" includes all residuals, also from the objective constraint where "z =e= expression" will give rise to the term Abs(z - expression) that may be nonzero if z has not been initialized. You may stop CONOPT after iteration 0 with `Option IterLim = 0;` in GAMS. The solution returned to GAMS will contain the input point and the values of the constraints in this point. The marginals of both variables and equations have not yet been computed and they will be returned as EPS.

This possibility can be used for debugging when you have a reference point that should be feasible, but is infeasible for unknown reasons. Initialize all variables to their reference values, also all intermediate variables, and call CONOPT with IterLim = 0. Then compute and display the following measures of infeasibility for each block of constraints, represented by the generic name eq:

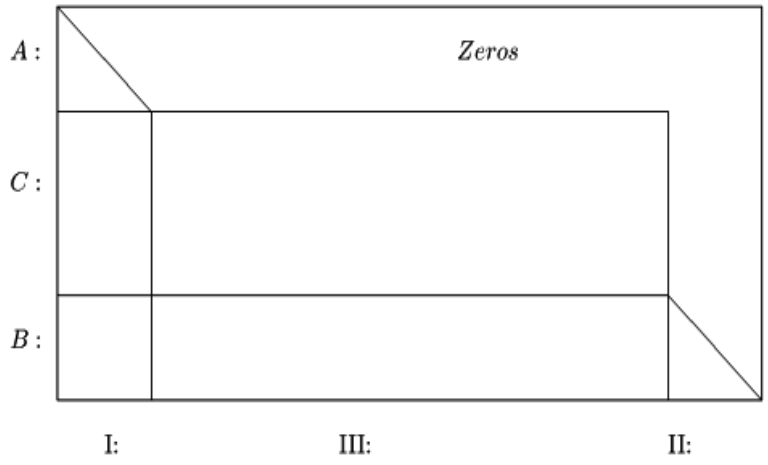
```
=e= constraints: Round(Abs(eq.L - eq.Lo),3)
=l= constraints: Round(Min(0,eq.L - eq.Up),3)
=g= constraints: Round(Min(0,eq.Lo - eq.L),3)
```

The Round function rounds to 3 decimal places so GAMS will only display the infeasibilities that are larger than 5.e-4.

Similar information can be derived from inspection of the equation listing generated by GAMS with `Option LimRow = nn;`, but although the method of going via CONOPT requires a little more work during implementation it can be convenient in many cases, for example for large models and for automated model checking.

5.7.8.4 Iteration 1: Preprocessing

Iteration 1 corresponds to a pre-processing step. Constraint-variable pairs that can be solved a priori (so-called pre-triangular equations and variables) are solved and the corresponding variables are assigned their final values. Constraints that always can be made feasible because they contain a free variable with a constant coefficient (so-called post-triangular equation-variable pairs) are excluded from the search for a feasible solution and from the Infeasibility measure in the iteration log. Implicitly, equations and variables are ordered as shown in Figure 1.



Preprocessing: Pre-triangular Variables and Constraints

The pre-triangular equations are those labeled A in Figure 1. They are solved one by one along the "diagonal" with respect to the pre-triangular variables labeled I. In practice, CONOPT looks for equations with only one non-fixed variable. If such an equation exists, CONOPT tries to solve it with respect to this non-fixed variable. If this is not possible the overall model is infeasible, and the exact reason for the infeasibility is easy to identify as shown in the examples below. Otherwise, the final value of the variable has been determined, the variable can for the rest of the optimization be considered fixed, and the equation can be removed from further consideration. The result is that the model has one equation and one non-fixed variable less. As variables are fixed new equations with only one non-fixed variable may emerge, and CONOPT repeats the process until no more equations with one non-fixed variable can be found.

This pre-processing step will often reduce the effective size of the model to be solved. Although the pre-triangular variables and equations are removed from the model during the optimization, CONOPT keeps them around until the final solution is found. The dual variables for the pre-triangular equations are then computed so they become available in GAMS.

CONOPT has a special option for analyzing and solving completely triangular models. This option is described in section Triangular Models .

The following small GAMS model shows an example of a model with pre-triangular variables and equations:

```
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Log(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
x1.Lo = 0.1;
Model demo / All /; Solve demo using NLP Minimizing obj;
```

Equation e2 is first solved with respect to x2 (result 3/5 = 0.6). It is easy to solve the equation since x2 appears linearly, and the result will be unique. x2 is then fixed and the equation is removed. Equation e1 is now a candidate since x1 is the only remaining non- fixed variable in the equation. Here x1 appears nonlinear and the value of x1 is found using an iterative scheme based on Newton's method. The iterations are started from the value provided by the modeler or from the default initial value. In this case x1 is started from the default initial value, i.e. the lower bound of 0.1, and the result after some iterations is x1 = 2.718 = Exp(1).

During the recursive solution process it may not be possible to solve one of the equations. If the lower bound on x1 in the model above is changed to 3.0 you will get the following output:

```
** An equation in the pre-triangular part of the model cannot
   be solved because the critical variable is at a bound.

   Residual=           9.86122887E-02
   Tolerance (RTNWTR)= 6.34931126E-07

   e1: Infeasibility in pre-triangular part of model.
   x1: Infeasibility in pre-triangular part of model.

   The solution order of the critical equations and
   variables is:

   e2 is solved with respect to
   x2. Solution value =  6.0000000000E-01

   e1 could not be solved with respect to
   x1. Final solution value =  3.0000000000E+00
   e1 remains infeasible with residual = 9.8612288668E-02
```

The problem is as indicated that the variable to be solved for is at a bound, and the value suggested by Newton's method is on the infeasible side of the bound. The critical variable is x1 and the critical equation is e1, i.e. x1 tries to exceed its bound when CONOPT solves equation e1 with respect to x1. To help you analyze the problem, especially for larger models, CONOPT reports the solution sequence that led to the infeasibility: In this case equation e2 was first solved with respect to variable x2, then equation e1 was attempted to be solved with respect to x1 at which stage the problem appeared. To make the analysis easier CONOPT will always report the minimal set of equations and variables that caused the infeasibility.

Another type of infeasibility is shown by the following model:

```
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Sqr(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
Model demo / All /; Solve demo using NLP Minimizing obj;
```

where Log(x1) has been replaced by Sqr(x1) and the lower bound on x1 has been removed. This model gives the message:

```
** An equation in the pre-triangular part of the model cannot
   be solved because of too small pivot.
   Adding a bound or initial value may help.

   Residual=           4.0000000
```

```
Tolerance (RTNWTR)= 6.34931126E-07

e1: Infeasibility in pre-triangular part of model.
x1: Infeasibility in pre-triangular part of model.

The solution order of the critical equations and
variables is:

e2 is solved with respect to
x2. Solution value =  6.0000000000E-01

e1 could not be solved with respect to
x1. Final solution value =  0.0000000000E+00
e1 remains infeasible with residual =-4.0000000000E+00
```

After equation e2 has been solved with respect to x2, equation e1 that contains the term Sqr(x) should be solved with respect to x1. The initial value of x1 is the default value zero. The derivative of e1 with respect to x1 is therefore zero, and it is not possible for CONOPT to determine whether to increase or decrease x1. If x1 is given a nonzero initial value the model will solve. If x1 is given a positive initial value the equation will give x1 = 1, and if x1 is given a negative initial value the equation will give x1 = -1. The last type of infeasibility that can be detected during the solution of the pre-triangular or recursive equations is shown by the following example

```
Variable x1, x2, x3, obj;
Equation e1, e2, e3;
e1 .. Log(x1) + x2 =e= 1.6;
e2 .. 5 * x2 =e= 3;
e3 .. obj =e= Sqr(x1) + 2 * Sqr(x2) + 3 * Sqr(x3);
e4 .. x1 + x2 =e= 3.318;
x1.Lo = 0.1;
Model demo / All /; Solve demo using NLP Minimizing obj;
```

that is derived from the first model by the addition of equation e4. This model produces the following output

```
** An equation is inconsistent with other equations in the
   pre-triangular part of the model.

   Residual=           2.81828458E-04
   Tolerance (RTNWTR)= 6.34931126E-07

   The pre-triangular feasibility tolerance may be relaxed with
   a line:

               SET       RTNWTR    X.XX

   in the CONOPT control program.

   e4: Inconsistency in pre-triangular part of model.

   The solution order of the critical equations and
   variables is:

   e2 is solved with respect to
```

```
x2. Solution value =  6.0000000000E-01

e1 is solved with respect to
x1. Solution value =  2.7182818285E+00

All variables in equation e4 are now fixed
and the equation is infeasible. Residual = 2.8182845830E-04
```

First e2 is solved with respect to x2, then e1 is solved with respect to x1 as indicated by the last part of the output. At this point all variables that appear in equation e4, namely x1 and x2, are fixed, but the equation is not feasible. e4 is therefore inconsistent with e1 and e2 as indicated by the first part of the output. In this case the inconsistency is fairly small, 2.8E-04, so it could be a tolerance problem. CONOPT will always report the tolerance that was used, `rtnwtr` - the triangular Newton tolerance, and if the infeasibility is small it will also tell how the tolerance can be relaxed. Section The CONOPT Options File gives further details on how to change tolerances, and a complete list of options is given in Appendix B.

You can turn the identification and solution of pre-triangular variables and equations off by adding the line `lspret = f` in the CONOPT control program. This can be useful in some special cases where the point defined by the pre-triangular equations gives a function evaluation error in the remaining equations. The following example shows this:

```
Variable x1, x2, x3, x4, obj;
Equation e1, e2, e3, e4;
e1 .. Log(1+x1) + x2 =e= 0;
e2 .. 5 * x2 =e= -3;
e3 .. obj =e= 1*Sqr(x1) + 2*Sqrt(0.01 + x2 - x4) + 3*Sqr(x3);
e4 .. x4 =l= x2;
MOdel fer / All /; Solve fer Minimizing obj using NLP;
```

All the nonlinear functions are defined in the initial point in which all variables have their default value of zero. The pre-processor will compute x2 = -0.6 from e2 and x1 = 0.822 from e1. When CONOPT continues and attempts to evaluate e3, the argument to the Sqrt function is negative when these new triangular values are used together with the initial x4 = 0, and CONOPT cannot backtrack to some safe point since the function evaluation error appears the first time e3 is evaluated. When the pre-triangular preprocessor is turned off, x2 and x4 are changed at the same time and the argument to the Sqrt function remains positive throughout the computations. Note, that although the purpose of the e4 inequality is to guarantee that the argument of the Sqrt function is positive in all points, and although e4 is satisfied in the initial point, it is not satisfied after the pre-triangular constraints have been solved. Only simple bounds are strictly enforced at all times. Also note that if the option `lspret = f` is used then feasible linear constraints will in fact remain feasible.

An alternative (and preferable) way of avoiding the function evaluation error is to define an intermediate variable equal to 0.01+x2-x4 and add a lower bound of 0.01 on this variable. The inequality e4 could then be removed and the overall model would have the same number of constraints.

Preprocessing: Post-triangular Variables and Constraints

Consider the following fragment of a larger GAMS model:

```
Variable util(t)  Utility in period t
         totutil  Total Utility;
Equation utilDef(T) Definition of Utility
         tutilDef   Definition of Total Utility;
utilDef(T).. util(t) =e= nonlinear function of other variables;
tutilDef  .. totutil =e= Sum( t , util(t) / (1+r)**Ord(t) );
Model demo / All /; Solve demo Maximizing totutil using NLP;
```

The part of the model shown here is easy to read and from a modeling point of view it should be considered well written. However, it could be more difficult to solve than a model in which variable util(t) was substituted out because all the utilDef equations are nonlinear constraints that the algorithms must ensure are satisfied.

To make well written models like this easy to solve CONOPT will move as many nonlinearities as possible from the constraints to the objective function. This automatically changes the model from the form that is preferable for the modeler to the form that is preferable for the algorithm. In this process CONOPT looks for free variables that only appear in one equation outside the objective function. If such a variable exists and it appears linearly in the equation, like util(t) appears with coefficient 1 in equation utilDef(t), then the equation can always be solved with respect to the variable. This means that the variable logically can be substituted out of the model and the equation can be removed. The result is a model that has one variable and one equation less, and a more complex objective function. As variables and equations are substituted out, new candidates for elimination may emerge, so CONOPT repeats the process until no more candidates exist.

This so-called post-triangular preprocessing step will often move several nonlinear constraints into the objective function where they are much easier to handle, and the effective size of the model will decrease. In some cases the result can even be a model without any general constraints. The name post-triangular is derived from the way the equations and variables appear in the permuted Jacobian in Figure 1. The post-triangular equations and variables are the ones on the lower right hand corner labeled B and II, respectively.

In the example above, the util variables will be substituted out of the model together with the nonlinear utilDef equations provided the util variables are free and do not appear elsewhere in the model. The resulting model will have fewer nonlinear constraints, but more nonlinear terms in the objective function.

Although you may know that the nonlinear functions on the right hand side of utilDef always will produce positive util values, you should in general not declare util to be a Positive Variable. If you do, CONOPT may not be able to eliminate util(t), and the model will be harder to solve. It is of course unfortunate that a redundant bound changes the solution behavior, and to reduce this problem CONOPT will try to estimate the range of nonlinear expressions using interval arithmetic. If the computed range of the right hand side of the utilDef constraint is within the bounds of util, then these bounds cannot be binding and util is a so-called implied free variable that can be eliminated.

The following model fragment from a least squares model shows another case where the preprocessing step in CONOPT is useful:

```
Variable residual(case)  Residuals
         ssq             Sum of Squared Residuals;
Equation eqEst(case)     Equation to be estimated
         ssqDef          Definition of objective;
eqEst(case).. residual(case) =e= expression in other variables;
SSQDEF     .. ssq =e= Sum( case, Sqr( residual(case) ) );
Model lsqLarge / All /; Solve lsqLarge using NLP Minimizing ssq;
```

CONOPT will substitute the residual variables out of the model using the eqEst equations. The model solved by CONOPT is therefore mathematically equivalent to the following GAMS model

```
Variable ssq     Sum of Squared Residuals;
Equation ssqd    Definition of objective;
Ssqd .. ssq =e= Sum( case, Sqr(expression in other variables));
Model lsqSmall / All /;
Solve lsqSmall using NLP Minimizing ssq;
```

However, if the "expression in other variables" is a little complicated, e.g. if it depends on several variables, then the first model, lsqLarge, will be much faster to generate with GAMS because its derivatives in equation qEst and ssqDef are much simpler than the derivatives in the combined ssqd equation in the second model, lsqSmall. The larger model will therefore be faster to generate, and it will also be faster to solve because the computation of both first and second derivatives will be faster.

Note that the comments about what are good model formulations are dependent on the preprocessing capabilities in CONOPT. Other algorithms may prefer models like lsqSmalL over lsqLarge. Also note that the variables and equations that are substituted out are still indirectly part of the model. CONOPT evaluates the equations and computes values for the variables each time the value of the objective function is needed, and their values are available in the GAMS solution.

It is not necessary to have a coefficient of 1 for the variable to be substituted out in the post-triangular phase. However, a non-zero coefficient cannot be smaller than the absolute pivot tolerance used by CONOPT, `rtpiva`.

The number of pre- and post-triangular equations and variables is printed in the log file between iteration 0 and 1 as shown in the iteration log in section Iteration Output of the main text. The sum of infeasibilities will usually decrease from iteration 0 to 1 because fewer constraints usually will be infeasible. However, it may increase as shown by the following example:

```
Positive Variable x, y, z;
Equation e1, e2;
e1.. x =e= 1;
e2.. 10*x - y + z =e= 0;
```

started from the default values x.L = 0, y.L = 0, and z.L = 0. The initial sum of infeasibilities is 1 (from e1 only). During pre-processing x is selected as a pre-triangular variable in equation e1 and it is assigned its final value 1 so e1 becomes feasible. After this change the sum of infeasibilities increases to 10 (from e2 only).

You may stop CONOPT after iteration 1 with `Option IterLim = 1;` in GAMS. The solution returned to GAMS will contain the pre-processed values for the variables that can be assigned values from the pre-triangular equations, the computed values for the variables used to solve the post-triangular equations, and the input values for all other variables. The pre- and post-triangular constraints will be feasible, and the remaining constraints will have values that correspond to this point. The marginals of both variables and equations have not been computed yet and will be returned as EPS.

The crash procedure described in the following sub-section is an optional part of iteration 1.

Preprocessing: The Optional Crash Procedure

In the initial point given to CONOPT the variables are usually split into a group with initial value provided by the modeler (in the following called the assigned variables) and a group of variables for which no initial value has been provided (in the following called the default variables). The objective of the optional crash procedure is to find a point in which as many of the constraints as possible are feasible, primarily by assigning values to the default variables and by keeping the assigned variables at their initial values. The implicit assumption in this procedure is that if the modeler has assigned an initial value to a variable then this value is "better" then a default initial value.

The crash procedure is an extension of the triangular pre-processing procedure described above and is based on a simple heuristic: As long as there is an equation with only one non-fixed variable (a singleton row) then we should assign a value to the variable so the equation is satisfied or satisfied as closely as possible, and we should then temporarily fix the variable. When variables are fixed additional singleton rows may emerge and we repeat the process. When there are no singleton rows we fix one or more variables at their initial value until a singleton row appears, or until all variables have been fixed. The variables to

be fixed at their initial value are selected using a heuristic that both tries to create many row singletons and tries to select variables with "good values". Since the values of many variables will come to depend in the fixed variables, the procedure favors assigned variables and among these it favors variables that appear in many feasible constraints.

Figure 2 shows a reordered version of Figure 1. The variables labeled IV are the variables that are kept at their initial values, primarily selected from the assigned variables. The equations labeled C are then solved with respect to the variables labeled III, called the crash-triangular variables. The crash-triangular variables will often be variables without initial values, e.g. intermediate variables. The number of crash-triangular variables is shown on the iteration output between iteration 0 and 1, but only if the crash procedure is turned on.

The result of the crash procedure is an updated initial point in which usually a large number of equations will be feasible, namely all equations labeled A, B, and C in Figure 2. There is, as already shown with the small example in Section Preprocessing: Post-triangular Variables and Constraints above, no guarantee that the sum of infeasibilities will be reduced, but it is often the case, and the point will often provide a good starting point for the following procedures that finds an initial feasible solution.

The crash procedure is activated by adding the line `lstcrs=t` in the options file. The default value of `lstcrs` (`lstcrs` = Logical Switch for Triangular Crash) is `f` or `false`, i.e. the crash procedure is not normally used. Before turning the crash procedure on you must turn the definitional equations (see next sub-section) off.

Preprocessing: Definitional Equations

From version 3.16 CONOPT has introduced the concept of Definitional Equations. In section Simple Expressions it was recommended to introduce intermediate variables to simplify complex expressions. If the intermediate variables are free or if the bounds defined by the modeler cannot be binding then we call the constraints that define the intermediate variables "Definitional Equations" and the intermediate variables "Defined Variables". Some models have a large number of definitional equations, and CONOPT tries to recognize them and take advantage of the special structure. Defined variables that only appear in or feed into the objective are recognized as post-triangular variables as discussed in section Preprocessing: Post-triangular Variables and Constraints but defined variables can also be used in the simultaneous constraints. The picture is similar to fig 2. with the C-rows representing the definitional constraints and the III-variables the defined variables. The main differences between crash- triangular variables and defined variable are that (1) defined variables are free or have non-binding bounds and the definitional equations can therefore always be made feasible, (2) defined variables are cheaper to recognize, (3) since they have a natural interpretation, using them is probably more numerical stable, and (4) there are most likely fewer defined variables than crash-triangular variables.

The number of definitional equations is printed in the log file between iteration 0 and 1 if CONOPT finds any. The definitional equations are used to give the defined variables new values, so it is no longer so important the give intermediate variables initial values. In the process the sum of infeasibilities may grow but CONOPT consider it more important to keep these constraints feasible. The defined variables are also made basic and they will most likely stay basic throughout the solution process.

There are three new options introduced to controls the detection of definitional equations: `lsusdf`, `lsuqdf`, and `lfusdf`. They are described in Appendix B. By default CONOPT will only look for unique definitional constraints, but the options allow the user to experiment with a more aggressive strategy.

From version 3.16F there is an additional option, `lmusdf`, used to control how the definitional equations are used during the optimization. The option is summarized in Appendix B. By default, definitional equations are only used to define initial values and an initial basis and their special properties are ignored during the optimization. If there are many definitional equations and they are fairly nonlinear then it can sometimes be beneficial to force the definitional variables to remain basic and to use the definitional equations to compute values for the defined variables in all intermediate trial points. This behavior is turned on with `lmusdf = 1`. The point where `lmusdf = 1` start to pay off depends on the model and the degree of nonlinearity, but a guess is that the number of definitional equations should exceed half the number of equations remaining after the pre- and post-triangular equations have been removed before it is worth while.

Preprocessing and Function evaluation errors

Function evaluation errors may occure during pre-processing is an equation that is a candidate for becoming pre-triangular. Since GAMS requires all functions to be defined in the starting point this can only happen if a previously solved pre-triangular variable has recived new a value that makes the function undefined. An example is:

```
positive variable x1, x2
equation e1, e2;
e1 .. x1 =E= 10;
e2 .. x2 =E= log( 5-x1 );
```

The pre-triangular variable x1 is changed to 10, a value that is inconsistent with equation e2. You can see the changes that CONOPT has made during pre-processing with the option `prprec = true` and this should help identify why the model does not solve.

After identifying and solving the pre-triangular part of the model CONOPT looks for implied bounds, and if an initial variable violates such an implied bound, CONOPT will move it inside the bound. This change can give rise to a function evaluation error in one of the remaining constraints. An example is:

```
positive variable x1, x2, x3, x4;
equation e1, e2;
e1.. x1 + x2 =L= 10;
e2.. x4 =E= log(x1+x3-20);
x1.l = 100; x3.up = 100;
```

From constraint e1 we can derive that both x1 and x2 must have (implied) upper bounds of 10. Since the initial value of x1 is above this implied bound it is changed by the pre-processor. After the pre-processor finishes, e2 will give a function evaluation error. Again, option `prprec = true` will give output that describes the changes in the variables which should help identify the problem.

5.7.8.5 Iteration 2: Scaling

Iteration 2 is the last dummy iteration during which the model is scaled, if scaling is turned on. The default is to turn scaling on. The Infeasibility column shows the scaled sum of infeasibilities. You may again stop CONOPT after iteration 2 with `Option IterLim = 2;` in GAMS, but the solution that is reported in GAMS will have been scaled back again so there will be no change from iteration 1 to iteration 2.

The following description of the automatic scaling procedure is included for completeness. Experiments have so far given mixed results with some advantage for scaling, and scaling is therefore by default turned on, corresponding to the CONOPT option `lsscal = t`. Users are recommended to be cautious with the automatic scaling procedure. If scaling is a problem, try to use manual scaling or scaling in GAMS (see section Scaling in the main text) based on an understanding of the model.

The scaling procedure multiplies all variables in group III and all constraints in group C (see Figure 1) by scale factors computed as follows:

1. CONOPT computes the largest term for each constraint, i. This is defined as the maximum of the constant right hand side, the slack (if any), and Abs(jac(i,j)∗x(j)) where jac(i,j) is the derivative and x(j) is the variable.

2. The constraint scale factor is defined as the largest term in the constraint, projected on the interval `[rtmins, rtmaxs]`. The constraint is then divided by the constraint scale factor. Ignoring the projection, the result is a model in which the largest term in each constraint is exactly 1. The purpose of the projection is to prevent extreme scaling. The default value of `rtmins` is 1 which implies that we do not scale the constraints up. Constraints with only small terms remain unchanged. The default value of `rtmaxs` is 2**30 or around 1.07e9 so terms much larger than 1.e9 are only partially scaled down and will still remain large.

3. The terms Abs(jac(i,j)*x(j)) after constraint scaling measure the importance of each variable in the particular constraint. The variable scale is selected so the largest importance of the variable over all constraints is 1. This gives a very simple variable scale factor, namely the absolute value of the variable. The variable is then divided by the variable scale factor. To avoid extreme scaling we again project on the interval `[rtmins, rtmaxs]`. Variables less than `rtmins` (default 1) are therefore not scaled up and variables over `rtmaxs` (default 2**30 = 1.07e9) are only partially scaled down.

You should note that CONOPT by default scales large numbers down, but it does not scale small numbers up. You should therefore try to avoid having variables or terms in expressions that are small but significant. If this is not possible, allow CONOPT to scale up by giving the option `rtmins` a value less than 1.

All scale factors are rounded down to a power of 2 to preserve precision in the internal computations. To avoid difficulties with rapidly varying variables and derivatives CONOPT recomputes the scale factors at regular intervals (see `lfscal`).

The options that control scaling, `lsscal`, `lfscal`, `rtmins`, and `rtmaxs`, are all described in Appendix B.

5.7.8.6 Finding a Feasible Solution: Phase 0

The GRG algorithm used by CONOPT is a feasible path algorithm. This means that once it has found a feasible point it tries to remain feasible and follow a path of improving feasible points until it reaches a local optimum. CONOPT starts with the point provided by GAMS. This point will always satisfy the bounds (3): GAMS will simply move a variable that is outside its bounds to the nearer bound before it is presented to the solver. If the general constraints (2) also are feasible then CONOPT will work with feasible solutions throughout the optimization. However, the initial point may not satisfy the general constraints (2). If this is not the case, CONOPT must first find an initial feasible point. This first step can be just as hard as finding an optimum for some models. For some models feasibility is the only problem.

CONOPT has two methods for finding an initial feasible point. The first method is not very reliable but it is fast when it works; the second method is reliable but slower. The fast method is called Phase 0 and it is described in this section. It is used first. The reliable method, called Phase 1 and 2, will be used if Phase 0 terminates without a feasible solution.

Phase 0 is based on the observation that Newton's method for solving a set of equations usually is very fast, but it may not always converge. Newton's method in its pure form is defined for a model with the same number of variables as equations, and no bounds on the variables. With our type of model there are usually too many variables, i.e. too many degrees of freedom, and there are bounds. To get around the problem of too many variables, CONOPT selects a subset with exactly m "basic" variables to be changed. The rest of the variables will remain fixed at their current values, that are not necessarily at bounds. To accommodate the bounds, CONOPT will try to select variables that are away from their bounds as basic, subject to the requirement that the Basis matrix, consisting of the corresponding columns in the Jacobian, must have full rank and be well conditioned.

The Newton equations are solved to yield a vector of proposed changes for the basic variables. If the full proposed step can be applied we can hope for the fast convergence of Newton's method. However, several things may go wrong:

1. The infeasibilities, measured by the 1-norm of g (i.e. the sum of the absolute infeasibilities, excluding the pre- and post-triangular equations), may not decrease as expected due to nonlinearities.

2. The maximum step length may have to be reduced if a basic variable otherwise would exceed one of its bounds.

In case 1. CONOPT tries various heuristics to find a more appropriate set of basic variables. If this does not work, some "difficult" equations, i.e. equations with large infeasibilities and significant nonlinearities, are temporarily removed from the model, and Newton's method is applied to the remaining set of "easy" equations.

In case 2. CONOPT will remove the basic variable that first reaches one of its bounds from the basis and replace it by one of the nonbasic variables. Newton's method is then applied to the new set of basic variables. The logic is very close to that of the dual simplex method. In cases where some of the basic variables are exactly at a bound CONOPT uses an anti degeneracy procedure based on Ryan and Osborne (1988) to prevent cycling.

Phase 0 will end when all equations except possibly some "difficult" equations are feasible within some small tolerance. If there are no difficult equations, CONOPT has found a feasible solution and it will proceed with Phase 3 and 4. Otherwise, Phase 1 and 2 is used to make the difficult equations feasible.

The iteration output will during Phase 0 have the following columns in the iteration log: Iter, Phase, Ninf, Infeasibility, Step, MX, and OK. The number in the Ninf column counts the number of "difficult" infeasible equations, and the number in the Infeasibility column shows the sum of the absolute infeasibilities in all the general constraints, both in the easy and in the difficult ones. There are three possible combinations of values in the MX and OK columns: combination (1) has F in the MX column and T in the OK column and it will always be combined with 1.0 in the Step column: this is an ideal Newton step. The infeasibilities in the easy equations should be reduced quickly, but the difficult equations may dominate the number in the Infeasibility column so you may not observe it. However, a few of these iterations is usually enough to terminate Phase 0. Combination (2) has T in the MX column indicating that a basic variable has reached its bound and is removed from the basis as in case 2. above. This will always be combined with T in the OK column. The Step column will show a step length less than the ideal Newton step of 1.0. Combination (3) has F in both the MX and OK column. It is the bad case and will always be combined with a step of 0.0: this is an iteration where nonlinearities are dominating and one of the heuristics from case 1. must be used.

The success of the Phase 0 procedure is based on being able to choose a good basis that will allow a full Newton step. It is therefore important that as many variables as possible have been assigned reasonable initial values so CONOPT has some variables away from their bounds to select from. This topic was discussed in more detail in section Initial Values .

The start and the iterations of Phase 0 can, in addition to the crash option described in section Finding a Feasible Solution: Phase 0 be controlled with the three options `lslack`, `lsmxbs`, and `lmmxsf` described in Appendix B.

5.7.8.7 Finding a Feasible Solution: Phase 1 and 2

Most of the equations will be feasible when phase 0 stops. To remove the remaining infeasibilities CONOPT uses a procedure similar to the phase 1 procedure used in Linear Programming: artificial variables are added to the infeasible equations (the equations with Large Residuals), and the sum of these artificial variables is minimized subject to the feasible constraints remaining feasible. The artificial variable are already part of the model as slack variables; their bounds are simply relaxed temporarily.

This infeasibility minimization problem is similar to the overall optimization problem: minimize an objective function subject to equality constraints and bounds on the variables. The feasibility problem is therefore solved with the ordinary GRG optimization procedure. As the artificial variables gradually become zero, i.e. as the infeasible equations become feasible, they are taken out of the auxiliary objective function. The number of infeasibilities (shown in the Ninf column of the log file) and the sum of infeasibilities (in the Infeasibility column) will therefore both decrease monotonically.

The iteration output will label these iterations as phase 1 and/or phase 2. The distinction between phases 1 (linear mode) and 2 (nonlinear mode) is similar to the distinction between phases 3 and 4, which are described in the next sections.

5.7.8.8 Linear and Nonlinear Mode: Phase 1 to 4

The optimization itself follows step 2 to 9 of the GRG algorithm shown in The CONOPT Algorithm above. The factorization in step 3 is performed using an efficient sparse LU factorization similar to the one described by Suhl and Suhl (1990). The matrix operations in step 4 and 5 are also performed sparse.

Step 7, selection of the search direction, has several variants, depending on how nonlinear the model is locally. When the model appears to be fairly linear in the area in which the optimization is performed, i.e. when the function and constraint values are close to their linear approximation for the steps that are taken, then CONOPT takes advantages of the linearity: The derivatives (the Jacobian) are not computed in every iteration, the basis factorization is updated using cheap LP techniques as described by Reid (1982), the search direction is determined without use of second order information, i.e. similar to a steepest descend algorithm, and the initial steplength is estimated as the step length where the first variable reaches a bound; very often, this is the only step length that has to be evaluated. These cheap almost linear iterations are referred to a Linear Mode and they are labeled Phase 1 when the model is infeasible and objective is the sum of infeasibilities and Phase 3 when the model is feasible and the real objective function is optimized.

When the constraints and/or the objective appear to be more nonlinear CONOPT will still follow step 2 to 9 of the GRG algorithm. However, the detailed content of each step is different. In step 2, the Jacobian must be recomputed in each iteration since the nonlinearities imply that the derivatives change. On the other hand, the set of basic variables will often be the same and CONOPT will take advantage of this during the factorization of the basis. In step 7 CONOPT uses the BFGS algorithm to estimate second order information and determine search directions. And in step 8 it will often be necessary to perform more than one step in the line search. These nonlinear iterations are labeled Phase 2 in the output if the solution is still infeasible, and Phase 4 if it is feasible. The iterations in phase 2 and 4 are in general more expensive than the iteration in phase 1 and 3.

Some models will remain in phase 1 (linear mode) until a feasible solution is found and then continue in phase 3 until the optimum is found, even if the model is truly nonlinear. However, most nonlinear models will have some iterations in phase 2 and/or 4 (nonlinear mode). Phase 2 and 4 indicates that the model has significant nonlinear terms around the current point: the objective or the constraints deviate significantly from a linear model for the steps that are taken. To improve the rate of convergence CONOPT tries to estimate second order information in the form of an estimated reduced Hessian using the BFGS formula.

Each iteration is, in addition to the step length shown in column "Step", characterized by two logicals: MX and OK. MX = T means that the step was maximal, i.e. it was determined by a variable reaching a bound. This is the expected value in Phase 1 and 3. MX = F means that no variable reached a bound and the optimal step length will in general be determined by nonlinearities. OK = T means that the line search was well-behaved and an optimal step length was found; OK = F means that the line search was ill-behaved, which means that CONOPT would like to take a larger step, but the feasibility restoring Newton process used during the line search did not converge for large step lengths. Iterations marked with OK = F (and therefore also with MX = F) will usually be expensive, while iterations marked with MX = T and OK = T will be cheap.

5.7.8.9 Linear Mode: The SLP Procedure

When the model continues to appear linear CONOPT will often take many small steps, each determined by a new variable reaching a bound. Although the line searches are fast in linear mode, each require one or more evaluations of the nonlinear constraints, and the overall cost may become high relative to the progress. In order to avoid the many nonlinear constraint evaluations CONOPT may replace the steepest descend direction in step 7 of the GRG algorithm with a sequential linear programming (SLP) technique to find a search direction that anticipates the bounds on all variables and therefore gives a larger expected change in objective in each line search. The search direction and the last basis from the SLP procedure are used in an ordinary GRG-type line search in which the solution is made feasible at each step. The

SLP procedure is only used to generate good directions; the usual feasibility preserving steps in CONOPT are maintained, so CONOPT is still a feasible path method with all its advantages, especially related to reliability.

Iterations in this so-called SLP-mode are identified by numbers in the column labeled `InItr` in the iteration log. The number in the InItr column is the number of non- degenerate SLP iterations. This number is adjusted dynamically according to the success of the previous iterations and the perceived linearity of the model.

The SLP procedure generates a scaled search direction and the expected step length in the following line search is therefore 1.0. The step length may be less than 1.0 for several reasons:

- The line search is ill-behaved. This is indicated with OK = F and MX = F.
- A basic variable reaches a bound before predicted by the linear model. This is indicated with MX = T and OK = T.
- The objective is nonlinear along the search direction and the optimal step is less than one. This is indicated with OK = T and MX = F.

CONOPT will by default determine if it should use the SLP procedure or not, based on progress information. You may turn it off completely with the line `lseslp = f` in the CONOPT options file (usually *conopt.opt*). The default value of `lseslp` (`lseslp` = Logical Switch Enabling SLP mode) is `t` or `true`, i.e. the SLP procedure is enabled and CONOPT may use it when considered appropriate. It is seldom necessary to define `lseslp`, but it can be useful if CONOPT repeatedly turns SLP on and off, i.e. if you see a mixture of lines in the iteration log with and without numbers in the `InItr` column.

5.7.8.10 Linear Mode: The Steepest Edge Procedure

When optimizing in linear mode (Phase 1 or 3) CONOPT will by default use a steepest descend algorithm to determine the search direction. CONOPT allows you to use a Steepest Edge Algorithm as an alternative. The idea, borrowed from Linear Programming, is to scale the nonbasic variables according to the Euclidean norm of the "updated column" in a standard LP tableau, the so-called edge length. A unit step for a nonbasic variable will give rise to changes in the basic variables proportional to the edge length. A unit step for a nonbasic variable with a large edge length will therefore give large changes in the basic variables which has two adverse effects relative to a unit step for a nonbasic variable with a small edge length: a basic variable is more likely to reach a bound after a very short step length, and the large change in basic variables is more likely to give rise to larger nonlinear terms.

The steepest edge algorithm has been very successful for linear programs, and our initial experience has also shown that it will give fewer iterations for most nonlinear models. However, the cost of maintaining the edge lengths can be more expensive in the nonlinear case and it depends on the model whether steepest edge results in faster overall solution times or not. CONOPT uses the updating methods for the edge lengths from LP, but it must re-initialize the edge lengths more frequently, e.g. when an inversion fails, which happens more frequently in nonlinear models than in linear models, especially in models with many product terms, e.g. blending models, where the rank of the Jacobian can change from point to point.

Steepest edge is turned on with the line, `lsanrm = t`, in the CONOPT options file (usually *conopt.opt*). The default value of `lsanrm` (`lsanrm` = Logical Switch for A- Norm) is `f` or `false`, i.e. the steepest edge procedure is turned off.

The steepest edge procedure is mainly useful during linear mode iterations. However, it has some influence in phase 2 and 4 also: The estimated reduced Hessian in the BFGS method is initialized to a diagonal matrix with elements on the diagonal computed from the edge lengths, instead of the usual scaled unit matrix.

5.7.8.11 Nonlinear Mode: The SQP Procedure

When progress is determined by nonlinearities CONOPT needs second order information. Some second order information can be derived from the line search and is used in the first iterations in Phase 2 or 4. Depending on progress, CONOPT may switch to a Sequential Quadratic Programming (SQP) procedure that works on a sub-model with linear constraints and a quadratic objective function. The constraints are a linearization of the nonlinear constraints, and the objective function is derived from the Hessian of the Lagrangian function. CONOPT will inside the SQP procedure use exact second order information computed by GAMS. The result of the SQP procedure is a search direction and a basis and CONOPT will afterwards use the same line search procedure and feasibility preserving steps as after the SLP procedure. CONOPT remains a feasible path method with all its advantages, especially related to reliability.

Iterations in this so-called SQP-mode are identified by numbers in the column labeled "InItr" in the iteration log. The number in the InItr column is the number of non-degenerate SQP iterations. The effort spend inside the SQP procedure is adjusted dynamically according to the success of the previous iterations and the reduction in reduced gradient in the quadratic model.

The SQP procedure generates a scaled search direction and the expected step length in the following line search is therefore 1.0. The step length may be less than 1.0 for several reasons:

- The line search is ill-behaved. This is indicated with OK = F and MX = F.
- A basic variable reaches a bound before predicted by the linear model of the constraints. This is indicated with MX = T and OK = T.
- The objective is much more nonlinear along the search direction than expected and the optimal step is not one. This is indicated with OK = T and MX = F.

CONOPT will by default determine if it should use the SQP procedure or not, based on progress information. You may turn it off completely with the line `lsesqp = f` in the CONOPT options file (usually `conopt.opt`). The default value of `lsesqp` (lsesqp = Logical Switch Enabling SQP mode) is `t` or `true`, i.e. the SQP procedure is enabled and CONOPT may use it when considered appropriate. It is seldom necessary to define `lsesqp`, but it can be used for experimentation.

In connection with 1st and 2nd derivatives the listing file (∗.lst) will have a few extra lines. The first looks as follows:

```
The model has 537 variables and 457 constraints
with 1597 Jacobian elements, 380 of which are nonlinear.
The Hessian of the Lagrangian has 152 elements on the diagonal,
228 elements below the diagonal, and 304 nonlinear variables.
```

The first two lines repeat information given in the GAMS model statistics and the last two lines describe second order information. CONOPT uses the matrix of second derivatives (the Hessian) of a linear combination of the objective and the constraints (the Lagrangian). The Hessian is symmetric and the statistics show that it has 152 elements on the diagonal and 228 below for a total of 380 elements in this case. This compares favorably to the number of elements in the matrix of first derivatives (the Jacobian).

For some models you may see the following message instead (before the usual CONOPT banner):

```
** Warning **  Memory Limit for Hessians exceeded.
You can use the Conopt option "rvhess"
```

The creation of the matrix of second derivatives has been interrupted because the matrix became too dense. A dense matrix of second derivatives will be slow to compute and it will need a lot of memory. In addition, it is likely that a dense Hessian will make some of the computations inside the SQP iterations so slow that the potential saving in number of iterations is used up computing and manipulating the Hessian.

CONOPT can use second derivatives even if the Hessian is not available. A special version of the function evaluation routine can compute the Hessian multiplied by a vector (the so-called directional second derivative) without computing the Hessian itself. This routine is used when the Hessian is not available. The directional second derivative approach will require one directional second derivative evaluation call per inner SQP iteration instead of one Hessian evaluation per SQP sub-model.

If you get the "Memory Limit for Hessians exceeded" message you may consider rewriting some equation. Look for nonlinear functions applied to long linear or separable expressions such as log(sum(i,x(i)); as discussed in Section Simple Expressions . An expression like this will create a dense Hessian with card(i) rows and columns. You should consider introducing an intermediate variable that is equal to the long linear or separable expression and then apply the nonlinear function to this single variable. You may also experiment with allocating more memory for the dense Hessian and use it despite the higher cost; it may reduce the number of iterations. This can be done by adding the option `rvhess = XX` to the CONOPT options file. rvhess is a memory factor with default value 10 so you need a larger value. The value 0.0 is special; it means do not impose a memory limit on the Hessian.

The time spend on the many types of function and derivative evaluations are reported in the listing file in a section like this:

```
CONOPT time Total                            0.734 seconds
  of which: Function evaluations             0.031 =  4.3%
            1st Derivative evaluations       0.020 =  2.7%
            2nd Derivative evaluations       0.113 = 15.4%
            Directional 2nd Derivative       0.016 =  2.1%
```

The function evaluations are computations of the nonlinear terms in the model, and 1st Derivatives evaluations are computations of the Jacobian of the model. 2nd Derivative evaluations are computations of the Hessian of the Lagrangian, and Directional 2nd derivative evaluations are computations of the Hessian multiplied by a vector, computed without computing the Hessian itself. The lines for 2nd derivatives will only be present if CONOPT has used this type of 2nd derivative.

If your model is not likely to benefit from 2nd derivative information or if you know you will run out of memory anyway you can save a small setup cost by telling CONOPT not to generate it using option `dohess = f`.

5.7.8.12 How to Select Non-default Options

The non-default options have an influence on different phases of the optimization and you must therefore first observe whether most of the time is spend in Phase 0, Phase 1 and 3, or in Phase 2 and 4.

Phase 0: The quality of Phase 0 depends on the number of iterations and on the number and sum of infeasibilities after Phase 0. The iterations in Phase 0 are much faster than the other iterations, but the overall time spend in Phase 0 may still be rather large. If this is the case, or if the infeasibilities after Phase 0 are large you may try to use the triangular crash options:

```
lstcrs = t
```

Observe if the initial sum of infeasibility after iteration 1 has been reduced, and if the number of phase 0 iterations and the number of infeasibilities at the start of phase 1 have been reduced. If lstcrs reduces the initial sum of infeasibilities but the number of iterations still is large you may try:

```
lslack = t
```

CONOPT will after the preprocessor immediately add artificial variables to all infeasible constraints so Phase 0 will be eliminated, but the sum and number of infeasibilities at the start of Phase 1 will be larger. You are in reality trading Phase 0 iterations for Phase 1 iterations.

You may also try the experimental bending line search with

```
lmmxsf = 1
```

The line search in Phase 0 will with this option be different and the infeasibilities may be reduced faster than with the default `lmmxsf = 0`. It is likely to be better if the number of iterations with both MX = F and OK∼=∼F is large. This option may be combined with `lstcrs = t`. Usually, linear constraints that are feasible will remain feasible. However, you should note that with the bending linesearch linear feasible constraints could become infeasible.

Phase 1 and 3: The number of iterations in Phase 1 and Phase 3 will probably be reduced if you use steepest edge, `lsanrm = t`, but the overall time may increase. Steepest edge seems to be best for models with less than 5000 constraints, but work in progress tries to push this limit upwards. Try it when the number of iterations is very large, or when many iterations are poorly behaved identified with OK = F in the iteration log. The default SLP mode is usually an advantage, but it is too expensive for a few models. If you observe frequent changes between SLP mode and non-SLP mode, or if many line searches in the SLP iterations are ill-behaved with OK = F, then it may be better to turn SLP off with `lseslp = f`.

Phase 2 and 4: There are currently not many options available if most of the time is spend in Phase 2 and Phase 4. If the change in objective during the last iterations is very small, you may reduce computer time in return for a slightly worse objective by reducing the optimality tolerance, `rtredg`.

5.7.8.13 Miscellaneous Topics

Triangular Models

A triangular model is one in which the non-fixed variables and the equations can be sorted such that the first equation only depends on the first variable, the second equation only depends on the first two variables, and the p-th equation only depends on the first p variables. Provided there are no difficulties with bounds or small pivots, triangular models can be solved one equation at a time using the method describe in section Preprocessing: Pre-triangular Variables and Constraints and the solution process will be very fast and reliable.

Triangular models can in many cases be useful for finding a good initial feasible solution: Fix a subset of the variables so the remaining model is known to be triangular and solve this triangular simulation model. Then reset the bounds on the fixed variables to their original values and solve the original model. The first solve will be very fast and if the fixed variables have been fixed at good values then the solution will also be good. The second solve will start from the good feasible solution generated by the first solve and it will usually optimize much more quickly than from a poor start.

The modeler can instruct CONOPT that a model is supposed to be triangular with the option `lstria = t`. CONOPT will then use a special version of the preprocessing routine (see section Preprocessing: Pre-triangular Variables and Constraints) that solves the model very efficiently. If the model is solved successfully then CONOPT terminates with the message:

```
** Feasible solution to a recursive model.
```

and the Model Status will be 2, Locally Optimal, or 1, Optimal, depending on whether there were any nonlinear pivots or not. All marginals on both variables and equations are returned as 0 (zero) or EPS.

Two SOLVEs with different option files can be arranged by writing the option files as they are needed from within the GAMS program with PUT statements followed by a PutClose. You can also have two different option files, e.g., *conopt.opt* and *conopt.op2*, and select the second with the GAMS statement `<model>.OptFile = 2;`.

The triangular facility handles a number of error situations:

1. Non-triangular models: CONOPT will ensure that the model is indeed triangular. If it is not, CONOPT will return model status 5, Locally Infeasible, plus some information that allows the modeler to identify the mistake. The necessary information is related to the order of the variables and equations and number of occurrences of variables and equations, and since GAMS does no have a natural place for this type of information CONOPT returns it in the marginals of the equations and variables. The solution order for the triangular equations and variables that have been solved successfully are defined with positive numbers in the marginals of the equations and variables. For the remaining non- triangular variables and equations CONOPT shows the number of places they appear as negative numbers, i.e. a negative marginal for an equation shows how many of the non-triangular variables that appear in this equation. You must fix one or more variables until at least one of the non-triangular equation only has one non-fixed variable left.

2. Infeasibilities due to bounds: If some of the triangular equations cannot be solved with respect to their variable because the variable will exceed the bounds, then CONOPT will flag the equation as infeasible, keep the variable at the bound, and continue the triangular solve. The solution to the triangular model will therefore satisfy all bounds and almost all equations. The termination message will be

   ```
   ** Infeasible solution. xx artificial(s) have been
      introduced into the recursive equations.
   ```

   and the model status will be 5, Locally Infeasible.
   The modeler may in this case add explicit artificial variables with high costs to the infeasible constraints and the resulting point will be an initial feasible point to the overall optimization model. You will often from the mathematics of the model know that only some of the constraints can be infeasible, so you will only need to check whether to add artificials in these equations. Assume that a block of equations matbal(m,t) could become infeasible. Then the artificials that may be needed in this equation can be modeled and identified automatically with the following GAMS constructs:

   ```
   Set aposart(m,t) Add a positive artificial in Matbal
       anegart(m,t) Add a negative artificial in Matbal;
   aposart(m,t) = No; anegart(m,t) = No;

   Positive Variable
       vposart(m,t) Positive artificial variable in Matbal
       vnegart(m,t) Negative artificial variable in Matbal;

   matbal(m,t).. Left hand side =e= right hand side
      + vposart(m,t)$aposart(m,t) - vnegart(m,t)$anegart(m,t);

   objDef.. obj =e= other_terms +
            weight * Sum((m,t), vposart(m,t)$aposart(m,t)
                               +vnegart(m,t)$anegart(m,t) );

   Solve triangular model ...

   aposart(m,t)$(matbal.l(m,t) > matbal.Up(m,t)) = Yes;
   anegart(m,t)$(matbal.l(m,t) < matbal.Lo(m,t)) = Yes;

   Solve final model ...
   ```

3. Small pivots: The triangular facility requires the solution of each equation to be locally unique which also means that the pivots used to solve each equation must be nonzero. The model segment

```
e1 .. x1 =e= 0;
e2 .. x1 * x2 =e= 0;
```

will give the message

```
   x2 appearing in
   e2: Pivot too small for triangular model. Value=0.000E+00

** Infeasible solution. The equations were assumed to be
   recursive but they are not. A pivot element is too small.
```

However, the uniqueness of x2 may not be relevant if the solution just is going to be used as an initial point for a second model. The option `lsismp = t` (for Logical Switch: Ignore Small Pivots) will allow zero pivots as long as the corresponding equation is feasible for the given initial values.

Constrained Nonlinear System or Square Systems of Equations

There is a special model class in GAMS called CNS - Constrained Nonlinear System. A constrained nonlinear system is a square system of equations, i.e. a model in which the number of non-fixed variables is equal to the number of constraints. Currently, CONOPT and PATH are the only solvers with special treatment for this model class. A CNS model can be solved with a solve statement like

```
Solve <model> using CNS;
```

without an objective term. In some cases it may be convenient to solve a CNS model with a standard solve statement combined with an options file that has the statement `lssqrs = t`. In the latter case, CONOPT will check that the number of non-fixed variables is equal to the number of constraints. In either case, CONOPT will attempt to solve the constraints with respect to the non-fixed variables using Newton's method. The solution process does not include a lot of the safeguards used for ordinary NLP models and when it work it is often very fast and it uses less memory than for the corresponding NLP model. The lack of safeguards means that the solution process just will stop with an error message in some difficult situations and return the current intermediate infeasible solution. Examples of difficulties are that the Jacobian to be inverted is singular, or if one of the non-fixed variables tries to move outside their bounds as described with examples below.

Slacks in inequalities are counted as non-fixed variables which effectively means that inequalities should not be binding. Bounds on the variables are allowed, especially to prevent function evaluation errors for functions that only are defined for some arguments, but the bounds should not be binding in the final solution.

The solution returned to GAMS will in all cases have marginal values equal to 0 or EPS, both for the variables and the constraints.

The termination messages for CNS models are different from the termination messages for optimization models. The message you hope for is

```
** Feasible solution to a square system.
```

that usually will be combined with model status 16-Solved. If CONOPT in special cases can guarantee that the solution is unique, for example if the model is linear, then the model status will be 15-Solved Unique.

There are two potential error termination messages related to CNS models. A model with the following two constraints

```
e1 ..   x1 +   x2 =e= 1;
e2 .. 2*x1 + 2*x2 =e= 2;
```

will result in the message

```
** Error in Square System: Pivot too small.
    e2: Pivot too small.
    x1: Pivot too small.
```

"Pivot too small" means that the set of constraints is linearly dependent in the current point and there is no unique search direction for Newtons method so CONOPT terminates. The message points to one variable and one constraint. However, this just indicates that the linearly dependent set of constraints and variables include the constraint and variable mentioned. The offending constraint and variable will also be labeled 'DEPND' for linearly dependent in the equation listing. The error will usually be combined with model status 5 - Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities the model status will be 4 - Infeasible. If the constraints are linearly dependent but the current point satisfy the constraints then the solution status will be 17 - Solved Singular, indicating that the point is feasible, but there is probably a whole ray of feasible solution through the current point.

It should be mentioned that the linear dependency and small pivot could be caused by the initial point and that the model could have a solution. An example is

```
e1.. x1*x2 =E= 1;
e2.. x1+x2 =E= 3;
x1.l = 1; x2.l = 1;
```

A model with these two constraints and the bound

```
e1 .. x1 + x2 =e= 2;
e2 .. x1 - x2 =e= 0;
x1.lo = 1.5;
```

will result in the message

```
** Error in Square System: A variable tries to exceed its bound.
    x1: The variable tries to exceed its bound.
```

because the solution, (x1,x2) = (1,1) violates the bound on x1. This error case will also be combined with model status 5-Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities the model status will be 4 - Infeasible. If you encounter problems with active bounds but you think it is caused by nonlinearities and that there is a solution, then you may try to use the bending linesearch with option `lmmxsf = t`.

The CNS facility can be used to generate an initial feasible solution in almost the same way as the triangular model facility: Fix a subset of the variables so the remaining model is uniquely solvable, solve this model with the CNS solver or with `lssqrs = t`, reset the bounds on the fixed variables, and solve the original model. The CNS facility can be used on a larger class of models that include simultaneous sets of equations. However, the square system must be non-singular and feasible; CONOPT cannot, like in the triangular case, add artificial variables to some of the constraints and solve the remaining system when a variable reaches one of its bounds.

Additional information on CNS can be found in the GAMS User's Guide.

Loss of Feasibility

During the optimization you may sometimes see a phase 0 iteration and in rare cases you will see the message "Loss of Feasibility - Return to Phase 0". The background for this is as follows:

To work efficiently, CONOPT uses dynamic tolerances for feasibility and during the initial part of the optimization where the objective changes rapidly fairly large infeasibilities may be acceptable. As the change in objective in each iteration becomes smaller it will be necessary to solve the constraints more accurately so the "noise" in objective value from the inaccurate constraints will remain smaller than the real change. The noise is measured as the scalar product of the constraint residuals with the constraint marginals.

Sometimes it is necessary to revise the accuracy of the solution, for example because the algorithmic progress has slowed down or because the marginal of an inaccurate constraint has grown significantly after a basis change, e.g. when an inequality becomes binding. In these cases CONOPT will tighten the feasibility tolerance and perform one or more Newton iterations on the basic variables. This will usually be very quick and it happens silently. However, Newton's method may fail, for example in cases where the model is degenerate and Newton tries to move a basic variable outside a bound. In this case CONOPT uses some special iteration similar to those discussed in section Finding a Feasible Solution: Phase 0 and they are labeled Phase 0.

These Phase 0 iterations may not converge, for example if the degeneracy is significant, if the model is very nonlinear locally, if the model has many product terms involving variables at zero, or if the model is poorly scaled and some constraints contain very large terms. If the iterations do not converge, CONOPT will issue the "Loss of feasibility ..." message, return to the real Phase 0 procedure, find a feasible solution with the smaller tolerance, and resume the optimization.

In rare cases you will see that CONOPT cannot find a feasible solution after the tolerances have been reduced, even though it has declared the model feasible at an earlier stage. We are working on reducing this problem. Until a final solution has been implemented you are encouraged to (1) consider if bounds on some degenerate variables can be removed, (2) look at scaling of constraints with large terms, and (3) experiment with the two feasibility tolerances, `rtnwma` and `rtnwmi` (see Appendix B), if this happens with your model.

Stalling

CONOPT will usually make steady progress towards the final solution. A degeneracy breaking strategy and the monotonicity of the objective function in other iterations should ensure that CONOPT cannot cycle. Unfortunately, there are a few places in the code where the objective function may move in the wrong direction and CONOPT may in fact cycle or move very slowly.

The objective value used to compare two points, in the following called the adjusted objective value, is computed as the true objective plus a noise adjustment term equal to the scalar product of the residuals with the marginals (see section Loss of Feasibility where this noise term also is used). The noise adjustment term is very useful in allowing CONOPT to work smoothly with fairly inaccurate intermediate solutions. However, there is a disadvantage: the noise adjustment term can change even though the point itself does not change, namely when the marginals change in connection with a basis change. The adjusted objective is therefore not always monotone. When CONOPT looses feasibility and returns to Phase 0 there is an even larger chance of non-monotone behavior.

To avoid infinite loops and to allow the modeler to stop in cases with very slow progress CONOPT has an anti-stalling option. An iteration is counted as a stalled iteration if it is not degenerate and (1) the adjusted objective is worse than the best adjusted objective seen so far, or (2) the step length was zero without being degenerate (see OK = F in section Linear and Nonlinear Mode: Phase 1 to 4). CONOPT will stop if the number of consecutive stalled iterations (again not counting degenerate iterations) exceeds `lfstal` and `lfstal` is positive. The default value of `lfstal` is 100. The message will be:

```
** Feasible solution. The tolerances are minimal and
   there is no change in objective although the reduced
   gradient is greater than the tolerance.
```

Large models with very flat optima can sometimes be stopped prematurely due to stalling. If it is important to find a local optimum fairly accurately then you may have to increase the value of `lfstal`.

Overflow and NaN (Not A Number)

Very large values or overflow can appear in a number of places. CONOPT cannot use these values in the optimization since the results would be unreliable or useless. CONOPT is therefore trying to detect these values and take appropriate action.

Even though most modern computers can work with numbers from 1.e-300 to 1.e+300 CONOPT considers all numbers that are larger than 1.e40 or NaN to be 'bad' and useles. NaN means Not A Number and includes Infinity and Real Overflow.

Bad numbers can have two sources. They can come from the modeler expressions or they can be generated internally in CONOPT. The nonlinear constraints or the derivatives of these constraints may return very large values. If a constraint returns a bad number you will see a message like

```
** A function value is very large or NaN (Not a Number).
   Add bound to ensure that the function values are defined and bounded.
```

and if a derivatives returns a bad number the message will be something like

```
** A derivative is very large or NaN (Not a Number).
   Add bound to ensure that the derivatives are defined and bounded.
```

The modeler must in both cases adjust the model to prevent that CONOPT receives these bad numbers so CONOPT stops immediately.

Bad numbers can also in rare cases appear as a result of computations inside CONOPT. Since all primal variables and all derivatives are bounded the bad numbers can only appear as a result of operations involving the factorization of the basis matrix, including the dual variables. You will in this case see a message like

```
** Overflow or Nan (Not A Number) has been encountered indicating
   numerical difficulties. Trying to repair by increasing the
   absolute and relative pivot tolerances (Rtpiva and Rvpivr)
   and allowing small values to be scaled up by decreasing
   the minimum scale factor, Rtmins.
```

Since the source of the problem is the factorization of the basis CONOPT will adjust the tolerances that are used while computing this factorization. Essentially, we must avoid very small pivots and the pivoting tolerances are therefore increased. The source of very small pivots can also be constraints were all terms are very small so CONOPT will also change the minimum scaling factor to try to avoid this source. CONOPT will continue the optimization after changing the tolerances and if the problem appears again if will change the tolerances even more, but since there is a limit to how much they can be adjusted CONOPT may have to give up and it will happen with this message

```
** Overflow or Nan (Not A Number) continues to be encountered
   after multiple attempt to repair by changed tolerances.
   CONOPT will give up.
```

The termination message will in this case be

```
** Feasible solution. The solution process has been terminated
   because intermediate results have become NaN (Not A Number).
```

or

```
** Feasible solution. The solution process has been terminated
   because intermediate results have become NaN (Not A Number).
```

If you encounter messages with NaN it is always a problem with scaling or structure. The most likely source is constraints with only small terms. Try to avoid them by scaling the variables and constraints appropriately, or try to use option `rtmins`. Or make CONOPT ignore these constraints by using a larger absolute pivot tolerance, `rtpiva`.

Another source are structured models with long chains of relationships. These models will usually have lags or leads and neighboring variables are related with a factor different from one, i.e.

```
dyn(i).. x(i) =e= x(i-1)*1.5 + u(i);
```

or

```
dif(i).. 2*x(i) =e= x(i-1) + x(i+1) + u(i);
```

CONOPT will try to solve the constraints in the proper order to avoid exploding variables, but a larger relative pivot tolerance, `rtpivr`, may also help. If you have a dynamic model and the variables are supposed to grow rapidly over time then you may consider having a scale factor that also grows with time.

External Equations and Extrinsic Functions

CONOPT can be used with external equations and extrinsic functions written in a programming language such as Fortran or C. Additional information is available in the GAMS User's Guide External Equations and Extrinsic Functions.

Extrinsic functions can be debugged using the function suffixes `gradn` and `hessn` which use finite differences to approximate the gradient and Hessian using multiple function calls. For details check model **derivtst** in the GAMS Model Library. If external equations are present CONOPT will automatically turn the Function and Derivative Debugger on in the initial point to discover potential errors in the gradient calculation inside the external library. The debugger will not only check the gradients of the external library but even check the gradients calculated by GAMS. In rare cases the debugger may report problems in the regular algebra part of the model for which GAMS has calculated the gradients. These violates should be small and can be ignored. After verifying that the external part of the model has been programmed correctly you may turn debugging off again by setting `Lkdebg` to 0 in an options file.

The debugger has two types of check. The first type ensures that the external equations do not depend on other variables than the ones you have specified in the GAMS representation. Structural errors found by these check are usually caused by programming mistakes and must be corrected. The second type of check verifies that the derivatives returned by the external equations and extrinsic functions are consistent with the rate of change in function values. A derivative is considered to be wrong if the value returned by the modeler deviates from the value computed using numerical differences by more than `rtmxj2` times the step used for the numerical difference (usually around 1.e-7). This check is correct if second derivatives are less than `rtmxj2`. `rtmxj2` has a default value of 1.e4. If your model has larger second derivatives you may increase it in order not to get wrong error messages.

The number of error messages from the Function and Derivative Debugger is limited by `lfderr` with a default value of 10.

See Debugging options for a list of options that control the debugger.

5.7.9 APPENDIX B - Options

The options that ordinary GAMS users can access are listed below. Options starting on R assume real values, options starting on LS assume logical values (TRUE, T, 1, or FALSE, F, or 0), and all other CR-Cells starting on L assume integer values. The logical option `dohess` is only used by the interface between GAMS and CONOPT.

5.7.9.1 Algorithmic options

Option	Description	Default
LF2DRV	Limit on errors in Directional Second Derivative evaluation.	10
LFDEGI	Limit on number of degenerate iterations before starting degeneracy breaking strategy.	10
LFEERR	Limit on number of function evaluation errors. Overwrites GAMS Domlim option	GAMS DomLim
LFHSOK	Limit on errors in Hessian evaluation.	10
LFITER	Maximum number of iterations. Overwrites GAMS Iterlim option.	GAMS IterLim
LFMXNS	Maximum number of new superbasic variables added in one iteration.	auto
LFNICR	Limit on number of iterations with slow progress (relative less than Rtobjl).	20
LFNSUP	Maximum number of superbasic variables in the approximation to the Reduced Hessian.	auto
LFSCAL	Rescaling frequency.	5
LFSTAL	Limit on the number of stalled iterations.	100
LFUSDF	Limit on the number of candidates for defined variable in one constraint	2
LMDEBG	Method used by the function and derivative debugger.	0
LMMXSF	Method used to determine the step in Phase 0.	0
LMMXST	Method used to determine the maximum step while tightening tolerances.	0
LMNDIA	Method for initializing the diagonal of the approximate Reduced Hessian	0
LMSCAL	Method used for scaling.	3
LMUSDF	Method used with defined variables	0
LS2NDI	Flag for approximating Hessian information for incoming superbasics.	0
LS2PTJ	Flag for use of perturbations to compute 2nd derivatives in SQP method.	1
LSANRM	Flag for turning Steepest Edge on.	0
LSCRSH	Flag for crashing an initial basis without fixed slacks	1
LSESLP	Flag for enabling SLP mode.	1
LSESQP	Flag for enabling of SQP mode.	1
LSISMP	Flag for Ignoring Small Pivots in Triangular models	0
LSLACK	Flag for selecting initial basis as Crash-triangular variables plus slacks.	0
LSPOST	Pre-processor flag for identifying and using post-triangular equations.	1
LSPRET	Pre-processor flag for identifying and using pre-triangular equations.	1

Option	Description	Default
LSSCAL	Flag for dynamic scaling.	1
LSSQRS	Flag for Square System. Alternative to defining modeltype=CNS in GAMS	0
LSTCRS	Flag for using the triangular crash method.	0
LSTRIA	Flag for triangular or recursive system of equations.	0
LSTRID	Flag for turning diagnostics on for the post-triangular equations.	0
LSUQDF	Flag for requiring defined variables to be unique	1
LSUSDF	Flag for forcing defined variables into the basis	1
PRDEF	Flag for printing the defined variables and their defining constraints.	0
PRPOST	Flag for printing the post-triangular part of the model	0
PRPREC	Flag for printing the variables changed by the pre-processor	0
PRPRET	Flag for printing the pre-triangular part of the model	0
RTBND1	Bound filter tolerance for solution values close to a bound.	1.e-7
RTBNDT	Bound tolerance for defining variables as fixed.	1.e-7
RTIPVA	Absolute Pivot Tolerance for building initial basis.	1.e-7
RTIPVR	Relative Pivot Tolerance for building initial basis	1.e-3
RTMAXJ	Upper bound on the value of a function value or Jacobian element.	1.e10
RTMAXS	Upper bound on scale factors.	1.e9
RTMAXV	Upper bound on solution values and equation activity levels	1.e10
RTMINA	Zero filter for Jacobian elements and inversion results.	1.e-20
RTMINJ	Filter for small Jacobian elements to be ignored during scaling.	1.e-5
RTMINS	Lower bound for scale factors computed from values and 1st derivatives.	1
RTMNS2	Lower bound for scale factors based on large 2nd derivatives.	1.e-6
RTNWMA	Maximum feasibility tolerance (after scaling).	1.e-7
RTNWMI	Minimum feasibility tolerance (after scaling).	4.e-10
RTNWTR	Feasibility tolerance for triangular equations.	2.0e-8
RTOBJL	Limit for relative change in objective for well-behaved iterations.	3.0e-12
RTOBJR	Relative accuracy of the objective function.	3.0e-13
RTONED	Accuracy of One-dimensional search.	0.2
RTPIVA	Absolute pivot tolerance.	1.e-10
RTPIVR	Relative pivot tolerance during basis factorizations.	0.05
RTPIVT	Absolute pivot tolerance for nonlinear elements in pre-triangular equations.	1.e-5
RTPIVU	Relative pivot tolerance during basis updates.	0.05
RTPREC	Tolerance for printing variables changed by the pre-processor	0.0
RTPREL	Tolerance for defining large changes in variables in pre-processor	0.01

Option	Description	Default
RTREDG	Optimality tolerance for reduced gradient.	1.e-7
RVFILL	Fill in factor for basis factorization.	5
RVTIME	Time Limit. Overwrites the GAMS Reslim option.	GAMS ResLim

5.7.9.2 Debugging options

Option	Description	Default
LFDERR	Limit on number of error messages from function and derivative debugger.	10
LKDEBG	Flag for debugging of first derivatives	0
RTMXJ2	Upper bound on second order terms.	1.e4
RTZERN	Zero-Noise in external equations	0.0

5.7.9.3 Output options

Option	Description	Default
LFEMSG	Limit on number of error messages related to large function value and Jacobian elements.	10
LFILOG	Frequency for log-lines for non-SLP/SQP iterations.	auto
LFILOS	Frequency for log-lines for SLP or SQP iterations.	auto
LFTMSG	Limit on number of error messages related to infeasible pre-triangle.	25

5.7.9.4 Interface options

Option	Description	Default
cooptfile		
DO2DIR	Flag for computing and using directional 2nd derivatives.	auto
DOHESS	Flag for computing and using 2nd derivatives as Hessian of Lagrangian.	auto
heaplimit	Maximum Heap size in MB allowed	Infinite
pretri2log	Send messages about the pre-triangular analyser to the log	0
RVHESS	Memory factor for Hessian generation: Skip if #Hessian elements > #Jacobian elements∗Rvhess, 0 means unlimited.	10

cooptfile *(string)*: ↩

DO2DIR *(boolean)*: Flag for computing and using directional 2nd derivatives. ↩

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off of the model has external

equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see DOHESS) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: `auto`

DOHESS *(boolean)*: Flag for computing and using 2nd derivatives as Hessian of Lagrangian. ↩

If turned on, compute the structure of the Hessian of the Lagrangian and make it available to CONOPT. The default is usually on, but it will be turned off if the model has external equations (defined with =X=) or if the Hessian becomes too dense. See also DO2DIR and RVHESS.

Default: `auto`

heaplimit *(real)*: Maximum Heap size in MB allowed ↩

Default: `Infinite`

LF2DRV *(integer)*: Limit on errors in Directional Second Derivative evaluation. ↩

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lf2drv times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: `10`

LFDEGI *(integer)*: Limit on number of degenerate iterations before starting degeneracy breaking strategy. ↩

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds LFDEGI CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: `10`

LFDERR *(integer)*: Limit on number of error messages from function and derivative debugger. ↩

The function and derivative debugger (see LKDEBG) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after LFDERR error have been found.

Range: {`1`, ..., ∞}

Default: `10`

LFEERR *(integer)*: Limit on number of function evaluation errors. Overwrites GAMS Domlim option ↩

Synonym: domlim

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lfeerr times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: `GAMS DomLim`

LFEMSG *(integer)*: Limit on number of error messages related to large function value and Jacobian elements. ↩

Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function value and derivatives. This bound is 1.e30 for scaled models and RTMAXJ for unscaled models. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating function value and Jacobian elements, up to a limit of Lfemsg error messages.

Range: {1, ..., ∞}

Default: `10`

LFHSOK *(integer)*: Limit on errors in Hessian evaluation. ↩

If the evaluation of Hessian information has failed more than Lfhsok times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: `10`

LFILOG *(integer)*: Frequency for log-lines for non-SLP/SQP iterations. ↩

Lfilog and Lfilos can be used to control the amount of iteration send to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Range: {1, ..., ∞}

Default: `auto`

LFILOS *(integer)*: Frequency for log-lines for SLP or SQP iterations. ↩

Lfilog and Lfilos can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 500 constraints or 1000 variables.

Range: {1, ..., ∞}

Default: `auto`

LFITER *(integer)*: Maximum number of iterations. Overwrites GAMS Iterlim option. ↩

Synonym: iterlim

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option RVTIME) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: `GAMS IterLim`

LFMXNS *(integer)*: Maximum number of new superbasic variables added in one iteration. ↩

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lfmxns is positive then the limit is min(500,Lfmxns). If Lfmxns is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: `auto`

LFNICR *(integer)*: Limit on number of iterations with slow progress (relative less than Rtobjl). ↩

The optimization is stopped if the relative change in objective is less than RTOBJL for Lfnicr consecutive well-behaved iterations.

Range: {2, ..., ∞}

Default: `20`

LFNSUP *(integer)*: Maximum number of superbasic variables in the approximation to the Reduced Hessian. ↩

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on on the size. The limit is LFNSUP if LFNSUP is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasics exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Range: {5, ..., ∞}

Default: `auto`

LFSCAL *(integer)*: Rescaling frequency. ↩

The row and column scales are recalculated at least every Lfscal new point (degenerate iterations do not count), or more frequently if conditions require it.

Range: {1, ..., ∞}

Default: `5`

LFSTAL *(integer)*: Limit on the number of stalled iterations. ↩

An iteration is considered a stalled iteration it there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will usually try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, so to prevent cycling CONOPT stops after Lfstal stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Range: {2, ..., ∞}

Default: `100`

LFTMSG *(integer)*: Limit on number of error messages related to infeasible pre-triangle. ↩

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than LFTMSG elements the report is considered difficult to use and it is skipped.

Default: `25`

LFUSDF *(integer)*: Limit on the number of candidates for defined variable in one constraint ↩

When there are more than one candidate to be selected as a defined variable in a constraint CONOPT tries to select the most appropriate in order to select as many defined variables as possible. However, to avoid too much arbitrariness this is only attempted if there are not more than Lfusdf candidates.

Default: `2`

LKDEBG *(integer)*: Flag for debugging of first derivatives ↩

Lkdebg controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with =X=. The amount of debugging is controlled by LMDEBG. See RTMXJ2 for a definition of when derivatives are considered wrong.

Default: `0`

value	meaning
`-1`	The derivatives are tested in the initial point only.
`0`	No debugging
`+n`	The derivatives are tested in all iterations that can be divided by Lkdebg, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)

LMDEBG *(integer)*: Method used by the function and derivative debugger. ↩

The function and derivative debugger (turned on with LKDEBG) can perform a fairly cheap test or a more extensive test, controlled by LMDEBG. See RTMXJ2 for a definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: `0`

value	meaning
`0`	Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.
`1`	As 0 plus make extensive test to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used of the cheap test does not find an error but one is expected to exist.

LMMXSF *(integer)*: Method used to determine the step in Phase 0. ↩

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by LMMXSF:

Default: `0`

value	meaning
0	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.
1	A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending. The method does not use anti-degeneracy. This will to be taken care off by removing difficult constraints from the Newton Process at regular intervals. The bending method can sometimes be useful for CNS models that stop when a variable exceeds its bound in an intermediate point even though the final solution is known to be inside the bounds.

LMMXST *(integer)*: Method used to determine the maximum step while tightening tolerances. ↩

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by LMMXST:

Default: 0

value	meaning
0	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.
1	A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.

LMNDIA *(integer)*: Method for initializing the diagonal of the approximate Reduced Hessian ↩

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by LMNDIA:

Default: 0

value	meaning
0	The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.
1	The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.

LMSCAL *(integer)*: Method used for scaling. ↩

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution, see

LSSCAL and LMSCAL. The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see RTMAXS and RTMINS. Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: `3`

value	meaning
`0`	Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than RTMINJ are considered equal to RTMINJ.
`1`	Similar to 3 below, but the projection on the interval [Rtmins,Rtmaxs] is applied at a different stage. With method 1, abs(X)∗abs(Jac) with small X and very large Jac is scaled very aggressively with a factor abs(Jac). With method 3, the scale factor is abs(X)∗abs(Jac). The difference is seen in models with terms like Sqrt(X) close to X = 0.
`2`	As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.
`3`	Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by by the maximum of the largest term and the value of the variable. A term is here defined as abs(X)∗abs(Jac) where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factors are then projected on the interval between Rtmins and Rtmaxs.

LMUSDF *(integer)*: Method used with defined variables ↩

When defined variables are identified (see LSUSDF) they can be used in two ways, controlled by LMUSDF:

Default: `0`

value	meaning
`0`	Defined variables are only used in the initial point and for the initial basis (default).
`1`	Defined variables are kept basic and the defining constraints are used to recursively assign values to the defined variables in all trial points.

LS2NDI *(boolean)*: Flag for approximating Hessian information for incoming superbasics. ↩

If Ls2ndi is turned on (1) CONOPT will try to estimate second order Hessian information for incoming superbasic variables based on directional second derivatives. This is more costly than the standard method described under LMNDIA.

Default: `0`

LS2PTJ *(boolean)*: Flag for use of perturbations to compute 2nd derivatives in SQP method. ↩

If on (1) CONOPT may use perturbations of the Jacobian to compute directional 2nd derivatives if they are not provided with other cheaper and more accorate methods. With GAMS it is only relevant for models with functions defined in external function libraries or models with external equations defined with the =X= equation type.

Default: `1`

LSANRM *(boolean)*: Flag for turning Steepest Edge on. ↩

Flag used to turn steepest edge pricing on (1) or off (0). Steepest edge pricing makes the individual iterations more expensive but it may decrease their number. Only experimentation can show if it is worth while.

Default: `0`

LSCRSH *(boolean)*: Flag for crashing an initial basis without fixed slacks ↩

When turned on (1) CONOPT will try to crash a basis without fixed slacks in the basis. Fixed slacks are only included in a last round to fill linearly dependent rows. When turned off, large infeasible slacks will be included in the initial basis with preference for variables and slacks far from bound.

Default: `1`

LSESLP *(boolean)*: Flag for enabling SLP mode. ↩

If Lseslp is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.

Default: `1`

LSESQP *(boolean)*: Flag for enabling of SQP mode. ↩

If Lsesqp is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: `1`

LSISMP *(boolean)*: Flag for Ignoring Small Pivots in Triangular models ↩

Ignore SMall Pivots. When turned on CONOPT will ignore the non-uniqueness from small pivots during a triangular solve (see LSTRIA). Note, that the non-uniqueness may propagate to later equations, but we cannot check for it in nonlinear equations.

Default: `0`

LSLACK *(boolean)*: Flag for selecting initial basis as Crash-triangular variables plus slacks. ↩

When turned on together with LSTCRS CONOPT will use the triangular crash procedure and select the initial basis as the crash-triangular variables plus slacks in all remaining rows.

Default: `0`

LSPOST *(boolean)*: Pre-processor flag for identifying and using post-triangular equations. ↩

When turned on (the default) CONOPT will try to identify post-triangular equations. Otherwise this phase is ignored.

Default: `1`

LSPRET *(boolean)*: Pre-processor flag for identifying and using pre-triangular equations. ↩

When turned on (the default) CONOPT will try to identify pre-triangular equations. Otherwise this phase is ignored.

Default: `1`

LSSCAL *(boolean)*: Flag for dynamic scaling. ↩

When Lsscal is on (the default) CONOPT will use dynamic scaling of equations and variables. See also LMSCAL.

Default: `1`

LSSQRS *(boolean)*: Flag for Square System. Alternative to defining modeltype=CNS in GAMS ↩

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: `0`

LSTCRS *(boolean)*: Flag for using the triangular crash method. ↩

When turned on CONOPT will try to crash a triangular basis using ideas by Gould and Reid. The procedure relies on identifying and using good initial values provided by the modeler and only assigning values to variables that are not initialized. Should only be used when several important variables have been given reasonable initial values. The sum of infeasibilities may for some models grow during the crash procedure, so modelers are advised that the option should be used with caution. The option will be ignored if defined variables are forced into the bases Lsusdf.

Default: `0`

LSTRIA *(boolean)*: Flag for triangular or recursive system of equations. ↩

If turned on the equations must form a recursive system. Equations that depend on known variables are allowed as long as they are consistent, e.g. x = 1 and 2∗x = 2. If the equations are not recursive the model is considered infeasible, and the equations with minimum row count are flagged together with the columns they intersect. See also LSISMP.

Default: `0`

LSTRID *(boolean)*: Flag for turning diagnostics on for the post-triangular equations. ↩

If turned on certain diagnostic messages related to the post-triangular equations will be printed. The messages are mainly related to unusual modeling constructs where linear variables for example only appear in the objective or where certain constraints are guarantied redundant.

Default: `0`

LSUQDF *(boolean)*: Flag for requiring defined variables to be unique ↩

When turned on (1) CONOPT will not allow defined variables unless they are unique. We exclude a variable if it can be defined from more than one equation, and we exclude equations if they can be used to define more than one variable.

Default: `1`

LSUSDF *(boolean)*: Flag for forcing defined variables into the basis ↩

When turned on (1) CONOPT will identify defined variables from constraints of the type x(i) = f(x) where x(i) is free or implied free. The largest number of defined variables possible will be made basic and will be assigned initial values that are consistent with their defining constraint. When turned off (0) defined variables and their defining constraints are treated like all other variables and constraints. When turned on the triangular crash (LSTCRS) will not be used

Default: `1`

PRDEF *(boolean)*: Flag for printing the defined variables and their defining constraints. ↩

When turned on (1) CONOPT will print a list of the defined variables and their defining constraints in the order in which they can be evaluated.

Default: `0`

pretri2log *(boolean)*: Send messages about the pre-triangular analyser to the log ↩

Default: `0`

PRPOST *(boolean)*: Flag for printing the post-triangular part of the model ↩

When turned on (1) CONOPT will print a list of the post-triangular constraints and the variables they are solved for in the order in which they can be evaluated.

Default: `0`

PRPREC *(boolean)*: Flag for printing the variables changed by the pre-processor ↩

When turned on (1) CONOPT will print a list of the variables that are changed by the pre-processor. The list includes pre-triangular variables, variables changed by implied bounds, and definitional variables. The three lists can for some models be very long and you can limit the list to variables that are changed by more than (RTPREC)

Default: `0`

PRPRET *(boolean)*: Flag for printing the pre-triangular part of the model ↩

When turned on (1) CONOPT will print a list of the pre-triangular constraints and the variables they are solved for, including the solution values, in the order in which they are solved.

Default: `0`

RTBND1 *(real)*: Bound filter tolerance for solution values close to a bound. ↩

A variable is considered to be at a bound if its distance from the bound is less than Rtbnd1 Max(1,ABS(Bound)). If you need a very small value then your model is probably poorly scaled.

Range: [`3.e-13`, `1.e-5`]

Default: `1.e-7`

RTBNDT *(real)*: Bound tolerance for defining variables as fixed. ↩

A variable is considered fixed if the distance between the bounds is less than Rtbndt $*$ Max(1,Abs(Bound)). The tolerance is also used on implied bounds (from converted inequalities) and these implied bounds may be infeasible up to Rtbndt.

Range: [`3.e-13`, `1.e-5`]

Default: `1.e-7`

RTIPVA *(real)*: Absolute Pivot Tolerance for building initial basis. ↩

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: [`3.e-13`, `1.e-3`]

Default: `1.e-7`

RTIPVR *(real)*: Relative Pivot Tolerance for building initial basis ↩

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: [`1.e-4`, `0.9`]

Default: `1.e-3`

RTMAXJ *(real)*: Upper bound on the value of a function value or Jacobian element. ↩

Very large values of variables, function value, and derivatives and in particular large variations in the absolute value of the variables, functions, and derivatives makes the model harder to solve and poses problems for both feasibility and optimality tests. CONOPT will usually try to scale the model (see LSSCAL) to remove these problems. However, scaling can also make important aspects of a model appear un-important and there is therefore a limit to how aggressively we can scale a model (see RTMAXS and RTMINS). To avoid serious scaling problems CONOPT poses upper bounds on all variables (see RTMAXV) and all function value and derivatives, RTMAXJ.

Range: [`1.e4`, `1.e30`]

Default: `1.e10`

RTMAXS *(real)*: Upper bound on scale factors. ↩

Scale factors are projected on the interval from Rtmins to Rtmaxs. Is used to prevent very large or very small scale factors due to pathological types of constraints. RTMAXS is silently increased to max(RTMAXV,RTMAXS)/100 if RTMAXV or RTMAXJ have large non-default values.

Range: [`1`, `1.e20`]

Default: `1.e9`

RTMAXV *(real)*: Upper bound on solution values and equation activity levels ↩

See RTMAXJ for a discussion of why CONOPT poses upper bounds on variables and derivatives. If the value of a variable, including the objective function value, exceeds RTMAXV then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded.

Range: [`1.e5`, `1.e30`]

Default: `1.e10`

RTMINA *(real)*: Zero filter for Jacobian elements and inversion results. ↩

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than RTPIVA/10.

Range: [`1.e-30`, ∞]

Default: `1.e-20`

RTMINJ *(real)*: Filter for small Jacobian elements to be ignored during scaling. ↩

A Jacobian element is considered insignificant if it is less than Rtminj. The value is used to select which small values are scaled up during scaling of the Jacobian.

Range: [`1.e-7`, `1.e-3`]

Default: `1.e-5`

RTMINS *(real)*: Lower bound for scale factors computed from values and 1st derivatives. ↩

Scale factors used to scale variables and equations are projected on the range Rtmins to Rtmaxs. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for Rtmins is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of Rtmins < 1.

Range: [`1.e-10`, `1`]

Default: `1`

RTMNS2 *(real)*: Lower bound for scale factors based on large 2nd derivatives. ↩

Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than Rtmins. CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than Rtmns2.

Range: [`1.e-9`, `1`]

Default: `1.e-6`

RTMXJ2 *(real)*: Upper bound on second order terms. ↩

The function and derivative debugger (see LKDEBG) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses RTMXJ2 as an upper bound on second order derivatives in the model. Larger RTMXJ2 values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Range: [`1`, ∞]

Default: `1.e4`

RTNWMA *(real)*: Maximum feasibility tolerance (after scaling). ↩

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. RTNWMA is the upper bound on the dynamic feasibility tolerance and RTNWMI is the lower bound.

Range: [`1.e-10`, `1.e-3`]

Default: `1.e-7`

RTNWMI *(real)*: Minimum feasibility tolerance (after scaling). ↩

See RTNWMA for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: [4.e-11, 1.e-5]

Default: 4.e-10

RTNWTR *(real)*: Feasibility tolerance for triangular equations. ↩

Triangular equations are usually solved to an accuracy of RTNWMI. However, if a variable reaches a bound or a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to Rtnwtr.

Range: [3.e-13, 1.e-4]

Default: 2.0e-8

RTOBJL *(real)*: Limit for relative change in objective for well-behaved iterations. ↩

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than Rtobjl $*$ Max(1,Abs(Objective)). See also LFNICR.

Range: [3.0e-13, 1.0e-5]

Default: 3.0e-12

RTOBJR *(real)*: Relative accuracy of the objective function. ↩

It is assumed that the objective function can be computed to an accuracy of Rtobjr $*$ max(1, abs(Objective)). Smaller changes in objective are considered to be caused by round-off errors.

Range: [3.0e-14, 10.e-6]

Default: 3.0e-13

RTONED *(real)*: Accuracy of One-dimensional search. ↩

The onedimensional search is stopped if the expected decrease in then objective estimated from a quadratic approximation is less than Rtoned times the decrease so far in this onedimensional search.

Range: [0.05, 0.8]

Default: 0.2

RTPIVA *(real)*: Absolute pivot tolerance. ↩

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Rtpiva. There is also a relative test, see RTPIVR.

Range: [2.2e-16, 1.e-7]

Default: 1.e-10

RTPIVR *(real)*: Relative pivot tolerance during basis factorizations. ↩

During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least Rtpivr $*$ the largest absolute value in the column. Small values or Rtpivr will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of Rtpivr may help.

Range: [`1.e-3`, `0.9`]

Default: `0.05`

RTPIVT *(real)*: Absolute pivot tolerance for nonlinear elements in pre-triangular equations. ↩

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is Rtpiva. The value cannot be less that Rtpiva.

Range: [`2.2e-16`, `1.e-3`]

Default: `1.e-5`

RTPIVU *(real)*: Relative pivot tolerance during basis updates. ↩

During basischanges CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least Rtpivu $*$ the other element. Smaller values of Rtpivu will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: [`1.e-3`, `0.9`]

Default: `0.05`

RTPREC *(real)*: Tolerance for printing variables changed by the pre-processor ↩

The list of variables changed by the pre-processor (see (PRPREC)) can be limited to the variables that are changed by more than RTPREC, defined as deltaX $>$ RTPREC $*$ max(1, abs(X)).

Range: [`0.0`, ∞]

Default: `0.0`

RTPREL *(real)*: Tolerance for defining large changes in variables in pre-processor ↩

The statistics for the number of variables that are changed in the pro-processor are classified as small and large changes. The change, DeltaX, is defined as large if deltaX $>$ RTPREL $*$ max(1, abs(X)).

Range: [`0.0`, ∞]

Default: `0.01`

RTREDG *(real)*: Optimality tolerance for reduced gradient. ↩

The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than Rtredg.

Range: [3.e-13, 1]

Default: 1.e-7

RTZERN *(real)*: Zero-Noise in external equations ↩

By default CONOPT will debug the derivatives returned from External functions in GAMS in the initial point (see LKDEBG). If external functions have constant derivatives then the constant terms are still part of the external function and this can give rise to small inaccuracies in the contribution of the constant derivatives to the function value. This noise can cause the debugger to incorrectly state that a the external equation depend on the variable with the constant derivative. A larger value of Rtzern should remove the error.

Range: [0.0, 1]

Default: 0.0

RVFILL *(real)*: Fill in factor for basis factorization. ↩

Rvfill is used in the initial allocation of memory for the factorization of the basis. The fill-in (number of new nonzeros) is assumed to be Rvfill-1 times the initial number of nonzeros in the basis. The default is 5 but you may experiment with a smaller value (down to 1.0) for models that use too much memory to get started. If Rvfill is small you may get slower execution due to increased memory movement. And you may still run out of memory later in the optimization.

Range: [1.00, 20]

Default: 5

RVHESS *(real)*: Memory factor for Hessian generation: Skip if #Hessian elements > #Jacobian elements∗Rvhess, 0 means unlimited. ↩

The Hessian of the Lagrangian is considered too dense and is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by Rvhess. The assumption is that a very dense Hessian is expensive both to compute and use. If Rvhess = 0.0 then there is no limit on the number of Hessian elements.

Default: 10

RVTIME *(real)*: Time Limit. Overwrites the GAMS Reslim option. ↩

Synonym: reslim

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Rvtime is overwritten by Reslim when called from GAMS. Rvtime is defined in ProbSize and/or UpdtSize when used as a subroutine library.

Default: GAMS ResLim

5.8 CONOPT

Author

Arne Drud, ARKI Consulting and Development A/S, Bagsvaerd, Denmark

5.8.1 Introduction

CONOPT4 is an NLP solver derived from CONOPT3 but with many improvements. This documentation is intended to be self-contained, and there will therefore be some repetitions from the CONOPT3 documentation. We will refer to CONOPT4 as CONOPT in the following.

Nonlinear models created with GAMS must be solved with a nonlinear programming (NLP) algorithm. There are many solvers available, and the number is growing. It is almost impossible to predict how easy or difficult it is to solve a particular model with a particular algorithm, especially for NLP models, so GAMS cannot automatically select the best algorithm. The only reliable way to find which solver to use for a particular class of models is to experiment. However, it may be useful to classify different solvers and describe where CONOPT fits into this picture.

The most important distinction between NLP solvers is whether they attempt to find a local or a global solution. Solvers that attempt to find a global solution, called Global Solvers, will usually use some branch and bound technique and they can usually not solve very large models. As a contrast, most Local Solvers that only search for a locally optimal solution, can work with much larger models. If the model has the right mathematical properties, e.g., is convex, then Local Solvers will find a global optimum. Unfortunately, the theory for testing whether a general NLP model is convex is not very developed and is expected to be in the class of hard problems. CONOPT belongs to the class of Local Solvers, and it can be used for very large models.

Within the class of Local Solvers, the main distinction is between solvers based on Active Set methods and Interior Point methods. Active Set solvers are generally good for models with many equality constraints and few bounds. Interior Point solvers are generally good for models with many inequalities and many bounds, where the combinatorial nature of which inequalities and bounds are active play an important role. CONOPT is an Active Set solver.

Finally, within Active Set solvers we distinguish between Feasible Path methods and methods where feasibility only is found in the final point together with optimality. Feasible Path methods iterate through a sequence of feasible points, gradually improving the solution. It is assumed that the feasibility of the intermediate points will give more relevant derivatives and therefore better directions towards the optimal solution, and therefore will reduce the number of iterations relative to methods that do not enforce feasibility. On the other hand, each iteration will be more expensive because maintaining feasibility comes at a cost. CONOPT is a Feasible Path method, and great care has been taken to find an initial feasible solution and to reduce the cost of maintaining feasibility.

In addition to NLP models CONOPT has a good algorithm for CNS (Constrained Nonlinear Systems or Square Systems of equations) and CONOPT has been used to solve CNS models with many million variables and constraints.

This documentation will describe the basic algorithm and how the iteration output can help the user understand the solution progress. It will also describe some options that can be used to control the behavior of the algorithm. It should be emphasized that most users do not need any options. CONOPT has been designed to adjust its behavior based on statistics for the model and information about the progress of the algorithm.

5.8.2 The CONOPT Algorithm

The algorithm used in CONOPT is based on the GRG algorithm first suggested by Abadie and Carpentier (1969). The actual implementation has many modifications to make it efficient for large models. Here we will just give a short verbal description of the major steps in a generic GRG algorithm applied to the model:

```
Min or max f(x)
s.t. g(x) = 0
lb <= x <= ub
```

where x represents the set of variables, f represents the objective function, g represents a vector of constraints, and lb and ub represent vectors of lower and upper bounds. Inequalities are handled by adding properly bounded slack variables. The key steps in any GRG algorithm are:

1. Initialize and find a feasible solution.
2. Compute the Jacobian of the constraints, J.
3. Select a set of n basic variables, x_b, from x such that B, the sub-matrix of basic columns selected from J, is nonsingular. Factorize B. The remaining variables, x_n, are called nonbasic.
4. Solve $B^T u = df/dx_b$ for the multipliers u.
5. Compute the reduced gradient, $rgra = df/dx - J^T u$. `rgra` will be zero for the basic variables.
6. If rgra projected on the bounds is small, then stop. The current point is close to local optimality.
7. Select the set of superbasic variables, xs, as a subset of the nonbasic variables that have a reduced gradient pointing away from the bounds, and find a search direction, ds, for the superbasic variables based on $rgra$ and possibly on second order information.

8. Perform a line search along the direction ds. For each step, xs is changed in the direction ds and the basic variables x_b are subsequently adjusted to satisfy the constraints $g(x_b, x_s) = 0$ using an iterative Newton-like process with the factored B from step 3. When feasible the objective function $f(x)$ is evaluated and used to adjust the step and/or decide to terminate the search.

9. Go to 2.

The individual steps are of course much more detailed in the practical implementation in CONOPT. Step 1 consists of several pre-processing steps that usually create a smaller and easier model to be optimized. Step 1 also has a special Phase 0 and a scaling procedure as described in the following sections. The work involving the basis B, the LU factorization of B, and all operations involving B (step 3, 4, and 8) have been optimized to work even for very large models. The selection of search direction and optimizing step-lengths are specialized according to whether the model appears to be almost linear or not. For almost linear models some of the linear algebra work involving the matrices J and B is done using cheap LP-type updating techniques, second order information is not relevant in step 7, and the line search in step 8 has been improved by observing that the optimal step almost always will be determined by the first variable that reaches a bound. Similarly, when the model appears to be nonlinear, other aspects are optimized: the sets of basic and superbasic variables will often remain constant over several iterations, and the search direction is improved by using 2$^{\text{nd}}$ order information provided by GAMS. The choice of whether to use the almost linear or the nonlinear components is taken dynamically based on observations of the progress of the algorithm. Finally, the one-dimensional search and the feasibility restoring Newton iterations in step 8 have been optimized using quadratic inter- and extrapolations and they take advantage of linearity in the relevant constraints.

5.8.3 Iteration Output

When running CONOPT you will get a log-file that will look like this:

```
 CONOPT 4         44.2.0 7d8c2acc Aug 17, 2023          WEI x86 64bit/MS Window

```
** Optimal solution. Reduced gradient less than tolerance.
```

The first few lines identify the version of CONOPT. CONOPT is updated at regular intervals, and if you want to report a problem, it is important to identify the version you are using.

The next lines show the size of the model measured in constraints, variables, and Jacobian elements; these numbers are also shown in the GAMS log. Usually, you will also see information about the Hessian (the matrix of 2nd derivatives) of the Lagrangian (a function combining the objective function and the constraints, $L = f(x) + u^T g(x)$ where u is a vector of dual variables). For some very large or dense models and models with few degrees of freedom, 2nd order information is not automatically available and these lines will be missing. You can force 2nd order information to be used with the option Flg_Hessian.

When CONOPT has received the model from GAMS it evaluates the constraint and determines the initial (sum of) Infeasibilities in the input point. It then executes a preprocessor that tries to reduce the size of the model and to find a solution that is closer to feasibility. The information from the preprocessor depends on the model and is described in the section Preprocessor.

After the preprocessors finishes, the model is scaled, and all later reporting of infeasibilities refers to the scaled model.

The remaining part of the log file describes the optimization iterations with the iteration number in the first column. For very small models you may not see all iterations in the iteration log. The options Frq_Log_SlpSqp and Frq_Log_Simple can be used to increase or decrease the log frequency.

The type of each iteration is described by the value of "Phase" in column 2. During Phase 0, 1, and 2 the model is infeasible and the Sum of Infeasibilities in column 4, labeled "Infeasibility", is being minimized. During Phase 1 and 2 the number in column "Ninf" tells how many constraints are still infeasible. These infeasibilities are minimized subject to the feasible constraints remaining feasible, and Ninf will therefore usually not increase. During Phase 3 and 4 the model is feasible and the actual objective function, also shown in column 4 and now labeled "Objective", is either minimized or maximized according to the Solve statement in GAMS.

Phase 0 iterations are Newton-like iterations. The background is described in the section Phase 0 - Finding an Initial Feasible Solution. During Phase 1 and 3 the model behaves almost linearly and CONOPT applies special linear iterations that take advantage of the linearity. These iterations are usually combined into several inner "Sequential Linear Programming" (SLP) iterations, and the number of these inner iterations are shown in the "InItr" column. During Phase 2 and 4 the model behaves more nonlinearly, either in the objective (Phase 4 only) or in the constraints, and most aspects of the iterations are therefore changed: the line search is more elaborate, and CONOPT needs second order information to improve the convergence. CONOPT uses inner "Sequential Quadratic Programming" (SQP) iterations based on exact second derivatives computed by GAMS. The number of these inner iterations are shown in the "InItr" column.

The algorithm in Phase 1 and 3 is almost the same; the only difference is in the set of constraints (in Phase 3 all constraints and in Phase 1 the feasible constraints) and in the objective function (in Phase 3 the user objective function and in Phase 1 the sum of the residuals in the infeasible constraints). The same applies to Phase 2 vs. Phase 4.

The SLP or SQP iterations will define a search direction on the tangent plane of the nonlinear constraints. CONOPT will follow this direction and use one or more steps to find the best solution in the direction. This process is called the one-dimensional search. Because CONOPT is a Feasible Path Method and the constraints in general are nonlinear, the points on the tangent plane are usually not feasible and CONOPT will therefore adjust some of the variables to make the constraints feasible, before the objective function is evaluated in a feasible point. The feasibility restoring process is based on an adaption of Newton's method where only a subset of the variables, the Basic variables, are adjusted.

The remaining numbers in the iteration log describes the one-dimensional search. The column "NSB" for Number of SuperBasics defines the degree of freedom or the dimension of the current search space,

and "Rgmax" measures the largest reduced gradient among the non-optimal variables. Rgmax should eventually converge to zero, but convergence will in general not be monotone. The last two columns labeled "MX" and "OK" give information about the one-dimensional search. OK = T means that the one-dimensional search was well-behaved, and the step described in column "Step" is close to the local optimum in the selected search direction. OK = F means that the one-dimensional search was stopped short of an optimal step, usually because the Newton iterations used to find a feasible solution only converge for small steps. MX = T means that the one-dimensional search was terminated because a variable reached a bound or an inequality became binding. This is always combined with OK = T. MX = F means that the step length was determined by the nonlinearity of the objective function.

The step suggested by the SLP or SQP procedure is always 1.0. The linear or quadratic approximation is therefore good when the optimal step is 1.0. Iterations with step 1.0 are often faster because it is sufficient to evaluate a single step. The last iteration in phase 1, iteration 11 and 12 in the log-file above, are very good and the last iterations before optimality, iteration 41 to 46 in phase 4, are also very good.

In the initial part of the optimization, when we are far from the final solution, the direction found by the SLP or SQP procedure will often suggest large changes in the variables, and the feasibility restoring Newton iterations may not converge due to large nonlinearities. We will therefore see more iteration with OK = F and Step < 1 in the beginning, e.g., iteration 15 to 17 in phase 3 and iteration 31 to 39 in phase 4.

5.8.4 Termination Messages

When CONOPT has finished it will show a termination message describing why it has finished. This section will show most of these messages followed by a short explanation. It will also show the Model Status returned to GAMS in <model>.ModelStat, where <model> represents the name of the GAMS model. The Solver Status returned in <model>.SolveStat will be given if it is different from 1 (Normal Completion). We will in all cases first show the message from CONOPT followed by a short explanation.

The first 4 messages are used for optimal solutions and CONOPT will return ModelStat = 2 (Locally Optimal), except as noted below:

```
** Optimal solution. There are no superbasic variables.
```

The solution is a locally optimal corner solution. The solution is determined by constraints only, and both the values of the variables and the value of the objective function are usually very accurate. In some cases, CONOPT can determine that the solution is globally optimal, and it will return ModelStat = 1 (Optimal).

```
** Optimal solution. Reduced gradient less than tolerance.
```

The solution is a locally optimal interior solution. The largest component of the reduced gradient is less than the optimality tolerance, Tol_Optimality, with default value $1.e^{-7}$. The value of the objective function is very accurate while the values of the variables can be less accurate due to a flat objective function in the interior of the feasible area.

```
** Optimal solution. The error on the optimal objective function
   value estimated from the reduced gradient and the estimated
   Hessian is less than the minimal tolerance on the objective.
```

The solution is a locally optimal interior solution. The largest component of the reduced gradient is larger than the optimality tolerance, Tol_Optimality. However, when the reduced gradient is scaled with second order information the solution seems optimal. For this to happen the objective must be large or the reduced objective must have large second derivatives, so it is advisable to scale the model if possible.

```
** Optimal solution. Convergence too slow. The change in
   objective has been less than xx.xx for xx consecutive
   iterations.
```

CONOPT stops with a solution that seems optimal. The solution process is stopped because of slow progress. The largest component of the reduced gradient is greater than the optimality tolerance, `Tol_Optimality`, but less than `Tol_Optimality` multiplied by the largest Jacobian element divided by 100. The model must have large derivatives, so it is advisable to scale it.

The four messages above all exist in versions where "Optimal" is replaced by "Infeasible" and ModelStat will be 5 (Locally Infeasible) or 4 (Infeasible). The infeasible messages indicate that the Sum of Infeasibility objective function in Phase 1 or 2 is locally minimal, but positive. If the model is convex, it does not have a feasible solution; if the model is non-convex it may have a feasible solution in a different region. See the section on Initial Values in the Tutorial and Examples section of the GAMS User's Guide for hints on what to do.

```
** Feasible solution. Convergence too slow. The change in
   objective has been less than xx.xx for xx consecutive
   iterations.

** Feasible solution. The tolerances are minimal and
   there is no change in objective although the reduced
   gradient is greater than the tolerance.
```

The two messages above tell that CONOPT stops with a feasible solution. In the first case the solution process is very slow and in the second there is no progress at all and the optimality criteria have not been satisfied. These messages are accompanied by ModelStat = 7 (Feasible Solution) and SolveStat = 4 (Terminated by Solver). The problem can be caused by discontinuities if the model is of type DNLP; in this case you should consider alternative, smooth formulations as discussed in section Reformulating DNLP Models in the Tutorials and Examples. The problem can also be caused by a poorly scaled model. See section Good NLP formulation and in particular the section on Scaling variables and Equations in Tutorials and Examples. Finally, it can be caused by stalling as described in section Stalling. The two messages also exist in a version where "Feasible" is replaced by "Infeasible". ModelStat is in this case 6 (Intermediate Infeasible) and SolveStat is still 4 (Terminated by Solver); these versions tell that CONOPT cannot make progress towards feasibility, but the Sum of Infeasibility objective function does not have a well-defined local minimum.

```
** Unbounded solution. A variable has reached 'infinity'.
   Largest legal value (Lim_Variable) is xx.xx
```

CONOPT considers a solution to be unbounded if a variable exceeds the indicated value of Lim_Variable (default $1.e^{15}$) and it returns ModelStat = 3 (Unbounded). The check for unboundedness is done at every iteration which means that CONOPT will stop if an intermediate solution has a variable that is very large, even if none of the variables in the optimal solution have large values. The variable that has reached 'Infinity' is shown in the listing file. You should check whether the solution appears unbounded, or the problem is caused by the scaling of the unbounded variable. If the model seems correct you are advised to scale it. There is also a lazy solution: you can increase the largest legal value, `Lim_Variable`, as mentioned in the section on options. However, you will most likely pay through reduced reliability or increased solution times. Unlike LP models, where an unbounded model is recognized by an unbounded ray and the iterations are stopped far from "infinity", CONOPT will make a line search and move to a region with large values of the variables. This may lead to bad scaling and derived tolerance and round off problems, including problems of determining whether a solution is feasible or not.

The message above exists in a version where "Unbounded" is replaced by "Infeasible" and ModelStat is 5 (Locally Infeasible). You may also see a message like

```
** Infeasible solution. A free variable exceeds the allowable
   range.  Current value is xx.xx and current upper bound
   (Lim_Variable) is xx.xx
```

These Infeasible messages indicate that some variables become very large before a feasible solution has been found. You should again check whether the problem is caused by the scaling of the unbounded variable. If the model seems correct you should scale it.

```
** The time limit has been reached.
```

The time or resource limit defined in GAMS, either by default (usually 1000 seconds) or by `Option ResLim = xx;` or `<model>.ResLim = xx;` statements, has been reached. CONOPT will return with SolveStat = 3 (Resource Interrupt) and ModelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

```
** The iteration limit has been reached.
```

The iteration limit defined in GAMS, either by default (usually 2000000000 iterations) or by `Option IterLim = xx;` or `<model>.IterLim = xx;` statements, has been reached. CONOPT will return with SolveStat = 2 (Iteration Interrupt) and ModelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

```
** Domain error(s) in nonlinear functions.              -or-
** Domain error(s) in nonlinear functions. NaN returned -or-
** Domain error(s) in nonlinear functions. Residual too large.
   Check bounds on variables.
```

The number of function evaluation errors or bad function values has reached the limit defined in GAMS by `Option DomLim = xx;` or `<model>.DomLim = xx;` statements or the default limit of 0 function evaluation errors. CONOPT will return with SolveStat = 5 (Evaluation Error Limit) and ModelStat either 6 (Locally Infeasible) or 7 (Feasible Solution).

Many of the nonlinear functions available with GAMS are not defined for all values of their arguments. Log is not defined for negative arguments, Exp overflows for large arguments, and division by zero is illegal. To avoid evaluating functions outside their domain of definition you should add reasonable variable bounds. CONOPT will in return guarantee that the nonlinear functions never are evaluated with variables outside their bounds. For more advice, see details in section Good NLP Formulations in the Tutorials and Examples section of the GAMS User's Guide.

```
** An initial derivative is too large (larger than xx.xx)
   Scale the variables and/or equations or add bounds.

   <var> appearing in
   <equ>: Initial Jacobian element too large = xx.xx
```

and

```
** A derivative is too large (larger than xx.xx).
   Scale the variables and/or equations or add bounds.

   <var> appearing in
   <equ>: Jacobian element too large = xx.xx
```

These two messages appear if a derivative or Jacobian element is very large, either in the initial point or in a later intermediate point. The relevant variable and equation pair(s) will be shown in the listing file and will guide you where to look. A large derivative means that the function changes very rapidly even after a very small change in the variable and it will most likely create numerical problems for many parts of the optimization algorithm. Instead of attempting to solve a model that most likely will fail, CONOPT will stop, and you are advised to adjust the model.

If the offending derivative is associated with a `Log(x)` or `1/x` term you may try to increase the lower bound on `x`. If the offending derivative is associated with an `Exp(x)` term you must decrease the upper bound on `x`. You may also try to scale the model, either manually or using the variable.Scale and/or equation.Scale option in GAMS as described in the section Scaling variables and Equations in the Tutorials and Examples part of the GAMS documentation.

5.8.5 Preprocessor

The preprocessor in CONOPT3 identifies pre- and post-triangular variables and constraints, and it handles these variables and constraints in a special way to make some internal routines run more efficiently.

CONOPT goes one step further and distinguishes between a 'user model' as defined by the user via the GAMS language, and an 'internal model'. Pre-triangular variables and constraints are simply removed from the user model and are not present in the internal model. Post-triangular variables and constraints are collapsed into a single condensed objective function. And definitional constraints are eliminated. After the internal model has been solved, CONOPT translates the internal solution back into the solution for the user model and reports this solution to the user.

In addition to the simple pre- and post-triangular variables and constraints, the preprocessor in CONOPT looks at more possibilities for simplifying the model. Some of the new features are:

- Fixed variables are removed completely.
- Constraints that represent simple inequalities are identified and changed into simple bounds on the variables and the constraints are removed.
- Simple monotone constraints such as `exp(x) =L= c1 or log(y) =L= c2` are converted into simple bounds on the variables and then removed.
- Forcing constraints such as `x1 + x2 =L= 0` with `x1.lo = 0` and `x2.lo = 0` are identified, the variables are fixed, and the constraints are removed.
- Redundant constraints such as `x1 + x2 =L= 3` with `x1.lo = 0`, `x1.up = 1`, `x2.lo = 0`, and `x2.up = 1` are identified and removed.
- Linear and monotone constraints are used to compute 'implied bounds' on many variables and these bounds can help CONOPT get a better starting point for finding an initial feasible solution. The implied bounds may also change a non-monotone constraint into a monotone constraint, and they may help identify redundant constraints.
- Some non-monotone constraints such as `sqr(x1) + sqr(x2) =L= 1` can also be used to derive implied bounds (here `-1` $<$ `x1` $<$ `+1 and -1` $<$ `x2` $<$ `+1`) that both can improve the starting point and can be used to determine that other terms are monotone or redundant.
- Constraints with exactly two variables, e.g., simple linear identities such as `x1 =E= a*x2 + b` or simple monotone identities such as `x3 =E= exp(x4)`, are used to move bounds between the two variables and this may result in more variables being included in the post-triangle.
- Linear constraints that are identical or proportional to others are identified and removed.
- Pairs of constraints that define a lower and an upper bound on the same linear expression or proportional linear expressions, e.g., `1 =L= x1 + x2` and `2*x1+2*x2 =L= 4`, are turned into a single ranged constraint with a double-bounded slack variable.

- Nonlinear constraints that become linear when the pre-triangular variables are fixed are recognized as being linear with the resulting simplifications.

Some of the new preprocessing steps are useful when solving sub-models in a Branch and Bound environment. A constraint like `x =L= M*y` where `y` is a binary variable fixed at either `0` or `1` is turned into a simple bound on `x`. And a constraint like `sum(i, x(i) ) =L= Cap*y (with x.lo(i) = 0)` combined with `y` fixed at zero will force all `x(i)` to zero.

The preprocessor also identifies constructs that are easy to make feasible. There are currently two types:

- Penalty terms: A penalty constraint is defined as a constraint of the form `f(x1,x2,..) + p - n =E= 0`, where `p` and `n` are positive variables, and where `p` and `n` only appear in post-triangular constraints or in previously identified penalty constraint. For any feasible values of the x-variables it is easy to find values of `p` and `n` that make the penalty constraint feasible: `p = max(0,-f(x))` and `n = max(0,f(x))`. The definition is easily generalized to constraints where p and n have coefficients different from one and nonzero bounds; the essence is the presence of two linear unbounded terms of opposite sign.
- Minimax terms: A minimax group is defined as a group of constraints of the form `eq(i).. fi(x1,x2,..) =L= z` where `z` is common to the group and otherwise only appears in post-triangular constraints, and `z` is unbounded from above. For any feasible value of the x-variables it is easy to find a value of z that makes the minimax group feasible: `z = smin(i: fi(x))`. The definition is easily generalized to groups of constraints where z has coefficients different from one and where the direction of the inequality is reversed.

The preprocessor will also recognize definitional constraints: constraints of the form `x =E= f(y)`, where `x` is a free variable or the bounds on `x` cannot be binding, are called definitional constraints and `x` is called a defined variable. If there are many potential defined variables the preprocessor will select a recursive set and logically eliminate them from the internal model: The values of the defined variables are easily derived from the values of all other variables by solving the definitional constraints in their recursive order. These values are then substituted into the remaining constraints before their residuals are computed. The matrix of derivatives of the remaining constraints is computed from the overall matrix of derivatives via an efficient elimination of the triangular definitional constraints.

The following extract from the log-file for the **otpop.gms** model in the GAMS Library shows the main output from the preprocessor:

```
The user model has 77 constraints and 104 variables
with 285 Jacobian elements, 100 of which are nonlinear.
The Hessian of the Lagrangian has 17 elements on the diagonal,
33 elements below the diagonal, and 66 nonlinear variables.

Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK
0   0          4.0939901439E+03 (Input point)

The pre-triangular part of the model has 32 constraints and 43 variables.
The post-triangular part of the model has 9 constraints and variables.
There are 13 definitional constraints and defined variables.

Preprocessed model has 23 constraints and 39 variables
with 88 Jacobian elements, 25 of which are nonlinear.

Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK
                  1.0510968588E+03 (Full preprocessed model)
                  4.5063072017E+01 (After scaling)
```

The first few lines define the size of the user model. After the description of the initial sum of infeasibilities there are three lines with statistics from the preprocessor. Note that the pre-triangular part of the model has more variables than constraints, in this case because there are fixed variables. The post-triangular part will always have the same number of constraints as variables, and the same is true for definitional constraints and defined variables.

After the statistics from the preprocessor the size of the resulting internal model is shown. The number of constraints in the preprocessed model, here 23, is computed from 77 constraints in the user model minus 32 removed in the pre-triangle, 9 removed in the post-triangle, and 13 removed as definitional constraints. Similarly, the number of variables in the preprocessed model, here 39, is computed from 104 variables in the user model minus 43 removed in the pre-triangle, 9 removed in the post-triangle, and 13 removed as definitional variables. The Jacobian counts cannot be derived easily. And there is no Hessian information for the internal model; it is costly to compute the Hessian for the internal model and it will in most cases be very dense so all use of 2^{nd} order information in the internal model is computed by mapping variables and constraints to the user model and using the Hessian in the user model.

Other examples of output from the preprocessor are explained in the section on Alternative Sub-Models.

There are some options that control the preprocessor:

- You can turn the preprocessor off using the option Flg_Prep = false. Note that CONOPT still will generate an internal model, but it will be very close to the user model.
- You can turn the search for definitional constraints off using option Flg_NoDefc = true. The time used for the search will usually be recovered later by cheaper iterations, except for models that solve in very few iterations.

5.8.6 Adjust Initial Point

If the preprocessed model is infeasible, CONOPT starts with a new 'Adjust Initial Point' procedure. The procedure reduces the sum of infeasibilities by changing individual variables one at a time. The procedure is very cheap because changing a single variable only involves a small part of the overall model. The procedure will as a by-product produce a large part of a good initial basis and many constraints will become feasible. If the Adjust Initial Point procedure reduces the infeasibilities, the log file will have a line as shown below (from otpop.gms):

```
Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK
                    1.0510968588E+03 (Full preprocessed model)
                    4.5063072017E+01 (After scaling)
                    2.7782397440E+00 (After adjusting individual variables)
  5   0             1.5284282657E+00                 1.0E+00     1 T  T
```

As this example shows, the procedure can in some cases reduce the sum of infeasibilities significantly. In rarer cases it will find a feasible solution.

The time used by the Adjust Initial Point procedure can in rare cases, usually for very dense models, be large. If you experience this, you can turn the procedure off with option Flg_AdjIniP = false.

5.8.7 Phase 0 - Finding an Initial Feasible Solution

CONOPT is a feasible path method, but the initial point defined by the user will not always be feasible, and the Adjust Initial Point procedure may not reduce the infeasibilities to zero.

Phase 0 searches for a feasible solution using a procedure based on Newton's method for solving nonlinear equalities. If a basis has been provided by GAMS (see the GAMS Option Bratio for details) then the initial basis will be as chosen from the GAMS basis with adjustments to make it non-singular. Otherwise, a set of basic variables is selected with preference for variables away from their bounds. It may not be possible to find a full basis with variables away from their bounds so the initial basis may also have some slack variables. The standard Newton's method defines a change direction for these basic variables but bounds and basic slacks will sometimes prevent this direction from reducing the sum of infeasibilities. CONOPT is therefore using an LP-like pricing step to select a subset of the constraints for with Newton's method will reduce the sum of infeasibilities. Newton's method applied to this subset gives a search direction and if a full step can be taken without reaching any bounds the constraints in the subset will usually become feasible rather quickly. If bounds become active the basis is changed and the process is repeated. The constraints that are not in the Newton subset, usually few, will subsequently be made feasible using a phase 1 procedure.

This log file extract showing Phase 0 is from GAMS Library model mathopt3.gms:

The `InItr` column shows the number of basis changes for each outer iteration and `Step = 1` indicates that the full solution from Newton's method was used. For some of the iterations Step is less than 1 indicating that the direction found by the inner linear model could not be used in full due to nonlinearities. There are some lines with 'S0' instead of 0 in the Phase column. The S tells that the model was scaled before the iteration and the sum of infeasibilities was increased during this scaling procedure. The sum of infeasibilities is therefore not monotone decreasing, even if each outer iteration does decrease them.

Phase 0 terminates when the Newton subset is made feasible and CONOPT switches to Phase 1 where the remaining constraints are handled. In this model there are just 2 infeasible constraints left.

5.8.8 Transition between SLP and SQP

The transition from SLP (Phase 1 or 3) to SQP (Phase 2 or 4) and back again is in CONOPT3 based on monitoring failure. This logic has been changed in CONOPT, so transition is based on continuous measurements of curvature, both in the general constraints and in the objective function, combined with estimates of computational costs and progress for SLP and SQP.

The continuation of the log file for GAMS Library model otpop.gms shows some of this:

```
 Iter Phase   Ninf     Objective     RGmax      NSB   Step  InItr MX OK
    6   3          2.3861517936E+02 3.6E+02      12 2.1E-01     7 F  T

** Optimal solution. Reduced gradient less than tolerance.
```

Iterations 6 to 9 are SLP iterations (Phase 3) and iterations 10 to 14 are SQP iterations (Phase 4). The SLP iterations have Step less than 1 due to nonlinear objective terms and CONOPT jumps directly from SLP to SQP. You may in other models see that SQP is replaced by SLP after some iterations where the nonlinearities are measured to be very small.

5.8.9 Bad Iterations

Bad iterations, flagged with "F" in the "OK" column can be a problem. They appear if the output from the SLP or SQP procedure is a search direction where CONOPT cannot move very far because it is difficult to make the nonlinear constraints feasible again. The efforts spent in solving the SLP or SQP procedure is therefore partially wasted. The problem is usually associated with a basis that is ill-conditioned or has Jacobian elements that change very fast.

CONOPT monitors the quality of the basis using information that already has been computed such as the size of elements of the tangent for basic variables relative to similar elements for superbasic variables and intermediate results from the computation of the reduced costs. This information is then used to trigger the search for a better basis, that usually will allow CONOPT to make larger steps in the following one-dimensional searches.

5.8.10 Saddle Points and Directions of Negative Curvature

CONOPT is based on moving in a direction derived from the gradient, or the reduced gradient for models with constraints. If the reduced gradient projected on the bounds is zero, then the solution satisfies the first-order optimality conditions (the KKT or Karush-Kuhn-Tucker conditions), and it is standard procedure to stop. Unfortunately, this means that we can stop in a saddle-point.

It is not very common to move towards a saddle-point and get stuck there. However, it is not uncommon that the initial point, provided by a user or by default, is a saddle point. A simple example is the constraint `x*y =E= 1` started with `x.l = y.l = 0;` this construct can easily end with a locally infeasible solution. Another example is `minimize z`, `z =E= x*y` with the same starting point; it could end locally optimal without moving even though better points exist in the neighborhood.

CONOPT has added a procedure that tries to find a direction of negative curvature that can move the solution point away from a saddle-point. The procedure is only called in points that satisfy the first order optimality conditions and it is therefore usually only called once, and it is a cheap safeguard. The theory behind the method is developed for models without degeneracy and it works very well in practice for these models. Models with some kind of degeneracy (basic variables at bound or nonbasic variables with zero reduced cost) use the same procedure, but it is in this case only a heuristic that cannot be guaranteed to find a direction of negative curvature, even if one exists.

If you know that there are no directions of negative curvature, you can turn the procedure off by setting the logical option Flg_NegCurve to `false`. If the model is known to be convex you can set the logical option Flg_Convex to `true` and it will also turn this procedure off. The saving is usually very small, except for models that solve in very few iterations and for models with very many super basics.

There is no output in the log file for negative curvature. If a direction of negative curvature is found CONOPT will follow this direction and the optimization continues. Otherwise, the solution is declared locally optimal.

5.8.11 Alternative Sub-Models

During an optimization CONOPT can work with up to three different internal sub-models. These models are:

- Full Model: This model consists of the constraints in the user's model excluding all pre- and post-triangular constraints and with the definitional variables eliminated by their defining constraints. The objective function is the user's objective function.
- No-Penalty Model: This model consists of the Full Model excluding all penalty and mini-max constraints. This model does not have an objective function and it is terminated when a feasible solution has been found.
- Linear Feasibility Model: This model consists of the subset of linear constraints of the Full Model. The Linear Feasibility model is either solved without an objective function or minimizing a quadratic distance measure; this is discussed below.

The pre-triangular variables are considered fixed, and they do not appear in any of the sub-models. Their influence comes through their contribution to coefficients and constant terms. The post-triangular variables are considered intermediate variables in the definition of the objective function. They do not appear in the last two models that only are concerned with feasibility, and they only appear indirectly via the objective in the Full Model. The defined variables are considered intermediate variables in the definition of the remaining constraints in the same way as post-triangular variables are intermediate in the objective. The variables in the Full Model are all variables excluding pre- and post-triangular variables and excluding defined variables; this set can include variables that do not appear in any constraints. The constraints of the full models are all constraints excluding pre- and post-triangular constraints and with the definitional constraints logically eliminated. The variables in the Linear Feasibility Model and in the No-Penalty Model are the variables that appear in the constraints of these models, excluding pre-triangular variables.

5.8.11.1 No-Penalty Model

CONOPT always starts by searching for a feasible solution and the sub-models only play a role in this part of the optimization. Therefore, these sub-models are irrelevant if the initial point provided by the modeler is feasible. If there are many penalty and/or minimax constraints then the No-Penalty Model will be much smaller than the Full Model and it is more efficient to use the smaller model while searching for feasibility. The No-Penalty model is therefore only introduced for efficiency reasons. It is by default solved before the Full Model if all the following conditions are satisfied:

- The Flg_NoPen options is true (the default value),
- The model is not a CNS model,
- The user did not provide an initial basis,
- Some of the constraints in the No-Penalty Model are infeasible,
- The number of penalty and minimax constraints is more than the number of constraints in the Full Model multiplied by the value of option Rat_NoPen. The default value of `Rat_NoPen` is `0.1`, i.e., the No-Penalty Model is only defined and solved if it is at least 10% smaller than the Full Model.

An example of a log-file for a model with a No-Penalty model is from the **prolog.gms** model in the GAMS Library:

```
The user model has 23 constraints and 21 variables
with 129 Jacobian elements, 14 of which are nonlinear.
The Hessian of the Lagrangian has 0 elements on the diagonal,
4 elements below the diagonal, and 6 nonlinear variables.

Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK
   0   0          1.2977431398E+03 (Input point)

The post-triangular part of the model has 1 constraints and variables.
There are 17 penalty and minimax constraints with 3 variables.

Reduced model without penalty components has 5 constraints and
17 variables with 46 Jacobian elements, 0 of which are nonlinear.

Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK
                    1.2960000000E+03 (Model without penalty constraints)
                    5.0625000000E+00 (After scaling)
                    0.0000000000E+00 (After adjusting individual variables)

Previous model terminated and penalty components are added back in.
Full preprocessed model has 22 constraints and 20 variables
with 120 Jacobian elements, 8 of which are nonlinear.

Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK
                    0.0000000000E+00 (After adjusting penalty variables)
```

There are no pre-triangular variables and constraints, and the pre-triangular line is therefore missing. There are also no definitional constraints and the line describing definitional constraints is also missing. On the other hand, there is a line saying that the model has 17 penalty and minimax constraints involving a total of 3 variables.

Since there is a significant number of penalty and minimax constraints, CONOPT starts by generating the No-Penalty model without the penalty and minimax constraints and without the pre- and post-triangular constraints. The 23 constraints in the user model are reduced by 1 post-triangular constraint and 17 minimax and penalty constraints, leaving 5 constraints. Similarly, the 21 variables in the user model are reduced by 1 post-triangular variable and 3 variables in the penalty and minimax constraints, leaving 17 variables.

This No-Penalty model is scaled and made feasible, in this case by the Adjust Initial Point procedure described above. After the No-Penalty model has become feasible CONOPT generates the full internal model, and the 3 variables from the penalty and minimax constraints are adjusted as described in the section on the Preprocessor and the Full Model is then feasible.

5.8.11.2 Linear Feasibility Model

The Linear Feasibility Model is introduced to avoid locally infeasible solutions where some linear constraints are infeasible and some feasible nonlinear constraint block for the linear constraint becoming feasible. The Linear Feasibility Model is used to produce a starting point to one of the nonlinear sub-models (the No-Penalty Model or the Full Model) that satisfies all linear constraints. If the Linear Feasibility Model is proved to be infeasible then the overall model is proved to be globally infeasible (independent of nonlinearities) and there is no reason to proceed with the nonlinear part of the model.

The Linear Feasibility Model is only useful if the model has some linear constraints and if the initial point provided by the modeler does not satisfy these constraints. If the Linear Feasibility Model finds a feasible solution to the linear constraints, it continues in one of four possible ways:

A. Use the first feasible solution directly without using extra effort to improve the solution.

B. Perform an approximate minimization of the weighted distance from the user's initial point. Only the variables that have non-default initial values are included in the distance measure, i.e. variables with an initial value (`xini`) that is different from zero projected on the bounds, i.e. `xini ne min(max(0,x.lo),x.up)`. The distance measure is `sqr( (x-xini) / max(1,abs(xini)) )`.

C. As in B, but with all variables included in the distance measure.

D. As in C, but with xini defined as a value between the lower and upper bounds.

Possibility A is fast, but it may give a starting point for the nonlinear model far from the initial point provided by the user. B is slower but gives a starting point for the nonlinear model that is close to the point provided by the user. The variables included in the distance measure in B are the variables that the user has given a value to and therefore are expected to be important. C and D are also slower, but because they have different objective functions, they may provide different starting points for the nonlinear model and may therefore avoid locally infeasible solutions.

Once the Linear Feasibility Model has been solved, with or without a distance objective function, the No-Penalty Model and/or the Full Model are started. All variables that appear in the Linear Feasibility Model are started from the solution values from this model and the remaining variables, that only appear in nonlinear constraints, are started from the values received from the modeler.

The order in which the sub-models are solved depends on the Linear Feasibility Model strategy, defined with option, Lin_Method:

1. If `Lin_Method` has the default value 1 then the initial point and basis is assumed to be good and CONOPT will start with the No-Penalty Model (only if the conditions mentioned above are satisfied) followed by the Full Model. If the model terminates locally optimal, unbounded, or on some resource limit (time, iterations, function evaluations) CONOPT terminates. We only build and solve the Linear Feasibility Model if the No-Penalty or Full model terminates locally infeasible. If the Linear Feasibility Model is infeasible, the overall model is infeasible and CONOPT terminates. Otherwise, we minimize objective B and use the solution point as a second starting point for the nonlinear model. If this attempt also terminates locally infeasible, we try to generate an alternative initial point with objective C and then with objective D. If all these attempts fail, the model is labeled locally infeasible.
2. With `Lin_Method = 2` CONOPT will start directly with the Linear Feasibility Model with objective A followed by the No-Penalty and Full models. If they are locally infeasible from this starting point, we followed the procedure from above with objective B, C, and then D.
3. `Lin_Method = 3` is like `Lin_Method = 2` except that the first objective A is skipped.

Sometimes the objective functions are identical. If all variables have default initial values, then A and B are the same, and if all variables have non-default initial values, then B and C are the same. CONOPT will check for this and will not solve identical sub-models.

The number of times we restart after a locally infeasible solution is controlled by the option, Num_Rounds. The default value is 4, i.e., we will by default try very hard to find a feasible point as shown in the example below. The value 1 will make CONOPT terminate immediately if a locally infeasible point is found, without going back to the Linear Feasibility Model. Num_Rounds can be used if you are not interested in spending extra time on a model that is likely to be infeasible. This is particularly relevant when CONOPT is used as the sub-solver inside SBB, where infeasible sub-problems are common.

An example of a log-file where all Linear Feasibility objectives are used is taken from `ex5_3_2.gms` in the GlobalLib collection of test models. It shows the repeated starts of the Linear Feasibility Model followed by the Full Preprocessed model:

```
   Preprocessed model has 22 variables and 16 constraints
   with 59 Jacobian elements, 24 of which are nonlinear.

   Iter Phase   Ninf   Infeasibility   RGmax      NSB   Step  InItr MX OK

```

The Full Model is infeasible when started directly from the values provided by the user. The Linear Feasibility model is then solved to get a different starting point for the Full model where the linear part is feasible. The Full Model is also infeasible from this point, and it is necessary to solve the Linear Feasibility model three times with different objective functions before the full model becomes feasible.

If the model is defined to be convex with option `Flg_Convex = true` then a locally infeasible solution is labeled globally infeasible with ModelStat = 4, and the Linear Feasibility Model will not be used. A locally optimal solution is also labeled (globally) optimal with ModelStat = 1.

5.8.12 Scaling

The Tutorials and Examples section of the GAMS User's Guide has some general recommendations about scaling the user's model. These recommendations also apply to CONOPT.

In addition to the scaling done by the user, CONOPT will also scale the model internally by defining scale factors for both variables and constraints. The purpose of scaling is to get a scaled Jacobian matrix where the nonzero elements are neither very large nor very small, and scaled variables that are neither very large nor very small.

Variables are scaled with the formula xint = xuser / vscale and constraints are scaled with the formula gint = guser / gscale, where 'int' and 'user' represent the user model and the internal (scaled) model and vscale and gscale are scale factors for variables and constraints. As a result, the Jacobian elements changes with Jacint = Jacuser $*$ vscale / gscale.

For LP models the Jacobian is constant and scaling is usually done once. For nonlinear models the Jacobian changes with the solution point and scaling is therefore done at regular intervals.

In a nonlinear model a small variable or a small Jacobian element may be small because it is insignificant, but it may also be significant and just small in the current point. CONOPT is therefore using a scaling

procedure that scales large variables values and large Jacobian terms down to around 1, but it does not scale small variables values and small Jacobian terms up. The modeler is therefore advised to make sure that the expected solution values are not very small and that the terms in constraint are not all very small.

There are two options relevant for scaling: Tol_Scale_Max is the largest scaling factor that CONOPT will use. The default value is $1.e^{15}$ and it is applied to both variables and constraints. Tol_Scale_Min is the smallest scaling factor that CONOPT will use. The default value is 1 and it is also applied to both variables and constraints. The default values imply what was mentioned above, that very large terms can be scaled down, but small terms are not scaled up. If you have small but significant terms you may set Tol_Scale_Min below 1 but notice that insignificant small terms may also be scaled up and may disturb the solution process.

If the largest value of a variable, option Lim_Variable or the internal value of 'infinity', is increased you may consider increasing Tol_Scale_Max as well.

5.8.13 CNS Models

There is a special model class in GAMS called CNS - Constrained Nonlinear System. A constrained nonlinear system is a square system of equations, i.e., a model in which the number of non-fixed variables is equal to the number of constraints. A CNS model can be solved with a solve statement like

```
Solve <model> using CNS;
```

without an objective term. CONOPT will attempt to solve the constraints with respect to the non-fixed variables using Newton's method. When it works, it is often very fast, and it uses less memory than for the corresponding NLP model, but the solution process does not include a lot of the safeguards used for ordinary NLP models. The lack of safeguards means that the solution process will stop with an error message in some difficult situations and return the current intermediate infeasible solution. Some examples are shown below.

Slacks in inequalities are counted as non-fixed variables which effectively means that inequalities should not be binding. Bounds on the variables are allowed, especially to prevent function evaluation errors for functions that only are defined for some arguments, but the bounds should not be binding in the final solution.

Since there is no objective function the solution returned to GAMS will in all cases have marginal values equal to 0 or EPS, both for the variables and the constraints.

The termination messages for CNS models are different from the termination messages for optimization models. The message you hope for is this:

```
** Feasible solution to a square system.
```

that usually will be combined with ModelStat = 16 - Solved. If CONOPT in special cases can guarantee that the solution is unique, for example if the model is linear, then ModelStat will be 15 - Solved Unique.

There are two potential error termination messages related to CNS models. A model with the following two constraints

```
e1 ..   x1 +   x2 =e= 1;
e2 .. 2*x1 + 2*x2 =e= 2;
```

will result in this message

```
** Error in Square System: Pivot too small.
    e2: Pivot too small.
    x1: Pivot too small.
```

"Pivot too small" means that the set of constraints is linearly dependent on the current point and there is no unique search direction for Newton's method, so CONOPT terminates. In the listing file (but not the log-file) the message points to one variable and one constraint. However, this pair of constraint and variable just indicates that the linearly dependent set of constraints and variables include the constraint and variable mentioned. The offending constraint and variable will also be labeled 'DEPND' for linearly dependent in the equation listing. The error will usually be combined with ModelStat = 5 - Locally Infeasible. In cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities ModelStat will be 4 - Infeasible. If the constraints are linearly dependent but the current point satisfies the constraints then the solution status will be 17 - Solved Singular, indicating that the point is feasible, but there is probably a whole ray of feasible solution through the current point.

It should be mentioned that linear dependency and small pivot could be caused by the initial point and that the model could have a solution. An example is:

```
e1.. x1*x2 =E= 1;
e2.. x1+x2 =E= 3;
x1.l = 1; x2.l = 1;
```

A model with these two constraints and the bound

```
e1 .. x1 + x2 =e= 2;
e2 .. x1 - x2 =e= 0;
x1.lo = 1.5;
```

will result in the message

```
** Error in Square System: A variable tries to exceed its bound.
    x1: The variable tries to exceed its bound.
```

because the solution, (x1,x2) = (1,1) violates the lower bound on x1. This error case will also be combined with ModelStat = 5 - Locally Infeasible. In the cases where CONOPT can guarantee that the infeasibility is not caused by nonlinearities ModelStat will be 4 - Infeasible.

CNS can in some cases be used to generate an initial feasible solution: Fix a subset of the variables so the remaining model is uniquely solvable, solve this model with the CNS solver, reset the bounds on the fixed variables, and solve the original model. This two-solve method gives better control over the first feasible solution and can be useful for very large models.

Additional information on CNS can be found in the GAMS User's Guide

5.8.14 Multiple Threads

CONOPT can use multiple threads for some internal computations and GAMS can use multiple threads for function and derivative evaluations. In addition to function and derivative evaluations, multiple threads are only used for certain very large and dense computations and there are not so many of these in the types of models usually built with GAMS. In addition, multiple threads have some overhead, and they are therefore mainly useful for very large models. Currently, the best improvements have been for very large models with more than 100,000 variables or constraints, and especially for very large CNS models.

Threads can be turned on with the GAMS command-line option Threads=n or with the CONOPT option threads.

5.8.15 Loss of Feasibility

During the optimization you may sometimes see a phase 0 iteration and in rare cases you will see the message "Loss of Feasibility - Return to Phase 0". The background for this is as follows:

To work efficiently, CONOPT uses dynamic tolerances for feasibility and during the initial part of the optimization, where the objective changes rapidly, larger infeasibilities are accepted. As the change in objective between iterations becomes smaller it is necessary to solve the constraints more accurately so the uncertainty of the objective value caused by inaccurate constraints will remain smaller than the actual change. The accuracy of the objective is measured as the scalar product of the constraint residuals with the constraint marginals.

Sometimes it is necessary to revise the accuracy of the solution, for example because the algorithmic progress has slowed down or because the marginal of an inaccurate constraint has grown significantly after a basis change, e.g., when an inequality becomes binding. In these cases, CONOPT will reduce the feasibility tolerance and perform one or more Newton iterations on the basic variables. This will usually be very quick, and it happens silently. However, Newton's method may fail, for example in cases where the model is degenerate, and Newton tries to move a basic variable outside a bound. In this case CONOPT uses some special iteration similar to those discussed in section Phase 0 - Finding an Initial Feasible Solution and they are labeled Phase 0.

These Phase 0 iterations may not converge, for example if the degeneracy is significant, if the model is very nonlinear locally, if the model has many product terms involving variables at zero, or if the model is poorly scaled and some constraints contain very large terms. If the iterations do not converge, CONOPT will issue the "Loss of feasibility ..." message, return to the real Phase 0 procedure, find a feasible solution with the smaller tolerance, and resume the optimization.

In rare cases you will see that CONOPT cannot find a feasible solution after the tolerances have been reduced, even though it has declared the model feasible at an earlier stage. In this case CONOPT will stop, restore the last point that was labeled feasible and return this point as an intermediate feasible solution.

Although the problems may appear to be with too tight tolerances it is not a good idea to relax the feasibility tolerances. Relaxed feasibility tolerances will give more inaccurate objective function values that result in difficulties for the progress of the optimization as discussed in the next section.

5.8.16 Stalling

CONOPT will usually make steady progress towards the final solution. A degeneracy breaking strategy and the monotonicity of the objective function in other iterations should ensure that CONOPT cannot cycle. Unfortunately, there are a few places in the code where the objective function may move in the wrong direction and CONOPT may in fact cycle or move very slowly.

The objective value used to compare two points, in the following called the adjusted objective value, is computed as the true objective plus an accuracy adjustment term equal to the scalar product of the residuals with the marginals (see the previous section where this accuracy term also is used). The accuracy adjustment term is very useful in allowing CONOPT to work smoothly with inaccurate intermediate solutions. However, there is a disadvantage: the accuracy adjustment term can change even though the point itself does not change, namely when the marginals change in connection with a basis change. The adjusted objective is therefore not always monotone. When CONOPT loses feasibility and returns to Phase 0 there is an even larger chance of non-monotone behavior.

To prevent infinite loops and to allow the modeler to stop in cases with very slow progress CONOPT has an anti-stalling option. An iteration is counted as a stalled iteration if it is not degenerate and (1) the adjusted objective is worse than the best adjusted objective seen so far, or (2) the step length was zero without being degenerate (see OK = F in section Linear and Nonlinear Mode: Phase 1 to 4). CONOPT will stop if the number of consecutive stalled iterations (again not counting degenerate iterations) exceeds `Lim_StallIter` and `Lim_StallIter` is positive. The default value of `Lim_StallIter` is 100. The message will be:

```
** Feasible solution. The tolerances are minimal and
   there is no change in objective although the reduced
   gradient is greater than the tolerance.
```

Large models with very flat optima can sometimes be stopped prematurely due to stalling. If it is important to find a local optimum accurately then you may have to increase the value of `Lim_StallIter`.

5.8.17 APPENDIX A - Options

The options that ordinary GAMS users can access are listed below.

5.8.17.1 Algorithmic options

Option	Description	Default
Flg_AdjIniP	Flag for calling Adjust Initial Point	1
Flg_Convex	Flag for defining a model to be convex	0
Flg_Crash_Slack	Flag for pre-selecting slacks for the initial basis.	0
Flg_Dbg_Intv	Flag for debugging interval evaluations.	0
Flg_NegCurve	Flag for testing for negative curvature when apparently optimal	1
Flg_NoDefc	Flag for turning definitional constraints off. The default is false.	0
Flg_NoPen	Flag for allowing the Model without penalty constraints	1
Flg_SLPMode	Flag for enabling SLP mode.	1
Flg_SQPMode	Flag for enabling of SQP mode.	1
Flg_Square	Flag for Square System. Alternative to defining modeltype=CNS in GAMS	0
Flg_TraceCNS	Flag for tracing a CNS solution.	0
Frq_Rescale	Rescaling frequency.	5
Lim_Err_2DDir	Limit on errors in Directional Second Derivative evaluation.	10
Lim_Err_Fnc_Drv	Limit on number of function evaluation errors. Overwrites GAMS Domlim option	GAMS DomLim
Lim_Err_Hessian	Limit on errors in Hessian evaluation.	10
Lim_Iteration	Maximum number of iterations. Overwrites GAMS Iterlim option.	GAMS IterLim
Lim_NewSuper	Maximum number of new superbasic variables added in one iteration.	auto
Lim_RedHess	Maximum number of superbasic variables in the approximation to the Reduced Hessian.	auto
Lim_SlowPrg	Limit on number of iterations with slow progress (relative less than Tol_Obj_Change).	20
Lim_StallIter	Limit on the number of stalled iterations.	100
Lim_Start_Degen	Limit on number of degenerate iterations before starting degeneracy breaking strategy.	100

Option	Description	Default
Lim_Time	Time Limit. Overwrites the GAMS Reslim option.	GAMS ResLim
Lim_Variable	Upper bound on solution values and equation activity levels	1.e15
Lin_Method	Method used to determine if and/or which Linear Feasibility Models to use	1
Mtd_Dbg_1Drv	Method used by the function and derivative debugger.	0
Mtd_RedHess	Method for initializing the diagonal of the approximate Reduced Hessian	0
Mtd_Scale	Method used for scaling.	3
Mtd_Step_Phase0	Method used to determine the step in Phase 0.	auto
Mtd_Step_Tight	Method used to determine the maximum step while tightening tolerances.	0
Num_Rounds	Number of rounds with Linear Feasibility Model	4
Rat_NoPen	Limit on ratio of penalty constraints for the No_Penalty model to be solved	0.1
Tol_Bound	Bound filter tolerance for solution values close to a bound.	1.e-7
Tol_BoxSize	Initial box size for trust region models for overall model	10
Tol_BoxSize_Lin	Initial box size for trust region models for linear feasibility model	1000
Tol_Box_LinFac	Box size factor for linear variables applied to trust region box size	10
Tol_Def_Mult	Largest growth factor allowed in the block of definitional constraints	1.e4
Tol_Feas_Max	Maximum feasibility tolerance (after scaling).	1.e-7
Tol_Feas_Min	Minimum feasibility tolerance (after scaling).	4.e-10
Tol_Feas_Tria	Feasibility tolerance for triangular equations.	1.0e-8
Tol_Fixed	Tolerance for defining variables as fixed based on initial or derived bounds.	4.e-10
Tol_Jac_Min	Filter for small Jacobian elements to be ignored during scaling.	1.e-5
Tol_Linesearch	Accuracy of One-dimensional search.	0.2
Tol_Obj_Acc	Relative accuracy of the objective function.	3.0e-13
Tol_Obj_Change	Limit for relative change in objective for well-behaved iterations.	3.0e-12
Tol_Optimality	Optimality tolerance for reduced gradient when feasible.	1.e-7
Tol_Opt_Infeas	Optimality tolerance for reduced gradient when infeasible.	1.e-7
Tol_Opt_LinF	Optimality tolerance when infeasible in Linear Feasibility Model	1.e-10
Tol_Piv_Abs	Absolute pivot tolerance.	1.e-10
Tol_Piv_Abs_Ini	Absolute Pivot Tolerance for building initial basis.	1.e-7
Tol_Piv_Abs_NLTr	Absolute pivot tolerance for nonlinear elements in pre-triangular equations.	1.e-5
Tol_Piv_Ratio	Relative pivot tolerance during ratio-test	1.e-8
Tol_Piv_Rel	Relative pivot tolerance during basis factorizations.	0.05
Tol_Piv_Rel_Ini	Relative Pivot Tolerance for building initial basis	1.e-3

Option	Description	Default
Tol_Piv_Rel_Updt	Relative pivot tolerance during basis updates.	0.05
Tol_Scale2D_Min	Lower bound for scale factors based on large 2nd derivatives.	1.e-6
Tol_Scale_Max	Upper bound on scale factors.	1.e25
Tol_Scale_Min	Lower bound for scale factors computed from values and 1st derivatives.	1
Tol_Scale_Var	Lower bound on x in x∗Jac used when scaling.	1.e-5
Tol_Zero	Zero filter for Jacobian elements and inversion results.	1.e-20
Trace_MinStep	Minimum step between Reinversions when using TraceCNS.	0.001

5.8.17.2 Debugging options

Option	Description	Default
Flg_Interv	Flag for using intervals in the Preprocessor	1
Flg_Prep	Flag for using the Preprocessor	1
Flg_Range	Flag for identifying sets of ranged constraints	1
Lim_Dbg_1Drv	Flag for debugging of first derivatives	0
Lim_Hess_Est	Upper bound on second order terms.	1.e4
Lim_Msg_Dbg_1Drv	Limit on number of error messages from function and derivative debugger.	10

5.8.17.3 Output options

Option	Description	Default
Frq_Log_Simple	Frequency for log-lines for non-SLP/SQP iterations.	auto
Frq_Log_SlpSqp	Frequency for log-lines for SLP or SQP iterations.	auto
Lim_Msg_Large	Limit on number of error messages related to large function value and Jacobian elements.	10
Lim_Pre_Msg	Limit on number of error messages related to infeasible pre-triangle.	25

5.8.17.4 Interface options

Option	Description	Default
cooptfile		
Flg_2DDir	Flag for computing and using directional 2nd derivatives.	auto
Flg_Hessian	Flag for computing and using 2nd derivatives as Hessian of Lagrangian.	auto
HEAPLIMIT	Maximum Heap size in MB allowed	1e20
HessianMemFac	Memory factor for Hessian generation: Skip if Hessian elements > Nonlinear Jacobian elements∗HessianMemFac, 0 means unlimited.	0

Option	Description	Default
THREADC	Number of compatibility threads used for comparing different values of THREADS	1
THREADF	Number of threads used for function evaluation	1
threads	Number of threads used by Conopt internally	GAMS Threads

cooptfile *(string)*: ↩

Flg_2DDir *(boolean)*: Flag for computing and using directional 2nd derivatives. ↩

If turned on, make directional second derivatives (Hessian matrix times directional vector) available to CONOPT. The default is on, but it will be turned off of the model has external equations (defined with =X=) and the user has not provided directional second derivatives. If both the Hessian of the Lagrangian (see Flg_Hessian) and directional second derivatives are available then CONOPT will use both: directional second derivatives are used when the expected number of iterations in the SQP sub-solver is low and the Hessian is used when the expected number of iterations is large.

Default: auto

Flg_AdjIniP *(boolean)*: Flag for calling Adjust Initial Point ↩

If Flg_AdjIniP is on (the default) then the Adjust Initial Point routine is called after the pre-processor. Can be turned off if the routine is very slow.

Default: 1

Flg_Convex *(boolean)*: Flag for defining a model to be convex ↩

When turned on (the default is off) CONOPT knows that a local solution is also a global solution, whether it is optimal or infeasible, and it will be labeled appropriately. At the moment, Flg_NegCurve will be turned off. Other parts of the code will gradually learn to take advantage of this flag.

Default: 0

Flg_Crash_Slack *(boolean)*: Flag for pre-selecting slacks for the initial basis. ↩

When turned on (1) CONOPT will select all infeasible slacks as the first part of the initial basis.

Default: 0

Flg_Dbg_Intv *(boolean)*: Flag for debugging interval evaluations. ↩

Flg_Dbg_Intv controls whether interval evaluations are debugged. Currently we check that the lower bound does not exceed the upper bound for all intervals returned, both for function values and for derivatives.

Default: 0

Flg_Hessian *(boolean)*: Flag for computing and using 2nd derivatives as Hessian of Lagrangian. ↩

If turned on, compute the structure of the Hessian of the Lagrangian and make it available to CONOPT. The default is usually on, but it will be turned off if the model has external equations (defined with =X=) or cone constraints (defined with =C=) or if the Hessian becomes too dense. See also Flg_2DDir and HessianMemFac.

Default: auto

Flg_Interv *(boolean)*: Flag for using intervals in the Preprocessor ↩

If turned on (default), CONOPT will attempt to use interval evaluations in the preprocessor to determine if functions are monotone or if intervals for some of the variables can be excluded as infeasible.

Default: 1

Flg_NegCurve *(boolean)*: Flag for testing for negative curvature when apparently optimal ↩

When turned on (the default) CONOPT will try to identify directions with negative curvature when the model appears to be optimal. The objective is to move away from saddlepoints. Can be turned off when the model is known to be convex and cannot have negative curvature.

Default: 1

Flg_NoDefc *(boolean)*: Flag for turning definitional constraints off. The default is false. ↩

If Flg_NoDefc is on, the Preprocessor will not look for definitional constraints and variables.

Default: 0

Flg_NoPen *(boolean)*: Flag for allowing the Model without penalty constraints ↩

When turned on (the default) CONOPT will create and solve a smaller model without the penalty constraints and variables and the minimax constraints and variables if the remaining constraints are infeasible in the initial point. This is often a faster way to start the solution process.

Default: 1

Flg_Prep *(boolean)*: Flag for using the Preprocessor ↩

If turned on (default), CONOPT will use its preprocessor to try to determine pre- and post-triangluar components of the model and find definitional constraints.

Default: 1

Flg_Range *(boolean)*: Flag for identifying sets of ranged constraints ↩

If turned on (default), CONOPT will as part of its preprocessor look for sets of parallel linear constraints and turn each set into a single ranged constraints. There is currently a potential problem with the duals on these constraints and if duals are important ranges can be turned off with this flag.

Default: 1

Flg_SLPMode *(boolean)*: Flag for enabling SLP mode. ↩

If Flg_SLPMode is on (the default) then the SLP (sequential linear programming) sub-solver can be used, otherwise it is turned off.

Default: `1`

Flg_SQPMode *(boolean)*: Flag for enabling of SQP mode. ↩

If Flg_SQPMode is on (the default) then the SQP (sequential quadratic programming) sub-solver can be used, otherwise it is turned off.

Default: `1`

Flg_Square *(boolean)*: Flag for Square System. Alternative to defining modeltype=CNS in GAMS ↩

When turned on the modeler declares that this is a square system, i.e. the number of non-fixed variables must be equal to the number of constraints, no bounds must be active in the final solution, and the basis selected from the non-fixed variables must always be nonsingular.

Default: `0`

Flg_TraceCNS *(boolean)*: Flag for tracing a CNS solution. ↩

When turned on the model must, for fixed value of the objective variable, be a CNS model and must satisfy the conditions of a CNS. The model is first solved as a CNS with the initial value of the objective fixed and the objective is then minimized or maximized subject to the CNS constraints.

Default: `0`

Frq_Log_Simple *(integer)*: Frequency for log-lines for non-SLP/SQP iterations. ↩

Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration send to the log file. The non-SLP/SQP iterations, i.e. iterations in phase 0, 1, and 3, are usually fast and writing a log line for each iteration may be too much, especially for smaller models. The default value for the log frequency for these iterations is therefore set to 10 for small models, 5 for models with more than 500 constraints or 1000 variables and 1 for models with more than 2000 constraints or 3000 variables.

Default: `auto`

Frq_Log_SlpSqp *(integer)*: Frequency for log-lines for SLP or SQP iterations. ↩

Frq_Log_Simple and Frq_Log_SlpSqp can be used to control the amount of iteration send to the log file. Iterations using the SLP and/or SQP sub-solver, i.e. iterations in phase 2 and 4, may involve several inner iterations and the work per iteration is therefore larger than for the non-SLP/SQP iterations and it may be relevant to write log lines more frequently. The default value for the log frequency is therefore 5 for small models and 1 for models with more than 500 constraints or 1000 variables.

Default: `auto`

Frq_Rescale *(integer)*: Rescaling frequency. ↩

The row and column scales are recalculated at least every Frq_Rescale new point (degenerate iterations do not count), or more frequently if conditions require it.

Default: `5`

HEAPLIMIT *(real)*: Maximum Heap size in MB allowed ↩

Range: [0, ∞]

Default: 1e20

HessianMemFac *(real)*: Memory factor for Hessian generation: Skip if Hessian elements > Nonlinear Jacobian elements∗HessianMemFac, 0 means unlimited. ↩

The Hessian of the Lagrangian is considered too dense therefore too expensive to evaluate and use, and it is not passed on to CONOPT if the number of nonzero elements in the Hessian of the Lagrangian is greater than the number of nonlinear Jacobian elements multiplied by HessianMemFac. See also Flg_Hessian. If HessianMemFac = 0.0 (the default value) then there is no limit on the number of Hessian elements.

Default: 0

Lim_Dbg_1Drv *(integer)*: Flag for debugging of first derivatives ↩

Lim_Dbg_1Drv controls how often the derivatives are tested. Debugging of derivatives is only relevant for user-written functions in external equations defined with =X=. The amount of debugging is controlled by Mtd_Dbg_1Drv. See Lim_Hess_Est for a definition of when derivatives are considered wrong.

Default: 0

value	meaning
-1	The derivatives are tested in the initial point only.
0	No debugging
+n	The derivatives are tested in all iterations that can be divided by Lim_Dbg_1Drv, provided the derivatives are computed in this iteration. (During phase 0, 1, and 3 derivatives are only computed when it appears to be necessary.)

Lim_Err_2DDir *(integer)*: Limit on errors in Directional Second Derivative evaluation. ↩

If the evaluation of Directional Second Derivatives (Hessian information in a particular direction) has failed more than Lim_Err_2DDir times CONOPT will not attempt to evaluate them any more and will switch to methods that do not use Directional Second Derivatives. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: 10

Lim_Err_Fnc_Drv *(integer)*: Limit on number of function evaluation errors. Overwrites GAMS Domlim option ↩

Function values and their derivatives are assumed to be defined in all points that satisfy the bounds of the model. If the function value or a derivative is not defined in a point CONOPT will try to recover by going back to a previous safe point (if one exists), but it will not do it more than at most Lim_Err_Fnc_Drv times. If CONOPT is stopped by functions or derivatives not being defined it will return with a intermediate infeasible or intermediate non-optimal model status.

Default: GAMS DomLim

Lim_Err_Hessian *(integer)*: Limit on errors in Hessian evaluation. ↩

If the evaluation of Hessian information has failed more than Lim_Err_Hessian times CONOPT will not attempt to evaluate it any more and will switch to methods that do not use the Hessian. Note that second order information may not be defined even if function and derivative values are well-defined, e.g. in an expression like power(x,1.5) at x=0.

Default: `10`

Lim_Hess_Est *(real)*: Upper bound on second order terms. ↩

The function and derivative debugger (see `Lim_Dbg_1Drv`) tests if derivatives computed using the modelers routine are sufficiently close to the values computed using finite differences. The term for the acceptable difference includes a second order term and uses Lim_Hess_Est as an estimate of the upper bound on second order derivatives in the model. Larger Lim_Hess_Est values will allow larger deviations between the user-defined derivatives and the numerically computed derivatives.

Default: `1.e4`

Lim_Iteration *(integer)*: Maximum number of iterations. Overwrites GAMS Iterlim option. ↩

The iteration limit can be used to prevent models from spending too many resources. You should note that the cost of the different types of CONOPT iterations (phase 0 to 4) can be very different so the time limit (GAMS Reslim or option `Lim_Time`) is often a better stopping criterion. However, the iteration limit is better for reproducing solution behavior across machines.

Default: `GAMS IterLim`

Lim_Msg_Dbg_1Drv *(integer)*: Limit on number of error messages from function and derivative debugger. ↩

The function and derivative debugger (see `Lim_Dbg_1Drv`) may find a very large number of errors, all derived from the same source. To avoid very large amounts of output CONOPT will stop the debugger after Lim_Msg_Dbg_1Drv error(s) have been found.

Default: `10`

Lim_Msg_Large *(integer)*: Limit on number of error messages related to large function value and Jacobian elements. ↩

Very large function value or derivatives (Jacobian elements) in a model will lead to numerical difficulties and most likely to inaccurate primal and/or dual solutions. CONOPT is therefore imposing an upper bound on the value of all function values and derivatives. This bound is 1.e30. If the bound is violated CONOPT will return with an intermediate infeasible or intermediate non-optimal solution and it will issue error messages for all the violating Jacobian elements, up to a limit of Lim_Msg_Large error messages.

Default: `10`

Lim_NewSuper *(integer)*: Maximum number of new superbasic variables added in one iteration. ↩

When there has been a sufficient reduction in the reduced gradient in one subspace new non-basics can be selected to enter the superbasis. The ones with largest reduced gradient of proper sign are selected, up to a limit. If Lim_NewSuper is positive then the limit is min(500,Lim_NewSuper). If Lim_NewSuper is zero (the default) then the limit is selected dynamically by CONOPT depending on model characteristics.

Default: `auto`

Lim_Pre_Msg *(integer)*: Limit on number of error messages related to infeasible pre-triangle. ↩

If the pre-processor determines that the model is infeasible it tries to define a minimal set of variables and constraints that define the infeasibility. If this set is larger than Lim_Pre_Msg elements the report is considered difficult to use and it is skipped.

Default: `25`

Lim_RedHess *(integer)*: Maximum number of superbasic variables in the approximation to the Reduced Hessian. ↩

CONOPT uses and stores a dense lower-triangular matrix as an approximation to the Reduced Hessian. The rows and columns correspond to the superbasic variable. This matrix can use a large amount of memory and computations involving the matrix can be time consuming so CONOPT imposes a limit on on the size. The limit is Lim_RedHess if Lim_RedHess is defined by the modeler and otherwise a value determined from the overall size of the model. If the number of superbasics exceeds the limit, CONOPT will switch to a method based on a combination of SQP and Conjugate Gradient iterations assuming some kind of second order information is available. If no second order information is available CONOPT will use a quasi-Newton method on a subset of the superbasic variables and rotate the subset as the reduced gradient becomes small.

Default: `auto`

Lim_SlowPrg *(integer)*: Limit on number of iterations with slow progress (relative less than Tol_Obj_Change). ↩

The optimization is stopped if the relative change in objective is less than `Tol_Obj_Change` for Lim_SlowPrg consecutive well-behaved iterations.

Default: `20`

Lim_StallIter *(integer)*: Limit on the number of stalled iterations. ↩

An iteration is considered a stalled iteration if there is no change in objective because the linesearch is limited by nonlinearities or numerical difficulties. Stalled iterations will have Step = 0 and F in the OK column of the log file. After a stalled iteration CONOPT will try various heuristics to get a better basis and a better search direction. However, the heuristics may not work as intended or they may even return to the original bad basis, especially if the model does not satisfy standard constraints qualifications and does not have a KKT point. To prevent cycling CONOPT will therefore stop after Lim_StallIter stalled iterations and returns an Intermediate Infeasible or Intermediate Nonoptimal solution.

Default: `100`

Lim_Start_Degen *(integer)*: Limit on number of degenerate iterations before starting degeneracy breaking strategy. ↩

The default CONOPT pivoting strategy has focus on numerical stability, but it can potentially cycle. When the number of consecutive degenerate iterations exceeds Lim_Start_Degen CONOPT will switch to a pivoting strategy that is guaranteed to break degeneracy but with slightly weaker numerical properties.

Default: `100`

Lim_Time *(real)*: Time Limit. Overwrites the GAMS Reslim option. ↩

The upper bound on the total number of seconds that can be used in the execution phase. There are only tests for time limit once per iteration. The default value is 10000. Lim_Time is overwritten by Reslim when called from GAMS.

Range: [0, ∞]

Default: GAMS ResLim

Lim_Variable *(real)*: Upper bound on solution values and equation activity levels ↩

If the value of a variable, including the objective function value and the value of slack variables, exceeds Lim_Variable then the model is considered to be unbounded and the optimization process returns the solution with the large variable flagged as unbounded. A bound cannot exceed this value.

Range: [1.e5, 1.e30]

Default: 1.e15

Lin_Method *(integer)*: Method used to determine if and/or which Linear Feasibility Models to use ↩

The Linear Feasibility Model can use different objectives: Objective 1 is no objective, i.e. the first point that satisfies the Linear Feasibility Model is used as a starting point for the Full Model. Objective 2 minimizes a scaled distance from the initial point for all variables defined by the modeler. Objective 3 minimizes a scaled distance from the initial point for all variables including those not defined by the modeler. Objective 4 minimizes a scaled distance from random a point selected away from bounds.

Default: 1

value	meaning
1	Ignore Linear Feasibility Model in the first round and use objective 2, 3, and 4 (see above) in the following rounds as long as model is locally infeasible. This is the default method.
2	Use Linear Feasibility Model with objective 1 in the first round and continue with objective 2, 3, and 4 in the following rounds as long as model is locally infeasible.
3	Use Linear Feasibility Model with objective 2 in the first round and continue with objective 3 and 4 in the following rounds as long as model is locally infeasible.

Mtd_Dbg_1Drv *(integer)*: Method used by the function and derivative debugger. ↩

The function and derivative debugger (turned on with Lim_Dbg_1Drv) can perform a fairly cheap test or a more extensive test, controlled by Mtd_Dbg_1Drv. See Lim_Hess_Est for a definition of when derivatives are considered wrong. All tests are performed in the current point found by the optimization algorithm.

Default: 0

value	meaning
0	Perform tests for sparsity pattern and tests that the numerical values of the derivatives appear to be correct. This is the default.
1	As 0 plus make extensive test to determine if the functions and their derivatives are continuous around the current point. These tests are much more expensive and should only be used of the cheap test does not find an error but one is expected to exist.

Mtd_RedHess *(integer)*: Method for initializing the diagonal of the approximate Reduced Hessian ↩

Each time a nonbasic variable is made superbasic a new row and column is added to the approximate Reduced Hessian. The off-diagonal elements are set to zero and the diagonal to a value controlled by Mtd_RedHess:

Default: `0`

value	meaning
`0`	The new diagonal element is set to the geometric mean of the existing diagonal elements. This gives the new diagonal element an intermediate value and new superbasic variables are therefore not given any special treatment. The initial steps should be of good size, but build-up of second order information in the new sub-space may be slower. The larger diagonal element may also in bad cases cause premature convergence.
`1`	The new diagonal elements is set to the minimum of the existing diagonal elements. This makes the new diagonal element small and the importance of the new superbasic variable will therefore be high. The initial steps can be rather small, but better second order information in the new sub-space should be build up faster.

Mtd_Scale *(integer)*: Method used for scaling. ↩

CONOPT will by default use scaling of the equations and variables of the model to improve the numerical behavior of the solution algorithm and the accuracy of the final solution (see also `Frq_Rescale`.) The objective of the scaling process is to reduce the values of all large primal and dual variables as well as the values of all large first derivatives so they become closer to 1. Small values are usually not scaled up, see `Tol_Scale_Max` and `Tol_Scale_Min`. Scaling method 3 is recommended. The others are only kept for backward compatibility.

Default: `3`

value	meaning
`0`	Scaling is based on repeatedly dividing the rows and columns by the geometric means of the largest and smallest elements in each row and column. Very small elements less than Tol_Jac_Min are considered equal to Tol_Jac_Min.
`1`	Similar to 3 below, but the projection on the interval [Tol_Scale_Min,Tol_Scale_Max] is applied at a different stage. With method 1, abs(X)∗abs(Jac) with small X and very large Jac is scaled very aggressively with a factor abs(Jac). With method 3, the scale factor is abs(X)∗abs(Jac). The difference is seen in models with terms like Sqrt(X) close to X = 0.
`2`	As 1 but the terms are computed based on a moving average of the squares X and Jac. The purpose of the moving average is to keep the scale factor more stable. This is often an advantage, but for models with very large terms (large variables and in particular large derivatives) in the initial point the averaging process may not have enough time to bring the scale factors into the right region.
`3`	Rows are first scaled by dividing by the largest term in the row, then columns are scaled by dividing by by the maximum of the largest term and the value of the variable. A term is here defined as abs(X)∗abs(Jac) where X is the value of the variable and Jac is the value of the derivative (Jacobian element). The scale factor are then projected on the interval between Tol_Scale_Min and Tol_Scale_Max.

Mtd_Step_Phase0 *(integer)*: Method used to determine the step in Phase 0. ↩

The steplength used by the Newton process in phase 0 is computed by one of two alternative methods controlled by Mtd_Step_Phase0:

Default: `auto`

value	meaning
`0`	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this method. It is the default method for optimization models.
`1`	A method based on bending (projecting the target values of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum. Linear constraints that initially are feasible may become infeasible due to bending.

Mtd_Step_Tight *(integer)*: Method used to determine the maximum step while tightening tolerances. ↩

The steplength used by the Newton process when tightening tolerances is computed by one of two alternative methods controlled by Mtd_Step_Tight:

Default: `0`

value	meaning
`0`	The standard ratio test method known from the Simplex method. CONOPT adds small perturbations to the bounds to avoid very small pivots and improve numerical stability. Linear constraints that initially are feasible will remain feasible with this default method.
`1`	A method based on bending (projecting the target value of the basic variables on the bounds) until the sum of infeasibilities is close to its minimum.

Num_Rounds *(integer)*: Number of rounds with Linear Feasibility Model ↩

Lin_Method defined which Linear Feasibility Model are going to be solved if the previous models end Locally Infeasible. The number of rounds is limited by Num_Rounds.

Range: {`1`, ..., `4`}

Default: `4`

Rat_NoPen *(real)*: Limit on ratio of penalty constraints for the No_Penalty model to be solved ↩

The No-Penalty model can only be generated and solved if the number of penalty and minimax constraints exceed Rat_NoPen times the constraints in the Full Model.

Default: `0.1`

THREADC *(integer)*: Number of compatibility threads used for comparing different values of THREADS ↩

Range: {`0`, ..., ∞}

Default: `1`

THREADF *(integer)*: Number of threads used for function evaluation ↩

Range: {`0`, ..., ∞}

Default: `1`

threads *(integer)*: Number of threads used by Conopt internally ↩

Range: {0, ..., ∞}

Default: GAMS Threads

Tol_Bound *(real)*: Bound filter tolerance for solution values close to a bound. ↩

A variable is considered to be at a bound if its distance from the bound is less than Tol_Bound * Max(1,ABS(Bound)). The tolerance is used to build the initial bases and is used to flag variables during output.

Range: [3.e-13, 1.e-5]

Default: 1.e-7

Tol_BoxSize *(real)*: Initial box size for trust region models for overall model ↩

The new Phase 0 methods solves an LP model based on a scaled and linearized version of the model with an added trust region box constraint around the initial point. Tol_BoxSize defines the size of the initial trust region box. During the optimization the trust region box is adjusted based on how well the linear approximation fits the real model.

Range: [0.01, 1.e6]

Default: 10

Tol_BoxSize_Lin *(real)*: Initial box size for trust region models for linear feasibility model ↩

Similar to Tol_BoxSize but applied to the linear feasibility model. Since this model has linear constraints the default initial box size is larger.

Range: [0.01, 1.e8]

Default: 1000

Tol_Box_LinFac *(real)*: Box size factor for linear variables applied to trust region box size ↩

The trust region box used in the new Phase 0 method limits the change of variables so 2nd order terms will not become too large. Variables that appear linearly do not have 2nd order terms and the initial box size is therefore larger by a factor Tol_Box_LinFac.

Range: [1, 1.e4]

Default: 10

Tol_Def_Mult *(real)*: Largest growth factor allowed in the block of definitional constraints ↩

The block of definitional constraints form a triangular matrix. This triangular matrix can hide large accumulating growth factors that can lead to increases in the initial sum of infeasibilities and to numerical instability. Tol_Def_Mult is an upper bound on these growth factors. If it is exceeded some critical chains of definitional constraints will be broken leading to a larger internal model, that should be numerically better behaved.

Range: [1.01, ∞]

Default: 1.e4

Tol_Feas_Max *(real)*: Maximum feasibility tolerance (after scaling). ↩

The feasibility tolerance used by CONOPT is dynamic. As long as we are far from the optimal solution and make large steps it is not necessary to compute intermediate solutions very accurately. When we approach the optimum and make smaller steps we need more accuracy. Tol_Feas_Max is the upper bound on the dynamic feasibility tolerance and Tol_Feas_Min is the lower bound. It is NOT recommended to use loose feasibility tolerances since the objective, including the sum of infeasibility objective, will be less accurate and it may prevent convergence.

Range: [1.e-10, 1.e-3]

Default: 1.e-7

Tol_Feas_Min *(real)*: Minimum feasibility tolerance (after scaling). ↩

See Tol_Feas_Max for a discussion of the dynamic feasibility tolerances used by CONOPT.

Range: [3.e-13, 1.e-5]

Default: 4.e-10

Tol_Feas_Tria *(real)*: Feasibility tolerance for triangular equations. ↩

Triangular equations are usually solved to an accuracy of Tol_Feas_Min. However, if a variable reaches a bound or if a constraint only has pre-determined variables then the feasibility tolerance can be relaxed to Tol_Feas_Tria.

Range: [3.e-13, 1.e-4]

Default: 1.0e-8

Tol_Fixed *(real)*: Tolerance for defining variables as fixed based on initial or derived bounds. ↩

A variable is considered fixed if the distance between the bounds is less than Tol_Fixed $*$ Max(1,Abs(Bound)). The tolerance is used both on the users original bounds and on the derived bounds that the preprocessor implies from the constraints of the model.

Range: [3.e-13, 1.e-8]

Default: 4.e-10

Tol_Jac_Min *(real)*: Filter for small Jacobian elements to be ignored during scaling. ↩

A Jacobian element is considered insignificant if it is less than Tol_Jac_Min. The value is used to select which small values are scaled up during scaling of the Jacobian. Is only used with scaling method Mtd_Scale = 0.

Range: [1.e-7, 1.e-3]

Default: 1.e-5

Tol_Linesearch *(real)*: Accuracy of One-dimensional search. ↩

The onedimensional search is stopped if the expected decrease in then objective estimated from a quadratic approximation is less than Tol_Linesearch times the decrease so far in this onedimensional search.

Range: [0.05, 0.8]

Default: 0.2

Tol_Obj_Acc *(real)*: Relative accuracy of the objective function. ↩

It is assumed that the objective function can be computed to an accuracy of Tol_Obj_Acc ∗ max(1, abs(Objective)). Smaller changes in objective are considered to be caused by round-off errors.

Range: [3.0e-14, 1.e-6]

Default: 3.0e-13

Tol_Obj_Change *(real)*: Limit for relative change in objective for well-behaved iterations. ↩

The change in objective in a well-behaved iteration is considered small and the iteration counts as slow progress if the change is less than Tol_Obj_Change ∗ Max(1,Abs(Objective)). See also Lim_SlowPrg.

Range: [3.0e-13, 1.0e-5]

Default: 3.0e-12

Tol_Optimality *(real)*: Optimality tolerance for reduced gradient when feasible. ↩

The reduced gradient is considered zero and the solution optimal if the largest superbasic component of the reduced gradient is less than Tol_Optimality.

Range: [3.e-13, 1]

Default: 1.e-7

Tol_Opt_Infeas *(real)*: Optimality tolerance for reduced gradient when infeasible. ↩

The reduced gradient is considered zero and the solution infeasible if the largest superbasic component of the reduced gradient is less than Tol_Opt_Infeas.

Range: [3.e-13, 1]

Default: 1.e-7

Tol_Opt_LinF *(real)*: Optimality tolerance when infeasible in Linear Feasibility Model ↩

This is a special optimality tolerance used when the Linear Feasibility Model is infeasible. Since the model is linear the default value is smaller than for nonlinear submodels.

Range: [3.e-13, 1.e-4]

Default: 1.e-10

Tol_Piv_Abs *(real)*: Absolute pivot tolerance. ↩

During LU-factorization of the basis matrix a pivot element is considered large enough if its absolute value is larger than Tol_Piv_Abs. There is also a relative test, see Tol_Piv_Rel.

Range: [2.2e-16, 1.e-7]

Default: 1.e-10

Tol_Piv_Abs_Ini *(real)*: Absolute Pivot Tolerance for building initial basis. ↩

Absolute pivot tolerance used during the search for a first logically non-singular basis. The default is fairly large to encourage a better conditioned initial basis.

Range: [3.e-13, 1.e-3]

Default: 1.e-7

Tol_Piv_Abs_NLTr *(real)*: Absolute pivot tolerance for nonlinear elements in pre-triangular equations. ↩

The smallest pivot that can be used for nonlinear or variable Jacobian elements during the pre-triangular solve. The pivot tolerance for linear or constant Jacobian elements is Tol_Piv_Abs. The value cannot be less that Tol_Piv_Abs.

Range: [2.2e-16, 1.e-3]

Default: 1.e-5

Tol_Piv_Ratio *(real)*: Relative pivot tolerance during ratio-test ↩

During ratio-rests, the lower bound on the slope of a basic variable to potentially leave the basis is Tol_Piv_Ratio $*$ the largest term in the computation of the tangent.

Range: [1.e-10, 1.e-6]

Default: 1.e-8

Tol_Piv_Rel *(real)*: Relative pivot tolerance during basis factorizations. ↩

During LU-factorization of the basis matrix a pivot element is considered large enough relative to other elements in the column if its absolute value is at least Tol_Piv_Rel $*$ the largest absolute value in the column. Small values or Tol_Piv_Rel will often give a sparser basis factorization at the expense of the numerical accuracy. The value used internally is therefore adjusted dynamically between the users value and 0.9, based on various statistics collected during the solution process. Certain models derived from finite element approximations of partial differential equations can give rise to poor numerical accuracy and a larger user-value of Tol_Piv_Rel may help.

Range: [1.e-3, 0.9]

Default: 0.05

Tol_Piv_Rel_Ini *(real)*: Relative Pivot Tolerance for building initial basis ↩

Relative pivot tolerance used during the search for a first logically non-singular basis.

Range: [1.e-4, 0.9]

Default: 1.e-3

Tol_Piv_Rel_Updt *(real)*: Relative pivot tolerance during basis updates. ↩

During basischanges CONOPT attempts to use cheap updates of the LU-factors of the basis. A pivot is considered large enough relative to the alternatives in the column if its absolute value is at least Tol_Piv_Rel_Updt $*$ the other element. Smaller values of Tol_Piv_Rel_Updt will allow sparser basis updates but may cause accumulation of larger numerical errors.

Range: [1.e-3, 0.9]

Default: 0.05

Tol_Scale2D_Min *(real)*: Lower bound for scale factors based on large 2nd derivatives. ↩

Scaling of the model is in most cases based on the values of the variables and the first derivatives. However, if the scaled variables and derivatives are reasonable but there are large values in the Hessian of the Lagrangian (the matrix of 2nd derivatives) then the lower bound on the scale factor can be made smaller than Tol_Scale_Min. CONOPT will try to scale variables with large 2nd derivatives by one over the square root of the diagonal elements of the Hessian. However, the revised scale factors cannot be less than Tol_Scale2D_Min.

Range: [`1.e-9`, `1`]

Default: `1.e-6`

Tol_Scale_Max *(real)*: Upper bound on scale factors. ↩

Scale factors are projected on the interval from Tol_Scale_Min to Tol_Scale_Max. Is used to prevent very large or very small scale factors due to pathological types of constraints. The upper limit is selected such that Square(X) can be handled for X close to Lim_Variable. More nonlinear functions may not be scalable for very large variables.

Range: [`1`, `1.e30`]

Default: `1.e25`

Tol_Scale_Min *(real)*: Lower bound for scale factors computed from values and 1st derivatives. ↩

Scale factors used to scale variables and equations are projected on the range Tol_Scale_Min to Tol_Scale_Max. The limits are used to prevent very large or very small scale factors due to pathological types of constraints. The default value for Tol_Scale_Min is 1 which means that small values are not scaled up. If you need to scale small value up towards 1 then you must define a value of Tol_Scale_Min < 1.

Range: [`1.e-10`, `1`]

Default: `1`

Tol_Scale_Var *(real)*: Lower bound on x in x∗Jac used when scaling. ↩

Rows are scaled so the largest term x∗Jac is around 1. To avoid difficulties with models where Jac is very large and x very small a lower bound of Tol_Scale_Var is applied to the x-term.

Range: [`1.e-8`, `1`]

Default: `1.e-5`

Tol_Zero *(real)*: Zero filter for Jacobian elements and inversion results. ↩

Contains the smallest absolute value that an intermediate result can have. If it is smaller, it is set to zero. It must be smaller than `Tol_Piv_Abs`/10.

Default: `1.e-20`

Trace_MinStep *(real)*: Minimum step between Reinversions when using TraceCNS. ↩

The optimization is stopped with a slow convergence message if the change in trace variable or objective is less than this tolerance between reinversions for more than two consecutive reinversions. The step is scaled by the distance from the initial value to the critical bound.

Range: [`0`, `1`]

Default: `0.001`

5.9 CONVERT

5.9.1 Introduction

CONVERT is a utility which transforms a GAMS model instance into a scalar model where all confidential information has been removed or into formats used by other modeling and solution systems. CONVERT is designed to achieve the following goals:

- Permit users to convert a confidential model into GAMS scalar format so that any idenifiable structure is removed. It can then be passed on to others for investigation without confidentiality being lost.
- A way of sharing GAMS test problems for use with other modeling systems or solvers.

CONVERT comes free of charge with any licensed GAMS system and can convert GAMS models into a number of formats, see Section Target languages and formats for a list.

5.9.2 How to use CONVERT

CONVERT is run like any other GAMS solver. From the command line this is:

```
>> gams modelname modeltype=convert
```

where `modelname` is the GAMS model name and `modeltype` the solver indicator for a particular model type (e.g. LP, MIP, RMIP, QCP, MIQCP, RMIQCP, NLP, DNLP, CNS, MINLP, or MCP). CONVERT can also be specified via the option statement within the model itself before the solve statement:

```
option modeltype=convert;
```

5.9.3 The GAMS Scalar Format

By default, CONVERT generates a scalar GAMS model (`gams.gms`) from the input model. The scalar model exhibits the following characteristics:

- A model without sets or indexed parameters. It does not exhibit any of the advanced characteristics of modeling systems and is easily transformable.
- A model with a new set of individual variables, depicting each variable in the GAMS model as one of 3 types: positive, integer or binary. Each variable is numbered sequentially, i.e. all positive GAMS variables are mapped into n single variables `x1, x2, ..., xn`.
- A model with individual equations depicting each variable in the GAMS model. All equations are also numbered sequentially, that is equations `e1, e2, ..., em`.

Equation and variable bounds, as well as variable starting values are preserved from the original GAMS formulation.

As an example, suppose the user wishes to translate the GAMS Model Library model **trnsport** into scalar format, One would run

```
gams trnsport.gms lp=convert
```

which would generate the following scalar model `gams.gms`:

```
* LP written by GAMS Convert at 11/19/20 15:28:05
*
* Equation counts
*     Total        E        G        L        N        X        C        B
*         6        1        3        2        0        0        0        0
*
* Variable counts
*                  x        b        i      s1s      s2s       sc       si
*     Total     cont   binary  integer     sos1     sos2    scont     sint
*         7        7        0        0        0        0        0        0
* FX      0
*
* Nonzero counts
*     Total    const       NL
*        19       19        0

* Solve m using LP minimizing x7;

Variables
    x1,x2,x3,x4,x5,x6,x7;

Positive Variables
    x1,x2,x3,x4,x5,x6;

Equations
    e1,e2,e3,e4,e5,e6;

e1..  -0.225 * x1 - 0.153 * x2 - 0.162 * x3 - 0.225 * x4 - 0.162 * x5 - 0.126 *
      x6 + x7 =E= 0;
e2..  x1 + x2 + x3 =L= 350;
e3..  x4 + x5 + x6 =L= 600;
e4..  x1 + x4 =G= 325;
e5..  x2 + x5 =G= 300;
e6..  x3 + x6 =G= 275;

Model m / all /;

m.limrow = 0;
m.limcol = 0;

Solve m using LP minimizing x7;
```

Note that the resulting scalar model does not contain any of the descriptive information about the data or the context of the constraints.

Additionally, a dictionary file (`dict.txt`) is created by default which specifies a mapping between the variable and equation names in the scalar model and their corresponding names in the original model.

For the above example, the dictionary file is

```
LP written by GAMS Convert at 11/19/20 15:28:05
```

```
Equation counts
    Total        E        G        L        N        X        C        B
        6        1        3        2        0        0        0        0

Variable counts
                 x        b        i      s1s      s2s       sc       si
    Total     cont   binary  integer     sos1     sos2    scont     sint
        7        7        0        0        0        0        0        0
FX      0

Nonzero counts
    Total    const       NL
       19       19        0

Equations 1 to 6
  e1  cost
  e2  supply(seattle)
  e3  supply(san-diego)
  e4  demand(new-york)
  e5  demand(chicago)
  e6  demand(topeka)

Variables 1 to 7
  x1  x(seattle,new-york)
  x2  x(seattle,chicago)
  x3  x(seattle,topeka)
  x4  x(san-diego,new-york)
  x5  x(san-diego,chicago)
  x6  x(san-diego,topeka)
  x7  z
```

Conversion of a GAMS model to a scalar one may be handy for model debugging. However, in this case, it may be good to retain the original variable and equation names. The following simple sed command attempts to achieve this:

```
sed -n -e "s:^ *\([exbi][0-9][0-9]*\)  \(.*\):s/\1/\2/g:gp" dict.txt | sed -n '1!G;h;$p' > mod.txt
sed -f mod.txt gams.gms
```

For the above example, this outputs:

```
Variables
    x(seattle,new-york),x(seattle,chicago),x(seattle,topeka),x(san-diego,new-york),x(san-diego,chicag

Positive Variables
    x(seattle,new-york),x(seattle,chicago),x(seattle,topeka),x(san-diego,new-york),x(san-diego,chicag

Equations
    cost,supply(seattle),supply(san-diego),demand(new-york),demand(chicago),demand(topeka);

cost..  -0.225 * x(seattle,new-york) - 0.153 * x(seattle,chicago) - 0.162 * x(seattle,topeka) - 0.225
      x(san-diego,topeka) + z =E= 0;
supply(seattle)..  x(seattle,new-york) + x(seattle,chicago) + x(seattle,topeka) =L= 350;
supply(san-diego)..  x(san-diego,new-york) + x(san-diego,chicago) + x(san-diego,topeka) =L= 600;
demand(new-york)..  x(seattle,new-york) + x(san-diego,new-york) =G= 325;
demand(chicago)..  x(seattle,chicago) + x(san-diego,chicago) =G= 300;
demand(topeka)..  x(seattle,topeka) + x(san-diego,topeka) =G= 275;
```

Of course, this is not a valid GAMS code and cannot be compiled, but it may be sufficient to view the model algebra as generated by the GAMS compiler.

By using

```
sed -n -e "y/(),-/____/" -e "s:^ *\([exbi][0-9][0-9]*\)  \(.*\):s/\1/\2/g:gp" dict.txt | sed -n '1!G
sed -f mod.txt gams.gms
```

one gets for this example

```
Variables
    x_seattle_new_york_,x_seattle_chicago_,x_seattle_topeka_,x_san_diego_new_york_,x_san_diego_chica

Positive Variables
    x_seattle_new_york_,x_seattle_chicago_,x_seattle_topeka_,x_san_diego_new_york_,x_san_diego_chica

Equations
    cost,supply_seattle_,supply_san_diego_,demand_new_york_,demand_chicago_,demand_topeka_;

cost..  -0.225 * x_seattle_new_york_ - 0.153 * x_seattle_chicago_ - 0.162 * x_seattle_topeka_ - 0.225
      x_san_diego_topeka_ + z =E= 0;
supply_seattle_..  x_seattle_new_york_ + x_seattle_chicago_ + x_seattle_topeka_ =L= 350;
supply_san_diego_..  x_san_diego_new_york_ + x_san_diego_chicago_ + x_san_diego_topeka_ =L= 600;
demand_new_york_..  x_seattle_new_york_ + x_san_diego_new_york_ =G= 325;
demand_chicago_..  x_seattle_chicago_ + x_san_diego_chicago_ =G= 300;
demand_topeka_..  x_seattle_topeka_ + x_san_diego_topeka_ =G= 275;
```

This can even be compiled by GAMS and gives the correct solution.

The proposed commands come with several limitations and may not produce in all cases the desired output. For example, wrong results would be printed if the original model contains variable or equation names that start with `{b,i,e,x}[digit]`. Also semicontinuous or semiinteger variables or special ordered sets are not supported by the above. We leave it to the experienced user to extend the command appropriately.

5.9.4 The OSiL Format

The Optimization Services Instance Language (OSiL) [70] specifies an XML-based format to represent optimization problem instances. GAMS/CONVERT can write MINLP model instances in `OSiL format`. Expression trees are written in `OSnL format`.

Next to the indexed operations for sum, product, minimum, and maximum, and the operations for subtraction and division, the following intrinsic functions are mapped to their `OSnL` counterparts: `sqr`, `sqrt`, `exp`, `log`, `log2`, `log10`, `abs`, `cos`, `sin`, `tan`, `arccos`, `arcsin`, `arctan`, `sinh`, `cosh`, `tanh`, `pi`, `div`, `gamma`, `loggamma`, `floor`, `ceil`, `round`, `trunc`, `sign fact`, `binomial`. The functions `cvPower`, `power`, `rpower`, `vcpower` are all mapped to OSnL's `power` operator, thus conditions on arguments are not preserved. Functions `arctan2`, `centropy`, `edist`, `errorf`, and `poly` are represented by an expression according to their algebraic definition. The intrinsic functions `signpower`, `entropy`, `sigmoid`, `gammareg`, `beta`, `logbeta`, and `betareg` are also written to OSiL files, but do not follow the OSnL standard (as it currently does not offer these functions). Thus, OSiL readers may reject XML files that use these functions. Finally, also the logical functions are written to OSiL by using their OSnL counterpart.

5.9.5 User-Specified Options

CONVERT options are passed on through option files. If you specify <modelname>.optfile = 1; before the SOLVE statement in your GAMS model, CONVERT will look for and read an option file with the name convert.opt (see The Solver Options File for general use of solver option files). The syntax for the CONVERT option file is

```
optname value
```

with one option on each line. For example,

```
ampl
```

This option file would tell CONVERT to produce an AMPL input file. For file format options, the user can specify the filename for the file to be generated. For example, the option file entry

```
lingo myfile.lng
```

would generate a LINGO input file format called myfile.lng. Using the option lingo by itself, would produce the default output file for that option (lingo.lng).

All available options are listed in the following tables.

5.9.5.1 Target languages and formats

Option	Description	Default
All	Generates all supported file formats	
Ampl	Generates Ampl input file	ampl.mod
AmplNL	Generates Ampl .nl file	ampl.nl
CplexLP	Generates CPLEX LP format input file	cplex.lp
CplexMPS	Generates CPLEX MPS format input file	cplex.mps
Dict	Generates Convert to GAMS Dictionary	dict.txt
DictMap	Generates Convert to GAMS Dictionary Map	dictmap.gdx
DumpGDX	Generates GDX with model data incl. Jacobian and Hessian evaluated at current point	dump.gdx
FileList	Generates file list of file formats generated	files.txt
FixedMPS	Generates fixed format MPS file	fixed.mps
Gams	Generates GAMS scalar model. This is the default conversion format used.	gams.gms
JuMP	Generates JuMP scalar model	jump.jl
Lingo	Generates Lingo input file	lingo.lng
NLP2dual	Generates the Wolfe dual of a smooth optimization model	gamsdual.gms
NLP2MCP	Generates GAMS scalar MCP model	gamsmcp.gms
OSiL	Generates Optimization Services instance Language (OSiL) file	osil.xml
Pyomo	Generates Pyomo Concrete scalar model	pyomo.py

5.9.5.2 Other options

Option	Description	Default
AmplNLBin	Enables binary .nl file	0
AmplNlInitDual	Which initial equation marginal values to write to .nl file 0: Write no values 1: Write only nondefault values 2: Write all values	1
AmplNlInitPrimal	Which initial variable level values to write to .nl file 0: Write no values 1: Write only nondefault values 2: Write all values	2
DualType	Controls type of Wolfe dual to generate in NLP2dual None: No Wolfe dual generated NLPScalarBounds: NLP dual where variable bounds become scalars used in equations NLPConstantBounds: NLP dual where finite variable bounds become constants in equations BiLevel: Bilevel model with outer problem optimizing over the duals MPEC: MPEC obtained by explicitly including FOC of BiLevel inner problem	None
GDXHessian	Enable hessian information for DumpGDX	0
GDXNames	Enable variable and equation names for DumpGDX	1
GDXQuadratic	Enable quadratic information for DumpGDX	0
GDXUELs	Enable UELs for DumpGDX	1
GmsInsert	Line to be inserted before the solve statement	$if NOT 'gams.u1' == '' $include 'gams.u1'
HeaderTimeStamp	Control format of time stamp in header of output file None: Use no timestamp default: Use the traditional default timestamp	default
IntervalEval	Include interval evaluations in DumpGDX	0
ObjVar	Name of objective variable	GAMS index name, e.g. x1
PermuteEqus	Random seed for permutation of equations (0: no permutation)	0
PermuteVars	Random seed for permutation of variables (0: no permutation)	0

Option	Description	Default
QExtractAlg	quadratic extraction algorithm in GAMS interface 0: Automatic 1: ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage. 2: DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists. 3: Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.	0
Reform	Force reformulations	100
SkipNRows	Skip constraints of type =N=	0
Width	Max line width of output format Range: {40, ..., ∞}	80

5.10 COPT

Cardinal Optimizer by Cardinal Operations is a solver for mixed-integer linear and convex quadratic programming problems.

5.10.1 Usage

A GAMS/COPT or GAMS/COPT-Link license is required to use the GAMS/COPT interface that is distributed with GAMS. If only a GAMS/COPT-Link license is available, also a separate COPT license needs to be installed on the system, see the "Cardinal Operations User Guide" for details.

The following statement can be used inside your GAMS program to specify using COPT

```
Option MIP = COPT;     { or LP, QCP, MIQCP, ... }
```

The above statement should appear before the Solve statement. If COPT was specified as the default solver during GAMS installation, the above statement is not necessary.

COPT supports special ordered sets (SOS), but no semicontinuous or semiinteger variables.

5.10.1.1 Specification of COPT Options

The following GAMS parameters are currently supported by GAMS/COPT: reslim, iterlim, nodlim, optcr, optca, tryint, and threads.

Further options can be set via a solver options file, see Section The Solver Option File for further information. Following is an example options file `copt.opt`:

```
TreeCutLevel 0
SimplexThreads 4
```

It will cause COPT to use cut generators only in the root node (for a MI(QC)P solve) and specifies to use 4 threads in the simplex algorithm.

5.10.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to COPT via a GAMS/COPT solver options file, see Indicator Constraints for more details on its syntax.

5.10.1.3 MIP Starting Point

When solving a MIP, by default all values that are specified as variable levels in the GAMS model are passed as starting point to COPT (unless MipStartMode = 0). However, if GAMS option tryint is set to a nonzero value or MipStartMode = 2, then only values of binary and integer variables which fractionality is at most the value tryint are passed as starting point to COPT (possible fractional values are rounded to integers). COPT will then try to complete this partial solution to a feasible solution.

5.10.1.4 Solution Pool

When COPT solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option solnpool is specified, then all alternative solutions found by COPT are written into GDX files and an index file with the name given by the this option is written. If the option solnpoolmerge is specified, then all alternative solutions found by COPT are written into a single GDX file, which name is given by the this option.

The GAMS testlib model **dumpsol** shows an example use for this option.

5.10.1.5 Infeasible and unbounded LPs

If an LP is found infeasible by COPT, a primal infeasibility certificate in form of a Farkas proof (see also Mosek manual) is computed. The GAMS/COPT link returns the values of this certificate in the equations marginal values and sets the `INFES` markers (see solution listing) for those equations that are included in the Farkas proof.

If an LP is found unbounded by COPT, a dual infeasibility certificate in form of a primal ray is computed. If the problem is feasible, then the primal ray gives a direction in which the objective function can be infinitely improved. The GAMS/COPT link returns the values of the primal ray in the variable level values and sets `UNBND` markers (see solution listing) for those variables that are included in the ray.

COPT option ReqFarkasRay can be used to disable the calculation of these infeasibility certificates.

5.10.1.6 Finding an Irreducible Inconsistent Subsystem (IIS) of Constraints

If an LP or MIP is infeasible, COPT has the capability to identify a subset of the constraints that are infeasible and become feasible once any one of them is eliminated. Option iis can be used to enable finding an IIS.

As an example, consider a GAMS model containing

```
Positive Variables x, y;
Equation e1;
e1.. x + y =l= -1;
```

The corresponding COPT output when iis has been set to 1 will look like

```
Starting the simplex solver using 1 thread

Method   Iteration           Objective  Primal.NInf   Dual.NInf        Time
Dual             0    0.0000000000e+00            1           0       0.00s

Solving finished
Status: Infeasible  Objective: -  Iterations: 0  Time: 0.00s
Start the IIS computation for an LP

 Iteration  Min RowBnd  Max RowBnd  Min ColBnd  Max ColBnd      Time
         0           0           1           0           2      0.00s
         1           0           1           0           2      0.00s
         2           1           1           0           2      0.00s
         3           1           1           1           2      0.00s
         4           1           1           2           2      0.00s

IIS summary: 1 rows, 2 bounds of columns
IIS computation finished (0.000s)
IIS is minimal
Number of equations in IIS: 1
  Upper: e1 <= -1
Number of variables in IIS: 2
  Lower: x >= 0
  Lower: y >= 0
```

That is, COPT finds the problem infeasible. Then the IIS computation is started and an IIS is found. The IIS is then printed to the log and listing file. It consists of the lower bounds of variables `x` and `y` and equation `e1`. This suggests that the entire model can be made feasible by lowering the lower bound of `x` or `y` or by increasing the right-hand side of `e1`.

If one knows in advance that the problem is infeasible, then option iis can be set to 2 to skip the initial solve.

5.10.1.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the FeasRelax parameter in a COPT solver option file.

With the FeasRelax option COPT selectively relaxes the variable bounds and constraint sides of an infeasible model instance in a way that a weighted penalty function is minimized. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

Attention

> At the moment, COPT can only relax sides of linear constraints. Indicator and quadratic constraints are not considered for relaxation.

By default all equation sides are candidates for relaxation and weighted equally but none of the variable bounds can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the dot option feaspref. A zero preference means that the associated bound or constraint side is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given variable bound or constraint side will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a COPT solver option file. The syntax is:

(variable or equation) `.feaspref` *(value)*

For example, suppose we have a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the `copt.opt` file can be specified by:

```
feasrelax 1
v.feaspref            1
v.feaspref('i1',*)    2
v.feaspref('i1','j2') 0

e.feaspref(*,'j1')    0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables `v(i,j)` have preference of 1, except variables over set element `i1`, which have a preference of 2. The variable over set element `i1` and `j2` has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter FeasRelaxMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasRelaxMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations). Also check model **feasopt1** in the GAMS model library.

5.10.1.8 Parameter Tuning Tool

The COPT tuning tool performs multiple solves on a model instance, choosing different parameter settings for each run, in a search for settings that improve runtime or other quality measures. The longer it is run, the more likely it is to find a significant improvement. For notes on the limitation of parameter tuning tools, see also the GAMS/Gurobi manual.

A number of tuning-related parameters allow to control the operation of the tuning tool. To enable tuning, option Tuning needs to be set. The value of `Tuning` will be used as a prefix for the name of option files written by the solver link. The amount of time spend for tuning can be controlled by option TuneTimeLimit. Options TuneMode and TuneMeasure allow to specify whether solving time or bounds on the optimal value should be used as quality measure for the tuning time.

Options that are set in a GAMS/COPT options file are considered as fixed parameters and are not changed by the tuning tool. Since the GAMS/COPT link changes the default for a few COPT options, please check the log for the fixed parameters.

Using option TuneParams, a COPT options file with parameters that should be tuned can be specified. Note that this parameter file is read by COPT directly, so that its syntax may deviate from the one of GAMS/COPT solver option files. The file allows multiple values for each parameter name. For example,

if the file contains the lines `RootCutLevel 0 1 2 3` and `TreeCutLevel 0 1 2 3`, then the tuner will optimize only the amount of cutting plane generation for the given instance. If `TuneParams` is not set, the tuner will generate tuning parameter sets automatically.

If the tuning tool found one or several parameter sets that improve performance, then these will be written into files named <`Tuning`>.<`idx`>, where `Tuning` is the value of option Tuning and `idx` the index of the parameter set. The parameter set that yields best performance has index `000`. GAMS/COPT does not return a solution if the tuning tool is used. Tuning cannot be used at the same time as other advanced features, like feasibility relaxation.

5.10.2 List of COPT Options

In the following, we give a detailed list of available COPT options.

5.10.2.1 Limits and Tolerances

Option	Description	Default
AbsGap	The absolute gap for MIP Range: [0, ∞]	GAMS optca
BarIterLimit	Barrier iteration limit Range: {0, ..., ∞}	GAMS iterlim
DualTol	The tolerance for dual solutions and reduced cost Range: [1e-09, 0.0001]	1e-06
FeasTol	The feasibility tolerance Range: [1e-09, 0.0001]	1e-06
IntTol	The integer feasibility tolerance Range: [1e-09, 0.1]	1e-06
