During solution of QP subproblems, the pivot tolerance r is used to prevent columns entering the basis if they would cause the basis to become almost singular.

- When x changes to $x + \alpha p$ for some search direction p, a ratio test is used to determine which component of x reaches an upper or lower bound first. The corresponding element of p is called the pivot element.
- Elements of p are ignored (and therefore cannot be pivot elements) if they are smaller than the pivot tolerance r.
- It is common for two or more variables to reach a bound at essentially the same time. In such cases, the minor feasibility tolerance (say t) provides some freedom to maximize the pivot element and thereby improve numerical stability. Excessively small values of t should therefore not be specified.
- To a lesser extent, the expand frequency (say f) also provides some freedom to maximize the pivot element. Excessively *large* values of f should therefore not be specified.

Default: `3.67e-11`

print frequency *(integer)*: Number of iterations between each log line (listing file) ↩

Synonym: log_frequency

When sysout is turned on and minor print level is positive, a line of the QP iteration log will be printed on the listing file every kth minor iteration.

Range: {`1`, ..., ∞}

Default: `100`

proximal point method *(integer)*: Controls promimal point method used for solving linear constraints ↩

Once the linear constraints are satisfied, the proximal point method chooses a linear feasible point that is closest to x_0, the initial point for the nonlinear variables. The idea is to both satisfy the linear constraints and stay close to the starting values provided for the nonlinear variables. This option is used to disable the proximal point method or to select the norm used.

Default: `1`

value	meaning
0	disable PPM Do not use the proximal point method.

| 1 | one-norm
Minimize the one-norm $||x - x_0||_1$.| | 2 | two-norm
Minimize the two-norm $\frac{1}{2}||x - x_0||_2^2$.|

qpsolver *(string)*: Controls method used for QP subproblems ↩

This specifies the method used to solve system (5) for the search directions in phase 2 of the QP subproblem.

- The Cholesky QP solver is the most robust, but may require a significant amount of computation if the number of superbasics is large.
- The quasi-Newton QP solver does not require the computation of the R at the start of each QP subproblem. It may be appropriate when the number of superbasics is large but relatively few major iterations are needed to reach a solution (e.g., if SNOPT is called with a warm start).
- The conjugate-gradient QP solver is appropriate for problems with many degrees of freedom (say, more than 2000 superbasics).

Default: `Cholesky`

value	meaning
`Cholesky`	full Cholesky factor `QPSolver Cholesky` holds the full Cholesky factor R of the reduced Hessian Z^THZ. As the minor iterations proceed, the dimension of R changes with the number of superbasic variables. If the number of superbasic variables needs to increase beyond the value of reduced hessian dimension, the reduced Hessian cannot be stored and the solver switches to `QPSolver CG`. The Cholesky solver is reactivated if the number of superbasics stabilizes at a value less than the reduced hessian dimension.
`QN`	quasi-Newton method `QPSolver QN` solves the QP using a quasi-Newton method similar to that of MINOS. In this case, R is the factor of a quasi-Newton approximate Hessian.
`CG`	conjugate-gradient method `QPSolver CG` uses an active-set method similar to `QPSolver QN`, but uses the conjugate-gradient method to solve all systems involving the reduced Hessian.

reduced hessian dimension *(integer)*: Size of Hessian matrix ↩

Synonym: hessian_dimension

This specifies that an $i \times i$ triangular matrix R is to be available for use by the `QPSolver Cholesky` option (to define the reduced Hessian according to $R^TR = Z^THZ$). The value of i affects when `QPSolver CG` is activated. The default is computed internally by SNOPT, currently as $\min\{2000, n_1 + 1\}$.

Range: {1, ..., ∞}

Default: `auto`

scale option *(integer)*: Controls problem scaling ↩

Three scale options are available. By default, option 2 is used for linear models and option 1 for nonlinear models. See also scale tolerance and scale print.

Default: `auto`

value	meaning
`0`	No scaling This is recommended if it is known that x and the constraint matrix and Jacobian never have very large elements (say, larger than 100).
`1`	Scale linear variables Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see Fourer [69]). This will sometimes improve the performance of the solution procedures.
`2`	Scale linear + nonlinear variables All constraints and variables are scaled by the iterative procedure. Also, an additional scaling is performed that takes into account columns of $(A \quad -I)$ that are fixed or have positive lower bounds or negative upper bounds. If nonlinear constraints are present, the scales depend on the Jacobian at the first point that satisfies the linear constraints. `Scale option 2` should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear.

scale print *(no value)*: Print scaling factors (listing file) ↩

`Scale print` causes the row-scales $r(i)$ and column-scales $c(j)$ to be printed. The scaled matrix coefficients are $\bar{a}_{ij} = a_{ij}c(j)/r(i)$, and the scaled bounds on the variables and slacks are $\bar{l}_j = l_j/c(j)$, $\bar{u}_j = u_j/c(j)$, where $c(j) \equiv r(j-n)$ if $j > n$.

The listing file will only show these values if the sysout option is turned on. See also scale option and scale tolerance.

scale tolerance *(real)*: Scale tolerance ↩

The scale tolerance t affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$\rho_j = \max_i |a_{ij}| / \min_i |a_{ij}| \qquad (a_{ij} \neq 0).$$

If $\max_j \rho_j$ is less than r times its previous value, another scaling pass is performed to adjust the row and column scales. Raising r from 0.9 to 0.99 (say) usually increases the number of scaling passes through A. At most 10 passes are made.

See also scale option and scale print.

Range: [`0`, `1`]

Default: `0.9`

solution *(string)*: Prints SNOPT solution (listing file) ↩

This option causes the SNOPT solution file to be printed to the GAMS listing file, provided the sysout option is also turned on.

Default: turned off.

Default: `NO`

value	meaning
NO	Turn off printing of solution
YES	Turn on printing of solution

summary frequency *(integer)*: Number of iterations between each log line (log file) ↩

If minor print level is positive, a line of the QP iteration log is output every kth minor iteration.

Range: {1, ..., ∞}

Default: 100

superbasics limit *(integer)*: Maximum number of superbasics ↩

This places a limit on the storage allocated for superbasic variables. Ideally, i should be set slightly larger than the number of degrees of freedom expected at an optimal solution.

For linear programs, an optimum is normally a basic solution with no degrees of freedom. The default value of i is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the "number of independent variables".

Normally, i need not be greater than $n_1 + 1$, where n_1 is the number of nonlinear variables. For many problems, i may be considerably smaller than n_1. This will save storage if n_1 is very large.

This parameter also sets the reduced hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, based on problem characteristics.

Range: {1, ..., ∞}

Default: 1

suppress parameters *(no value)*: Suppress printing of parameters (listing file) ↩

Normally SNOPT prints the option file as it is being read, and then prints a complete list of the available keywords and their final values. The `suppress parameters` option tells SNOPT not to print the full list. Used in conjunction with the sysout option.

system information *(string)*: Provides additional information on the progress of the iterations (listing file) ↩

The `Yes` option provides additional information on the progress of the iterations, including basis repair details when ill-conditioned bases are encountered and the LU factorization parameters are strengthened.

Default: NO

value	meaning
NO	Turn off additional printing of information on progress of algorithm
YES	Turn on additional printing of information on progress of algorithm

timing level *(integer)*: Amount of timing information (listing file) ↩

Amount of timing information written to the listing file. Used in conjunction with the sysout option.

Range: {0, ..., 3}

Default: 3

unbounded objective value *(real)*: Determines when a problem is called unbounded ↩

This parameter sets the value $f_{\max}$ *intended* to detect unboundedness in nonlinear problems. See unbounded step size for the setting of $\alpha_{\max}$.

During a line search, f_0 is evaluated at points of the form $x + \alpha p$, where x and p are fixed and α varies. If $|f_0|$ exceeds $f_{\max}$ or α exceeds $\alpha_{\max}$, iterations are terminated with the exit message `Problem is unbounded (or badly scaled)`.

Unboundedness in x is best avoided by placing finite upper and lower bounds on the variables.

Default: 1.0e15

unbounded step size *(real)*: Determines when a problem is called unbounded ↩

This parameter sets the value $\alpha_{\max}$ used in the unboundedness test: see unbounded objective value for details.

Default: 1.0e18

verify level *(integer)*: Finite-difference checks on the derivatives ↩

This option refers to finite-difference checks on the derivatives computed by the user-provided routines. Derivatives are checked at the first point that satisfies all bounds and linear constraints.

This option has limited use in a GAMS environment.

Default: -1

value	meaning
0	Cheap test
1	Check individual gradients
2	Check individual columns of the Jacobian
3	Combines verify level 1 and 2
-1	Derivative checking is disabled

violation limit *(integer)*: Limit on maximum constraint violation after the linesearch ↩

This parameter τ is used to define an absolute limit on the magnitude of the maximum constraint violation after the line search. On completion of the line search, the new iterate x_{k+1} satisfies the condition

$$v_i(x_{k+1}) \leq \tau \max\{1, v_i(x_0)\},$$

where x_0 is the point at which the nonlinear constraints are first evaluated and $v_i(x)$ is the ith nonlinear constraint violation $v_i(x) = \max(0, l_i - F_i(x), F_i(x) - u_i)$.

The effect of this violation limit is to restrict the iterates to lie in an *expanded* feasible region whose size depends on the magnitude of τ. This makes it possible to keep the iterates within a

region where the objective is expected to be well-defined and bounded below. If the objective is bounded below for all values of the variables, then τ may be any large positive value.

Default: 10

warm start *(no value)*: Use advanced basis provided by GAMS ↩

Use an advanced basis provided by GAMS. This option takes precedence over the GAMS bratio option.

5.36.6 The SNOPT log

When GAMS/SNOPT solves a linearly constrained problem the following log is visible on the screen:

```
 ==============================

The SNOPT log shows the following columns:

Major

The current major iteration number.

Minors

The number of iterations required by both the feasibility and optimality phases of the QP subproblem. Generally, `Minor` will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see Section Description of the method)

Step

The step length α taken along the current search direction p. The variables x have just been changed to $x + \alpha p$. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.

nObj

The number of times the nonlinear objective function has been evaluated. `nObj` is printed as a guide to the amount of work required for the linesearch.

nCon

The number of times SNOPT evaluated the nonlinear constraint functions.

MeritFunction

The value of the augmented Lagrangian merit function (6). This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see Section Description of the method). As the solution is approached, `Merit` will converge to the value of the objective at the solution.

In elastic mode, the merit function is a composite function involving the constraint violations weighted by the elastic weight.

If the constraints are linear, this item is labeled `Objective`, the value of the objective function. It will decrease monotonically to its optimal value.

Feasible

The value of `rowerr`, the maximum component of the scaled nonlinear constraint residual. The solution is regarded as acceptably feasible if `Feasible` is less than the Major feasibility tolerance.

If the constraints are linear, all iterates are feasible and this entry is not printed.

Optimal

The value of `maxgap`, the maximum complementarity gap. It is an estimate of the degree of nonoptimality of the reduced costs. The solution is considered to be optimal if `Optimal` is less than the major optimality tolerance.

nS

The current number of superbasic variables.

Penalty

The Euclidean norm of the vector of penalty parameters used in the augmented Lagrangian merit function (not printed if the constraints are linear).

The summary line may include additional code characters that indicate what happened during the course of the iteration.

`c` Central differences have been used to compute the unknown components of the objective and constraint gradients. This should not happen in a GAMS environment.

`d` During the linesearch it was necessary to decrease the step in order to obtain a maximum constraint violation conforming to the value of violation limit.

`l` The norm-wise change in the variables was limited by the value of the major step limit. If this output occurs repeatedly during later iterations, it may be worthwhile increasing the value of major step limit.

`i` If SNOPT is not in elastic mode, an "i" signifies that the QP subproblem is infeasible. This event triggers the start of nonlinear elastic mode, which remains in effect for all subsequent iterations. Once in elastic mode, the QP subproblems are associated with the elastic problem NP(γ).

If SNOPT is already in elastic mode, an "i" indicates that the minimizer of the elastic subproblem does not satisfy the linearized constraints. (In this case, a feasible point for the usual QP subproblem may or may not exist.)

`M` An extra evaluation of the problem functions was needed to define an acceptable positive-definite quasi-Newton update to the Lagrangian Hessian. This modification is only done when there are nonlinear constraints.

`m` This is the same as "M" except that it was also necessary to modify the update to include an augmented Lagrangian term.

`n` No positive-definite BFGS update could be found. The approximate Hessian is unchanged from the previous iteration.

`R` The approximate Hessian has been reset by discarding all but the diagonal elements. This reset will be forced periodically by the hessian frequency and hessian updates keywords. However, it may also be necessary to reset an ill-conditioned Hessian from time to time.

`r` The approximate Hessian was reset after ten consecutive major iterations in which no BFGS update could be made. The diagonals of the approximate Hessian are retained if at least one update has been done since the last reset. Otherwise, the approximate Hessian is reset to the identity matrix.

`s` A self-scaled BFGS update was performed. This update is always used when the Hessian approximation is diagonal, and hence always follows a Hessian reset.

`S` This is the same as a "s" except that it was necessary to modify the self-scaled update to maintain positive definiteness.

`t` The minor iterations were terminated at the minor iterations limit.

`T` The minor iterations were terminated at the new superbasics limit.

`u` The QP subproblem was unbounded.

`w` A weak solution of the QP subproblem was found.

`z` The superbasics limit was reached.

Finally SNOPT prints an exit message. See Section EXIT conditions.

5.36.6.1 EXIT conditions

When the solution procedure terminates, an `SNOPTA EXIT` and `SNOPTA INFO` message is printed to summarize the final result. Here we describe each message and suggest possible courses of action.

`1 -- optimality conditions satisfied`

The final point seems to be a solution. This means that x is feasible (it satisfies the constraints to the accuracy requested), the reduced gradient is negligible, the reduced costs are optimal, and R is nonsingular. In all cases, some caution should be exercised. For example, if the objective value is much better than expected, SNOPT may have obtained an optimal solution to the wrong problem! Almost any item of data could have that effect if it has the wrong value. Verifying that the problem has been defined correctly is one of the more difficult tasks for a model builder.

If nonlinearities exist, one must always ask the question: could there be more than one local optimum? When the constraints are linear and the objective is known to be convex (e.g., a sum of squares) then all will be well if we are *minimizing* the objective: a local minimum is a global minimum in the sense that no other point has a lower function value. (However, many points could have the *same* objective value, particularly if the objective is largely linear.) Conversely, if we are *maximizing* a convex function, a local maximum cannot be expected to be global, unless there are sufficient constraints to confine the feasible region.

Similar statements could be made about nonlinear constraints defining convex or concave regions. However, the functions of a problem are more likely to be neither convex nor concave. Our advice is always to specify a starting point that is as good an estimate as possible, and to include reasonable upper and lower bounds on all variables, in order to confine the solution to the specific region of interest. We expect modelers to *know something about their problem*, and to make use of that knowledge as they themselves know best.

One other caution about the "Optimal solution" message. Some of the variables or slacks may lie outside their bounds more than desired, especially if scaling was requested. If sysout is on, the listing file will contain several indicators of potential issues. `Max Primal infeas` indicates the largest bound infeasibility and which variable is involved. If it is too large, consider restarting with a smaller minor feasibility tolerance (say 10 times smaller) and perhaps a scale option of 0.

Similarly, `Max Dual infeas` indicates which variable is most likely to be at a non-optimal value. Broadly speaking, if

$$\text{Max Dual infeas/Norm of pi} = 10^{-d},$$

then the objective function would probably change in the dth significant digit if optimization could be continued. If d seems too large, consider restarting with smaller values of major feasibility tolerance and minor feasibility tolerance.

Finally, `Nonlinear constraint violn` shows the maximum infeasibility for nonlinear rows. If it seems too large, consider restarting with a smaller major feasibility tolerance.

`2 -- feasible point found`

Occurs only if feasible point is enabled.

`3 -- requested accuracy could not be achieved`

If the requested accuracy could not be achieved, a feasible solution has been found, but the requested accuracy in the dual infeasibilities could not be achieved. An abnormal termination has occurred, but SNOPT is within 10^{-2} of satisfying the major optimality tolerance. Check that the major optimality tolerance is not too small.

`11 -- infeasible linear constraints`

`12 -- infeasible linear equality constraints`

When the constraints are linear, the output messages are based on a relatively reliable indicator of infeasibility. Feasibility is measured with respect to the upper and lower bounds on the variables and slacks. Among all the points satisfying the general constraints $Ax - s = 0$, there is apparently no point that satisfies the bounds on x and s. Violations as small as the minor feasibility tolerance are ignored, but at least one component of x or s violates a bound by more than the tolerance.

`13 -- nonlinear infeasibilities minimized`

`14 -- linear infeasibilities minimized`

`15 -- infeasible linear constraints in QP subproblem`

`16 -- infeasible nonelastic constraints`

When nonlinear constraints are present, infeasibility is *much* harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation, when solving each QP subproblem, SNOPT is prepared to relax the bounds on the slacks associated with nonlinear rows.

If a QP subproblem proves to be infeasible or unbounded (or if the Lagrange multiplier estimates for the nonlinear constraints become large), SNOPT enters so-called "nonlinear elastic" mode. The subproblem includes the original QP objective and the sum of the infeasibilities—suitably weighted using the elastic weight parameter. In elastic mode, the nonlinear rows are made "elastic"—i.e., they are allowed to violate their specified bounds. Variables subject to elastic bounds are known as *elastic variables*. An elastic variable is free to violate one or both of its original upper or lower bounds. If the original problem has a feasible solution and the elastic weight is sufficiently large, a feasible point eventually will be obtained for the perturbed constraints, and optimization can continue on the subproblem. If the nonlinear problem has no feasible solution, SNOPT will tend to determine a "good" infeasible point if the elastic weight is sufficiently large. (If the elastic weight were infinite, SNOPT would locally minimize the nonlinear constraint violations subject to the linear constraints and bounds.)

Unfortunately, even though SNOPT locally minimizes the nonlinear constraint violations, there may still exist other regions in which the nonlinear constraints are satisfied. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

```
21 -- unbounded objective
```

```
22 -- constraint violation limit reached
```

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased or decreased by an arbitrary amount without causing a basic variable to violate a bound. Adding a bound on the objective will allow SNOPT to find a solution, and inspection of this solution will show the variables that can become too large due to missing restrictions.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the scale option.

For nonlinear problems, SNOPT monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (see unbounded step size and unbounded objective value), the problem is terminated and declared UNBOUNDED. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

The second message indicates an abnormal termination while enforcing the limit on the constraint violations. This exit implies that the objective is not bounded below in the feasible region defined by expanding the bounds by the value of the violation limit.

```
31 -- iteration limit reached
```

An iteration limit was reached. Most often this is cured by increasing the GAMS iterlim option. If an SNOPT option file was used, also the iterations limit may have been set too small.

Check the iteration log to be sure that progress was being made. If so, repeat the run with higher limits. If not, consider specifying new initial values for some of the nonlinear variables.

```
32 -- major iteration limit reached
```

This indicates SNOPT was running out the limit on major iterations. This can be changed using the major iterations limit.

```
33 -- the superbasics limit is too small
```

The problem appears to be more nonlinear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and a PRICE operation is necessary to continue, but there are already as many superbasics as allowed (and no room for any more).

When increasing the superbasics limit, be aware that this also increases the reduced hessian dimension unless both options are set explicitly. This may increase the amount of memory required by SNOPT dramatically. Consider also increasing the amount memory available to SNOPT via the workfactor option, or setting a more moderate value for the reduced hessian dimension option and possibly getting slower convergence.

```
34 -- time limit reached
```

A time limit was hit. Increase the GAMS reslim option.

```
41 -- current point cannot be improved
```

The algorithm could not find a better solution although optimality was not achieved within the optimality tolerance. Possibly scaling can lead to better function values and derivatives. Raising the major optimality tolerance will probably make this message go away. Try better scaling, better bounds or a better starting point.

`42 -- singular basis`

The first factorization attempt found the basis to be structurally or numerically singular. (Some diagonals of the triangular matrix U were deemed too small.) The associated variables were replaced by slacks and the modified basis refactorized, but singularity persisted. Try better scaling, better bounds or a better starting point.

`43 -- cannot satisfy the general constraints`

The basic variables x_B have been recomputed, given the present values of the superbasic and nonbasic variables. A step of "iterative refinement" has also been applied to increase the accuracy of x_B, but a row check has revealed that the resulting solution does not satisfy the QP constraints $Ax - s = b$ sufficiently well. Try better scaling, better bounds or a better starting point.

`44 -- ill-conditioned null-space basis`

During computation of the reduced Hessian $Z^T HZ$, some column(s) of Z continued to contain very large values. Try better scaling, better bounds or a better starting point.

`51 -- incorrect objective derivatives`

`52 -- incorrect constraint derivatives`

The derivatives are not deemed to be correct. This message should not occur using a GAMS model without external equations.

`53 -- irregular or badly scaled problem functions`

The problem function can be badly scaled in case of DNLPs (which SNOPT was not designed for) or because of evaluations at singular points.

`61 -- undefined function at the first feasible point`

`62 -- undefined function at the initial point`

SNOPT was unable to proceed because the functions are undefined at the initial point or the first feasible point. Try to add better bounds or linear equations such that non-linear functions can be evaluated or use a better starting point.

`63 -- unable to proceed into undefined region`

Repeated attempts to move into a region where the functions are not defined resulted in the change in variables being unacceptably small. At the final point, it appears that the only way to decrease the merit function is to move into a region where the problem functions are not defined.

Try to add better bounds or linear equations such that non-linear functions can be evaluated or use a better starting point.

`71 -- terminated during function evaluation`

`72 -- terminated from monitor routine`

These messages indicate trouble evaluating the non-linear functions or derivatives. Usually these errors show a "Function evaluation error limit" message.

`81 -- work arrays must have at least 500 elements`

`82 -- not enough character storage`

`83 -- not enough integer storage`

`84 -- not enough real storage`

Increase the memory allocation by using workfactor > 1.

5.37 SoPlex

SoPlex (**S**equential **o**bject-oriented sim**Plex**) is an optimization package for solving linear programming problems (LPs) based on an advanced implementation of the primal and dual revised simplex algorithm. SoPlex is developed at the Zuse-Institute Berlin.

For more detailed information, we refer to [74] [127] [88] [89] [75] [206] and the SoPlex web site.

5.37.1 Usage

The following statement can be used inside your GAMS program to specify using SOPLEX

```
Option LP = SOPLEX;     { or RMIP }
```

The above statement should appear before the Solve statement. If SoPlex was specified as the default solver during GAMS installation, the above statement is not necessary.

5.37.1.1 Specification of SoPlex Options

GAMS/SoPlex supports the GAMS parameters reslim and iterlim.

To allow to run without an iteration limit (SoPlex default), the GAMS/SoPlex link does not pass on a setting of GAMS option iterlim to 2147483647.

Setting the GAMS option integer1 to a nonzero value enables writing of detailed solution statistics to the log.

Setting the GAMS option integer3 to a nonzero value leads to writing the model instance to a file in LP or MPS format before starting the solution process (`integer3=1` writes an MPS file, `integer3=2` writes an LP files, `integer3=4` writes SoPlex state files (.mps, .bas, .set); sum these values to write several files). The name of the output file is chosen to be the name of the GAMS model file with the extension `.gms` replaced. Setting the GAMS option integer2 to a nonzero value makes variable and equation names available when writing the LP or MPS files. These options may be useful for debugging purposes.

Options can be specified by a SoPlex options file. A SoPlex options file consists of one option or comment per line. A pound sign (`#`) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (`=`) and any amount of white space (blanks or tabs).

A small example for a soplex.opt file is:

```
bool:rowboundflips = true
int:algorithm = 0
real:feastol = 1e-5
```

It causes GAMS/SoPlex to use bound flipping also for row representations, use the primal simplex, and use a primal feasibility tolerance of 1e-5.

5.37.2 List of SoPlex Options

In the following, we give a detailed list of all SoPlex options.

Option	Description	Default
bool:acceptcycling	should cycling solutions be accepted during iterative refinement? Range: boolean	0
bool:computedegen	should the degeneracy be computed for each basis? Range: boolean	0
bool:decompositiondualsimplex	should the decomposition based dual simplex be used to solve the LP? Range: boolean	0
bool:ensureray	re-optimize the original problem to get a proof (ray) of infeasibility/unboundedness? Range: boolean	0
bool:explicitviol	Should violations of the original problem be explicitly computed in the decomposition simplex? Range: boolean	0
bool:forcebasic	try to enforce that the optimal solution is a basic solution Range: boolean	0
bool:fullperturbation	should perturbation be applied to the entire problem? Range: boolean	0
bool:lifting	should lifting be used to reduce range of nonzero matrix coefficients? Range: boolean	0
bool:persistentscaling	should persistent scaling be used? Range: boolean	1
bool:powerscaling	round scaling factors for iterative refinement to powers of two? Range: boolean	1
bool:ratfacjump	continue iterative refinement with exact basic solution if not optimal? Range: boolean	0
bool:rowboundflips	use bound flipping also for row representation? Range: boolean	0
bool:testdualinf	should dual infeasibility be tested in order to try to return a dual solution even if primal infeasible? Range: boolean	0
bool:usecompdual	should the dual of the complementary problem be used in the decomposition simplex? Range: boolean	0

Option	Description	Default
int:algorithm	type of algorithm (0 - primal, 1 - dual) Range: {0, ..., 1}	1
int:decomp_displayfreq	the frequency that the decomposition based simplex status output is displayed. Range: {1, ..., ∞}	50
int:decomp_iterlimit	the number of iterations before the decomposition simplex initialisation solve is terminated Range: {1, ..., ∞}	100
int:decomp_maxaddedrows	maximum number of rows that are added to the reduced problem when using the decomposition based simplex Range: {1, ..., ∞}	500
int:decomp_verbosity	the verbosity of decomposition based simplex (0 - error, 1 - warning, 2 - debug, 3 - normal, 4 - high, 5 - full). Range: {1, ..., 5}	0
int:displayfreq	display frequency Range: {1, ..., ∞}	200
int:factor_update_max	maximum number of LU updates without fresh factorization (0 - auto) Range: {0, ..., ∞}	0
int:factor_update_type	type of LU update (0 - eta update, 1 - Forrest-Tomlin update) Range: {0, ..., 1}	1
int:hyperpricing	mode for hyper sparse pricing (0 - off, 1 - auto, 2 - always) Range: {0, ..., 2}	1
int:iterlimit	iteration limit (-1 - no limit) Range: {-1, ..., ∞}	GAMS iterlim
int:leastsq_maxrounds	maximum number of conjugate gradient iterations in least square scaling Range: {0, ..., ∞}	50
int:pricer	pricing method (0 - auto, 1 - dantzig, 2 - parmult, 3 - devex, 4 - quicksteep, 5 - steep) Range: {0, ..., 5}	0
int:printbasismetric	print basis metric during the solve (-1 - off, 0 - condition estimate , 1 - trace, 2 - determinant, 3 - condition) Range: {-1, ..., 3}	-1
int:ratiotester	method for ratio test (0 - textbook, 1 - harris, 2 - fast, 3 - boundflipping) Range: {0, ..., 3}	3

Option	Description	Default
int:reflimit	refinement limit (-1 - no limit) Range: {-1, ..., ∞}	-1
int:representation	type of computational form (0 - auto, 1 - column representation, 2 - row representation) Range: {0, ..., 2}	0
int:scaler	scaling (0 - off, 1 - uni-equilibrium, 2 - bi-equilibrium, 3 - geometric, 4 - iterated geometric, 5 - least squares, 6 - geometric-equilibrium) Range: {0, ..., 6}	2
int:simplifier	simplifier (0 - off, 1 - auto, 2 - PaPILO, 3 - internal) Range: {0, ..., 3}	3
int:stallreflimit	stalling refinement limit (-1 - no limit) Range: {-1, ..., ∞}	-1
int:starter	crash basis generated when starting from scratch (0 - none, 1 - weight, 2 - sum, 3 - vector) Range: {0, ..., 3}	0
int:stattimer	measure for statistics, e.g. factorization time (0 - off, 1 - user time, 2 - wallclock time) Range: {0, ..., 2}	1
int:timer	type of timer (1 - cputime, aka. usertime, 2 - wallclock time, 0 - no timing) Range: {0, ..., 2}	2
int:verbosity	verbosity level (0 - error, 1 - warning, 2 - debug, 3 - normal, 4 - high, 5 - full) Range: {0, ..., 5}	3
real:epsilon_factorization	zero tolerance used in factorization Range: [0, 1]	1e-20
real:epsilon_pivot	pivot zero tolerance used in factorization Range: [0, 1]	1e-10
real:epsilon_update	zero tolerance used in update of the factorization Range: [0, 1]	1e-16
real:epsilon_zero	general zero tolerance Range: [0, 1]	1e-16
real:feastol	primal feasibility tolerance Range: [0, 1]	1e-06
real:fpfeastol	working tolerance for feasibility in floating-point solver during iterative refinement Range: [1e-12, 1]	1e-09

Option	Description	Default
real:fpopttol	working tolerance for optimality in floating-point solver during iterative refinement Range: [1e-12, 1]	1e-09
real:infty	infinity threshold Range: [1e+10, ∞]	∞
real:leastsq_acrcy	accuracy of conjugate gradient method in least squares scaling (higher value leads to more iterations) Range: [1, ∞]	1000
real:liftmaxval	lower threshold in lifting (nonzero matrix coefficients with smaller absolute value will be reformulated) Range: [10, ∞]	1024
real:liftminval	lower threshold in lifting (nonzero matrix coefficients with smaller absolute value will be reformulated) Range: [0, 0.1]	0.000976562
real:maxscaleincr	maximum increase of scaling factors between refinements Range: [1, ∞]	1e+25
real:min_markowitz	minimal Markowitz threshold in LU factorization Range: [0.0001, 0.9999]	0.01
real:minred	minimal reduction (sum of removed rows/cols) to continue simplification Range: [0, 1]	0.0001
real:objlimit_lower	lower limit on objective value Range: real	GAMS cutoff, if maximizing, else -∞
real:objlimit_upper	upper limit on objective value Range: real	GAMS cutoff, if minimizing, else +∞
real:opttol	dual feasibility tolerance Range: [0, 1]	1e-06
real:refac_basis_nnz	refactor threshold for nonzeros in last factorized basis matrix compared to updated basis matrix Range: [1, 100]	10
real:refac_mem_factor	refactor threshold for memory growth in factorization since last refactorization Range: [1, 10]	1.5
real:refac_update_fill	refactor threshold for fill-in in current factor update compared to fill-in in last factorization Range: [1, 100]	5

Option	Description	Default
real:representation_switch	threshold on number of rows vs. number of columns for switching from column to row representations in auto mode Range: [0, ∞]	1.2
real:simplifier_modifyrowfac	modify constraints when the number of nonzeros or rows is at most this factor times the number of nonzeros or rows before presolving Range: [0, 1]	1
real:sparsity_threshold	sparse pricing threshold (violations < dimension ∗ SPARSITY_THRESHOLD activates sparse pricing) Range: [0, 1]	0.6
real:timelimit	time limit in seconds Range: [0, ∞]	GAMS reslim

5.38 XPRESS

5.38.1 Introduction

The GAMS/XPRESS solver is based on the XPRESS Optimization Subroutine Library, and runs only in conjunction with the GAMS modeling system. GAMS/XPRESS (also simply referred to as XPRESS) is a versatile, high-performance optimization system. The system integrates:

- a powerful simplex-based LP solver.
- a MIP module with cut generation for integer programming problems.
- a barrier module implementing a state-of-the-art interior point algorithm for very large LP problems.
- a sequential linear programming solver (SLP) for (mixed-integer) nonlinear programs NLP, CNS and MINLP.

The GAMS/XPRESS solver is installed automatically with your GAMS system. There are different license options:

- **GAMS/XPRESS:**
  Continuous and discrete linear and convex quadratic models.
- **GAMS/XPRESS-NLP:**
  Continuous linear, quadratic and nonlinear models. In order to use GAMS Knitro, a GAMS/KNITRO license must be included.
- **GAMS/XPRESS-MINLP:**
  All model types. In order to use GAMS Knitro, a GAMS/KNITRO license must be included.
- **GAMS/XPRESS Link:**
  Users must have a separate, licensed XPRESS system. For users who wish to use XPRESS within GAMS and also in other environments. All model types, if XPRESS license enables it. In order to use GAMS Knitro, the user's Xpress license must enable it.
- **demo:**
  Like GAMS/XPRESS but with demo limits (small models only).

Attention

The free bare-bone link mode (previously GAMS/OSIXPRESS) that allowed to solve LP and MIP when the user had a separate XPRESS license installed has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@gams.com to arrange for a GAMS/XPRESS Link license.

5.38.2 Usage

To explicitly request that a model be solved with XPRESS, insert the statement

```
option LP = xpress;  { or MIP, RMIP, NLP, CNS, DNLP, RMINLP, MINLP, QCP, MIQCP, or RMIQCP }
```

somewhere before the solve statement. If XPRESS has been selected as the default solver (e.g. during GAMS installation) for the model type in question, the above statement is not necessary.

The standard GAMS options (e.g. iterlim, optcr) can be used to control XPRESS. For more details, see section Controlling a Solver via GAMS Options. Please note however that - apart from reslim - these are only used for linear and quadratic programs and not the nonlinear solves. Termination conditions for XPRESS SLP can be set in SLP Termination Options.

In addition, XPRESS-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

An example of a valid XPRESS option file is:

```
* sample XPRESS options file
algorithm simplex
presolve   0
IterLim    50000
```

In general this is enough knowledge to solve your models. In some cases you may want to use some of the XPRESS options to gain further performance improvements or for other reasons.

5.38.2.1 Linear and Quadratic Programming

The options advBasis, lpFlags, defaultAlg, basisOut, mpsOutputFile, reform, reRun, and reslim control the behavior of the GAMS/XPRESS link. The options crash, lpIterlimit, presolve, scaling, threads, and trace set XPRESS library control variables, and can be used to fine-tune XPRESS. See section General LP / MIP / QP Options for more details of XPRESS general options.

LP

See section LP Options for more details of XPRESS library control variables which can be used to fine-tune the XPRESS LP solver.

MIP

In some cases, the branch-and-bound MIP algorithm will stop with a proven optimal solution or when unboundedness or (integer) infeasibility is detected. In most cases, however, the global search is stopped through one of the generic GAMS options:

1. iterlim (on the cumulative pivot count) or reslim (in seconds of CPU time),
2. optca & optcr (stopping criteria based on gap between best integer solution found and best possible) or
3. nodlim (on the total number of nodes allowed in the B&B tree).

It is also possible to set the maxNode and maxMipSol options to stop the global search: see section MIP Options for XPRESS control variables for MIP. The options loadMipSol, mipCleanup, mipTrace, mipTraceNode, and mipTraceTime control the behavior of the GAMS/XPRESS link on MIP models. The other options in section MIP Options set XPRESS library control variables, and can be used to fine-tune the XPRESS MIP solver.

MIP Solution Pool

Typically, XPRESS finds a number of integer feasible points during its global search, but only the final solution is available. The MIP solution pool capability makes it possible to store multiple integer feasible points (aka solutions) for later processing. The MIP solution pool operates in one of two modes: by default `(solnpoolPop = 1)` the global search is not altered, but with `(solnpoolPop = 2)` a selected set (potentially all) of the integer feasible solutions are enumerated.

The MIP enumeration proceeds until all MIP solutions are enumerated or cut off, or until a user-defined limit is reached. Whenever a new solution is generated by the enumerator, it is presented to the solution pool manager. If there is room in the pool, the new solution is added. If the pool is full, a *cull round* is performed to select a number of solutions to be thrown out - these solutions can be those stored in the pool and/or the new solution. Solutions can be selected for culling based on their MIP objective value and/or the overall diversity of the solutions in the pool. If neither is chosen, a default choice is made to throw out one solution based on objective values. Whenever a solution is thrown out based on its MIP objective, the enumeration space is pruned based on the cutoff defined by this objective value.

By default, the capacity of the pool is set very large, as is the number of cull rounds to perform, so selecting only `solnpoolPop = 2` will result in full enumeration. However, many different strategies can be executed by setting the solution pool options. For example, to choose the N-best solutions, simply set the solution pool capacity to N. When the pool is full, new solutions will force a cull round, and the default is to reject one solution based on its objective and update the cutoff accordingly. To generate all solutions with an objective as good as X, leave the pool capacity set at a high level but set the cutoff to X using the `mipabscutoff` option. To return the N-first solutions, set the solution pool capacity to N and `solnpoolCullRounds = 0`: as soon as the pool is full the enumeration will stop on the cull round limit.

A number of other strategies for controlling the solution pool behavior are possible by combining different options. Several working examples are provided in the GAMS Test Library in models `xpress03.gms`, `xpress04.gms`, and `xpress05.gms`.

See section MIP Solution Pool Options for XPRESS control variables for MIP Solution Pool.

Newton-Barrier

The barrier method is invoked by default for quadratic problems, and can be selected for linear models by using one of the options

```
algorithm       barrier
defaultalg      4
```

The barrier method is likely to use more memory than the simplex method. No warm start is done, so if an advanced basis exists, you may not wish to use the barrier solver.

See section Newton-barrier Options for XPRESS control variables for the Newton-Barrier method.

5.38.2.2 Nonlinear Programming

XPRESS can solve nonlinear programs of type NLP, CNS and MINLP (and its relaxed version) using the sequential linear programming solver XPRESS SLP or the interior-point / sequential quadratic programming solver XPRESS Knitro. Convexity is not required, but for non-convex programs XPRESS will in general find local optimal solutions only. The XPRESS multistart can be used to increase the likelihood of finding a good solution by starting from many different initial points.

XPRESS SLP solves nonlinear programs by successive linearization of the nonlinearities. These linearizations, which can be controlled by the options in NLP Augmentation and Linearization Options, are solved by the LP or QCP solver. Therefore, XPRESS user options for LP or QCP are also relevant when solving nonlinear programs. Note, that the NLP Presolve is independent from the LP presolve that is executed in each XPRESS SLP iteration.

Termination

In most cases it is sufficient to control the termination of XPRESS SLP by xslp_iterLimit, reslim, xslp_validationTarget_k and xslp_ValidationTarget_r as the latter two automatically control the other XPRESS SLP convergence measures on default. More experienced users may want to modify the other convergence measures, which group into:

- Strict convergence: Describes the numerical behaviour of convergence in the formal, mathematical sense. User options: xslp_cTol, xslp_aTol_a, xslp_aTol_r.
- Extended convergence: Measures the quality of the linearization, including the effect of changes to the nonlinear terms that contribute to a variable in the linearization: User options: xslp_mTol_a, xslp_mTol_r, xslp_iTol_a, xslp_iTol_r, xslp_sTol_a, xslp_sTol_r.

When each variable has converged in one of the above cases, XPRESS SLP terminates based on the following stopping criteria:

- Baseline static objective convergence measure that compares changes in the objective over a given number of iterations relative to the average objective value. User options: xslp_vCount, xslp_vLimit, xslp_vTol_a, xslp_vTol_r.
- Static objective convergence measure that is applied when there are no unconverged variables in active constraints. User options: slpOCount, xslp_oTol_a, xslp_oTol_r.
- Static objective convergence measure that is applied when a pratical solution (all variables have converged and there are no active step bounds) has been found. User options: xslp_xCount, xslp_xLimit, xslp_xTol_a, xslp_xTol_r.
- Extended convergence continuation that is applied when a practical solution has been found. It checks if it is worth continuing. User options: xslp_wCount, xslp_wTol_a, xslp_wTol_r.

The user option slpConvergenceOps enables/disables the different convergence measures and stopping conditions.

Output

The output or logging can be controlled by the NLP Log Options. The default XPRESS SLP iteration output shows:

- `It`: Iteration number.
- `LP`: The LP status of the linearization (`O`: optimal; `I`: infeasible; `U`: unbounded; `X`: interrupted)
- `NetObj`: The net objective of the SLP iteration.
- `ValObj`: The original objective function value.
- `ErrorSum`: Sum of the error delta variables. A measure of infeasibility.
- `ErrorCost`: The value of the weighted error delta variables in the objective. A measure of the effort needed to push the model towards feasibility.
- `Validate`: Relative feasibility measure (calculated only if convergence is likely)
- `KKT`: Relative optimality measure (calculated only if convergence is likely)
- `Unconv`: The number of SLP variables that are not converged.
- `Ext`: The number of SLP variables that are converged, but only by extended criteria.
- `Action`: Special actions (`O`: failed line search; `B`: enforcing step bounds; `E`: some infeasible rows were enforced; `G`: global variables were fixed; `P`: solution needed polishing, postsolve instability; `P!`: solution polishing failed; `R`: penalty error vectors removed; `V`: feasibility validation induces further iterations; `K`: optimality validation induces further iterations)
- `T`: Time.

XPRESS Knitro

Nonlinear programs can also be solved by XPRESS Knitro using the option xslp_solver. In this case, the nonlinear program is passed to Knitro after the NLP Presolve. Setting xslp_solver to auto will enable XPRESS to choose XPRESS SLP or XPRESS Knitro automatically based on the problem instance. XPRESS Knitro options can be specified in a Knitro solver option file, which needs to be selected in knitroOptFile. Note, that XPRESS Knitro does not support all Knitro options. Specified but unsupported options trigger a warning and are then ignored.

For more information about this nonlinear programming solver, see the GAMS/Knitro documentation.

5.38.3 Summary of XPRESS Options

5.38.3.1 General LP / MIP / QP Options

Option	Description	Default
advBasis	Use advanced basis provided by GAMS	`auto`
algorithm	Choose between simplex and barrier algorithm	`simplex`
basisOut	Directs optimizer to output an MPS basis file	`none`
clamping	Allows for the adjustment of returned solution values such that they are always within bounds	`0`

Option	Description	Default
clamping_dual	Adjust primal slack values to always be within constraint bounds	0
clamping_primal	Adjust primal solution to always be within primal bounds	0
clamping_rdj	Adjust reduced costs to always be within dual bounds implied by the primal solution	0
clamping_slacks	Adjust dual solution to always be within the dual bounds implied by the slacks	0
cpuTime	How time should be measured when timings are reported in the log and when checking against time limits	0
globalBoundingBox	If a nonlinear problem cannot be solved due to appearing unbounded, it can automatically be regularized by the application of a bounding box on the variables	1e+06
inputTol	Tolerance on input values elements	0
ioTimeout	Maximum number of seconds to wait for an I/O operation before it is cancelled	30
lpIterLimit	Maximum number of iterations that will be performed by primal simplex or dual simplex before the optimization process terminates	maxint
lpRefineIterLimit	Simplex iteration limit the solution refiner can spend in attempting to increase the accuracy of an LP solution	auto
maxScaleFactor	Determines the maximum scaling factor that can be applied during scaling	64
mpsNameLength	Maximum length of MPS names in characters	0
mpsOutputFile	Name of MPS output file	none
numericalEmphasis	How much emphasis to place on numerical stability instead of solve speed	auto
outputControls	Toggles the printing of all control settings at the beginning of the search	1
outputLog	Controls the level of output produced by the Optimizer during optimization	1
outputTol	Zero tolerance on print values	1e-05
qextractalg	quadratic extraction algorithm in GAMS interface	0
randomSeed	Sets the initial seed to use for the pseudo-random number generator in the Optimizer	1
refineOps	Specifies when the solution refiner should be executed to reduce solution infeasibilities	19
refineOps_iterativeRefiner	Apply the iterative refiner to refine the solution	0
refineOps_lpOptimal	Run the solution refiner on an optimal solution of a continuous problem	1
refineOps_lpPresolve	Run the solution refiner on an optimal solution before postsolve on a continuous problem	1
refineOps_mipFixGlobals	Refine MIP solutions such that rounding them keeps the problem feasible when reoptimized	0
refineOps_mipFixGlobalsTarget	Attempt to refine MIP solutions such that rounding them keeps the problem feasible when reoptimized, but accept integers solutions even if refinement fails	0
refineOps_mipNodeLp	Run the solution refiner on each node of the MIP search	0

Option	Description	Default
refineOps_mipSolution	Run the solution refiner when a new solution is found during a tree search	1
refineOps_refinerPrecision	Use higher precision in the iterative refinement	0
refineOps_refinerUseDual	If set, the iterative refiner will use the dual simplex algorithm	0
refineOps_refinerUsePrimal	If set, the iterative refiner will use the primal simplex algorithm	0
reform	Substitute out objective var and equ when possible	1
reRun	Rerun with primal simplex when not optimal/feasible	0
reslim	Overrides GAMS reslim option	
solTimeLimit	Maximum time in seconds that the Optimizer will run a MIP solve before it terminates, given that a solution has been found	1e+20
timeLimit	Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time	1e+20
trace	Display the infeasibility diagnosis during presolve	0
writePrtSol	Directs optimizer to output a "printsol" file	0

5.38.3.2 Hardware Related Options

Option	Description	Default
barCores	If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm	auto
barOrderThreads	If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton-barrier method	auto
barThreads	If set to a positive integer it determines the number of threads implemented to run the Newton-barrier algorithm	auto
concurrentThreads	Determines the number of threads used by the concurrent solver	auto
coresPerCpu	Used to override the detected value of the number of cores on a CPU	auto
cpuPlatform	Newton Barrier: Selects the AMD, Intel x86 or ARM vectorization instruction set that Barrier should run optimized code for	-1
crossoverThreads	Determines the maximum number of threads that parallel crossover is allowed to use	auto
dualThreads	Determines the maximum number of threads that dual simplex is allowed to use	auto
heurThreads	Branch and Bound: Number of threads to dedicate to running heuristics on the root node	0
maxMemoryHard	Sets the maximum amount of memory in megabytes the optimizer should allocate	unlimited
maxMemorySoft	When resourceStrategy is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate	unlimited
mipThreads	If set to a positive integer it determines the number of threads implemented to run the parallel MIP code	auto

Option	Description	Default
relaxTreeMemoryLimit	When the memory used by the branch and bound search tree exceeds the target specified by the treeMemoryLimit control, the optimizer will try to reduce this by writing nodes to the tree file	0.1
resourceStrategy	Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve	0
threads	Default number of threads used during optimization	1
treeCompression	When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the tree file on disk	2
treeMemoryLimit	Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree	auto
treeMemorySavingTarget	When the memory used by the branch-and-bound search tree exceeds the limit specified by the treeMemoryLimit control, the optimizer will try to save memory by writing lower-rated sections of the tree to the tree file	0.4

5.38.3.3 Presolve Options

Option	Description	Default
barPresolveOps	Newton barrier: Controls the Newton-Barrier specific presolve operations	0
barPresolveOps_extra	Extra effort is spent in barrier specific presolve	0
barPresolveOps_full	Do full matrix eliminations (reduce matrix size)	0
barPresolveOps_standard	Use standard presolve	0
dualize	Whether presolve should form the dual of the problem	auto
dualizeOps	Bit-vector control for adjusting the behavior when a problem is dualized	1
elimFillin	Amount of fill-in allowed when performing an elimination in presolve	10
elimTol	Markowitz tolerance for the elimination phase of the presolve	0.001
indLinBigM	During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough	100000
indPreLinBigM	During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough	100
lpFolding	Simplex and barrier: Whether to fold an LP problem before solving it	auto
maxImpliedBound	Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than maxImpliedBound will be applied to the problem	1e+08
mipPresolve	Branch and Bound: Type of integer processing to be performed	-1
mipPresolve_allowChangeBounds	If node preprocessing is allowed to change bounds on continuous columns	1

Option	Description	Default
mipPresolve_allowTreeRestart	[Unused] This bit is no longer used to control restarts	1
mipPresolve_dualReductions	Dual reductions will be performed at each node	1
mipPresolve_globalCoefTightening	Allow global (non-bound) tightening of the problem during the tree search	1
mipPresolve_logicPreprocessing	Primal reductions will be performed at each node	1
mipPresolve_objBasedReductions	Objective function will be used to find reductions at each node	1
mipPresolve_reducedCostFixing	Reduced cost fixing will be performed at each node	1
mipPresolve_symmetryReductions	Allow that symmetry is used to presolve the node problem	1
preAnalyticCenter	Determines if analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs (-1: Auto 0: Off, 1: Fixing, 2: Redcost, 3: Both)	auto
preBasisRed	Determines if a lattice basis reduction algorithm should be attempted as part of presolve	0
preBndRedCone	Determines if second order cone constraints should be used for inferring bound reductions on variables when solving a MIP	auto
preBndRedQuad	Determines if convex quadratic contraints should be used for inferring bound reductions on variables when solving a MIP	auto
preCliqueStrategy	Determines how much effort to spend on clique covers in presolve	-1
preCoefElim	Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem	2
preComponents	Presolve: Determines whether small independent components should be detected and solved as individual subproblems during root node processing	auto
preComponentsEffort	Presolve: Adjusts the overall effort for the independent component presolver	1
preConeDecomp	Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components	auto
preConfiguration	MIP Presolve: Determines whether binary rows with only few repeating coefficients should be reformulated	auto
preConvertSeparable	Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints	auto
preDomCol	Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem	auto
preDomRow	Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem	auto
preDupRow	Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem	auto

Option	Description	Default
preElimQuad	Presolve: Allows for elimination of quadratic variables via doubleton rows	auto
preFolding	Presolve: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition	auto
preImplications	Presolve: Determines whether to use implication structures to remove redundant rows	auto
preLinDep	Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem	auto
preObjCutDetect	Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed	1
preProbing	Presolve: Amount of probing to perform on binary variables during presolve	auto
presolve	Determines whether presolving should be performed prior to starting the main algorithm	1
presolveMaxGrow	Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem	0.1
presolveOps	Specifies the operations which are performed during the presolve	511
presolveOps_dualReductions	Dual reductions	1
presolveOps_duplicateColRemoval	Duplicate column removal	1
presolveOps_duplicateRowRemoval	Duplicate row removal	1
presolveOps_forcingRowRemoval	Forcing row removal	1
presolveOps_linDependRowRemoval	Linearly dependant row removal	0
presolveOps_noAdvIpReductions	No advanced IP reductions	0
presolveOps_noGlobalDomainChange	No semi-continuous variable detection	0
presolveOps_noIntVarAndSosDetect	No integer variable and SOS detection	0
presolveOps_noIntVarEliminations	No eliminations on integers	0
presolveOps_noIpReductions	No IP reductions	0
presolveOps_redundantRowRemoval	Redundant row removal	1
presolveOps_singletonColRemoval	Singleton column removal	1
presolveOps_singletonRowRemoval	Singleton row removal	1
presolveOps_strongDualReductions	Strong dual reductions	1
presolveOps_variableEliminations	Variable eliminations	1
presolvePasses	Number of reduction rounds to be performed in presolve	1

Option	Description	Default
rootPresolve	Determines if presolving should be performed on the problem after the tree search has finished with root cutting and heuristics	auto
siftPresolveOps	Determines the presolve operations for solving the subproblems during the sifting algorithm	-1

5.38.3.4 Scaling Options

Option	Description	Default
autoScaling	Whether the Optimizer should automatically select between different scaling algorithms	auto
barFreeScale	Defines how the barrier algorithm scales free variables	1e-06
barObjScale	Defines how the barrier scales the objective	auto
barRhsScale	Defines how the barrier scales the right hand side	auto
objScaleFactor	Custom objective scaling factor, expressed as a power of 2	0
scaling	Determines how the Optimizer will rescale a model internally before optimization	163
scaling_beforePresolve	Scale before presolve	0
scaling_bigM	Treat big-M rows as normal rows	0
scaling_byMaxElemNotGeoMean	0: scale by geometric mean	1
scaling_colScaling	Column scaling	1
scaling_curtisReid	Curtis-Reid	0
scaling_disableGlobalObjScaling	Do not apply automatic objective scaling	0
scaling_ignoreQuadRowPart	Exclude the quadratic part of constraint when calculating scaling factors	0
scaling_maximum	Maximum	0
scaling_noAggressiveQScaling	Disable aggressive quadratic scaling	0
scaling_noScalingColsDown	Do not scale columns down	0
scaling_noScalingRowsUp	Do not scale rows up	0
scaling_rhsScaling	RHS scaling	0
scaling_rowScaling	Row scaling	1
scaling_rowScalingAgain	Row scaling again	0
scaling_simplexObjScaling	Scale objective function for the simplex method	1
scaling_slackScaling	Enable explicit linear slack scaling	0

5.38.3.5 LP Options

Option	Description	Default
algAfterNetwork	Algorithm to be used for the clean up step after the network simplex solver	auto
autoPerturb	Simplex: Indicates whether automatic perturbation is performed	auto
bigM	Infeasibility penalty used if the "Big M" method is implemented	auto
bigMMethod	Simplex: Whether to use the "Big M" method, or the standard phase I (achieving feasibility) and phase II (achieving optimality)	1
crash	Simplex: Determines the type of crash used when the algorithm begins	2
defaultAlg	Selects the algorithm that will be used to solve the LP	auto
dualGradient	Simplex: Dual simplex pricing method	auto
dualPerturb	Factor by which the problem will be perturbed prior to optimization by dual simplex	auto
dualStrategy	Bit-vector control specifies the dual simplex strategy	1
etaTol	Tolerance on eta elements	1e-13
feasTol	Determines when a solution is treated as feasible	1e-06
feasTolPerturb	Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes	1e-06
feasTolTarget	Target feasibility tolerance for the solution refiner	0
forceParallelDual	Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm	0
invertFreq	Simplex: Frequency with which the basis will be inverted	auto
invertMin	Simplex: Minimum number of iterations between full inversions of the basis matrix	3
lpFlags	Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem	0
lpFlags_barrier	Use the barrier method	0
lpFlags_dual	Use the dual simplex method	0
lpFlags_network	Use the network simplex method	0
lpFlags_primal	Use the primal simplex method	0
lpLog	Simplex: Frequency at which the simplex log is printed	100
lpLogDelay	Time interval between two LP log lines	1
lpLogStyle	Simplex: Style of the simplex log	1
markowitzTol	Markowitz tolerance used for the factorization of the basis matrix	0.01
matrixTol	Zero tolerance on matrix elements	1e-09
netStallLimit	Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex, depending on algAfterNetwork	auto
optimalityTol	Simplex: Zero tolerance for reduced costs	1e-06
optimalityTolTarget	Target optimality tolerance for the solution refiner	0

Option	Description	Default
penalty	Minimum absolute penalty variable coefficient	auto
pivotTol	Simplex: Zero tolerance for matrix elements	1e-09
ppFactor	Partial pricing candidate list sizing parameter	1
pricingAlg	Simplex: Determines the primal simplex pricing method	auto
primalOps	Primal simplex: Allows fine tuning the variable selection in the primal simplex solver	-1
primalPerturb	Factor by which the problem will be perturbed prior to optimization by primal simplex	auto
primalUnshift	Determines whether primal is allowed to call dual to unshift	0
relPivotTol	Simplex: Minimum size of pivot element relative to largest element in column	1e-06
sifting	Determines whether to enable sifting algorithm with the dual simplex method	auto
siftPasses	Determines how quickly we allow to grow the worker problems during the sifting algorithm	4
siftSwitch	Determines which algorithm to use for solving the subproblems during sifting	-1

5.38.3.6 QP Options

Option	Description	Default
eigenvalueTol	Quadratic matrix is considered not to be positive semi-definite, if its smallest eigenvalue is smaller than the negative of this value	1e-06
ifCheckConvexity	Determines if the convexity of the problem is checked before optimization	1
qSimplexOps	Controls the behavior of the quadratic simplex solvers	0
quadraticUnshift	Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual)	auto
repairIndefInitEq	Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible	1

5.38.3.7 Newton-barrier Options

Option	Description	Default
algAfterCrossover	Algorithm to be used for the final clean up step after the crossover	auto
barAlg	Determines which barrier algorithm is to be used to solve the problem	auto
barCrash	Newton barrier: Determines the type of crash used for the crossover	4
barDualStop	Newton barrier: Convergence parameter, representing the tolerance for dual infeasibilities	auto
barFailIterLimit	Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm	auto
barGapStop	Newton barrier: Convergence parameter, representing the tolerance for the relative duality gap	auto

Option	Description	Default
barGapTarget	Newton barrier: Target tolerance for the relative duality gap	auto
barIndefLimit	Newton Barrier: Limits the number of consecutive indefinite barrier iterations that will be performed	15
barIterLimit	Newton barrier: Maximum number of iterations	500
barKernel	Newton barrier: Defines how centrality is weighted in the barrier algorithm	0
barObjPerturb	Defines how the barrier perturbs the objective	1e-06
barOrder	Newton barrier: Controls the Cholesky factorization in the Newton-Barrier	auto
barOutput	Newton barrier: Level of solution output provided	1
barPerturb	Newton barrier: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties	0
barPrimalStop	Newton barrier: Convergence parameter, indicating the tolerance for primal infeasibilities	auto
barRefIter	Newton barrier: After terminating the barrier algorithm, further refinement steps can be performed	0
barRegularize	Determines how the barrier algorithm applies regularization on the KKT system	-1
barStart	Newton barrier: Controls the computation of the starting point for the barrier algorithm	auto
barStepStop	Newton barrier: Convergence parameter, representing the minimal step size	1e-16
choleskyAlg	Newton barrier: Type of Cholesky factorization used	auto
choleskyTol	Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm	1e-15
crossover	Newton barrier: Determines whether the barrier method will cross over to the simplex method when at optimal solution has been found, to provide an end basis and advanced sensitivity analysis information	auto
crossoverAccuracyTol	Newton barrier: Determines how crossover adjusts the default relative pivot tolerance	1e-06
crossoverIterLimit	Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates	2147483647
crossoverOps	Newton barrier: Bit vector for adjusting the behavior of the crossover procedure	0
denseColLimit	Newton barrier: Controls trigger point for special treatment of dense columns in Cholesky factorization	auto

5.38.3.8 MIP Options

Option	Description	Default
backTrack	Branch and Bound: Specifies how to select the next node to work on when a full backtrack is performed	3
backtrackTie	Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed	-1

Option	Description	Default
branchChoice	Once a MIP entity has been selected for branching, this control determines which of the branches is solved first	0
branchDisj	Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search	auto
branchStructural	Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search	auto
breadthFirst	Number of nodes to include in the best-first search before switching to the local first search (nodeSelection = 4)	11
deterministic	Selects whether to use a deterministic or opportunistic mode when solving a problem using multiple threads	1
feasibilityPump	Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node	auto
fixoptfile	name of option file which is read just before solving the fixed problem	
genConsAbsTransformation	Specifies the reformulation method for absolute value general constraints at the beginning of the search	auto
genConsDualReductions	Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs	1
historyCosts	Branch and Bound: How to update the pseudo cost for a MIP entity when a strong branch or a regular branch is applied	auto
loadMipSol	Loads a MIP solution (the initial point)	0
localChoice	Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree	auto
maxLocalBacktrack	Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node	auto
maxMipSol	Branch and Bound: Limit on the number of integer solutions to be found by the Optimizer	0
maxMipTasks	Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve	auto
maxNode	Branch and Bound: Maximum number of nodes that will be explored	maxint
maxStallTime	Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent	0
mipAbsCutoff	Branch and Bound: If the user knows that they are interested only in values of the objective function which are better than some value, this can be assigned to mipAbsCutoff	auto
mipAbsStop	Branch and Bound: Absolute tolerance determining whether the tree search will continue or not	0
mipAddCutoff	Branch and Bound: Amount to add to the objective function of the best integer solution found to give the new CURRMIPCUTOFF	0
mipCleanup	Clean up the MIP solution (round-fix-solve) to get duals	1
mipComponents	Determines whether disconnected components in a MIP should be solved as separate MIPs	auto
mipConcurrentNodes	Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled	auto

Option	Description	Default
mipConcurrentSolves	Selects the number of concurrent solves to start for a MIP	0
mipDualReductions	Branch and Bound: Limits operations that can reduce the MIP solution space	1
mipFracReduce	Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions	auto
mipKappaFreq	Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search	0
mipLog	MIP log print control	-100
mipRampUp	Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search	auto
mipRefineIterLimit	Defines an effort limit expressed as simplex iterations for the MIP solution refiner	auto
mipRelCutoff	Branch and Bound: Percentage of the LP solution value to be added to the value of the objective function when an integer solution is found, to give the new value of CURRMIPCUTOFF	0
mipRelStop	Branch and Bound: Determines when the branch and bound tree search will terminate	0.0001
mipRestart	Branch and Bound: Controls strategy for in-tree restarts	auto
mipRestartFactor	Branch and Bound: Fine tune initial conditions to trigger an in-tree restart	1
mipRestartGapThreshold	Branch and Bound: Initial gap threshold to delay in-tree restart	0.02
mipstopexpr	Stopping expression for branch and bound	
mipTol	Branch and Bound: Tolerance within which a decision variable's value is considered to be integral	5e-06
mipToltarget	Target mipTol value used by the automatic MIP solution refiner as defined by refineOps	0
mipTrace	Name of MIP trace file	none
mipTraceNode	Node interval between MIP trace file entries	100
mipTraceTime	Time interval, in seconds, between MIP trace file entries	5
miqcpAlg	Determines which algorithm is to be used to solve mixed integer quadratic constrained and mixed integer second order cone problems	auto
nodeProbingEffort	Adjusts the overall level of node probing	1
nodeSelection	Branch and Bound: Determines which nodes will be considered for solution once the current node has been solved	auto
objGoodEnough	Stop once an objective this good is found	none
pseudoCost	Branch and Bound: Default pseudo cost used in estimation of the degradation associated with an unexplored node in the tree search	0.01
qcRootAlg	Determines which algorithm is to be used to solve the root of a mixed integer quadratic constrained or mixed integer second order cone problem, when outer approximation is used	auto

Option	Description	Default
sbBest	Number of infeasible MIP entities to initialize pseudo costs for on each node	auto
sbEffort	Adjusts the overall amount of effort when using strong branching to select an infeasible MIP entity to branch on	1
sbEstimate	Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible MIP entity to branch on	auto
sbIterLimit	Number of dual iterations to perform the strong branching for each entity	auto
sbSelect	Size of the candidate list of MIP entities for strong branching	-2
sosRefTol	Minimum relative gap between the ordering values of elements in a special ordered set	1e-06
symmetry	Adjusts the overall amount of effort for symmetry detection	1
symSelect	Adjusts the overall amount of effort for symmetry detection	-1
varSelection	Branch and Bound: Determines the formula used to calculate the estimate of each integer variable, and thus which integer variable is selected to be branched on at a given node	auto

5.38.3.9 MIP Cuts Options

Option	Description	Default
autoCutting	Automatically decide whether to generate cutting planes at local nodes in the tree	auto
conflictCuts	Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts	auto
coverCuts	Branch and Bound: Number of rounds of lifted cover inequalities at the top node	auto
cutDepth	Branch and Bound: Sets the maximum depth in the tree search at which cuts will be generated	auto
cutFactor	Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during tree search	auto
cutFreq	Branch and Bound: Frequency at which cuts are generated in the tree search	auto
cutSelect	Bit vector providing detailed control of the cuts created for the root node of a MIP solve	-1
cutSelect_clique	Clique cuts	1
cutSelect_cover	Lifted cover cuts	1
cutSelect_disableCutRows	Disable cutting from cut rows	1
cutSelect_farkas	Farkas cuts	1
cutSelect_flowpath	Flow path cuts	1
cutSelect_gomory	Strong Chvatal-Gomory cuts	1
cutSelect_gubCover	Lifted GUB cover cuts	1
cutSelect_implication	Implication cuts	1

Option	Description	Default
cutSelect_indicator	Indicator constraint cuts	1
cutSelect_liftAndProject	Turn on automatic Lift-and-Project cutting strategy	1
cutSelect_mir	Mixed Integer Rounding (MIR) cuts	1
cutSelect_mirRowAggregation	Turn on row aggregation for MIR cuts	1
cutSelect_zeroHalf	Zero-half cuts	1
cutStrategy	Branch and Bound: Cut strategy	auto
gomCuts	Branch and Bound: Number of rounds of Gomory or lift-and-project cuts at the top node	auto
lnpBest	Number of infeasible MIP entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see gomCuts)	50
lnpIterLimit	Number of iterations to perform in improving each lift-and-project cut	auto
maxCutTime	Maximum amount of time allowed for generation of cutting planes and reoptimization	0
netCuts	Determines the addition of multi-commodity network cuts to a problem	0
qcCuts	Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation	auto
treeCoverCuts	Branch and Bound: Number of rounds of lifted cover inequalities generated at nodes other than the top node in the tree	auto
treeCutSelect	Bit vector providing detailed control of the cuts created during the tree search of a MIP solve	-1
treeCutSelect_clique	Clique cuts	1
treeCutSelect_cover	Lifted cover cuts	1
treeCutSelect_disableCutRows	Disable cutting from cut rows	1
treeCutSelect_farkas	Farkas cuts	1
treeCutSelect_flowpath	Flow path cuts	1
treeCutSelect_gomory	Strong Chvatal-Gomory cuts	1
treeCutSelect_gubCover	Lifted GUB cover cuts	1
treeCutSelect_implication	Implication cuts	1
treeCutSelect_indicator	Indicator constraint cuts	1
treeCutSelect_liftAndProject	Turn on automatic Lift and Project cutting strategy	1
treeCutSelect_mir	Mixed Integer Rounding (MIR) cuts	1
treeCutSelect_mirRowAggregation	Turn on row aggregation for MIR cuts	1
treeCutSelect_zeroHalf	Zero-half cuts	1

Option	Description	Default
treeGomCuts	Branch and Bound: Number of rounds of Gomory cuts generated at nodes other than the first node in the tree	auto
treeQCCuts	Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation	auto

5.38.3.10 MIP Heuristics Options

Option	Description	Default
feasibilityJump	MIP: Decides if the Feasibility Jump heuristic should be run	1
heurBeforeLp	Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved	auto
heurDiveIterLimit	Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic	auto
heurDiveRandomize	Level of randomization to apply in the diving heuristic	0
heurDiveSoftRounding	Branch and Bound: Enables a more cautious strategy for the diving heuristic, where it tries to push binaries and integer variables to their bounds using the objective, instead of directly fixing them	auto
heurDiveSpeedUp	Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed	-1
heurDiveStrategy	Branch and Bound: Chooses the strategy for the diving heuristic	auto
heurEmphasis	Branch and Bound: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap	-1
heurForceSpecialObj	Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer	0
heurFreq	Branch and Bound: Frequency at which heuristics are used in the tree search	-1
heurSearchEffort	Adjusts the overall level of the local search heuristics	1
heurSearchFreq	Branch and Bound: How often the local search heuristic should be run in the tree	auto
heurSearchRootCutFreq	How frequently to run the local search heuristic during root cutting	auto
heurSearchRootSelect	Bit vector control for selecting which local search heuristics to apply on the root node of a MIP solve	117
heurSearchTreeSelect	Bit vector control for selecting which local search heuristics to apply during the tree search of a MIP solve	17

5.38.3.11 MIP Solution Pool Options

Option	Description	Default
solnpool	Solution pool file name	none

Option	Description	Default
solnpoolCapacity	Limit on number of solutions to store	999999999
solnpoolCullDiversity	Cull N solutions based on solution diversity	-1
solnpoolCullObj	Cull N solutions based on objective values	-1
solnpoolCullRounds	Terminate solution generation after N culling rounds	999999999
solnpoolDupPolicy	Policy to use when handling storage of duplicate solutions	0
solnpoolmerge	Solution pool file name for merged solutions	none
solnpoolnumsym	Maximum number of variable symbols when writing merged solutions	10
solnpoolPop	Controls method used to populate the solution pool	1
solnpoolPrefix	File name prefix for GDX solution files	soln
solnpoolVerbosity	Controls verbosity of solution pool routines	0

5.38.3.12 General NLP / MINLP Options

Option	Description	Default
knitroOptFile	Option file for NLP solver KNITRO	
xslp_algorithm	Bit map describing the SLP algorithm(s) to be used	166
xslp_algorithm_cascadeBounds	Step bounds are updated to accomodate cascaded values (otherwise cascaded values are pushed to respect step bounds)	0
xslp_algorithm_clampExtendedActiveSB	Apply clamping when converged on extended criteria only with some variables having active step bounds	0
xslp_algorithm_clampExtendedAll	Apply clamping when converged on extended criteria only	0
xslp_algorithm_dynamicDamping	Use dynamic damping	0
xslp_algorithm_escalatePenalties	Escalate penalties	0
xslp_algorithm_estimateStepBounds	Estimate step bounds from early SLP iterations	1
xslp_algorithm_holdValues	Do not update values which are converged within strict tolerance	0
xslp_algorithm_maxCostOption	Continue optimizing after penalty cost reaches maximum	0
xslp_algorithm_noLPPolishing	Skip the solution polishing step if the LP postsolve returns a slightly infeasible, but claimed optimal solution	0
xslp_algorithm_noStepBounds	Do not apply step bounds	0
xslp_algorithm_quickConvergenceCheck	Quick convergence check	1
xslp_algorithm_resetDeltaZ	Reset xslp_delta_z to zero when converged and continue SLP	0
xslp_algorithm_residualErrors	Accept a solution which has converged even if there are still significant active penalty error vectors	0

Option	Description	Default
xslp_algorithm_retainPreviousValue	Retain previous value when cascading if determining row is zero	1
xslp_algorithm_stepBoundsAsRequired	Apply step bounds to SLP delta vectors only when required	1
xslp_algorithm_switchToPrimal	Use the primal simplex algorithm when all error vectors become inactive	0
xslp_calcThreads	Number of threads used for formula and derivatives evaluations	auto
xslp_filter	Bit map for controlling solution updates	3
xslp_filterKeepBest	Retrain solution best according to the merit function	1
xslp_filterZeroLineSearch	Force minimum step sizes in line search	0
xslp_filterZeroLineSearchTR	Accept the trust region step is the line search returns a zero step size	0
xslp_findIV	Option for running a heuristic to find a feasible initial point	auto
xslp_infinity	Value returned by a divide-by-zero in a formula	1e+10
xslp_primalIntegralRef	Reference solution value to take into account when calculating the primal integral	1e+20
xslp_scale	When to re-scale the SLP problem	1
xslp_scaleCount	Iteration limit used in determining when to re-scale the SLP matrix	0
xslp_solver	Selects the library to use for local solves	auto
xslp_threads	Default number of threads to be used	auto
xslp_zero	Absolute tolerance	1e-15

5.38.3.13 NLP Presolve Options

Option	Description	Default
xslp_linQuadBR	Use linear and quadratic constraints and objective function to further reduce bounds on all variables	auto
xslp_postsolve	Determines whether postsolving should be performed automatically	-1
xslp_presolve	Determines whether presolving should be performed prior to starting the main algorithm	1
xslp_presolveLevel	Determines the level of changes presolve may carry out on the problem	4
xslp_presolveOps	Bitmap indicating the SLP presolve actions to be taken	2104
xslp_presolveOps_domain	Bound tightening based on function domains	1
xslp_presolveOps_eliminations	Allow eliminations on determined variables	1
xslp_presolveOps_fixAll	Explicitly fix all columns identified as fixed	0
xslp_presolveOps_fixZero	Explicitly fix columns identified as fixed to zero	0
xslp_presolveOps_general	Generic SLP presolve	0

Option	Description	Default
xslp_presolveOps_intBounds	MISLP bound tightening	1
xslp_presolveOps_noCoefficients	Do not presolve coefficients	0
xslp_presolveOps_noDeltas	Do not remove delta variables	0
xslp_presolveOps_noDualSide	Avoid reductions that can not be dual postsolved	0
xslp_presolveOps_noLinear	Avoid performing linear reductions at the nlp level	0
xslp_presolveOps_noSimplifier	Avoid simplifying nonlinear expressions	0
xslp_presolveOps_setBounds	SLP bound tightening	1
xslp_presolveZero	Minimum absolute value for a variable which is identified as nonzero during SLP presolve	1e-09
xslp_probing	Determines whether probing on a subset of variables should be performed prior to starting the main algorithm	auto

5.38.3.14 NLP Augmentation and Linearization Options

Option	Description	Default
xslp_augmentation	Bit map describing the SLP augmentation method(s) to be used	12
xslp_augmentation_allErrorVectors	Penalty error vectors on all non-linear inequality constraints	1
xslp_augmentation_allRowErrorVectors	Penalty error vectors on all constraints	0
xslp_augmentation_aMeanWeight	Use arithmetic means to estimate penalty weights	0
xslp_augmentation_equalityErrorVectors	Penalty error vectors on all non-linear equality constraints	1
xslp_augmentation_evenHanded	Even handed augmentation	0
xslp_augmentation_minimum	Minimum augmentation	0
xslp_augmentation_noUpdateIfOnlyIV	Intial values do not imply an SLP variable	0
xslp_augmentation_penaltyDeltaVectors	Penalty vectors to exceed step bounds	0
xslp_augmentation_sbFromAbsValues	Estimate step bounds from absolute values of row coefficients	0
xslp_augmentation_sbFromValues	Estimate step bounds from values of row coefficients	0
xslp_augmentation_stepBoundRows	Row-based step bounds	0
xslp_delta_x	Minimum absolute value of delta coefficients to be retained	1e-06
xslp_feasTolTarget	When set, this defines a target feasibility tolerance to which the linearizations are solved to	not set
xslp_optimalityTolTarget	When set, this defines a target optimality tolerance to which the linearizations are solved to	not set
xslp_unfinishedLimit	Number of consecutive SLP iterations that may have an unfinished status before the solve is terminated	3

Option	Description	Default
xslp_zeroCriterion	Bitmap determining the behavior of the placeholder deletion procedure	0
xslp_zeroCriterionCount	Number of consecutive times a placeholder entry is zero before being considered for deletion	0
xslp_zeroCriterionStart	SLP iteration at which criteria for deletion of placeholder entries are first activated	0
xslp_zeroCriterion_deltaNBDRRow	Remove placeholders in a basic delta variable if the determining row for the corresponding SLP variable is nonbasic	0
xslp_zeroCriterion_deltaNBUpdateRow	Remove placeholders in a basic delta variable if its update row is nonbasic and the corresponding SLP variable is nonbasic	0
xslp_zeroCriterion_nbDelta	Remove placeholders in nonbasic delta variables	0
xslp_zeroCriterion_nbSLPVar	Remove placeholders in nonbasic SLP variables	0
xslp_zeroCriterion_print	Print information about zero placeholders	0
xslp_zeroCriterion_slpVarNBUpdateRow	Remove placeholders in a basic SLP variable if its update row is nonbasic	0

5.38.3.15 NLP Barrier Options

Option	Description	Default
xslp_barCrossOverStart	Default crossover activation behaviour for barrier start	0
xslp_barLimit	Number of initial SLP iterations using the barrier method	0
xslp_barStallingLimit	Number of iterations to allow numerical failures in barrier before switching to dual	3
xslp_barStallingObjLimit	Number of iterations over which to measure the objective change for barrier iterations with no crossover	3
xslp_barStallingTol	Required change in the objective when progress is measured in barrier iterations without crossover	0.05
xslp_barStartOps	Controls behaviour when the barrier is used to solve the linearizations	-1
xslp_barStartOps_allowInteriorSol	If a non-vertex converged solution found by barrier without crossover can be returned as a final solution	1
xslp_barStartOps_stallingNumerical	Fall back to dual simplex if too many numerical problems are reported by the barrier	1
xslp_barStartOps_stallingObjective	Check objective progress when no crossover is applied	1

5.38.3.16 NLP Penalty Options

Option	Description	Default
xslp_deltaCost	Initial penalty cost multiplier for penalty delta vectors	200
xslp_deltaCostFactor	Factor for increasing cost multiplier on total penalty delta vectors	1.3

Option	Description	Default
xslp_deltaMaxCost	Maximum penalty cost multiplier for penalty delta vectors	1e+20
xslp_enforceCostShrink	Factor by which to decrease the current penalty multiplier when enforcing rows	1e-05
xslp_enforceMaxCost	Maximum penalty cost in the objective before enforcing most violating rows	1e+11
xslp_errorCost	Initial penalty cost multiplier for penalty error vectors	200
xslp_errorCostFactor	Factor for increasing cost multiplier on total penalty error vectors	1.3
xslp_errorMaxCost	Maximum penalty cost multiplier for penalty error vectors	1e+20
xslp_errorTol_a	Absolute tolerance for error vectors	1e-05
xslp_errorTol_p	Absolute tolerance for printing error vectors	0.0001
xslp_escalation	Factor for increasing cost multiplier on individual penalty error vectors	1.25
xslp_eTol_a	Absolute tolerance on penalty vectors	0.0001
xslp_eTol_r	Relative tolerance on penalty vectors	0.0001
xslp_evTol_a	Absolute tolerance on total penalty costs	-1
xslp_evTol_r	Relative tolerance on total penalty costs	-1
xslp_granularity	Base for calculating penalty costs	4
xslp_maxWeight	Maximum penalty weight for delta or error vectors	100
xslp_minWeight	Minimum penalty weight for delta or error vectors	0.01
xslp_objToPenaltyCost	Factor to estimate initial penalty costs from objective function	0
xslp_penaltyInfoStart	Iteration from which to record row penalty information	3

5.38.3.17 NLP Step Bounds Options

Option	Description	Default
xslp_clampShrink	Shrink ratio used to impose strict convergence on variables converged in extended criteria only	0.3
xslp_clampValidationTol_a	Absolute validation tolerance for applying xslp_clampShrink	not set
xslp_clampValidationTol_r	Relative validation tolerance for applying xslp_clampShrink	not set
xslp_defaultStepBound	Minimum initial value for the step bound of an SLP variable if none is explicitly given	16
xslp_djTol	Tolerance on DJ value for determining if a variable is at its step bound	1e-06
xslp_expand	Multiplier to increase a step bound	2
xslp_minSBFactor	Factor by which step bounds can be decreased beneath xslp_aTol_a	1
xslp_sameCount	Number of steps reaching the step bound in the same direction before step bounds are increased	3
xslp_sbStart	SLP iteration after which step bounds are first applied	8

Option	Description	Default
xslp_shrink	Multiplier to reduce a step bound	0.5
xslp_shrinkBias	Defines an overwrite / adjustment of step bounds for improving iterations	not set

5.38.3.18 NLP Variable Update Options

Option	Description	Default
xslp_damp	Damping factor for updating values of variables	1
xslp_dampExpand	Multiplier to increase damping factor during dynamic damping	1
xslp_dampMax	Maximum value for the damping factor of a variable during dynamic damping	1
xslp_dampMin	Minimum value for the damping factor of a variable during dynamic damping	1
xslp_dampShrink	Multiplier to decrease damping factor during dynamic damping	1
xslp_dampStart	SLP iteration at which damping is activated	0
xslp_lsIterLimit	Number of iterations in the line search	0
xslp_lsPatternLimit	Number of iterations in the pattern search preceding the line search	0
xslp_lsStart	Iteration in which to active the line search	8
xslp_lsZeroLimit	Maximum number of zero length line search steps before line search is deactivated	5
xslp_meritLambda	Factor by which the net objective is taken into account in the merit function	0
xslp_sameDamp	Number of steps in same direction before damping factor is increased	3

5.38.3.19 NLP Termination Options

Option	Description	Default
xslp_aTol_a	Absolute delta convergence tolerance	auto
xslp_aTol_r	Relative delta convergence tolerance	auto
xslp_convergenceOps	Bit map describing which convergence tests should be carried out	7167
xslp_convergenceOps_aTol	Execute the delta tolerance checks	1
xslp_convergenceOps_cTol	Execute the closure tolerance checks	1
xslp_convergenceOps_extendedScaling	Take scaling of individual variables / rows into account	0
xslp_convergenceOps_iTol	Execute the impact tolerance checks	1
xslp_convergenceOps_mTol	Execute the matrix tolerance checks	1
xslp_convergenceOps_oTol	Execute the objective range + active step bound check	1
xslp_convergenceOps_sTol	Execute the slack impact tolerance checks	1

Option	Description	Default
xslp_convergenceOps_validation	Execute the validation target convergence checks	1
xslp_convergenceOps_validationK	Execute the first order optimality target convergence checks	1
xslp_convergenceOps_vTol	Execute the objective range checks	1
xslp_convergenceOps_wTol	Execute the convergence continuation check	1
xslp_convergenceOps_xTol	Execute the objective range + constraint activity check	1
xslp_cTol	Closure convergence tolerance	auto
xslp_ecfCheck	Check feasibility at the point of linearization for extended convergence criteria	1
xslp_ecfTol_a	Absolute tolerance on testing feasibility at the point of linearization	auto
xslp_ecfTol_r	Relative tolerance on testing feasibility at the point of linearization	auto
xslp_infeasLimit	Maximum number of consecutive infeasible SLP iterations which can occur before Xpress-SLP terminates	3
xslp_iterLimit	Maximum number of SLP iterations	auto
xslp_iTol_a	Absolute impact convergence tolerance	auto
xslp_iTol_r	Relative impact convergence tolerance	auto
xslp_mTol_a	Absolute effective matrix element convergence tolerance	auto
xslp_mTol_r	Relative effective matrix element convergence tolerance	auto
xslp_mvTol	Marginal value tolerance for determining if a constraint is slack	auto
xslp_oCount	Number of SLP iterations over which to measure objective function variation for static objective (2) convergence criterion	5
xslp_oTol_a	Absolute static objective (2) convergence tolerance	auto
xslp_oTol_r	Relative static objective (2) convergence tolerance	auto
xslp_sTol_a	Absolute slack convergence tolerance	auto
xslp_sTol_r	Relative slack convergence tolerance	auto
xslp_stopOutOfRange	Stop optimization and return error code if internal function argument is out of range	0
xslp_validationTarget_k	Optimality target tolerance	1e-06
xslp_validationTarget_r	Feasiblity target tolerance	1e-06
xslp_vCount	Number of SLP iterations over which to measure static objective (3) convergence	0
xslp_vLimit	Number of SLP iterations after which static objective (3) convergence testing starts	0
xslp_vTol_a	Absolute static objective (3) convergence tolerance	auto

Option	Description	Default
xslp_vTol_r	Relative static objective (3) convergence tolerance	auto
xslp_wCount	Number of SLP iterations over which to measure the objective for the extended convergence continuation criterion	0
xslp_wTol_a	Absolute extended convergence continuation tolerance	auto
xslp_wTol_r	Relative extended convergence continuation tolerance	auto
xslp_xCount	Number of SLP iterations over which to measure static objective (1) convergence	5
xslp_xLimit	Number of SLP iterations up to which static objective (1) convergence testing starts	100
xslp_xTol_a	Absolute static objective function (1) tolerance	auto
xslp_xTol_r	Relative static objective function (1) tolerance	auto

5.38.3.20 NLP Multistart Options

Option	Description	Default
xslp_msMaxBoundRange	Defines the maximum range inside which initial points are generated by multistart presets	1000
xslp_multistartPreset	Enable multistart	0
xslp_multistart_maxSolves	Maximum number of jobs to create during the multistart search	unlimited
xslp_multistart_maxTime	Maximum total time to be spent in the mutlistart search	unlimited
xslp_multistart_poolsize	Maximum number of problem objects allowed to pool up before synchronization in the deterministic multistart	2
xslp_multistart_seed	Random seed used for the automatic generation of initial point when loading multistart presets	0
xslp_multistart_threads	Maximum number of threads to be used in multistart	auto

5.38.3.21 NLP Derivative Options

Option	Description	Default
xslp_cdTol_a	Absolute tolerance for deducing constant derivatives	1e-08
xslp_cdTol_r	Relative tolerance for deducing constant derivatives	1e-08
xslp_deltaZLimit	Number of SLP iterations during which to apply xslp_delta_z	0
xslp_delta_a	Absolute perturbation of values for calculating numerical derivatives	0.001
xslp_delta_r	Relative perturbation of values for calculating numerical derivatives	0.001
xslp_delta_z	Tolerance used when calculating derivatives	1e-05
xslp_delta_zero	Absolute zero acceptance tolerance used when calculating derivatives	-1
xslp_derivatives	Bitmap describing the method of calculating derivatives	1

Option	Description	Default
xslp_hessian	Second order differentiation mode when using analytical derivatives	-1
xslp_jacobian	First order differentiation mode when using analytical derivatives	-1

5.38.3.22 NLP Log Options

Option	Description	Default
xslp_analyze	Bit map activating additional options supporting model / solution path analyzis	0
xslp_analyze_extendedFinalSummary	Include an extended iteration summary	0
xslp_analyze_infeasibleIteration	Run infeasibility analysis on infeasible iterations	0
xslp_analyze_saveFile	Create an Xpress SLP save file at every xslp_autosave iterations	0
xslp_analyze_saveIterBasis	Write the initial basis of the linearizations to disk at every xslp_autosave iterations	0
xslp_analyze_saveLinearizations	Write the linearizations to disk at every xslp_autosave iterations	0
xslp_autosave	Frequency with which to save the model	0
xslp_log	Level of printing during SLP iterations	0
xslp_slpLog	Frequency with which SLP status is printed	1

5.38.3.23 MINLP Options

Option	Description	Default
xslp_cutStrategy	Determines whihc cuts to apply in the MISLP search when the default SLP-in-MIP strategy is used	0
xslp_heurStrategy	Branch and Bound: MINLP heuristic strategy	auto
xslp_mipAlgorithm	Bitmap describing the MISLP algorithms to be used	17
xslp_mipAlgorithm_finalFixSLP	Fix step bounds according to xslp_mipFixStepBounds after MIP solution is found	0
xslp_mipAlgorithm_finalRelaxSLP	Relax step bounds according to xslp_mipRelaxStepBounds after MIP solution is found	0
xslp_mipAlgorithm_initialFixSLP	Fix step bounds according to xslp_mipFixStepBounds after initial node	0
xslp_mipAlgorithm_initialRelaxSLP	Relax step bounds according to xslp_mipRelaxStepBounds after initial node	0
xslp_mipAlgorithm_initialSLP	Solve initial SLP to convergence	1
xslp_mipAlgorithm_nodeFixSLP	Fix step bounds according to xslp_mipFixStepBounds at each node	0

Option	Description	Default
xslp_mipAlgorithm_nodeLimitSLP	Limit iterations at each node to xslp_mipIterLimit	0
xslp_mipAlgorithm_nodeRelaxSLP	Relax step bounds according to xslp_mipRelaxStepBounds at each node	1
xslp_mipAlgorithm_slpThenMIP	Use MIP on converged SLP solution and then SLP on the resulting MIP solution	0
xslp_mipAlgorithm_withinSLP	Use MIP at each SLP iteration instead of SLP at each node	0
xslp_mipCutOffCount	Number of SLP iterations to check when considering a node for cutting off	5
xslp_mipCutOffLimit	Number of SLP iterations to check when considering a node for cutting off	10
xslp_mipCutOff_a	Absolute objective function cutoff for MIP termination	1e-05
xslp_mipCutOff_r	Absolute objective function cutoff for MIP termination	1e-05
xslp_mipDefaultAlgorithm	Default algorithm to be used during the tree search in MISLP	auto
xslp_mipErrorTol_a	Absolute penalty error cost tolerance for MIP cut-off	0
xslp_mipErrorTol_r	Relative penalty error cost tolerance for MIP cut-off	0
xslp_mipFixStepBounds	Bitmap describing the step-bound fixing strategy during MISLP	0
xslp_mipFixStepBounds_coef	Fix step bounds on SLP variables appearing in coefficients	0
xslp_mipFixStepBounds_coefOnly	Fix step bounds on SLP variables appearing only in coefficients	0
xslp_mipFixStepBounds_structAll	Fix step bounds on all structural SLP variables	0
xslp_mipFixStepBounds_structNotCoef	Fix step bounds on structural SLP variables which are not in coefficients	0
xslp_mipIterLimit	Maximum number of SLP iterations at each node	0
xslp_mipLog	Frequency with which MIP status is printed	0
xslp_mipOCount	Number of SLP iterations at each node over which to measure objective function variation	5
xslp_mipOTol_a	Absolute objective function tolerance for MIP termination	1e-05
xslp_mipOTol_r	Relative objective function tolerance for MIP termination	1e-05
xslp_mipRelaxStepBounds	Bitmap describing the step-bound relaxation strategy during MISLP	15
xslp_mipRelaxStepBounds_coef	Relax step bounds on SLP variables appearing in coefficients	1
xslp_mipRelaxStepBounds_coefOnly	Relax step bounds on SLP variables appearing only in coefficients	1
xslp_mipRelaxStepBounds_structAll	Relax step bounds on all structural SLP variables	1
xslp_mipRelaxStepBounds_structNotCoef	Relax step bounds on structural SLP variables which are not in coefficients	1

5.38.4 Detailed Descriptions of XPRESS Options

advBasis *(boolean)*: Use advanced basis provided by GAMS ↩

Default: `auto`

algAfterCrossover *(integer)*: Algorithm to be used for the final clean up step after the crossover ↩

Default: `auto`

value	meaning
1	Automatically determined.
2	Dual simplex.
3	Primal simplex.
4	Concurrent.

algAfterNetwork *(integer)*: Algorithm to be used for the clean up step after the network simplex solver ↩

Default: `auto`

value	meaning
-1	Automatically determined.
2	Dual simplex.
3	Primal simplex.

algorithm *(string)*: Choose between simplex and barrier algorithm ↩

This option is used to select the barrier method to solve LPs. By default the barrier method will do a crossover to find a basic solution.

Default: `simplex`

value	meaning
barrier	Use the barrier algorithm
simplex	Use the simplex algorithm

autoCutting *(integer)*: Automatically decide whether to generate cutting planes at local nodes in the tree ↩

If the cutFreq control is set, no automatic selection will be made and local cutting will be enabled.

Default: `auto`

value	meaning
-1	Automatic.
0	Disabled.
1	Enabled.

autoPerturb *(boolean)*: Simplex: Indicates whether automatic perturbation is performed ↩

If this is set to 1, the problem will be perturbed whenever the simplex method encounters an excessive number of degenerate pivot steps, thus preventing the Optimizer being hindered by degeneracies.

Default: `auto`

value	meaning
`0`	No perturbation performed.
`1`	Automatic perturbation is performed.

autoScaling *(integer)*: Whether the Optimizer should automatically select between different scaling algorithms ↩

If the scaling control is set, no automatic scaling will be applied.

Default: `auto`

value	meaning
`-1`	Automatic.
`0`	Disabled.
`1`	Cautious strategy. Non-standard scaling will only be selected if it appears to be clearly superior.
`2`	Moderate strategy.
`3`	Aggressive strategy. Standard scaling will only be selected if it appears to be clearly superior.

backTrack *(integer)*: Branch and Bound: Specifies how to select the next node to work on when a full backtrack is performed ↩

Note When two nodes are rated the same according to the backTrack selection, a secondary rating is performed using the method set by backtrackTie.

Default: `3`

value	meaning
`-1`	Automatically determined.
`1`	Unused.
`2`	Select the node with the best estimated solution.
`3`	Select the node with the best bound on the solution.
`4`	Select the deepest node in the search tree (equivalent to depth-first search).
`5`	Select the highest node in the search tree (equivalent to breadth-first search).
`6`	Select the earliest node created.
`7`	Select the latest node created.
`8`	Select a node randomly.
`9`	Select the node whose LP relaxation contains the fewest number of infeasible MIP entities.
`10`	Combination of 2 and 9.
`11`	Combination of 2 and 4.
`12`	Combination of 3 and 4.

backtrackTie *(integer)*: Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed ↩

The options are the same as for the backTrack control.

Default: `-1`

value	meaning
`-1`	Default selection.
`1`	Unused.
`2`	Select the node with the best estimated solution.
`3`	Select the node with the best bound on the solution.
`4`	Select the deepest node in the search tree (equivalent to depth-first search).
`5`	Select the highest node in the search tree (equivalent to breadth-first search).
`6`	Select the earliest node created.
`7`	Select the latest node created.
`8`	Select a node randomly.
`9`	Select the node whose LP relaxation contains the fewest number of infeasible MIP entities.
`10`	Combination of 2 and 9.
`11`	Combination of 2 and 4.
`12`	Combination of 3 and 4.

barAlg *(integer)*: Determines which barrier algorithm is to be used to solve the problem ↩

The automatic setting uses 1 for LP and QP problems and 3 for QCQP problems. Usually the detection of primal or dual infeasibility is more robust with settings 2 or 3, therefore, it is advantageous to use one of these values if the model is presumably infeasible.

Default: `auto`

value	meaning
`-1`	Determined automatically.
`0`	Unused.
`1`	Use the infeasible-start barrier algorithm.
`2`	Use the homogeneous self-dual barrier algorithm.
`3`	Start with 2 and optionally switch to 1 during the execution.

barCores *(integer)*: If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm ↩

If the value is set to the default value (-1), Xpress will automatically detect the number of cores.

The control is provided for cross-hardware reproducibility purposes. The count does not include logical cores created by Hyper-Threading.

Range: {`-1`, ..., ∞}

Default: `auto`

barCrash *(integer)*: Newton barrier: Determines the type of crash used for the crossover ↩

During the crash procedure, an initial basis is determined which attempts to speed up the crossover. A good choice at this stage will significantly reduce the number of iterations required to crossover to an optimal solution. The possible values increase proportionally to their time-consumption.

Default: `4`

value	meaning
`0`	Turns off all crash procedures.
`1-6`	Available strategies with 1 being conservative and 6 being aggressive.

barDualStop *(real)*: Newton barrier: Convergence parameter, representing the tolerance for dual infeasibilities ↩

If the difference between the constraints and their bounds in the dual problem falls below this tolerance in absolute value, optimization will stop and the current solution will be returned.

Range: [`0`, ∞]

Default: `auto`

barFailIterLimit *(integer)*: Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm ↩

Default: `auto`

value	meaning
`0`	Determined automatically
`>0`	Maximum number of consecutive barrier iterations allowed without progress.

barFreeScale *(real)*: Defines how the barrier algorithm scales free variables ↩

When using smaller values the barrier algorithm scales free variables more aggressively which can improve performance but may impact numerical stability.

Range: [`0`, ∞]

Default: `1e-06`

barGapStop *(real)*: Newton barrier: Convergence parameter, representing the tolerance for the relative duality gap ↩

When the difference between the primal and dual objective function values falls below this tolerance, the Optimizer determines that the optimal solution has been found.

Range: [`0`, ∞]

Default: `auto`

barGapTarget *(real)*: Newton barrier: Target tolerance for the relative duality gap ↩

The barrier algorithm will keep iterating until either barGapTarget is satisfied or until no further improvements are possible. In the latter case, if barGapStop is satisfied, it will declare the problem optimal.

When a solution returned by the barrier algorithm has not converged tightly enough for an application, for example if the dual solution is not accurate enough or crossover is taking too long, setter barGapTarget to a small value often resolves the problem, without the risk of the solve failing due to a complementarity level not being numerically achievable. Typical suggested values can be between 1-10 and 1-18.

Range: [0, ∞]

Default: auto

barIndefLimit *(integer)*: Newton Barrier: Limits the number of consecutive indefinite barrier iterations that will be performed ↩

The optimizer will try to minimize (resp. maximize) a QP problem even if the Q matrix is not positive (resp. negative) semi-definite. However, the optimizer may detect that the Q matrix is indefinite and this can result in the optimizer not converging. This control specifies how many indefinite iterations may occur before the optimizer stops and reports that the problem is indefinite. It is usual to specify a value greater than one, and only stop after a series of indefinite matrices, as the problem may be found to be indefinite incorrectly on a few iterations for numerical reasons.

Range: {1, ..., ∞}

Default: 15

barIterLimit *(integer)*: Newton barrier: Maximum number of iterations ↩

While the simplex method usually performs a number of iterations which is proportional to the number of constraints (rows) in a problem, the barrier method standardly finds the optimal solution to a given accuracy after a number of iterations which is independent of the problem size. The penalty is rather that the time for each iteration increases with the size of the problem. barIterLimit specifies the maximum number of iterations which will be carried out by the barrier.

Range: {0, ..., ∞}

Default: 500

barKernel *(real)*: Newton barrier: Defines how centrality is weighted in the barrier algorithm ↩

Increasing this parameter may increase the number of iterations, therefore the recommended range is [1,2] and [-2,-1].

Default: 0

value	meaning
>=+1.0	Increases the emphasis on centrality when larger value is set.
<=-1.0	Selects a value adaptively in every iteration from [+1, -barKernel].

barObjPerturb *(real)*: Defines how the barrier perturbs the objective ↩

The perturbation scale should be set carefully with consideration to the optimality tolerance. The parameter affects only the barrier solve.

Default: `1e-06`

value	meaning
`0`	Turn off objective perturbation.
`>0`	Let the optimizer decide if the objective is perturbed or not and use the parameter value as the scale of the perturbation.
`<0`	Always perturb the objective by the absolute value of the parameter.

barObjScale *(real)*: Defines how the barrier scales the objective ↩

The scaling perfromed by the barrier is applied on top of any other scaling in the problem and only affects the barrier solve.

Default: `auto`

value	meaning
`-1`	Let the optimizer decide.
`0`	Scale by geometric mean.
`>=0`	Scale such that the largest objective coefficient's largest element does not exceed this number. In quadratic problems, the quadratic diagonal is used as reference valuses instead of the linear objective.

barOrder *(integer)*: Newton barrier: Controls the Cholesky factorization in the Newton-Barrier ↩

Default: `auto`

value	meaning
`0`	Choose automatically.
`1`	Minimum degree method. This selects diagonal elements with the smallest number of nonzeros in their rows or columns.
`2`	Minimum local fill method. This considers the adjacency graph of nonzeros in the matrix and seeks to eliminate nodes that minimize the creation of new edges.
`3`	Nested dissection method. This considers the adjacency graph and recursively seeks to separate it into non-adjacent pieces.

barOrderThreads *(integer)*: If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton-barrier method ↩

Larger values than barCores will be automatically reduced to the value of barCores.

Range: {`0`, ..., ∞}

Default: `auto`

barOutput *(boolean)*: Newton barrier: Level of solution output provided ↩

Output is provided either after each iteration of the algorithm, or else can be turned off completely by this parameter.

Default: `1`

value	meaning
0	No output.
1	At each iteration.

barPerturb *(real)*: Newton barrier: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties ↩

barPerturb controlls how much perturbation is allowed during the barrier iterations. By default no perturbation is allowed. Set this parameter with care as larger perturbations may lead to less efficient iterates and the best settings are problem-dependent.

Range: [0, ∞]

Default: 0

barPresolveOps *(integer)*: Newton barrier: Controls the Newton-Barrier specific presolve operations ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
bit 0 = 1	Equivalent to barPresolveOps_standard.
bit 1 = 2	Equivalent to barPresolveOps_extra.
bit 2 = 4	Equivalent to barPresolveOps_full.

barPresolveOps_extra *(boolean)*: Extra effort is spent in barrier specific presolve ↩

See also barPresolveOps.

Default: 0

barPresolveOps_full *(boolean)*: Do full matrix eliminations (reduce matrix size) ↩

See also barPresolveOps.

Default: 0

barPresolveOps_standard *(boolean)*: Use standard presolve ↩

See also barPresolveOps.

Default: 0

barPrimalStop *(real)*: Newton barrier: Convergence parameter, indicating the tolerance for primal infeasibilities ↩

If the difference between the constraints and their bounds in the primal problem falls below this tolerance in absolute value, the Optimizer will terminate and return the current solution.

Range: [0, ∞]

Default: auto

barRefIter *(integer)*: Newton barrier: After terminating the barrier algorithm, further refinement steps can be performed ↩

Such refinement steps are especially helpful if the solution is near to the optimum and can improve primal feasibility and decrease the complementarity gap. It is also often advantageous for the crossover algorithm. barRefIter specifies the maximum number of such refinement iterations.

Range: {0, ..., ∞}

Default: 0

barRegularize *(integer)*: Determines how the barrier algorithm applies regularization on the KKT system ↩

The parameter is a bit set but value -1 (the default value) is treated in a special way: if the parameter is set to -1 then the solver will automatically select the bits it deems most useful.

Default: -1

value	meaning
bit 0 = 1	Standard regularization is turned on/off.
bit 1 = 2	Reduced regularization is turned on/off. This option reduces the perturbation effect of the standard regularization.
bit 2 = 4	Forces to keep dependent rows in the KKT system.
bit 3 = 8	Forces to preserve degenerate rows in the KKT system.
bit 4 = 16	Restrict regularization to infeasible iterates.
bit 5 = 32	Disable iterative regularizations.
bit 6 = 64	Apply iterative regularization more often.

barRhsScale *(real)*: Defines how the barrier scales the right hand side ↩

The scaling perfromed by the barrier is applied on top of any other scaling in the problem and only affects the barrier solve.

Default: auto

value	meaning
-1	Let the optimizer decide.
0	Scale by geometric mean.
>=0	Scale such that the largest right hand side coefficient's largest element does not exceed this number.

barStart *(integer)*: Newton barrier: Controls the computation of the starting point for the barrier algorithm ↩

Default: auto

value	meaning
-1	Uses the available solution for warm-start.
0	Determine automatically.
1	Uses simple heuristics to compute the starting point based on the magnitudes of the matrix entries.

value	meaning
2	Uses the pseudoinverse of the constraint matrix to determine primal and dual initial solutions. Less sensitive to scaling and numerically more robust, but in several case less efficient than 1.
3	Uses the unit starting point for the homogeneous self-dual barrier algorithm.

barStepStop *(real)*: Newton barrier: Convergence parameter, representing the minimal step size ↩

On each iteration of the barrier algorithm, a step is taken along a computed search direction. If that step size is smaller than barStepStop, the Optimizer will terminate and return the current solution.

If the barrier method is making small improvements on barGapStop on later iterations, it may be better to set this value higher, to return a solution after a close approximation to the optimum has been found.

Range: [0, ∞]

Default: `1e-16`

barThreads *(integer)*: If set to a positive integer it determines the number of threads implemented to run the Newton-barrier algorithm ↩

If the value is set to the default value (-1), the threads control will determine the number of threads used.

There is a practical upper limit of 50 on the number of parallel threads the optimizer will create.

Range: {`-1`, ..., ∞}

Default: `auto`

basisOut *(string)*: Directs optimizer to output an MPS basis file ↩

In general this option is not used in a GAMS environment, as GAMS maintains basis information for you automatically.

Default: `none`

bigM *(real)*: Infeasibility penalty used if the "Big M" method is implemented ↩

Range: [0, ∞]

Default: `auto`

bigMMethod *(boolean)*: Simplex: Whether to use the "Big M" method, or the standard phase I (achieving feasibility) and phase II (achieving optimality) ↩

In the "Big M" method, the objective coefficients of the variables are considered during the feasibility phase, possibly leading to an initial feasible basis which is closer to optimal. The side-effects involve possible round-off errors due to the presence of the "Big M" factor in the problem.

Default: `1`

value	meaning
0	For phase I / phase II.
1	If "Big M" method to be used.

branchChoice *(integer)*: Once a MIP entity has been selected for branching, this control determines which of the branches is solved first ↩

Default: 0

value	meaning
0	Minimum estimate branch first.
1	Maximum estimate branch first.
2	If an incumbent solution exists, solve the branch satisfied by that solution first. Otherwise solve the minimum estimate branch first (option 0).
3	Solve first the branch that forces the value of the branching variable to move farther away from the value it had at the root node. If the branching entity is not a simple variable, solve the minimum estimate branch first (option 0).

branchDisj *(integer)*: Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search ↩

Note Split disjunctions are a special form of disjunctions that can be written as $\sum$j mj xj $\leq$ m0 v $\sum$j mj xj $\geq$ m0+1 The split disjunctions created by the optimizer will use a combination of binary or integer variables xj, with integer coefficients mj. Split disjunctions for branching will always be created with a default priority value of 400 instead of the default value of 500 for regular entity branches.

Default: auto

value	meaning
-1	Automatic selection of the strategy.
0	Disabled.
1	Cautious strategy. Disjunctive branches will be created only for general integers with a wide range.
2	Moderate strategy.
3	Aggressive strategy. Disjunctive branches will be created for both binaries and integers.

branchStructural *(integer)*: Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search ↩

Structural branches will often involve branching on more than a single MIP entity at a time. As a result of a structural branch, a parent node could therefore end up with more than two child nodes, unlike the standard single entity branches. Structural branches will always be created with a default priority value of 400 instead of the default value of 500 for regular entity branches.

Default: auto

value	meaning
-1	Automatically determined.
0	Disabled.
1	Enabled.

breadthFirst *(integer)*: Number of nodes to include in the best-first search before switching to the local first search (nodeSelection = 4) ↩

Range: {0, ..., ∞}

Default: 11

choleskyAlg *(integer)*: Newton barrier: Type of Cholesky factorization used ↩

Default: auto

value	meaning
bit 0 = 1	Matrix blocking: 0: automatic setting; 1: manual setting.
bit 1 = 2	If manual selection of matrix blocking: 0: multi-pass; 1: single-pass.
bit 2 = 4	Nonseparable QP relaxation: 0: off; 1: on.
bit 3 = 8	Corrector weight: 0: automatic setting; 1: manual setting.
bit 4 = 16	If manual selection of corrector weight: 0: off; 1: on.
bit 5 = 32	Refinement: 0: automatic setting; 1: manual setting.
bit 6 = 64	Preconditioned conjugate gradient method (PCGM): 0: PCGM off; 1: PCGM on.
bit 7 = 128	Preconditioned quasi minimal residual (QMR) to refine solution: 0: QMR off; 1: QMR on.
bit 8 = 256	Perform refinement on the augmented system 0: off; 1: on.
bit 9 = 512	Force highest accuracy in refinement 0: off; 1: on.

choleskyTol *(real)*: Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm ↩

If the absolute value of the pivot element is less than or equal to choleskyTol, it merits special treatment in the Cholesky decomposition process.

Range: [0, ∞]

Default: 1e-15

clamping *(integer)*: Allows for the adjustment of returned solution values such that they are always within bounds ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
-1	Determined automatically.
0	Equivalent to clamping_primal.
1	Equivalent to clamping_dual.
2	Equivalent to clamping_slacks.
3	Equivalent to clamping_rdj.

clamping_dual *(boolean)*: Adjust primal slack values to always be within constraint bounds ↩

See also clamping.

Default: `0`

clamping_primal *(boolean)*: Adjust primal solution to always be within primal bounds ↩

Slacks if provided will be adjusted accordingly.

See also clamping.

Default: `0`

clamping_rdj *(boolean)*: Adjust reduced costs to always be within dual bounds implied by the primal solution ↩

See also clamping.

Default: `0`

clamping_slacks *(boolean)*: Adjust dual solution to always be within the dual bounds implied by the slacks ↩

Reduced costs, if provided, will be adjusted accordingly.

See also clamping.

Default: `0`

concurrentThreads *(integer)*: Determines the number of threads used by the concurrent solver ↩

Default: `auto`

value	meaning
`-1`	Determined automatically
`>0`	Number of threads to use.

conflictCuts *(integer)*: Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts ↩

Conflict cuts are in-tree cuts derived from nodes found to be infeasible or cut off, which can be used to cut off other branches of the search tree.

Default: `auto`

value	meaning
`-1`	Automatic.
`0`	Disable conflict cuts.
`1`	Cautious application of conflict cuts.
`2`	Medium application of conflict cuts.
`3`	Aggressive application of conflict cuts.

coresPerCpu *(integer)*: Used to override the detected value of the number of cores on a CPU ↩

The cache size (either detected or specified via the CACHESIZE control) used in Barrier methods will be divided by this amount, and this scaled-down value will be the amount of cache allocated to each Barrier thread.

Range: {-1, ..., ∞}

Default: auto

coverCuts *(integer)*: Branch and Bound: Number of rounds of lifted cover inequalities at the top node ↩

A lifted cover inequality is an additional constraint that can be particularly effective at reducing the size of the feasible region without removing potential integral solutions. The process of generating these can be carried out a number of times, further reducing the feasible region, albeit incurring a time penalty. There is usually a good payoff from generating these at the top node, since these inequalities then apply to every subsequent node in the tree search.

Range: {-1, ..., ∞}

Default: auto

cpuPlatform *(integer)*: Newton Barrier: Selects the AMD, Intel x86 or ARM vectorization instruction set that Barrier should run optimized code for ↩

On AMD / Intel x86 platforms the SSE2, AVX and AVX2 instruction sets are supported while on ARM platforms the NEON architecture extension can be activated.

Generic code, SSE2 and AVX optimized code will all result in the same solution path. Using AVX2 or NEON might result in a different solution path.

Default: -1

value	meaning
-2	Highest supported [Generic, SSE2, AVX or AVX2].
-1	Highest supported solve path consistent code [Generic, SSE2 or AVX].
0	Use generic code compatible with all CPUs.
1	Use SSE2 / NEON optimized code.
2	Use AVX optimized code.
3	Use AVX2 optimized code.

cpuTime *(integer)*: How time should be measured when timings are reported in the log and when checking against time limits ↩

Default: 0

value	meaning
-1	Disable the timer.
0	Use elapsed time.
1	Use process time.

crash *(integer)*: Simplex: Determines the type of crash used when the algorithm begins ↩

During the crash procedure, an initial basis is determined which is as close to feasibility and triangularity as possible. A good choice at this stage will significantly reduce the number of iterations required to find an optimal solution. The possible values increase proportionally to their time-consumption.

For primal simplex the non-bit-vector choices are relevant.

For dual simplex the bit-vector choices are relevant.

Default: 2

value	meaning
0	Turns off all crash procedures.
1	For singletons only (one pass).
2	For singletons only (multi pass).
3	Multiple passes through the matrix considering slacks.
4	Multiple (≤ 10) passes through the matrix but only doing slacks at the very end.
bit 0 = 1	Perform standard crash.
bit 1 = 2	Perform additional numerical checks during crash.
bit 2 = 4	Extend the set of column candidates for crash.
bit 3 = 8	Extend the set of row candidates for crash.
bit 4 = 16	Force crash, i.e., consider all suitable columns/rows as candidates for crash.
n>10	As for value 4 but performing at most n - 10 passes.

crossover *(integer)*: Newton barrier: Determines whether the barrier method will cross over to the simplex method when at optimal solution has been found, to provide an end basis and advanced sensitivity analysis information ↩

The full primal and dual solution is available whether or not crossover is used. The crossover must not be disabled if the barrier is used to reoptimize nodes of a MIP. By default crossover will not be performed on QP and MIQP problems.

Default: auto

value	meaning
-1	Determined automatically.
0	No crossover.
1	Primal crossover first.
2	Dual crossover first.

crossoverAccuracyTol *(real)*: Newton barrier: Determines how crossover adjusts the default relative pivot tolerance ↩

When re-inversion is necessary, crossover will compare the recalculated working basic solution with the assumed ones just before re-inversion took place. If the error is above this threshold, crossover will adjust the relative pivot tolerance to address the build-up of numerical inaccuracies.

The full primal and dual solution is available whether or not crossover is used. The crossover must not be disabled if the barrier is used to reoptimize nodes of a MIP. By default crossover will not be performed on QP and MIQP problems.

Range: [0, ∞]

Default: 1e-06

crossoverIterLimit *(integer)*: Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates ↩

Range: {0, ..., ∞}

Default: 2147483647

crossoverOps *(integer)*: Newton barrier: Bit vector for adjusting the behavior of the crossover procedure ↩

Default: 0

value	meaning
bit 0 = 1	Returned solution when the crossover terminates prematurely: 0: Return the last basis from the crossover; 1: Return the barrier solution.
bit 1 = 2	Select the crossover stages to be performed: 0: Perform both crossover stages; 1: Skip second crossover stage.
bit 2 = 4	Set crossover behaviour: 0: Force to perform all pivots; 1: Skip pivots that are numerically less reliable.
bit 3 = 8	Set crossover behaviour: 0: Perform standard crossover; 1: Perform a slower, but numerically more careful crossover.

crossoverThreads *(integer)*: Determines the maximum number of threads that parallel crossover is allowed to use ↩

If crossoverThreads is set to the default value (-1), the barThreads control will determine the number of threads used.

Range: {-1, ..., ∞}

Default: auto

cutDepth *(integer)*: Branch and Bound: Sets the maximum depth in the tree search at which cuts will be generated ↩

Generating cuts can take a lot of time, and is often less important at deeper levels of the tree since tighter bounds on the variables have already reduced the feasible region. A value of 0 signifies that no cuts will be generated.

Does not affect cutting on the root node.

Range: {-1, ..., ∞}

Default: auto

cutFactor *(real)*: Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during tree search ↩

The cuts and cut coefficients are limited by cutFactor times the number of rows and coefficients in the initial matrix.

A value of 0.0 prevents cuts from being added, and a value of e.g. 1.0 will allow the problem to grow to twice the initial number of rows and coefficients.

Default: auto

value	meaning
-1	Let the optimizer decide on the maximum amount of cuts based on cutStrategy.
>=0	Multiple of number of rows and coefficients to use.

cutFreq *(integer)*: Branch and Bound: Frequency at which cuts are generated in the tree search ↩

If the depth of the node modulo cutFreq is zero, then cuts will be generated.

Range: {-1, ..., ∞}

Default: auto

cutSelect *(integer)*: Bit vector providing detailed control of the cuts created for the root node of a MIP solve ↩

Use treeCutSelect to control cuts during the tree search.

The default value is -1 which enables all bits. Any bits not listed in the above table should be left in their default 'on' state, since the interpretation of such bits might change in future versions of the optimizer.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

value	meaning
bit 5 = 32	Equivalent to cutSelect_clique.
bit 6 = 64	Equivalent to cutSelect_mir.
bit 7 = 128	Equivalent to cutSelect_cover.
bit 8 = 256	Equivalent to cutSelect_mirRowAggregation.
bit 11 = 2048	Equivalent to cutSelect_flowpath.
bit 12 = 4096	Equivalent to cutSelect_implication.
bit 13 = 8192	Equivalent to cutSelect_liftAndProject.
bit 14 = 16384	Equivalent to cutSelect_disableCutRows.
bit 15 = 32768	Equivalent to cutSelect_gubCover.
bit 16 = 65536	Equivalent to cutSelect_zeroHalf.
bit 17 = 131072	Equivalent to cutSelect_indicator.
bit 18 = 262144	Equivalent to cutSelect_gomory.
bit 20 = 1048576	Equivalent to cutSelect_farkas.

cutSelect_clique *(boolean)*: Clique cuts ↩

See also cutSelect.

Default: 1

cutSelect_cover *(boolean)*: Lifted cover cuts ↩

See also cutSelect.

Default: 1

cutSelect_disableCutRows *(boolean)*: Disable cutting from cut rows ↩

See also cutSelect.

Default: 1

cutSelect_farkas *(boolean)*: Farkas cuts ↩

See also cutSelect.

Default: `1`

cutSelect_flowpath *(boolean)*: Flow path cuts ↩

See also cutSelect.

Default: `1`

cutSelect_gomory *(boolean)*: Strong Chvatal-Gomory cuts ↩

See also cutSelect.

Default: `1`

cutSelect_gubCover *(boolean)*: Lifted GUB cover cuts ↩

See also cutSelect.

Default: `1`

cutSelect_implication *(boolean)*: Implication cuts ↩

See also cutSelect.

Default: `1`

cutSelect_indicator *(boolean)*: Indicator constraint cuts ↩

See also cutSelect.

Default: `1`

cutSelect_liftAndProject *(boolean)*: Turn on automatic Lift-and-Project cutting strategy ↩

See also cutSelect.

Default: `1`

cutSelect_mir *(boolean)*: Mixed Integer Rounding (MIR) cuts ↩

See also cutSelect.

Default: `1`

cutSelect_mirRowAggregation *(boolean)*: Turn on row aggregation for MIR cuts ↩

See also cutSelect.

Default: `1`

cutSelect_zeroHalf *(boolean)*: Zero-half cuts ↩

See also cutSelect.

Default: `1`

cutStrategy *(integer)*: Branch and Bound: Cut strategy ↩

A more aggressive cut strategy, generating a greater number of cuts, will result in fewer nodes to be explored, but with an associated time cost in generating the cuts. The fewer cuts generated, the less time taken, but the greater subsequent number of nodes to be explored.

Default: `auto`

value	meaning
-1	Automatic selection of the cut strategy.
0	No cuts.
1	Conservative cut strategy.
2	Moderate cut strategy.
3	Aggressive cut strategy.

defaultAlg *(integer)*: Selects the algorithm that will be used to solve the LP ↩

Please note that this will affect how the MIP node LP problems are solved during the global search.

Default: auto

value	meaning
1	Automatically determined.
2	Dual simplex.
3	Primal simplex.
4	Newton barrier.

denseColLimit *(integer)*: Newton barrier: Controls trigger point for special treatment of dense columns in Cholesky factorization ↩

Columns with more than denseColLimit elements are considered to be dense. Such columns will be handled specially in the Cholesky factorization of this matrix.

Range: {0, ..., ∞}

Default: auto

deterministic *(integer)*: Selects whether to use a deterministic or opportunistic mode when solving a problem using multiple threads ↩

In deterministic mode thread synchronization is performed in deterministic order, which guarantees that repeated solves of the same problems under the same starting conditions will always produce the same outcome. This assumes that there are no non-deterministic events affecting the solve, such as interruption due to time limits or non-deterministic interaction through callback functions. In opportunistic mode the solver will always schedule work on any available thread. This can produce higher CPU utilization, but will sacrifice reproducability.

Default: 1

value	meaning
0	Use opportunistic mode.
1	Use deterministic mode.
2	Use deterministic mode, except allow the initial concurrent continuous solve of a MIP to be opportunistic.

dualGradient *(integer)*: Simplex: Dual simplex pricing method ↩

Default: auto

value	meaning
-1	Determine automatically.
0	Devex.
1	Steepest edge.
2	Direct steepest edge.
3	Sparse Devex.

dualize *(integer)*: Whether presolve should form the dual of the problem ↩

Default: auto

value	meaning
-1	Determine automatically.
0	Solve the primal problem.
1	Solve the dual problem.

dualizeOps *(boolean)*: Bit-vector control for adjusting the behavior when a problem is dualized ↩

Default: 1

value	meaning
bit 0 = 1	Swap the simplex algorithm to run. If dual simplex is selected for the original problem then primal simplex will be run on the dualized problem, and simiarly if primal simplex is selected.

dualPerturb *(real)*: Factor by which the problem will be perturbed prior to optimization by dual simplex ↩

A value of 0.0 results in no perturbation prior to optimization. Note the interconnection to the autoPerturb control. If autoPerturb is set to 1, the decision whether to perturb or not is left to the Optimizer. When the problem is automatically perturbed in dual simplex, however, the value of dualPerturb will be used for perturbation.

Range: [-∞, ∞]

Default: auto

dualStrategy *(integer)*: Bit-vector control specifies the dual simplex strategy ↩

Default: 1

value	meaning
bit 0 = 1	Switch to primal when re-optimization goes dual infeasible and numerically unstable.
bit 1 = 2	When dual intend to switch to primal, stop the solve instead of switching to primal.
bit 2 = 4	Use more aggressive cut-off in MIP search.
bit 3 = 8	Use dual simplex to remove cost perturbations.
bit 4 = 16	Enable more aggressive dual pivoting strategy.
bit 5 = 32	Keep using dual simplex even when it's numerically unstable.

dualThreads *(integer)*: Determines the maximum number of threads that dual simplex is allowed to use ↩

If dualThreads is set to the default value (-1), the threads control will determine the number of threads used.

When solving a linear MIP, the dual simplex algorithm will use multiple threads only when solving the initial LP relaxation or when reoptimizing between rounds of cuts on the root node. The parallel dual simplex algorithm differs from the sequential dual simplex algorithm and might follow a different solve path. For dualThreads > 1 the solve path is independent of the number of threads used, although the practical limit for observing performance benefits is around dualThreads $= 8$.

Range: {`-1`, ..., ∞}

Default: `auto`

eigenvalueTol *(real)*: Quadratic matrix is considered not to be positive semi-definite, if its smallest eigenvalue is smaller than the negative of this value ↩

Range: [`0`, ∞]

Default: `1e-06`

elimFillin *(integer)*: Amount of fill-in allowed when performing an elimination in presolve ↩

Range: {`0`, ..., ∞}

Default: `10`

elimTol *(real)*: Markowitz tolerance for the elimination phase of the presolve ↩

Range: [`0`, ∞]

Default: `0.001`

etaTol *(real)*: Tolerance on eta elements ↩

During each iteration, the basis inverse is premultiplied by an elementary matrix, which is the identity except for one column - the eta vector. Elements of eta vectors whose absolute value is smaller than etaTol are taken to be zero in this step.

Range: [`0`, ∞]

Default: `1e-13`

feasibilityJump *(boolean)*: MIP: Decides if the Feasibility Jump heuristic should be run ↩

Default: `1`

value	meaning
`0`	Turned off.
`1`	Run the heuristic.

feasibilityPump *(integer)*: Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node ↩

Default: `auto`

value	meaning
`-1`	Automatic.
`0`	Turned off.
`1`	Always try the Feasibility Pump.
`2`	Try the Feasibility Pump only if other heuristics have failed to find an integer solution.

feasTol *(real)*: Determines when a solution is treated as feasible ↩

If the amount by which a constraint's activity violates its right-hand side or ranged bound is less in absolute magnitude than feasTol, then the constraint is treated as satisfied. Similarly, if the amount by which a column violates its bounds is less in absolute magnitude than feasTol, those bounds are also treated as satisfied.

Range: [0, ∞]

Default: `1e-06`

feasTolPerturb *(real)*: Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes ↩

The tolerance feasTol is always considered as an upper limit for the perturbations, but in some cases smaller value can be more desirable.

Range: [0, ∞]

Default: `1e-06`

feasTolTarget *(real)*: Target feasibility tolerance for the solution refiner ↩

Zero and negative values are ignored, and the value of feasTol is used.

Use very small values like 1e-100 to state the refinement should continue as long as an improvement is made. Use very large values like 1e+100 to disable only this aspect of the refiner.

Refining solutions to match the feastoltarget can influence and worsen their objective value in case the previous objective could only be achieved through slight infeasibilities.

Range: [-∞, ∞]

Default: `0`

fixoptfile *(string)*: name of option file which is read just before solving the fixed problem ↩

forceParallelDual *(boolean)*: Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm ↩

By default, when using a single thread, the dual simplex solver will execute a dedicated sequential simplex algorithm.

Default: `0`

value	meaning
0	Disabled.
1	Enabled. Force the dual simplex solver to use the parallel algorithm.

genConsAbsTransformation *(integer)*: Specifies the reformulation method for absolute value general constraints at the beginning of the search ↩

Default: auto

value	meaning
-1	Automatic.
0	Use a formulation based on indicator constraints.
1	Use a formulation based on SOS1-contraints.

genConsDualReductions *(boolean)*: Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs ↩

Default: 1

value	meaning
0	Disabled. No dual reductions, add columns and rows.
1	Enabled. Only add neccessary columns and rows, drop those implied by the objective sense.

globalBoundingBox *(real)*: If a nonlinear problem cannot be solved due to appearing unbounded, it can automatically be regularized by the application of a bounding box on the variables ↩

If this control is set to a negative value, in a second solving attempt all original variables will be bounded by the absolute value of this control. If set to a positive value, there will be a third solving attempt afterwards, if necessary, in which also all auxiliary variables are bounded by this value.

Default: 1e+06

value	meaning
0	Disabled. Problem will return unbounded.
n<0	Enabled. Apply lower and upper bounds of this magnitude to all original variables if initial LP is unbounded.
n>0	Enabled. Apply lower and upper bounds of this magnitude to all original and auxiliary variables if initial LP and first regularization are unbounded.

gomCuts *(integer)*: Branch and Bound: Number of rounds of Gomory or lift-and-project cuts at the top node ↩

Range: {-1, ..., ∞}

Default: auto

heurBeforeLp *(integer)*: Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved ↩

It is possible that a heuristic will find an optimal integer solution that will result in the LP relaxation solution being cut off. If dedicated heuristic threads are enabled through the heurThreads control, then the initial heuristics will be run in parallel with the LP solve, instead of before.

Default: `auto`

value	meaning
`-1`	Automatic - let the optimizer decide if heuristics should be run.
`0`	Disabled.
`1`	Enabled.

heurDiveIterLimit *(real)*: Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic ↩

Default: `auto`

value	meaning
`0`	No iteration limit.
`>=1`	Fixed iteration limit.
`<0`	Automatic selection of the iteration limit based on the problem size. The absolute value is used as a multiplier on the automatic selection.

heurDiveRandomize *(real)*: Level of randomization to apply in the diving heuristic ↩

The diving heuristic uses priority weights on rows and columns to determine the order in which to e.g. round fractional columns, or the direction in which to round them. This control determines by how large a random factor these weights should be changed.

Default: `0`

value	meaning
`0.0-1.0`	Amount of randomization (0.0=none, 1.0=full)

heurDiveSoftRounding *(integer)*: Branch and Bound: Enables a more cautious strategy for the diving heuristic, where it tries to push binaries and integer variables to their bounds using the objective, instead of directly fixing them ↩

This can be useful when the default diving heuristics fail to find any feasible solutions.

Default: `auto`

value	meaning
`-1`	Automatic selection.
`0`	Do not use soft rounding.
`1`	Cautious use of the soft rounding strategy.
`2`	More aggressive use of the soft rounding strategy.

heurDiveSpeedUp *(integer)*: Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed ↩

Default: `-1`

value	meaning
-2	Automatic selection biased towards quality
-1	Automatic selection biased towards speed.
0-4	Manual emphasis bias from emphasis on quality (0) to emphasis on speed (4).

heurDiveStrategy *(integer)*: Branch and Bound: Chooses the strategy for the diving heuristic ↩

Default: auto

value	meaning
-1	Automatic selection of strategy.
0	Disables the diving heuristic.
1-18	Available pre-set strategies for rounding infeasible MIP entities and reoptimizing during the heuristic dive.

heurEmphasis *(integer)*: Branch and Bound: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap ↩

For problems where the goal is to achieve a small gap but not neccessarily solving them to optimality, it is recommended to set heurEmphasis to 1. This setting triggers many additional heuristic calls, aiming for reducing the gap at the beginning of the search, typically at the expense of an increased time for proving optimality.

Default: -1

value	meaning
-1	Optimizer default strategy.
0	Disables all heuristics.
1	Focus on reducing the primal-dual gap in the early part of the search.
2	Extremely aggressive search heuristics.

heurForceSpecialObj *(boolean)*: Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer ↩

Deactivated by default.

Default: 0

value	meaning
0	Disabled.
1	Enabled. Run special objective heuristics on large problems and even if incumbent exists.

heurFreq *(integer)*: Branch and Bound: Frequency at which heuristics are used in the tree search ↩

Heuristics will only be used at a node if the depth of the node is a multiple of heurFreq.

Range: {-1, ..., ∞}

Default: -1

heurSearchEffort *(real)*: Adjusts the overall level of the local search heuristics ↩

heurSearchEffort is used as a multiplier on the default amount of work the local search heuristics should do. A higher value means the local search heuristics will be run more often and that they are allowed to search larger neighborhoods.

Range: [0, ∞]

Default: 1

heurSearchFreq *(integer)*: Branch and Bound: How often the local search heuristic should be run in the tree ↩

Default: auto

value	meaning
-1	Automatic.
0	Disabled in the tree.
n>0	Number of nodes between each run.

heurSearchRootCutFreq *(integer)*: How frequently to run the local search heuristic during root cutting ↩

This is given as how many cut rounds to perform between runs of the heuristic. Set to zero to avoid applying the heuristic during root cutting. Branch and Bound: This specifies how often the local search heuristic should be run in the tree.

Default: auto

value	meaning
-1	Automatic.
0	Disabled heuristic during cutting.
n>0	Number of cutting rounds between each run.

heurSearchRootSelect *(integer)*: Bit vector control for selecting which local search heuristics to apply on the root node of a MIP solve ↩

Use heurSearchTreeSelect to control local search heuristics during the tree search.

Some of the local search heuristics will benefit from having an existing incumbent solution, but it is not required.

Default: 117

value	meaning
bit 0 = 1	Local search with a large neighborhood. Potentially slow but is good for finding solutions that differs significantly from the incumbent.
bit 1 = 2	Local search with a small neighborhood centered around a node LP solution.
bit 2 = 4	Local search with a small neighborhood centered around an integer solution. This heuristic will often provide smaller, incremental improvements to an incumbent solution.
bit 3 = 8	Local search with a neighborhood set up through the combination of multiple integer solutions.

value	meaning
`bit 4 = 16`	Unused
`bit 5 = 32`	Local search without an objective function. Called seldom and only when no feasible solution is available.
`bit 6 = 64`	Local search with an auxiliary objective function. Called seldom and only when no feasible solution is available.

heurSearchTreeSelect *(integer)*: Bit vector control for selecting which local search heuristics to apply during the tree search of a MIP solve ↩

Use heurSearchRootSelect to control local search heuristics on the root node.

Some of the local search heuristics will benefit from having an existing incumbent solution, but it is not required.

Default: `17`

value	meaning
`bit 0 = 1`	Local search with a large neighborhood. Potentially slow but is good for finding solutions that differs significantly from the incumbent.
`bit 1 = 2`	Local search with a small neighborhood centered around a node LP solution.
`bit 2 = 4`	Local search with a small neighborhood centered around an integer solution. This heuristic will often provide smaller, incremental improvements to an incumbent solution.
`bit 3 = 8`	Local search with a neighborhood set up through the combination of multiple integer solutions.
`bit 4 = 16`	Unused
`bit 5 = 32`	Local search without an objective function. Called seldom and only when no feasible solution is available.
`bit 6 = 64`	Local search with an auxiliary objective function. Called seldom and only when no feasible solution is available.

heurThreads *(integer)*: Branch and Bound: Number of threads to dedicate to running heuristics on the root node ↩

When heuristic threads are enable, the heuristics will be run in parallel with the initial LP solve, if possible, and in parallel with the root cutting.

Default: `0`

value	meaning
`-1`	Automatically determined from the threads control.
`0`	Disabled. Heuristics will be run sequentially with the root LP solve and cutting.
`>=1`	Number of root threads to dedicate to parallel heuristics.

historyCosts *(integer)*: Branch and Bound: How to update the pseudo cost for a MIP entity when a strong branch or a regular branch is applied ↩

Default: `auto`

value	meaning
`-1`	Automatically determined.

value	meaning
0	No update.
1	Update using only regular branches from the root to the current node.
2	Same as 1, but update with strong branching results as well.
3	Update using any regular branching or strong branching information from all nodes solves before the current node.

ifCheckConvexity *(boolean)*: Determines if the convexity of the problem is checked before optimization ↩

Applies to quadratic, mixed integer quadratic and quadratically constrained problems. Checking convexity takes some time, thus for problems that are known to be convex it might be reasonable to switch the checking off.

Default: 1

value	meaning
0	Turn off convexity checking.
1	Turn on convexity checking.

indLinBigM *(real)*: During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough ↩

This control defines the largest BigM for which such a linearized version will be added to the problem in addition to the original constraint. If the BigM is even smaller than indPreLinBigM, then the original indicator constraint will additionally be dropped from the problem.

indLinBigM should always be at least as large as indPreLinBigM. For any value less or equal to indPreLinBigM, indicator constraints will never be duplicated and only indPreLinBigM is taken into account for linearization.

Range: [0, ∞]

Default: 100000

indPreLinBigM *(real)*: During presolve, indicator constraints will be linearized using a BigM coefficient whenever that BigM coefficient is small enough ↩

This control defines the largest BigM for which the original constraint will be replaced by the linearized version. If the BigM is larger than indPreLinBigM but smaller than indLinBigM, the linearized row will be added but the original indicator constraint is kept as a numerically stable way to check feasibility.

Replacing an indicator constraint with a BigM row has a side effect on tolerances. In the indicator constraint form, the constraint part is satisfied with feasTol tolerance; while after changing it to BigM form, the constraint also includes the binary indicator variable (with a coefficient up to indPreLinBigM and an integrality tolerance of mipTol), therefore the constraint part of the indicator contraint is satisfied with tolerance feasTol+mipTol∗indPreLinBigM.

Range: [0, ∞]

Default: 100

inputTol *(real)*: Tolerance on input values elements ↩

If any value is less than or equal to inputTol in absolute value, it is treated as zero. For the internal zero tolerance see matrixTol.

This control needs to be set before inputting the problem, as it has no effect afterwards.

Range: [0, ∞]

Default: 0

invertFreq *(integer)*: Simplex: Frequency with which the basis will be inverted ↩

The basis is maintained in a factorized form and on most simplex iterations it is incrementally updated to reflect the step just taken. This is considerably faster than computing the full inverted matrix at each iteration, although after a number of iterations the basis becomes less well-conditioned and it becomes necessary to compute the full inverted matrix. The value of invertFreq specifies the maximum number of iterations between full inversions.

Range: {-1, ..., ∞}

Default: auto

invertMin *(integer)*: Simplex: Minimum number of iterations between full inversions of the basis matrix ↩

See the description of invertFreq for details.

Range: {0, ..., ∞}

Default: 3

ioTimeout *(integer)*: Maximum number of seconds to wait for an I/O operation before it is cancelled ↩

Range: {0, ..., ∞}

Default: 30

knitroOptFile *(string)*: Option file for NLP solver KNITRO ↩

lnpBest *(integer)*: Number of infeasible MIP entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see gomCuts) ↩

Range: {0, ..., ∞}

Default: 50

lnpIterLimit *(integer)*: Number of iterations to perform in improving each lift-and-project cut ↩

By setting the number to zero a Gomory cut will be created instead.

Range: {-1, ..., ∞}

Default: auto

loadMipSol *(boolean)*: Loads a MIP solution (the initial point) ↩

If true, the initial point provided by GAMS will be passed to the optimizer to be treated as an integer feasible point. The optimizer uses the values for the discrete variables only: the level values for the continuous variables are ignored and are calculated by fixing the integer variables and reoptimizing. In some cases, loading an initial MIP solution can improve performance. In addition, there will always be a feasible solution to return.

Default: 0

localChoice *(integer)*: Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree ↩

Default: auto

value	meaning
1	Never backtrack from the first child, unless it is dropped (infeasible or cut off).
2	Always solve both child nodes before deciding which child to continue with.
3	Automatically determined.

lpFlags *(integer)*: Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem ↩

When more than one bit is set, then the LP problem will be solved with the concurrent solver. When this control and `algorithm` is set at the same time, `algorithm` will overrule the value of this control.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `0`

value	meaning
`bit 0 = 1`	Equivalent to lpFlags_dual.
`bit 1 = 2`	Equivalent to lpFlags_primal.
`bit 2 = 4`	Equivalent to lpFlags_barrier.
`bit 3 = 8`	Equivalent to lpFlags_network.

lpFlags_barrier *(boolean)*: Use the barrier method ↩

See also lpFlags.

Default: `0`

lpFlags_dual *(boolean)*: Use the dual simplex method ↩

See also lpFlags.

Default: `0`

lpFlags_network *(boolean)*: Use the network simplex method ↩

See also lpFlags.

Default: `0`

lpFlags_primal *(boolean)*: Use the primal simplex method ↩

See also lpFlags.

Default: `0`

lpFolding *(integer)*: Simplex and barrier: Whether to fold an LP problem before solving it ↩

Default: `auto`

value	meaning
-1	Automatic.
0	Disable LP folding.
1	Enable LP folding. Attempt to fold all LP problems and MIP initial relaxations.

lpIterLimit *(integer)*: Maximum number of iterations that will be performed by primal simplex or dual simplex before the optimization process terminates ↩

Synonym: iterlim

For MIP problems, this is the maximum total number of iterations over all nodes explored by the Branch and Bound method.

Range: {0, ..., ∞}

Default: `maxint`

lpLog *(integer)*: Simplex: Frequency at which the simplex log is printed ↩

This control only has an effect if lpLogStyle is set to 0.

Default: `100`

value	meaning
0	Log displayed at the end of the optimization only.
n<0	Detailed output every - n iterations.
n>0	Summary output every n iterations.

lpLogDelay *(real)*: Time interval between two LP log lines ↩

This control only has an effect if lpLogStyle is set to 1.

Range: [0, ∞]

Default: `1`

lpLogStyle *(boolean)*: Simplex: Style of the simplex log ↩

Default: `1`

value	meaning
0	Simplex log is printed based on simplex iteration count, at a fixed frequency as specified by the lpLog control.
1	Simplex Log is printed based on an estimation of elapsed time, determined by an internal deterministic timer.

lpRefineIterLimit *(integer)*: Simplex iteration limit the solution refiner can spend in attempting to increase the accuracy of an LP solution ↩

The solution refiner iteratively attempts to increase the accuracy of the solution until either both feasTolTarget and optimalityTolTarget is satisfied, or accuracy cannot further be increased, or the effort limit determined by lpRefineIterLimit is exhausted.

Range: {-1, ..., ∞}

Default: `auto`

markowitzTol *(real)*: Markowitz tolerance used for the factorization of the basis matrix ↩

Range: [0, ∞]

Default: 0.01

matrixTol *(real)*: Zero tolerance on matrix elements ↩

If the value of a matrix element is less than or equal to matrixTol in absolute value, it is treated as zero. The control applies when solving a problem, for an input tolerance see inputTol.

Range: [0, ∞]

Default: 1e-09

maxCutTime *(real)*: Maximum amount of time allowed for generation of cutting planes and reoptimization ↩

The limit is checked during generation and no further cuts are added once this limit has been exceeded.

Default: 0

value	meaning
0	No time limit.
>0	Stop cut generation after the given number of seconds.

maxImpliedBound *(real)*: Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than maxImpliedBound will be applied to the problem ↩

For numerically challenging MIP problems, it can sometimes help make the solve more stable by reducing the value of maxImpliedBound to something smaller - e.g. 1.0E+06. It is not recommended to increase this parameter beyond the default of 1.0E+08.

Range: [0, ∞]

Default: 1e+08

maxLocalBacktrack *(integer)*: Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node ↩

If this control is set to k, then the candidate set of nodes for a local backtrack will consist of all active nodes in the subtree rooted at height k above the current node. For example, a setting of 1 will result in only sibling nodes of the current node being considered.

Default: auto

value	meaning
-1	Automatic.
n>0	Local backtrack limit.

maxMemoryHard *(integer)*: Sets the maximum amount of memory in megabytes the optimizer should allocate ↩

If this limit is exceeded, the solve will terminate. This control is designed to make the optimizer stop in a controlled manner, so that the problem object is valid once termination occurs.

The solve state will be set to incomplete. This is different to an out of memory condition in which case the optimizer returns an error. The optimizer may still allocate memory once the limit is exceeded to be able to finsish the operations and stop in a controlled manner. When resourceStrategy is enabled, the control also has the same effect as maxMemorySoft and will cause the optimizer to try preserving memory when possible.

Range: {0, ..., ∞}

Default: `unlimited`

maxMemorySoft *(integer)*: When resourceStrategy is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate ↩

This may change the solving path, but will not cause the solve to terminate early. To set a hard version of the same, please set maxMemoryHard.

Range: {0, ..., ∞}

Default: `unlimited`

maxMipSol *(integer)*: Branch and Bound: Limit on the number of integer solutions to be found by the Optimizer ↩

It is possible that during optimization the Optimizer will find the same objective solution from different nodes. However, maxMipSol refers to the total number of integer solutions found, and not necessarily the number of distinct solutions.

Setting maxMipSol=1 can alter the solution path as this will put the emphasis on finding any feasible solution by triggering additional heuristics.

Range: {0, ..., ∞}

Default: `0`

maxMipTasks *(integer)*: Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve ↩

The MIP solver will create smaller tasks from individual active nodes or based on local search heuristics. These are tasks that will be executed in parallel by the number of threads set by mipThreads.

If maxMipTasks is set to a fixed, positive value, the branch-and-bound tree nodes will always be solved in the same deterministic way, independent of the actual number of executing threads implied by mipThreads. How a MIP is solved will still depend on the number of threads used for solving the continuous relaxation and therefore on the settings for the controls barThreads, barCores, dualThreads and concurrentThreads). To obtain a MIP solve that is completely independent of the number of threads, it is sufficient to set maxMipTasks, forceParallelDual, barThreads and barCores. The concurrent LP solver should be avoided in this case.

While you can set this control to large value, the implementation will limit the number of tasks for performance reasons. This limit is currently 32 on 32bit platforms and 256 on 64 bit platforms.

Default: `auto`

value	meaning
`-1`	Task limit determined automatically from mipThreads.
`>0`	Fixed task limit.

maxNode *(integer)*: Branch and Bound: Maximum number of nodes that will be explored ↩

Range: {0, ..., ∞}

Default: `maxint`

maxScaleFactor *(integer)*: Determines the maximum scaling factor that can be applied during scaling ↩

The maximum is provided as an exponent of a power of 2.

Default: `64`

value	meaning
0-64	The maximum is provided an exponent of a power of 2.

maxStallTime *(real)*: Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent ↩

Default: `0`

value	meaning
0	No stall time limit.
>0	If an integer solution has been found, stop MIP search after the given number of seconds without a new incumbent. No effect as long as no solution was found.

mipAbsCutoff *(real)*: Branch and Bound: If the user knows that they are interested only in values of the objective function which are better than some value, this can be assigned to mipAbsCutoff ↩

This allows the Optimizer to ignore solving any nodes which may yield worse objective values, saving solution time.

Range: [-∞, ∞]

Default: `auto`

mipAbsStop *(real)*: Branch and Bound: Absolute tolerance determining whether the tree search will continue or not ↩

It will terminate if | MIPOBJVAL - BESTBOUND| ≤ mipAbsStop where MIPOBJVAL is the value of the best solution's objective function, and BESTBOUND is the current best solution bound. For example, to stop the tree search when a MIP solution has been found and the Optimizer can guarantee it is within 100 of the optimal solution, set mipAbsStop to 100.

Range: [0, ∞]

Default: `0`

mipAddCutoff *(real)*: Branch and Bound: Amount to add to the objective function of the best integer solution found to give the new CURRMIPCUTOFF ↩

Once an integer solution has been found whose objective function is equal to or better than CURRMIPCUTOFF, improvements on this value may not be interesting unless they are better by at least a certain amount. If mipAddCutoff is nonzero, it will be added to CURRMIPCUTOFF each time an integer solution is found which is better than this new value. This cuts off sections of the tree whose solutions would not represent substantial improvements in the objective function, saving processor time. The control mipAbsStop provides a similar function but works in a different way.

Range: [-∞, ∞]

Default: `0`

mipCleanup *(boolean)*: Clean up the MIP solution (round-fix-solve) to get duals ↩

If nonzero, clean up the integer solution obtained, i.e. round and fix the discrete variables and re-solve as an LP to get some marginal values for the discrete vars.

Default: `1`

mipComponents *(integer)*: Determines whether disconnected components in a MIP should be solved as separate MIPs ↩

There can be significant performence benefits from solving disconnected components individual instead of being part of the main branch-and-bound search.

If there are no constraints linking two variables, either directly or indirectly through other variables, they are said to belong to two separate disconnected components. When a problem contains disconnected components of signficant size, it can be advantageous to solve each component as a separate MIP. When significant disconnected components are detected in the problem, the solver will switch to a different solve mode where each component is solved separately. This switch will happen after the root node processing has completed and when the solve is about to enter the branch-and-bound search.

Solving disconnected components separately is not compatible with concurrent MIP solves. If concurrent MIP solves has been turned off, disconnected components will be solved as part of the standard branch-and-bound search in each concurrent solve.

Disabling MIP dual reductions through mipDualReductions will also disable the separate solve of disconnected components.

Default: `auto`

value	meaning
`-1`	Automatic - let the solver decide.
`0`	Disable solving disconnected components separately.
`1`	Solve disconnected components separately.

mipConcurrentNodes *(integer)*: Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled ↩

When multiple MIP solves are started, they each run up to the mipConcurrentNodes node limit and only one winning solve is selected for contuinuing the search with.

Default: `auto`

value	meaning
-1	Automatic - let the solver decide on a node limit.
>0	Number of nodes each concurrent solve should complete before a winner is selected.

mipConcurrentSolves *(integer)*: Selects the number of concurrent solves to start for a MIP ↩

Each solve will use a unique random seed for its random number generator, but will otherwise apply the same user controls. The first concurrent solve to complete will have solved the MIP and all the concurrent solves will be terminated at this point. Using concurrent solves can be advantageous when a MIP displays a high level of performance variability.

A node limit is imposed on each concurrent solve, through mipConcurrentNodes. When a concurrent solve reaches this node limit, it will be suspended until all concurrent solves have reached the limit. At this point a winner will be declared, based on which solve made the most progress towards optimality and only the winning solve will continue, using all threading resources. If a concurrent solve completes its MIP search before reaching the node limit, all solves will be stopped.

Default: 0

value	meaning
-1	Enabled. The number of concurrent solves depends on mipThreads.
n>1	Enabled. The number of concurrent solves to start is given by n.
0, 1	Disabled

mipDualReductions *(integer)*: Branch and Bound: Limits operations that can reduce the MIP solution space ↩

The mipDualReductions control, when set to a value different from 1 will adjust the values of other controls in order to prevent MIP solver operations that can result in the removal of dominated solutions. For example, dual reductions during preprocessing attempts to remove dominated solutions based on objective arguments, assuming that all constraints are known to the Optimizer. If a problem is detected to have symmetries, the solver might also remove some symmetrical solutions from the search space. In both cases, the set of feasible MIP solutions might be reduced. With default settings, it is only guaranteed that at least one optimal solution remains.

When attempting to collect the n-best solutions, it is recommended to set mipDualReductions=2. This will ensure that the only solutions missed by the enumeration are those that only differ from an existing solution in the values of the continuous variables.

Default: 1

value	meaning
0	Prevent all dual reductions.
1	Allow all dual reductions.
2	Allow dual reductions on continuous variables only.

mipFracReduce *(integer)*: Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions ↩

This heuristic is only applicable to problems that are dual degenerate. These are problems that contain multiple solutions with identical objective function value. The more dual degenerate a problem is, the more likely it will be for this heuristic to have an improving effect.

Default: `auto`

value	meaning
`-1`	Automatic.
`0`	Disabled.
`1`	Run before and after cutting on the root node.
`2`	Run also during root cutting.
`3`	Run also during the tree search.

mipKappaFreq *(integer)*: Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search ↩

The condition number is calculated as the norm of the basis matrix multiplied by the norm of its inverse. This uses the Froebenius norm.

A summary will be printed at the end of the solve, summarizing the collected condition numbers collected:

- Nodes kappa stable: No. of stable sampled nodes (kappa < `10^7`)
- Nodes kappa suspicius: No. of suspicious sampled nodes (`10^7` ≤ kappa < `10^10`)
- Nodes kappa unstable: No. of unstable sampled nodes (`10^10` ≤ kappa < `10^13`)
- Nodes kappa ill-posed: No. of ill-posed sampled nodes (`10^13` ≤ kappa)
- Largest kappa seen: The largest condition number calculated through all sampled nodes.
- Kappa attention level: A measure of how ill-posed the problem is (between 0 and 1).

Default: `0`

value	meaning
`0`	Do not calculate condition numbers.
`1`	Calculate conditions numbers on every node, including after each round of root cutting.
`n>1`	Calculate a condition number once per node of every n'th level of the branch-and-bound tree.

mipLog *(integer)*: MIP log print control ↩

Default: `-100`

value	meaning
`0`	No printout during MIP tree search.
`1`	Only print out summary statement at the end.
`2`	Print out detailed log at all solutions found.
`3`	Print out detailed log at each node.
`-n`	Print out summary log at each n th node.

mipPresolve *(integer)*: Branch and Bound: Type of integer processing to be performed ↩

If set to 0, no processing will be performed.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `-1`

value	meaning
`bit 0 = 1`	Equivalent to mipPresolve_reducedCostFixing.
`bit 1 = 2`	Equivalent to mipPresolve_logicPreprocessing.
`bit 2 = 4`	[Unused] This bit is no longer used to control probing. Refer to the integer control preProbing for setting probing level during presolve.
`bit 3 = 8`	Equivalent to mipPresolve_allowChangeBounds.
`bit 4 = 16`	Equivalent to mipPresolve_dualReductions.
`bit 5 = 32`	Equivalent to mipPresolve_globalCoefTightening.
`bit 6 = 64`	Equivalent to mipPresolve_objBasedReductions.
`bit 7 = 128`	Equivalent to mipPresolve_allowTreeRestart.
`bit 8 = 256`	Equivalent to mipPresolve_symmetryReductions.

mipPresolve_allowChangeBounds *(boolean)*: If node preprocessing is allowed to change bounds on continuous columns ↩

See also mipPresolve.

Default: `1`

mipPresolve_allowTreeRestart *(boolean)*: [Unused] This bit is no longer used to control restarts ↩

Refer to the integer control mipRestart for disabling tree restarts.

See also mipPresolve.

Default: `1`

mipPresolve_dualReductions *(boolean)*: Dual reductions will be performed at each node ↩

See also mipPresolve.

Default: `1`

mipPresolve_globalCoefTightening *(boolean)*: Allow global (non-bound) tightening of the problem during the tree search ↩

See also mipPresolve.

Default: `1`

mipPresolve_logicPreprocessing *(boolean)*: Primal reductions will be performed at each node ↩

Uses constraints of the node to tighten the range of variables, often resulting in fixing their values. This greatly simplifies the problem and may even determine optimality or infeasibility of the node.

See also mipPresolve.

Default: `1`

mipPresolve_objBasedReductions *(boolean)*: Objective function will be used to find reductions at each node ↩

See also mipPresolve.

Default: `1`

mipPresolve_reducedCostFixing *(boolean)*: Reduced cost fixing will be performed at each node ↩

This can simplify the node before it is solved, by deducing that certain variables' values can be fixed based on additional bounds imposed on other variables at this node.

See also mipPresolve.

Default: `1`

mipPresolve_symmetryReductions *(boolean)*: Allow that symmetry is used to presolve the node problem ↩

See also mipPresolve.

Default: `1`

mipRampUp *(integer)*: Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search ↩

The branch-and-bound tree search starts from the single root node, and only through branching on this root node and the resulting child nodes, are enough active nodes created to produce sufficient tasks to keep all MIP workers busy. This is referred to as the ramp-up phase of a parallel MIP. In a typical MIP solve, the solutions found during the initial dives will typically provide a significant improvement over the root heuristic solutions. It can therefore be advantageous to let these initial dives run as fast as possible, by limiting resource contention. This can be accomplished by restricting the number of parallel tasks and thereby reducing the memory bus contention. The mipRampUp control can be used to turn this initial task restriction of a parallel MIP solve on or off.

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	No special treatment during the ramp-up phase. Always run with the maximal number of tasks.
`1`	Limit the number of tasks until the initial dives have completed.

mipRefineIterLimit *(integer)*: Defines an effort limit expressed as simplex iterations for the MIP solution refiner ↩

The limit is per reoptimizations in the MIP refiner.

Range: {`-1`, ..., ∞}

Default: `auto`

mipRelCutoff *(real)*: Branch and Bound: Percentage of the LP solution value to be added to the value of the objective function when an integer solution is found, to give the new value of CURRMIPCUTOFF ↩

The effect is to cut off the search in parts of the tree whose best possible objective function would not be substantially better than the current solution. The control mipRelStop provides a similar functionality but works in a different way.

Range: [`0`, ∞]

Default: `0`

mipRelStop *(real)*: Branch and Bound: Determines when the branch and bound tree search will terminate ↩

Branch and bound tree search will stop if: | MIPOBJVAL - BESTBOUND| ≤ mipRelStop x max(| BESTBOUND|,| MIPOBJVAL|) where MIPOBJVAL is the value of the best solution's objective function and BESTBOUND is the current best solution bound. For example, to stop the tree search when a MIP solution has been found and the Optimizer can guarantee it is within 5% of the optimal solution, set mipRelStop to 0.05.

This control is a stopping criteria only and different values of the control will not affect the solution path before termination. Unlike other stopping criteria, like time and node count, termination on mipRelStop will cause the final solution to be declared optimal and the problem to be returned to its original state.

Tolerances, such as mipRelCutoff and mipAbsCutoff, determine how much the objective value of a new MIP solution has to differ from the incumbent for it to be accepted. These controls therefore also influence the final gap at the end of a MIP solve.

Range: [0, ∞]

Default: `0.0001`

mipRestart *(integer)*: Branch and Bound: Controls strategy for in-tree restarts ↩

Default: `auto`

value	meaning
`-1`	Determined automatically (XPRS_MIPRESTART_DEFAULT).
`0`	Disable in-tree restarts (XPRS_MIPRESTART_OFF).
`1`	Allow in-tree restarts at normal aggressiveness (XPRS_MIPRESTART_MODERATE).
`2`	Allow in-tree restarts at higher aggressiveness (more likely to trigger a restart) (XPRS_MIPRESTART_AGGRESSIVE).

mipRestartFactor *(real)*: Branch and Bound: Fine tune initial conditions to trigger an in-tree restart ↩

Use a value > 1 to increase the aggressiveness with which the Optimizer restarts. Use a value < 1 to relax the aggressiveness with which the Optimizer restarts. Note that this control does not affect the initial condition on the gap, which must be set separately.

Range: [0, ∞]

Default: `1`

mipRestartGapThreshold *(real)*: Branch and Bound: Initial gap threshold to delay in-tree restart ↩

The restart is delayed initially if the gap, given as a fraction between 0 and 1, is below this threshold. The optimizer adjusts the threshold every time a restart is delayed. Note that there are other criteria that can delay or prevent a restart.

Range: [0, 1]

Default: `0.02`

mipstopexpr *(string)*: Stopping expression for branch and bound ↩

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: resusd, nodusd, objest, objval. Supported operators are: +, -, ∗, /, ^, %, !=, ==, <, <=, >, >=, !, &&, ||, (,), abs, ceil, exp, floor, log, log10, pow, sqrt . Example:
```
nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1
```

If multiple stop expressions are given in an option file, the algorithm stops if any of them is true (|| concatenation).

mipThreads *(integer)*: If set to a positive integer it determines the number of threads implemented to run the parallel MIP code ↩

If mipThreads is set to the default value (-1), the threads control will determine the number of threads used.

Range: {`-1`, ..., ∞}

Default: `auto`

mipTol *(real)*: Branch and Bound: Tolerance within which a decision variable's value is considered to be integral ↩

Range: [`0`, ∞]

Default: `5e-06`

mipToltarget *(real)*: Target mipTol value used by the automatic MIP solution refiner as defined by refineOps ↩

Negative and zero values are ignored.

Refining solutions to match the miptoltarget can influence and worsen their objective value in case the previous objective could only be achieved through slight infeasibilities.

Range: [-∞, ∞]

Default: `0`

mipTrace *(string)*: Name of MIP trace file ↩

A miptrace file with the specified name will be created. This file records the best integer and best bound values every mipTraceNode nodes and at mipTraceTime-second intervals.

Default: `none`

mipTraceNode *(integer)*: Node interval between MIP trace file entries ↩

Default: `100`

mipTraceTime *(real)*: Time interval, in seconds, between MIP trace file entries ↩

Default: `5`

miqcpAlg *(integer)*: Determines which algorithm is to be used to solve mixed integer quadratic constrained and mixed integer second order cone problems ↩

Default: `auto`

value	meaning
-1	Determined automatically.
0	Use the barrier algorithm in the branch and bound algorithm.
1	Use outer approximations in the branch and bound algorithm.

mpsNameLength *(integer)*: Maximum length of MPS names in characters ↩

Internally it is rounded up to the smallest multiple of 8. MPS names are right padded with blanks. Maximum value is 64.

Range: {0, ..., ∞}

Default: 0

mpsOutputFile *(string)*: Name of MPS output file ↩

If specified XPRESS-MP will generate an MPS file corresponding to the GAMS model: the argument is the file name to be used. You can prefix the file name with an absolute or relative path.

Default: none

netCuts *(integer)*: Determines the addition of multi-commodity network cuts to a problem ↩

The parameter is defined as a bit string, and values 1, 2, 4 can be summed up if the user wants more classes of cuts to be added.

If the user wants to add both cut-set inequalities and lifted flow-cover inequalities but not node cut-set inequalities, the value of the control should be set to 1+4=5.

Default: 0

value	meaning
-1	Automatically determined.
0	Do not add these cuts.
1	Add cut-set inequalities.
2	Add node cut-set inequalities, i.e., cut-set inequalities that are based on a network cut defined on a single network node.
4	Add lifted flow-cover inequalities.

netStallLimit *(integer)*: Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex, depending on algAfterNetwork ↩

Default: auto

value	meaning
-1	Automatically determined limit
0	No limit.
n>0	Limit to n network simplex iterations.

nodeProbingEffort *(real)*: Adjusts the overall level of node probing ↩

nodeProbingEffort is used as a multiplier on the default amount of work node probing should do. Setting the control to zero disables node probing.

Range: [0, ∞]

Default: 1

nodeSelection *(integer)*: Branch and Bound: Determines which nodes will be considered for solution once the current node has been solved ↩

Default: auto

value	meaning
1	Local first: Choose between descendant and sibling nodes if available; choose from all outstanding nodes otherwise.
2	Best first: Choose from all outstanding nodes.
3	Local depth first: Choose between descendant and sibling nodes if available; choose from the deepest nodes otherwise.
4	Best first, then local first: Best first is used for the first breadthFirst nodes, after which local first is used.
5	Pure depth first: Choose from the deepest outstanding nodes.

numericalEmphasis *(integer)*: How much emphasis to place on numerical stability instead of solve speed ↩

Default: auto

value	meaning
-1	Automatic. The emphasis might be influenced by the setting of other controls.
0	Emphasize speed.
1	Mild emphasis on numerical stability.
2	Medium emphasis on numerical stability.
3	Strong emphasis on numerical stability.

objGoodEnough *(real)*: Stop once an objective this good is found ↩

Default: none

objScaleFactor *(integer)*: Custom objective scaling factor, expressed as a power of 2 ↩

When set, it overwrites the automatic objective scaling factor. A value of 0 means no objective scaling. This control is applied for the full solve, and is independent of any extra scaling that may occur specifically for the barrier or simplex solvers. As it is a power of 2, to scale by 16, set the value of the control to 4.

Range: {0, ..., ∞}

Default: 0

optimalityTol *(real)*: Simplex: Zero tolerance for reduced costs ↩

On each iteration, the simplex method searches for a variable to enter the basis which has a negative reduced cost. The candidates are only those variables which have reduced costs less than the negative value of optimalityTol.

Range: [0, ∞]

Default: 1e-06

optimalityTolTarget *(real)*: Target optimality tolerance for the solution refiner ↩

Zero and negative values are ignored, and the value of optimalityTol is used.

Use very small values like 1e-100 to state the refinement should continue as long as an improvement is made. Use very large values like 1e+100 to disable only this aspect of the refiner.

Refining solutions to match the optimalitytoltarget can influence and increase their infeasibility in case the previous feasibility could only be achieved through slight dual violations.

Range: [-∞, ∞]

Default: 0

outputControls *(boolean)*: Toggles the printing of all control settings at the beginning of the search ↩

This includes the printing of controls that have been explicitly assigned to their default value. All unset controls are omitted as they keep their default value.

Setting outputControls to 0 has no effect on the function XPRSdumpcontrols

Default: 1

value	meaning
0	Turn off printing of user-specified control settings.
1	Print controls.

outputLog *(integer)*: Controls the level of output produced by the Optimizer during optimization ↩

Default: 1

value	meaning
0	Turn all output off.
1	Print all messages.
3	Print error and warning messages.
4	Print error messages only.

outputTol *(real)*: Zero tolerance on print values ↩

Range: [0, ∞]

Default: 1e-05

penalty *(real)*: Minimum absolute penalty variable coefficient ↩

Range: [0, ∞]

Default: auto

pivotTol *(real)*: Simplex: Zero tolerance for matrix elements ↩

On each iteration, the simplex method seeks a nonzero matrix element to pivot on. Any element with absolute value less than pivotTol is treated as zero for this purpose.

Range: [0, ∞]

Default: 1e-09

ppFactor *(real)*: Partial pricing candidate list sizing parameter ↩

Range: [0, ∞]

Default: 1

preAnalyticCenter *(integer)*: Determines if analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs (-1: Auto 0: Off, 1: Fixing, 2: Redcost, 3: Both) ↩

Default: auto

value	meaning
-1	Automatic.
0	Disable analytic center presolving.
1	Use analytic center for variable fixing only.
2	Use analytic center for reduced cost computation only.
3	Use analytic centers for both, variable fixing and reduced cost computation.

preBasisRed *(integer)*: Determines if a lattice basis reduction algorithm should be attempted as part of presolve ↩

Default: 0

value	meaning
-1	Automatic.
0	Disable basis reduction.
1	Enable basis reduction.

preBndRedCone *(integer)*: Determines if second order cone constraints should be used for inferring bound reductions on variables when solving a MIP ↩

Default: auto

value	meaning
-1	Automatic.
0	Disable bound reductions from second order cone constraints.
1	Enable bound reductions from second order cone constraints.

preBndRedQuad *(integer)*: Determines if convex quadratic contraints should be used for inferring

bound reductions on variables when solving a MIP ↩

Default: `auto`

value	meaning
`-1`	Automatic.
`0`	Disable bound reductions from quadratic constraints.
`1`	Enable bound reductions from quadratic constraints.

preCliqueStrategy *(integer)*: Determines how much effort to spend on clique covers in presolve ↩

Range: {`-1`, ..., ∞}

Default: `-1`

preCoefElim *(integer)*: Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem ↩

Default: `2`

value	meaning
`0`	Disabled.
`1`	Remove as many coefficients as possible.
`2`	Cautious eliminations. Will not perform a reduction if it might destroy problem structure useful to e.g. heuristics or cutting.

preComponents *(integer)*: Presolve: Determines whether small independent components should be detected and solved as individual subproblems during root node processing ↩

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Disable detection of independent components.
`1`	Enable detection of independent components.

preComponentsEffort *(real)*: Presolve: Adjusts the overall effort for the independent component presolver ↩

This control affects working limits for the subproblem solving as well as thresholds when it is called. Increase to put more emphasis on component presolving.

Range: [`0`, ∞]

Default: `1`

preConeDecomp *(integer)*: Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components ↩

Default: `auto`

value	meaning
-1	Automatically determined.
0	Disable cone decomposition.
1	Enable cone decomposition by replacing large cones with small ones in the presolved problem.
2	Similar to 1, plus decomposition is enabled even if the cone variable is fixed.
3	Cones are decomposed within the Outer Approximation domain only, i.e., the problem maintains the original cones.

preConfiguration *(integer)*: MIP Presolve: Determines whether binary rows with only few repeating coefficients should be reformulated ↩

The reformulation enumerates the extremal feasible configurations of a row and introduces new columns and rows to model the choice between these extremal configurations. This presolve operation can be disabled as part of the (advanced) IP reductions presolveOps.

Default: `auto`

value	meaning
-1	Automatically determined.
0	Disable configuration presolving.

preConvertSeparable *(integer)*: Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints ↩

This control is only used in MIQPs and MIQCQPs, and has no effect when used on continuous quadratic problems.

Default: `auto`

value	meaning
-1	Automatically determined.
0	Disable reformulation.
1	Enable reformulation to diagonal quadratic constraints.
2	Similar to 1, plus reduction to second-order cones.
3	Similar to 2, plus the objective function is converted to a constraint and treated as a quadratic constraint.

preDomCol *(integer)*: Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem ↩

Only binary columns will be checked.

Default: `auto`

value	meaning
-1	Automatically determined.
0	Disabled.
1	Cautious strategy.
2	All candidate binaries will be checked for domination.

preDomRow *(integer)*: Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem ↩

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Disabled.
`1`	Cautious strategy.
`2`	Medium strategy.
`3`	Aggressive strategy. All candidate row combinations will be considered.

preDupRow *(integer)*: Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem ↩

Duplicate rows can also be disabled by clearing the corresponding bit of the presolveOps integer control.

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Do not eliminate duplicate rows.
`1`	Eliminate only rows that are identical in all variables.
`2`	Same as option 1 plus eliminate duplicate rows with simple penalty variable expressions. (MIP only).
`3`	Same as option 2 plus eliminate duplicate rows with more complex penalty variable expressions. (MIP only).

preElimQuad *(integer)*: Presolve: Allows for elimination of quadratic variables via doubleton rows ↩

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Do not eliminate duplicate rows.
`1`	Eliminate at least one quadratic variable for each doubleton row.

preFolding *(integer)*: Presolve: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition ↩

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Disabled.
`1`	Enabled.

preImplications *(integer)*: Presolve: Determines whether to use implication structures to remove redundant rows ↩

If implication sequences are detected, they might also be used in probing.

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Do not use implications for sparsification.
`1`	Use implications to remove reduandant rows.

preLinDep *(integer)*: Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem ↩

Default: `auto`

value	meaning
`-1`	Automatically determined.
`0`	Do not check for linearly dependent equality constraints.
`1`	Check for and remove linearly dependent equality constraints.

preObjCutDetect *(boolean)*: Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed ↩

This reduction applies to MIPs only.

Default: `1`

value	meaning
`0`	Disable check and reductions.
`1`	Enable check and reductions.

preProbing *(integer)*: Presolve: Amount of probing to perform on binary variables during presolve ↩

This is done by fixing a binary to each of its values in turn and analyzing the implications.

Default: `auto`

value	meaning
`-1`	Let the optimizer decide on the amount of probing.
`0`	Disabled.
`1`	Light probing — only few implications will be examined.
`2`	Full probing — all implications for all binaries will be examined.
`3`	Full probing and repeat as long as the problem is significantly reduced.

presolve *(integer)*: Determines whether presolving should be performed prior to starting the main algorithm ↩

Presolve attempts to simplify the problem by detecting and removing redundant constraints, tightening variable bounds, etc. In some cases, infeasibility may even be determined at this stage, or the optimal solution found.

Memory for presolve is dynamically resized. If the Optimizer runs out of memory for presolve, an error message (245) is produced. Presolve settings 2 and 3 can sometimes make the barrier solves more efficient.

Default: `1`

value	meaning
`-1`	Presolve applied, but a problem will not be declared infeasible if primal infeasibilities are detected. The problem will be solved by the LP optimization algorithm, returning an infeasible solution, which can sometimes be helpful.
`0`	Presolve not applied.
`1`	Presolve applied.
`2`	Presolve applied, but redundant bounds are not removed. This can sometimes increase the efficiency of the barrier algorithm.
`3`	Presolve is applied, and bounds detected to be redundant are always removed.

presolveMaxGrow *(real)*: Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem ↩

Range: [`0`, ∞]

Default: `0.1`

presolveOps *(integer)*: Specifies the operations which are performed during the presolve ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `511`

value	meaning
`bit 0 = 1`	Equivalent to presolveOps_singletonColRemoval.
`bit 1 = 2`	Equivalent to presolveOps_singletonRowRemoval.
`bit 2 = 4`	Equivalent to presolveOps_forcingRowRemoval.
`bit 3 = 8`	Equivalent to presolveOps_dualReductions.
`bit 4 = 16`	Equivalent to presolveOps_redundantRowRemoval.
`bit 5 = 32`	Equivalent to presolveOps_duplicateColRemoval.
`bit 6 = 64`	Equivalent to presolveOps_duplicateRowRemoval.
`bit 7 = 128`	Equivalent to presolveOps_strongDualReductions.
`bit 8 = 256`	Equivalent to presolveOps_variableEliminations.
`bit 9 = 512`	Equivalent to presolveOps_noIpReductions.
`bit 10 = 1024`	Equivalent to presolveOps_noGlobalDomainChange.
`bit 11 = 2048`	Equivalent to presolveOps_noAdvIpReductions.
`bit 12 = 4096`	Equivalent to presolveOps_noIntVarEliminations.
`bit 14 = 16384`	Equivalent to presolveOps_linDependRowRemoval.
`bit 15 = 32768`	Equivalent to presolveOps_noIntVarAndSosDetect.

presolveOps_dualReductions *(boolean)*: Dual reductions ↩

See also presolveOps.

Default: `1`

presolveOps_duplicateColRemoval *(boolean)*: Duplicate column removal ↩

See also presolveOps.

Default: `1`

presolveOps_duplicateRowRemoval *(boolean)*: Duplicate row removal ↩

See also presolveOps.

Default: `1`

presolveOps_forcingRowRemoval *(boolean)*: Forcing row removal ↩

See also presolveOps.

Default: `1`

presolveOps_linDependRowRemoval *(boolean)*: Linearly dependant row removal ↩

See also presolveOps.

Default: `0`

presolveOps_noAdvIpReductions *(boolean)*: No advanced IP reductions ↩

See also presolveOps.

Default: `0`

presolveOps_noGlobalDomainChange *(boolean)*: No semi-continuous variable detection ↩

See also presolveOps.

Default: `0`

presolveOps_noIntVarAndSosDetect *(boolean)*: No integer variable and SOS detection ↩

See also presolveOps.

Default: `0`

presolveOps_noIntVarEliminations *(boolean)*: No eliminations on integers ↩

See also presolveOps.

Default: `0`

presolveOps_noIpReductions *(boolean)*: No IP reductions ↩

See also presolveOps.

Default: `0`

presolveOps_redundantRowRemoval *(boolean)*: Redundant row removal ↩

See also presolveOps.

Default: `1`

presolveOps_singletonColRemoval *(boolean)*: Singleton column removal ↩

See also presolveOps.

Default: `1`

presolveOps_singletonRowRemoval *(boolean)*: Singleton row removal ↩

See also presolveOps.

Default: `1`

presolveOps_strongDualReductions *(boolean)*: Strong dual reductions ↩

See also presolveOps.

Default: `1`

presolveOps_variableEliminations *(boolean)*: Variable eliminations ↩

See also presolveOps.

Default: `1`

presolvePasses *(integer)*: Number of reduction rounds to be performed in presolve ↩

Range: {`0`, ..., ∞}

Default: `1`

pricingAlg *(integer)*: Simplex: Determines the primal simplex pricing method ↩

It is used to select which variable enters the basis on each iteration. In general Devex pricing requires more time on each iteration, but may reduce the total number of iterations, whereas partial pricing saves time on each iteration, but may result in more iterations.

Default: `auto`

value	meaning
`-1`	Partial pricing.
`0`	Determined automatically.
`1`	Devex pricing.
`2`	Steepest edge.
`3`	Steepest edge with unit initial weights.

primalOps *(integer)*: Primal simplex: Allows fine tuning the variable selection in the primal simplex solver ↩

If both bits 0 and 1 are both set or unset then the dj scaling strategy is determined automatically.

Default: `-1`

value	meaning
`bit 0 = 1`	Use aggressive dj scaling.

value	meaning
bit 1 = 2	Conventional dj scaling.
bit 2 = 4	Use reluctant switching back to partial pricing.
bit 3 = 8	Use dynamic switching between cheap and expensive pricing strategies.
bit 4 = 16	Keep solving even after potential cycling is detected.

primalPerturb *(real)*: Factor by which the problem will be perturbed prior to optimization by primal simplex ↩

A value of 0.0 results in no perturbation prior to optimization. Note the interconnection to the autoPerturb control. If autoPerturb is set to 1, the decision whether to perturb or not is left to the Optimizer. When the problem is automatically perturbed in primal simplex, however, the value of primalPerturb will be used for perturbation.

Range: [-∞, ∞]

Default: auto

primalUnshift *(boolean)*: Determines whether primal is allowed to call dual to unshift ↩

Default: 0

value	meaning
0	Allow the dual algorithm to be used to unshift.
1	Don't allow the dual algorithm to be used to unshift.

pseudoCost *(real)*: Branch and Bound: Default pseudo cost used in estimation of the degradation associated with an unexplored node in the tree search ↩

A pseudo cost is associated with each integer decision variable and is an estimate of the amount by which the objective function will be worse if that variable is forced to an integral value.

Range: [0, ∞]

Default: 0.01

qcCuts *(integer)*: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation ↩

This control only has an effect for problems with quadratic or second order cone constraints, and only if outer approximation has not been disabled by setting miqcpAlg to 0.

Range: {-1, ..., ∞}

Default: auto

qcRootAlg *(integer)*: Determines which algorithm is to be used to solve the root of a mixed integer quadratic constrained or mixed integer second order cone problem, when outer approximation is used ↩

This control only has an effect if miqcpAlg is set to 1.

Default: auto

value	meaning
-1	Determined automatically.
0	Use the barrier algorithm.
1	Use the dual simplex on a relaxation of the problem constructed using outer approximation.

qextractalg *(integer)*: quadratic extraction algorithm in GAMS interface ↩

Default: 0

value	meaning
0	Automatic
1	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
2	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.
3	Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.

qSimplexOps *(integer)*: Controls the behavior of the quadratic simplex solvers ↩

Default: 0

value	meaning
bit 0 = 1	Force traditional primal first phase.
bit 1 = 2	Force BigM primal first phase.
bit 2 = 4	Force traditional dual first phase.
bit 3 = 8	Force BigM dual first phase.
bit 4 = 16	Always use artificial bounds in dual.
bit 5 = 32	Use original problem basis only when warmstarting the KKT.
bit 6 = 64	Skip the primal bound flips for ranged primals (might cause more trouble than good if the bounds are very large).
bit 7 = 128	Also do the single pivot crash.
bit 8 = 256	Do not apply aggressive perturbation in dual.

quadraticUnshift *(integer)*: Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual) ↩

Default: auto

value	meaning
-1	Determined automatically.
0	No purification step.
1	Always do the purification step.

randomSeed *(integer)*: Sets the initial seed to use for the pseudo-random number generator in the Optimizer ↩

The sequence of random numbers is always reset using the seed when starting a new optimization run.

Range: {-∞, ..., ∞}

Default: 1

refineOps *(integer)*: Specifies when the solution refiner should be executed to reduce solution infeasibilities ↩

The refiner will attempt to satisfy the target tolerances for all original linear constraints before presolve or scaling has been applied.

If neither the 7th nor 8th bit is set, the refiner will use the primal simplex if the primal violations are larger than the dual violations, otherwise it will use the dual simplex. If both the 7th and 8th bit are set then the refiner will split the problem into a primal feasible and dual feasible part, and solve the first with primal simplex and the second with dual simplex.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 19

value	meaning
bit 0 = 1	Equivalent to refineOps_lpOptimal.
bit 1 = 2	Equivalent to refineOps_mipSolution.
bit 3 = 8	Equivalent to refineOps_mipNodeLp.
bit 4 = 16	Equivalent to refineOps_lpPresolve.
bit 5 = 32	Equivalent to refineOps_iterativeRefiner.
bit 6 = 64	Equivalent to refineOps_refinerPrecision.
bit 7 = 128	Equivalent to refineOps_refinerUsePrimal.
bit 8 = 256	Equivalent to refineOps_refinerUseDual.
bit 9 = 512	Equivalent to refineOps_mipFixGlobals.
bit 10 = 1024	Equivalent to refineOps_mipFixGlobalsTarget.

refineOps_iterativeRefiner *(boolean)*: Apply the iterative refiner to refine the solution ↩

See also refineOps.

Default: 0

refineOps_lpOptimal *(boolean)*: Run the solution refiner on an optimal solution of a continuous problem ↩

See also refineOps.

Default: 1

refineOps_lpPresolve *(boolean)*: Run the solution refiner on an optimal solution before postsolve on a continuous problem ↩

See also refineOps.

Default: 1

refineOps_mipFixGlobals *(boolean)*: Refine MIP solutions such that rounding them keeps the problem feasible when reoptimized ↩

See also refineOps.

Default: `0`

refineOps_mipFixGlobalsTarget *(boolean)*: Attempt to refine MIP solutions such that rounding them keeps the problem feasible when reoptimized, but accept integers solutions even if refinement fails ↩

See also refineOps.

Default: `0`

refineOps_mipNodeLp *(boolean)*: Run the solution refiner on each node of the MIP search ↩

See also refineOps.

Default: `0`

refineOps_mipSolution *(boolean)*: Run the solution refiner when a new solution is found during a tree search ↩

The refiner will be applied to the presolved solution before any post-solve operations are applied.

See also refineOps.

Default: `1`

refineOps_refinerPrecision *(boolean)*: Use higher precision in the iterative refinement ↩

See also refineOps.

Default: `0`

refineOps_refinerUseDual *(boolean)*: If set, the iterative refiner will use the dual simplex algorithm ↩

See also refineOps.

Default: `0`

refineOps_refinerUsePrimal *(boolean)*: If set, the iterative refiner will use the primal simplex algorithm ↩

See also refineOps.

Default: `0`

reform *(boolean)*: Substitute out objective var and equ when possible ↩

Default: `1`

relaxTreeMemoryLimit *(real)*: When the memory used by the branch and bound search tree exceeds the target specified by the treeMemoryLimit control, the optimizer will try to reduce this by writing nodes to the tree file ↩

In rare cases, usually where the solve has many millions of very small nodes, the tree structural data (which cannot be written to the tree file) will grow large enough to approach or exceed the tree's memory target. When this happens, optimizer performance can degrade greatly as the solver makes heavy use of the tree file in preference to memory. To prevent this, the solver will automatically relax the tree memory limit when it detects this case; the relaxTreeMemoryLimit control specifies the proportion of the previous memory limit by which to relax it. Set relaxTreeMemoryLimit to 0.0 to force the Xpress Optimizer to never relax the tree memory limit in this way.

While setting higher values of relaxTreeMemoryLimit can improve performance significantly for a small number of models in low memory situations, the user is advised to use the treeMemoryLimit control to tune the memory usage of the branch and bound tree, according to the solve characteristics of their problem, rather than increasing relaxTreeMemoryLimit.

Range: [0, ∞]

Default: 0.1

relPivotTol *(real)*: Simplex: Minimum size of pivot element relative to largest element in column ↩

At each iteration a pivot element is chosen within a given column of the matrix. The relative pivot tolerance, relPivotTol, is the size of the element chosen relative to the largest possible pivot element in the same column.

Range: [0, ∞]

Default: 1e-06

repairIndefInitEq *(boolean)*: Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible ↩

Default: 1

value	meaning
0	Repair if possible.
1	Do not repair.

reRun *(boolean)*: Rerun with primal simplex when not optimal/feasible ↩

Applies only in cases where presolve is turned on and the model is diagnosed as infeasible or unbounded. If rerun is nonzero, we rerun the model using primal simplex with presolve turned off in hopes of getting better diagnostic information. If rerun is zero, no good diagnostic information exists, so we return no solution, only an indication of unboundedness/infeasibility.

Default: 0

reslim *(real)*: Overrides GAMS reslim option ↩

Sets the resource limit. When the solver has used more than this amount of CPU time (in seconds) the system will stop the search and report the best solution found so far. timeLimit and solTimeLimit overwrite this option.

resourceStrategy *(boolean)*: Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve ↩

Available memory (or container limits) are automatically detected but can also be changed by maxMemorySoft and maxMemoryHard.

Default: 0

value	meaning
1	Allow the optimizer to change the solve path if necessary to preserve memory when getting close to one of the memory limits.

rootPresolve *(integer)*: Determines if presolving should be performed on the problem after the tree search has finished with root cutting and heuristics ↩

Default: auto

value	meaning
-1	Let the optimizer decide if the problem should be presolved again.
0	Disabled.
1	Always presolve the root problem.

sbBest *(integer)*: Number of infeasible MIP entities to initialize pseudo costs for on each node ↩

If sbBest is set to zero, the control historyCosts will also be treated as zero and no past branching or strong branching information will be used in the MIP entity selection.

Default: auto

value	meaning
-1	Determined automatically.
0	Disable strong branching.
n>0	Perform strong branching on up to n entities at each node.

sbEffort *(real)*: Adjusts the overall amount of effort when using strong branching to select an infeasible MIP entity to branch on ↩

sbEffort is used as a multiplier on other strong branching related controls, and affects the values used for sbBest, sbSelect and sbIterLimit when those are set to automatic.

Range: [0, ∞]

Default: 1

sbEstimate *(integer)*: Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible MIP entity to branch on ↩

These pseudo costs are used in combination with local strong branching and history costs to select the branch candidate.

Default: auto

value	meaning
-1	Automatically determined.
1-6	Different variants of local pseudo costs.

sbIterLimit *(integer)*: Number of dual iterations to perform the strong branching for each entity ↩

This control can be useful to increase or decrease the amount of effort (and thus time) spent performing strong branching at each node. Setting sbIterLimit=0 will disable dual strong

branch iterations. Instead, the entity at the head of the candidate list will be selected for branching.

Range: {-1, ..., ∞}

Default: auto

sbSelect *(integer)*: Size of the candidate list of MIP entities for strong branching ↩

Before strong branching is applied on a node of the branch and bound tree, a list of candidates is selected among the infeasible MIP entities. These entities are then evaluated based on the local LP solution and prioritized. Strong branching will then be applied to the sbBest candidates. The evaluation is potentially expensive and for some problems it might improve performance if the size of the candidate list is reduced.

Default: -2

value	meaning
-2	Automatic (low effort).
-1	Automatic (high effort).
n>=0	Include n entities in the candidate list (but always at least sbBest candidates).

scaling *(integer)*: Determines how the Optimizer will rescale a model internally before optimization ↩

If set to 0, no scaling will take place.

Setting scaling to 0 will preserve the current scaling of the problem. Note that the Optimizer might automatically select a different scaling strategy, when the control autoScaling is not disabled. However, if scaling is set to any value by the user, autoScaling will be ignored.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 163

value	meaning
bit 0 = 1	Equivalent to scaling_rowScaling.
bit 1 = 2	Equivalent to scaling_colScaling.
bit 2 = 4	Equivalent to scaling_rowScalingAgain.
bit 3 = 8	Equivalent to scaling_maximum.
bit 4 = 16	Equivalent to scaling_curtisReid.
bit 5 = 32	Equivalent to scaling_byMaxElemNotGeoMean.
bit 6 = 64	Equivalent to scaling_bigM.
bit 7 = 128	Equivalent to scaling_simplexObjScaling.
bit 8 = 256	Equivalent to scaling_ignoreQuadRowPart.
bit 9 = 512	Equivalent to scaling_beforePresolve.
bit 10 = 1024	Equivalent to scaling_noScalingRowsUp.
bit 11 = 2048	Equivalent to scaling_noScalingColsDown.
bit 12 = 4096	Equivalent to scaling_disableGlobalObjScaling.
bit 13 = 8192	Equivalent to scaling_rhsScaling.
bit 14 = 16384	Equivalent to scaling_noAggressiveQScaling.
bit 15 = 32768	Equivalent to scaling_slackScaling.

scaling_beforePresolve *(boolean)*: Scale before presolve ↩

See also scaling.

Default: `0`

scaling_bigM *(boolean)*: Treat big-M rows as normal rows ↩

See also scaling.

Default: `0`

scaling_byMaxElemNotGeoMean *(boolean)*: 0: scale by geometric mean ↩

1: scale by maximum element.

See also scaling.

Default: `1`

scaling_colScaling *(boolean)*: Column scaling ↩

See also scaling.

Default: `1`

scaling_curtisReid *(boolean)*: Curtis-Reid ↩

See also scaling.

Default: `0`

scaling_disableGlobalObjScaling *(boolean)*: Do not apply automatic objective scaling ↩

See also scaling.

Default: `0`

scaling_ignoreQuadRowPart *(boolean)*: Exclude the quadratic part of constraint when calculating scaling factors ↩

See also scaling.

Default: `0`

scaling_maximum *(boolean)*: Maximum ↩

See also scaling.

Default: `0`

scaling_noAggressiveQScaling *(boolean)*: Disable aggressive quadratic scaling ↩

See also scaling.

Default: `0`

scaling_noScalingColsDown *(boolean)*: Do not scale columns down ↩

See also scaling.

Default: 0

scaling_noScalingRowsUp *(boolean)*: Do not scale rows up ↩

See also scaling.

Default: 0

scaling_rhsScaling *(boolean)*: RHS scaling ↩

See also scaling.

Default: 0

scaling_rowScaling *(boolean)*: Row scaling ↩

See also scaling.

Default: 1

scaling_rowScalingAgain *(boolean)*: Row scaling again ↩

See also scaling.

Default: 0

scaling_simplexObjScaling *(boolean)*: Scale objective function for the simplex method ↩

See also scaling.

Default: 1

scaling_slackScaling *(boolean)*: Enable explicit linear slack scaling ↩

See also scaling.

Default: 0

sifting *(integer)*: Determines whether to enable sifting algorithm with the dual simplex method ↩

Default: auto

value	meaning
-1	Automatically determined.
0	Disable sifting.
1	Enable sifting.

siftPasses *(integer)*: Determines how quickly we allow to grow the worker problems during the sifting algorithm ↩

Using larger values can increase the number of columns added to the worker problem which often results in increased solve times for the worker problems but the number of necessary sifting iterations may be reduced.

Range: {0, ..., ∞}

Default: 4

siftPresolveOps *(integer)*: Determines the presolve operations for solving the subproblems during the sifting algorithm ↩

Default: -1

value	meaning
-1	Use the presolveOps setting specified for the original problem.
>=0	Use the value for the presolveOps parameter for solving the subproblems during the sifting algorithm.

siftSwitch *(integer)*: Determines which algorithm to use for solving the subproblems during sifting ↩

Default: -1

value	meaning
-1	Dual simplex.
0	Barrier.
>0	Use the barrier algorithm while the number of dual infeasibilities is larger than this value, otherwise use dual simplex.

solnpool *(string)*: Solution pool file name ↩

If set, the integer feasible solutions generated during the global search will be saved to a solution pool. A GDX file whose name is given by this option will be created and will contain an index to separate GDX files containing the individual solutions in the solution pool.

Default: none

solnpoolCapacity *(integer)*: Limit on number of solutions to store ↩

Range: {1, ..., ∞}

Default: 999999999

solnpoolCullDiversity *(integer)*: Cull N solutions based on solution diversity ↩

When performing a round of culls due to a full solution pool, this control sets the maximum number to cull based on the diversity of the solutions in the pool.

Range: {-1, ..., ∞}

Default: -1

solnpoolCullObj *(integer)*: Cull N solutions based on objective values ↩

When performing a round of culls due to a full solution pool, this control sets the maximum number to cull based on the MIP objective function.

Range: {-1, ..., ∞}

Default: -1

solnpoolCullRounds *(integer)*: Terminate solution generation after N culling rounds ↩

Limits the rounds of culls performed due to a full solution pool.

Default: 999999999

solnpoolDupPolicy *(integer)*: Policy to use when handling storage of duplicate solutions ↩

Default: 0

value	meaning
0	Keep all: All solutions are kept including duplicates.
1	Continuous: All variables are compared with an exact match. Duplicate solutions are discarded.
2	Discrete and continuous separate: Both the discrete component of a solution pair and the continuous solution variables are compared. The continuous variables are compared with an exact match. Duplicate solutions are discarded.
3	Discrete only: Only the discrete component of a solution pair is compared. Duplicate solutions are discarded.

solnpoolmerge *(string)*: Solution pool file name for merged solutions ↩

Default: `none`

solnpoolnumsym *(integer)*: Maximum number of variable symbols when writing merged solutions ↩

Range: {1, ..., ∞}

Default: `10`

solnpoolPop *(integer)*: Controls method used to populate the solution pool ↩

By default the MIP solution pool merely stores the incumbent solutions that are found during the global search, without changing the behavior of the search itself. In constrast, the MIP solution enumerator makes it possible to enumerate all or many of the feasible solutions for the MIP, instead of searching for the best solution.

Default: `1`

value	meaning
1	generate solutions using the normal search algorithm
2	invoke the solution enumerator to generate solutions

solnpoolPrefix *(string)*: File name prefix for GDX solution files ↩

Default: `soln`

solnpoolVerbosity *(integer)*: Controls verbosity of solution pool routines ↩

Default: `0`

value	meaning
-1	no output
0	output only messages coming from the XPRESS libraries
1	add some messages logging the effect of solution pool options
2	debugging mode

solTimeLimit *(real)*: Maximum time in seconds that the Optimizer will run a MIP solve before it terminates, given that a solution has been found ↩

As long as no solution has been found, this control will have no effect.

This control has been newly introduced with Xpress Optimizer version 9.0 and should be used instead of the deprecated MAXTIME control. It can be combined with the timeLimit control.

Default: `1e+20`

value	meaning
>0	If an integer solution has been found, stop MIP search after the given number of seconds, otherwise continue until an integer solution is finally found.

sosRefTol *(real)*: Minimum relative gap between the ordering values of elements in a special ordered set ↩

The gap divided by the absolute value of the larger of the two adjacent values must be at least sosRefTol.

This tolerance must not be set lower than 1.0E-06.

Range: [0, ∞]

Default: `1e-06`

symmetry *(integer)*: Adjusts the overall amount of effort for symmetry detection ↩

Default: `1`

value	meaning
0	No symmetry detection.
1	Conservative effort.
2	Intensive symmetry search.

symSelect *(integer)*: Adjusts the overall amount of effort for symmetry detection ↩

Default: `-1`

value	meaning
0	Search the whole matrix (otherwise the 0, 1 and -1 coefficients only).
1	Search all entities (otherwise binaries only).

threads *(integer)*: Default number of threads used during optimization ↩

Controls the number of threads to use. Positive values will be compared to the number of available cores detected and reduced if greater than this amount. Non- positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

Range: {-∞, ..., ∞}

Default: `1`

timeLimit *(real)*: Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time ↩

For MIP problems, this is the total time taken to solve all nodes.

This control has been newly introduced with Xpress Optimizer version 9.0 and should be used instead of the deprecated MAXTIME control. Note that the meaning of positive values differs between timeLimit and MAXTIME. When both controls are set, timeLimit takes precedence. The functionality of positive MAXTIME values is covered by solTimeLimit.

Default: `1e+20`

value	meaning
>0	Stop LP or MIP search after the given number of seconds.

trace *(integer)*: Display the infeasibility diagnosis during presolve ↩

If non-zero, an explanation of the logical deductions made by presolve to deduce infeasibility or unboundedness will be displayed on screen or sent to the message callback function.

Presolve is sometimes able to detect infeasibility and unboundedness in problems. The set of deductions made by presolve can allow the user to diagnose the cause of infeasibility or unboundedness in their problem. However, not all infeasibility or unboundedness can be detected and diagnosed in this way.

Range: {0, ..., ∞}

Default: `0`

treeCompression *(integer)*: When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the tree file on disk ↩

The treeCompression control determines the strength of the data-compression algorithm used; higher values give superior data- compression at the affect of decreasing performance, while lower values compress quicker but not as effectively. Where treeCompression is set to 0, no data compression will be used on the tree file.

Range: {0, ..., ∞}

Default: `2`

treeCoverCuts *(integer)*: Branch and Bound: Number of rounds of lifted cover inequalities generated at nodes other than the top node in the tree ↩

Compare with the description for coverCuts. A value of -1 indicates the number of rounds is determined automatically.

Range: {-1, ..., ∞}

Default: `auto`

treeCutSelect *(integer)*: Bit vector providing detailed control of the cuts created during the tree search of a MIP solve ↩

Use cutSelect to control cuts on the root node.

The default value is -1 which enables all bits. Any bits not listed in the above table should be left in their default 'on' state, since the interpretation of such bits might change in future versions of the optimizer.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `-1`

value	meaning
bit 5 = 32	Equivalent to treeCutSelect_clique.
bit 6 = 64	Equivalent to treeCutSelect_mir.
bit 7 = 128	Equivalent to treeCutSelect_cover.
bit 8 = 256	Equivalent to treeCutSelect_mirRowAggregation.
bit 11 = 2048	Equivalent to treeCutSelect_flowpath.
bit 12 = 4096	Equivalent to treeCutSelect_implication.
bit 13 = 8192	Equivalent to treeCutSelect_liftAndProject.
bit 14 = 16384	Equivalent to treeCutSelect_disableCutRows.
bit 15 = 32768	Equivalent to treeCutSelect_gubCover.
bit 16 = 65536	Equivalent to treeCutSelect_zeroHalf.
bit 17 = 131072	Equivalent to treeCutSelect_indicator.
bit 18 = 262144	Equivalent to treeCutSelect_gomory.
bit 20 = 1048576	Equivalent to treeCutSelect_farkas.

treeCutSelect_clique *(boolean)*: Clique cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_cover *(boolean)*: Lifted cover cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_disableCutRows *(boolean)*: Disable cutting from cut rows ↩

See also treeCutSelect.

Default: 1

treeCutSelect_farkas *(boolean)*: Farkas cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_flowpath *(boolean)*: Flow path cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_gomory *(boolean)*: Strong Chvatal-Gomory cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_gubCover *(boolean)*: Lifted GUB cover cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_implication *(boolean)*: Implication cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_indicator *(boolean)*: Indicator constraint cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_liftAndProject *(boolean)*: Turn on automatic Lift and Project cutting strategy ↩

See also treeCutSelect.

Default: 1

treeCutSelect_mir *(boolean)*: Mixed Integer Rounding (MIR) cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_mirRowAggregation *(boolean)*: Turn on row aggregation for MIR cuts ↩

See also treeCutSelect.

Default: 1

treeCutSelect_zeroHalf *(boolean)*: Zero-half cuts ↩

See also treeCutSelect.

Default: 1

treeGomCuts *(integer)*: Branch and Bound: Number of rounds of Gomory cuts generated at nodes other than the first node in the tree ↩

Compare with the description for gomCuts. A value of -1 indicates the number of rounds is determined automatically.

Range: {-1, ..., ∞}

Default: auto

treeMemoryLimit *(integer)*: Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree ↩

This doesn't include memory used for presolve, heuristics, solving the LP relaxation, etc. When set to 0 (the default), the optimizer will calculate a limit automatically based on the amount of free physical memory detected in the machine. When the memory used by the branch and bound tree exceeds this limit, the optimizer will try to reduce the memory usage by writing lower-rated sections of the tree to a file called the "tree file". Though the solve can continue if it cannot bring the tree memory usage below the specified limit, performance will be inhibited and a message will be printed to the log.

Range: {0, ..., ∞}

Default: auto

treeMemorySavingTarget *(real)*: When the memory used by the branch-and-bound search tree exceeds the limit specified by the treeMemoryLimit control, the optimizer will try to save memory by writing lower-rated sections of the tree to the tree file ↩

The target amount of memory to save will be enough to bring memory usage back below the limit, plus enough extra to give the tree room to grow. The treeMemorySavingTarget control specifies the extra proportion of the tree's size to try to save; for example, if the tree memory limit is 1000Mb and treeMemorySavingTarget is 0.1, when the tree size exceeds 1000Mb the optimizer will try to reduce the tree size to 900Mb. Reducing the value of treeMemorySavingTarget will cause less extra nodes of the tree to be written to the tree file, but will result in the memory saving routine being triggered more often (as the tree will have less room in which to grow), which can reduce performance. Increasing the value of treeMemorySavingTarget will cause additional, more highly-rated nodes, of the tree to be written to the tree file, which can cause performance issues if these nodes are required later in the solve.

Range: [0, ∞]

Default: 0.4

treeQCCuts *(integer)*: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation ↩

This control only has an effect for problems with quadratic or second order cone constraints, and only if outer approximation has not been disabled by setting miqcpAlg to 0.

Range: {-1, ..., ∞}

Default: auto

varSelection *(integer)*: Branch and Bound: Determines the formula used to calculate the estimate of each integer variable, and thus which integer variable is selected to be branched on at a given node ↩

The variable selected to be branched on is the one with the maximum estimate.

Default: auto

value	meaning
-1	Determined automatically.
1	The minimum of the 'up' and 'down' pseudo costs.
2	The 'up' pseudo cost plus the 'down' pseudo cost.
3	The maximum of the 'up' and 'down' pseudo costs, plus twice the minimum of the 'up' and 'down' pseudo costs.
4	The maximum of the 'up' and 'down' pseudo costs.
5	The 'down' pseudo cost.
6	The 'up' pseudo cost.
7	A weighted combination of the 'up' and 'down' pseudo costs, where the weights depend on how fractional the variable is.
8	The product of the 'up' and 'down' pseudo costs.

writePrtSol *(boolean)*: Directs optimizer to output a "printsol" file ↩

Default: `0`

xslp_algorithm *(integer)*: Bit map describing the SLP algorithm(s) to be used ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `166`

value	meaning
`bit 0 = 1`	Equivalent to xslp_algorithm_noStepBounds.
`bit 1 = 2`	Equivalent to xslp_algorithm_stepBoundsAsRequired.
`bit 2 = 4`	Equivalent to xslp_algorithm_estimateStepBounds.
`bit 3 = 8`	Equivalent to xslp_algorithm_dynamicDamping.
`bit 4 = 16`	Equivalent to xslp_algorithm_holdValues.
`bit 5 = 32`	Equivalent to xslp_algorithm_retainPreviousValue.
`bit 6 = 64`	Equivalent to xslp_algorithm_resetDeltaZ.
`bit 7 = 128`	Equivalent to xslp_algorithm_quickConvergenceCheck.
`bit 8 = 256`	Equivalent to xslp_algorithm_escalatePenalties.
`bit 9 = 512`	Equivalent to xslp_algorithm_switchToPrimal.
`bit 11 = 2048`	Equivalent to xslp_algorithm_maxCostOption.
`bit 12 = 4096`	Equivalent to xslp_algorithm_residualErrors.
`bit 13 = 8192`	Equivalent to xslp_algorithm_noLPPolishing.
`bit 14 = 16384`	Equivalent to xslp_algorithm_cascadeBounds.
`bit 15 = 32768`	Equivalent to xslp_algorithm_clampExtendedActiveSB.
`bit 16 = 65536`	Equivalent to xslp_algorithm_clampExtendedAll.

xslp_algorithm_cascadeBounds *(boolean)*: Step bounds are updated to accomodate cascaded values (otherwise cascaded values are pushed to respect step bounds) ↩

Normally, cascading will respect the step bounds of the SLP variable being cascaded. However, allowing the cascaded value to fall outside the step bounds (i.e. expanding the step bounds) can lead to better linearizations, as cascading will set better values for the SLP variables regarding their determining rows; note, that this later strategy might interfere with convergence of the cascaded variables.

See also xslp_algorithm.

Default: `0`

xslp_algorithm_clampExtendedActiveSB *(boolean)*: Apply clamping when converged on extended criteria only with some variables having active step bounds ↩

When clamping is applied, then in any iteration when the solution would normally be deemed converged on extended criteria only, an extra step bound shrinking step is applied to help imposing strict convergence. In this variant, clamping is only applied on variables that have converged on extended criteria only and have active step bounds.

See also xslp_algorithm.

Default: `0`

xslp_algorithm_clampExtendedAll *(boolean)*: Apply clamping when converged on extended criteria only ↩

When clamping is applied, then in any iteration when the solution would normally be deemed converged on extended criteria only, an extra step bound shrinking step is applied to help imposing strict convergence. In this variant, clamping is applied on all variables that have converged on extended criteria only.

See also xslp_algorithm.

Default: `0`

xslp_algorithm_dynamicDamping *(boolean)*: Use dynamic damping ↩

Dynamic damping is sometimes an alternative to step bounding as a means of encouraging convergence, but it does not have the same power to force convergence as do step bounds.

See also xslp_algorithm.

Default: `0`

xslp_algorithm_escalatePenalties *(boolean)*: Escalate penalties ↩

Constraint penalties are increased after each SLP iteration where penalty vectors are present in the solution. Escalation applies an additional scaling factor to the penalty costs for active errors. This helps to prevent successive solutions becoming "stuck" because of a particular constraint, because its cost will be raised so that other constraints may become more attractive to violate instead and thus open up a new region to explore.

See also xslp_algorithm.

Default: `0`

xslp_algorithm_estimateStepBounds *(boolean)*: Estimate step bounds from early SLP iterations ↩

If initial step bounds are not being explicitly provided, this gives a good method of calculating reasonable values. Values will tend to be larger rather than smaller, to reduce the risk of infeasibility caused by excessive tightness of the step bounds.

See also xslp_algorithm.

Default: `1`

xslp_algorithm_holdValues *(boolean)*: Do not update values which are converged within strict tolerance ↩

Models which are numerically unstable may benefit from this setting, which does not update values which have effectively hardly changed. If a variable subsequently does move outside its strict convergence tolerance, it will be updated as usual.

See also xslp_algorithm.

Default: `0`

xslp_algorithm_maxCostOption *(boolean)*: Continue optimizing after penalty cost reaches maximum ↩

Normally if the penalty cost reaches its maximum (by default the value of infinity), the optimization will terminate with an unconverged solution. If the maximum value is set to a smaller value, then it may make sense to continue, using other means to determine when to stop.

See also xslp_algorithm.

Default: 0

xslp_algorithm_noLPPolishing *(boolean)*: Skip the solution polishing step if the LP postsolve returns a slightly infeasible, but claimed optimal solution ↩

Due to the nature of the SLP linearizations, and in particular because of the large differences in the objective function (model objective against penalty costs) some dual reductions in the linear presolver might introduce numerically instable reductions that cause slight infeasibilities to appear in postsolve. It is typically more efficient to remove these infeasibilities with an extra call to the linear optimizer; compared to switching these reductions off, which usually has a significant cost in performance. This bit is provided for numerically very hard problems, when the polishing step proves to be too expensive (Xpress SLP will report these if any in the final log summary).

See also xslp_algorithm.

Default: 0

xslp_algorithm_noStepBounds *(boolean)*: Do not apply step bounds ↩

The default algorithm uses step bounds to force convergence. Step bounds may not be appropriate if dynamic damping is used.

See also xslp_algorithm.

Default: 0

xslp_algorithm_quickConvergenceCheck *(boolean)*: Quick convergence check ↩

Normally, each variable is checked against all convergence criteria until either a criterion is found which it passes, or it is declared "not converged". Later (extended convergence) criteria are more expensive to test and, once an unconverged variable has been found, the overall convergence status of the solution has been established. The quick convergence check carries out checks on the strict criteria, but omits checks on the extended criteria when an unconverged variable has been found.

See also xslp_algorithm.

Default: 1

xslp_algorithm_resetDeltaZ *(boolean)*: Reset xslp_delta_z to zero when converged and continue SLP ↩

One of the mechanisms to avoid local optima is to retain small non-zero coefficients between delta vectors and constraints, even when the coefficient should strictly be zero. If this option is set, then a converged solution will be continued with zero coefficients as appropriate.

See also xslp_algorithm.

Default: 0

xslp_algorithm_residualErrors *(boolean)*: Accept a solution which has converged even if there are still significant active penalty error vectors ↩

Normally, the optimization will continue if there are active penalty vectors in the solution. However, it may be that there is no feasible solution (and so active penalties will always be present). Setting bit 12 means that, if other convergence criteria are met, then the solution will be accepted as converged and the optimization will stop.

See also xslp_algorithm.

Default: 0

xslp_algorithm_retainPreviousValue *(boolean)*: Retain previous value when cascading if determining row is zero ↩

If the determining row is zero (that is, all the coefficients interacting with it are either zero or in columns with a zero activity), then it is impossible to calculate a new value for the vector being cascaded. The choice is to use the solution value as it is, or to revert to the assumed value

See also xslp_algorithm.

Default: 1

xslp_algorithm_stepBoundsAsRequired *(boolean)*: Apply step bounds to SLP delta vectors only when required ↩

Step bounds can be applied to all vectors simultaneously, or applied only when oscillation of the delta vector (change in sign between successive SLP iterations) is detected.

See also xslp_algorithm.

Default: 1

xslp_algorithm_switchToPrimal *(boolean)*: Use the primal simplex algorithm when all error vectors become inactive ↩

The primal simplex algorithm often performs better than dual during the final stages of SLP optimization when there are relatively few basis changes between successive solutions. As it is impossible to establish in advance when the final stages are being reached, the disappearance of error vectors from the solution is used as a proxy.

See also xslp_algorithm.

Default: 0

xslp_analyze *(integer)*: Bit map activating additional options supporting model / solution path analyzis ↩

In most cases, the value of this control does not affect the solution process itself. However, bit 3 (extended summary) will cause SLP to do more function evaluations, and the presence of non-deterministic user functions might cause changes in the solution process. These options are off by default due to performance considerations.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
bit 3 = 8	Equivalent to xslp_analyze_extendedFinalSummary.
bit 4 = 16	Equivalent to xslp_analyze_infeasibleIteration.
bit 6 = 64	Equivalent to xslp_analyze_saveLinearizations.
bit 7 = 128	Equivalent to xslp_analyze_saveIterBasis.
bit 8 = 256	Equivalent to xslp_analyze_saveFile.

xslp_analyze_extendedFinalSummary *(boolean)*: Include an extended iteration summary ↩

See also xslp_analyze.

Default: `0`

xslp_analyze_infeasibleIteration *(boolean)*: Run infeasibility analysis on infeasible iterations ↩

See also xslp_analyze.

Default: `0`

xslp_analyze_saveFile *(boolean)*: Create an Xpress SLP save file at every xslp_autosave iterations ↩

See also xslp_analyze.

Default: `0`

xslp_analyze_saveIterBasis *(boolean)*: Write the initial basis of the linearizations to disk at every xslp_autosave iterations ↩

See also xslp_analyze.

Default: `0`

xslp_analyze_saveLinearizations *(boolean)*: Write the linearizations to disk at every xslp_autosave iterations ↩

See also xslp_analyze.

Default: `0`

xslp_aTol_a *(real)*: Absolute delta convergence tolerance ↩

The absolute delta convergence criterion assesses the change in value of a variable (δX) against the absolute delta convergence tolerance. If $\delta X <$ xslp_aTol_a then the variable has converged on the absolute delta convergence criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_aTol_r *(real)*: Relative delta convergence tolerance ↩

The relative delta convergence criterion assesses the change in value of a variable (δX) relative to the value of the variable (X), against the relative delta convergence tolerance. If $\delta X <$ $X *$ xslp_aTol_r then the variable has converged on the relative delta convergence criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_augmentation *(integer)*: Bit map describing the SLP augmentation method(s) to be used ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `12`

value	meaning
`bit 0 = 1`	Equivalent to xslp_augmentation_minimum.
`bit 1 = 2`	Equivalent to xslp_augmentation_evenHanded.
`bit 2 = 4`	Equivalent to xslp_augmentation_equalityErrorVectors.
`bit 3 = 8`	Equivalent to xslp_augmentation_allErrorVectors.
`bit 4 = 16`	Equivalent to xslp_augmentation_penaltyDeltaVectors.
`bit 5 = 32`	Equivalent to xslp_augmentation_aMeanWeight.
`bit 6 = 64`	Equivalent to xslp_augmentation_sbFromValues.
`bit 7 = 128`	Equivalent to xslp_augmentation_sbFromAbsValues.
`bit 8 = 256`	Equivalent to xslp_augmentation_stepBoundRows.
`bit 9 = 512`	Equivalent to xslp_augmentation_allRowErrorVectors.
`bit 10 = 1024`	Equivalent to xslp_augmentation_noUpdateIfOnlyIV.

xslp_augmentation_allErrorVectors *(boolean)*: Penalty error vectors on all non-linear inequality constraints ↩

The linearization of a nonlinear constraint is inevitably an approximation and so may not be feasible except at the point of linearization. Adding penalty error vectors allows the linear approximation to be violated at a cost and so ensures that the linearized constraint is feasible.

See also xslp_augmentation.

Default: `1`

xslp_augmentation_allRowErrorVectors *(boolean)*: Penalty error vectors on all constraints ↩

If the linear portion of the underlying model may actually be infeasible, then applying penalty vectors to all rows may allow identification of the infeasibility and may also allow a useful solution to be found.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_aMeanWeight *(boolean)*: Use arithmetic means to estimate penalty weights ↩

Penalty weights are estimated from the magnitude of the elements in the constraint or interacting rows. Geometric means are normally used, so that a few excessively large or small values do not distort the weights significantly. Arithmetic means will value the coefficients more equally.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_equalityErrorVectors *(boolean)*: Penalty error vectors on all non-linear equality constraints ↩

The linearization of a nonlinear equality constraint is inevitably an approximation and so will not generally be feasible except at the point of linearization. Adding penalty error vectors allows the linear approximation to be violated at a cost and so ensures that the linearized constraint is feasible.

See also xslp_augmentation.

Default: `1`

xslp_augmentation_evenHanded *(boolean)*: Even handed augmentation ↩

Standard augmentation treats variables which appear in non-constant coefficients in a different way from those which contain non-constant coefficients. Even- handed augmentation treats them all in the same way by replacing each non- constant coefficient C in a vector V by a new coefficient C∗V in the "equals" column (which has a fixed activity of 1) and creating delta vectors for all types of variable in the same way.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_minimum *(boolean)*: Minimum augmentation ↩

Standard augmentation includes delta vectors for all variables involved in nonlinear terms (in non-constant coefficients or as vectors containing non- constant coefficients). includes delta vectors only for variables in non- constant coefficients. This produces a smaller linearization, but there is less control on convergence, because convergence control (for example, step bounding) cannot be applied to variables without deltas.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_noUpdateIfOnlyIV *(boolean)*: Intial values do not imply an SLP variable ↩

Having an initial value will not cause the augmentation to include the corresponding delta variable; i.e. treat the variable as an SLP variable. Useful to provide initial values necessary in the first linearization in case of a minimal augmentation, or as a convenience option when it's easiest to set an initial value for all variables for some reason.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_penaltyDeltaVectors *(boolean)*: Penalty vectors to exceed step bounds ↩

Although it has rarely been found necessary or desirable in practice, Xpress-SLP allows step bounds to be violated at a cost. This may help with feasibility but it generally slows down or prevents convergence, so it should be used only if found absolutely necessary.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_sbFromAbsValues *(boolean)*: Estimate step bounds from absolute values of row coefficients ↩

If step bounds are to be imposed from the start, the best approach is to provide explicit values for the bounds. Alternatively, Xpress-SLP can estimate the values from the largest estimated magnitude of the coefficients in the relevant rows.

See also xslp_augmentation.

Default: `0`

xslp_augmentation_sbFromValues *(boolean)*: Estimate step bounds from values of row coefficients ↩

If step bounds are to be imposed from the start, the best approach is to provide explicit values for the bounds. Alternatively, Xpress-SLP can estimate the values from the range of estimated coefficient sizes in the relevant rows.

See also xslp_augmentation.

Default: 0

xslp_augmentation_stepBoundRows *(boolean)*: Row-based step bounds ↩

Step bounds are normally applied as bounds on the delta variables. Some applications may find that using explicit rows to bound the delta vectors gives better results.

See also xslp_augmentation.

Default: 0

xslp_autosave *(integer)*: Frequency with which to save the model ↩

A value of zero means that the model will not automatically be saved. A positive value of n will save model information at every nth SLP iteration as requested by xslp_analyze.

Range: {0, ..., ∞}

Default: 0

xslp_barCrossOverStart *(integer)*: Default crossover activation behaviour for barrier start ↩

When xslp_barLimit is set, xslp_barCrossOverStart offers an overwrite control on when crossover is applied. A positive value indicates that crossover should be disabled in iterations smaller than xslp_barCrossOverStart and should be enabled afterwards, or when stalling is detected as described in xslp_barStartOps. A value of 0 indicates to respect the value of crossover and only overwrite its value when stalling is detected. A value of -1 indicates to always rely on the value of crossover.

Range: {0, ..., ∞}

Default: 0

xslp_barLimit *(integer)*: Number of initial SLP iterations using the barrier method ↩

Particularly for larger models, using the Newton barrier method is faster in the earlier SLP iterations. Later on, when the basis information becomes more useful, a simplex method generally performs better. xslp_barLimit sets the number of SLP iterations which will be performed using the Newton barrier method.

Range: {0, ..., ∞}

Default: 0

xslp_barStallingLimit *(integer)*: Number of iterations to allow numerical failures in barrier before switching to dual ↩

On large problems, it may be beneficial to warm start progress by running a number of iterations with the barrier solver as specified by xslp_barLimit. On some numerically difficult problems, the barrier may stop prematurely due to numerical issues. Such solves can sometimes be finished if crossover is applied. After xslp_barStallingLimit such attempts, SLP will automatically switch to use the dual simplex.

Range: {0, ..., ∞}

Default: 3

xslp_barStallingObjLimit *(integer)*: Number of iterations over which to measure the objective change for barrier iterations with no crossover ↩

On large problems, it may be beneficial to warm start progress by running a number of iterations with the barrier solver without crossover by setting xslp_barLimit to a positive value and setting crossover to 0. A potential drawback is slower convergence due to the interior point provided by the barrier solve keeping a higher number of variables active. This may lead to stalling in progress, negating the benefit of using the barrier. When in the last xslp_barStallingObjLimit iterations no significant progress has been made, crossover is automatically enabled.

Range: {0, ..., ∞}

Default: 3

xslp_barStallingTol *(real)*: Required change in the objective when progress is measured in barrier iterations without crossover ↩

Minumum objective variability change required in relation to control xslp_barStallingObjLimit for the iterations to be regarded as making progress. The net objective, error cost and error sum are taken into account.

Range: [0, ∞]

Default: 0.05

xslp_barStartOps *(integer)*: Controls behaviour when the barrier is used to solve the linearizations ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

value	meaning
bit 0 = 1	Equivalent to xslp_barStartOps_stallingObjective.
bit 1 = 2	Equivalent to xslp_barStartOps_stallingNumerical.
bit 2 = 4	Equivalent to xslp_barStartOps_allowInteriorSol.

xslp_barStartOps_allowInteriorSol *(boolean)*: If a non-vertex converged solution found by barrier without crossover can be returned as a final solution ↩

See also xslp_barStartOps.

Default: 1

xslp_barStartOps_stallingNumerical *(boolean)*: Fall back to dual simplex if too many numerical problems are reported by the barrier ↩

See also xslp_barStartOps.

Default: 1

xslp_barStartOps_stallingObjective *(boolean)*: Check objective progress when no crossover is applied ↩

See also xslp_barStartOps.

Default: 1

xslp_calcThreads *(integer)*: Number of threads used for formula and derivatives evaluations ↩

When beneficial, SLP can calculate formula values and partial derivative information in parallel.

Range: {-1, ..., 1}

Default: auto

xslp_cdTol_a *(real)*: Absolute tolerance for deducing constant derivatives ↩

The absolute tolerance test for constant derivatives is used as follows: If the value of the user function at point X0 is Y0 and the values at (X0-δX) and (X0+δX) are Yd and Yu respectively, then the numerical derivatives at X0 are: "down" derivative Dd = (Y0 - Yd) / δX "up" derivative Du = (Yu - Y0) / δX If abs(Dd-Du) $\leq$ xslp_cdTol_a then the derivative is regarded as constant.

Range: [0, ∞]

Default: 1e-08

xslp_cdTol_r *(real)*: Relative tolerance for deducing constant derivatives ↩

The relative tolerance test for constant derivatives is used as follows: If the value of the user function at point X0 is Y0 and the values at (X0-δX) and (X0+δX) are Yd and Yu respectively, then the numerical derivatives at X0 are: "down" derivative Dd = (Y0 - Yd) / δX "up" derivative Du = (Yu - Y0) / δX If abs(Dd-Du) $\leq$ xslp_cdTol_r $*$ abs(Yd+Yu)/2 then the derivative is regarded as constant.

Range: [0, ∞]

Default: 1e-08

xslp_clampShrink *(real)*: Shrink ratio used to impose strict convergence on variables converged in extended criteria only ↩

If the solution has converged but there are variables converged on extended criteria only, the xslp_clampShrink acts as a shrinking ratio on the step bounds and the problem is optimized (if necessary multiple times), with the purpose of expediting strict convergence on all variables. xslp_algorithm controls if this shrinking is applied at all, and if shrinking is applied to of the variables converged on extended criteria only with active step bounds only, or if on all variables.

Range: [0, 1]

Default: 0.3

xslp_clampValidationTol_a *(real)*: Absolute validation tolerance for applying xslp_clampShrink ↩

If set and the absolute validation value is larger than this value, then control xslp_clampShrink is checked once the solution has converged, but there are variables converged on extended criteria only.

Range: [0, ∞]

Default: not set

xslp_clampValidationTol_r *(real)*: Relative validation tolerance for applying xslp_clampShrink ↩

If set and the relative validation value is larger than this value, then control xslp_clampShrink is checked once the solution has converged, but there are variables converged on extended criteria only.

Range: [0, ∞]

Default: not set

xslp_convergenceOps *(integer)*: Bit map describing which convergence tests should be carried out ↩

Provides fine tuned control (over setting the related convergence tolerances) of which convergence checks are carried out.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 7167

value	meaning
bit 0 = 1	Equivalent to xslp_convergenceOps_cTol.
bit 1 = 2	Equivalent to xslp_convergenceOps_aTol.
bit 2 = 4	Equivalent to xslp_convergenceOps_mTol.
bit 3 = 8	Equivalent to xslp_convergenceOps_iTol.
bit 4 = 16	Equivalent to xslp_convergenceOps_sTol.
bit 5 = 32	Check for user provided convergence.
bit 6 = 64	Equivalent to xslp_convergenceOps_vTol.
bit 7 = 128	Equivalent to xslp_convergenceOps_xTol.
bit 8 = 256	Equivalent to xslp_convergenceOps_oTol.
bit 9 = 512	Equivalent to xslp_convergenceOps_wTol.
bit 10 = 1024	Equivalent to xslp_convergenceOps_extendedScaling.
bit 11 = 2048	Equivalent to xslp_convergenceOps_validation.
bit 12 = 4096	Equivalent to xslp_convergenceOps_validationK.

xslp_convergenceOps_aTol *(boolean)*: Execute the delta tolerance checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_cTol *(boolean)*: Execute the closure tolerance checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_extendedScaling *(boolean)*: Take scaling of individual variables / rows into account ↩

See also xslp_convergenceOps.

Default: 0

xslp_convergenceOps_iTol *(boolean)*: Execute the impact tolerance checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_mTol *(boolean)*: Execute the matrix tolerance checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_oTol *(boolean)*: Execute the objective range + active step bound check ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_sTol *(boolean)*: Execute the slack impact tolerance checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_validation *(boolean)*: Execute the validation target convergence checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_validationK *(boolean)*: Execute the first order optimality target convergence checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_vTol *(boolean)*: Execute the objective range checks ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_wTol *(boolean)*: Execute the convergence continuation check ↩

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_xTol *(boolean)*: Execute the objective range + constraint activity check ↩

See also xslp_convergenceOps.

Default: 1

xslp_cTol *(real)*: Closure convergence tolerance ↩

The closure convergence criterion measures the change in value of a variable (δX) relative to the value of its initial step bound (B), against the closure convergence tolerance. If $\delta X < B * xslp\_cTol$ then the variable has converged on the closure convergence criterion. If no explicit initial step bound is provided, then the test will not be applied and the variable can never converge on the closure criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_cutStrategy *(integer)*: Determines whihc cuts to apply in the MISLP search when the default SLP-in-MIP strategy is used ↩

Cuts are derived from the linearizations and are local cuts in that they are valid in the linearization and not necessarily valid for the full problem. The values mirror that of XPRS_CUTSTRATEGY.

Range: {-1, ..., 3}

Default: 0

xslp_damp *(real)*: Damping factor for updating values of variables ↩

The damping factor sets the next assumed value for a variable based on the previous assumed value (X0) and the actual value (X1). The new assumed value is given by X1∗xslp_damp + X0∗(1-xslp_damp)

Range: [0, 1]

Default: 1

xslp_dampExpand *(real)*: Multiplier to increase damping factor during dynamic damping ↩

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp_sameDamp successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to D∗xslp_dampExpand + xslp_dampMax∗(1-xslp_dampExpand)

Range: [0, 1]

Default: 1

xslp_dampMax *(real)*: Maximum value for the damping factor of a variable during dynamic damping ↩

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp_sameDamp successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to D∗xslp_dampExpand + xslp_dampMax∗(1-xslp_dampExpand)

Range: [0, 1]

Default: 1

xslp_dampMin *(real)*: Minimum value for the damping factor of a variable during dynamic damping ↩

If dynamic damping is enabled, the damping factor for a variable will be decreased if successive changes are in the opposite direction. More precisely, the damping factor (D) for the variable will be reset to D∗xslp_dampShrink + xslp_dampMin∗(1-xslp_dampExpand)

Range: [0, 1]

Default: 1

xslp_dampShrink *(real)*: Multiplier to decrease damping factor during dynamic damping ↩

If dynamic damping is enabled, the damping factor for a variable will be decreased if successive changes are in the opposite direction. More precisely, the damping factor (D) for the variable will be reset to D∗xslp_dampShrink + xslp_dampMin∗(1-xslp_dampExpand)

Range: [0, 1]

Default: 1

xslp_dampStart *(integer)*: SLP iteration at which damping is activated ↩

If damping is used as part of the SLP algorithm, it can be delayed until a specified SLP iteration. This may be appropriate when damping is used to encourage convergence after an un-damped algorithm has failed to converge.

Range: {0, ..., ∞}

Default: 0

xslp_defaultStepBound *(real)*: Minimum initial value for the step bound of an SLP variable if none is explicitly given ↩

If no initial step bound value is given for an SLP variable, this will be used as a minimum value. If the algorithm is estimating step bounds, then the step bound actually used for a variable may be larger than the default. A default initial step bound is ignored when testing for the closure tolerance xslp_cTol: if there is no specific value, then the test will not be applied.

Range: [0, ∞]

Default: 16

xslp_deltaCost *(real)*: Initial penalty cost multiplier for penalty delta vectors ↩

If penalty delta vectors are used, this parameter sets the initial cost factor. If there are active penalty delta vectors, then the penalty cost may be increased.

Range: [0, ∞]

Default: 200

xslp_deltaCostFactor *(real)*: Factor for increasing cost multiplier on total penalty delta vectors ↩

If there are active penalty delta vectors, then the penalty cost multiplier will be increased by a factor of xslp_deltaCostFactor up to a maximum of xslp_deltaMaxCost

Range: [1, ∞]

Default: 1.3

xslp_deltaMaxCost *(real)*: Maximum penalty cost multiplier for penalty delta vectors ↩

If there are active penalty delta vectors, then the penalty cost multiplier will be increased by a factor of xslp_deltaCostFactor up to a maximum of xslp_deltaMaxCost

Range: [0, ∞]

Default: 1e+20

xslp_deltaZLimit *(integer)*: Number of SLP iterations during which to apply xslp_delta_z ↩

xslp_delta_z is used to retain small derivatives which would otherwise be regarded as zero. This is helpful in avoiding local optima, but may make the linearized problem more difficult to solve because of the number of small nonzero elements in the resulting matrix. xslp_deltaZLimit can be set to a nonzero value, which is then the number of iterations for which xslp_delta_z will be used. After that, small derivatives will be set to zero. A negative value indicates no automatic perturbations to the derivatives in any situation.

Range: {0, ..., ∞}

Default: 0

xslp_delta_a *(real)*: Absolute perturbation of values for calculating numerical derivatives ↩

First-order derivatives are calculated by perturbing the value of each variable in turn by a small amount. The amount is determined by the absolute and relative delta factors as follows: xslp_delta_a + abs(X)*xslp_delta_r where (X) is the current value of the variable. If the perturbation takes the variable outside a bound, then the perturbation normally made only in the opposite direction.

Range: [0, ∞]

Default: 0.001

xslp_delta_r *(real)*: Relative perturbation of values for calculating numerical derivatives ↩

First-order derivatives are calculated by perturbing the value of each variable in turn by a small amount. The amount is determined by the absolute and relative delta factors as follows: xslp_delta_a + abs(X)*xslp_delta_r where (X) is the current value of the variable. If the perturbation takes the variable outside a bound, then the perturbation normally made only in the opposite direction.

Range: [0, ∞]

Default: 0.001

xslp_delta_x *(real)*: Minimum absolute value of delta coefficients to be retained ↩

If the value of a coefficient in a delta column is less than this value, it will be reset to zero. Larger values of xslp_delta_x will result in matrices with fewer elements, which may be easier to solve. However, there will be increased likelihood of local optima as some of the small relationships between variables and constraints are deleted. There may also be increased difficulties with singular bases resulting from deletion of pivot elements from the matrix.

Range: [0, ∞]

Default: 1e-06

xslp_delta_z *(real)*: Tolerance used when calculating derivatives ↩

If the absolute value of a variable is less than this value, then a value of xslp_delta_z will be used instead for calculating derivatives. If a nonzero derivative is calculated for a formula which always results in a matrix coefficient less than xslp_delta_z, then a larger value will be substituted so that at least one of the coefficients is xslp_delta_z in magnitude. If xslp_deltaZLimit is set to a positive number, then when that number of iterations have passed, values smaller than xslp_delta_z will be set to zero.

Range: [0, ∞]

Default: 1e-05

xslp_delta_zero *(real)*: Absolute zero acceptance tolerance used when calculating derivatives ↩

Provides an override value for the xslp_delta_z behavior. Derivatives smaller than xslp_delta_zero will not be substituted by xslp_delta_z, defining a range in which derivatives are deemed nonzero and are affected by xslp_delta_z. A negative value means that this tolerance will not be applied.

Range: [-∞, ∞]

Default: -1

xslp_derivatives *(boolean)*: Bitmap describing the method of calculating derivatives ↩

If no bits are set then numerical derivatives are calculated using finite differences. Analytic derivatives cannot be used for formulae involving discontinuous functions. They may not work well with functions which are not smooth (such as MAX), or where the derivative changes very quickly with the value of the variable (such as LOG of small values). Both first and second order analytic derivatives can either be calculated as symbolic formulas, or by the means of auto-differentiation, with the exception that the second order symbolic derivatives require that the first order derivatives are also calculated using the symbolic method.

Default: 1

value	meaning
bit 0 = 1	Analytic derivatives where possible
bit 1 = 2	Avoid embedding numerical derivatives of instantiated functions into analytic derivatives

xslp_djTol *(real)*: Tolerance on DJ value for determining if a variable is at its step bound ↩

If a variable is at its step bound and within the absolute delta tolerance xslp_aTol_a or closure tolerance xslp_cTol then the step bounds will not be further reduced. If the DJ is greater in magnitude than xslp_djTol then the step bound may be relaxed if it meets the necessary criteria.

Range: [0, ∞]

Default: 1e-06

xslp_ecfCheck *(integer)*: Check feasibility at the point of linearization for extended convergence criteria ↩

The extended convergence criteria measure the accuracy of the solution of the linear approximation compared to the solution of the original nonlinear problem. For this to work, the linear approximation needs to be reasonably good at the point of linearization. In particular, it needs to be reasonably close to feasibility. xslp_ecfCheck is used to determine what checking of feasibility is carried out at the point of linearization. If the point of linearization at the start of an SLP iteration is deemed to be infeasible, then the extended convergence criteria are not used to decide convergence at the end of that SLP iteration. If all that is required is to decide that the point of linearization is not feasible, then the search can stop after the first infeasible constraint is found (parameter is set to 1). If the actual number of infeasible constraints is required, then xslp_ecfCheck should be set to 2, and all constraints will be checked. The number of infeasible constraints found at the point of linearization is returned in XSLP_ECFCOUNT.

Default: 1

value	meaning
0	No check (extended criteria are always used);
1	Check until one infeasible constraint is found;
2	Check all constraints.

xslp_ecfTol_a *(real)*: Absolute tolerance on testing feasibility at the point of linearization ↩

The extended convergence criteria test how well the linearization approximates the true problem. They depend on the point of linearization being a reasonable approximation — in particular, that it should be reasonably close to feasibility. Each constraint is tested at the point of linearization, and the total positive and negative contributions to the constraint from the columns in the problem are calculated. A feasibility tolerance is calculated as the largest of xslp_ecfTol_a and max(abs(Positive), abs(Negative)) ∗ xslp_ecfTol_r If the calculated infeasibility is greater than the tolerance, the point of linearization is regarded as infeasible and the extended convergence criteria will not be applied. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-1 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_ecfTol_r *(real)*: Relative tolerance on testing feasibility at the point of linearization ↩

The extended convergence criteria test how well the linearization approximates the true problem. They depend on the point of linearization being a reasonable approximation — in particular, that it should be reasonably close to feasibility. Each constraint is tested at the point of linearization, and the total positive and negative contributions to the constraint from the columns in the problem are calculated. A feasibility tolerance is calculated as the largest of xslp_ecfTol_a and max(abs(Positive), abs(Negative)) ∗ xslp_ecfTol_r If the calculated infeasibility is greater than the tolerance, the point of linearization is regarded as infeasible and the extended convergence criteria will not be applied. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-1 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_enforceCostShrink *(real)*: Factor by which to decrease the current penalty multiplier when enforcing rows ↩

When feasiblity of a row cannot be achieved by increasing the penalty cost on its error variable, removing the variable (fixing it to zero) can force the row to be satisfied, as set by xslp_enforceMaxCost. After the error variables have been removed (which is equivalent to setting to row to be enforced) the penalties on the remaining error variables are rebalanced to allow for a reduction in the size of the penalties in the objective in order to achive better numerical behaviour.

Range: [`0`, `1`]

Default: `1e-05`

xslp_enforceMaxCost *(real)*: Maximum penalty cost in the objective before enforcing most violating rows ↩

When feasiblity of a row cannot be achieved by increasing the penalty cost on its error variable, removing the variable (fixing it to zero) can force the row to be satisfied. After the error variables have been removed (which is equivalent to setting to row to be enforced) the penalties on the remaining error variables are rebalanced to allow for a reduction in the size of the penalties in the objective in order to achive better numerical behaviour, controlled by xslp_enforceCostShrink.

Range: [`0`, ∞]

Default: `1e+11`

xslp_errorCost *(real)*: Initial penalty cost multiplier for penalty error vectors ↩

If penalty error vectors are used, this parameter sets the initial cost factor. If there are active penalty error vectors, then the penalty cost may be increased.

Range: [`0`, ∞]

Default: `200`

xslp_errorCostFactor *(real)*: Factor for increasing cost multiplier on total penalty error vectors ↩

If there are active penalty error vectors, then the penalty cost multiplier will be increased by a factor of xslp_errorCostFactor up to a maximum of xslp_errorMaxCost

Range: [1, ∞]

Default: 1.3

xslp_errorMaxCost *(real)*: Maximum penalty cost multiplier for penalty error vectors ↩

If there are active penalty error vectors, then the penalty cost multiplier will be increased by a factor of xslp_errorCostFactor up to a maximum of xslp_errorMaxCost

Range: [0, ∞]

Default: 1e+20

xslp_errorTol_a *(real)*: Absolute tolerance for error vectors ↩

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than xslp_errorTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_r ∗ Obj where Obj is the current objective function value.

Range: [0, ∞]

Default: 1e-05

xslp_errorTol_p *(real)*: Absolute tolerance for printing error vectors ↩

The solution log includes a print of penalty delta and penalty error vectors with an activity greater than xslp_errorTol_p.

Range: [0, ∞]

Default: 0.0001

xslp_escalation *(real)*: Factor for increasing cost multiplier on individual penalty error vectors ↩

If penalty cost escalation is activated in xslp_algorithm then the penalty cost multiplier will be increased by a factor of xslp_escalation for any active error vector up to a maximum of xslp_maxWeight.

Range: [1, ∞]

Default: 1.25

xslp_eTol_a *(real)*: Absolute tolerance on penalty vectors ↩

For each penalty error vector, the contribution to its constraint is calculated, together with the total positive and negative contributions to the constraint from other vectors. If its contribution is less than xslp_eTol_a or less than Positive∗xslp_eTol_r or less than abs(Negative)∗xslp_eTol_r then it will be regarded as insignificant and will not have its penalty increased. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: 0.0001

xslp_eTol_r *(real)*: Relative tolerance on penalty vectors ↩

For each penalty error vector, the contribution to its constraint is calculated, together with the total positive and negative contributions to the constraint from other vectors. If its contribution is less than xslp_eTol_a or less than Positive∗xslp_eTol_r or less than abs(Negative)∗xslp_eTol_r then it will be regarded as insignificant and will not have its penalty increased. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `0.0001`

xslp_evTol_a *(real)*: Absolute tolerance on total penalty costs ↩

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than xslp_errorTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_r ∗ Obj where Obj is the current objective function value. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-2 and 1e-6, but normally a magnitude larger than xslp_eTol_a.

Range: [-∞, ∞]

Default: `-1`

xslp_evTol_r *(real)*: Relative tolerance on total penalty costs ↩

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than xslp_errorTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_r ∗ Obj where Obj is the current objective function value. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-2 and 1e-6, but normally a magnitude larger than xslp_eTol_r.

Range: [-∞, ∞]

Default: `-1`

xslp_expand *(real)*: Multiplier to increase a step bound ↩

If step bounding is enabled, the step bound for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp_sameCount successive changes reaching the step bound and in the same direction for a variable, then the step bound (B) for the variable will be reset to B∗xslp_expand.

Range: [1, ∞]

Default: `2`

xslp_feasTolTarget *(real)*: When set, this defines a target feasibility tolerance to which the linearizations are solved to ↩

This is a soft version of XPRS_FEASTOL, and will dynamically revert back to XPRS_FEASTOL if the desired accuracy could not be achieved.

Range: [0, ∞]

Default: `not set`

xslp_filter *(integer)*: Bit map for controlling solution updates ↩

Bits 0 determine if XSLPgetslpsol should return the final converged solution, or the solution which had the best value according to the merit function. If bit 1 is set, a cascaded solution which does not improve the merit function will be rejected (Xpress SLP will revert to the solution of the linearization). Bits 2-3 determine the strategy for when the step direction is not improving according to the merit function.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `3`

value	meaning
`bit 0 = 1`	Equivalent to xslp_filterKeepBest.
`bit 1 = 2`	Check cascaded solutions against improvements in the merit function.
`bit 2 = 4`	Equivalent to xslp_filterZeroLineSearch.
`bit 3 = 8`	Equivalent to xslp_filterZeroLineSearchTR.

xslp_filterKeepBest *(boolean)*: Retrain solution best according to the merit function ↩

See also xslp_filter.

Default: `1`

xslp_filterZeroLineSearch *(boolean)*: Force minimum step sizes in line search ↩

See also xslp_filter.

Default: `0`

xslp_filterZeroLineSearchTR *(boolean)*: Accept the trust region step is the line search returns a zero step size ↩

See also xslp_filter.

Default: `0`

xslp_findIV *(integer)*: Option for running a heuristic to find a feasible initial point ↩

The procedure uses bound reduction (and, up to an extent, probing) to obtain a point in the initial bounding box that is feasible for the bound reduction techniques. If an initial point is already specified and is found not to violate bound reduction, then the heuristic is not run and the given point is used as the initial solution.

Default: `auto`

value	meaning
`-1`	Automatic (default).
`0`	Disable the heuristic.
`1`	Enable the heuristic.

xslp_granularity *(real)*: Base for calculating penalty costs ↩

If xslp_granularity > 1, then initial penalty costs will be powers of xslp_granularity.

Range: [1, ∞]

Default: 4

xslp_hessian *(integer)*: Second order differentiation mode when using analytical derivatives ↩

Symbolic mode differentiation for the second order derivatives is only available when xslp_jacobian is also set to symbolic mode.

Default: -1

value	meaning
1	Numerical derivatives (finite difference)
2	Symbolic differentiation
3	Automatic differentiation
-1,0	Automatic selection

xslp_heurStrategy *(integer)*: Branch and Bound: MINLP heuristic strategy ↩

On some problems it is worth trying more comprehensive heuristic strategies by setting HEURSTRATEGY to 2 or 3. Note that HEURSTRATEGY is deprecated, use heurEmphasis instead.

Default: auto

value	meaning
-1	Automatic selection of heuristic strategy.
0	No heuristics.
1	Basic heuristic strategy.
2	Enhanced heuristic strategy.
3	Extensive heuristic strategy.
4	Run all heuristics without effort limits.

xslp_infeasLimit *(integer)*: Maximum number of consecutive infeasible SLP iterations which can occur before Xpress-SLP terminates ↩

An infeasible solution to an SLP iteration means that is likely that Xpress-SLP will create a poor linear approximation for the next SLP iteration. Sometimes, small infeasibilities arise because of numerical difficulties and do not seriously affect the solution process. However, if successive solutions remain infeasible, it is unlikely that Xpress-SLP will be able to find a feasible converged solution. xslp_infeasLimit sets the number of successive SLP iterations which must take place before Xpress-SLP terminates with a status of "infeasible solution".

Range: {0, ..., ∞}

Default: 3

xslp_infinity *(real)*: Value returned by a divide-by-zero in a formula ↩

Range: [0, ∞]

Default: 1e+10

xslp_iterLimit *(integer)*: Maximum number of SLP iterations ↩

If Xpress-SLP reaches xslp_iterLimit without finding a converged solution, it will stop. For MISLP, the limit is on the number of SLP iterations at each node.

Range: {-1, ..., ∞}

Default: auto

xslp_iTol_a *(real)*: Absolute impact convergence tolerance ↩

The absolute impact convergence criterion assesses the change in the effect of a coefficient in a constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. E = X ∗ C where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as E1 = X ∗ C0 + δX ∗ C'0 where X is as before, C0 is the value of the coefficient C calculated using the assumed values for the variables and C'0 is the value of ∂C ∂X calculated using the assumed values for the variables. If C1 is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by δE = X ∗ C1 - (X ∗ C0 + δX ∗ C'0) If δE < xslp_iTol_a then the variable has passed the absolute impact convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_iTol_r *(real)*: Relative impact convergence tolerance ↩

The relative impact convergence criterion assesses the change in the effect of a coefficient in a constraint in relation to the magnitude of the constituents of the constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. E = X ∗ C where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as E1 = X ∗ C0 + δX ∗ C'0 where X is as before, C0 is the value of the coefficient C calculated using the assumed values for the variables and C'0 is the value of ∂C ∂X calculated using the assumed values for the variables. If C1 is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by δE = X ∗ C1 - (X ∗ C0 + δX ∗ C'0) All the elements of the constraint are examined, excluding delta and error vectors: for each, the contribution to the constraint is evaluated as the element multiplied by the activity of the vector in which it appears; it is then included in a total positive contribution or total negative contribution depending on the sign of the contribution. If the predicted effect of the coefficient is positive, it is tested against the total positive contribution; if the effect of the coefficient is negative, it is tested against the total negative contribution. If T0 is the total positive or total negative contribution to the constraint (as appropriate) and δE < T0∗xslp_iTol_r then the variable has passed the relative impact convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_jacobian *(integer)*: First order differentiation mode when using analytical derivatives ↩

Symbolic mode differentiation for the second order derivatives is only available when xslp_jacobian is set to symbolic mode.

Default: `-1`

value	meaning
`1`	Numerical derivatives (finite difference)
`2`	Symbolic differentiation
`3`	Automatic differentiation
`-1,0`	Automatic selection

xslp_linQuadBR *(integer)*: Use linear and quadratic constraints and objective function to further reduce bounds on all variables ↩

While bound reduction is effective when performed on nonlinear, nonquadratic constraints and objective function, it can be useful to obtain tightened bounds from linear and quadratic constraints, as the corresponding variables may appear in other nonlinear constraints. This option then allows for a slightly more expensive bound reduction procedure, at the benefit of further reduction in the problem's bounds.

Default: `auto`

value	meaning
`-1`	Automatic selection
`0`	Disable
`1`	Enable

xslp_log *(integer)*: Level of printing during SLP iterations ↩

Default: `0`

value	meaning
`-1`	None
`0`	Minimal
`1`	Normal: iteration, penalty vectors
`2`	Omit from convergence log any variables which have converged
`3`	Omit from convergence log any variables which have already converged (except variables on step bounds)
`4`	Include all variables in convergence log
`5`	Include user function call communications in the log

xslp_lsIterLimit *(integer)*: Number of iterations in the line search ↩

The line search attempts to refine the step size suggested by the trust region step bounds. The line search is a local method; the control sets a maximum on the number of model evaluations during the line search.

Range: {`0`, ..., ∞}

Default: `0`

xslp_lsPatternLimit *(integer)*: Number of iterations in the pattern search preceding the line search ↩

When positive, defines the number of samples taken along the step size suggested by the trust region step bounds before initiating the line search. Useful for highly non-convex problems.

Range: {0, ..., ∞}

Default: 0

xslp_lsStart *(integer)*: Iteration in which to active the line search ↩

Range: {0, ..., ∞}

Default: 8

xslp_lsZeroLimit *(integer)*: Maximum number of zero length line search steps before line search is deactivated ↩

When the line search repeatedly returns a zero step size, counteracted by bits set on xslp_filter, the effort spent in line search is redundant, and line search will be deactivated after xslp_lsZeroLimit consecutive such iteration.

Range: {0, ..., ∞}

Default: 5

xslp_maxWeight *(real)*: Maximum penalty weight for delta or error vectors ↩

When penalty vectors are created, or when their weight is increased by escalation, the maximum weight that will be used is given by xslp_maxWeight.

Range: [0, ∞]

Default: 100

xslp_meritLambda *(real)*: Factor by which the net objective is taken into account in the merit function ↩

The merit function is evaluated in the original, non-augmented / linearized space of the problem. A solution is deemed improved, if either feasibility improved, or if feasibility is not deteriorated but the net objective is improved, or if the combination of the two is improved, where the value of the xslp_meritLambda control is used to combine the two measures. A nonpositive value indicates that the combined effect should not be checked.

Range: [0, ∞]

Default: 0

xslp_minSBFactor *(real)*: Factor by which step bounds can be decreased beneath xslp_aTol_a ↩

Normally, step bounds are not decreased beneath xslp_aTol_a, as such variables are treated as converged. However, it may be beneficial to decrease step bounds further, as individual variable value changes might affect the convergence of other variables in the model, even if the variablke itself is deemed converged.

Range: [0, ∞]

Default: 1

xslp_minWeight *(real)*: Minimum penalty weight for delta or error vectors ↩

When penalty vectors are created, the minimum weight that will be used is given by xslp_minWeight.

Range: [0, ∞]

Default: 0.01

xslp_mipAlgorithm *(integer)*: Bitmap describing the MISLP algorithms to be used ↩

xslp_mipAlgorithm determines the strategy of XSLPnlpoptimize for solving MINLP problems. The recommended approach is to solve the problem first without reference to the discrete variables. This can be handled automatically by setting bit 0 of xslp_mipAlgorithm; if done manually, then optimize using the "l" option to prevent the Optimizer presolve from changing the problem. Some versions of the optimizer re-run the initial node as part of the tree search; it is possible to initiate a new SLP optimization at this point by relaxing or fixing step bounds (use bits 2 and 3). If step bounds are fixed for a class of variable, then the variables in that class will not change their value in any child node. At each node, it is possible to relax or fix step bounds. It is recommended that step bounds are relaxed, so that the new problem can be solved starting from its parent, but without undue restrictions cased by step bounding (use bit 4). Exceptionally, it may be preferable to restrict the freedom of child nodes by relaxing fewer types of step bound or fixing the values of some classes of variable (use bit 5). When the optimal node has been found, it is possible to fix the discrete variables and then re-optimize with SLP. Step bounds can be relaxed or fixed for this optimization as well (use bits 7 and 8). Although it is ultimately necessary to solve the optimal node to convergence, individual nodes can be truncated after xslp_mipIterLimit SLP iterations. Set bit 6 to activate this feature. The normal MISLP algorithm uses SLP at each node. One alternative strategy is to use the MIP optimizer for solving each SLP iteration. Set bit 9 to implement this strategy ("MIP within SLP"). Another strategy is to solve the problem to convergence ignoring the nature of the integer variables. Then, fixing the linearization, use MIP to find the optimal setting of the discrete variables. Then, fixing the discrete variables, but varying the linearization, solve to convergence. Set bit 10 to implement this strategy ("SLP then MIP"). For mode details about MISLP algorithms and strategies, see the separate section.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 17

value	meaning
bit 0 = 1	Equivalent to xslp_mipAlgorithm_initialSLP.
bit 2 = 4	Equivalent to xslp_mipAlgorithm_initialRelaxSLP.
bit 3 = 8	Equivalent to xslp_mipAlgorithm_initialFixSLP.
bit 4 = 16	Equivalent to xslp_mipAlgorithm_nodeRelaxSLP.
bit 5 = 32	Equivalent to xslp_mipAlgorithm_nodeFixSLP.
bit 6 = 64	Equivalent to xslp_mipAlgorithm_nodeLimitSLP.
bit 7 = 128	Equivalent to xslp_mipAlgorithm_finalRelaxSLP.
bit 8 = 256	Equivalent to xslp_mipAlgorithm_finalFixSLP.
bit 9 = 512	Equivalent to xslp_mipAlgorithm_withinSLP.
bit 10 = 1024	Equivalent to xslp_mipAlgorithm_slpThenMIP.

xslp_mipAlgorithm_finalFixSLP *(boolean)*: Fix step bounds according to xslp_mipFixStepBounds after MIP solution is found ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_finalRelaxSLP *(boolean)*: Relax step bounds according to xslp_mipRelaxStepBounds after MIP solution is found ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_initialFixSLP *(boolean)*: Fix step bounds according to xslp_mipFixStepBounds after initial node ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_initialRelaxSLP *(boolean)*: Relax step bounds according to xslp_mipRelaxStepBounds after initial node ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_initialSLP *(boolean)*: Solve initial SLP to convergence ↩

See also xslp_mipAlgorithm.

Default: 1

xslp_mipAlgorithm_nodeFixSLP *(boolean)*: Fix step bounds according to xslp_mipFixStepBounds at each node ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_nodeLimitSLP *(boolean)*: Limit iterations at each node to xslp_mipIterLimit ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_nodeRelaxSLP *(boolean)*: Relax step bounds according to xslp_mipRelaxStepBounds at each node ↩

See also xslp_mipAlgorithm.

Default: 1

xslp_mipAlgorithm_slpThenMIP *(boolean)*: Use MIP on converged SLP solution and then SLP on the resulting MIP solution ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipAlgorithm_withinSLP *(boolean)*: Use MIP at each SLP iteration instead of SLP at each node ↩

See also xslp_mipAlgorithm.

Default: 0

xslp_mipCutOffCount *(integer)*: Number of SLP iterations to check when considering a node for cutting off ↩

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xslp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xslp_mipCutOff_a and OBJ ∗ xslp_mipCutOff_r where OBJ is the best integer solution obtained so far. The test is not applied until at least xslp_mipCutOffLimit SLP iterations have been carried out at the current node.

Range: {0, ..., ∞}

Default: 5

xslp_mipCutOffLimit *(integer)*: Number of SLP iterations to check when considering a node for cutting off ↩

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xslp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xslp_mipCutOff_a and OBJ ∗ xslp_mipCutOff_r where OBJ is the best integer solution obtained so far. The test is not applied until at least xslp_mipCutOffLimit SLP iterations have been carried out at the current node.

Range: {0, ..., ∞}

Default: 10

xslp_mipCutOff_a *(real)*: Absolute objective function cutoff for MIP termination ↩

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xslp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xslp_mipCutOff_a and OBJ ∗ xslp_mipCutOff_r where OBJ is the best integer solution obtained so far. The MIP cutoff tests are only applied after xslp_mipCutOffLimit SLP iterations at the current node.

Range: [0, ∞]

Default: 1e-05

xslp_mipCutOff_r *(real)*: Absolute objective function cutoff for MIP termination ↩

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xslp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xslp_mipCutOff_a and OBJ ∗ xslp_mipCutOff_r where OBJ is the best integer solution obtained so far. The MIP cutoff tests are only applied after xslp_mipCutOffLimit SLP iterations at the current node.

Range: [0, ∞]

Default: 1e-05

xslp_mipDefaultAlgorithm *(integer)*: Default algorithm to be used during the tree search in MISLP ↩

The default algorithm used within SLP during the MISLP optimization can be set using xslp_mipDefaultAlgorithm. It will not necessarily be the same as the one best suited to the initial SLP optimization.

Range: {1, ..., 5}

Default: auto

xslp_mipErrorTol_a *(real)*: Absolute penalty error cost tolerance for MIP cut-off ↩

The penalty error cost test is applied at each node where there are active penalties in the solution. If xslp_mipErrorTol_a is nonzero and the absolute value of the penalty costs is greater than xslp_mipErrorTol_a, the node will be declared infeasible. If xslp_mipErrorTol_a is zero then no test is made and the node will not be declared infeasible on this criterion.

Range: [0, ∞]

Default: 0

xslp_mipErrorTol_r *(real)*: Relative penalty error cost tolerance for MIP cut-off ↩

The penalty error cost test is applied at each node where there are active penalties in the solution. If xslp_mipErrorTol_r is nonzero and the absolute value of the penalty costs is greater than xslp_mipErrorTol_r ∗ abs(Obj) where Obj is the value of the objective function, then the node will be declared infeasible. If xslp_mipErrorTol_r is zero then no test is made and the node will not be declared infeasible on this criterion.

Range: [0, ∞]

Default: 0

xslp_mipFixStepBounds *(integer)*: Bitmap describing the step-bound fixing strategy during MISLP ↩

At any node (including the initial and optimal nodes) it is possible to fix the step bounds of classes of variables so that the variables themselves will not change. This may help with convergence, but it does increase the chance of a local optimum because of excessive artificial restrictions on the variables.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

value	meaning
bit 0 = 1	Equivalent to xslp_mipFixStepBounds_structNotCoef.
bit 1 = 2	Equivalent to xslp_mipFixStepBounds_structAll.
bit 2 = 4	Equivalent to xslp_mipFixStepBounds_coefOnly.
bit 3 = 8	Equivalent to xslp_mipFixStepBounds_coef.

xslp_mipFixStepBounds_coef *(boolean)*: Fix step bounds on SLP variables appearing in coefficients ↩

See also xslp_mipFixStepBounds.

Default: 0

xslp_mipFixStepBounds_coefOnly *(boolean)*: Fix step bounds on SLP variables appearing only in coefficients ↩

See also xslp_mipFixStepBounds.

Default: 0

xslp_mipFixStepBounds_structAll *(boolean)*: Fix step bounds on all structural SLP variables ↩

See also xslp_mipFixStepBounds.

Default: 0

xslp_mipFixStepBounds_structNotCoef *(boolean)*: Fix step bounds on structural SLP variables which are not in coefficients ↩

See also xslp_mipFixStepBounds.

Default: 0

xslp_mipIterLimit *(integer)*: Maximum number of SLP iterations at each node ↩

If bit 6 of xslp_mipAlgorithm is set, then the number of iterations at each node will be limited to xslp_mipIterLimit.

Range: {0, ..., ∞}

Default: 0

xslp_mipLog *(integer)*: Frequency with which MIP status is printed ↩

By default (zero or negative value) the MIP status is printed after syncronization points. If xslp_mipLog is set to a positive integer, then the current MIP status (node number, best value, best bound) is printed every xslp_mipLog nodes.

Range: {0, ..., ∞}

Default: 0

xslp_mipOCount *(integer)*: Number of SLP iterations at each node over which to measure objective function variation ↩

The objective function test for MIP termination is applied only when step bounding has been applied (or xslp_sbStart SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last xslp_mipOCount SLP iterations is within xslp_mipOTol_a or within OBJ ∗ xslp_mipOTol_r where OBJ is the average value of the objective function over those iterations.

Range: {0, ..., ∞}

Default: 5

xslp_mipOTol_a *(real)*: Absolute objective function tolerance for MIP termination ↩

The objective function test for MIP termination is applied only when step bounding has been applied (or xslp_sbStart SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last xslp_mipOCount SLP iterations is within xslp_mipOTol_a or within OBJ * xslp_mipOTol_r where OBJ is the average value of the objective function over those iterations.

Range: [0, ∞]

Default: 1e-05

xslp_mipOTol_r *(real)*: Relative objective function tolerance for MIP termination ↩

The objective function test for MIP termination is applied only when step bounding has been applied (or xslp_sbStart SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last xslp_mipOCount SLP iterations is within xslp_mipOTol_a or within OBJ * xslp_mipOTol_r where OBJ is the average value of the objective function over those iterations.

Range: [0, ∞]

Default: 1e-05

xslp_mipRelaxStepBounds *(integer)*: Bitmap describing the step-bound relaxation strategy during MISLP ↩

At any node (including the initial and optimal nodes) it is possible to relax the step bounds of classes of variables so that the variables themselves are completely free to change. This may help with finding a global optimum, but it may also increase the solution time, because more SLP iterations are necessary at each node to obtain a converged solution.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 15

value	meaning
bit 0 = 1	Equivalent to xslp_mipRelaxStepBounds_structNotCoef.
bit 1 = 2	Equivalent to xslp_mipRelaxStepBounds_structAll.
bit 2 = 4	Equivalent to xslp_mipRelaxStepBounds_coefOnly.
bit 3 = 8	Equivalent to xslp_mipRelaxStepBounds_coef.

xslp_mipRelaxStepBounds_coef *(boolean)*: Relax step bounds on SLP variables appearing in coefficients ↩

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_mipRelaxStepBounds_coefOnly *(boolean)*: Relax step bounds on SLP variables appearing only in coefficients ↩

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_mipRelaxStepBounds_structAll *(boolean)*: Relax step bounds on all structural SLP variables ↩

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_mipRelaxStepBounds_structNotCoef *(boolean)*: Relax step bounds on structural SLP variables which are not in coefficients ↩

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_msMaxBoundRange *(real)*: Defines the maximum range inside which initial points are generated by multistart presets ↩

The is the maximum range in which initial points are generated; the actual range is expected to be smaller as bounds are domains are also considered.

Range: [0, ∞]

Default: 1000

xslp_mTol_a *(real)*: Absolute effective matrix element convergence tolerance ↩

The absolute effective matrix element convergence criterion assesses the change in the effect of a coefficient in a constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. E = X ∗ C where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as E = X ∗ C0 + δX ∗ C'0 where V is as before, C0 is the value of the coefficient C calculated using the assumed values for the variables and C'0 is the value of ∂C ∂X calculated using the assumed values for the variables. If C1 is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by δE = X ∗ C1 - (X ∗ C0 + δX ∗ C'0) If δE < X ∗ xslp_mTol_a then the variable has passed the absolute effective matrix element convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_mTol_r *(real)*: Relative effective matrix element convergence tolerance ↩

The relative effective matrix element convergence criterion assesses the change in the effect of a coefficient in a constraint relative to the magnitude of the coefficient. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. E = X ∗ C where X is the activity of the matrix column in which the coefficient appears, and C is the value of the coefficient. The linearization approximates the effect of the coefficient as E1 = X ∗ C0 + δX ∗ C'0 where V is as before, C0 is the value of the coefficient C calculated using the assumed values for the variables and C'0 is the value of ∂C ∂X calculated using the assumed values for the variables. If C1 is the value of the coefficient C calculated using the actual values for the variables, then the error in the effect of the coefficient is given by δE = X ∗ C1 - (X ∗ C0 + δX ∗ C'0) If δE < E1 ∗ xslp_mTol_r then the variable has passed the relative effective matrix element convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_multistartPreset *(integer)*: Enable multistart ↩

Default: 0

value	meaning
0	Disable multistart preset.
1	Generate xslp_multistart_maxSolves number of random base points.
2	Generate xslp_multistart_maxSolves number of random base points, filtered by a merit function centred on initial feasibility.
3	Load the most typical SLP tuning settings. A maximum of xslp_multistart_maxSolves jobs are loaded.
4	Load a comprehensive set of SLP tuning settings. A maximum of xslp_multistart_maxSolves jobs are loaded.

xslp_multistart_maxSolves *(integer)*: Maximum number of jobs to create during the multistart search ↩

This control can be increased on the fly during the mutlistart search: for example, if a job gets refused by a user callback, the callback may increase this limit to account for the rejected job.

Range: {-1, ..., ∞}

Default: `unlimited`

xslp_multistart_maxTime *(integer)*: Maximum total time to be spent in the mutlistart search ↩

XSLP_MAXTIME applies on a per job instance basis. There will be some time spent even after xslp_multistart_maxTime has elapsed, while the running jobs get terminated and their results collected.

Range: {0, ..., ∞}

Default: `unlimited`

xslp_multistart_poolsize *(integer)*: Maximum number of problem objects allowed to pool up before synchronization in the deterministic multistart ↩

Deterministic multistart is ensured by guaranteeing that the multistart solve results are evaluated in the same order every time. Solves that finish too soon can be pooled until all earlier started solves finish, allowing the system to start solving other multistart instances in the meantime on idle threads. Larger pool sizes will provide better speedups, but will require larger amounts of memory. Positive values are interpreted as a multiplier on the maximum number of active threads used, while negative values are interpreted as an absolute limit (and the absolute value is used). A value of zero will mean no result pooling.

Range: {0, ..., ∞}

Default: 2

xslp_multistart_seed *(integer)*: Random seed used for the automatic generation of initial point when loading multistart presets ↩

Range: {-∞, ..., ∞}

Default: 0

xslp_multistart_threads *(integer)*: Maximum number of threads to be used in multistart ↩

The current hard upper limit on the number of threads to be sued in multistart is 64.

Range: {-1, ..., ∞}

Default: auto

xslp_mvTol *(real)*: Marginal value tolerance for determining if a constraint is slack ↩

If the absolute value of the marginal value of a constraint is less than xslp_mvTol, then (1) the constraint is regarded as not constraining for the purposes of the slack tolerance convergence criteria; (2) the constraint is not regarded as an active constraint when identifying unconverged variables in active constraints. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_objToPenaltyCost *(real)*: Factor to estimate initial penalty costs from objective function ↩

The setting of initial penalty error costs can affect the path of the optimization and, indeed, whether a solution is achieved at all. If the penalty costs are too low, then unbounded solutions may result although Xpress-SLP will increase the costs in an attempt to recover. If the penalty costs are too high, then the requirement to achieve feasibility of the linearized constraints may be too strong to allow the system to explore the nonlinear feasible region. Low penalty costs can result in many SLP iterations, as feasibility of the nonlinear constraints is not achieved until the penalty costs become high enough; high penalty costs force feasibility of the linearizations, and so tend to find local optima close to an initial feasible point. Xpress-SLP can analyze the problem to estimate the size of penalty costs required to avoid an initial unbounded solution. xslp_objToPenaltyCost can be used in conjunction with this procedure to scale the costs and give an appropriate initial value for balancing the requirements of feasibility and optimality. Not all models are amenable to the Xpress-SLP analysis. As the analysis is initially concerned with establishing a cost level to avoid unboundedness, a model which is sufficiently constrained will never show unboundedness regardless of the cost. Also, as the analysis is done at the start of the optimization to establish a penalty cost, significant changes in the coefficients, or a high degree of nonlinearity, may invalidate the initial analysis. A setting for xslp_objToPenaltyCost of zero disables the analysis. A setting of 3 or 4 has proved successful for many models. If xslp_objToPenaltyCost cannot be used because of the problem structure, its effect can still be emulated by some initial experiments to establish the cost required to avoid unboundedness, and then manually applying a suitable factor. If the problem is initially unbounded, then the penalty cost will be increased until either it reaches its maximum or the problem becomes bounded.

Range: [0, ∞]

Default: 0

xslp_oCount *(integer)*: Number of SLP iterations over which to measure objective function variation for static objective (2) convergence criterion ↩

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least xslp_mvTol) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_oCount most recent SLP iterations and Obj is the

corresponding objective function value. If ABS(δObj) $\leq$ xslp_oTol_a then the problem has converged on the absolute static objective (2) convergence criterion. The static objective function (2) test is applied only if xslp_oCount is at least 2.

Range: {0, ..., ∞}

Default: 5

xslp_optimalityTolTarget *(real)*: When set, this defines a target optimality tolerance to which the linearizations are solved to ↩

This is a soft version of optimalityTol, and will dynamically revert back to optimalityTol if the desired accuracy could not be achieved.

Range: [0, ∞]

Default: not set

xslp_oTol_a *(real)*: Absolute static objective (2) convergence tolerance ↩

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least xslp_mvTol) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_oCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ xslp_oTol_a then the problem has converged on the absolute static objective (2) convergence criterion. The static objective function (2) test is applied only if xslp_oCount is at least 2. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_oTol_r *(real)*: Relative static objective (2) convergence tolerance ↩

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least xslp_mvTol) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_oCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ AVGIter(Obj)$*$xslp_oTol_r then the problem has converged on the relative static objective (2) convergence criterion. The static objective function (2) test is applied only if xslp_oCount is at least 2. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_penaltyInfoStart *(integer)*: Iteration from which to record row penalty information ↩

Information about the size (current and total) of active penalties of each row and the number of times a penalty vector has been active is recorded starting at the SLP iteration number given by xslp_penaltyInfoStart.

Range: {0, ..., ∞}

Default: 3

xslp_postsolve *(integer)*: Determines whether postsolving should be performed automatically ↩

Default: -1

value	meaning
-1	Postsolve if the problem could be solved to optimality/infeasibility.
0	Do not automatically postsolve.
1	Postsolve automatically.

xslp_presolve *(integer)*: Determines whether presolving should be performed prior to starting the main algorithm ↩

The Xpress NonLinear nonlinear presolve (which is carried out once, before augmentation) is independent of the Optimizer presolve (which is carried out during each SLP iteration).

Default: 1

value	meaning
0	Disable SLP presolve.
1	Activate SLP presolve.
2	Low memory presolve. Original problem is not restored by postsolve and dual solution may not be completely postsolved.

xslp_presolveLevel *(integer)*: Determines the level of changes presolve may carry out on the problem ↩

xslp_presolveOps controls the operations carried out in presolve. xslp_presolveLevel controls how those operations may change the problem.

Default: 4

value	meaning
1	Individual rows only presolve, no nonlinear transformations.
2	Individual rows and bounds only presolve, no nonlinear transformations.
3	Presolve allowing changing problem dimension, no nonlinear transformations.
4	Full presolve.

xslp_presolveOps *(integer)*: Bitmap indicating the SLP presolve actions to be taken ↩

The Xpress NonLinear nonlinear presolve (which is carried out once, before augmentation) is independent of the Optimizer presolve (which is carried out during each SLP iteration). Linear reductions are performed according to presolveOps if bit 12 is not set.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 2104

value	meaning
bit 0 = 1	Equivalent to xslp_presolveOps_general.
bit 1 = 2	Equivalent to xslp_presolveOps_fixZero.
bit 2 = 4	Equivalent to xslp_presolveOps_fixAll.
bit 3 = 8	Equivalent to xslp_presolveOps_setBounds.
bit 4 = 16	Equivalent to xslp_presolveOps_intBounds.
bit 5 = 32	Equivalent to xslp_presolveOps_domain.
bit 8 = 256	Equivalent to xslp_presolveOps_noCoefficients.

value	meaning
`bit 9 = 512`	Equivalent to xslp_presolveOps_noDeltas.
`bit 10 = 1024`	Equivalent to xslp_presolveOps_noDualSide.
`bit 11 = 2048`	Equivalent to xslp_presolveOps_eliminations.
`bit 12 = 4096`	Equivalent to xslp_presolveOps_noLinear.
`bit 13 = 8192`	Equivalent to xslp_presolveOps_noSimplifier.

xslp_presolveOps_domain *(boolean)*: Bound tightening based on function domains ↩

See also xslp_presolveOps.

Default: `1`

xslp_presolveOps_eliminations *(boolean)*: Allow eliminations on determined variables ↩

See also xslp_presolveOps.

Default: `1`

xslp_presolveOps_fixAll *(boolean)*: Explicitly fix all columns identified as fixed ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_fixZero *(boolean)*: Explicitly fix columns identified as fixed to zero ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_general *(boolean)*: Generic SLP presolve ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_intBounds *(boolean)*: MISLP bound tightening ↩

See also xslp_presolveOps.

Default: `1`

xslp_presolveOps_noCoefficients *(boolean)*: Do not presolve coefficients ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_noDeltas *(boolean)*: Do not remove delta variables ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_noDualSide *(boolean)*: Avoid reductions that can not be dual postsolved ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_noLinear *(boolean)*: Avoid performing linear reductions at the nlp level ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_noSimplifier *(boolean)*: Avoid simplifying nonlinear expressions ↩

See also xslp_presolveOps.

Default: `0`

xslp_presolveOps_setBounds *(boolean)*: SLP bound tightening ↩

See also xslp_presolveOps.

Default: `1`

xslp_presolveZero *(real)*: Minimum absolute value for a variable which is identified as nonzero during SLP presolve ↩

During the SLP (nonlinear)presolve, a variable may be identified as being nonzero (for example, because it is used as a divisor). A bound of plus or minus xslp_presolveZero will be applied to the variable if it is identified as non-negative or non-positive.

Range: [0, ∞]

Default: `1e-09`

xslp_primalIntegralRef *(real)*: Reference solution value to take into account when calculating the primal integral ↩

When a global optimum is known, this can used to calculate a globally valid primal integral. It can also be used to indicate the target objective value still to be taken into account in the integral.

Range: [-∞, ∞]

Default: `1e+20`

xslp_probing *(integer)*: Determines whether probing on a subset of variables should be performed prior to starting the main algorithm ↩

Probing runs multiple times bound reduction in order to further tighten the bounding box.

The Xpress NonLinear nonlinear probing, which is carried out once, is independent of the Optimizer presolve (which is carried out during each SLP iteration). The probing level allows for probing on an expanding set of variables, allowing for probing on all variables (level 5) or only those for which probing is more likely to be useful (binary variables).

Default: `auto`

value	meaning
-1	Automatic.
0	Disable SLP probing.
1	Activate SLP probing only on binary variables.
2	Activate SLP probing only on binary or unbounded integer variables.
3	Activate SLP probing only on binary or integer variables.
4	Activate SLP probing only on binary, integer variables, and unbounded continuous variables.
5	Activate SLP probing on any variable.

xslp_sameCount *(integer)*: Number of steps reaching the step bound in the same direction before step bounds are increased ↩

If step bounding is enabled, the step bound for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp_sameCount successive changes reaching the step bound and in the same direction for a variable, then the step bound (B) for the variable will be reset to B∗xslp_expand.

Range: {0, ..., ∞}

Default: 3

xslp_sameDamp *(integer)*: Number of steps in same direction before damping factor is increased ↩

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp_sameDamp successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to D∗xslp_dampExpand + xslp_dampMax∗(1-xslp_dampExpand)

Range: {0, ..., ∞}

Default: 3

xslp_sbStart *(integer)*: SLP iteration after which step bounds are first applied ↩

If step bounds are used, they can be applied for the whole of the SLP optimization process, or started after a number of SLP iterations. In general, it is better not to apply step bounds from the start unless one of the following applies: (1) the initial estimates are known to be good, and explicit values can be provided for initial step bounds on all variables; or (2) the problem is unbounded unless all variables are step-bounded.

Range: {0, ..., ∞}

Default: 8

xslp_scale *(integer)*: When to re-scale the SLP problem ↩

During the SLP optimization, matrix entries can change considerably in magnitude, even when the formulae in the coefficients are not very nonlinear. Re-scaling of the matrix can reduce numerical errors, but may increase the time taken to achieve convergence.

Default: 1

value	meaning
0	No re-scaling.
1	Re-scale every SLP iteration up to xslp_scaleCount iterations after the end of barrier optimization.
2	Re-scale every SLP iteration up to xslp_scaleCount iterations in total.
3	Re-scale every SLP iteration until primal simplex is automatically invoked.
4	Re-scale every SLP iteration

xslp_scaleCount *(integer)*: Iteration limit used in determining when to re-scale the SLP matrix ↩

If xslp_scale is set to 1 or 2, then xslp_scaleCount determines the number of iterations (after the end of barrier optimization or in total) in which the matrix is automatically re-scaled.

Range: {0, ..., ∞}

Default: 0

xslp_shrink *(real)*: Multiplier to reduce a step bound ↩

If step bounding is enabled, the step bound for a variable will be decreased if successive changes are in opposite directions. The step bound (B) for the variable will be reset to B∗xslp_shrink. If the step bound is already below the strict (delta or closure) tolerances, it will not be reduced further.

Range: [0, 1]

Default: 0.5

xslp_shrinkBias *(real)*: Defines an overwrite / adjustment of step bounds for improving iterations ↩

Positive values overwrite xslp_shrink only if the objective is improving. A negative value is used to scale all step bounds in improving iterations.

Range: [-∞, ∞]

Default: not set

xslp_slpLog *(integer)*: Frequency with which SLP status is printed ↩

If xslp_log is set to zero (minimal logging) then a nonzero value for xslp_slpLog defines the frequency (in SLP iterations) when summary information is printed out.

Range: {0, ..., ∞}

Default: 1

xslp_solver *(integer)*: Selects the library to use for local solves ↩

The presence of KNITRO is detected automatically. KNITRO can be used to solve any problem loaded into XSLP, independently from how the problem was loaded. xslp_solver is set to automatic, Xpress SLP will be selected if any SLP specific construct has been loaded (these are ignored if KNITRO is selected manually). When solving problems to global optimality, the xslp_solver control is used to decide which local solver to call for reoptimizing NLP- infeasible solutions heuristically.

Default: auto

value	meaning
-1	Automatic selection, based on model characteristics and solver availability
0	Use Xpress-SLP (always available)
1	Use Knitro if available
2	Use Xpress-Optimizer if possible (convex quadratic problems only)

xslp_sTol_a *(real)*: Absolute slack convergence tolerance ↩

The slack convergence criterion is identical to the impact convergence criterion, except that the tolerances used are xslp_sTol_a (instead of xslp_iTol_a) and xslp_sTol_r (instead of xslp_iTol_r). See xslp_iTol_a for a description of the test. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_sTol_r *(real)*: Relative slack convergence tolerance ↩

The slack convergence criterion is identical to the impact convergence criterion, except that the tolerances used are xslp_sTol_a (instead of xslp_iTol_a) and xslp_sTol_r (instead of xslp_iTol_r). See xslp_iTol_r for a description of the test. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_stopOutOfRange *(boolean)*: Stop optimization and return error code if internal function argument is out of range ↩

If xslp_stopOutOfRange is set to 1, then if an internal function receives an argument which is out of its allowable range (for example, LOG of a negative number), an error code is set and the optimization is terminated.

Default: `0`

xslp_threads *(integer)*: Default number of threads to be used ↩

Overall thread control value, used to determine the number of threads used where parallel calculations are possible.

Range: {`-1`, ..., ∞}

Default: `auto`

xslp_unfinishedLimit *(integer)*: Number of consecutive SLP iterations that may have an unfinished status before the solve is terminated ↩

If the optimization of the current linear approximation terminates with an "unfinished" status, then first a number of strategies are applied to attempt a successful solve of the same linearization. If this fails, then a new iteration is started to change the linearization itself. This control limits the numner of such repeated attempts.

Range: {`0`, ..., ∞}

Default: `3`

xslp_validationTarget_k *(real)*: Optimality target tolerance ↩

Primary optimality control for SLP. When the relevant optimality based convergence controls are left at their default values, SLP will adjust their value to match the target. The control defines a target value, that may not necessarily be attainable for problem with no strong constraint qualifications.

Range: [0, ∞]

Default: `1e-06`

xslp_validationTarget_r *(real)*: Feasiblity target tolerance ↩

Primary feasiblity control for SLP. When the relevant feasibility based convergence controls are left at their default values, SLP will adjust their value to match the target. The control defines a target value, that may not necessarily be attainable.

Range: [0, ∞]

Default: `1e-06`

xslp_vCount *(integer)*: Number of SLP iterations over which to measure static objective (3) convergence ↩

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ xslp_vTol_a then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit + xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced.

Range: {0, ..., ∞}

Default: `0`

xslp_vLimit *(integer)*: Number of SLP iterations after which static objective (3) convergence testing starts ↩

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ xslp_vTol_a then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit + xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced.

Range: {0, ..., ∞}

Default: `0`

xslp_vTol_a *(real)*: Absolute static objective (3) convergence tolerance ↩

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ xslp_vTol_a then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit + xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_vTol_r *(real)*: Relative static objective (3) convergence tolerance ↩

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ AVGIter(Obj) $*$ xslp_vTol_r then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit

- xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_wCount *(integer)*: Number of SLP iterations over which to measure the objective for the extended convergence continuation criterion ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last

converged solution is given by: δObj = Obj - LastConvergedObj For a minimization problem, the sign is reversed. If δObj > xslp_wTol_a and δObj > ABS(ConvergedObj) * xslp_wTol_r then the solution is deemed to have a significantly better objective function value than the converged solution. When a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the xslp_wCount most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. If xslp_wCount is zero, then the extended convergence continuation criterion is disabled.

Range: {0, ..., ∞}

Default: 0

xslp_wTol_a *(real)*: Absolute extended convergence continuation tolerance ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last converged solution is given by: δObj = Obj - LastConvergedObj For a minimization problem, the sign is reversed. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_wTol_r *(real)*: Relative extended convergence continuation tolerance ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution

will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last converged solution is given by: δObj = Obj - LastConvergedObj For a minimization problem, the sign is reversed. If δObj > xslp_wTol_a and δObj > ABS(ConvergedObj) * xslp_wTol_r then the solution is deemed to have a significantly better objective function value than the converged solution. If xslp_wCount is greater than zero, and a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the xslp_wCount most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-4 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_xCount *(integer)*: Number of SLP iterations over which to measure static objective (1) convergence ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. Because all the variables have converged, the solution is already converged but the fact that some variables are at their step bound limit suggests that the objective function could be improved by going further. The variation in the objective function is defined as δObj = MAXIter(Obj) - MINIter(Obj) where Iter is the xslp_xCount most recent SLP iterations and Obj is the corresponding objective function value. If ABS(δObj) $\leq$ xslp_xTol_a then the objective function is deemed to be static according to the absolute static objective function (1) criterion. If ABS(δObj) $\leq$ AVGIter(Obj) * xslp_xTol_r then the objective function is deemed to be static according to the relative static objective function (1) criterion. The static objective function (1) test is applied only until xslp_xLimit SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged.

Range: {0, ..., ∞}

Default: `5`

xslp_xLimit *(integer)*: Number of SLP iterations up to which static objective (1) convergence testing starts ↩

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration.

However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test is applied only until xslp_xLimit SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-4 and 1e-6.

Range: [-∞, ∞]

Default: `auto`

xslp_zero *(real)*: Absolute tolerance ↩

If a value is below xslp_zero in magnitude, then it will be regarded as zero in certain formula calculations: an attempt to divide by such a value will give a "divide by zero" error; an exponent of a negative number will produce a "negative number, fractional exponent" error if the exponent differs from an integer by more than xslp_zero.

Range: [0, ∞]

Default: `1e-15`

xslp_zeroCriterion *(integer)*: Bitmap determining the behavior of the placeholder deletion procedure ↩

Setting single boolean options will overwrite the single bits of this bit map option.

Default: `0`

value	meaning
`bit 0 = 1`	Equivalent to xslp_zeroCriterion_nbSLPVar.
`bit 1 = 2`	Equivalent to xslp_zeroCriterion_nbDelta.
`bit 2 = 4`	Equivalent to xslp_zeroCriterion_slpVarNBUpdateRow.
`bit 3 = 8`	Equivalent to xslp_zeroCriterion_deltaNBUpdateRow.
`bit 4 = 16`	Equivalent to xslp_zeroCriterion_deltaNBDRRow.
`bit 5 = 32`	Equivalent to xslp_zeroCriterion_print.

xslp_zeroCriterionCount *(integer)*: Number of consecutive times a placeholder entry is zero before being considered for deletion ↩

Range: {0, ..., ∞}

Default: `0`

xslp_zeroCriterionStart *(integer)*: SLP iteration at which criteria for deletion of placeholder entries are first activated ↩

Range: {0, ..., ∞}

Default: 0

xslp_zeroCriterion_deltaNBDRRow *(boolean)*: Remove placeholders in a basic delta variable if the determining row for the corresponding SLP variable is nonbasic ↩

See also xslp_zeroCriterion.

Default: 0

xslp_zeroCriterion_deltaNBUpdateRow *(boolean)*: Remove placeholders in a basic delta variable if its update row is nonbasic and the corresponding SLP variable is nonbasic ↩

See also xslp_zeroCriterion.

Default: 0

xslp_zeroCriterion_nbDelta *(boolean)*: Remove placeholders in nonbasic delta variables ↩

See also xslp_zeroCriterion.

Default: 0

xslp_zeroCriterion_nbSLPVar *(boolean)*: Remove placeholders in nonbasic SLP variables ↩

See also xslp_zeroCriterion.

Default: 0

xslp_zeroCriterion_print *(boolean)*: Print information about zero placeholders ↩

See also xslp_zeroCriterion.

Default: 0

xslp_zeroCriterion_slpVarNBUpdateRow *(boolean)*: Remove placeholders in a basic SLP variable if its update row is nonbasic ↩

See also xslp_zeroCriterion.

Default: 0

5.38.5 Helpful Hints

The comments below should help both novice and experienced GAMS users to better understand and make use of GAMS/XPRESS.

- **Infeasible and unbounded models** The fact that a model is infeasible/unbounded can be detected at two stages: during the presolve and during the simplex or barrier algorithm. In the first case we cannot recover a solution, nor is any information regarding the infeasible/unbounded constraint or variable provided (at least in a way that can be returned to GAMS). In such a situation, the GAMS link will automatically rerun the model using primal simplex with presolve turned off (this can be avoided by setting the rerun option to 0). It is possible (but very unlikely) that the simplex method will solve a model to optimality while the presolve claims the model is infeasible/unbounded (due to feasibility tolerances in the simplex and barrier algorithms).
- The barrier method does not make use of `iterlim`. Use `bariterlim` in an options file instead. The number of barrier iterations is echoed to the log and listing file. If the barrier iteration limit is reached during the barrier algorithm, XPRESS continues with a simplex algorithm, which will obey the iterlim setting.
- Semi-integer variables are not implemented in the link, nor are they supported by XPRESS; if present, they trigger an error message.
- SOS1 and SOS2 variables are required by XPRESS to have lower bounds of 0 and nonnegative upper bounds.

5.38.6 Setting up a GAMS/XPRESS-Link license

To use the GAMS/XPRESS solver with a GAMS/XPRESS-Link license you have to set up the XPRESS portion of the licensing. To do so, copy your XPRESS license `xpauth.xpr` to the GAMS system directory. As of version 24.2 GAMS already comes with a file `xpauth.xpr` . You might consider copying this file to `xpauth.xpr.bak` or similar before overwriting it with your own XPRESS license file.

Chapter 6

Tools Manuals

A large number of tools are included in GAMS distribution. Below are a functional categorization of all tools, an alphabetically sorted list of all tools, and a brief description of each tool with their Supported Platforms.

Note

> Traditionally, GAMS tools consisted of a collection of *executables* with a file (mostly GDX) interface. These tool executables will be replaced over time by GAMS Connect agents and a collection of tools in a new GAMS tools library. For some time both ways will be supported but the executable tools will go away, so when in doubt what tool to pick, select Connect or a GAMS tool.

6.1 Tools Category

All tools included in GAMS distribution are categorized as

6.1.1 GAMS Integrated Development Environments

There are two integrated model development environments including a general text editor with the ability to launch and monitor the compilation and execution of GAMS models: GAMS Studio and the `GAMS IDE` (deprecated).

6.1.2 GAMS Tools Library

In the GAMS Tools Library, various tools are collected to provide an easy access to complex task. The tools in this library complement facilities of GAMS Connect and tools available as executables (e.g. GDXXRW). Currently the library includes the following tool categories:

6.1.2.1 Algorithmic tools (alg)

Provide algorithmic functionality like sorting data: Rank.

6.1.2.2 Data tools (data)

Provide access to external data sources: ExcelDump.

6.1.2.3 GDX Service (gdxservice)

Provide functionality for GDX file manipulation: GDXEncoding and GDXRename.

6.1.2.4 Linear Algebra (linalg)

Provide functionality for computational linear algebra: Cholesky, Eigenvalue, Eigenvector, Invert and Ordinary Least Squares (OLS).

6.1.2.5 Windows Only Tools (win32)

Provide functionality specific to the Windows operating system: ShellExecute, MSAppAvail, ExcelTalk and ExcelMerge.

There are a couple of things to note:

- A tool can be invoked directly in the model code during compile ($callTool) or execution time (executeTool) or by using the standalone command line utility gamstool.
- When invoked from the model code the exchange of GAMS symbols is done in memory. If a tool is called from the command line, this is not possible and hence for some tools that deal with GAMS symbols it is necessary to specify GDX input and/or output files. Even for use inside GAMS models the GDX file interface can be useful (e.g. for debugging) hence the specification of GDX input/output files is optional in that case.
- Similar to the $call (compile time) and execute (execution time) commands, a GAMS tool returns a shell code that can be checked via `errorLevel`. In case one expects the tools to perform without error, it is recommended to add the suffix .checkErrorLevel. This will stop the entire execution of GAMS if an error occurs while executing the tool.
- If a tool of the GAMS Tool library is used at execution time to populate a GAMS symbol with data for the first time, the compiler does not know the outcome of the tool. As a result, the compiler does not have information about any symbols that might be filled with data, and therefore cannot reliably define these symbols at compile time. Code that later on references a corresponding symbol would result in a compilation error 141: `Symbol declared but no values have been assigned`. In order to be able to load symbols implicitly during execution time, the dollar control option $onImplicitAssign needs to be set. There are other methods to convince the compiler that the symbols has been defined, e.g. `execute_load$0 symName;` which is otherwise a no-op.
- The compile time variant of a tool ($callTool [...]) is ignored while $onExternalInput is active and IDCGDXInput is set.
- Tool arguments: All tools follow the same logic to process arguments. The list of arguments starts with a number of *positional* arguments followed by *named* argument `[-]name=val`.
- For each tool there is a short and a long help available. If a tool is called without arguments or with `-h` , a short description is displayed, e.g. `gamstool linalg.eigenvector -h`. With the argument `--help` a detailed help text appears: `gamstool linalg.eigenvector --help`. If only the category and not a contained tool is requested, the help text of all included tools will be displayed: `gamstool linalg` or `gamstool linalg --help`.

For more information please refer to the individual tool manuals.

6.1.2.6 Command Line Utility gamstool

The GAMS system directory contains the utility `gamstool` to run GAMS Tool instructions directly from the command line. On Windows the utility has the callable extension `.cmd` which does not need to part of the command because the shell automatically checks for the extension. This script wraps the Python script `tooldriver.py` by calling the Python interpreter that ships with GAMS. `gamstool` is called like this:

```
gamstool [toolCategory.]toolName positionalArguments [namedArguments]
```

6.1.3 Data Exchange

A collection of tools that provide functionality to exchange data between GAMS and other data sources. This category contains tools for popular data sources and high-level programming environment and like databases (GDX2ACCESS, GDX2SQLITE, MDB2GMS, SQL2GMS), Matlab (GDXMRW), and R (GDXRRW). There are also tools for specialized systems like VEDA (GDX2VEDA).

6.1.3.1 Excel

A collection of tools that provide functionality to exchange data between GAMS and Excel. The tools in this category are GDX2XLS, GDXXRW, XLS2GMS, and ExcelDump. Many of the tools described here use the GAMS Data eXchange facility GAMS Data eXchange (GDX). Note that the executable tools in this category will be or have been replaced over time by GAMS GAMS Connect agents and tools from the GAMS Tools Library.

6.1.4 GDX Service

A collection of tools that operate directly on GAMS Data eXchange (GDX) containers to e.g. compare (GDXDIFF), copy (GDXCOPY), merge (GDXMERGE), label rename (GDXRename) and encoding (GDXEncoding).

6.1.5 Data Transformation

A collection of tools that perform very specific tasks that are awkward or inefficient to implement in GAMS directly. The tools in this category are MessageReceiverWindow, Rank, SCENRED, SCENRED2 and all tools from Linear Algebra (linalg).

6.1.6 Other Tools

A collection of more exotic tools that can become handy in some some special circumstances. The tools in this category are ASK, ENDECRYPT, FINDTHISGAMS, GAMS Posix Utilities, MODEL2TEX, and all tools from Windows Only Tools (win32). Most notably, the collection contains the tool MODEL2TEX to document the model algebra in LaTeX format.

6.2 List of Tools

The following table gives an alphabetically sorted list of all available tools.

Tool	Description
ASK	The utility can be used to get input from an user interactively.
[LINALG.]CHOLESKY	Calculates the cholesky decomposition of a symmetric positive definite matrix.
CSV2GDX	Reads a CSV file (comma separated values) and writes to a GDX file.
[LINALG.]EIGENVALUE	Calculates the Eigenvalues of a symmetric positive definite matrix.
[LINALG.]EIGENVECTOR	Calculates the Eigenvalues and Eigenvectors of a symmetric positive definite matrix.
ENDECRYPT	A tool to encrypt and decrypt text files.
[DATA.]EXCELDUMP	Writes all worksheets of an Excel workbook to GAMS symbols.
[WIN32.]EXCELMERGE	Merges the sheets of the source Excel workbook into the destination workbook.
[WIN32.]EXCELTALK	Performs command on an Excel workbook specified by filename.
FINDTHISGAMS	Windows command line tool for modifying GAMS specific registry entries created by the GAMS installer.
GAMS IDE	Classic Integrated Development Environment.
GAMS STUDIO	Integrated Development Environment.
GDX2ACCESS	Converts GDX data to MS Access tables.
GDX2SQLITE	Dumps the complete contents of a GDX file into a SQLite2 database. From Amsterdam Optimization Modeling Group.
GDX2VEDA	Translates a GDX file into the VEDA format.
GDX2XLS	Converts GDX data into a MS Excel spreadsheet.
GDXCOPY	Converts a GDX file into different GDX formats.
GDXDIFF	Compares the data of symbols with the same name, type and dimension in two GDX files and writes the differences to a third GDX file.
GDXDUMP	Writes scalars, sets and parameters (tables) to standard output formatted as a GAMS program with data statements.
[GDXSERVICE.]GDXENCODING	Label encoding conversion.
GDXMERGE	Combines multiple GDX files into one file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.
GDXMRW	A suite of utilities to import/export data between GAMS and MATLAB and to call GAMS models from MATLAB and get results back into MATLAB.
[GDXSERVICE.]GDXRENAME	Renames labels in a GDX file.
GDXRRW	An interface between GAMS and R. It includes functions to transfer data between GDX and R and a function to call GAMS from R.
GDXVIEWER	Views and converts data contained in GDX files.
GDXXRW	Preferred utility to read and write MS Excel spreadsheet data.
GMSUNZIP	Decompression tool unzip with Debian patches, but renamed to "gmsunzip".
GMSZIP	Compression and archiving tool zip with Debian patches, but renamed to "gmszip".
IDECMDS	Sends commands to the GAMSIDE.
[LINALG.]INVERT	Calculates the inverse of a square matrix A.
MDB2GMS	Converts data from an MS Access database into a GAMS readable format.

Tool	Description
MESSAGE RECEIVER WINDOW	A graphical tool that receives and displays Windows messages.
MODEL2TEX	Translates a GAMS model into LaTeX
MPS2GMS	Translates an MPS or LP file into an equivalent short generic GAMS program using a GDX file to store data.
[WIN32.]MSAPPAVAIL	Checks if a MS Office Application is available.
[LINALG.]OLS	Ordinary Least Squares: Estimates the unknown parameters in a linear regression model.
POSIX	A collection of `POSIX` utilities which are usually available for Windows and the different Unix systems and therefore help to write platform independent scripts.
[ALG.]RANK	Ranks one-dimensional numeric data.
SCENRED	A tool for the reduction of scenarios that model random data processes of a stochastic program. From Humboldt-University Berlin.
SCENRED2	Scenred2 is a fundamental update of Scenred and offers a scenario tree construction algorithm. From Humboldt-University Berlin.
[WIN32.]SHELLEXECUTE	Spawns an external program.
SQL2GMS	Converts data from an SQL database into a GAMS readable format.
XLS2GMS	Converts spreadsheet data from a MS Excel spreadsheet into a GAMS readable format.
XLSDUMP	Writes all worksheets of a MS Excel workbook to a GDX file. Unlike gdxxrw, the program does not require that Excel is installed.

6.3.1 LibInclude Tools Library

In the LibInclude Tools Library, various tools are collected to provide an easy access to complex task. The tools are located in the `inclib` folder in the GAMS system directory and can be invoked using the $libInclude command.

Note

The default library include directory `inclib` can be changed with the libIncDir command line parameter. Hence, make sure you point to the correct directory when using `$libInclude`.

Usage:

```
$libInclude <library_file> [<tool_name>] [<option(s)>]
```

Currently the library includes the following tools:

Libinclude file	Description
moo	Provides methods for multi-objective optimization in GAMS.
pyEmbMI	Provide access to a model instance that can be modified and resolved without regenerating the model over and over.
rank	Routine for ranking one-dimensional numeric data. Unlike the GAMS tool alg.rank, rank can handle percentile levels.

6.4 ASK

Writing a GUI (Graphical User Interface) for a GAMS application requires some serious programming, and therefore place a burden on the knowledge and time of the modeler. In this section we show how extremely simple user interfaces can be built using a few simple tools. The main purpose of these tools is to allow a developer quickly put an application together such that an end-user does not have to edit GAMS files. We assume the end-user runs a GAMS model from the GAMS-IDE.

The ASK utility can be used to get input from an end-user and the GDXViewer tool can be used to present end-results. Together these tools allow you to build a minimalist GUI without any programming.

6.4.1 Usage

```
ask <options>
```

where the **options** are

`T=string`

where the `string` identifies the type of input item to go after and can be

- `integer` - when one wants an integer number
- `float` - when one wants a real number
- `radiobutton` - when one wants a radio button choice
- `combobox` - when one wants a combo (drop down choice) box
- `checklistbox` - when one wants a check list box
- `fileopenbox` - when one wants the name of a file to open
- `filesavebox` - when one wants the name of a file to save

Example: `T=integer`

`M="string"`

where the `string` is the text to in the box.
Example: `M="Enter a number"`

`O="filename"`

where the `filename` is the name of a file in which to place the results for subsequent inclusion into GAMS
Example: `O="file.inc"`

`D="string 1|string 2..."`

where the "string 1|string 2|string 3|...|string n" gives the n strings to be associated with multiple choices when using checkbox, radiobutton, combobox, or checklistbox. The individual strings are separated by the delimiter "|"
Example: `D="Small data set|Medium data set|Large data set"`

`E="number 1|number 2..."`

where the "number 1|number 2|number 3|...|number n" gives the n numbers to be returned to GAMS associated with the choices made when using checkbox, radiobutton, combobox, or checklistbox. The individual numbers are separated by the delimiter "|"
Example: `E="1|2|3|4|5"`

`I="filepath"`

where `filepath` gives the path in which to look for the file under the fileopenbox and filesavebox dialogues. If not specified this is the project directory
Example: I="C:\gams\mine"

`F="filemask"`

where `filemask` gives the mask for acceptable files under the fileopenbox and filesavebox dialogues. If not specified this is ∗.∗.
Example: `I="*.gdx"`

`R="string"`

where the `string` gives a line of GAMS code to place in the include file.
This can contain a s parameter in which the information to return is substituted
Example: R="$include '%s'" or R="set i /1990∗%s/;"

`C="string"`

A title for the dialogue box being used
Example: `C="Box to ask for a file"`

`L=number`

where the `number` gives a lower bound on a numeric entry
Example: `L=15`

`U=number`

where the `number` gives an upper bound on a numeric entry
Example: `U=15`

@"filename"

where `filename` gives the name of a file of input instructions containing the options above in this table
Example: `@ask.opt`

In addition a number by itself can be entered to put multiple entries into columns under the `checkbox`, `radiobutton`, `combobox`, or `checklistbox` entries.

6.4.2 Calling ASK utility from GAMS

The ASK utility is a simple tool to ask simple interactive questions to the end-user. For instance, if your model requires a scalar to be changed regularly, instead of letting the end-user change the `.gms` source file, it may be better to pop up a window, with a question text, where the required number can be entered. The ASK tool allows you to do this. As the ASK tool generates a standard GAMS include file, this file can then be used through a `$include` statement:

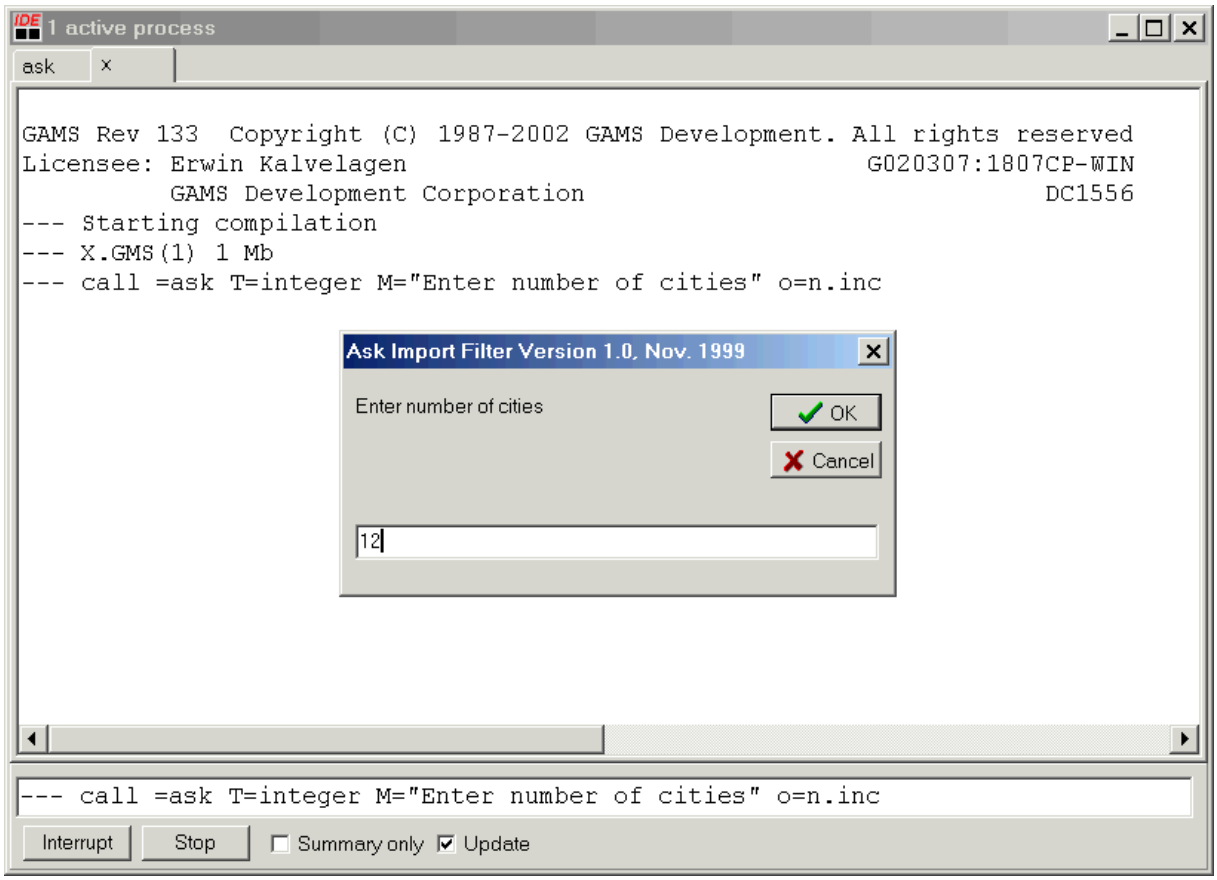
```
$call =ask T=integer M="Enter number of cities" o=n.inc
Scalar n 'number of cities' /
$include n.inc
/;
display n;
```

The `$call` statement will invoke the ASK tool. If `ASK.EXE` is not located in the GAMS system directory but placed somewhere else you may have to provide a path, as in:

```
$call =d:\util\ask T=integer M="Enter number of cities" o=n.inc
```

The parameter `T=integer` indicates we want to ask for an integer number (`T` means type). The parameter `M="text"` specifies the question text. Finally `O=filename` sets the name of the include file that ASK should create.

When we run this GAMS fragment from the IDE, we will see:



After enter a number and hitting the OK button GAMS will continue. The listing file will demonstrate clearly how the include file was formed:

```
 2  scalar n 'number of cities' /
INCLUDE    D:\GAMS PROJECTS\ASK\N.INC
 4  * Ask Import Filter Version 1.0, Nov. 1999
 5  * Erwin Kalvelagen, GAMS Development Corp.
 6  12
 7  /;
 8  display n;
Include File Summary
 SEQ   GLOBAL TYPE      PARENT   LOCAL  FILENAME
   1        1 INPUT          0       0  D:\GAMS PROJECTS\ASK\X.GMS
   2        1 CALL           1       1  =ask T=integer M="Enter number of cities" o=n.inc
   3        3 INCLUDE        1       3  .D:\GAMS PROJECTS\ASK\N.INC
```

In this case `12` was entered and the `OK` button was pressed. If the user pressed the `CANCEL` button, an error will be generated and the listing file will show that the `CANCEL` button was pressed:

```
   2  scalar n 'number of cities' /
  INCLUDE    D:\GAMS PROJECTS\ASK\N.INC
   4  * Ask Import Filter Version 1.0, Nov. 1999
   5  * Erwin Kalvelagen, GAMS Development Corp.
   6  * Cancel was pressed
   7  /;
* ****  $1
* **** LINE      4 INPUT       D:\GAMS PROJECTS\ASK\X.GMS
* ****   1  Real number expected
   8  display n;
```

In case you want to limit the integer that the user is allowed to enter you can specify a lower and an upperbound as in:

```
$call =ask T=integer M="Give integer, between 0 and 5" L=0 U=5 O=n1.inc
Scalar n1 'an integer 0..5' /
$include n1.inc
/;
display n1;
```

This will only accept values between `0` and `5`.

To allow the user to specify a floating point number, we can use `T=float`. An example is:

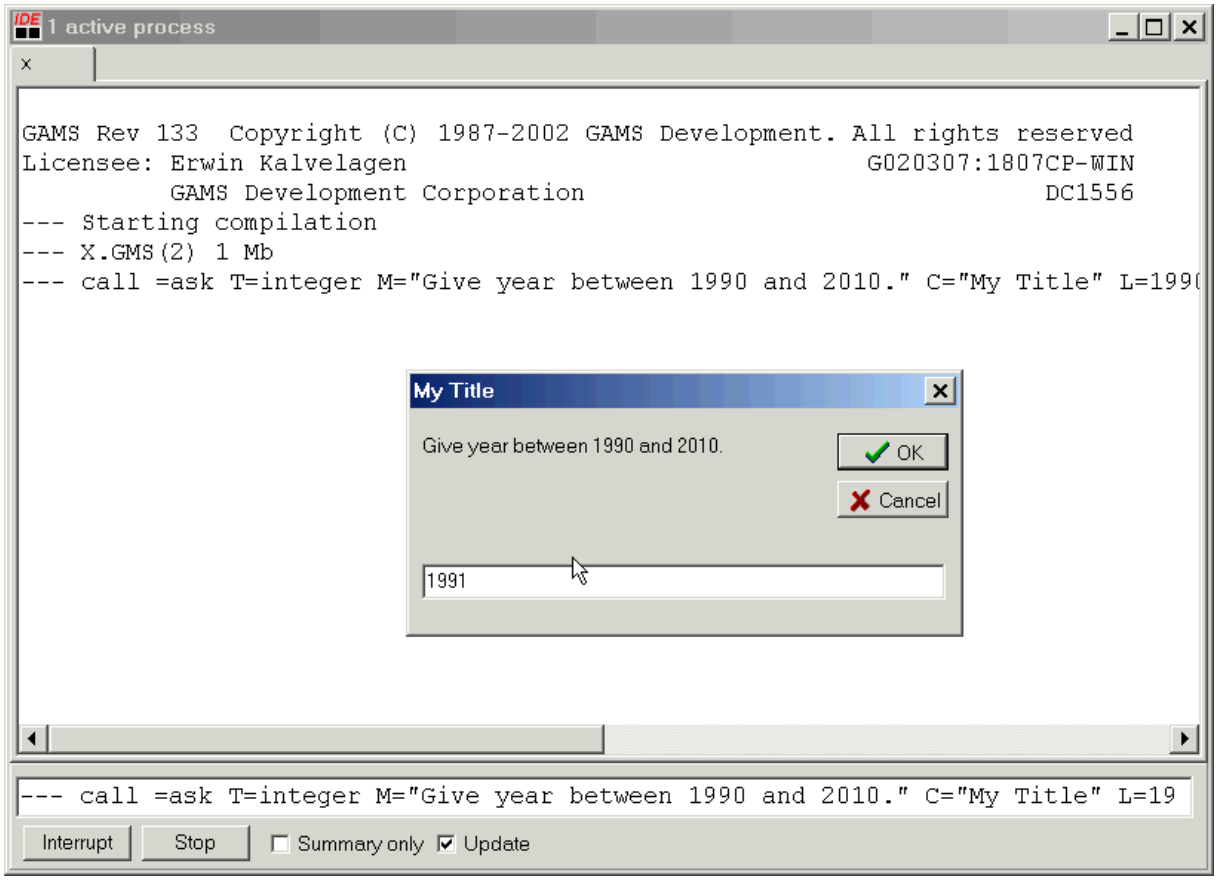
```
$call =ask T=float M="Give floating point number, no bounds" O=x.inc
Scalar x 'real' /
$include x.inc
/;
display x;
```

The floating point popup window can be told to make sure the number entered is within certain bounds, using the `L=lowerbound` and `U=upperbound` syntax:

```
$call =ask T=float M="Give floating point number, between 0 and 5" L=0 U=5.0 O=x1.inc
Scalar x1 'real' /
$include x1.inc
/;
display x1;
```

Up to now, the include file generated by ASK just contained a single number. ASK can generate mode complicated include files. Consider the example:

```
* import a set
$call =ask T=integer M="Give year between 1990 and 2010." C="My Title" L=1990 U=2010 R="set i /1990*
$include i.inc
display i;
```



The parameters `C="caption"` and `R="resultstring"` are new. The caption is simple: it sets the name of the window. The result string is a string that is returned after ASK has substituted `s` for the result. I.e. if we enter `1991`, then the result written to the include file is `set i /1990*1991/;`.

The listing file can be used to check the correct behavior:

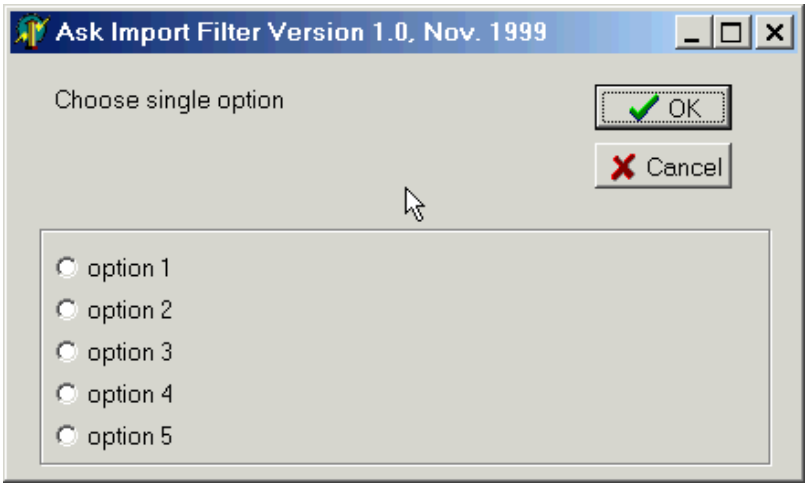
```
 1  * import a set
INCLUDE    D:\GAMS PROJECTS\ASK\I.INC
 4  * Ask Import Filter Version 1.0, Nov. 1999
 5  * Erwin Kalvelagen, GAMS Development Corp.
 6  set i /1990*1991/;
```

```
 7  display i;
Include File Summary
 SEQ   GLOBAL TYPE      PARENT   LOCAL  FILENAME
   1        1 INPUT          0       0  D:\GAMS PROJECTS\ASK\X.GMS
   2        2 CALL           1       2  =ask T=integer M="Give year between 1990 and 2010." C="My Ti
                                        R="set i /1990*%s/;" O=i.inc
   3        3 INCLUDE        1       3  .D:\GAMS PROJECTS\ASK\I.INC
```

6.4.3 Radio Button

Radio buttons can be used through the parameter `T=radiobuttons` as in:

```
* import a number through radio buttons
$call =ask T=radiobuttons M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" I
$include n2.inc
display n2;
```



The parameter `D="option 1|option 2|option 3|option 4|option 5"` specifies the text of the options shown. The list `E="1|2|3|4|5"` gives the return (exit) strings when a certain option is chosen. I.e. if the second option os chosen in the list specified with the `D` parameter, then the second string in the `E` list is returned. The result is again substituted in the string specified in the `R` parameter if it exists.

In this example the command line became rather long and difficult to handle. In addition some Windows systems have restrictive maximum lengths for the command line. Therefore we offer the possibility to specify the command line arguments in a separate external text file. This text file is passed using

```
@filename
```

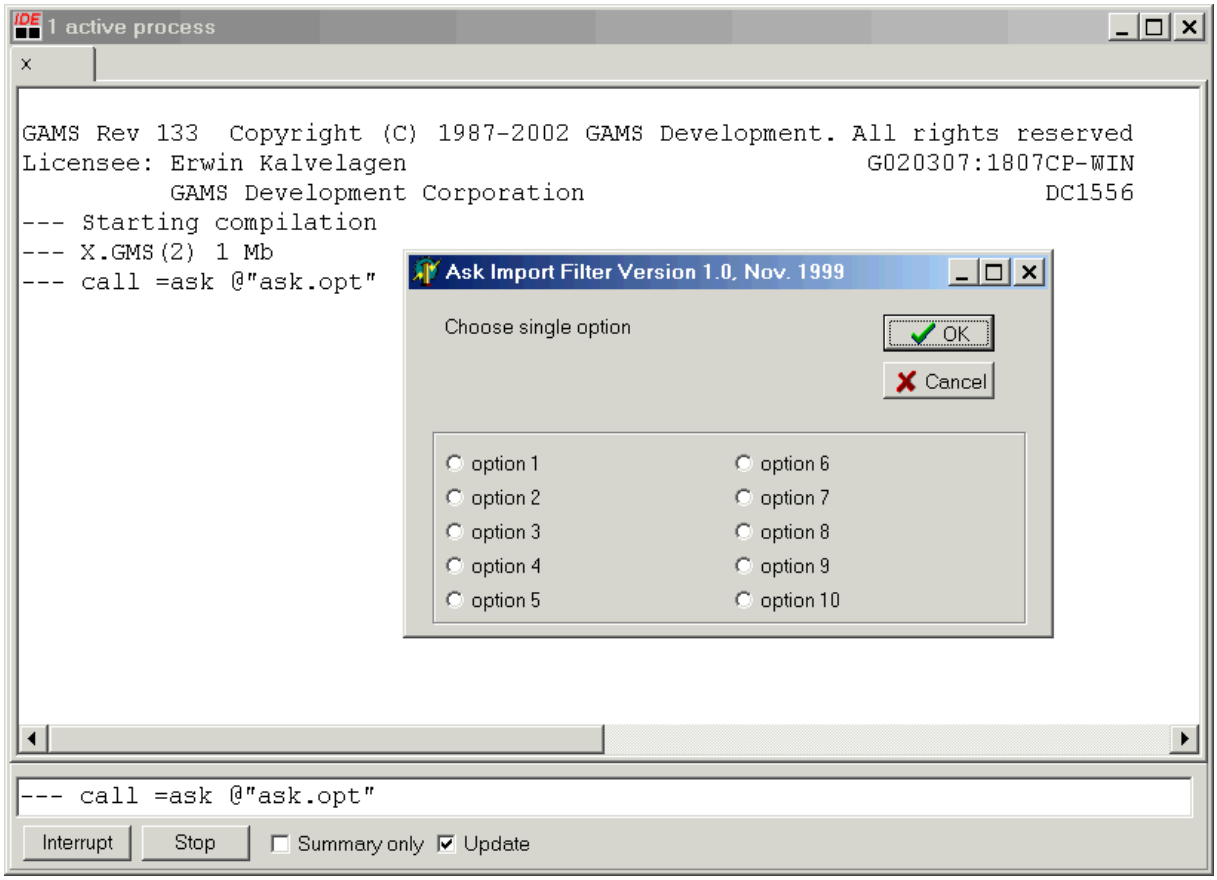
. Assume the file `ask.opt` looks like:

```
T=radiobuttons
M=Choose single option
D=option 1|option 2|option 3|option 4|option 5|option 6|option 7|option 8|option 9|option 10
E=1|2|3|4|5|6|7|8|9|10
2
R=scalar n3 option /%s/;
O=n3.inc
```

Every command line parameter is specified on a separate line. Notice the strange option 2; this tells ASK to display the radio buttons in two columns. We can use this option file as follows:

```
* id, now 2 columns and using a parameter file
$call =ask @"ask.opt"
$include n3.inc
display n3;
```

The quotes around the filename are optional, and really only needed if the filename contains blanks.



If you want to keep all the logic in one place, then one can use GAMS to generate the option file. It is noted that it is not possible to use the PUT facility for this. I.e.:

```
File f /asktest.opt/;
put f;
put 'T=checklistbox'/
  'M=Choose multiple options'/
  'D=option 1|option 2|option 3|option 4|option 5'/
  'E=1|2|3|4|5'/
  'R=%s checked list box choice'/
  'O=k2.inc'/;
putClose;
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

is not correct: the $call is handled at compile time, before the PUT statement has done its work. However, one could use the following:

```
$echo 'T=checklistbox'                                    > asktest.opt
$echo 'M=Choose multiple options'                        >> asktest.opt
$echo 'D=option 1|option 2|option 3|option 4|option 5' >> asktest.opt
$echo 'E=1|2|3|4|5'                                      >> asktest.opt
$echo 'R=%s checked list box choice'                     >> asktest.opt
$echo 'O=k2.inc'                                         >> asktest.opt
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

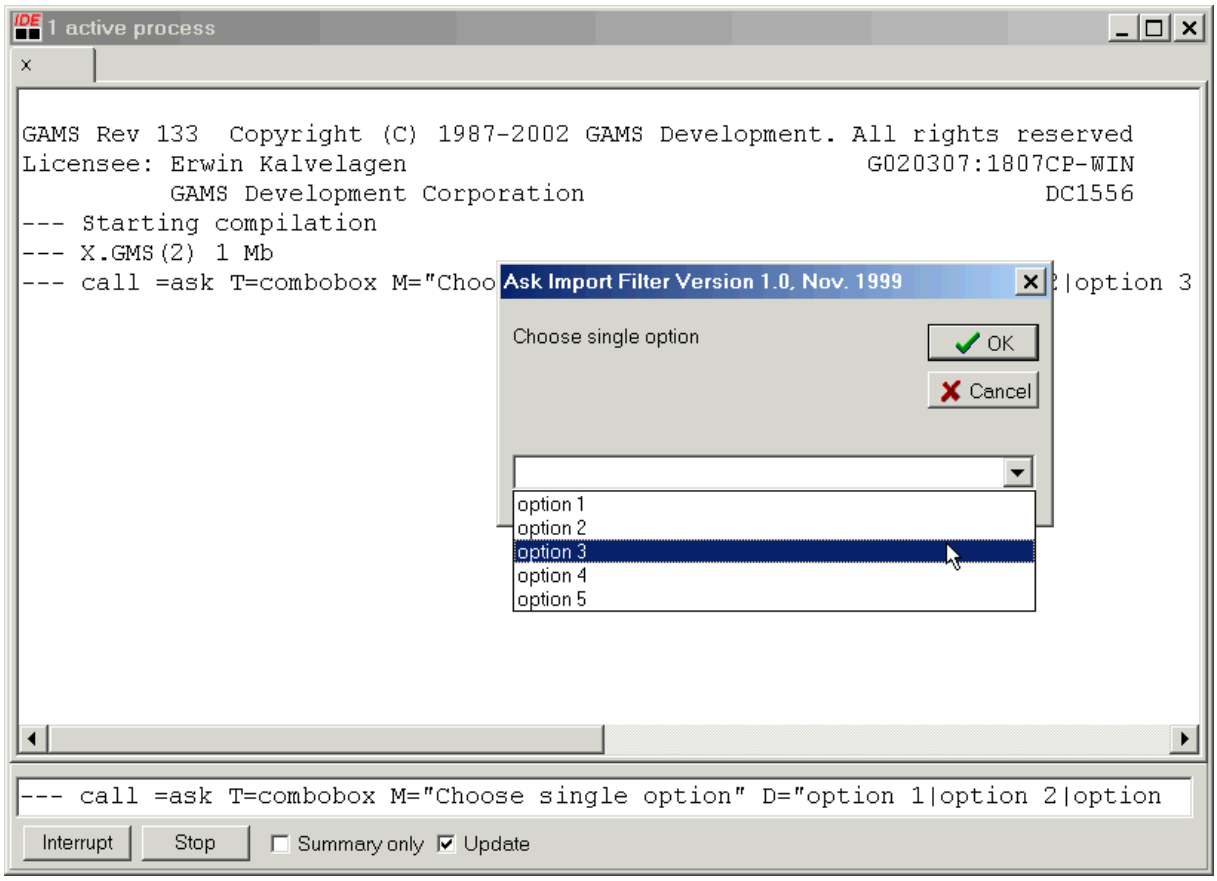
or better:

```
$onEcho > asktest.opt
T=checklistbox
M=Choose multiple options
D=option 1|option 2|option 3|option 4|option 5
E=1|2|3|4|5
R=%s checked list box choice
O=k2.inc
$offEcho
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

6.4.4 Combo Box

The next type is T=combobox which also allows a single selection:

```
* import a number through a combo box
$call =ask T=combobox M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" E="1
$include n4.inc
display n4;
```



As an example consider the case where the model comes with three data sets: a small one, a medium sized one and a large data set. Each data set is stored in a separate include file: `small.inc`, `medium.inc` and `large.inc`. We want to ask the user which data set should be used and the correct include file should be used. This can be accomplished by:

```
$echo 'T=combobox' > ask.opt
$echo 'M=choose data set' >> ask.opt
$echo 'D=Small data set|Medium data set|Large data set' >> ask.opt
$echo 'E=small.inc|medium.inc|large.inc' >> ask.opt
$echo 'R=$include %s' >> ask.opt
$echo 'O=dataset.inc' >> ask.opt
$call =ask @ask.opt
$include dataset.inc
```

Newer GAMS systems allow:

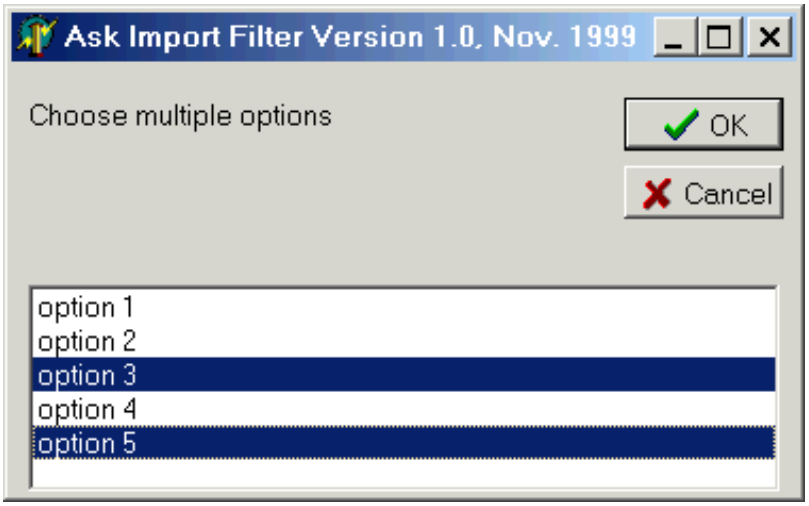
```
$onEcho > ask.opt
T=combobox
M=choose data set
D=Small data set|Medium data set|Large data set
E=small.inc|medium.inc|large.inc
R=$include %s
O=dataset.inc
$offEcho
$call =ask @ask.opt
$include dataset.inc
```

In this case `dataset.inc` will contain a single line: another include statement, which is either `$include small.inc`, `$include medium.inc` or `$include large.inc`.

6.4.5 List and Checklist Box

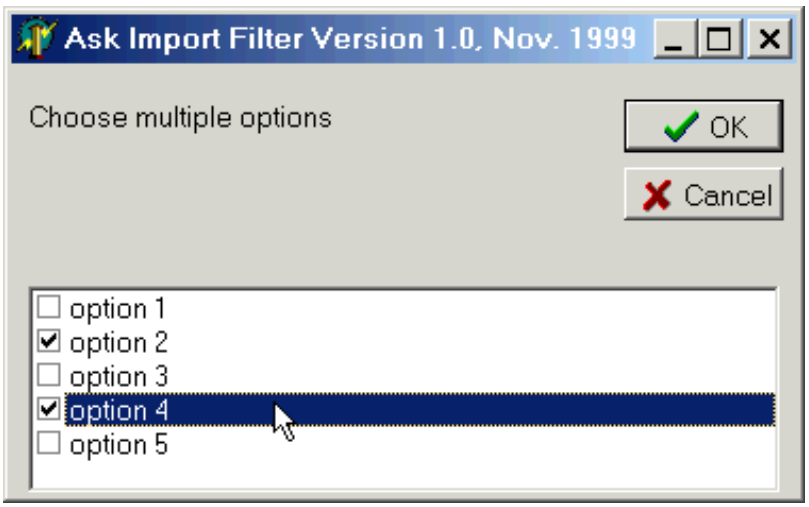
In some cases it may be useful to be able to select multiple items from a list. This can be done with T=listbox:

```
* import a set through a listbox
$call =ask T=listbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E=
Set k /
$include k.inc
/;
display k;
```



Selecting multiple entries involves holding down the CTRL key. Sometimes a convenient alternative is T=checklistbox :

```
* import a set through a checked listbox
$call =ask T=checklistbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option
Set k2 /
$include k2.inc
/;
display k2;
```



When we select options 1, 3 and 5, the following include file is generated:

```
* Ask Import Filter Version 1.1, Aug. 2002
* Erwin Kalvelagen, GAMS Development Corp.
1 'checked list box choice'
3 'checked list box choice'
5 'checked list box choice'
```

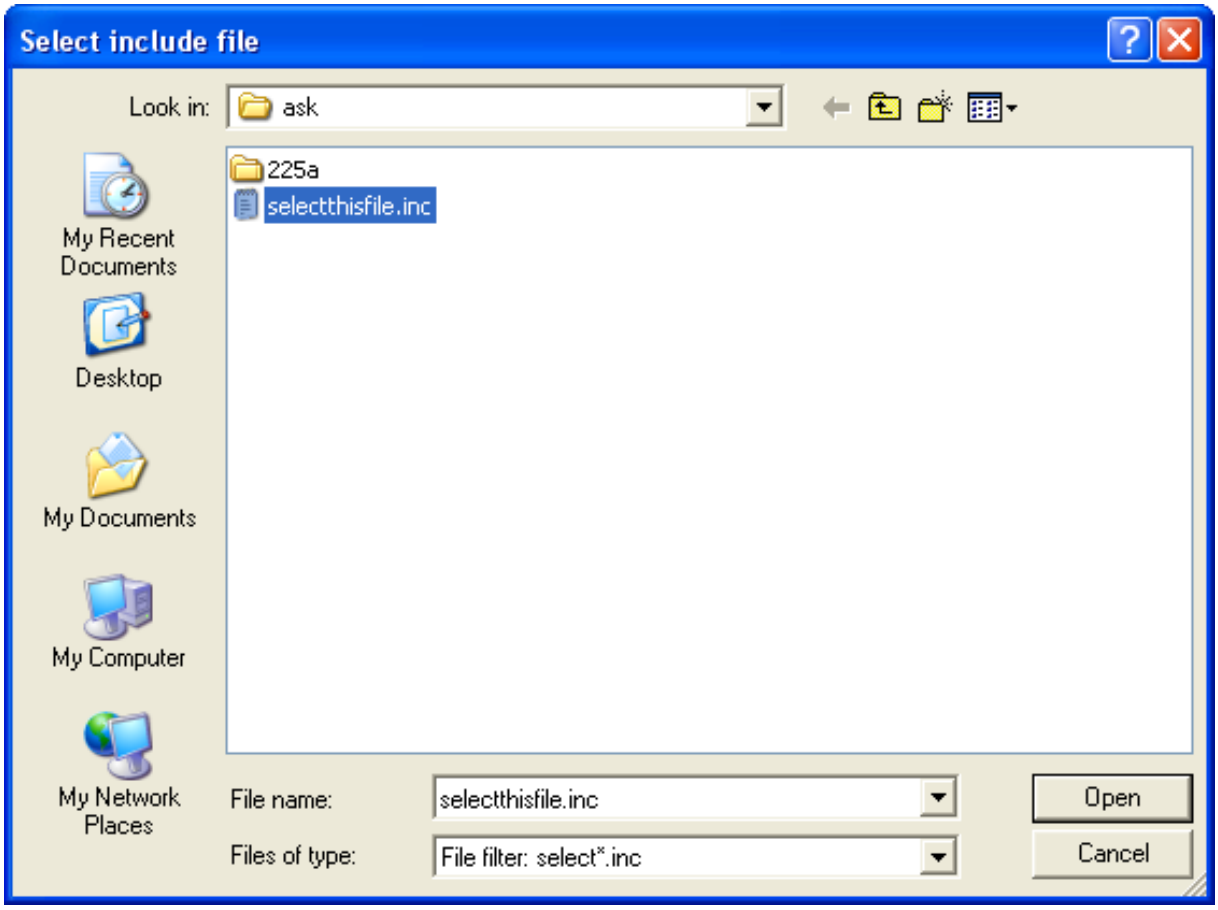
which will populate the set k2 as follows:

```
 1  * import a set through a checked listbox
 3  set k2 /
INCLUDE    D:\GAMS PROJECTS\ASK\K2.INC
 5  * Ask Import Filter Version 1.1, Aug. 2002
 6  * Erwin Kalvelagen, GAMS Development Corp.
 7  1 'checked list box choice'
 8  3 'checked list box choice'
 9  5 'checked list box choice'
10  /;
11  display k2;
----     11 SET k2
1,    3,    5
```

The last type is the generic string type: `T=string`. This allows the user to enter any string, which is then copied to an include file as is.

6.4.6 File Open Dialog Box

The type `T=fileopenbox` will display a file open dialog box from which the user can select a file.



Related options are `I=InitialDirectory` and `F=Filter`. A complete example to ask for an include file could be:

```
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$include '%s'" C="Select inclu
$include fln.inc
```

This will open a file open dialog box with the starting directory being the `GAMS project/working` directory (this is also where GAMS looks for include files by default). Only files with mask `SELECT*.INC` are shown. The file `FLN.INC` will contain an include statement with the file the user has selected.

A related method would be:

```
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$setglobal incfile '%s'" C="Se
$include fln.inc
$include %incfile%
```

where we use a `$setglobal` to set the macro incfile to contain the user-specified file name.

To let the user choose from a set of related GDX files, one could use something like:

```
$call =ask T=fileopenbox I="%system.fp%" F="myproject*.gdx" o=setgdxname.inc R="$setglobal gdxfile '
$include setgdxname.inc
$gdxIn %gdxfile%
$load i
$load j
```

In case you want to ask for a filename of a file to be written, use the type `T=filesavebox`. E.g.:

```
$call =ask T=filesavebox I="%system.fp%" o=fln.inc R="$setglobal gdxfile '%s'" C="Specify gdx file"
$include fln.inc
Set i / a, b, c /;
execute_unload '%gdxfile%', i;
```

In case you want to ask for a directory, use the type `T=selectdirectory`. In this case the filter option `F` is ignored. E.g.:

```
$call =ask T=selectdirectory I="%system.fp%" o=fln.inc R="$setglobal myInputdir '%s'" C="Select dire
$include fln.inc
$log Selected directory "%myInputdir%"
```

6.5 Cholesky

Note

> This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This calculates the Cholesky decomposition of a symmetric positive definite matrix A: $A = LL^t$ The matrix A is indexed over `A(i,i)`.

6.5.1 Usage

Command line:

```
gamstool [linalg.]Cholesky i A L gdxIn=fileIn.gdx gdxOut=fileOutgdx
```

Compile time:

```
$callTool [linalg.]Cholesky i A L [gdxIn=fileIn.gdx] [gdxOut=fileOutgdx]
```

Execution time:

```
executeTool '[linalg.]Cholesky i A L [gdxIn=fileIn.gdx] [gdxOut=fileOutgdx]';
```

Where:

Argument	Description
i	Name of set used in matrix i(*).
A	Name of two-dimensional matrix parameter A(i,i).
L	Name of two-dimensional parameter containing the factor L(i,i).

The following named parameters are available:

Parameter	Description
gdxIn=fileIn.gdx	Name of GDX file that contains symbols i and A. Mandatory if called from the command line, otherwise optional.
gdxOut=fileOut.gdx	Name of GDX file that contains symbol L after execution. Mandatory if called from the command line, otherwise optional.

6.5.2 Examples

```
executeTool.checkErrorLevel 'linalg.cholesky n Yl L';
* Check if Cholesky factorization is correct
Parameter Y_, Ydiff;
Y_(i,j)    = sum(n, L(i,n)*L(j,n));
Ydiff(i,j) = round(Y.l(i,j) - Y_(i,j),1e-6);
option Ydiff:8:0:1;
abort$card(Ydiff) Ydiff;
```

For the complete example, see model [**Maxcut**] in the GAMS Model Library.

```
execute_unload 'a.gdx', i, a;
executeTool.checkErrorLevel 'linalg.cholesky i a L gdxin=a.gdx gdxout=b.gdx';
execute_load 'b.gdx', L;
```

```
$callTool linalg.cholesky i a L;
```

6.6 CSV2GDX

CSV2GDX is a tool that reads a CSV file and writes to a GDX file. There are multiple ways to read [CSV] (https://en.wikipedia.org/wiki/Comma-separated_values) files (Comma Separated Values) inside GAMS (see Data Exchange with Text Files for instance), but a number of features available in CSV2GDX make it possible to read a CSV file where GAMS itself cannot be used. In addition to the syntax explanation and the basic functionalities demonstrated on some examples, this tutorial also discusses some advantages and disadvantages of CSV2GDX compared to the GAMS internal table statement.

6.6.1 Usage

CSV2GDX is called by specifying the CSV file and several options to define how to read the data.

```
csv2gdx filename {options}
```

Filename

The input file; the .csv file extension is assumed when no extension has been specified.

Parameters can also be read from a text file; the use of an external file for parameters is indicated by preceding the file name with a @ (at sign). When reading parameters from a text file, lines starting with an asterisk (∗) will be ignored. See also Example 8.

Option	Default	Description

6.6.2 Options

The following options can be used when calling `CSV2GDX`:

Option	Default	Description
acceptBadUels	`N`	Indicate if bad UELs are accepted or result in an error return code.
autoCol	none	Generate automatic UELs for each column.
autoRow	none	Generate automatic UELs for each row.
checkDate	`N`	Write GDX file only if the CSV file is more recent than the GDX file.
colCount	none	Number of columns in the input file.
decimalSep	Period	Specify a decimal separator.
fieldSep	Comma	Specify a field separator.
id	none	Identifier for the symbol in the GDX file.
index	none	Identify columns to get UELs from.
output	<CSVFilename>.gdx	Optional output filename.
password	none	Password for an encrypted input file.
storeZero	`N`	Indicate how zero values are handled.
text	none	Specify the column to get explanatory text from.
trace	1	Controls the amount of information written to the log.
useHeader	`N`	Indicate if the first row is a header row.
value	none	Specify the column to get the values from.
valueDim	`N`	Adds an extra dimension for values.
values	none	Specify the columns to get the values from.

Note

- The user has to specify an identifier for the symbol in the GDX file within the parameter `id`, regardless of the data structure in the CSV file.
- `CSV2GDX` determines the number of columns in the CSV file from the header row or from the user defined input specified in the parameter `colCount`. Therefore, the user must enable the option `useHeader` or has to specify the number of columns within `colCount` in any case.

Some more detailed remarks on the options:

acceptBadUels = *boolean* (default=`N`)

This option specifies how to proceed, when a bad UEL (e.g. too long) is encountered. If set to `N`, reading is stopped, and an error is signaled. When set to `Y`, a valid UEL is made up and reading is continued.

autoCol = *string*

Generate automatic UELs for each column. The autoCol string is used as the prefix for the column label numbers. This option overrides the use of a header row. However, if there is a header row, one must skip the row by enabling `useHeader`. This option is demonstrated in Example 3.

autoRow = *string*

Generate automatic UELs for each row. The autoRow string is used as the prefix for the row label numbers. The generated unique elements will be used in the first index position shifting other elements to the right. Using `autoRow` can be helpful when there are no labels that can be used as unique elements but also to store entries that would be a duplicate entry without an unique row label. This option is demonstrated in Example 3.

checkDate = *boolean* (default=`N`)

Write GDX file only if the CSV file is more recent than the GDX file to save resources when running the model containing the `CSV2GDX` call multiple times. This option is demonstrated in Example 5.

colCount = *integer*

Number of columns in the input file. This parameter is required if there is no header row, since `CSV2GDX` determines the number of columns from the header row. This option is demonstrated in Example 3. Note that the `lastCol` constant cannot be used for the `colCount` option.

decimalSep = [Period, Comma] (default=Period)

Specify a decimal separator. The decimal is normally a period, but this parameter allows a comma as the decimal separator, too. Special values recognized are `Eps`, `NA` resp. `N/A`, `Inf`, `True`, `False`, `None`, `Null` and `Undef` (case insensitive). A string that is not recognized as a valid number will be stored as `Undef`. This option is demonstrated in Example 2 and Example 6 (focusing on reading special values) for instance.

fieldSep = [Comma, SemiColon, Tab] (default=Comma)

Specify a field separator. Fields are normally separated by a comma, but this parameter allows some additional choices. Using tabs as delimiter should be avoided, since text editors act different on handling them. For instance, one must specify tabs in the GAMS IDE explicitly using %system.tab%:

```
$onEcho > tabSeparated.csv
USA%system.tab%100
GER%system.tab%70
$offEcho

$call csv2gdx tabSeparated.csv id=x fieldSep=tab index=1 colCount=2 value=lastCol
```

This option is demonstrated in Example 2 and Example 3 for instance.

id = *string*

Identifier for the symbol in the GDX file. Additional symbols, `Dim1`, `Dim2`, ... for the domain sets of the symbol id will be added automatically to the GDX file. Executing `CSV2GDX` without specifying an identifier will fail.

index = *list of columns*

Identify columns to get UELs from. The columns are represented as a list of integers separated by comma. For example `index=1,2,3,4` resp. `index=(1,2,3,4)`; in this case the notation `1..4` is allowed. Brackets can only be used on Windows systems. The `index` option is used in all examples.

output = *filename* (default=<CSVFilename>.gdx)

Optional output filename. If no output file is specified, `CSV2GDX` will use the input filename and change the file extension to .gdx. If no path is specified, the output file will be created in the current directory. This option is demonstrated in Example 2 for instance.

password = *string*

Password for an encrypted input file. Use ENDECRYPT to encrypt a file. This option is demonstrated in Example 7.

storeZero = *boolean* (default=`N`)

Indicate if zero values are ignored or written as `EPS`; an empty field is always ignored. This option is demonstrated in Example 6.

text = *integer*

Specify the column to get explanatory text from when reading a set. For example `text=5`. This option is demonstrated in Example 9.

trace = *integer* (default=1)

Controls the amount of information written to the log. Higher values will generate more output. Valid range is `0..3`. Set `trace=0` to prevent writing any information to the log. This feature is demonstrated in Example 6.

useHeader = *boolean* (default=`N`)

Indicate if the first row is a header row. The fields in the header row of the columns specified within the values option will be used as UELs. A header row is not needed or should be ignored when using the colCount or autoCol option. To skip one existing header row while using `autoCol`, enable `useHeader`. This option is demonstrated in Example 1 and Example 2 for instance.

value = *integer*

Specify the column to get the values from. For example `value=5`. This option is demonstrated in Example 2.

valueDim = *boolean* (default=`N`)

Indicate if an extra dimension for values is added to the parameter even if there is just one value column. This is ignored, if there is no value column. This feature is demonstrated in Example 2.

values = *list of columns*

Specify the columns to get the values from. When using a list of columns for the values and `useHeader` enabled, each field in the first row of the columns is used as UEL to identify the values in those columns. See also useHeader and autoCol below. If the number of columns is unknown, the symbolic constant `lastCol` can be useful: `values=2..lastCol`. This option is demonstrated in Example 1 and Example 5 for instance.

6.6.3 Advances and limitations

Advances

- CSV2GDX enables the user to read CSV data where the table statement cannot be used without doing further preprocessing, e.g. in case of semicolon- or tab separated data or comma separated decimals.
- In general, CSV2GDX is a quite performant tool compared to the GAMS internal table statement.

Limitations

- Suppose we want to skip some rows while reading the data. For example, if the CSV file contains some reference information in a specific row which we do not want to be stored in the domain sets or in the parameter. However, skipping rows cannot be done with CSV2GDX.
- There might be CSV files with no header and varying, unknown length of rows. Since CSV2GDX determines the number of columns based on the header row or by setting the colCount option in advance, CSV2GDX might return incorrect results or the execution is aborted.
- Reading several parameters from a CSV file cannot be done directly within the CSV2GDX call. The data must be split later on as demonstrated in Example 4.
- CSV2GDX cannot read CSV files containing line breaks within a (quoted) field. You will either get an error message - "Quoted field not terminated with closing quote" - or the result might not be correct for unquoted fields, because the field content will be cut by the line break.

6.6.4 Getting Started

We introduce the basic functionalities of CSV2GDX on some simple examples. Note that many CSV files can be read inside GAMS directly using a table statement, but a number of features available in CSV2GDX enable the user to read a CSV file where the table statement cannot be used, e.g. reading files with semicolon separated data or if the decimals are separated by comma instead of a period.

6.6.4.1 Example 1 - Reading CSV Files with CSV2GDX

The first example of this collection demonstrates the key commands of CSV2GDX. For instance, consider the table statement of the model [**trnsport**] from the GAMS Model Library:

```
Table d(i,j) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;
```

The data can be stored in distance.csv like this:

```
,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4
```

First of all, `CSV2GDX` is called now, to generate distance.gdx by processing the input file distance.csv:

```
csv2gdx distance.csv id=d index=1 values=2..lastCol useHeader=y
```

`CSV2GDX` generates one single parameter `d` and two domain sets from the input file. The name of the parameter in the GDX file must be declared within the id option, while the domain sets for this parameter will be labeled with `Dim1` and `Dim2` automatically. Column number one is specified as the first domain set within the index option. The values option is used to specify the column numbers `2,3,4` containing the data values. By enabling the useHeader option, the fields of the first row of the columns specified within the `values` option will be handled as the second domain set. If the number of columns is unknown in advance, one can use the lastCol constant in the `values` or `index` option.

However, to complete the declaration of the sets and parameter for the model trnsport, one must load the data from distance.gdx:

```
Set
   i 'canning plants'
   j 'markets';

$gdxIn distance.gdx
$load i = Dim1
$load j = Dim2

Parameter d(i,j) 'distance in thousands of miles';
$load d
$gdxIn
display i, j, d;
```

This example is also part of the GAMS Data Utilities Library, see model [**csv2gdx2**] for reference.

6.6.4.2 Example 2 - Reading Semicolon separated Data

In this example, the distances from the previous example are stored as a list. We want to read the cities and the column containing the miles measurement. Note, that the fields are separated by semicolon and the decimals by comma. As described in Data Exchange with Text Files the CSV file must be preprocessed with the `POSIX` tools in advance to replace commas by dots and semicolons by commas to read the data directly using a simple table statement.

```
i;j;miles
seattle;new-york;2,5
seattle;chicago;1,7
seattle;topeka;1,8
san-diego;new-york;2,5
san-diego;chicago;1,8
san-diego;topeka;1,4
```

The data will be stored as distanceOut.gdx by adding the output file option. One can specify the field and decimal separators within the fieldSep and decimalSep option. Domain sets for the parameter to be read are declared by `index=1,2`.

```
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHea
```

In order to load the data from the GDX file, execute the commands from the previous example. However, note that `Dim2` does not contain the UELs from the header row this time, but the unique elements of the second column specified in the `index` option. The option `useHeader` is enabled to indicate that there is a header row to be skipped when reading the values. Also note, that the symbol `d` in the GDX file has exactly two dimensions. It may be useful to add an additional dimension to the parameter `dmod`, e.g. if different measurement units for the distances may become relevant later on and need to be calculated (kilometer for instance).

This can be done by adding the option valueDim:

```
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHea
```

The option adds a third dimension to `d`. Now we want to add the distances in kilometer by calculating the values inside the model:

```
Set m 'measurement unit' / miles, km /;

Parameter dmod(i,j,m);

$gdxIn distanceOut.gdx
$load dmod = d
$gdxIn
display dmod;

dmod(i,j,'km') = 1.852*dmod(i,j,'miles');
display dmod;
```

Parameter `d` (`valueDim` disabled):

```
----     36 PARAMETER d  distance in thousands of miles

             new-york     chicago      topeka

seattle         2.500       1.700       1.800
san-diego       2.500       1.800       1.400
```

Parameter `dmod` resp. `d` with `valueDim` enabled before calculating further measurements:

```
----     49 PARAMETER dmod

                           miles

seattle  .new-york         2.500
seattle  .chicago          1.700
seattle  .topeka           1.800
san-diego.new-york         2.500
san-diego.chicago          1.800
san-diego.topeka           1.400
```

Parameter `dmod` with `valueDim` enabled after calculating the distances in kilometer inside the GAMS model:

```
----     52 PARAMETER dmod

                           miles          km

seattle  .new-york         2.500       4.630
seattle  .chicago          1.700       3.148
seattle  .topeka           1.800       3.334
san-diego.new-york         2.500       4.630
san-diego.chicago          1.800       3.334
san-diego.topeka           1.400       2.593
```

This example is also part of the GAMS Data Utilities Library, see model [**csv2gdx3**] for reference.

6.6.4.3 Example 3 - Dealing with missing Labels and Duplicates

Missing Labels

The file EUCData.csv contains the extracted euclidean coordinates of the first nine cities of berlin52.tsp from [TSPLib] (http://comopt.ifi.uni-heidelberg.de/software/TSPLIB95/). You might want to import the data to calculate a complete distance matrix inside GAMS to find an optimal traveling salesman tour for instance.

```
565.0;575.0
25.0;185.0
345.0;750.0
945.0;685.0
845.0;655.0
880.0;660.0
25.0;230.0
525.0;1000.0
580.0;1175.0
```

There is no header row, neither a column with labels to serve as domain sets for the coordinates of the cities. However, CSV2GDX automatically generates UELs for columns and rows by adding ascending numbers to an user-defined prefix specified within the autoCol and autoRow option. Also note, because of the missing header, the number of columns in the file must be manually determined and declared within colCount.

```
csv2gdx EUCData.csv id=coord fieldSep=semiColon autoCol=x autoRow=city colCount=2 values=1,2
```

The rows will be labeled with city1...city9, the columns with x1 and x2.

Load the parameter and sets from the GDX file to calculate the complete distance matrix. The set Dim1 contains the UELs city1...city9 for the set i of cities, Dim2 is the set of axes/coordinates i.e. containing the elements x1 and x2 to represent the x-axis and y-axis:

```
Set
   i    'cities'
   axes 'x1 and x2 axes';

$gdxIn EUCData.gdx
$load i    = Dim1
$load axes = Dim2

Parameter coord(i,axes) 'coordinate of city i';
$load coord
$gdxIn
display coord;
```

The display statement generates the following output:

```
----     43 PARAMETER coord  coordinate of city i

               x1          x2

city1     565.000     575.000
city2      25.000     185.000
city3     345.000     750.000
city4     945.000     685.000
city5     845.000     655.000
city6     880.000     660.000
city7      25.000     230.000
city8     525.000    1000.000
city9     580.000    1175.000
```

One could now easily proceed calculating a complete distance matrix:

```
Alias (i,j);

Parameter c(i,j) 'euclidean distance between city i and j';
c(i,j) = eDist(coord(i,"x1") - coord(j,"x1"),coord(i,"x2") - coord(j,"x2"));
```

Duplicates

In the previous example, using the `autoCol` and `autoRow` option had an additional benefit as we declared the set of the cities on the fly. However, one major advantage/purpose of these options is to prevent error messages or loss of data when reading rows with duplicate keys.

Consider the input file duplicates.csv:

```
red,red,1
red,red,2
red,green,3
blue,blue,4
```

Note the duplicate key in the first two rows. By the use of the `autoRow` parameter in the `CSV2GDX` call unique labels are added to each row. This way a GAMS program can store all data with duplicate keys and prepare for better error messages.

```
csv2gdx duplicates.csv id=data index=1,2 value=3 colCount=3 autoRow=row
```

Ascending numbers will be added to the 'row' prefix specified.

The data can be easily loaded into sets and parameter by executing the following lines:

```
Set
   row   'UELs generated by autoRow'
   color 'set of colors';

$gdxIn duplicates.gdx
$load  row   = Dim1
$load  color = Dim2
$loadm color = Dim3

Parameter data(row,color,color);
$load data
$gdxIn
display row, color, data;
```

Note the usage of the $loadm command to merge all colors into one set of colors. The display statement generates the following output in the listing file:

```
----     77 SET row  UELs generated by autoRow

row1,    row2,    row3,    row4

----     77 SET color  set of colors

red  ,    blue ,    green
```

```
----     77 PARAMETER data

                  red        blue       green

row1.red        1.000
row2.red        2.000
row3.red                                3.000
row4.blue                   4.000
```

The complete example is also part of the GAMS Data Utilities Library, see model [**csv2gdx4**] for reference.

6.6.4.4 Example 4 - Reading several Parameters from a single Input File

This example demonstrates how to read the data from a single input file into different parameters. However, this cannot be done directly using the `CSV2GDX` tool, since `CSV2GDX` writes to a single parameter (see section limitations). For instance, an energy supplier plans to build new transmission lines from their power plants to some distribution stations. There are different stages for the transmissions lines. The relevant data to be read are the plant and station identifiers, the capacity bounds per transmissions line on a certain stage and the associated cost. The data is all stored in a single file:

```
plant;station;length;minCap;maxCap;stage;cost
p1;s1;100;50;100;1;1200
p1;s2;75;35;65;1;500
p1;s1;100;100;150;2;1800
p2;s1;150;50;100;1;1400
p2;s1;150;100;150;2;2000
p2;s1;150;150;200;3;2350
p2;s2;75;25;50;1;600
p2;s2;75;50;75;2;800
p3;s1;80;40;100;1;1050
```

Read networkData.csv with `CSV2GDX` by calling:

```
csv2gdx networkData.csv id=dataPar useHeader=y fieldSep=semiColon index=1,2,6 values=4,5,7
```

Note that the stage stored in column six is a domain set, too, while the length of the transmission line in the third column is of no interest. Since `CSV2GDX` writes to a single parameter, one must split the data later on into `minCap`, `maxCap` and `cost` for instance:

```
Parameter
   dataPar
   minCap(plant,station,stage)
   maxCap(plant,station,stage)
   cost(plant,station,stage);

$gdxIn networkData.gdx
$load plant   = Dim1
$load station = Dim2
```

```
$load stage   = Dim3
$load dataPar
$gdxIn

minCap(plant,station,stage) = dataPar(plant,station,stage,'minCap');
maxCap(plant,station,stage) = dataPar(plant,station,stage,'maxCap');
cost(plant,station,stage)   = dataPar(plant,station,stage,'cost');
```

This example is also part of the GAMS Data Utilities Library, see model **[csv2gdx5]** for reference.

6.6.4.5 Example 5 - Reading economic Data from the World Bank Data Catalog

This example demonstrates how to read some real CSV data from the [World Bank Data Catalog] (https://datacatalog.worldbank.org/). Suppose we want to read some time series data, e.g. GDP growth rates. The data is structured as follows (rows shortened for presentation):

```
"Country Name","Country Code","Indicator Name","Indicator Code","1999","2000","2001","2002","2003","
"East Asia and Pacific","EAA","GDP growth, constant 2010 USD","NYGDPMKTPKDZ","","","","","","","","",
```

We are not interested in the "Country Code", "Indicator Name" and "Indicator Code". Since the annual GDP rate per country is unique, the `CSV2GDX` call is quite easy despite the large number of columns. Note that there are only a few limitations of `CSV2GDX`, discussed in the section Advances and limitations. Empty fields in the data will always be ignored, causing no trouble at all if the field separators are set correctly.

```
csv2gdx GDPData.csv id=GDPG index=1 values=5..lastCol useHeader=y checkDate=y
```

The option checkDate is enabled to save resources if you run the model multiple times, as the GDX file is only written if the CSV file is more recent than the GDX file. To load the sets and parameter from the GDX file, execute the following commands:

```
Set country, year;
$gdxIn GDPData.gdx
$load  country = Dim1
$load  year    = Dim2

Parameter GDPRate(country,year);
$load GDPRate
$gdxIn
display country, year, GDPRate;
```

The display statement generates the following output in the listing file. Obviously, double quotes are removed from the fields of the value columns, but also from the index columns:

```
----     12 SET country

East Asia and Pacific, Europe and Central Asia, Latin America and the Caribbean, Middle East and Nor
Afghanistan          , Albania                , Algeria                        , Angola

----     12 SET year

2015,    2016,    2017,    2018,    2019,    2020

----     12 PARAMETER GDPR

                                   2015        2016        2017        2018        2019        2
East Asia and Pacific             6.504       6.327       6.449       6.182       6.065       5.
Europe and Central Asia           0.963       1.672       3.782       2.901       3.029       2.
Latin America and the Caribbean  -0.562      -1.526       0.902       2.044       2.586       2.
```

Note that the listings have been shortened for presentation. However, there is no data for the years 1999-2014.

This example is also part of the GAMS Data Utilities Library, see model [**csv2gdx6**] for reference.

6.6.5 Additional Examples for extended Use

The examples in this section discuss some special features. Some topics were already mentioned briefly in the previous section like reading compressed and encrypted files or reading the CSV2GDX options from an external file.

6.6.5.1 Example 6 - Reading special Values

To illustrate how special values are interpreted, consider the following data:

```
one,two,three,four,five,six
red,red,,Undef,'3.3',red
red,red,"4.4",5.5,Eps,green
"red",'green',7.7e+02,8.8°,-Inf,blue
blue,blue,10,0,NA,purple
brown,blue,true,false,N/A,green
black,red,None,Null,"True",blue
```

Calling CSV2GDX to read the data and write to GDX:

```
csv2gdx data.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3
```

The GAMS log reports three occurrences of undefined values. Note that the amount of information written to the log was increased by setting the option trace=3.

```
--- call csv2gdx specialValues.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3
CSV2GDX          25.2.0 r67638 ALFA Released 15Aug18 WEI x86 64bit/MS Windows
Header enabled, number of columns = 6
  1: one
  2: two
  3: three
  4: four
  5: five
  6: six
  2: |red|, |red|, ||, |Undef|, |'3.3'|, |red|
  3: |red|, |red|, |4.4|, |5.5|, |Eps|, |green|
  4: |red|, |'green'|, |7.7e+02|, |8.8°|, |-Inf|, |blue|
  5: |blue|, |blue|, |10|, |0|, |NA|, |purple|
Undef Count = 3, No errors, CSV2GDX time = 157ms
```

As mentioned in decimalSep, `CSV2GDX` fails to recognize the number 8.8 from the string 8.8° because of the unknown special character, while 7.7e+02 is interpreted as a number of course. Watch out if there are quotes in the values or index columns. The number 4.4 enclosed by double quotes is interpreted as a number, while '3.3' is not (as you can see in the log, the double quotes are eliminated, while the single quotes remain). In the first column, the double quotes enclosing the string red are removed, while the single quotes in the second column enclosing the string green are not removed. The zero value is stored as `EPS` by setting `storeZero=y`. Note that no error was reported, even though some of the values stored as `Undef` may cause some trouble in your model later on (use $onUndf to enable loading parameters with undefined values).
The booleans `true` and `false` in the second last row are represented by the numericals 1 resp. 0 within GAMS. The special values `None` and `Null` will be converted to 0. Since `storeZore` is enabled in this example, the value displayed for `false`, `None` and `Null` is `EPS`.

Suppose we want to declare the parameter A as: A(color,color,color,number). We can proceed as follows:

```
Set color, number;
$gdxIn data.gdx
$load  color = Dim1
$loadm color = Dim2
$loadm color = Dim3
$load number = Dim4

Parameter A(color,color,color,number);
$onUndf
$load A
$offUndf
$gdxIn
display A;
```

Loading undefined values is enabled by adding $onUndf. This example is also part of the GAMS Data Utilities Library, see model [**csv2gdx7**] for reference.

6.6.5.2 Example 7 - Reading a compressed encrypted Input File

Reading a compressed input file is supported by `CSV2GDX`. The gzip program in the gbin sub-directory or ENDECRYPT must be used for compression. Call gzip to compress the CSV file by running the following command:

```
gzip compressMe.csv -c > compressedFile.csv.gz
```

Gzip writes to standard output by appending -c to keep the original file unchanged. The output is then redirected to compressedFile.csv.gz. To read the compressed file, call CSV2GDX with the same options as for processing the uncompressed file.

```
csv2gdx compressedFile.csv.gz output=unCompressedGzipFile.gdx id=d index=1 useHeader=y values=2..las
```

The data in this example is taken from Example 1.

While the main purpose of Endecrypt is about encrypting and decrypting files, it also compresses the file. If you want to compress a file with Endecrypt, do not specify an password file:

```
cat compressMe.csv | endecrypt -W compressedFile.csv
```

The option -W encrypts standard input and writes to compressedFile.csv. Although there will be no encryption because of the missing password file, one must set the option -W. You can read the compressed file with CSV2GDX:

```
csv2gdx compressedFile.csv output=unCompressedEndycryptFile.gdx id=d index=1 useHeader=y values=2..la
```

Note that there is no further file extension added.

By adding a password file (containing the password in the first line), Endecrypt encrypts and compresses the input file:

```
cat compressMe.csv | endecrypt -W compressedEncryptedFile.csv passwordFile.txt
```

The password file will be deleted. Execute the following command to read the compressed and encrypted file with CSV2GDX:

```
csv2gdx compressedEncryptedFile.csv output=unCompressedDecryptedFile.gdx password=Anton id=d index=1
```

The password option is added. You must set the password directly within the option, in this case "Anton", not the password file. Note that CSV2GDX does not support .gz, .7z etc. compressed files!

This example is also part of the GAMS Data Utilities Library, see model [**csv2gdx8**] for reference.

6.6.5.3 Example 8 - Reading Options from an external File

This example demonstrates how to read the options from an external text file as already mentioned in section Filename. The file distance.csv from the Getting Started Example 1 will be processed with CSV2GDX while reading the options from an external text file named howToRead.txt.

```
csv2gdx distance.csv @howToRead.txt
```

Swapping the order of the CSV filename and the instructions filename inside the call statement will cause an error. Note the leading @ (at sign) on the instructions file, containing the following options:

```
* These lines are interpreted as a comment
* This file specifies the options for reading distance.csv using CSV2GDX

id         = d
fieldSep   = semiColon
decimalSep = comma
index      = 1
useHeader  = y
values     = 2..lastCol
```

This example is also part of the GAMS Data Utilities Library, see model [**csv2gdx9**] for reference.

6.6.5.4 Example 9 - Reading Set Elements with explanatory Text

In this example, we will demonstrate how to read explanatory text of set elements using the CSV2GDX option text.

Consider the input file data.csv:

```
a1,b1,explanatory text of a1.b1,10
a1,b2,explanatory text of a1.b2,20
a2,b1,explanatory text of a2.b1,30
a2,b2,explanatory text of a2.b2,40
```

The set elements are stored in the first and second column, the explanatory text is stored in the third column and there is a fourth column containing some values. Suppose we want to read a two-dimensional set with explanatory text. By default, CSV2GDX does not read explanatory text, i.e. by running the following command:

```
csv2gdx data.csv id=abOnlyUELs index=1,2 colCount=4
```

CSV2GDX creates a GDX file containing the two-dimensional set abOnlyUELs without explanatory text (needless to say, we did not specify a column to get the explanatory text from). By specifying the third column within the index option, i.e. index=1..3, the result will be a three-dimensional set (without explanatory text, too). Using the value option is not suitable, as the data type will be a parameter instead of a set (in addition, CSV2GDX expects numeric data, potentially leading to undefined values). We can read the explanatory text easily by specifying column three within the text option:

```
csv2gdx data.csv id=abWithExpText index=1,2 text=3 colCount=4
```

The figure shows the set abOnlyUELs on the left without explanatory text and the set abWithExpText on the right:

Note that the text and value(s) options cannot be used at the same time (instead, use multiple CSV2GDX calls in scenarios when you wish to read set elements with explanatory text and parameters from a single data set).

6.7 Eigenvalue

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This calculates the Eigenvalues of a symmetric positive definite matrix. The matrix `A` is indexed over `A(i,i)`. `AVal(i)` is indexed over `i`.

6.7.1 Usage

Command line:

```
gamstool [linalg.]Eigenvalue i A AVal gdxIn=fileIn.gdx gdxOut=fileOut.gdx
```

Compile time:

```
$callTool [linalg.]Eigenvalue i A AVal [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]
```

Execution time:

```
executeTool '[linalg.]Eigenvalue i A AVal [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]';
```

Where:

Argument	Description
`i`	Name of set used in matrix `i(*)`.
`A`	Name of two-dimensional matrix parameter `A(i,i)`.
`AVal`	Name of one-dimensional parameter to store the Eigenvalues `AVal(i)`.

The following parameters are available:

Parameter	Description
`gdxIn=fileIn.gdx`	Name of GDX file that contains symbols `i` and `A`. Mandatory if called from the command line, otherwise optional.
`gdxOut=fileOut.gdx`	Name of GDX file that contains symbol `AVal` after execution. Mandatory if called from the command line, otherwise optional.

6.7.2 Example

```
set i /i1*i3/;
alias (i,j);

table a(i,j)
         i1   i2   i3
   i1     9    1    1
   i2     1    9    1
   i3     1    1    9

;

parameter e(i) 'eigenvalues';

execute_unload 'a.gdx', i, a;
executeTool.checkErrorLevel 'linalg.eigenvalue i a e gdxin=a.gdx gdxout=b.gdx';
execute_load 'b.gdx', e;
abort$(abs(e('i1')-8)>1e-3 or abs(e('i2')-8)>1e-3 or abs(e('i3')-11)>1e-3) 'Wrong Eingenvalues', e;

option clear=e;
executeTool.checkErrorLevel 'linalg.eigenvalue i a e';
abort$(abs(e('i1')-8)>1e-3 or abs(e('i2')-8)>1e-3 or abs(e('i3')-11)>1e-3) 'Wrong Eingenvalues', e;
```

6.8 Eigenvector

Note

> This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This calculates the Eigenvalues and Eigenvectors of a symmetric positive definite matrix. The matrices `A` and `AVec` are indexed over `(i,i)`. `AVal(i)` is indexed over `i`.

6.8.1 Usage

Command line:

```
gamstool [linalg.]Eigenvector i A AVal AVec gdxIn=fileIn.gdx gdxOut=fileOut.gdx
```

Compile time:

```
$callTool [linalg.]Eigenvector i A AVal AVec [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]
```

Execution time:

```
executeTool '[linalg.]Eigenvector i A AVal AVec [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]';
```

Where:

Argument	Description
i	Name of set used in matrix i(*).
A	Name of two-dimensional matrix parameter A(i,i).
AVal	Name of one-dimensional parameter to store the Eigenvalues AVal(i).
AVec	Name of two-dimensional matrix to store the Eigenvectors AVec(i,i).

The following parameters are available:

Parameter	Description
gdxIn=fileIn.gdx	Name of GDX file that contains symbols i and A. Mandatory if called from the command line, otherwise optional.
gdxOut=fileOut.gdx	Name of GDX file that contains symbols AVal and AVec after execution. Mandatory if called from the command line, otherwise optional.

6.8.2 Example

```
Set i / i1*i5 /;

Alias (i,j);

Table a(i,j)
        i1   i2   i3   i4   i5
   i1    1    2    4    7   11
   i2    2    3    5    8   12
   i3    4    5    6    9   13
   i4    7    8    9   10   14
   i5   11   12   13   14   15
;

Table expected(i,*)
              val          i1          i2          i3          i4          i5
   i1   -8.464425   0.5550905  -0.2642556   0.2892854   0.6748602   0.2879604
   i2   -1.116317   0.4820641  -0.2581518   0.2196341  -0.7349311   0.3355726
   i3   -0.512109   0.2865066   0.2159261  -0.8437897   0.0411896   0.3970041
   i4   -0.027481  -0.0992784   0.7711236   0.3943678   0.0055409   0.4898525
   i5   45.120332  -0.6062562  -0.4714561  -0.0238286   0.0520829   0.6378888
;

Parameter
   eval(i)   'Eigenvalues'
   evec(i,j) 'Eigenvectors';

execute_unload 'a.gdx', i, a;
executeTool.checkErrorLevel 'linalg.eigenvector i a eval evec gdxin=a.gdx gdxout=b.gdx';
```

```
execute_load 'b.gdx', eval, evec;
evec(i,j)$(evec('i1','i1')<0) = -evec(i,j);
abort$(sum(i$(abs(eval(i)-expected(i,'val'))>1e-4),1)) 'Wrong Eigenvalue', eval, expected;
abort$(sum((i,j)$(abs(evec(i,j)-expected(i,j))>1e-4),1)) 'Wrong Eigenvector', evec, expected;

option clear=eval, clear=evec;
executeTool.checkErrorLevel 'linalg.eigenvector i a eval evec';
evec(i,j)$(evec('i1','i1')<0) = -evec(i,j);
abort$(sum(i$(abs(eval(i)-expected(i,'val'))>1e-4),1)) 'Wrong Eigenvalue', eval, expected;
abort$(sum((i,j)$(abs(evec(i,j)-expected(i,j))>1e-4),1)) 'Wrong Eigenvector', evec, expected;
```

6.9 ENDECRYPT

A tool to encrypt and decrypt text files.

6.9.1 Usage

```
endecrypt option xfile [passwdfile]
```

option

-W

to encrypt standard input and write to **xfile**

-R

to decrypt **xfile** and write to standard output

xfile

Text file to encrypt or decrypt.

passwdfile (optional)

First line is used as password; will be deleted after use

6.10 ExcelDump

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This tool writes all worksheets of an Excel workbook to GAMS symbols.

6.10.1 Usage

Command line:

```
gamstool [data.]ExcelDump excelFile gdxOut=fileOut.gdx
```

Compile time:

```
$callTool [data.]ExcelDump excelFile [gdxOut=fileOut.gdx]
```

Execution time:

```
executeTool '[data.]ExcelDump excelFile [gdxOut=fileOut.gdx]';
```

Where:

Argument	Description
excelFile	Excel workbook filename

The following named parameters are available:

Parameter	Description
gdxOut=fileOut.gdx	Name of GDX file that contains symbols s, r, c, w, ws, vf, vs, and vu. Mandatory if called from the command line, otherwise optional.

6.10.2 example

```
Set s            'Workbook sheets'
    r            'Rows'
    c            'Columns'
    w            'Workbook sheets by name'
    l            'Labels'
    ws(s,w)      'Workbook map'
    vs(s,r,c)    'Cells with explanatory text'
    vu(s,r,c,l<) 'Cells with potential GAMS label';
Parameter
    vf(s,r,c)    'Cells with numerical value';

$callTool.checkErrorLevel data.ExcelDump input.xlsx;
display ws, vs, vu, vf;
```

6.11 ExcelMerge

Note

> This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

Merges the sheets of the source Excel workbook into the destination workbook.

6.11.1 Usage

Command line:

```
gamstool [win32.]ExcelMerge source destination
```

Compile time:

```
$callTool [win32.]ExcelMerge source destination
```

Execution time:

```
executeTool '[win32.]ExcelMerge source destination';
```

Argument	Description
source	Source workbook.
destination	Destination workbook.

6.11.2 Example

A model utilitzing ExcelMerge can be found in a GAMS Connect example.

6.12 ExcelTalk

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

Performs command on an Excel workbook specified by filename.

6.12.1 Usage

Command line:

```
gamstool [win32.]ExcelTalk command filename [quit=0|1]
```

Compile time:

```
$callTool [win32.]ExcelTalk [-quit=0|1] command filename
```

Execution time:

```
executeTool '[win32.]ExcelTalk [-quit=0|1] command filename';
```

The following commands are recognized:

Command	Description
close	Close workbook ignoring changes.
open	Opens workbook.
saveAndClose	Ask Excel to save & close the workbook.

The following named parameter is available:

Argument	Description
`quit=0 or 1`	Determines if Excel program should be terminated or not (default: 0).

6.12.2 Example: Save and close an Excel workbook

```
$callTool win32.ExcelTalk saveAndClose myFile.xlsx
```

6.13 FINDTHISGAMS

6.13.1 Introduction

The Windows command line tool `findthisgams` is used for modifying GAMS specific registry entries created by the GAMS installer. These registry entries are primarily used for Windows file associations for GAMS related files (`*.gms`, `*.gdx`, `*.gpr`) and for the Object-oriented GAMS APIs which use the registry key `gams.location`. for finding a valid GAMS system directory. This documentation uses the following registry hive abbreviations:

- HKCU: HKEY_CURRENT_USER
- HKLM: HKEY_LOCAL_MACHINE
- HKCR: HKEY_CLASSES_ROOT

Attention

> This tool should be used with caution and only when necessary, as it changes the state of the registry. Reading this documentation carefully before use is advised.

6.13.2 Usage

```
findthisgams.exe [-q] [ list | delete (HKLM|HKCU) | write (HKLM|HKCU) ] [ide]
```

Without arguments: When `findthisgams.exe` is run without arguments, the tool tries to register the current GAMS system directory by either writing to `HKCU` (which takes precedence over `HKLM`) or by deleting entries in `HKCU` that hide the correct entries (current system directory) in `HKLM`.

-q: Run quietly. No pop-ups.

list: Print a summary of GAMS related registry entries (old and new).

delete (HKLM|HKCU): Deletes the registry entries in either `HKLM` or `HKCU`. The tool tries to delete both the old and the new style registry entries.

write (HKLM|HKCU): Writes the registry entries for the current GAMS system directory either to `HKLM` or `HKCU`.

ide: Per default, when `findthisgams.exe` writes to the registry, it uses GAMS Studio for file associations. Specifying `ide` will register the GAMS IDE instead.

6.13.3 Registry Keys

The registry entries created by the Windows installer have changed with GAMS 32. When running `findthisgams` with command line parameter `list`, the registy is queried for both the old and the new style registry keys. This gives a good overview of the current state of the registry before initiating any actual modifications to the registry:

Old registry keys (up to GAMS 31):

```
[HKCR|HKCU]\.gms
[HKCR|HKCU]\.gdx
[HKCR|HKCU]\gamside.file
[HKCR|HKCU]\gamside.file\shell\open\command
[HKCR|HKCU]\.gpr
[HKCR|HKCU]\gamside.project
[HKCR|HKCU]\gamside.project\shell\open\command
[HKCR|HKCU]\gams.location
```

New registry keys (GAMS 32 and later):

```
[HKLM|HKCU]\Software\Classes\.gms
[HKLM|HKCU]\Software\Classes\.gdx
[HKLM|HKCU]\Software\Classes\gamside.file
[HKLM|HKCU]\Software\Classes\gamside.file\DefaultIcon
[HKLM|HKCU]\Software\Classes\gamside.file\shell\open\command
[HKLM|HKCU]\Software\Classes\.gpr
[HKLM|HKCU]\Software\Classes\gamside.project
[HKLM|HKCU]\Software\Classes\gamside.project\DefaultIcon
[HKLM|HKCU]\Software\Classes\gamside.project\shell\open\command
[HKLM|HKCU]\Software\Classes\gams.location
```

Additional registry keys (GAMS 37 and later):

```
[HKLM|HKCU]\Software\Classes\.gsp
[HKLM|HKCU]\Software\Classes\gamsstudio.project
[HKLM|HKCU]\Software\Classes\gamsstudio.project\DefaultIcon
[HKLM|HKCU]\Software\Classes\gamsstudio.project\shell\open\command
```

Note

In order to access registry entries in `HKLM`, `findthisgams` needs to be run with administrative privileges.

6.14 GAMS Studio

GAMS Studio is a completely new integrated development environment for GAMS, which is available for Windows, macOS, and Linux. It is based on C++ and Qt.

Note

In addition to this technical documentation, there is also a tutorial about the usage of GAMS Studio.

6.14.1 Motivation

The classic GAMS IDE has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, the existing IDE does not provide all the features we see in modern development environments. Due to its underlying software technology, implementing new features in the current IDE turned out to be a poor option, so work on a new development environment started from scratch. GAMS Studio is based on C++ and Qt, which makes it fast, reliable, and platform independent (Windows, macOS, and Linux). An overview about the differences between GAMS Studio and the classic GAMS IDE can be seen at the end of this chapter (for long-time GAMSIDE users, especially the difference between IDE projects and Studio projects might be interesting).

6.14.2 Central Widgets

6.14.2.1 Welcome Page

The Welcome page is the starting point of GAMS Studio. It is designed to give quick access to common actions and to offer helpful information. It is divided into four columns.

The first two columns labeled "Last Projects" and "Last Files" list all projects and files that have been opened recently in Studio with the most recent on top. A simple left click on an item in this list opens the corresponding file. The top left of each entry shows an "x" to remove it. The third column named "Getting Started" offers useful actions and links for new users. The upper half contains shortcuts to create new files in user defined locations, open the GAMS Model Library Explorer or load the Transport example. The lower half has a link to the Studio introduction video on YouTube and two further links that open the integrated help view showing either this Studio documentation or the page with the GAMS tutorial overview. The rightmost column "Further Help" contains a link to the recent changes of GAMS Studio, the latest GAMS release notes, the GAMS World Forum for support and information about how to contact GAMS.

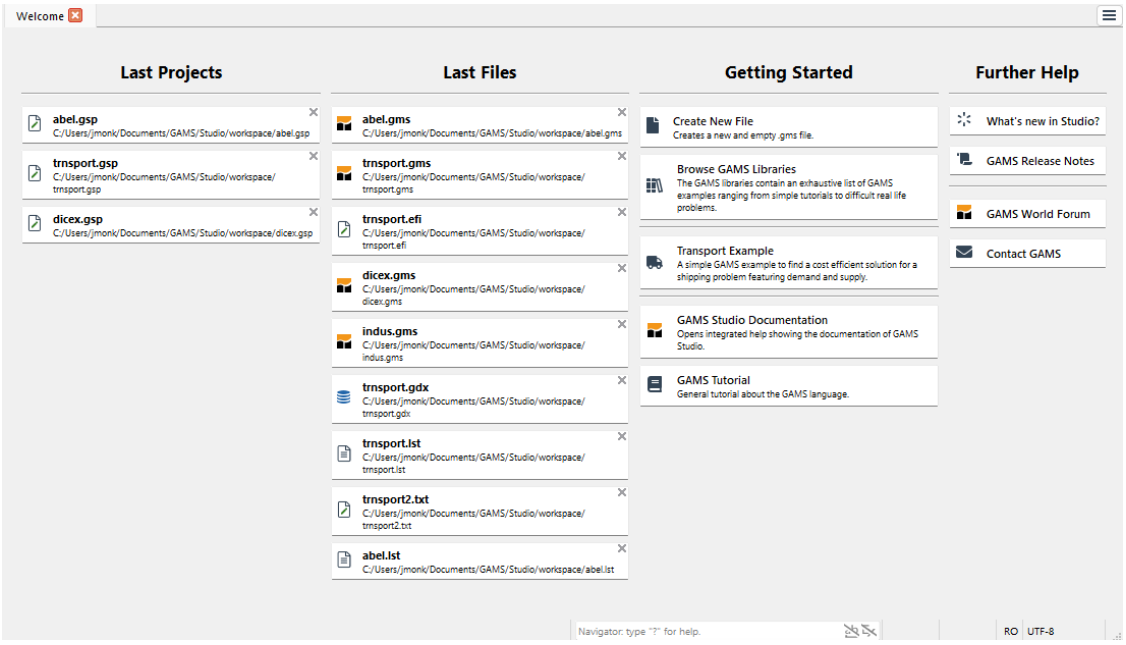


Figure 6.1 Welcome page

6.14.2.2 Code Editor

The Code Editor provides common functionality for editing with GAMS specific syntax highlighting. On the left side there is a special area displaying the line numbers and icons for links and errors generated by the compiler.

1. Basic Text Manipulation

Action	Shortcut	macOS	Description
Copy	**Ctrl - C**	**Command - C**	Copy selected text
Cut	**Ctrl - X**	**Command - X**	Cut selected text
Paste	**Ctrl - V**	**Command - V**	Paste text from clipboard
Select All	**Ctrl - A**	**Command - A**	Select whole document
Switch Comment	**Ctrl - ∗**	**Command - ∗**	(Un)Comment all lines in selection
Undo	**Ctrl - Z**	**Command - Z**	Reverts the latest text change
Redo	**Ctrl - Y** or **Ctrl - Shift - Z**	**Command - Shift - Z**	Restores a previous Undo

2. Advanced Text Manipulation

Action	Shortcut	macOS	Description
Remove Line	**Shift - Del**		Removes the current line
Duplicate Line	**Ctrl - D**	**Command - D**	Duplicates the current line(s)
Lowercase	**Alt - Shift - L**	**Option - Shift - L**	Toggle selection to lower case
Uppercase	**Alt - Shift - U**	**Option - Shift - U**	Toggle selection to upper case
Tab	**Tab**	**Tab**	Add spaces till next tab size
Untab	**Shift - Tab**	**Shift - Tab**	Remove spaces till previous tab size
Indent	**Ctrl - I**	**Command - I**	Indent complete line
Outdent	**Ctrl - Shift - I**	**Command - Shift - I**	Outdent complete line
Find	**Ctrl - F**	**Command - F**	Open Search & Replace window, filling search field with selected text if there is any.
Find Next	**F3**	**F3**	Jump to next search result if
Find Previous	**Shift - F3**	**Shift - F3**	Jump to previous search result

3. Navigation & Selection

Action	Shortcut	macOS	Description
Match Parentheses	**Ctrl - B**	**Command - B**	Jump to matching parenthesis
Select Parentheses	**Ctrl - Shift - B**	**Command - Shift - B**	Select to matching parenthesis
Toggle Bookmark	**Ctrl - M**	**Ctrl - M**	Toggle bookmark
Previous Bookmark	**Ctrl - ,**	**Ctrl - ,**	Go to previous bookmark
Next Bookmark	**Ctrl - .**	**Ctrl - .**	Go to next bookmark
Toggle Folding	**Alt - L**	**Alt - L**	Toggles the folding state of the current section
Fold all Sections	**Alt - O**	**Alt - O**	Folds all foldable sections
Fold DCO Sections	**Alt - I**	**Alt - I**	Folds all foldable DCO sections
Unfold all Sections	**Alt - Shift - O**	**Alt - Shift - O**	Unfolds all foldable sections

Action	Shortcut	macOS	Description
Open Code Completer	**Ctrl - Space**	**Ctrl - Space**	Opens the Code Completer
Jump to include	**Ctrl - Left Mouse Button** or **F2**	**Command - Left Mouse Button** or **F2**	Jumps to file referenced by $include
Scroll Up	**Ctrl - Up**	**Command - Up**	Scroll up (keeping cursor position)
Scroll Down	**Ctrl - Down**	**Command - Down**	Scroll down (keeping cursor position)
Scroll Page Up	**Ctrl - PageUp**	**Fn - Up**	Scroll page up (keeping cursor position)
Scroll Page Down	**Ctrl - PageDown**	**Fn - Down**	Scroll page down (keeping cursor position)
Start of Line	**Home**	**Command - Left**	Go to the start of line (or lines content)
End of Line	**End**	**Command - Right**	Go to the end of the line
Start of Document	**Ctrl - Home**	**Fn - Left**	Go to the start of the document
End of Document	**Ctrl - End**	**Fn - Right**	Go to the end of the document
Previous Word	**Ctrl - Left**	**Option - Left**	Go to previous start of word (or character class)
Next Word	**Ctrl - Right**	**Option - Right**	Go to next start of word (or character class)
Start/Change Block Edit	**Alt - Shift - Arrow Key**	**Option - Shift - Arrow Key**	Start/Change block edit selection
Start/Change Block Edit	**Alt - Left Mouse Button**	**Option - Shift - Left Mouse Button**	Draw block edit selection
Start/Change Block Edit	**Alt - Shift - Left Mouse Button**	**Option - Shift - Left Mouse Button**	Span block edit selection from text cursor to mouse click
Change Block Edit by Page	**Alt - PageUp / PageDown**	**Option - Fn - PageUp / PageDown**	Change block edit selection by a page step
Change Block Edit by Word	**Ctrl - Shift - Left / Right**	**Command - Shift - Left / Right**	Change block edit selection by word bounds
Change Block Edit by Word	**Ctrl - Left / Right**	**Command - Left / Right**	Change block edit position by word bounds (skip selection)
Change Block Edit Anchor	**Shift - Arrow Key**	**Shift - Arrow Key**	Change block edits anchor (start position)
Move Block Edit	**Arrow Key**	**Arrow Key**	Move block edit selection
Move Lines Up or Down	**Ctrl - Shift - Up / Down**	**Command - Shift - Up / Down**	Move line(s) up or down

The Code Editor looks for parenthesis to the right then to the left of the cursor and marks valid and invalid nesting. Hitting `Ctrl - B` moves the cursor to the matching parenthesis keeping the state inside/outside. To select the block to the matching parenthesis hit `Ctrl - Shift - B`.

To support navigating to files included by the gams source, place the mouse cursor over the file name and press the `Ctrl - Left Mousebutton` or place the cursor at the filename an hit `F2`. If found, Studio

will add the file to the current project and open it. Only plain text filenames can be detected this way, symbols are not resolved.

Code Folding

The Code Editor detects several kinds of sections in the source code that can be folded. These sections include all kinds of matching parentheses that extend over more than one line plus several $-control options that needs to come in pairs. To toggle the folding state of a section either the fold-marker can be clicked or the shortcut `Alt - L` can be pressed when the cursor is in a foldable line. To fold or unfold all foldable sections the main menu contains entries in the `View` menu. Additionally the shortcuts `Alt - O` to fold and `Alt - Shift - O` to unfold can be used.
To define individual blocks of folding the Dollar Control Options `$onFold` and `$offFold` can be added to the source.

List of $-control options that create a fold section:

- `$OnText` / `$OffText`
- `$OnEmbeddedCode[V/S]` / `$OffEmbeddedCode`
- `$OnEcho[V/S]` / `$OffEcho`
- `$OnPut[V/S]` / `$OffPut`
- `$OnExternalInput` / `$OffExternalInput`
- `$OnExternalOutput` / `$OffExternalOutput`
- `$ifThen[I/E]` / `$endIf`
- `$onFold` / `$offFold`

Syntax Highlighting

The GAMS Studio syntax highlighter recognizes different kinds of source code like

- **$control option** with some special treatments (like `$OffText`, `$OnText`, etc.)
- **comments**, e.g. `line comments` and `comment block`
- **keywords** like `declarations` or `loops`
- **description** as `descriptive text` for `identifiers`
- **data statements** for `identifiers` or `table data`
- ...

To get the best highlight result it is recommended to use strict GAMS syntax.

Code Completion

GAMS Studio offers a static code completion for fixed internal keywords known by the compiler. The code completer pops up after pressing `Ctrl - Space` and shows keywords that matches the current syntax and starts with the already typed characters of the word to the left of the cursor. Moving the cursor to the left shortens the matching pattern while moving the cursor to the right extends it. The keys `up`/`down`, `pageUp`/`pageDown`, and `home`/`end` are processed by the results list during the completer is visible. The selected word can be inserted with the keys `tab` or `enter`/`return` or by double clicking a word in the list. To hide the completer, hit `esc` or click outside of the completer window. Additionally the completer hides if there is no match for the current start of word.

Automatic closing of brackets and quote characters

This feature is meant to improve convenience for users typing source code. In GAMS, as in pretty much every other programming language, opening brackets or quote characters are followed at some point by a closing equivalent. So when a user types one of the following characters the matching closing character will also be inserted after the text cursor. This allows the user to easily type the content in between. When typing the closing character which should be right after the cursor the already existing character will be jumped over. So when a user types the closing character by force of habit the autoclose feature does not interfere or causes syntax errors. Also possible is to make a text selection and then type a bracket or quote character. The selected text will then be surrounded by the chosen character pair. In the GAMS Studio under **Settings** > **Editor** > **"Auto close opening brackets and quotes"** a switch is available to turn this auto-close feature off.

List of characters that trigger insertion of a closing character:

- (
- {
- [
- "
- '

Other editors also close the < character but in the GAMS language context it is used in a different way, making it unnecessary to be closed automatically (e.g. as a comparison operator). In some cases user might not like the closing character to be inserted automatically however, this is hard to predict. Other editors - like Qt Creator - check what the next character after the cursor is. Only a limited set of characters allows the automatic insertion of the closing character.

Following characters allow auto closing when being the next char after the text cursor:

- **Whitespaces**
- ,
- ;
-)
-]
- {
- }

All others will prevent the insertion of characters.

File Encoding

When opening a file Studio tries to assume the valid file-encoding. As it is not possible to safely determine the encoding the **Edit** > **Encoding** menu assists. To reload a file using another codec the **reload with ...** submenu can be used. With the **convert to ...** submenu the current file can be converted to another codec. A selection of encodings is preselected. This selection can be changed using the **Select encoding** submenu. It opens a dialog where the active encodings can be selected. One of them is marked as the `Default` encoding. Initially is is set to **utf-8**.

Bookmarks

The `Code Editor` provides the ability to set temporary `bookmarks` in the text files opened in main tabs. If Studio is closed they are dropped. Also if a file tab is closed the bookmarks for this file are dropped. A bookmark is placed at the current position of the current file using the `toggle bookmark` key. A line in the editor can only carry one bookmark. If this line has a bookmark already the existing one is removed. The keys for next/previous bookmark allow to navigate through the bookmarks beyond file bounds.

6.14.2.3 Listing Viewer

The Listing Viewer is used for displaying a GAMS output or listing file (`*.lst`) which is generated when running a GAMS (`.gms`) file. The Listing Viewer consists of two sides. On the left side, the content of the listing file is presented in a tree structure that allows for convenient navigation within the listing file. The right side shows the listing file itself.

By clicking on a specific item in the tree on the left hand side, the listing file will automatically jump to the corresponding location. Changes of the cursor position in the listing file are dynamically reflected in the tree by selecting the item that belongs to the current section of the listing file.

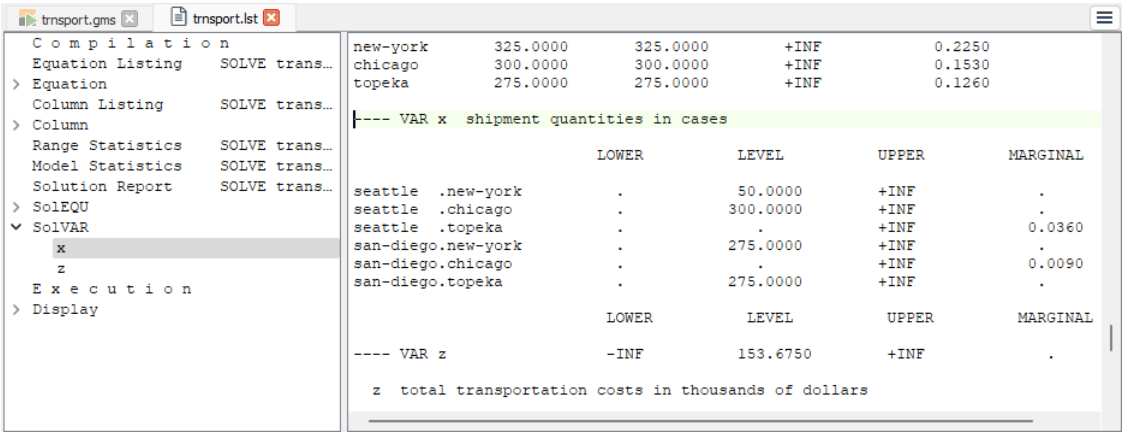

Figure 6.2 Listing Viewer showing trnsport.lst generated by running trnsport.gms from the GAMS Model Library

When the GAMS process returns with a compilation error the `Listing Viewer` contains links to the source file. If the source file doesn't exist anymore the link is still shown but striked out.

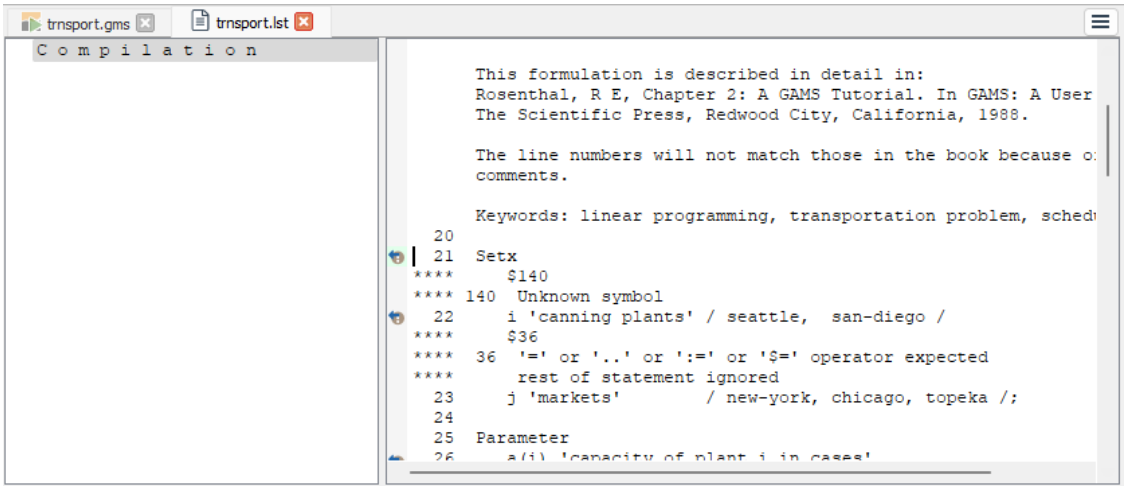

Figure 6.3 Listing Viewer showing trnsport.lst generated by running a modified trnsport.gms

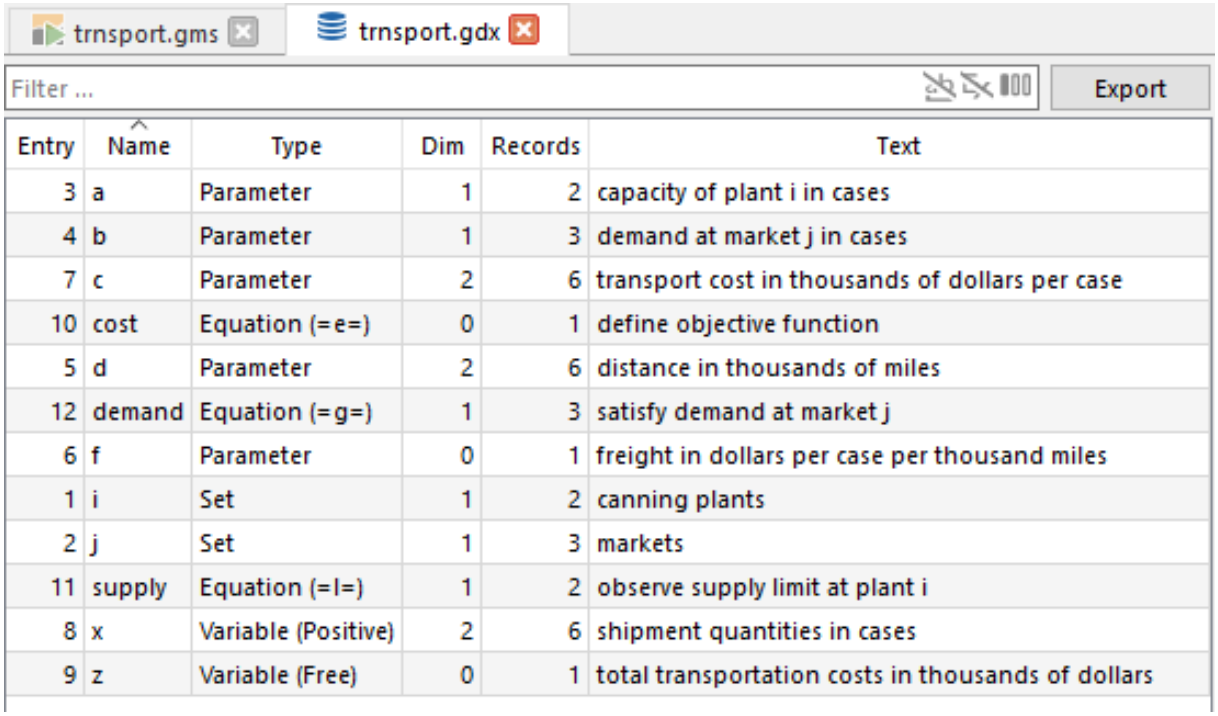
6.14.2.4 GDX Viewer

The GDX Viewer is used to open and inspect GDX (GAMS Data eXchange) files. A GDX file contains GAMS symbols such as sets, parameters, variables, and equations in a binary format that serves as input and output to GAMS. The GDX Viewer component consists of two sides. The left side displays the symbol table of the open GDX file in a table format. Every entry represents a symbol and consists of the following information:

- **Entry:** The index of the symbol
- **Name:** The identifier of the symbol
- **Type:** The type of the symbol (Alias, Equation, Parameter, Set, or Variable) including the sub type if available
- **Dim:** The dimension of the symbol
- **Records:** The number of records of the symbol
- **Text:** The explanatory text of the symbol



Entry	Name	Type	Dim	Records	Text
3	a	Parameter	1	2	capacity of plant i in cases
4	b	Parameter	1	3	demand at market j in cases
7	c	Parameter	2	6	transport cost in thousands of dollars per case
10	cost	Equation (=e=)	0	1	define objective function
5	d	Parameter	2	6	distance in thousands of miles
12	demand	Equation (=g=)	1	3	satisfy demand at market j
6	f	Parameter	0	1	freight in dollars per case per thousand miles
1	i	Set	1	2	canning plants
2	j	Set	1	3	markets
11	supply	Equation (=l=)	1	2	observe supply limit at plant i
8	x	Variable (Positive)	2	6	shipment quantities in cases
9	z	Variable (Free)	0	1	total transportation costs in thousands of dollars

Figure 6.4 Symbol table showing trnsport.gdx generated by running trnsport.gms from the GAMS Model Library

A specific column can be sorted by clicking on the respective column header. Clicking again toggles the sorting direction. The `Filter` facility provides dynamic filtering of the list of symbols contained in the GDX file. By default, only the `Name` column is taken into account by the filter. Clicking on the `Export` button will open the export dialog. The right side of the GDX Viewer displays the actual data of the symbol that is selected in the symbol table. Data can be displayed in either the List View or the Table View which can be toggled using the corresponding button in the upper part of the GDX Viewer.

The GDX Viewer automatically saves and restores its state on closing and as soon as data is reloaded due to changes to the underlying GDX file. Changes to the symbol table like an applied filter or the currently

selected symbol are kept. Individual symbols keep applied filters as well as the view settings (e.g. the currently selected view (List View or Table View), preferences and the visible attributes for variables and equations) as long as the name, type, and dimension of the symbol did not change during the update of the GDX file. Resetting the state of a symbol can be achieved by clicking on the `Reset` button. For each GDX file known by the Project Explorer the state is stored in the Settings. The context menu of the Project Explorer provides an entry to reset the GDX Viewer state for that file. Removing the GDX file from the project also clears its state.

Note

The GDX Viewer currently supports a maximum number of ∼107 million records to be shown for an individual symbol. As soon as a specific symbol reaches this limit, a warning is added to the system log and records exceeding this limit will be truncated from the view. Also a note about truncated data is displayed in the GDX Viewer itself. Applying filters might reduce the number of records to be displayed and as soon as filtered data is shrunk enough, the whole (filtered) data can be displayed again and the note gets removed.

List View

The `List View` is the default representation when looking at data using the GDX Viewer. The data is presented in the form of a table in which each row represents a record of the symbol. Each record consists of key columns corresponding to the symbols dimension. The value columns vary according to symbol type:

- **Set/Alias**: Column `Text` contains the explanatory text of a record, `Y` if no explanatory text is available.
- **Parameter:** Column `Value` contains the numerical value of a record.
- **Variable/Equation**: Five numerical columns: (`Level`, `Marginal`, `Lower`, `Upper`, `Scale`).

i [1]	j [2]	Value
seattle	new-york	2.5
seattle	chicago	1.7
seattle	topeka	1.8
san-diego	new-york	2.5
san-diego	chicago	1.8
san-diego	topeka	1.4

Figure 6.5 Right side of GDX Viewer showing the parameter `d` from the `trnsport` model

The header displays the individual domains as well as the original index position using superscript notation which is especially useful if the column order has been changed. Furthermore it allows to manipulate the displayed data in several ways. By left clicking on a column header, the corresponding column is sorted using a stable sort mechanism that does not change the order of equal entries. Clicking again changes the sorting direction. Due to the Extended Range Arithmetic used by GAMS, columns containing numerical data can contain special values. Those values are treated in a special way when being sorted:

- **-INF:** Smallest numerical value.
- **EPS:** Treated as value very close but different from 0.
- **+INF:** Largest numerical value.
- **NA:** Treated as first non-numerical value (sorted as being greater than +INF).
- **UNDEF:** Sorted as being greater than `NA`.
- **ACRONYMS:** Sorted as being greater than `UNDEF`. Relative order of acronyms is by their internal number.

The order of columns can be changed by dragging a column header and dropping it at a different position. Dragging the border between column headers allows for resizing the widths of the involved columns. The columns in the `List View` offer a filter facility which can be opened either by right clicking on the column header or by left clicking on the filter icon. The `Reset` button in the top right corner can be used to reset the view to defaults. This removes all filters, resets the applied sorting as well as the applied numerical format and switches back to the `List View` in case the `Table View` was active.

The button `Preferences` opens a menu containing different settings for the current symbol. `Squeeze Defaults` can be used on variables and equations in order to hide all columns that have the default value of the respective variable or equation type. `Squeeze Trailing Zeroes` allows to turn on/off the truncation of trailing zeroes. The displaying format of numerical values can be specified using the `Format` drop down menu and the `Precision` spin box.

The available options for the `Format` are as follows:

- **g-format**: The display format is chosen automatically: `f-format` for numbers closer to one and `e-format` otherwise. The value in the `Precision` spin box specifies the number of significant digits. When precision is set to `Full`, the number of digits used is the least possible such that the displayed value would convert back to the value stored in GDX. Trailing zeros do not exist when `precision=Full`.

desk [1]	Level	Marginal	Lower	Upper	Scale
d1	1333.33	0	0	+INF	1
d2	0	-6.66667	0	+INF	1
d3	0	-3.33333	0	+INF	1
d4	66.6667	0	0	+INF	1

Figure 6.6 Variable `mix` from the `prodmix` model using `g-format` with `precision=6`

desk [1]	Level	Marginal	Lower	Upper	Scale
d1	1333.3333333333333	0	0	+INF	1
d2	0	-6.666666666666665	0	+INF	1
d3	0	-3.3333333333333317	0	+INF	1
d4	66.66666666666666	0	0	+INF	1

Figure 6.7 Variable `mix` from the `prodmix` model using `g-format` with `precision=Full`

- **f-format**: Values are displayed in fixed format as long as appropriate. Large numbers are still displayed in scientific format. The value in the `Precision` spin box specifies the number of decimals.

desk [1]	Level	Marginal	Lower	Upper	Scale
d1	1333.333333	0	0	+INF	1
d2	0	-6.666667	0	+INF	1
d3	0	-3.333333	0	+INF	1
d4	66.666667	0	0	+INF	1

Figure 6.8 Variable `mix` from the `prodmix` model using `f-format` with `precision=6`

- **e-format**: Values are displayed in scientific format. The value in the `Precision` spin box specifies the number of significant digits. When precision is set to `Full`, the number of digits used is the least possible such that the displayed value would convert back to the value stored in GDX. Trailing zeros do not exist when `precision=Full`.

desk [1]	Level	Marginal	Lower	Upper	Scale
d1	1.33333e+03	0e+00	0e+00	+INF	1e+00
d2	0e+00	-6.66667e+00	0e+00	+INF	1e+00
d3	0e+00	-3.33333e+00	0e+00	+INF	1e+00
d4	6.66667e+01	0e+00	0e+00	+INF	1e+00

Figure 6.9 Variable `mix` from the `prodmix` model using `e-format` with `precision=6`

The value in the `Precision` spin box specifies the number of decimals or the number of significant digits depending on the chosen format:

- **g-format**: Significant digits [1..17, Full]
- **f-format**: Decimals [0..14]
- **e-format**: Significant digits [1..17, Full]

Next to Preferences is the `Attributes` button. This button opens a menu that allows to hide certain attribute columns of variables and equations explicitly. This is especially useful when using the `Table View`.

Table View

Switching to the `Table View` is possible for symbols that have at least two dimensions. This mode consists of two parts: A separate header view that shows the domains and attributes of the symbol as well as the actual data. The header view also allows to access the filter facility and highlights the positions of specific domains by using visual separators (from left to right: rows, columns, attributes). The data itself is reshaped into a format where the labels of the last dimension are moved into the column header while

the remaining dimensions go into the row header. The entries in the table are the numerical values (or explanatory text in case of GAMS sets) of the record with the corresponding labels of the headers. The following image shows the `List View` of a GAMS Parameter on the left side and its representation in the `Table View` on the right side:

i [1]	j [2]	Value
seattle	new-york	2.5
seattle	chicago	1.7
seattle	topeka	1.8
san-diego	new-york	2.5
san-diego	chicago	1.8
san-diego	topeka	1.4

i [1]	j [2]	Value

	new-york	chicago	topeka
seattle	2.5	1.7	1.8
san-diego	2.5	1.8	1.4

Figure 6.10 Two dimensional parameter as List View and Table View

In case of GAMS variables and equations, a virtual dimension for the five numerical values (Level, Marginal, Lower Bound, Upper Bound, Scale) is introduced and displayed in the column header. When looking at the data of variables or equations it is most of the time useful to visualize only a specific attribute like the variable levels. This can be achieved by using the `Attributes` menu in the upper part of the GDX Viewer. The menu allows to hide specific attributes explicitly by disabling the corresponding checkboxes.

Both column and row header dimensions can be moved into different positions in order to reshape the table view. This can be done by performing a drag-and-drop operation that starts by clicking (and holding) the left mouse button while the mouse cursor is located on the index that should be moved. Moving the mouse to an arbitrary location will bring up a drop indicator (in the form of a thin line) that previews the position in which the index will be dropped as soon as the mouse button is released. In general all index positions can be moved to arbitrary new locations, but there are a few restrictions:

- The (virtual) numerical dimension of variables and equations (Level, Marginal, Lower Bound, Upper Bound, Scale) can not be moved and is always the last dimension in the column header.

- If a header (column or row) runs out of dimensions, a dummy header (Value, Text) is introduced which can not be moved but can be used as a drop target for further drag-and-drop operations.

Figure 6.11 The table view representation of a GAMS parameter during a drag-and-drop operation that will move the dragged dimension into the position indicated by the drop indicator (thin black line)

While filters that have been applied in the `List View` will also be applied to the `Table View` and vice versa, sorting does not have any effect. The labels are sorted using the internal order which can not be changed by the user. For large data it is recommended to reduce the amount of visible records by applying filters in the `List View` and by disabling certain value columns in case of variables and equations. Once the data has been reduced, switching to the `Table View` allows to look at the data in a compact format.

Filter Facility

Filters can be applied in both the List View and the Table View through the header view that contains the domains as well as the (numerical) attributes. In the List View, the header is part of the data view itself, while the Table View offers a separate header view above the actual data. The filter dialog can be opened either by right clicking on the header or by left clicking on the filter icon. Depending on the type of the column (key or value), the appropriate filter dialog for labels or numerical values is opened.

The filter dialog for a specific key column shows all occurring labels of that column in a list. Per default all labels in all columns are visible. Shrinking the displayed data can be achieved by unchecking one or more labels. The filter is applied by clicking the `Apply` button. Instead of selecting labels manually one can also use the filter in the upper part of the filter dialog. More about the filter can be found in the Filter Section. The filter is automatically applied to the list of labels. Matching labels will be selected while all others will be deselected. The `Hide unselected items` checkbox can be used to automatically hide all deselected labels. This is especially useful for larger amounts of labels in combination with the filter as only the matching labels will remain in the list while typing. The `Select All`, `Invert`, and `Deselect All` buttons speed up getting the desired selection. Using `middle-click` or `Ctrl` - `left-click`(`Command` - `left-click` on macOS) allows to quickly select one specific label while all others are deselected. The filter gets applied automatically and the dialog closes without the need to click the `Apply` button. Sometimes it is convenient to select/deselect a range of labels. This is possible by selecting a certain label first and using `Shift` -

`left-click` on another label afterwards. This will change the selection state of all labels in the specific range to the same state. If no label has been selected in the first step, the range starts at the first label by default.

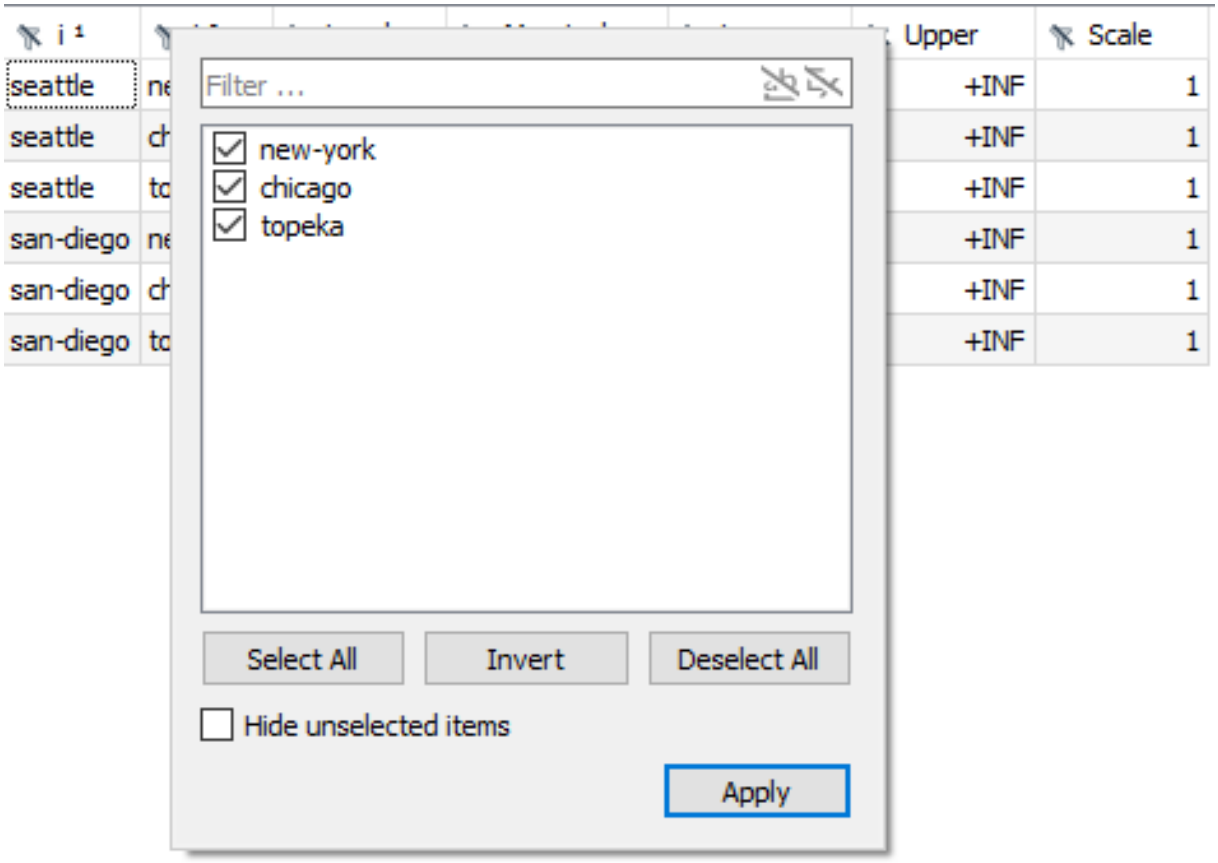

Figure 6.12 Filter dialog on column `j` for variable `x` in trnsport.gdx

Numerical columns offer a different filter type that allows to specify an interval for values that should be included or excluded in the view for this specific column. The `Min` value is the lowest and the `Max` value is the largest one still included in the view. When the `Exclude` check box is activated, the specified range is excluded from the view instead of included. The lower part of the filter contains check boxes for special values like `+INF` or `EPS`. Checking/unchecking will show/hide the corresponding values in the view. Clicking the `Apply` button adds the filter to the column and refreshes the view accordingly. The `Reset` button removes an active filter.

Note

When a filter on a numerical column is applied, the values used for comparison are the actual values from the GDX file. Since the displayed values are influenced by the `Format` and the `Precision` setting, they can differ from the internal ones from the GDX file. Here is an example: Let's assume we have a parameter `p(i)` with `p("i1")=1.34` and `p("i2")=2`. With format set to `g-format` and precision set to `2`, the values are displayed as `1.3` and `2`. When applying a filter with the bounds (`Min`, `Max`) set to `1.33` and `2` both records are still shown even though `1.33` is greater than `1.3` (number shown in the GDX Viewer) since the internal GDX value used for comparison is actually `1.34`.

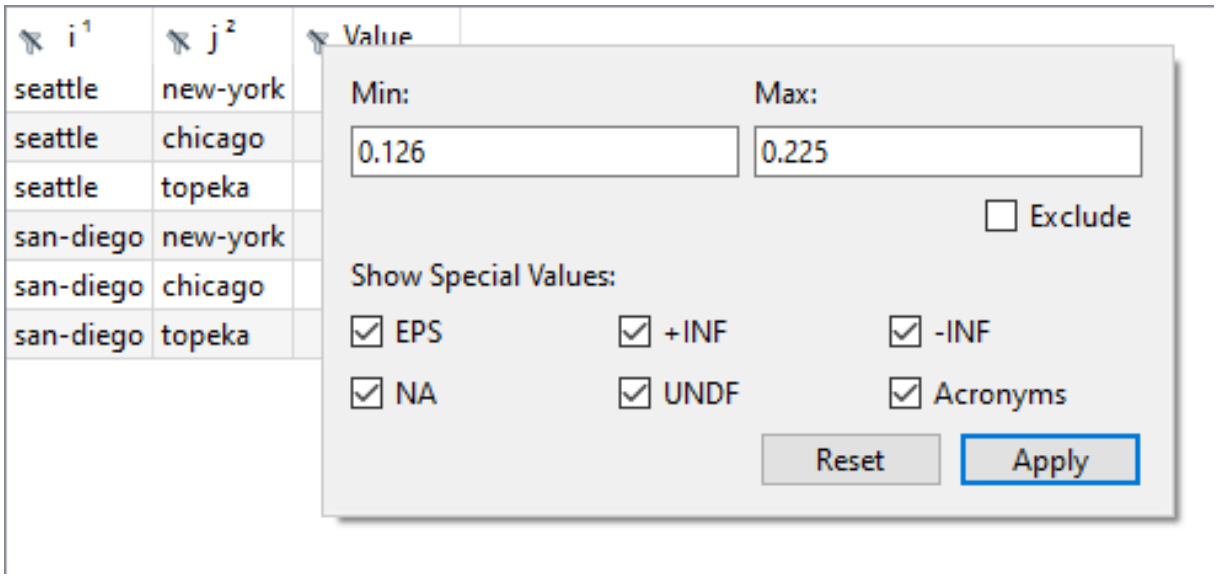

Figure 6.13 Filter dialog on numerical column `Value` for parameter `c` in trnsport.gdx

Search Facility

Both the List View and the Table View can be searched by adding a term into the search field which is located above the Data View. The search behavior can be customized using the buttons on the right hand side of the line edit. See Filter in Tables and Trees for more information. As soon as the content of the search field changes all matches in the Data View are highlighted automatically. The `Search Forward` (**F3**) and `Search Backward` (**Shift** - **F3**) buttons allow to select the next/previous element that matches the search criteria. Search is continued at the beginning of the Data View as soon as the end is reached and vice versa. In the List View, all cells except for the header are considered while in the table view all cells and all header entries are considered with the exception of symbol type specific extra headers which is `Value` (parameters), `Text` (sets/aliases), `Level`, `Marginal`, `Lower`, `Upper`, `Scale` (variables/equations).

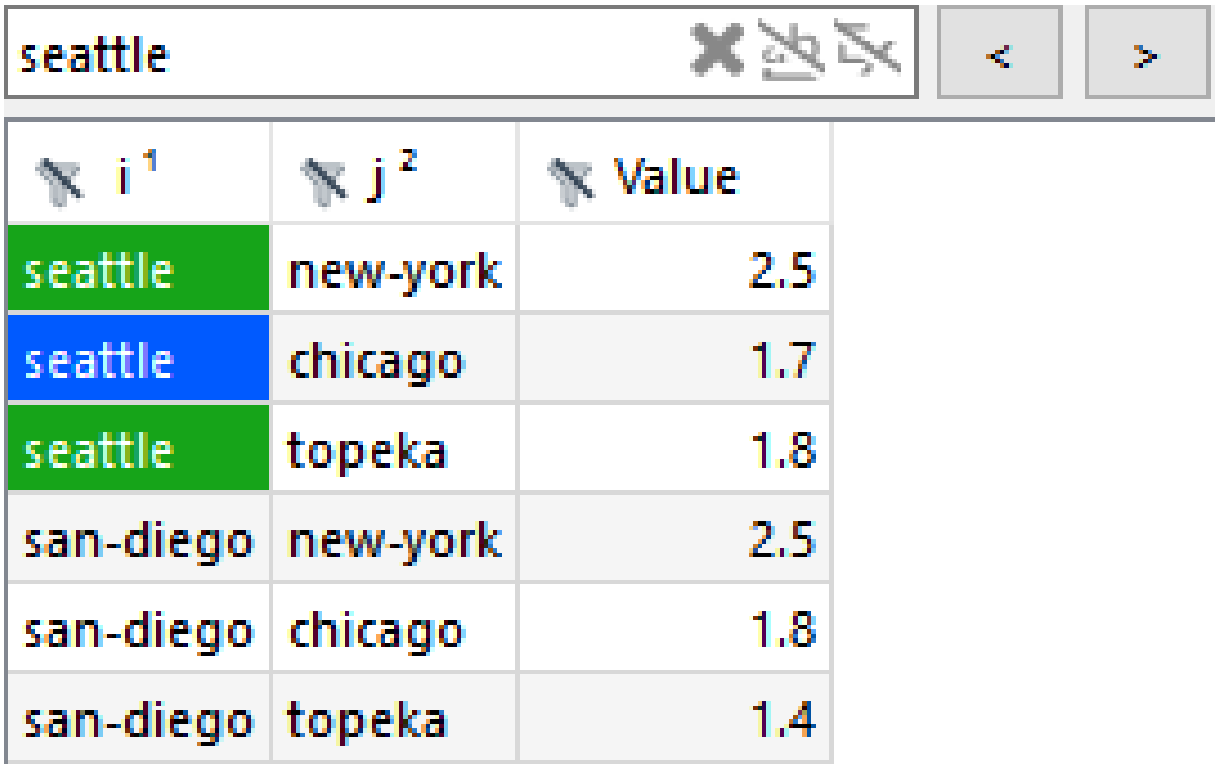

Figure 6.14 Searching the List View of a parameter by 'seattle'

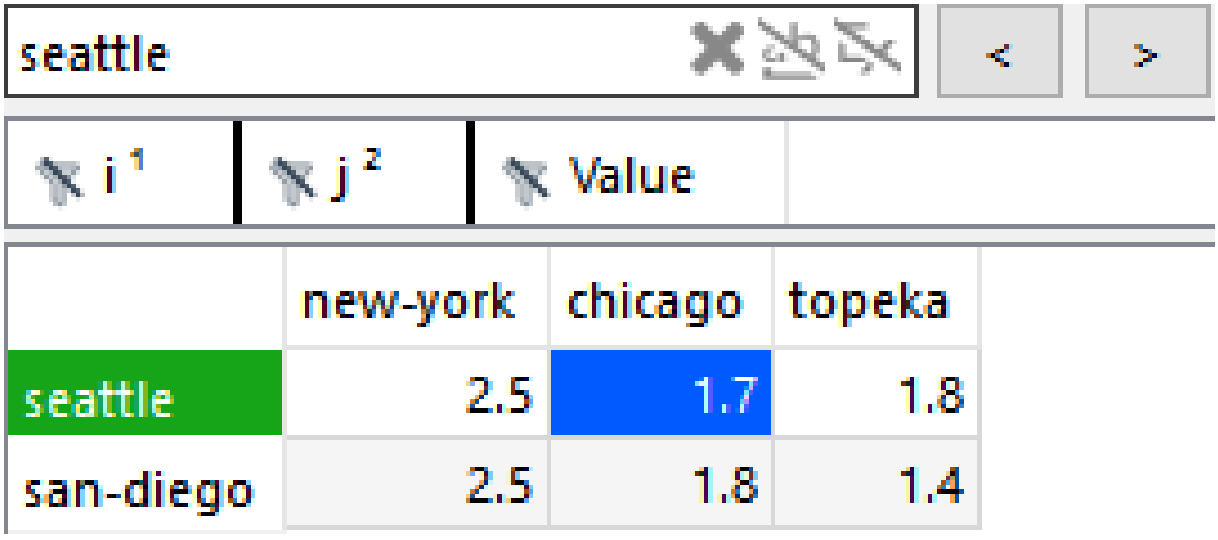

Figure 6.15 Searching the Table View of a parameter by 'seattle'

Export Dialog

The GDX Viewer offers an export functionality that can be accessed by clicking on the `Export` button above the symbol table on the left side of the GDX Viewer. The export dialog uses GAMS Connect in order to export data from a GDX file into another data format.

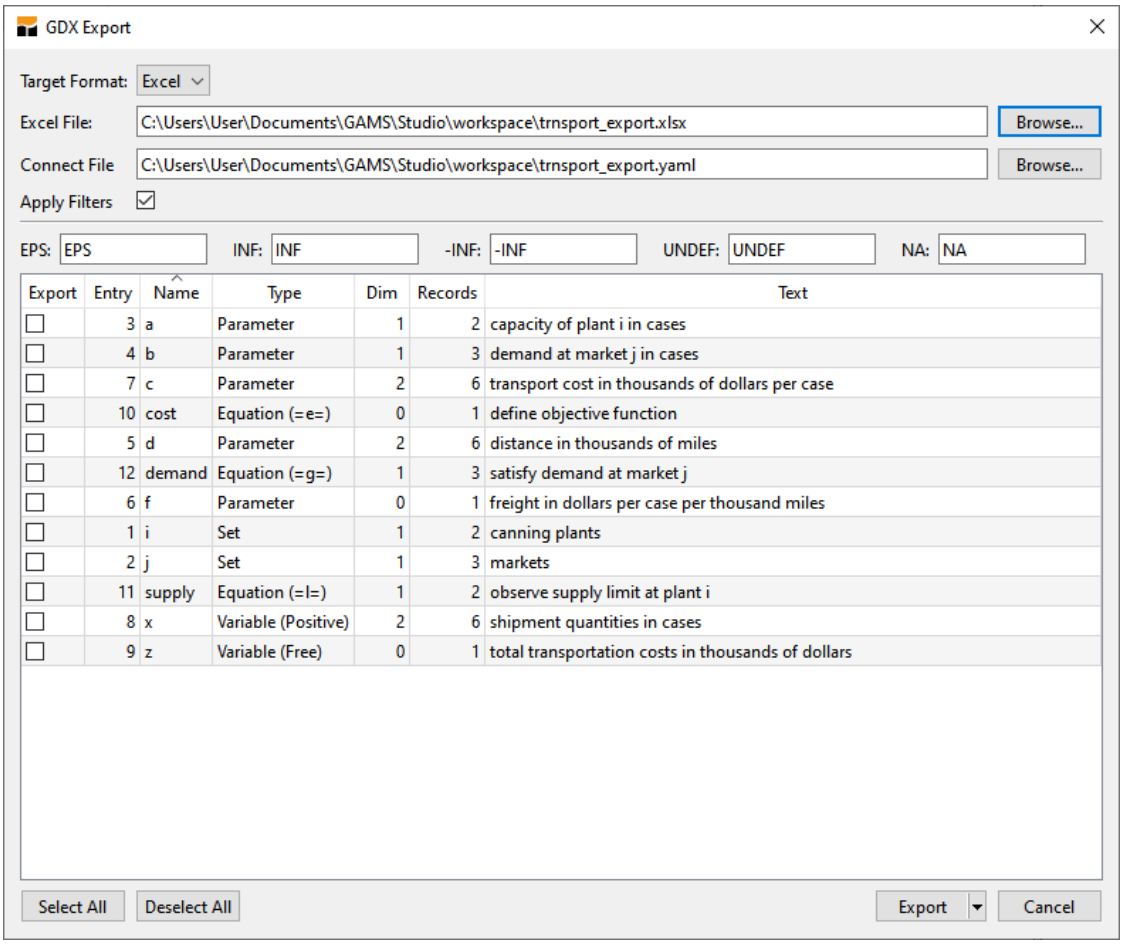

Figure 6.16 GDX Export dialog opened from trnsport.gdx

The `Target Format` drop down menu allows to select the format in which the data is exported (currently only Excel is available as target format). The upper part of the dialog also allows to specify the Excel output file as well as the GAMS Connect instructions file in YAML format. The `Apply Filters` checkbox controls if active filters in the GDX Viewer are applied to the exported data or not. The input fields for the representation of GAMS special values allow to customize those. A common use case is the export of GAMS special value `EPS` as `0` instead of the string representation `EPS` (default) which can be achieved by changing the corresponding input field to `0`. Symbols can be selected for export using the checkboxes in the `Export` column of the symbol table. The button `Select All/Deselect All` can be used in order to select/deselect all symbols for export. The `Export` button generates the GAMS Connect instructions file and executes it. Choosing `Save` instead will only generate the GAMS Connect instructions file but won't run it. As long as the export process is running the dialog will be disabled. Clicking the `Cancel` button closes the dialog and stops the export process that has not been finished yet.

The export mechanism uses the underlying GDX file that is opened in the GDX Viewer. If a symbol is currently in `table view` mode, the order and location of individual dimensions are reflected in the Excel output.

Summary of Actions and Shortcuts

Action	Shortcut	macOS	Description
Jump to Symbol Search/Data View Search	**Ctrl - F**	**Command - F**	Moves the focus either to the Symbol Search input field located above the symbol table or the Search input field of the Data View, depending on the current focus.
Find next	**F3**	**F3**	Jumps to the next match when searching the Data View
Find previous	**Shift - F3**	**Shift - F3**	Jumps to the previous match when searching the Data View
Select All	**Ctrl - A**	**Command - A**	Selects all data (right side only)
Copy (comma-separated)	**Ctrl - C**	**Command - C**	Copy selection to clipboard using comma as separator
Copy (tab-separated)	**Ctrl - Shift - C**	**Command - Shift - C**	Copy selection to clipboard using tab as separator (right side only)
Copy Without Labels (comma-separated)	context menu only	context menu only	Copy selection without labels to clipboard using comma as separator (Table View only)
Copy Without Labels (tab-separated)	context menu only	context menu only	Copy selection without labels to clipboard using tab as separator (Table View only)
Auto Resize Columns	**Ctrl - R**	**Command - R**	Resizes all columns to content (right side only)

6.14.2.5 Reference File Viewer

The Reference File Viewer is a useful tool to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS model and is created using the rf parameter when running the model.

Figure 6.17 Parameter to create a symbol reference file when running the model

When the model is compiled, the reference file with ".ref" extension is created and can be opened either using the menu: `File` > `Open` or double-clicking the "RefFile" entry in the Process Log:

```
--- Starting compilation
--- trnsport.gms(66) 3 Mb
--- RefFile /home/jeed/Documents/GAMS/Studio/workspace/trnsport.ref
--- Starting execution: elapsed 0:00:00.002
--- trnsport.gms(43) 4 Mb
--- Generating LP model transport
--- trnsport.gms(64) 4 Mb
```

Figure 6.18 Process Log showing clickable entry for the reference file

The Reference Viewer is categorized by a number of tabs:

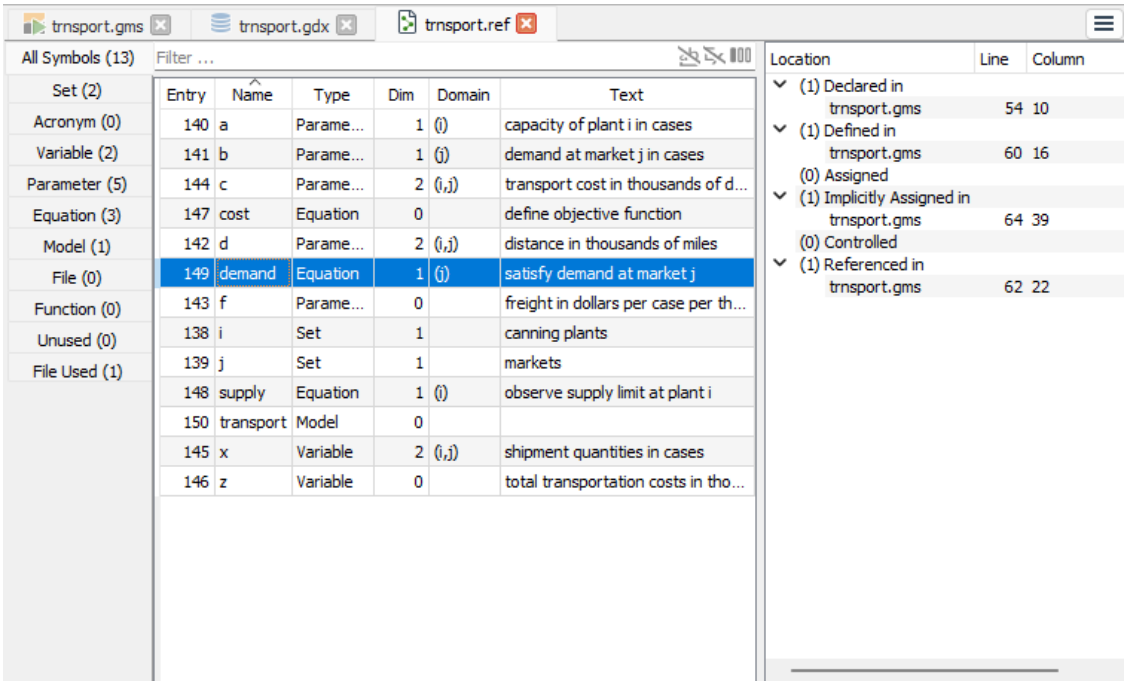

Figure 6.19 Reference File Viewer showing tabs and reference file information

- **All Symbols** shows an alphabetical listing of all symbols used in the model.
- **Set, Acronym, Variable, Parameter, Equation, and Model** shows an alphabetical listing of symbols of the same type. See Data Types and Definitions for more details on GAMS data types.
- **File** shows an alphabetical listing of all file statements used in the model.
- **Function** shows a list of GAMS built-in functions that has been used in the model.
- **Unused** shows an alphabetical listing of all symbols that have been declared in the model but are not used anywhere.
- **File used** shows an alphabetical listing of all files used in the model including the full file path. A double-click on an file entry of the table will jump to the beginning of the reference file.

The number next to the tab name indicates how many symbols in the category, where the number of All Symbols tab sums up the number of symbols in all other tabs except Unused tab and File used tab. A click on a symbol entry of the table in every tab (except File used tab) will show the detailed reference list containing the reference location in the right hand side of the reference viewer. A mouse-over on an entry of the reference list will show the tooltip of file location and position with the file that has been referenced. A double-click on an entry of the reference list will jump to the position in the corresponding file that has been referenced.

The reference list is organized by the following reference types:

Reference Type	Description
`declared`	Declaration of the symbol.
`defined`	Defined using a data statement.
`assigned`	When the symbol appears on the left side of an assignment statement.
`implicitly assigned`	Implicit assignment like a variable in a model.
`control`	When the set is used as a control set.
`reference`	Referenced in a statement.

The detailed description of the reference types and their shorthand symbols can be found in Reference Types in GAMS Output.

Sort and Filter referenced symbols

- **Sort** : A click on a table column header in the reference table will sort the symbol in the table by either Entry, Name, Type, Dim(ension), Domain, or Text.
- **Filter** : An input in the `Filter box` will filter the symbols in the reference table by `Name`. More about the filter can be found in the Filter Section.

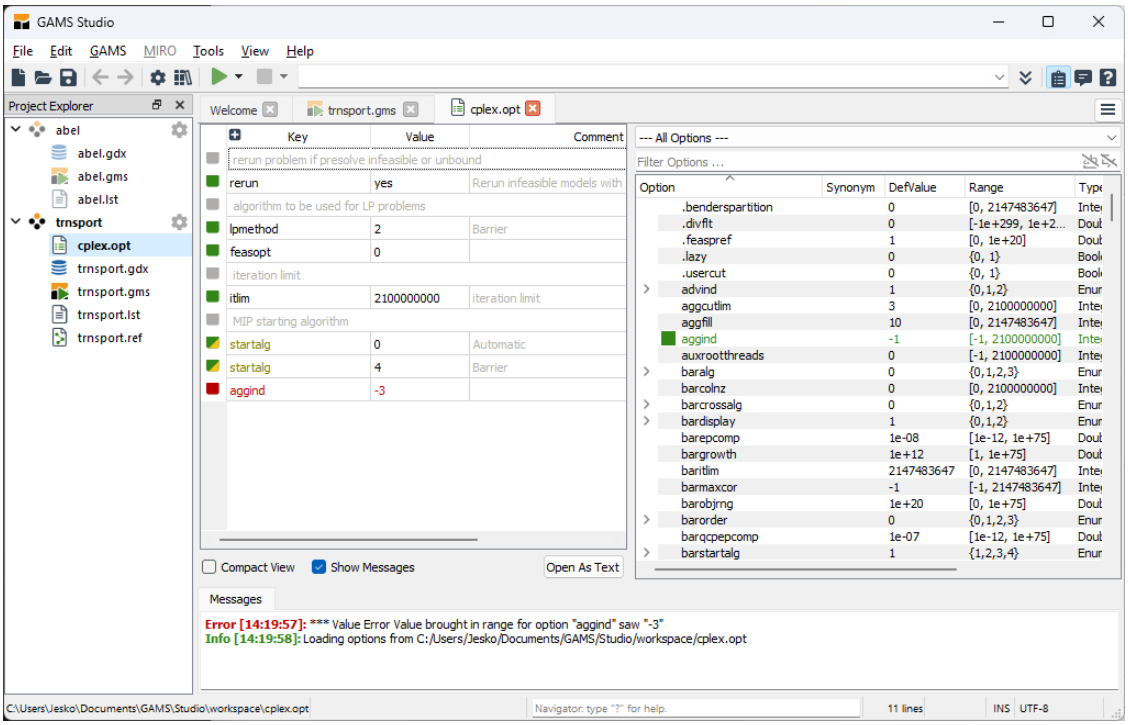
Summary of Actions and Shortcuts

Action	Shortcut	macOS	Description
Symbol Filter	**Ctrl - F**	**Command - F**	Jump to the Symbol Filter input field located above the symbol table
Auto Resize Columns	**Ctrl - R**	**Command - R**	Resize all columns to content (right side only)

6.14.2.6 Solver Option Editor

The Solver Option Editor is used to view and edit a solver-specific option file for controlling solver and interpreting results. See usage of The Solver Options File in Solver Usage and how to set optFile parameter to instruct gams to read an option file in The GAMS Call and Command Line Parameters. The Solver Option Editor provides an editor to edit the file contents in a table form where a row entry corresponds to a line in the solver option file. The Solver Option Editor also provides a browser of solver option definitions which can be displayed in group or be filtered by filter-term and where the option can be directly added into or deleted from the editor.

The Solver Option Editor consists of the contents editor in the left pane, option definition browser in the right pane, as well as message and configuration tab in the bottom pane.



- The left pane shows the contents editor of solver option file in a table form. Each row entry is either an option entry containing the option key, option value, as well as end-of-line comment (shown if there is definition of end-of-line comment characters for a solver option file) or a comment entry. Below the editor shows `Compact View` checkbox and `Open As Text` button
  - An option key and value are shown in green color when defined correctly according to the definition, otherwise in red color when there is an error. An end-of-line comment (if defined) and a comment entry are shown in grey color. (see section Toggle comment/option selection on how to turn an option entry into a comment entry and vice versa)
  - A comment row entry is shown in a merged cell as differences between option key van value are not identified in a comment line of a solver option file.
  - The `Compact View` checkbox enables the editor to display the file contents without comments. Note that some editing actions are suppressed when the editor is in compact view (see section Compact View for more details).
  - The `Show Messages` checkbox allows to display or hide the messages log at the bottom pane.
  - The `Open As Text` button allows to reopen the file in the text editor once contents of the file has been saved (see Open an existing solver option file and Save a solver option file in section Basic Operations for more details).
- The right pane shows a browser of solver option definitions.
  - The lower part of the browser lists all option definitions, each contains Option `Name`, `Synonym`, `Default Value`, `Range`, `Type`, and `Description`. The list can be sorted alphabetically in ascending or descending order by clicking the Option `Name` header. A checkbox in front of an option entry indicates whether there is an option of this definition entry defined in the left pane editor. An entry with enumeration type (`EnumStr` or `EnumInt`) can be expanded to show all enumerated values of the option by clicking the bullet in front of the option entry, clicking the bullet again hides all enumerated values of the option. By double clicking the entry or dragging the entry and dropping in the left pane editor adds the option key with the default value defined by this option definition in the left pane editor (See section Summary of Actions and Shortcuts on how to add or insert an option).
  - Above the list of all option definitions is a group of options and a filter box. Option groups filter the list of option definitions by group name. By default all option definitions are displayed. Filter box with placeholder text `Filter Options ...` allows to filter the option definitions. As a filter term has been typed into the filter box the results are displayed in the list of option definitions below. More about the filter can be found in the Filter Section.
- The bottom pane shows the message log which reports the operations that have been carried out such as the contents have been loaded and saved as well as errors resulting from editing the contents. By default the message log is shown unless the `Show Messages` checkbox in the left pane has been unmarked to hide the message log.

Basic Operations

- **Create a solver option file**: via either the Studio menu or the project context menu in Project Explorer.
  - From the Studio menu, choose `File` > `New...` then enter a valid solver option file name and suffix into the file dialog. choosing `Add new file` by right clicking on project name in Project Explorer brings up the same file dialog for entering a valid solver option file name and suffix (See how to set different suffix values for solver option file from optFile parameter).
  - From the project context menu, right clicking on project name in Project Explorer and choosing `Add new solver option file` brings up a list of solver names. Selecting a solver name from the list brings up a file dialog with the selected solver name as file name and the default option file suffix name `opt` (See how to set different suffix values for solver option file from optFile parameter).

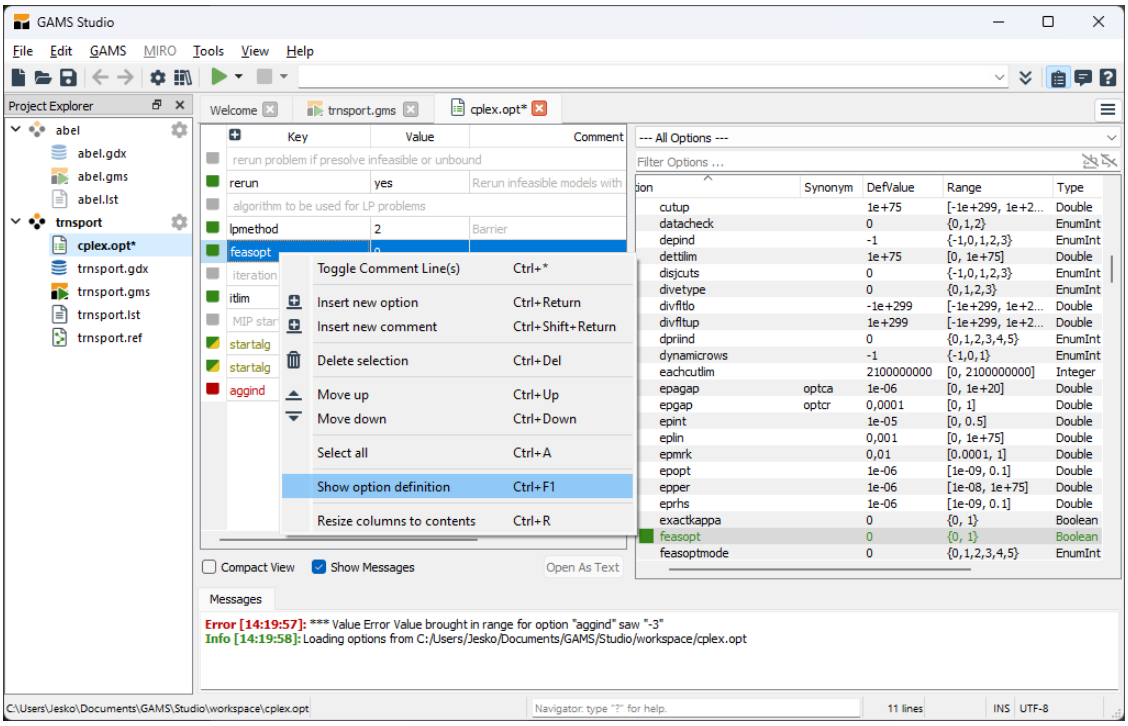
- **Open an existing solver option file**: via either the Studio menu or project context menu in Project Explorer.
  - From the Studio menu, choose `File` > `Open...` and select `Option Files` or `All Files` in the file dialog and then select a solver option file.
  - From the project context menu, right click on project name then choose `Add Existing file` then choose `Option Files` or `All Files` in the open file dialog and then select a solver option file.
  - In case a solver option file is already opened with solver option editor, the file can be reopened in text editor by choosing `Reopen File As Text` from the file context menu in Project Explorer.
  - It is possible to open the solver option file in either solver option editor or text editor.
    * In case a solver option file has already been opened in solver option editor, choosing `Reopen File As Text` from the file context menu in Project Explorer closes the solver option editor and reopens the file in the text editor. Note that `Open As Text` button in the left pane editor performs the same function.
    * In case a solver option file is already opened in text editor, choosing `Reopen File using Solver Option Editor` from the file context menu in Project Explorer closes the text editor and reopens the file in the solver option editor.
    * In case a file is already listed under the project entry but not yet opened, choosing `Open File` from the project context menu opens the file in the solver option editor; however, choosing `Open File As Text` from the project context menu opens the file in the text editor.
- **Save a solver option file**: activated by choosing either `File` > `Save` menu or `Ctrl - S` shortcut. Choosing `File` > `Save As` menu or `Ctrl - S` shortcut brings up a file dialog to choose a file with different name to be saved as (See also how to set different suffix values for solver option file from optFile parameter).

Navigating the contents

When a component of the solver option editor in focus, it is possible to perform further actions (see section Summary of Actions and Shortcuts for the list of actions and shortcuts). Clicking the component area will bring the component into focus or in selection. In addition to using mouse to navigate the solver option editor components, it is also possible using keyboard. Press `Tab` key navigates the components of the solver option editor. For example, when left pane editor is in focus, pressing `Tab` navigates from the left pane editor, to the right pane option group box, to the right pane Filter box, and to the right pane definition browser in the describing order. When the left pane editor is in focus, press `Up`, `Down`, `Left`, and `Right` keys to navigate the left pane editor table. When the right pane browser is in focus, press `Up` and `Down` to navigate the definition entries, press `Right` to expand/show the enumerated entries of the definition, and press `Left` to collapse/hide the enumerated entries of the definition.

There is a connection between an option entry in the left pane editor and a definition entry in the right pane browser. When navigating the solver option editor, it is possible to identify this connection from both the left pane editor and the right pane browser.

- From the left pane editor, right click on the selected entry and choose `show option definition` from the context menu. The entry in the right pane browser that contains the definition of the selected entry is highlighted and selected. When a cell or a row is already selected the shortcut `Ctrl - F1` delivers the same behavior.



- From the right pane browser, click or select on an entry. All entries in the left pane editor will be highlighted and selected if the definition has already been added. Otherwise there will be no selection in the left pane editor.

More editing actions can be performed on both the left pane editor and the right pane browser (See Editing the Contents for details).

Editing the Contents

The followings describe actions that can be performed when editing the contents:

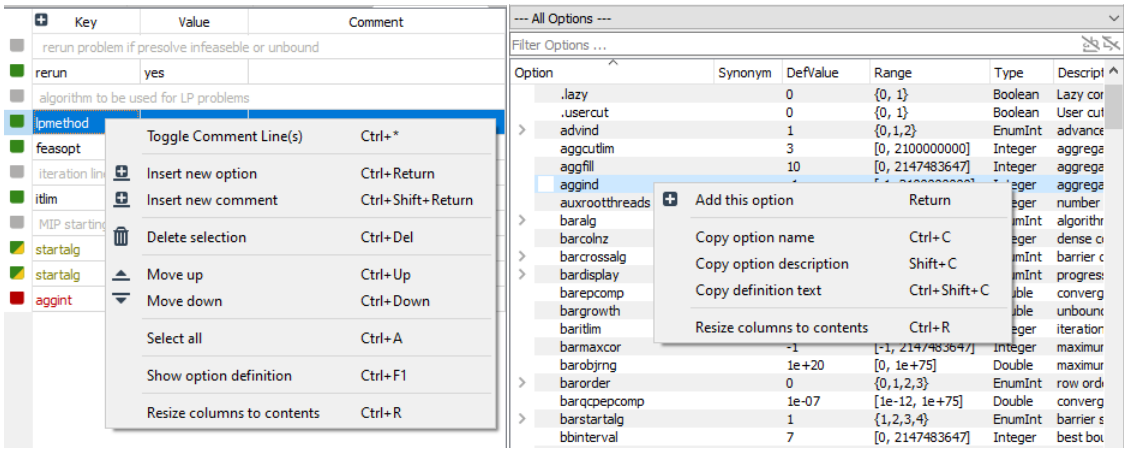


Figure 6.20 actions to be performed via the left pane editor and the right pane editor

- **Edit option key, value, and comment**: This action performs in the left pane editor.

– when the cell in the left pane editor is selected, double click on the cell or press platform-dependent edit key (eg. `F2`) in order to edit option key, value, or comment (if available). A drop-down list suggests possible option keys and option values as when possible. Press `Enter` to confirm the edit and press `Esc` to cancel the edit.

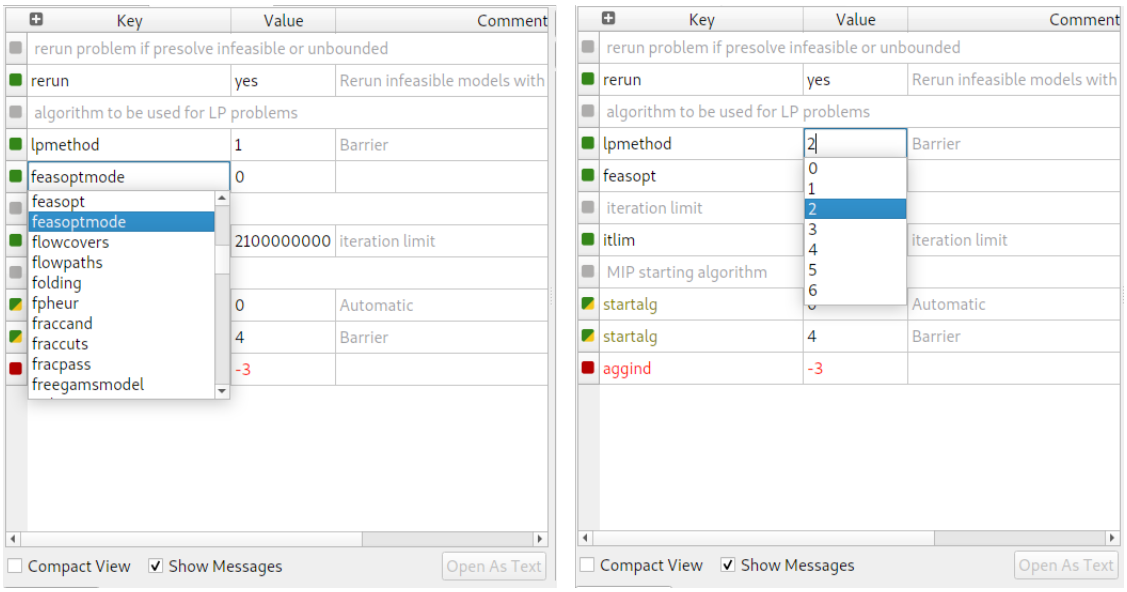

Figure 6.21 Drop-down lists suggest possible keys (left) and values (right)

- **Add new option**: This action appends a new option entry as the last entry of the left pane editor. There are several ways to add a new option entry.
  - click on the plus icon in the header of the left pane editor, a new option entry with dummy option key `[KEY]`, option value `[VALUE]`, and option comment `[comment]` (if available) is appended as the last entry.
  - it is also possible to add new option from the the right pane browser. Select the definition entry in the right pane browser that has not been added/inserted into the left pane editor (a solid checkbox in front of the entry is not marked), double click or right click on the selection then choose `add this option`. A new option entry ith the option key and default value of this definition will be added as the last entry in the left pane editor. and dummy option value `[VALUE]` is appended as the last entry.
- **Insert new option and comment**: It is possible to perform this action from the left pane editor and from the the right pane browser and there are several ways to insert a new option or a comment entry.
  - right click on the selected entry in the left pane editor and choose `insert new option` from the context menu. A new option entry with dummy option key `[KEY]`, option value `[VALUE]`, and option comment `[comment]` (if available) will be inserted before the selected entry. When a cell or a row is already selected the shortcut `Ctrl - Return` delivers the same behavior.
  - right click on the selected entry in left pane editor and choose `insert new comment` from the context menu. A new option entry with dummy text `[COMMENT]` will be inserted before the selected entry. When a cell or a row is already selected the shortcut `Ctrl - Shift - Return` delivers the same behavior.
  - double click on a definition entry in right pane browser.
    - In case this definition has not yet been added/inserted (a checkbox in front of the entry is not marked), a new option entry with the option key, default value, and comment (if available) of this definition will be added as the last entry in the left pane editor. When there is a selection on a cell or a row the shortcut `Return` delivers the same behavior.

    * In case this definition has already been added/inserted (a checkbox in front of the entry is marked), by default the studio option editor will ask for overriding existing option if there is an option from the same definition that has already been added/inserted into the left pane editor. A pop-up message box appears and offers three alternatives: either to `replace existing entry`, or to `add new entry`, or to `abort`. `Replace existing` entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition. `Add new entry` will add a new option entry with the option key and default value of this definition into the left pane editor. `Abort` will cancel the action. See section override existing option on how to suppress this default behavior.

  When double clicking an enumerated value entry of the definition a new option entry will be added with the option key of the parent entry and the selected enumerated value.

- drag a definition entry from the right pane browser and drop in the left pane editor.
    * In case this definition has not yet been added/inserted (a checkbox in front of the entry is not marked), a new option entry with the option key, default value, and comment (if available) of this definition will be dropped before the position of selected entry in the left pane editor.
    * In case this definition has already been added/inserted (a checkbox in front of the entry is marked), by default the studio option editor will ask for overriding existing option if there is an option from the same definition that has already been added/inserted into the left pane editor. A pop-up message box appears and offers three alternatives: either to `replace existing entry`, or to `add new entry`, or to `abort`. `Replace existing` entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition. `Add new entry` will insert a new option entry with the option key and value of this definition before the position of selected entry in the left pane editor. `Abort` will cancel the action. See section override existing option on how to suppress this default behavior.

  See also section Settings on how to insert a new option together with a comment from the definition.

- **Toggle comment/option**: This action performs in the left pane editor, turning an option entry into a comment entry and turning a comment entry into an option entry.
    - select the option entry and right click on the selection, then choose `toggle comment/option selection` from the context menu. In case of an option entry this action turns the entry into a comment entry (shown in grey color). In case of a comment entry this action turns the entry into an option entry entry (shown in either green or red color depending on whether or not there is an error). When a cell or a row is already selected the shortcut `Ctrl -` * delivers the same behavior. Clicking on the color box in front of the entry row also delivers the same behavior, even without a selection.

- **Move up and down**: These two actions perform in the left pane editor, changing the order of the option and comment entries.
    - to move an entry up in the left pane editor: select the option entry and right click on the selection, then choose `move up` from the context menu. The selected option entry will be moved one position up the option entry table. When a cell or a row is already selected the shortcut `Ctrl - Up` delivers the same behavior.
    - to move an entry up in the left pane editor: select the option entry and right click on the selection, then choose `move down` from the context menu. The selected option entry will be moved one position down the option entry table. When a cell or a row is already selected the shortcut `Ctrl - Down` delivers the same behavior.

- **Deleted option**: It is possible to perform this action from the left pane editor and from the the right pane browser.
    - from the left pane editor, select the option entry and right click on the selected, then choose `delete selection`. The selected option entry will be deleted from the option entry table. When there is a selection on a cell or a row the shortcut `Ctrl - Delete` delivers the same behavior.

– from the right pane browser, select the definition entry that has already been add/inserted into the left pane editor (a checkbox in front of the entry is marked) and right click on the selection then choose `remove this option`. All entries in the left pane editor defined by this definition will be deleted from the option entry table. When there is already a selection on a definition row the shortcut `Delete` delivers the same behavior.

- **Show option definition**: This action performs in the left pane editor. Right click on the left pane of the option editor and choose `Show option definition`. The option definition entry on the right pane will be highlighted. The shortcut `Ctrl - F1` delivers the same behavior.

- **Show all options of the same definition**: This action performs in the left pane editor. Right click on the left pane of the extended editor and choose `Show all options of the same definition`. All option entries on the left pane will be highlighted. The shortcut `Shift - F1` delivers the same behavior.

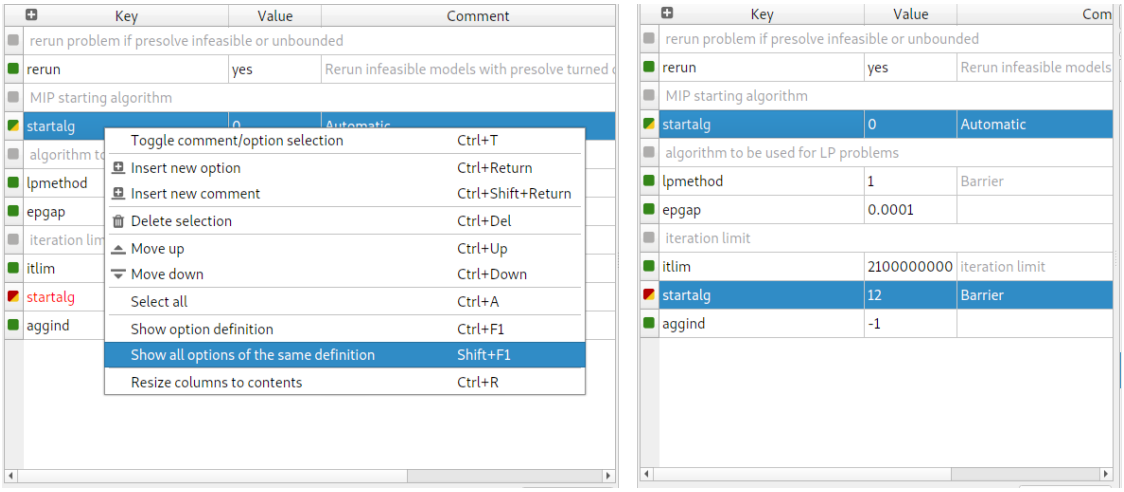

Figure 6.22 All entries of the same option are highlighted

Compact View

Compact View of the solver option editor allows to view and edit solver option without comments. Comments in a solver option file are not interpreted by either GAMS or the solver but used for documentation purpose. As the contents of the solver option file grows larger with several comment lines, it can be difficult to see which options eventually will be interpreted. To this end, the compact view becomes useful to hide all comments and show only non-comment lines. In the right pane editor, mark `Compact View` checkbox to activate the compact view and unmark the checkbox to deactivate the compact view. The comment entry is shown again once the compact view is deactivated.

Note that the result of some actions are not visible when in compact view. For example, action **toggle comment/option selection** when performed on an option row entry, turning the entry into a comment entry and therefore hidden from the compact view. Action **delete selection** when performed on an option row entry, removing the content entry and therefore no longer visible hidden from the compact view.

Some editing actions that can change the order of the contents are suppressed. These actions are **insert new option**, **insert new comment**, **move up**, and **move down**. Nevertheless adding or inserting option from the right pane are allowed, but a comment that has been inserted with the option (if set) are not visible in compact view. See also section Settings on how to insert a new option together with a comment from the definition.

Settings

The setting tab allows to configure the behavior when inserting new option from definition and deleting option. The setting can be accessed by opening the Settings dialog (`File` > `Settings`) and switching to the `Misc.` tab. These configurations are:

- **Override existing option**. This behavior allows Studio to override existing option when an option entry has been added or inserted from the right pane browser. In case there are more than one entry of the same option, Studio will pop-up a message box to offer three alternatives: either to `replace existing entry`, or to `add new entry`, or to `abort`.
  - *Replace existing* entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition.
  - *Add new entry* will add or insert a new option entry with the option key and default value of this definition into the left pane editor.
  - *Abort* will cancel the action.

  By default this behavior has been set. In the Settings dialog, unmark the checkbox in front of the text *overriding existing option* to suppress the behavior and mark to enable the behavior.
- **Add option description as comment above**. This behavior allows Studio to add option description as additional comment entry above an option entry that has been added or inserted from the right pane browser. The description has been taken from the option definition in the right pane browser. By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text *add option description as comment above* to enable the behavior and unmark the checkbox to suppress the behavior.
- **add option description as end of line comment** This behavior allows Studio to add option description as additional end-of-line comment of an option entry that has been added or inserted from the right pane browser. The end of line comment is only available when the solver defines valid end of line characters. The end-of-line comment column will be shown in the solver option editor only when available (there is definition of end-of-line comment characters for a solver option file). By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text *add option description as end of line comment* to enable this behavior and unmark the checkbox to suppress the behavior.
- **delete all immediate comments above** This behavior allows Studio to delete all immediate comments (if there is any) above when deleting an option. By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text *delete all immediate comments above* to enable this behavior and unmark the checkbox to suppress the behavior.

Summary of Actions and Shortcuts

Actions and their shortcuts that can be performed via the left pane of solver option editor are:

Action	Shortcut	macOS	Description
Toggle option/comment selection	**Ctrl** - ∗	**Command** - ∗	Toggle between option and comment
Insert new option	**Ctrl** - **Return**	**Command** - **Return**	Insert a new option
Insert new comment	**Ctrl** - **Shift** - **Return**	**Ctrl** - **Shift** - **Return**	Insert a new comment
Delete selection	**Ctrl** - **Delete**		Delete the selected option/comment
Move up	**Ctrl** - **Up**	**Command** - **Up**	Move the selected option/comment up for 1 row

Action	Shortcut	macOS	Description
Move down	**Ctrl - Down**	**Command - Down**	Move the selected option/comment down for 1 row
Select all	**Ctrl - A**	**Command - A**	Select all options
Show option definition	**Ctrl - F1**	**Command - F1**	Show definition of this selected option in the right pane
Show all options of the same definition	**Shift - F1**		Show all options of the same definition defined in the right pane
Resize columns to contents	**Ctrl - R**	**Command - R**	Resize the columns in the left pane to contents

Actions and their shortcuts that can be performed via the right pane of solver option editor are:

Action	Shortcut	macOS	Description
Option Filter	**Ctrl - F**	**Command - F**	Jump to the focus to the Option Filter input field
Add this option	**Return**	**Return**	Add option in the left pane from the selected definition
Remove this option	**Delete**		Remove option defined by this definition from the left pane
Copy option name	**Ctrl - C**	**Command - C**	Copy option key from this selected definition
Copy option description	**Shift - C**	**Shift - C**	Copy option description from this selected definition
Copy definition text	**Ctrl - Shift - C**	**Command - Shift - C**	Copy option text from this selected definition
Resize columns to contents	**Ctrl - R**	**Command - R**	Resize the columns in the right pane to contents

6.14.2.7 GAMS Configuration Editor

The GAMS Configuration Editor is used to view and edit a GAMS Configuration File in YAML Format. The editor shows the two configuration sections: command line parameters (`commandLineParameters`), and operating system environment variables (`environmentVariables`), in different tabs of the editor.

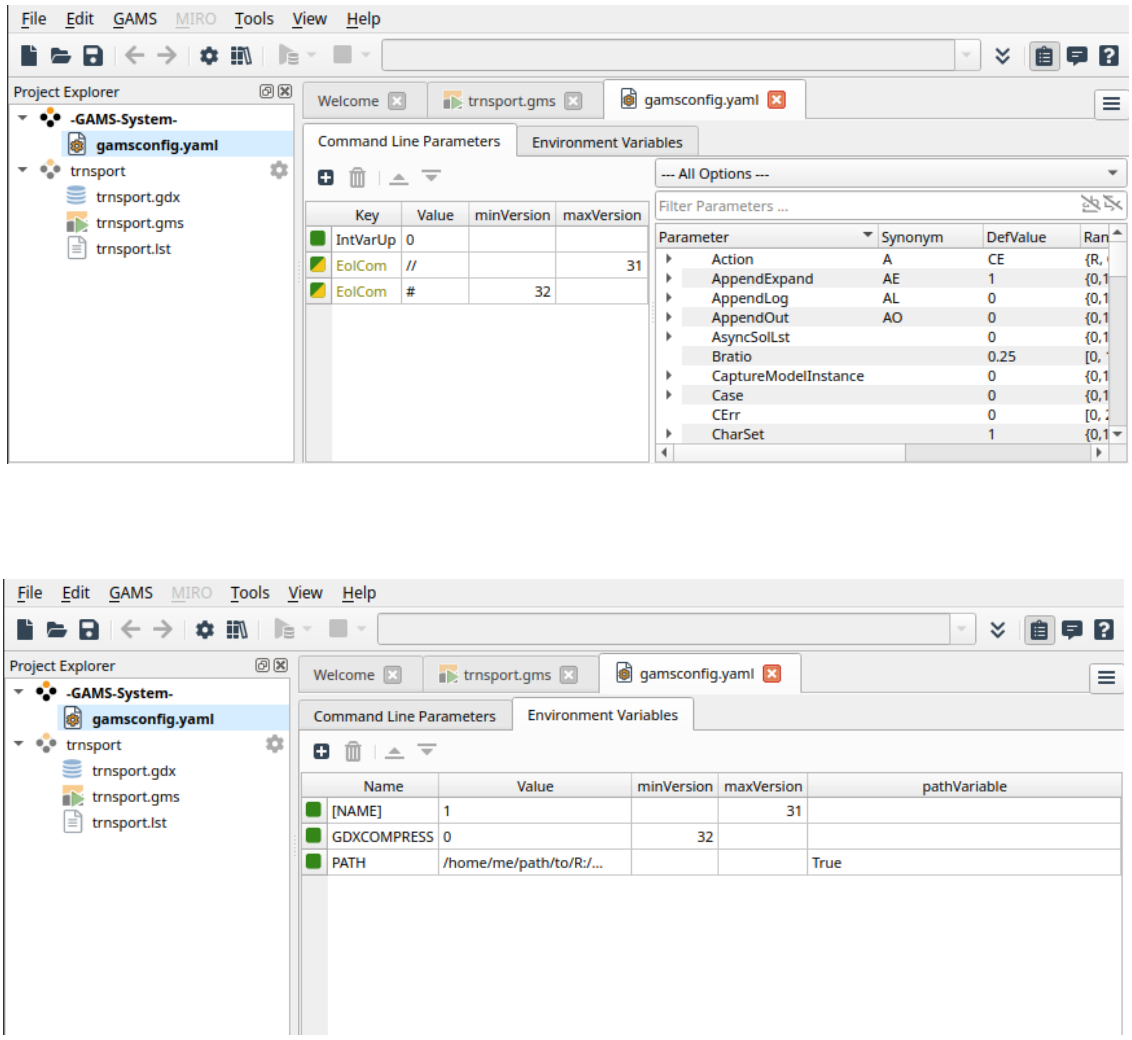

Figure 6.23 Contents of gamsconfig.yaml shown in GAMS Configuration Editor

Note that GAMS Configuration editor does not show the contents of the third section: external solver configuration (`solverConfig`) if exists. However, the contents in this section will be written out to the file when saving the file via the editor. It is possible to use `Reopen File as Text` from Project Explorer context menu to reopen and edit the file contents in text editor when the file is already opened in the GAMS Configuration Editor and use `Open File as Text` from Project Explorer context menu to open the file in text editor when the file is not yet opened in any editor. See the syntax of `gamsyconfig.yaml` file from GAMS Configuration File in YAML Format.

GAMS will process a sequence of `gamsconfig.yaml` files from different locations (see the location of GAMS Configruation file from The GAMS Configuration in YAML Format and the order of precedence for command line parameters from Order of Precedence for Options). Studio can create a new `gamsconfig.yaml` file at the default user-specific location and open the file in the editor when the file at the location does not exist. This can be done by choosing `GAMS > Default GAMS Configuration`. In case the file already exists at the default location, choosing `GAMS > Default GAMS Configuration` will not override the `gamsconfig.yaml` in the default user-specific location but open the file in the editor.

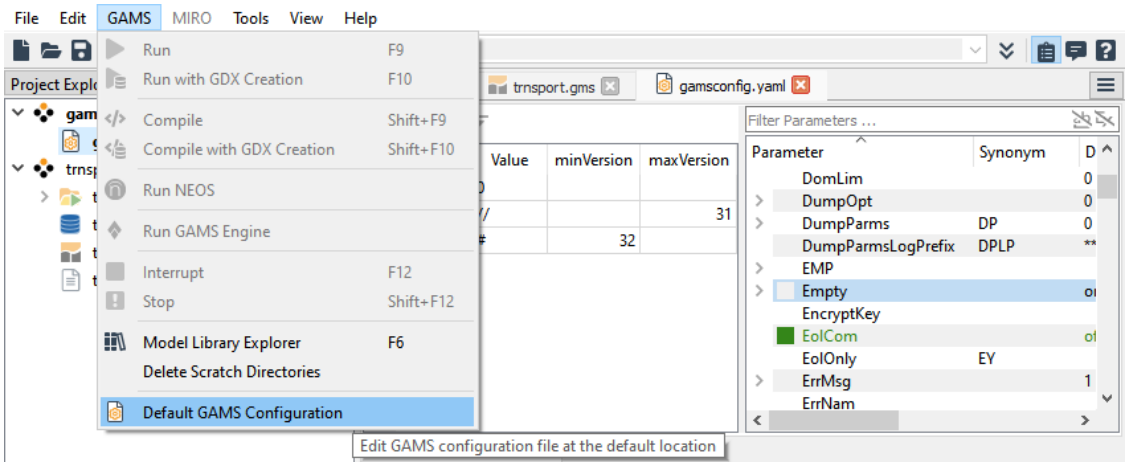

Figure 6.24 Menu entry point to create/open gamsconfig.yaml file from default location

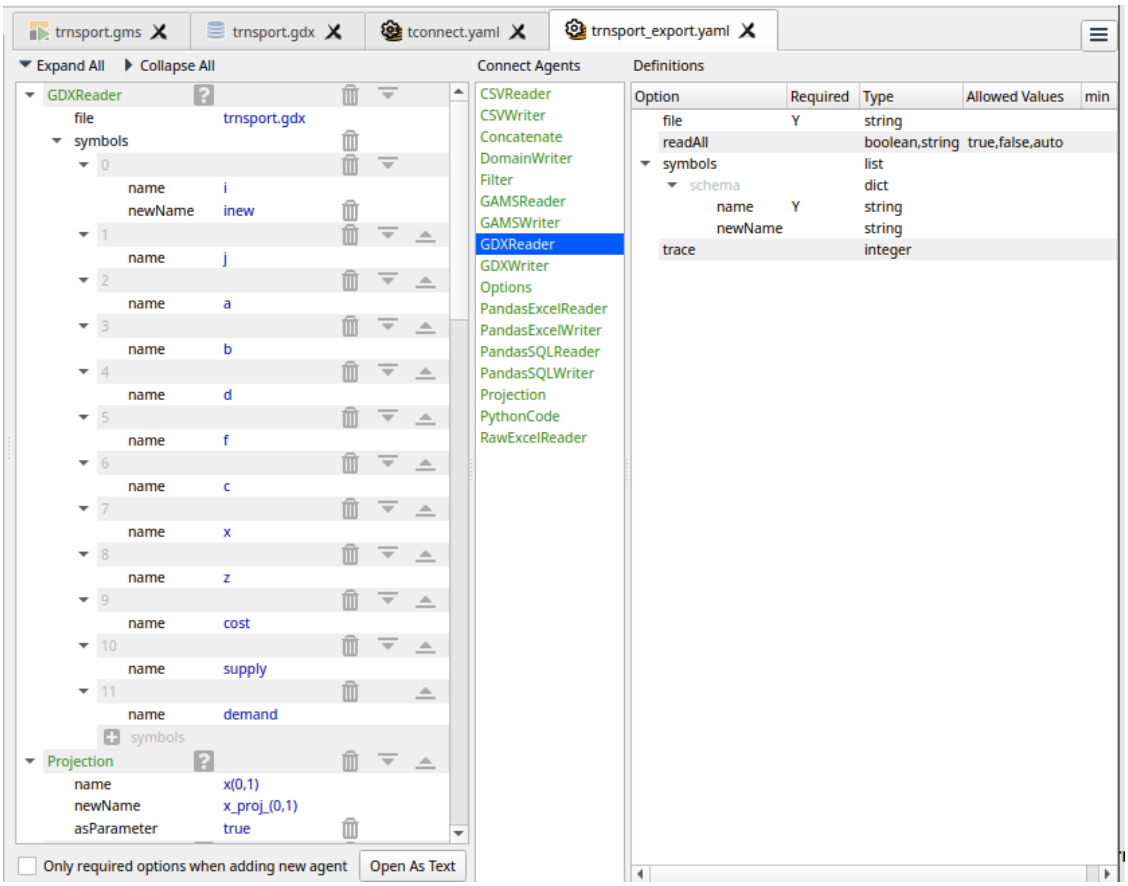
It is possible to save the `gamsconfig.yaml` file into different location using `File` > `Save As...`.

6.14.2.8 Connect Editor

Connect Editor provides fundamental functionalities for creating and editing GAMS Connect file, containing instructions in YAML syntax which will be processed by the GAMS Connect interfaces. The Connect Editor consists of three main sections:

- the left section displays instructions from the file in tree structure. The top level entries are Connect Agents names with option entries as its children.
- the middle section lists all available Connect Agents. Double click or drag-and-drop an agent name from this section into the left section will add or insert instructions for the selected agent in the left section.
- the right section shows Definition of the Connect Agents selected in the middle section. Clicking an agent name in the middle section will display definition of the selected agent in this section.



A new connect file can be created by selecting **Add new file** from the **File** menu or the project context menu in Project Explorer. An existing connect file can be edited by selecting **Open**... from the **File** menu or **Open in Current Project...** or **Add existing file** the project context menu in Project Explorer. In both cases, a file dialog opens to select the project folder, choose **Gams Connect Yaml File (∗.yaml)** as a type of files.

A top level entry of instructions is a connect agent name with option entries as its children. Each `option entry` is represented as either a map of `option key` to `option value` or a list of either `option values` or option `entries` depending on the definition of the agent. Only an `option value` can be edited. An edited `option value` that does not conform to the definition (eg. wrong type or unallowed value) will be highlighted in red and so is its agent name. By clicking `Help` icon next to the agent name at top level entry, the agent name in the middle section will be selected and the definition of the agent will be shown in the right section.

New instruction for an agent can be added by either double clicking an agent name in the middle section or dragging an agent name in the middle section and dropping it in the left section at the desired position. Double clicking an agent name will append instruction for the selected agent as the last agent entry in the left section, while dragging an agent name will either append instruction in the left section as the last agent entry or insert instruction for the selected agent below the drop position. When **Only required option when adding new agent** checkbox is marked, only the required options of the agent will be added. An option missing from the agent name entry can be inserted or appended by dragging the option from the definition in the right section and dropping it at the desired position in the left section. Dropping the option onto the agent name entry will append the option as the last child entry of the agent name. The missing option can still be added even when it is not required by definition and **Only required option when adding new agent** checkbox is marked.

A new child entry of a list entry can be added using the `plus` icon at the last child entry of the list. An option entry and all its children can be `removed`, `moved up`, and `moved down` using `delete` icon, `move up` icon, and `move down` icon accordingly at the end of each entry. An option entry with children can

be either `expanded` or `collapsed` by clicking an icon in front of the entry. The tree structure can be completely expanded by clicking **Expand All** and collapsed by clicking **Collapse All**.

The content of connect file can also be displayed and edited in plain yaml format using a text editor. Switching from connect editor to text editor can be done by either clicking **Open As Text** button or selecting **Reopen File as Text** from the context menu of the file in the Project Explorer.

- **Open As Text** button will be enabled once the content of the file has been saved, allowing a switch to the text editor.
- Selecting **Reopen File as Text** from the context menu, when the content of the file has been modified, will popup a dialog to report modified content and offer options to `discard the content` or to `save the content` or to `cancel the operation`.
  - In case of discarding the content, Studio will switch to the text editor to display the current file content before modifying.
  - In case of saving the content, Studio will save the content into a file before switching to the text editor.
  - Cancel operation will bring back to the current modifying state of connect editor.

6.14.2.9 Parameter File

To support fast switching between parameter sets, Studio contains an editor for "GAMS Parameter Files". To create a Parameter File, open the context menu of a project and select "Add New Gams Parameter File". The project settings contains a box to switch between different parameter files or to deselect it for the project.

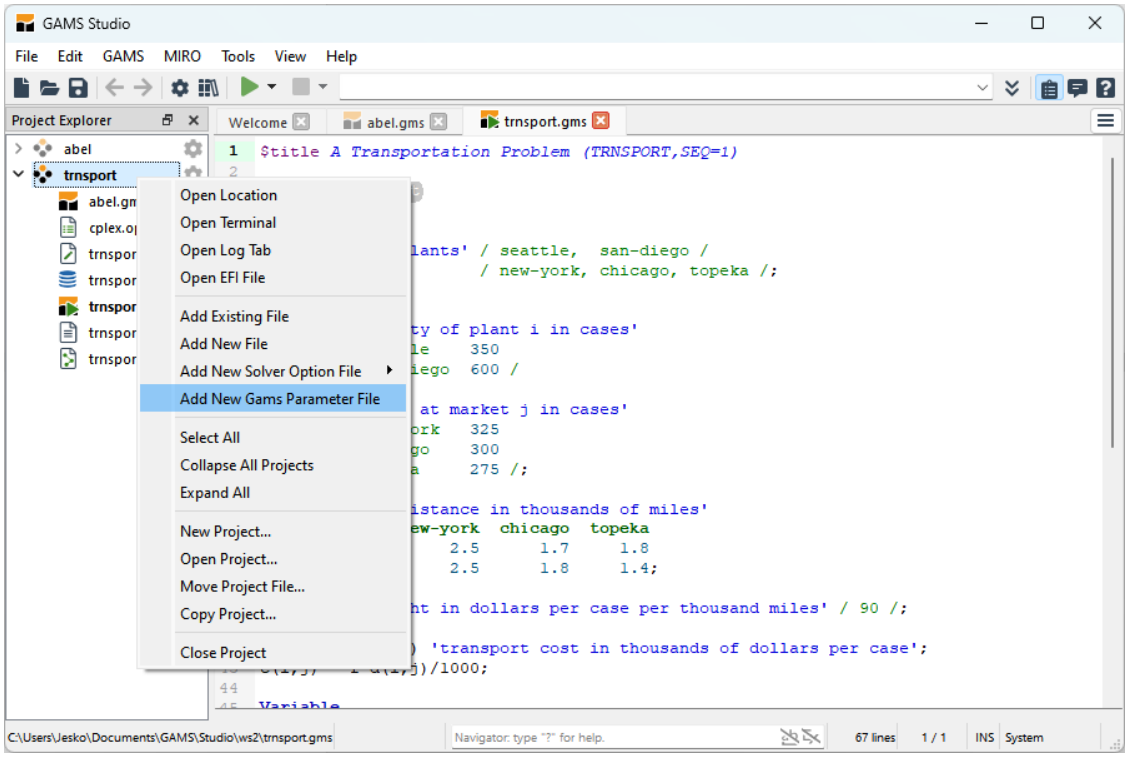


Figure 6.25 Pin View

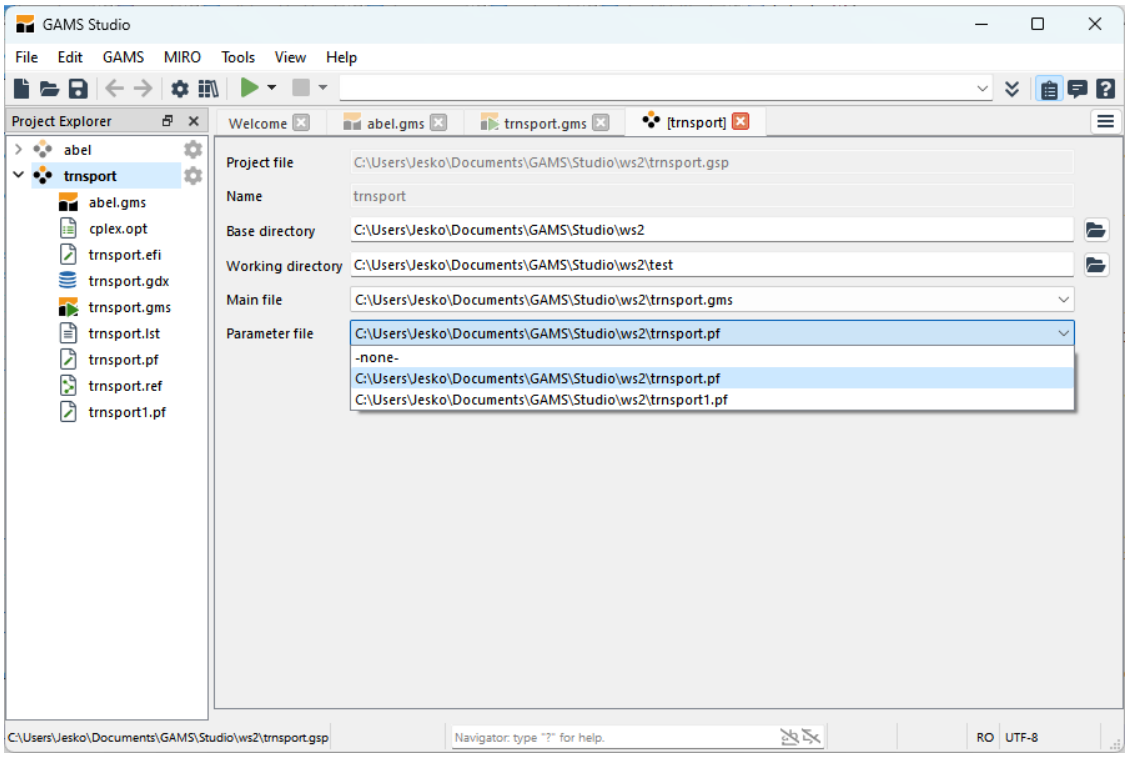

Figure 6.26 Pin View

Parameter defined in the parameter file will overlay parameters defined in the GAMS Configuration File. The usage of the editor is equivalent to the Solver Option Editor.

6.14.2.10 Tab Browser (Deprecated)

Deprecation Notice: This feature will be removed in a future version of GAMS as it is replaced by the Navigator.
The Tab Browser is accessible with a button next to the main tab bar or via the shortcut `Ctrl - 4`. It opens a list of all open files and features a search input field. When opening the tab browser, the search field is already focused. Typing updates the list in real time. The `Enter` key selects the first item in the list and opens it. It is also possible to use arrow up/down to navigate the list and select an item with `Enter`. The filter supports wildcard syntax.

6.14.2.11 Navigator

The Navigator allows users to quickly navigate between files and can be opened with the shortcut `Ctrl - K` or by clicking into the Navigator input field located in the Status Bar in the bottom right. The default view shows a list of all files from the Project Explorer with three columns. The first column contains the file name, the second the path relative to the current project's directory. If it is the same path the field is empty. And the third column contains additional information, by default which kind of result it is. Typing something into the input field filters this list. Using the arrow keys a result can be selected and confirmed with the `Enter` key. The filter also supports wildcards: to e.g. find all ".gdx" files one can input `*.gdx`. To narrow a search down even more the Navigator supports different modes which are accessed with prefixes in front of the search term. To see a list of all available modes just type "?" into the input field. This allows, for example, to only show files that are currently opened in a tab (`t`), associated with the current project (`p`), or all open log tabs (`l`). Additionally using the `:`prefix followed by a number users can jump to a certain line in the current file. There is the possibility to jump to files that are not yet known

to Studio: using the `f` prefix allows users to navigate the filesystem of the operating system, starting with the current project's workspace. Also, with the quick action prefix (`x`) it is possible to call often used Studio functions like "Open Model Library Explorer", "Clean Scratch Directories", "Run Engine", and many more. For a complete list just input `x` into the Navigator.

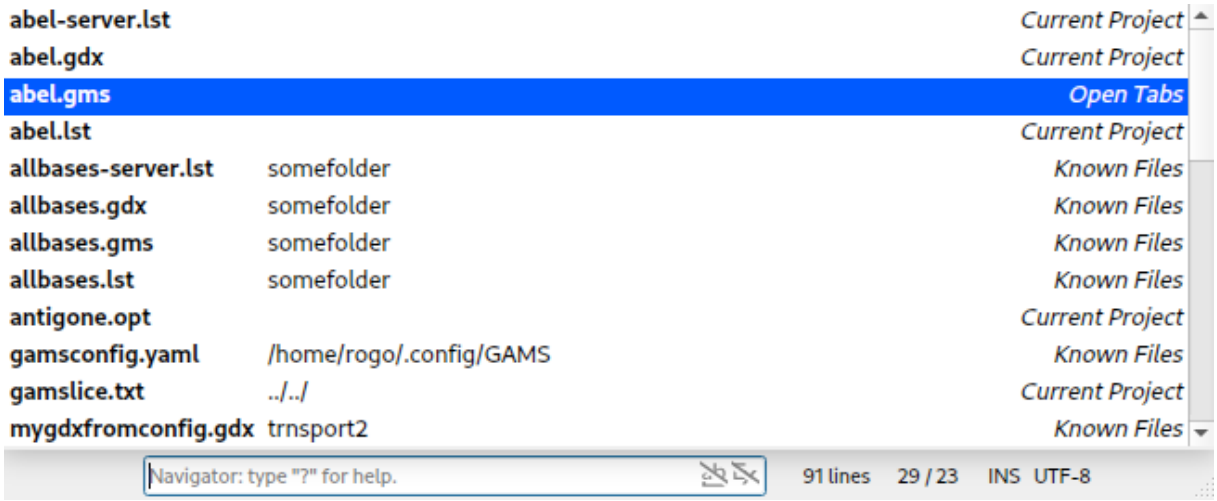

Figure 6.27 Navigator showing some example files

6.14.2.12 Pin View

Studio provides a Pin View to carry a clone of a selected tab. This allows to have two file contents visible at the same time. To pin a tab there are two entries in the tabbar: "Pin right" (shortcut `Ctrl - Click`) splits the edit area horizontally and opens the Pin View right to the main tabs. "Pin below" (shortcut `Ctrl - Shift - Click`) splits the edit area vertically and opens the Pin View below the main tabs. The state and size of the Pin View is restored on restarting Studio.

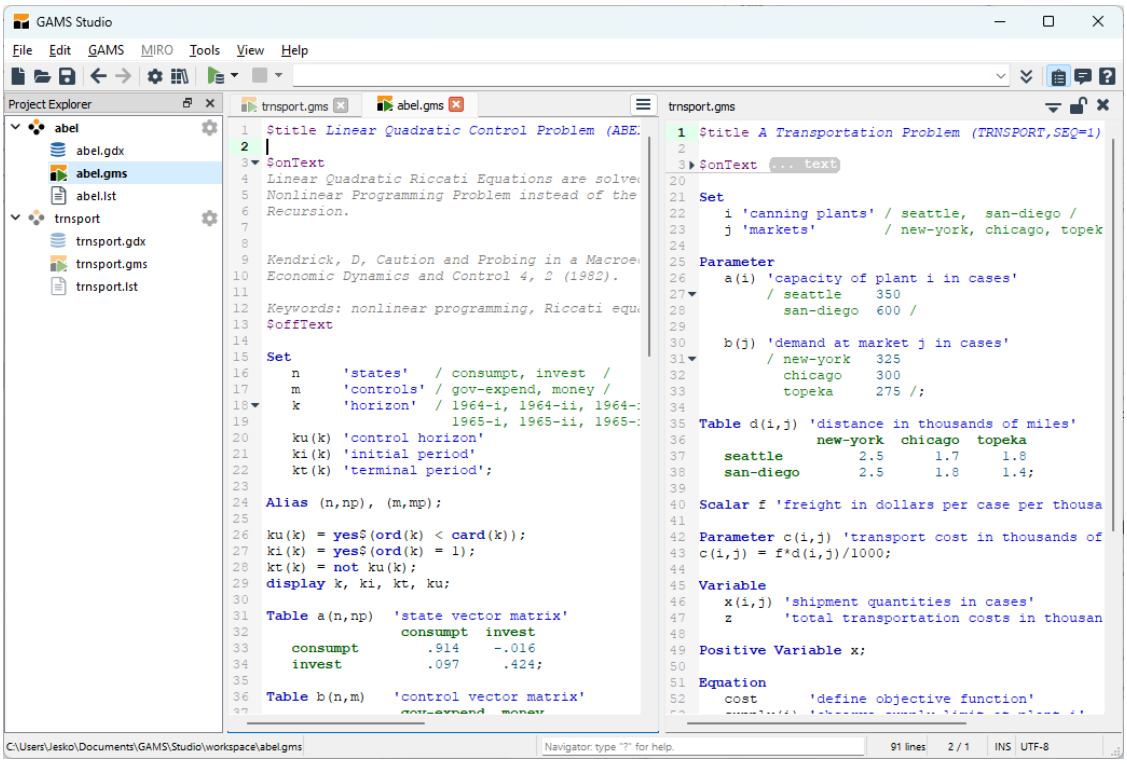

Figure 6.28 Pin View

The Pin View provides additional buttons. The first button switches the split orientation from right to below and vice versa. The second button allows to activate synchronized scrolling for the two visible editors. Synchronizing is always passed from the active editor containing the focus to the passive editor, which means that scrolling in the passive editor with the mouse wheel isn't passed back to the active editor allowing adjustments without switching the function off and on. The last button closes the Pin View.

6.14.2.13 Navigation History

The Navigation History records a navigation history event each time the cursor is moved in some kind of text file opened in the Studio central widget. This allows the user to quickly jump back (and forward again) to text passages that were recently edited. To reduce clutter some events are set to overwrite the previous event. This happens when the cursor is moved by only a single position in either direction, so that when a user jumps through text or types something only the latest position will be put into the history. The idea behind this is to make it easier and more convenient to jump to positions that actually matter. Using the navigation history is not limited to a single file. It is easy to jump between two or more files to go back and review recent changes. If a file was closed in the meantime it will be reopened when navigating through the history. This includes even files that were completely removed from Studio. When such a file is reopened through the Navigation History feature, due to technical limitations, the affiliation of the file to its previous project is lost. Please note that after navigating back in the history all "future" history events will be deleted and overwritten if the user creates new history events.

Action	Shortcut	macOS	Alternative Shortcut
Go Back	**Alt - Left Arrow**	**Ctrl - [**	**Mouse Button 4**
Go Forward	**Alt - Right Arrow**	**Ctrl -]**	**Mouse Button 5**

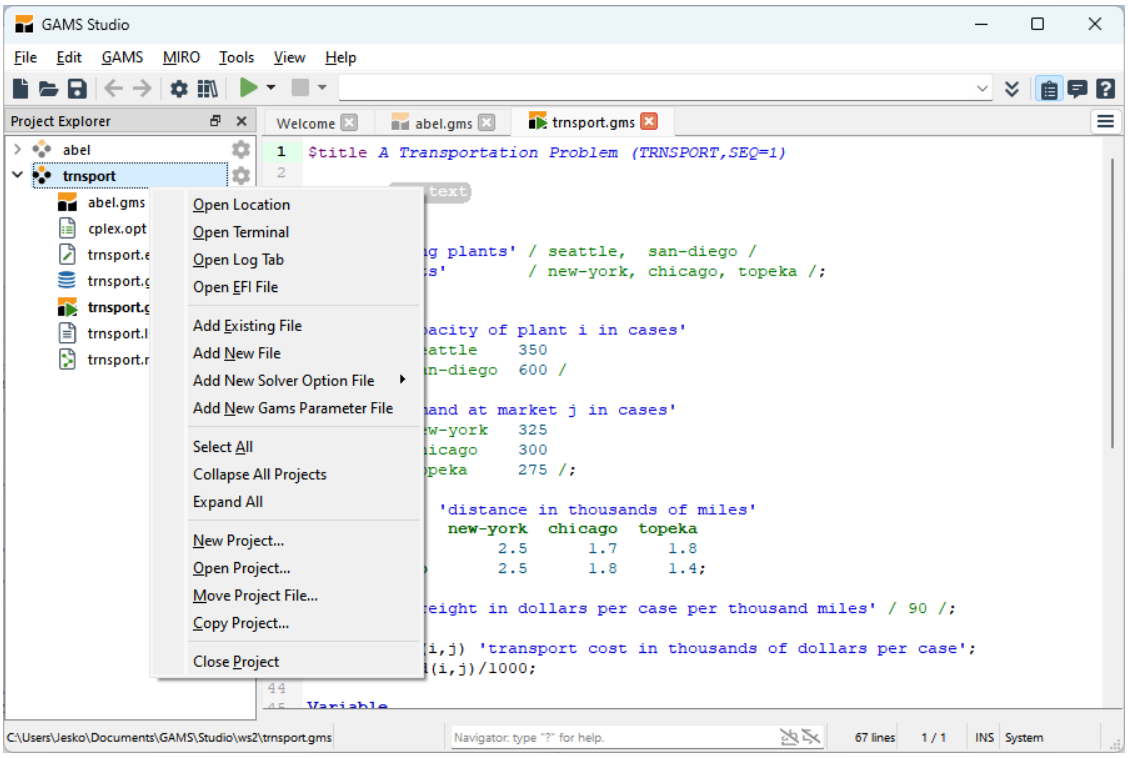
6.14.3 Further Studio Widgets

6.14.3.1 Project Explorer

The Project Explorer organizes the files opened in Studio into projects. Each project has its own base directory. All files associated to the project are organized in a hierarchical tree structure of folders relative to this base directory. A projects tooltip tells the location of the project in the file system, so it shows the location of the project file (the `.gsp` file - `gsp` standing for GamsStudioProject) . To support faster detection there are several icons for different file types:

- The runnable GAMS files (currently supported `.gms` and `.inc`) are listed with GAMS icon,
- the main GAMS file assigned to the project additionally contains a green play symbol,
- GDX files (.gdx) have an database icon,
- Reference files (.ref) are shown with a reference nodes on a sheet,
- editable files (e.g. `.txt`) contain a pen on a sheet,
- read-only files (e.g. `.log`) contain lines on a sheet.

The tooltip of a file or folder entry tells the location in the file system. The file location, the project location, and the folder location can be explored using the default file system explorer via the context menu `"Open Location"`. Selecting `"Open Terminal"` opens the systems terminal in the location of the selected file, project, or folder. The context menu of a `.gdx` file provides a special entry `"Open in GDX Diff"` that opens the specific GDX Diff Dialog.



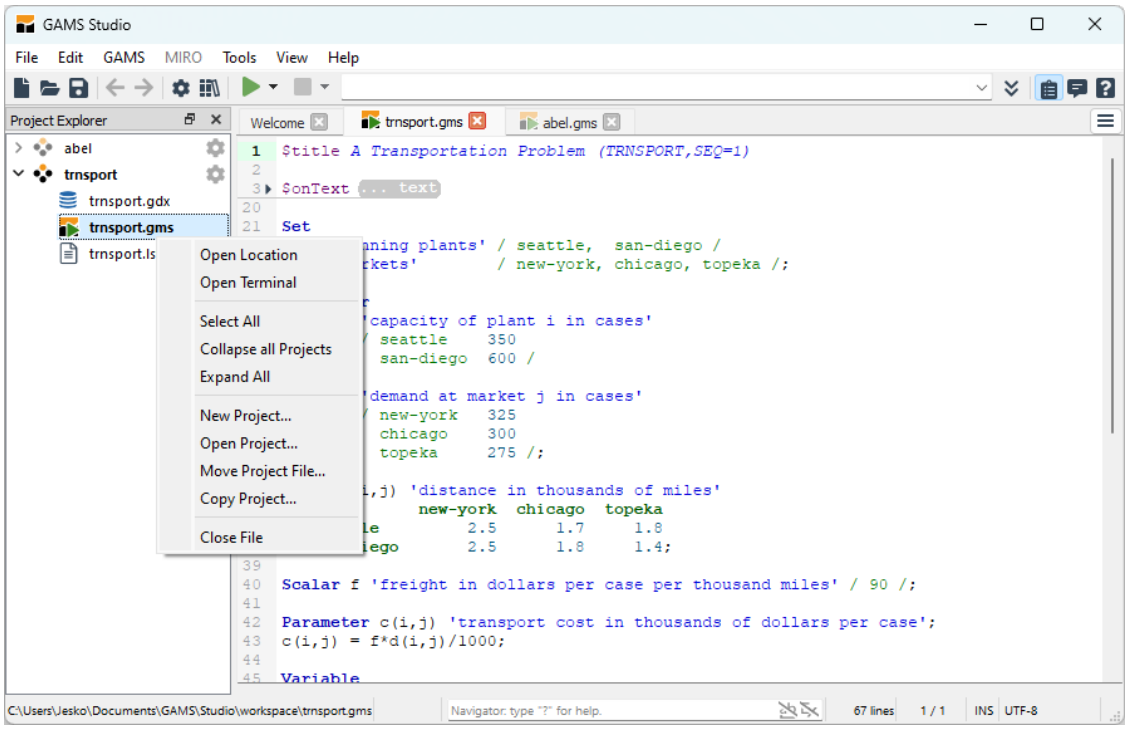


Figure 6.29 Project Explorer and its context menu

An empty project can be created by selecting `"New Project..."` from the `"File"` menu or the context menu in the Project Explorer. A file dialog opens to select the project file name. If a project with that name already exists, `Studio` looks for a number to append until the projects name is unique. Additionally a project is created automatically when opening a file. The projects name and location is determined by the name and location of the opened file. It is possible to add two projects of the same name to Studio. To help keeping them apart, a gray number is added to the project name of conflicting names.
One project may contain multiple runnable GAMS files but only one runnable GAMS file is set as the main file, marked with a green arrow overlay. By default the first runnable GAMS file in a project is considered the main file. The tooltip of a project also tells the location of the folder and the name of the current main file. Additionally the name of the recently created output file (.lst) is shown after the first run. The main file can be changed to a different runnable GAMS file in a project via the context menu `"Set as Main File"`. The project base directory remains unchanged if the runnable GAMS file is changed.

The **main file** of the active project will be executed when pressing `F9` or clicking the execute button (see how to set GAMS parameters and execute the main file in Quick Access Toolbar and GAMS Parameter Editor). To better recognize the active project, the current file and its project are in bold text and the icons of other projects are slightly dimmed. After executing the main file, the generated listing file (.lst) is added to its project and the output view (see Process Log) is opened. A clickable log line in the process log may add the corresponding file into the project and open the file in the Central Widgets area. Users can manually add more files to a project by right-clicking and choosing either `"Add Existing File"` or `"Add New File"` from the context menu. Additionally Drag and Drop from the systems file explorer is supported.

It is possible to select multiple items in the Project Explorer. A selection always contains items of one kind, files or projects never both depending on the first selected item. Folders in this case count as multiple file selection. The context menu then addresses all selected items.

Files can be removed from a project and projects can be removed from Project Explorer via the two actions `"Close File"` and `"Close Project"` from the context menu. The action `"Close Project"` closes the project and all files in the project if opened as well as removes all file entries and the project entry from

the Project Explorer without actually touching the files on the file system. The action "Close Files in This Folder" closes all files in this folder and it's subfolders. The action "Close File" closes the file if opened and removes the file entry from the project. In case the closed file is the only entry in a folder, the folder is also closed accordingly. In contrast a project can be empty during the current session but an empty project isn't restored on Studio restart. In case there are unsaved changes a message popup will appear, asking the user how to proceed.

Each project is stored in its unique file. Related paths are stored relatively to the location of the project file. The relative paths allows to share the project along with its other files. You can use "Move Project File" to rename a project or to move it to another folder. In this case the relative paths are adjusted to reach the original referenced files. The option "Copy Project" allows to create a copy of the project file and all of its referenced files.

Selected files can be dragged to another project. By dropping them they are moved to the destination project. If a folder is empty after this action its representation is removed from the project. Pressing the Ctrl key creates a copy of the file-reference in that project (no file copy). If the project already contains a specific file it is just ignored.

Next to each project there is a cog wheel button that opens the **Project options** page. It contains these actions:

- Project file: shows the location of the project file
- Name: shows the name of the project
- Base directory: defines the directory from where the folders to each file of the project are generated. Changing this will update the visible folder structure to all files of this project
- Working directory: defines the directory where the main GAMS file associated to the project will be executed
- Main file: informs about the current main GMS file

The changed Project Options can be applied by selecting "File > Save" or pressing Ctrl - S.

Actions like rename, move, or delete from file system are currently not supported but will be added in the future.

Note

> For long-time users of the classic GAMS IDE the section about the differences between IDE projects and Studio projects might be of particular interest.

6.14.3.2 Process Log

After starting a GAMS process the LogViewer is opened to view the process **Log**. Usually the **Log** stays at the bottom to keep tracking the latest log lines. The tracking can be paused by clicking on the up arrow of the vertical scrollbar. To continue tracking drag the scrollbar to the bottom.

The **Log** usually contains links of different kinds:

- compilation errors (red): Links to the gms file where the error occurred. Additionally contains a link to the listing file (.lst) at the beginning of the line (blue).
- listing links: Links to a specific line in the listing file
- file link (green): Links to a file without line numbers such as .gdx or .ref

Clicking on a link takes the focus to that file (and line). Double-clicking in the **Log** looks for the nearest link to the listing file and takes the focus there. Files that were not part of the current project are added when they are opened by link.

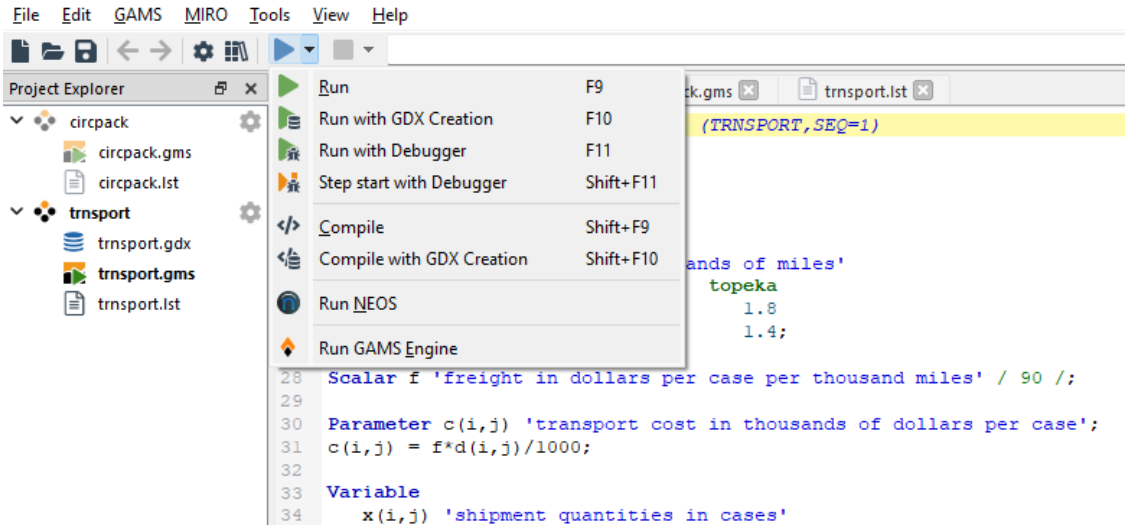
For general messages there is the **System Log** stacked together with all **Process Logs**. It keeps track of **Studio** related messages not originated from a specific GAMS run.

6.14.3.3 Quick Access Toolbar and GAMS Parameter Editor

The toolbar contains two parts: a quick access section and GAMS Parameter editor to customize how GAMS is executed the model (see The GAMS Call and Command Line Parameters).

The quick access section contains icons for performing common `File` actions like *New*, *Open*, and *Save* , as well as accessing *Settings* dialog, *Model Library Explorer* dialog, *Project Explorer* view, *Process* Log, and *Help* view.

The GAMS Parameter Editor provides a way to control and customize the execution of a GAMS model. The editor displays the parameters of the project of the file that is currently opened in Central Widgets (see also Project Explorer for project and its runnable files). The parameters can be typed into a combobox and the execution of a GAMS model can be carried out using the following pre-customized execution commands:



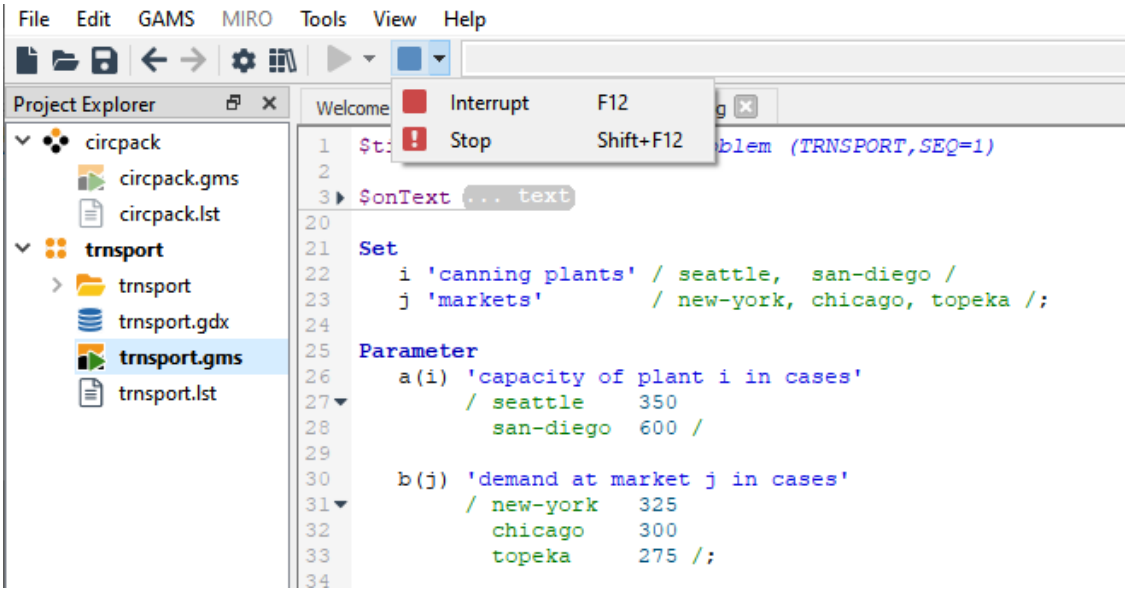
- **Run**: Choose `Run` or press `F9` to compile and execute GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the default parameter action=CE (Compile and Execution).
- **Run with GDX Creation**: Choose `Run with GDX Creation` or press `F10` to compile and execute GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two parameters action=CE and gdx=default.
- **Run with Debugger**: Choose `Run with Debugger` or press `F11` (macOS `Meta - F11`) to compile and execute GAMS statements in the main runnable file with the debugger enabled.
- **Step start with Debugger**: Choose `Step start with Debugger` or press `Shift - F11` to compile and execute GAMS statements in the main runnable file with the debugger enabled and pause the process at the first possible line.
- **Compile**: Choose `Compile` or press `Shift - F9` to compile GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the parameter action=C (CompileOnly).

- **Compile with GDX Creation**: Choose `Compile with GDX Creation` or press `Shift - F10` to compile GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two parameters action=C and gdx=default.
- **Run NEOS**: Choose `Run NEOS` to compile GAMS statements in the main runnable file locally and pass the execution to the NEOS server.
- **Run GAMS Engine**: Choose `Run GAMS Engine` to compile GAMS statements in the main runnable file locally and pass the execution to the GAMS Engine server.

The pre-customized execution command will operate on the main file (marked with a little green arrow over the regular icon) of the active project (see how to manage the main file in section Project Explorer). In case GAMS parameters have been set they will be appended to the pre-customized commands. Just like the GAMS Terminal, when there are identical parameters with different values the last one "wins" and overwrites the previous ones. Thus it is possible for a user to change and override GAMS Studio default parameters, which can possibly lead to problems if done incorrectly. In this case Studio prints out a warning message, informing users about potential problems. To debug what Studio does the full GAMS call parameters will be printed to the System Log. After execution, the parameters will be added into the project history. All files in a project share one parameter history. The previous GAMS parameters can be recalled from the project history via the drop-down menu of the combobox. Switching the file opened in Central Widgets will activate the different project history only when the project of the newly opened file is different from the project of the file before the switch.

The parameters `curDir` and `workDir` behave slightly differently in Studio compared to the terminal. When using one of these parameters on the command line GAMS expects the gms file to be in the given folder. In Studio the path to the input file is always given as an absolute one. Therefore, there is no need to use the `inputDir` parameter to make the gms file accessible to GAMS if it is not in the specified working directory.

The GAMS Parameter Editor provides a way to either interrupt or stop the currently running job when an execution of a GAMS model is in progress (indicating with animated icon over the project folder icon in Project Explorer) :



- **Interrupt**: Click the `Interrupt` button or press `F12` to send an interrupt request to the running job in order to perform a graceful stop and collect an incumbent result back from the execution if the solver supports this feature. The command is enabled when there is a job that is currently running in the project and disabled when there is no currently running job in the project.

- **Stop**: Click the `Stop` button or press `Shift - F12` to send a request to stop the running job immediately. The command is enabled when there is a job that is currently running in the project and disabled when there is no currently running job in the project.

The Extended GAMS Parameter Editor allows to configure the GAMS parameters. The extended parameter editor is shown when the Show button next the parameter combobox is clicked or with the shortcut `Ctrl - Alt - 3`. The editor can be hidden when the button is clicked again. When shown, the GAMS parameters from the parameter combobox will appear as a list of entries in the left pane of the extended parameter editor, each entry contains the `Key` and `Value`.

Note that the GAMS parameter combobox will be disabled when the extended parameter editor is shown and all editing has to be done in the extended parameter editor.

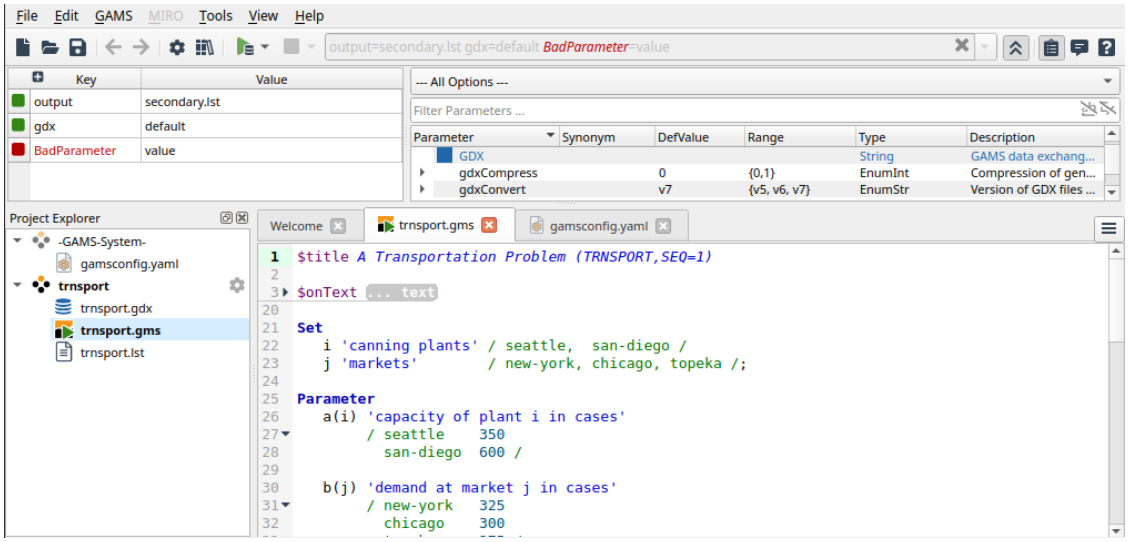


Figure 6.30 Extended GAMS Parameter Editor is shown when the button next to parameter combobox is clicked

The right pane of the extended editor displays the list of all valid parameter definitions, each contains `Parameter Name`, `Synonym`, `Default Value`, `Type`, and `Description`. The parameter definition entry with enumeration type (`EnumStr` or `EnumInt`) can be expanded to show all enumerated values of the parameter by clicking the bullet in front of the parameter entry, clicking the bullet again will hide all enumerated values of the parameter. Above the list of all valid parameter definitions is a filter box (with placeholder text `Filter Parameter...`) to allow to filter all parameter definitions. As a filter term has been typed into the search box the results will be displayed in the list below. More about the filter can be found in the Filter Section.

The parameter editor displays potential parameter errors in red color both in the combobox and in the left pane of the extended editor. When hovering a mouse over the error key or value, a tooltip with more detailed explanation of the error appears.

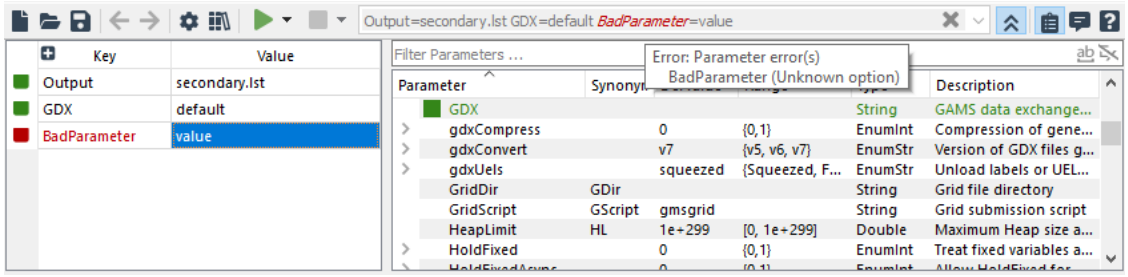

Figure 6.31 Parameter key turns red with pop-up tooltip when there is a potential error

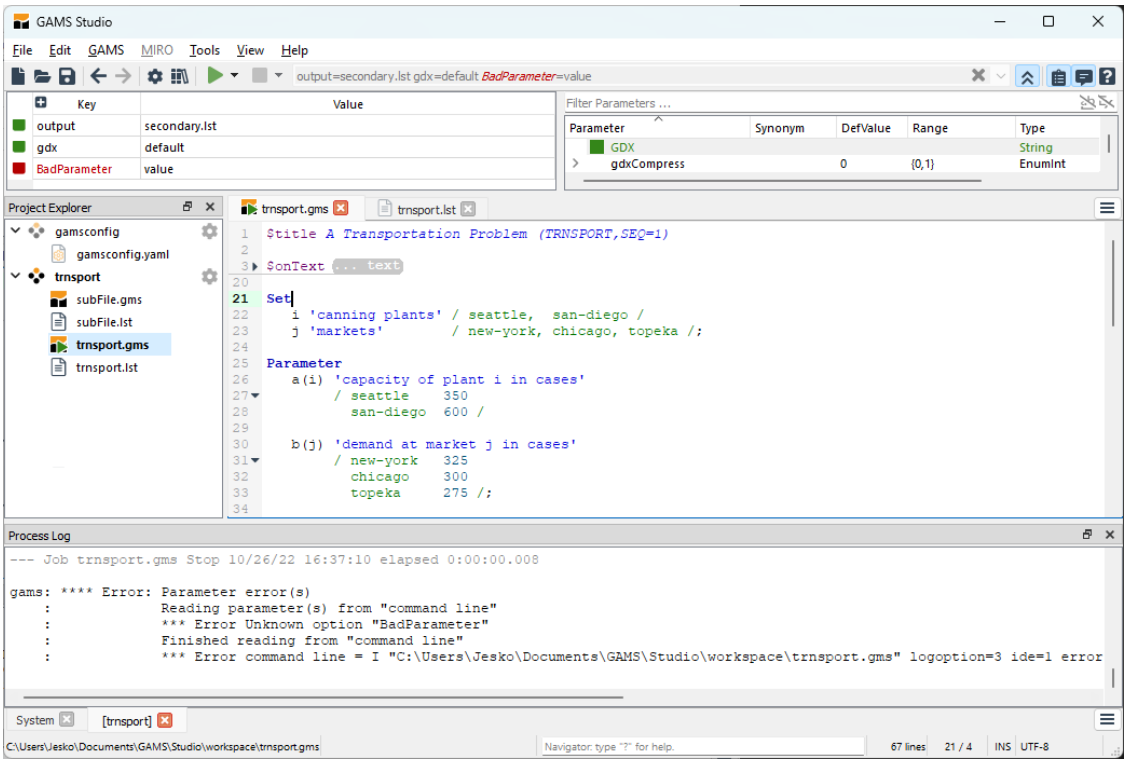

Figure 6.32 Process Log reports parameter errors when running the model with an unknown option parameter

When there are several entries of the same parameter, all other entries except the last entry will be ignored when gams executes the model. In such case, the combobox of parameter editor displays a warning in yellow and the icon in front of the parameter in the extended editor turns half-yellow in combination of another color, red or green, depending of whether or not there is a potential error.

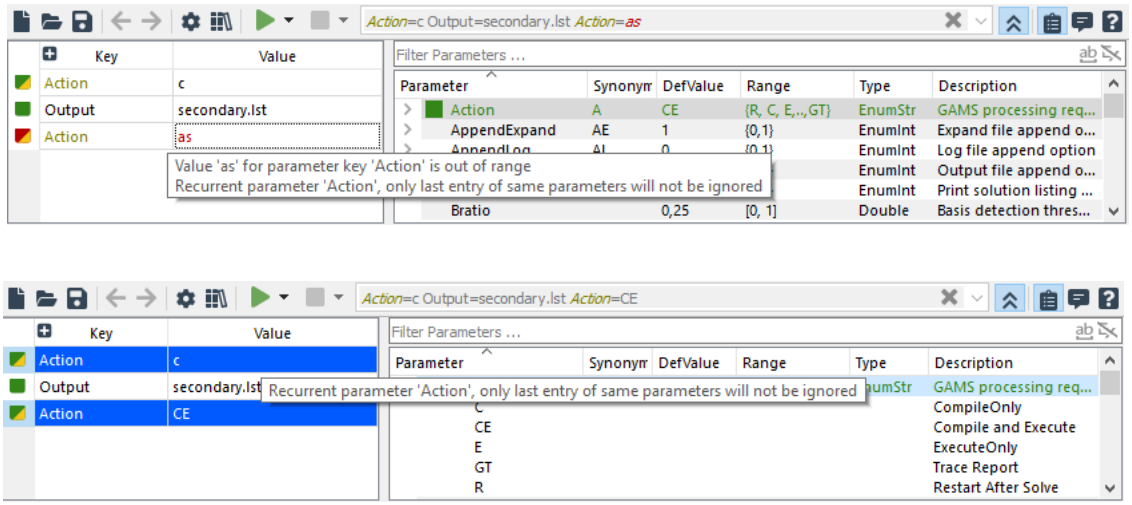

Figure 6.33 Parameter key turns yellow and the pop-up tooltip indicating a warning

See edit parameter key and value on how to edit parameter key and value that contains an error or a warning. See show all parameters of the same definition on how to locate all entries of the same parameter.

The followings describes all editing actions that can be performed via the extended parameter editor:

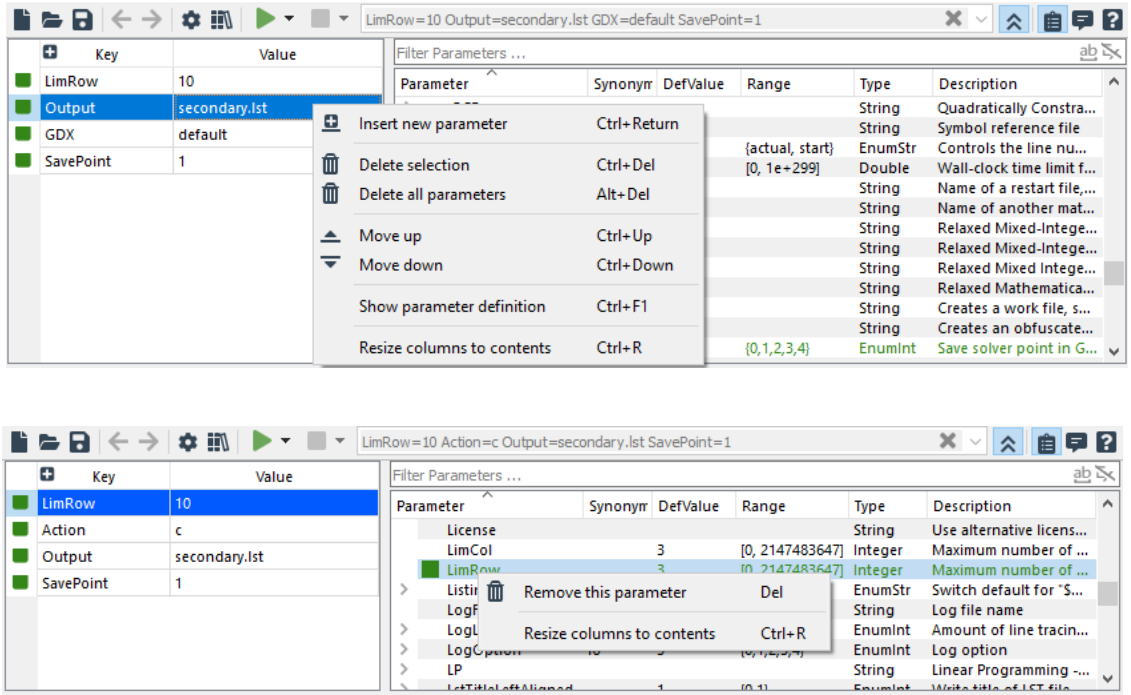

Figure 6.34 A number of actions that can be performed via the context menus of Extended Parameter Editor

- **Edit parameter key and value**: double click on key cell to edit `Key` and on value cell to edit `Value` of the entry. A drop-down list will suggest possible keys and values when possible. Press `Enter` to confirm the edit and press `Esc` to cancel the edit.

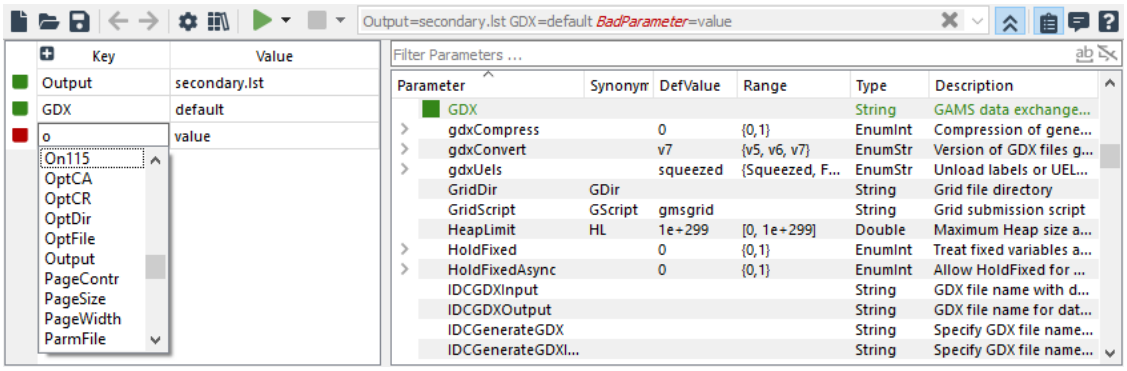

Figure 6.35 GAMS Parameter editor shows a drop-down list of all possible parameters started with 'o'

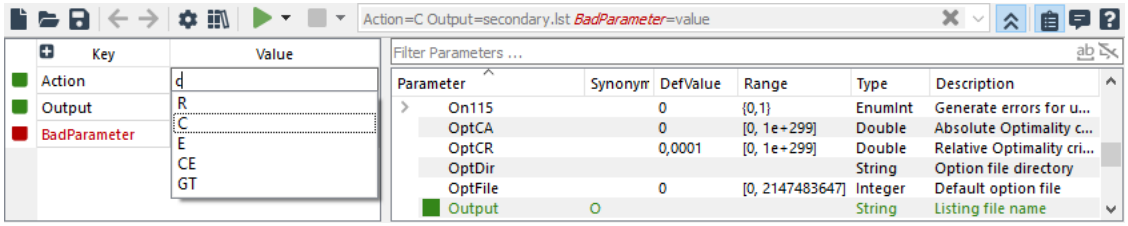

Figure 6.36 GAMS Parameter editor shows a drop-down list of all enumerated values of parameter 'action'

- **Add new parameter**: there are several ways to add a new parameter via extended parameter editor.
  - right click on the left pane of the parameter editor and choose `add new parameter` from the pop-up context menu
  - right click on the selected parameter entry of the parameter table and choose `add new parameter` from the pop-up context menu
  - click on the add new parameter button next to `Key` table header in the left pane

  A new entry will be added at the end of parameter entry table with dummy parameter key `[KEY]` and dummy parameter value `[VALUE]`. See edit parameter key and value on how to edit parameter key and Value.

  It is also possible to add a new parameter from the right pane of the parameter editor by double clicking at the definition entry in the right pane. The selected definition entry will be added as a new parameter entry at the end of table in the left pane. In case of double clicking an enumerated value entry of a parameter definition the definition entry will be added as a new parameter with the selected enumerated value. Otherwise the default value of the entry will be added.

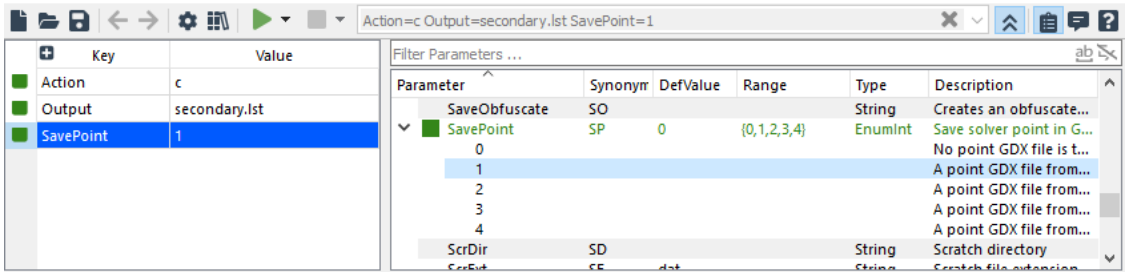

Figure 6.37 Parameter with enumerated value added by double clicking at the selected entry in the right pane

- **Insert new parameter**: right click on the selected entry and choose `insert new parameter`. A new entry will be inserted before the selected entry with dummy parameter key `[KEY]` and dummy parameter value `[VALUE]`. See edit parameter key and value on how to edit parameter key and value.

- **Move up**: right click on the selected entry and choose `Move Up`. The selected entry will be moved one position up the table. This action will change the order of parameters.

- **Move down**: right click on the selected entry and choose `Move Down`. The selected entry will be moved one position down the table. This action will change the order of parameters.

- **Delete selection**: right click on the selected entry and choose `Delete Selection`. The selected entry will be deleted from the table.

- **Delete all parameters**: right click on the left pane of the extended editor and choose `Delete all Parameters`. All entries will be deleted from the table.

- **Show parameter definition**: right click on the left pane of the extended editor and choose `Show parameter definition`. The parameter definition entry on the right pane will be highlighted.

- **Show all parameters of the same definition**: right click on the left pane of the extended editor and choose `Show all parameters of the same definition`. All parameter entries on the left pane will be highlighted.

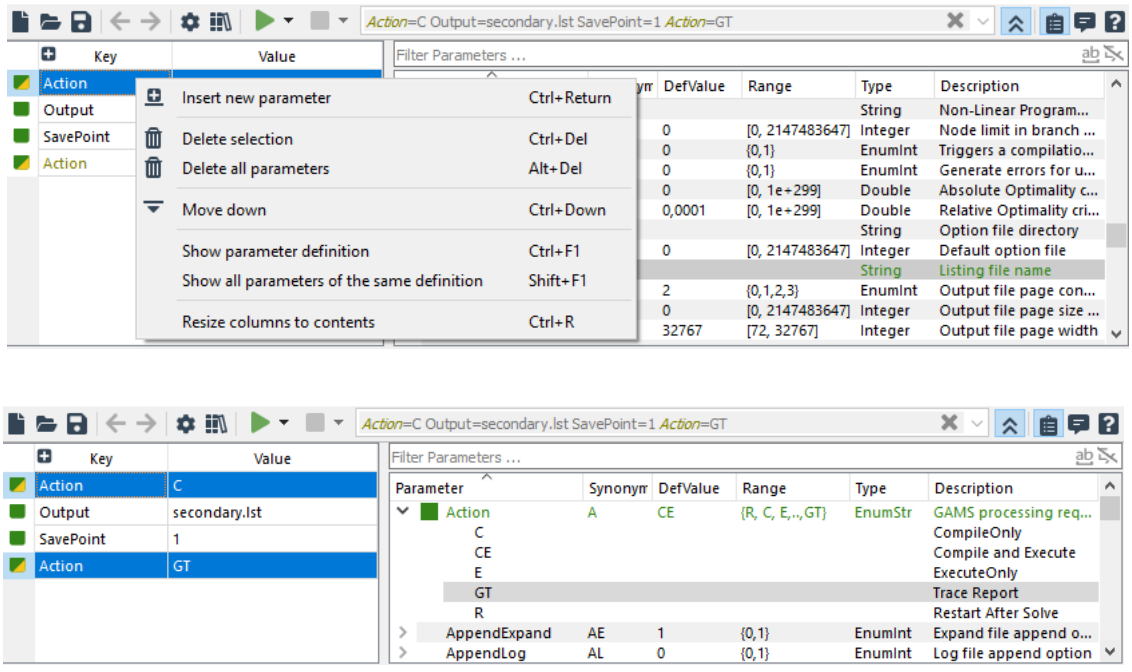

Figure 6.38 All entries of the same parameter are highlighted

- **Resize columns to contents**: right click on the left or right pane of the extended editor and choose `Resize columns to contents`. All columns will be resized according to their contents.
- **Add this parameter**: right click on the right pane of the extended editor and choose `Add this parameter`. The parameter with default value (if defined) of the selected definition will be added as the last entry on the left pane of the extended parameter editor. This action in the context menu is enabled only when there is no entry of this parameter on the left pane. Note that a double click on the definition will also perform add this parameter action. Performing the action on the parameter definition that has already been added will pop-up a dialog indicating that the parameter exists on the left pane and prompting for one of the followings:
  - replace existing entry If there is only one entry or replace the first entry and delete other entries if there is more than one entry, or
  - add new entry of the same definition, or
  - show details of all entries of the same parameter, or
  - abort the action

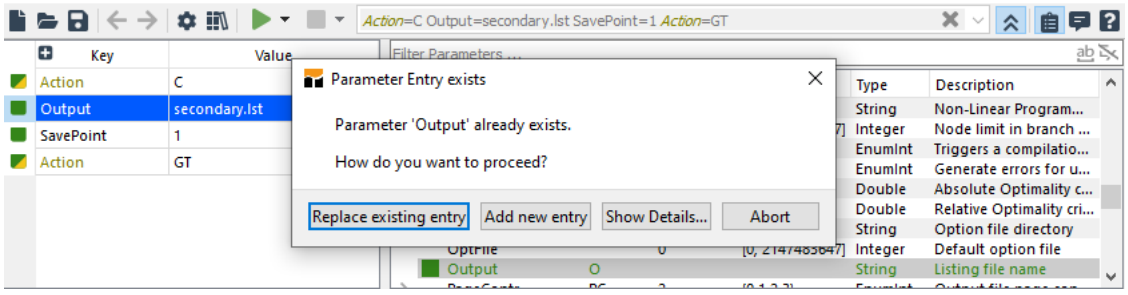

Figure 6.39 A pop-up dialog when adding the definition parameter that has already been added

- **Remove this parameter**: right click on the right pane of the extended editor and choose `Remove this parameter`. The parameter of the selected definition will be deleted from the left pane of

the extended parameter editor. This action in the context menu is enabled only when there is an entry of this parameter definition on the left pane. In case there are multiple entries of the same parameter, all entries on the left pane will be deleted.

Press F1 on a parameter entry in the extended parameter editor will activate the The GAMS Call and Command Line Par help page containing the detailed description of the GAMS parameter.

Summary of Actions and Shortcuts

Actions and their shortcuts that can be performed via Toolbar and GAMS parameter editor are:

Action	Shortcut	macOS	Description
New	**Ctrl - N**	**Command - N**	Open new file dialog
Open	**Ctrl - O**	**Command - O**	Open file open dialog
Save	**Ctrl - S**	**Command - S**	Save the current file. If the file does not exist on disk open the save file dialog
Settings	**F7**	**Command - ,**	Open the Settings dialog
Model Library	**F6**	**F6**	Open the Model Library Explorer dialog
Run	**F9**	**F9**	Run main file of current project with GAMS
Run with GDX Creation	**F10**	**F10**	Run main file of current project with GAMS and create a GDX file
Compile	**Shift - F9**	**Shift - F9**	Compile main file of current project with GAMS without execution
Compile with GDX Creation	**Shift - F10**	**Shift - F10**	Compile main file of current project with GAMS and create a GDX file without execution
Interrupt	**F12**	**F12**	(Gracefully) Interrupt currently running GAMS job
Stop	**Shift - F12**	**Shift - F12**	Stop currently running GAMS job
Show extended parameter	**Shift - Ctrl - 3**	**Control - Option - 3**	Open the extended GAMS parameter editor
Project Explorer	**Ctrl - 1**	**Command - 1**	Open Project Explorer
Process Log	**Ctrl - 5**	**Command - 5**	Open Process Log
Help	**F1**	**F1**	Open the GAMS Help.

Actions and their shortcuts that can be performed via the left pane of the extended GAMS parameter editor are:

Action	Shortcut	macOS	Description
Insert new parameter	**Ctrl - Return**	**Ctrl - Return**	Insert a new parameter
Delete selection	**Ctrl - Delete**		Delete the selected parameter
Delete all parameters	**Alt - Delete**		Delete all parameters

Action	Shortcut	macOS	Description
Move up	**Ctrl - Up**	**Command - Up**	Move the selected parameter up for 1 row
Move down	**Ctrl - Down**	**Command - Down**	Move the selected parameter down for 1 row
Select all	**Ctrl - A**	**Command - A**	Select all parameters
Show parameter definition	**Ctrl - F1**		Show definition of this selected parameter in the right pane
Show all parameters of the same definition	**Shift - F1**		Show all options of the same definition defined in the right pane
Resize columns to contents	**Ctrl - R**	**Command - R**	Resize the columns in the left pane to contents

Actions and their shortcuts that can be performed via the right pane of the extended GAMS parameter editor are:

Action	Shortcut	macOS	Description
Parameter Filter	**Ctrl - F**	**Command - F**	Jump to the focus to the Parameter Filter input field
Add this parameter	**Return**	**Return**	Add option in the left pane from the selected definition
Remove this parameter	**Delete**		Remove option defined by this definition from the left pane
Resize columns to contents	**Ctrl - R**	**Command - R**	Resize the columns in the right pane to contents

6.14.3.4 Integrated Help

The Help View is designed to integrate the navigation of the GAMS documentation into GAMS Studio. Press `F1` or choose `Help` > `GAMS Documentation` or check `View` > `Help` to start the Help View and browse the documentation. The start page of the Help View is the main document page available in the GAMS distribution that has been used to run GAMS Studio. See Home on how to always navigate back to the start page of the document. Alternatively, choose `Help` > `Studio Documentation` to directly jump the to start of the GAMS Studio documenation. Click Close button or uncheck `View` > `Help` to dismiss the Help View. GAMS Studio will remember the last viewed page along with its browsing history until GAMS Studio is restarted.

The Help View starts in docking state for the first time and can be docked around the editor in the central widgets area by either dragging the view to the desired location. Studio will remember last state of the Help View before it was closed.

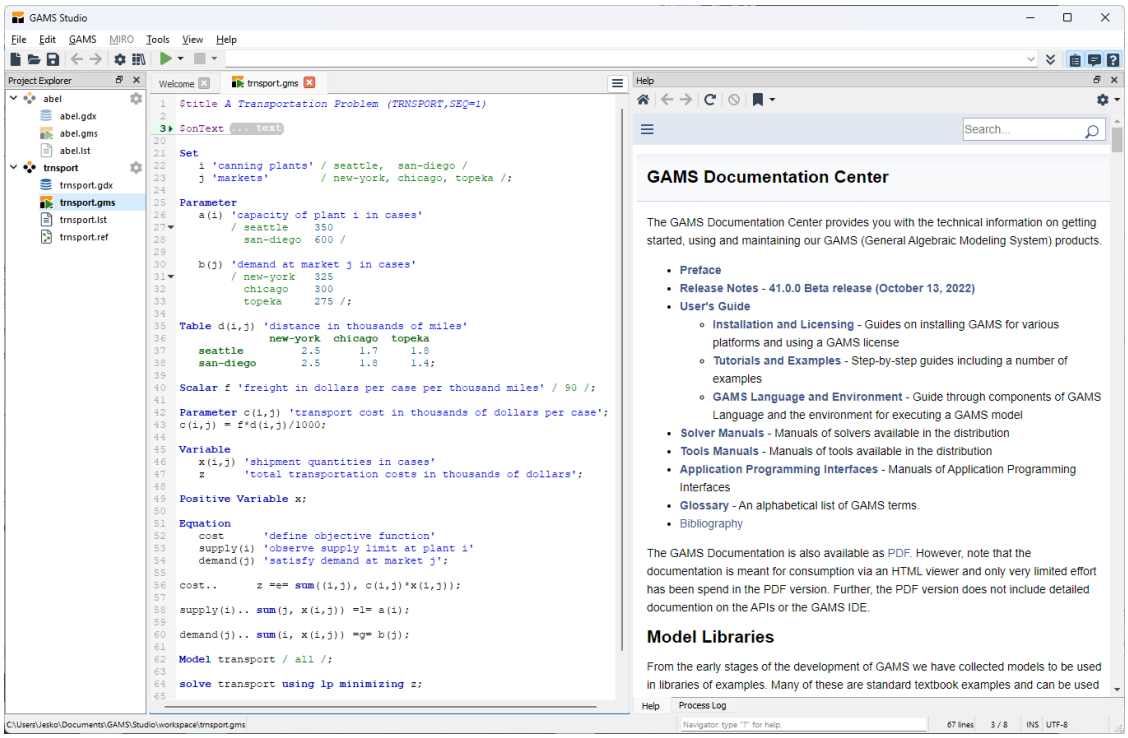

Figure 6.40 Help View when docked to the right of Code Editor

The Help View can also be floated by double clicking the title part of the Help View. Dragging or double clicking the title of the Help View again will dock the Help View.

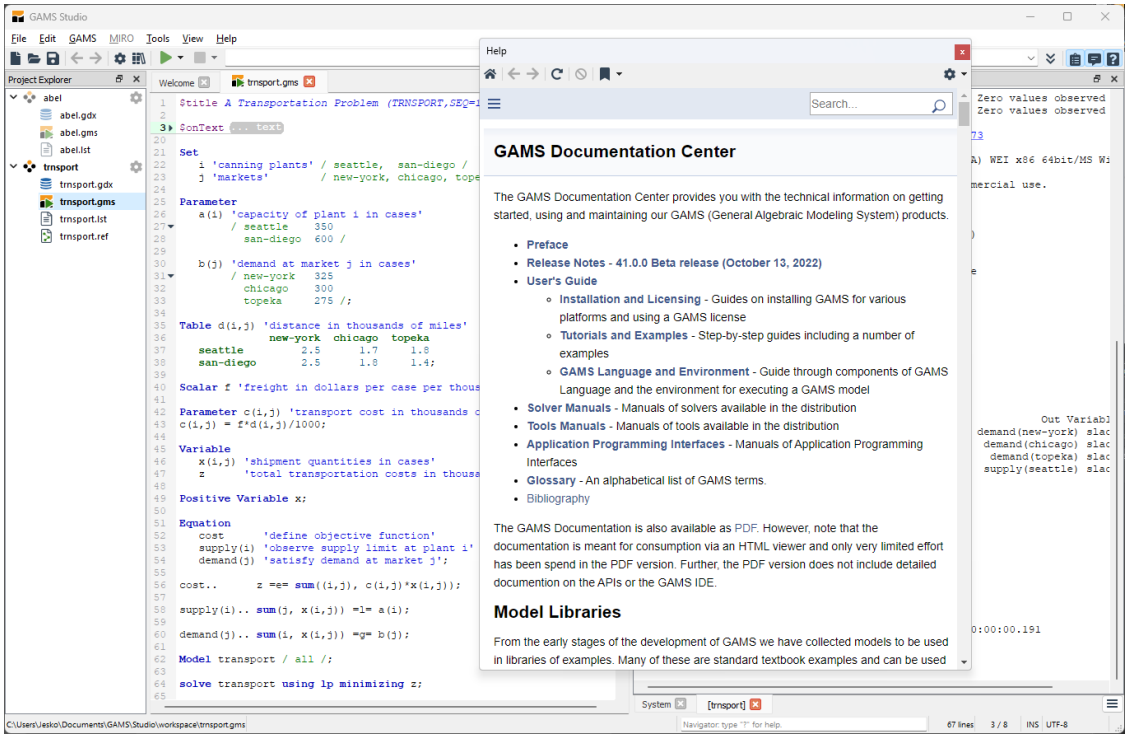

Figure 6.41 Help View when floated

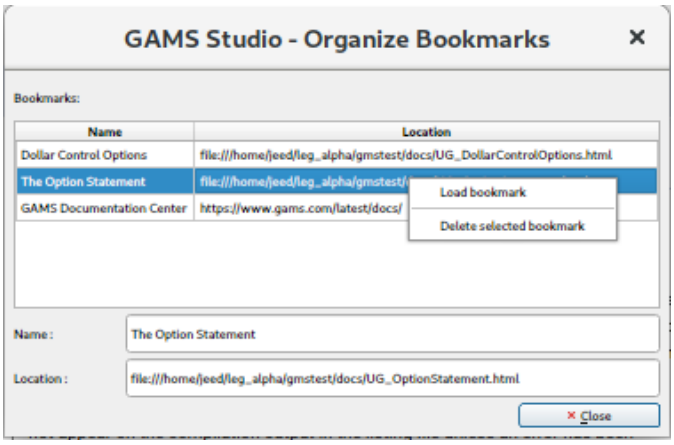
Note that the Help View does not offer the full browsing features of a web browser. Though the help view

offers a Open this page in Default Web Browser button to use the full features of a web browser.

An overview of Help features:

- **Home:** Start the start help page `[GAMSDir]/docs/index.html`
- **Back:** Back to previous page
- **Forward:** Go to next page
- **Reload:** Reload the content of this page
- **Stop:** Stop loading the content of this page
- **Bookmarks:**
  - **Bookmark this page**: Store the title of the page as the name of bookmark together with its location. The entry of the bookmark will appear below the Organize Bookmarks section. Click on an entry to jump to the page that has been bookmarked.

  - **Organize Bookmarks**: Open the bookmark dialog to edit or delete a bookmark entry. Right click on the selected entry in the bookmark table, then either load the selected bookmark in the Help View, or delete the selected bookmark. The selected bookmark Name and Location can be edited from the lower part of the bookmark dialog and press `Enter`. Press Esc to cancel the edit. Click close button to dismiss the bookmark dialog.



- **Zoom In**: Zoom in the page to increase the font size. Press `Ctrl - +`, or `Ctrl - Mousewheel Up` or choose `View > Zoom In` menu to zoom in the page.

- **Zoom Out**: Zoom out the page to reduce the font size. Press `Ctrl - -`, or `Ctrl - Mousewheel Down` or choose `View > Zoom Out` menu to zoom out the page.

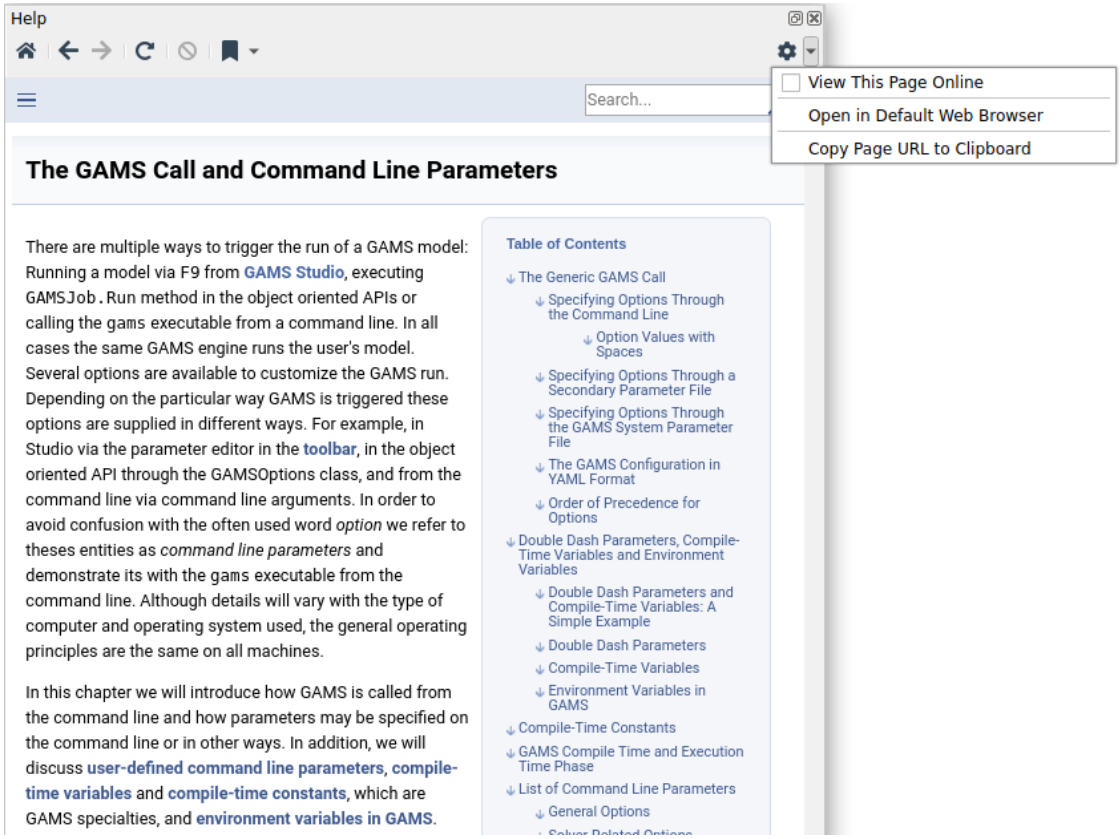
- **Reset Zoom**: Reset the font size of the page to its original size. Press `Ctrl - 0` or choose `View > Reset Zoom` menu to reset zoom in the page.

- **Help Option** :

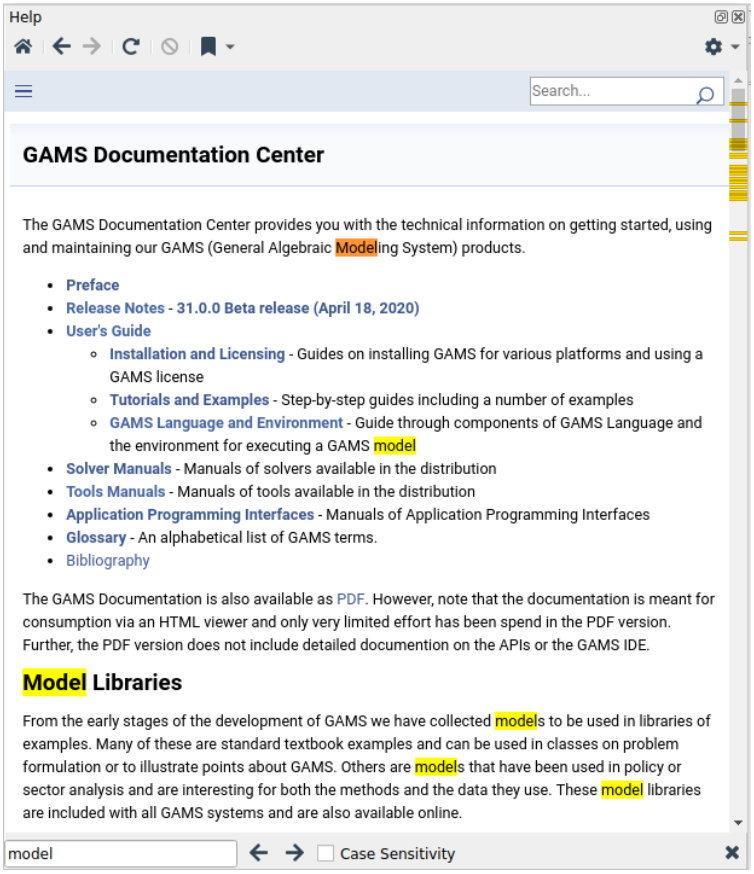
  - **View This Page Online** : Browse the same documentation on GAMS website. This, for example, allows to use more sophisticated search functionalities across all GAMS documentation of version 46.4 or to browse different version of documentation, or to browse the GAMS website from the Help View.

  - **Open in Default Web Browser** : Browse the same document in default web browser. As the help view does not offer the full features of a web browser, this allows to browse the documentation using the full web browser features in default web browser.

  - **Copy page URL to Clipboard** : Copy of the current page's URL to the clipboard. This, for example, help to see the URL of the currently viewed page of the document.



- **Find in page...** : Press `Ctrl - F` or choose `Edit > Search` menu to activate a search at the bottom area of the Help View. Type in a word to be found in the page. The word found in the page will be highlighted as it has been typed in and the number of found occurrences will be highlighted in the scrollbar of the Help View. Click `previous button` to find the previous occurrence, and click `next button` or press `Enter` to find the next occurrence. Check `Case Sensitivity box` to find a word case sensitively. Highlighting the word stays as the document is navigated from page to page until the keyword is clear or the search is dismissed or the Help View is closed or invisible. Click the close button or press Esc to dismiss the search.



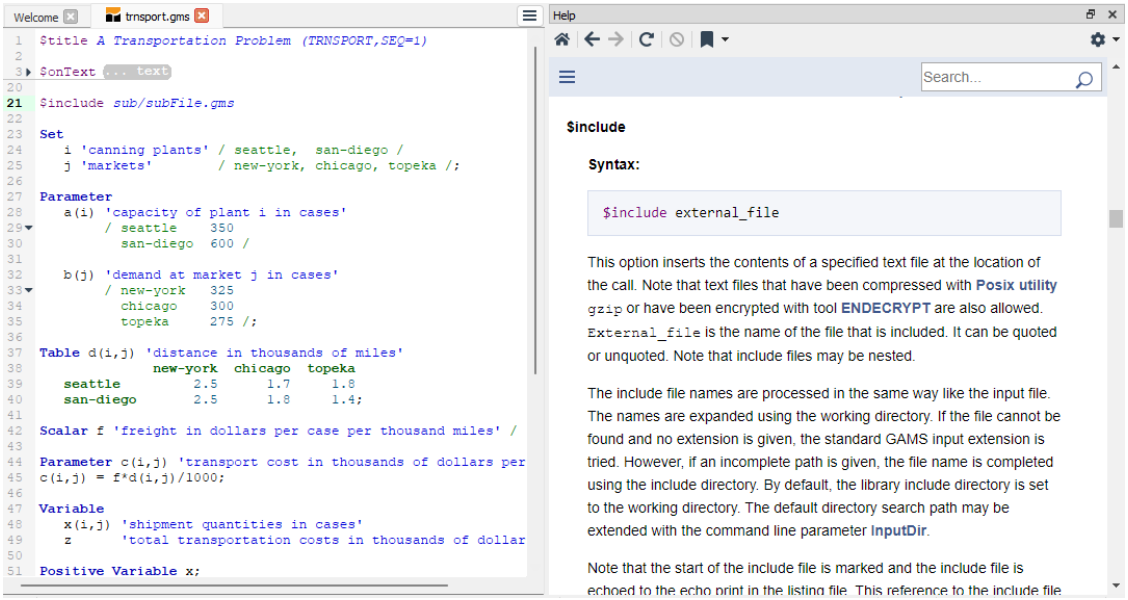
Help on Specific widgets

It is possible to jump directly from directly from different widgets (Welcome Page, Code Editor, Listing Viewer, GDX Viewer, Reference File Viewer, and Solver Option Editor) to the related part of the document.

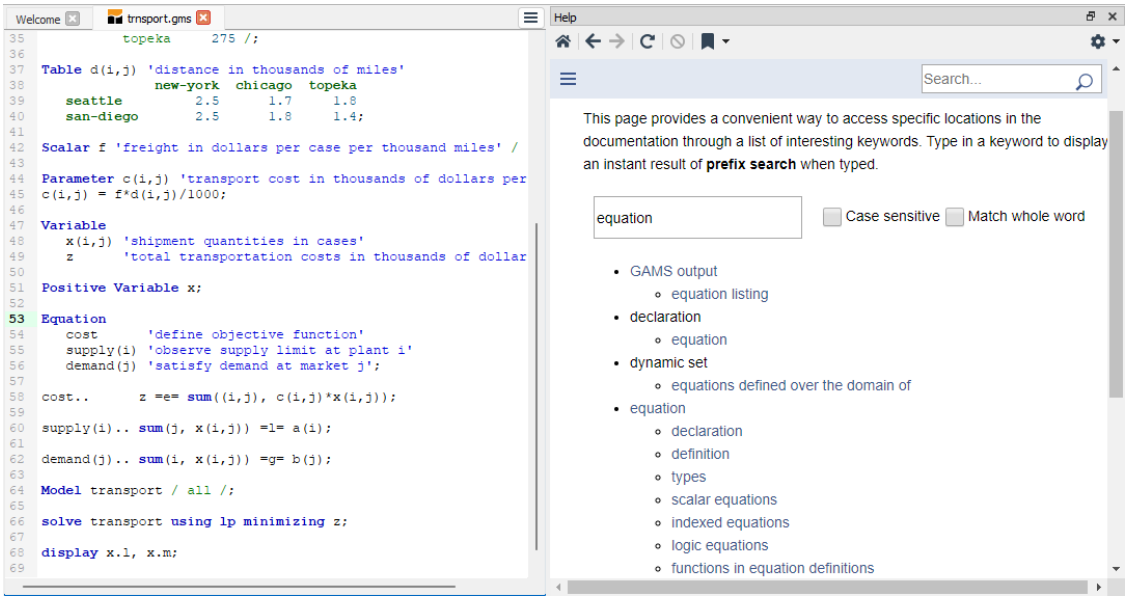
From Welcome Page, Listing Viewer, GDX Viewer, and Reference File Viewer, press `F1` will activate the GAMS Studio page and jump to the section corresponding to the widget. From GAMS Parameter Editor, press **F1** on a parameter entry in the extended parameter editor will activate the The GAMS Call and Command Line Parameters help page containing the detailed description of the GAMS parameter. From Solver Option Editor, press **F1** on an option entry in the editor will activate the related solver page containing the detailed description of the option.

From Code Editor, it is possible to jump to the document page that describes Dollar Control Options or to the index page that lists entries related to Data Types and Definitions and Language Items in Code Editor, as well as from the parameter editor to the GAMS parameter described in The GAMS Call and Command Line Parameters :

- Press `F1` on a Dollar Control Option within the editor will activate the page Dollar Control Options in the Help View and jump to the corresponding dollar control option described in Dollar Control Options chapter.



- Press `F1` on a keyword in Data Types and Definitions or in Language Items within the editor to activate the Index Page in the Help View that lists the index entries related to the keyword.



- Press `F1` on a parameter entry within the extended parameter editor to activate the help page displaying the detailed description of the GAMS parameters in The GAMS Call and Command Line Parameters.

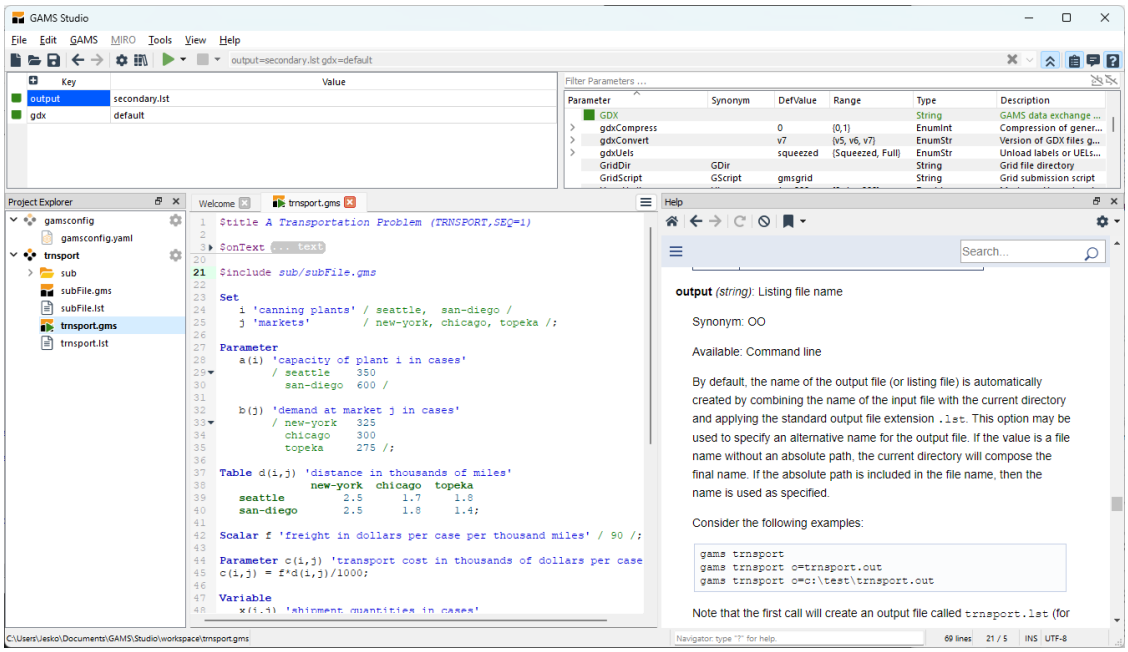


Figure 6.42 Help View when press F1 on parameter entry 'output' in extended parameter editor

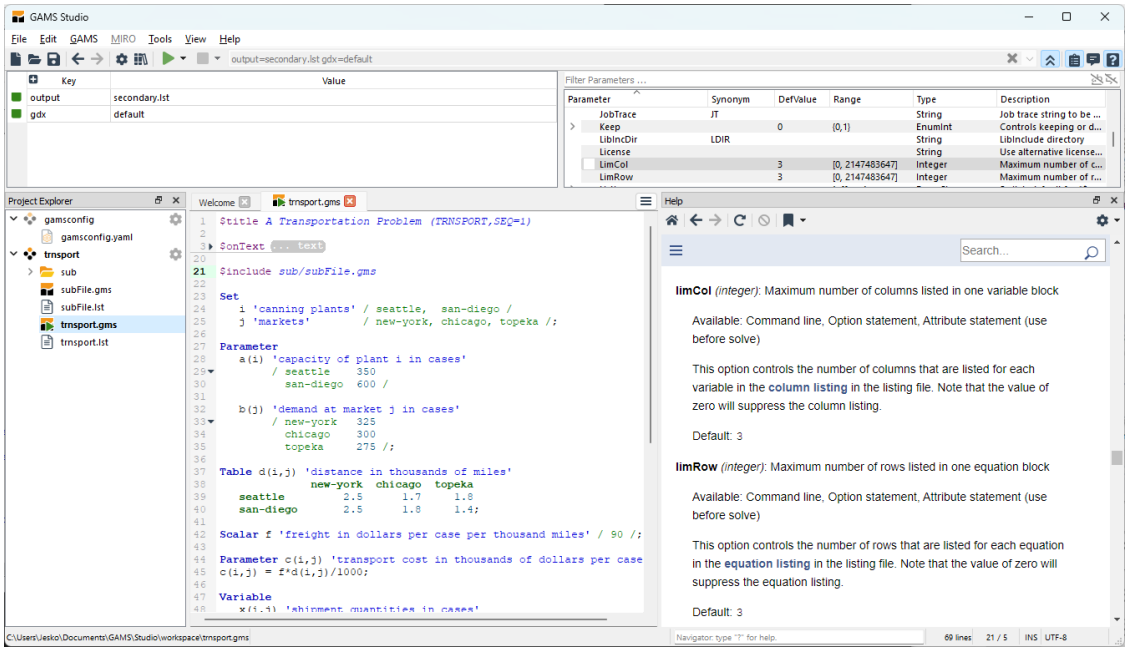

Figure 6.43 Help View when press F1 on parameter definition entry 'LimRow' in extended parameter editor

Summary of Actions and Shortcuts

Action	Shortcut	macOS	Description
Zoom In	**Ctrl- +** or **Ctrl - Wheel Up**	**Command - +** or **Command - Wheel Up**	Zoom in the page to increase the font size
Zoom Out	**Ctrl- -** or **Ctrl - Wheel Down**	**Command - -** or **Command - Wheel Down**	Zoom out the page to reduce the font size

Action	Shortcut	macOS	Description
Reset Zoom	**Ctrl - 0**	**Command - 0**	Reset the font size of the page to its original size
Search	**Ctrl - F**	**Command - F**	Jump to the help search box to search for a keyword in the current page

6.14.4 Debugger

GAMS Studio provides a debugger to detect errors. It is started by selecting `Run with Debugger` or `Step start with Debugger` from the `GAMS` menu or the Quick Access Toolbar. When pausing the process, GAMS Studio marks the line in the source code that will be processed next, and opens a temporary GDX file in the Pin View containing the current data state. It is possible to have more than one active debug sessions.

To pause a debug process you can

- set a **breakpoint**
- use **step**
- use **pause**

Breakpoints can be set to any line in the source code, although not all lines are valid spots where the process can be paused. GAMS can pause on lines that contains an operation. If a breakpoint is set to another kind of line (e.g. empty line, comment, or delcaration) it will be moved to the next possible line, or the last possible line in this file. The original line keeps a mark until the end of the debug session hinting its new line number.

Step can be triggered initially by selecting the menu `GAMS` > `Step start with Debugger` or by using the shortcut **F11** (**Meta - F11** on macOS). During the debug session **step** can be triggered in the debug pane below the editor and also using the shortcut.

Pause can be triggered when a debug session is running and not paused. This is available in the debug pane below the editor.

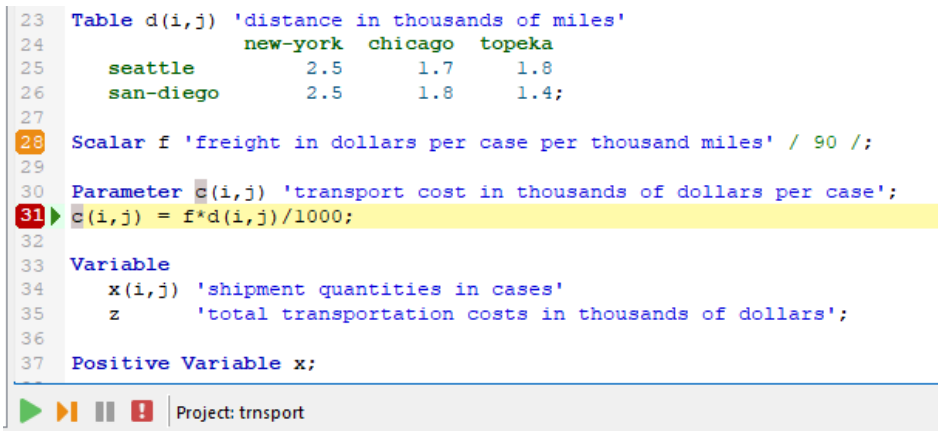

Figure 6.44 Debug pane and breakpoints

During a debug session the **Debug Pane** below the editor allows to control the flow:

- **Continue** - continues until the next breakpoint or the end of the program is reached
- **Step** - continues until the next possible pause line or the end of the program is reached
- **Pause** - pauses the process when the next possible pause line is reached
- **Stop** - stops the execution of this process
- the name of the active project follows right after the buttons

6.14.4.1 Debugger Shortcuts

Action	Shortcut	macOS	Description
Run Debugger	**F11**	**Meta - F11**	Run main file of current project in debug mode
Step Run Debugger	**Shift - F11**	**Shift - F11**	Run main file of current project in debug mode and pause at the first possible line

6.14.5 MIRO

GAMS Studio can be used to develop models for `GAMS MIRO`. Please go to the `GAMS MIRO documentation` to learn more about the features and workflow of the MIRO integration.

6.14.5.1 GAMS MIRO Shortcuts

Action	Shortcut	macOS	Description
Run base mode	**F8**	**F8**	Run main file of current project with MIRO in Base Mode
Run configuration mode	**Shift - F7**	**Shift - F7**	Run MIRO configuration mode

6.14.6 NEOS

GAMS Studio can remotely execute models on the `NEOS server`. The model is compiled locally before the compilation object is send to NEOS. Note that a GDX file can be created but always has the name `out.gdx`. On running a dialog pops up to enable further setup:

- "Email" - The email to submit a job. It can be predefined by setting NEOS_EMAIL in the GAMS User Configuration or by defining the environment variable NEOS_EMAIL.
- "Create a GDX file" - Create a GDX file even if the Command line parameter is not set.
- "Short priority" - The execution may start earlier and provides intermediate log output, but it is limited to an execution time of five minutes.
- "Long priority" - The execution may start later and provides no intermediate log output, but it is not limited in execution time.

The selections of the dialog are stored to the settings. To reveal the Terms of Use after checked `Don't show Terms of Use again` there is a checkbox in `Settings` > `Misc`.

The results of the remotely executed model are placed into a sub-folder named by the base name of the model. The log output of the remote execution has a different background color which can be configured in the settings dialog (Default Text, 3rd color). Links in the remote execution log output are replaced by their local counterpart.

6.14.7 GAMS Engine

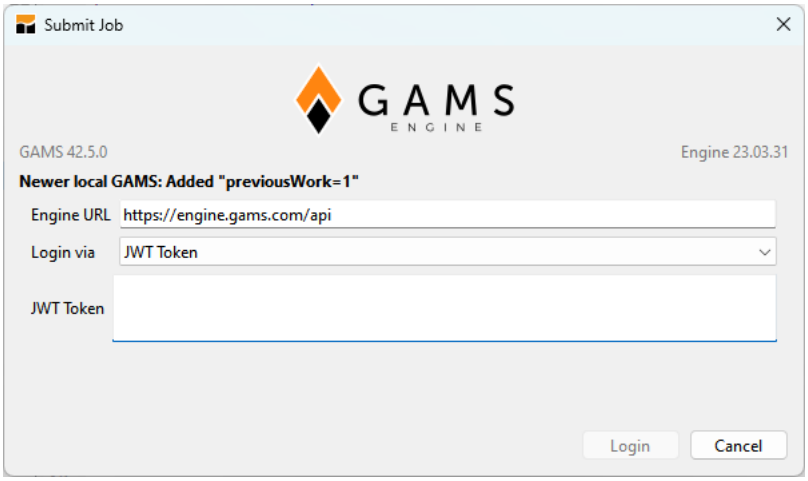
GAMS Studio can remotely execute models on your own `GAMS Engine server`. The model is compiled locally before the compilation object is sent to GAMS Engine. Additional files can be sent to the server by creating a file with the name of the model and the extension ".efi" (for "External FIles"). Each line in this file addresses an additional file. Files defined in the EFI file that should be actualized locally by changes from the GAMS Engine server can be marked by adding a < separated by a space.

Example: if an EFI file named `trnsport.efi` contains these lines:
`inc/trnsport.inc`
`inc/data.txt <`
and the model `trnsport.gms` is executed, both files will be transferred to GAMS Engine. After solving, the file `inc/trnsport.inc` will stay untouched but `inc/data.txt` will be replaced by the version returned from the server.

GAMS Studio provides an EFI editor to select the files. The context menu of a project in the Project Explorer allows to create or open the EFI file matching the current runnable GAMS model. With this editor files can be selected and selected files can be marked to be actualized locally. You can switch an open EFI editor to a text editor by selecting `Reopen as text` after changes have been saved. All operations (check, uncheck, select all, and clear) work on the visible files. In contrast the check state of a directory shows the select state of all files (visible and hidden by filter).

On running a dialog pops up asking the user to log in. If already logged in before and the login is still valid this first page is skipped. The login page offers several methods to authorize:

- *Login page*
  - "Url" - The `URL` to your GAMS Engine server
  - "Login via" - A list of available methods to authorize
    - "User" and "Password" - The username and password to login
    - "JWT Token" - A token can be used to login
    - "SSO" - An authorization provider
    - Additional predefined authorization providers (depending on the GAMS Engine installation)



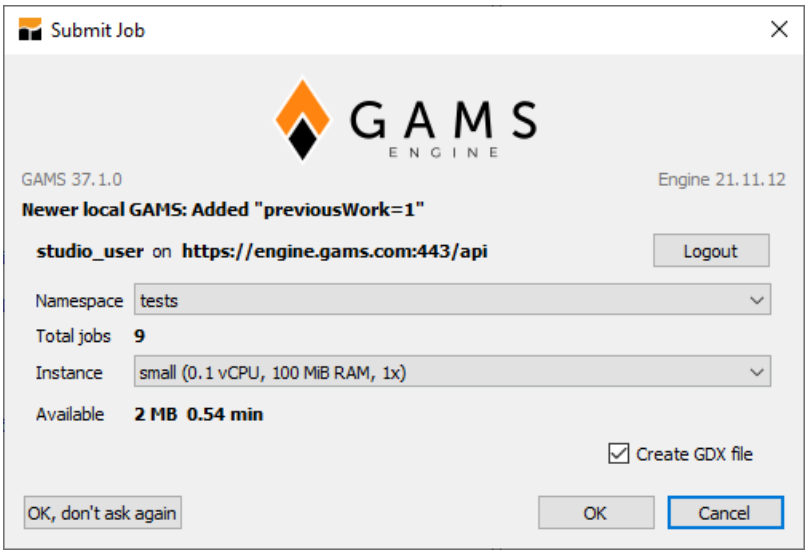
While changing the URL, `Studio` tries directly to access the server and requests version information. On success it gets the GAMS Engine version placed to the right and the version of the GAMS installation on the server to the left. If the local GAMS version is newer the command line parameter "previousWork=1"

will be added automatically if no "previousWork" is already present. The entries of the dialog (excluding the password) are stored to the settings. Further configuration can be done in the settings dialog.

To login via an authorization provider a SSO name can be entered or one of the predefined authorization providers can be selected. After selecting the "Login" button Studio contacts the provider and offers a code and a link to the provider where the code can be entered to verify the identity. For convenience the button "Copy and Visit" copies the code to the clipboard and opens the link in the systems default browser. Here the code can be entered using paste `Ctrl + V`.

Being logged in, the submit page allows to setup the remote job:

- *Submit page*
  - "Namespace" - The `namespace` to be used on the server
  - "Instance" - Allows to specify the user instance for GAMS Engine SaaS
  - "Create a GDX file" - Creates a GDX file even if the command line parameter is not set



To get back to the login page click the "Logout" Button. The job is submitted to the GAMS Engine server on clicking "OK". To always run the same setup, the "OK, don't ask" can be selected. For this Studio session the job is always submitted directly without showing this dialog. To see the dialog again, use `Ctrl-Click` on the Engine icon, or click on "Settings > Remote > Reactivate Dialog".

The selection of an user instance and the information of available space and time quota is only visible on connecting to a GAMS Engine SaaS server.

When a job is submitted, GAMS Studio continously shows the output received from the GAMS Engine server. As this may take some time it is possible to close Studio during the remote execution. In this case a dialog pops up asking weather the remote job should be kept or canceled. If "keep" has been chosen, the job token will be stored. On the next start of GAMS Studio a dialog will allow to resume to the job. On resume all pending messages will be polled from the Engine server and the execution will be followed until in the end the results are fetched, just like Studio hasn't been terminated in between.

The results of the remotely executed model are placed into the working directory:

- The LST and LXI files from the server are renamed to `"<model>-server.lst"` and `"<model>-server.lxi"` to protect the local files.
- All generated files will replace existing files of the same name (like GDX, REF, and LOG files).
- All file entries from the EFI file that end with `" <"` will replace the local existing file.

The log output of the remote execution has a different background color which can be configured in the settings dialog (Default Text, 3rd color). Links in the remote execution log output are replaced by their local counterpart.

6.14.8 Dialogs and Actions

6.14.8.1 GAMS Licensing

The GAMS Licensing dialog is part of the GAMS Studio Help menu. It provides information about the used GAMS as well as available solvers, which lists the solver licenses and their capabilities. Furthermore, the dialog can be used to install a GAMS license. To do so the steps below have to be applied.

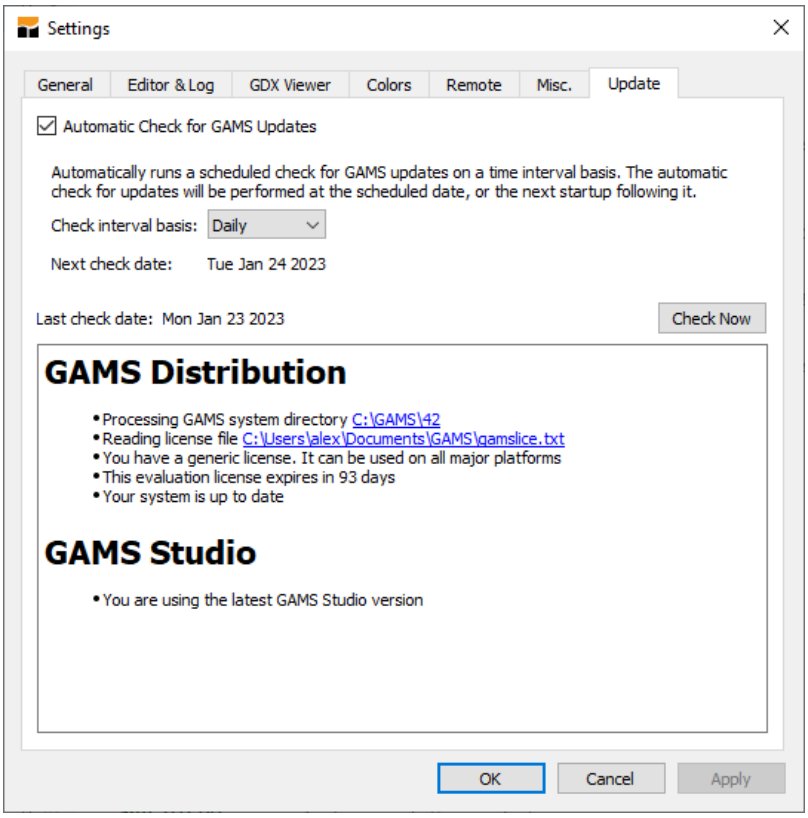
1. Copy the GAMS license to the clipboard
2. Open GAMS Studio and click on Help > GAMS Licensing
3. A messages box shows up if a GAMS license has been found on the clipboard. If 'Yes' is clicked the new license will be installed and presented via the GAMS Licensing dialog; otherwise the old license is shown.

Studio will also detect a license on the clipboard when it starts. If a license is detected the same message box will show up like if the GAMS Licensing dialog is used.

A license file can also be used as an alternative to the clipboard magic. To do so a GAMS license file needs to be selected via the 'Install License File' button. If the selected license is valid it will be installed; otherwise the previous license is kept.

6.14.8.2 Check for Update

Studio will check for a more recent GAMS version during startup. If a newer GAMS version has been found a hint will be displayed. In addition to that it is possible to check for GAMS and GAMS Studio updates at any given time. This can be done via *Help > Check for Update* or by opening *File > Settings > Update*. In both cases the following dialog is displayed. The dialog can be used to enable/disable the startup check and to configure the check interval.



6.14.8.3 Search and Replace

Action	Shortcut	macOS	Description
Open/Focus Search Dialog	**Ctrl - F**	**Command - F**	Opens the search dialog or focusses it if it is already open, if Text is selected it will automatically be entered as a search term
Find next	**F3** or **Enter**	**F3** or **Enter**	Jumps to the next match that fits all search criteria
Find previous	**Shift - F3**	**Shift - F3**	Jumps to the previous match
Find All	**Shift - Enter**	**Shift - Enter**	Starts a search, opens the page of search results and jumps to the first hit
Stop Search & Close Dialog	**Esc**	**Esc**	Closes the search dialog and stops an ongoing search. On second press any highlights of results will be removed

Pressing the `Ctrl - F` opens the Search and Replace window. If text is selected it will be pasted into the search field. Users can search specific files with it and do text replacement operations. Depending on which file type is openend in the editor, the search widget changes to visualize which actions are available. Due to technical limitations **.gdx** files cannot be searched. Also, replacing in read-only file types (e.g. lst or ref) is deactivated. For reasons of performance the search stops when reaching 50000 search results. This is visualized in all places where the number of matches is shown by showing "50000+" as the results number, indicating that there might be more results.

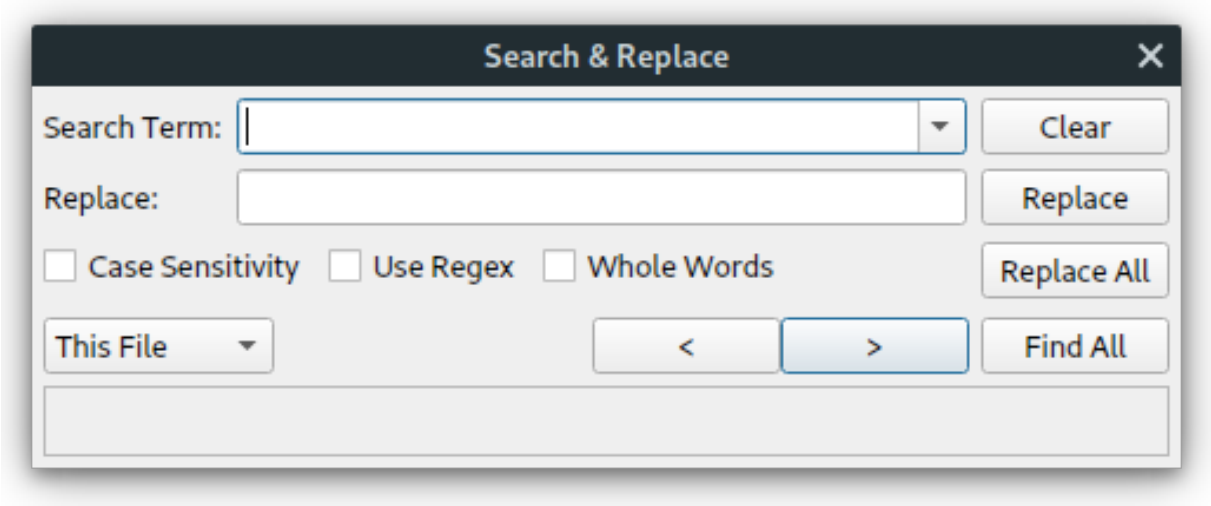


Figure 6.45 Search window in its default configuration

In the first row of the dialog there is the Search field, which takes the search term and saves a list of recent searches. Next to it is the "Clear" button that removes all highlights, results and clears both text fields. A shortcut to clear all results is to press the `Esc` key in the Code Editor. The next row houses items related to the replace functionality. Most of these are deactivated for files that are opened in read-only mode (e.g. **.lst**). First comes the replace input field where users can input the text which replaces the search term. The next button is "Replace": On the very first click it selects the next match, without replacing anything. On the next click it replaces the current selection with the replacement term and jumps to the next match in the same file, selecting it. Users can use this to click through a file, replacing words while keeping an overview over what is actually changed. Replacement actions can be undone by pressing either the undo button or hotkey `Ctrl - Z`.

"Replace All" replaces all matches *in the currently selected scope* after a pop-up is shown asking the user whether the replacement of **n** occurrences of **X** with **Y** is intended. In this pop-up the user can also decide to start a search instead, opening the results page showing all occurrences of the would-be replace action. Then come the options to narrow down a search. "Whole Words" excludes partial hits from matches. For example, when searching for "in" with this option checked only the word "in" is found but no occurrences in "information". "Case Sensitivity" sets if the case of letters in the search term matters. Reminder: The GAMS language is case insensitive, so this option can actually lead to incomplete results, depending on what it is used for. "Use Regex" actives an advanced search term interpretation mode and stands for *Regular Expressions*. When activated, instead of a single search term users can specify a pattern that matches an array of different words. `Click here` for further information about regular expressions.

In the next row is the scope selector. The scope of the search or replace action can be set here with five options available:

- "Selection" searches the text selected in the current file. The search dialog will give feedback if no selection is present. To remove the search selection press either `Esc` or the "Clear Selection" button. Keep in mind that starting a new search moves the search selection to the currently selected text.
- "This File" limits the search to the currently active file and is the default.
- "This Project" searches all files that belong to the same project as the currently opened file. These are all children of the same project in the Project Explorer.
- "Open Tabs" searches all files currently opened in Studio (except GDX files).
- "All Files" searches all files that appear in the Project Explorer and are searchable.
- "Folder" searches all files in a specified folder that can be located anywhere on disk and does not need to be opened in Studio beforehand. When opening a result the file will be added to the Project Explorer.

Next to it are the find previous occurrence and find next occurrence buttons, labeled "<" and ">" respectively. These will find and highlight the next word matching the search criteria either before or after the current text cursor position. Next to it there is the "Find All" button which starts a search in the scope selected by the user. In the output pane of studio a table containing all matches will open. Items can be double clicked to perform a jump to the result and the up and down arrow keys can be used to select quickly select and jump to results. Information about the file, the location of the match, plus some context information are also shown.

Depending on which scope is selected, additional elements of the search dialog will be shown:

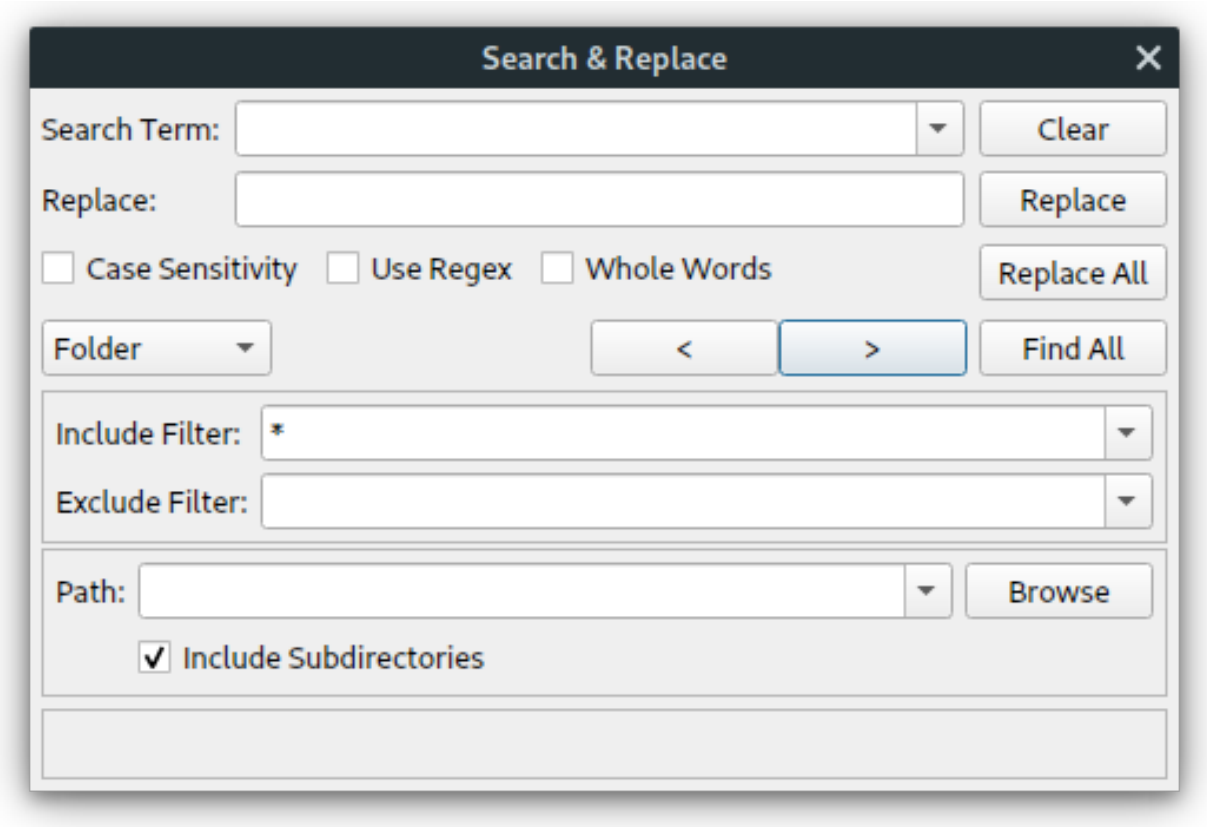

Figure 6.46 Search window fully expanded

The first section is the file filter section which is available for all modes except "Selection" and "This File". It gives the user the possibility to limit the search to certain files (Include Filter) but exclude others (Exclude Filter). Filenames can be specified by using a wildcard syntax. See the tooltips for some simple examples. The drop-down menus come with a few default options for GAMS specific file types but can also be used to enter own patterns. Comma-seperated lists of patterns are also supported. The second section is only available when "Folder" scope is selected and lets users set the path to search. It is a drop-down style textfield, so like the others it keeps a history of recent entries. Next to it is a browse button that opens the operating systems default folder picking dialog to easily find a path. Tooltips are available for most items in the search window and contain further information like keyboard shortcuts.

Workflow Tips

- Edit a file, hit `Ctrl - F` to open the search widget. The search field is focused automatically so you can start typing your search term. Pressing the `Enter` key is a shortcut for Find Next. Press `Enter` again or `F3` to step through all matches. Press `Shift - F3` to step backwards. Make changes to you document, press `Ctrl - F` again to re-focus the search widget without having to pick up the mouse.
- Enter a search term, and then `Shift - Enter` to trigger "Find All". This will open a list of results.
- The `Esc` key will close the search widget. Pressing `Esc` again will clear all highlighted search results.
- Use project or file prefixes when working with projects with many files. Use search filters to only search relevant files.
- Regular Expressions are a powerful tool and support - among other things - capture groups. This means that you can save a part of your match using parenthesis and reference the contained sequence in your replacement string. For example when some code references files with the naming

scheme of FILENAME_DD_MM_YYYY you could find all references using a regular expression like `(\w+)_(\d\d)_(\d\d)_(\d\d\d\d)`. To convert them into a more international and sorting friendly format you could use the following replacement string: `$4-$3-$2_$1` to change these to YYYY-MM-DD_FILENAME. Each pair of parenthesis created a so-called capture group. They are numbered counting from left to right starting with 1.

– It is also possible the reference a capture group in the search term itself. This is called a backreference. Creating backreferences works similarly, expcept that `\NUMBER` is used instead of `$NUMBER`. For example: `(\w+)\s*'\1'` would find symbols that have just their own name as descriptive text.

6.14.8.4 Model Library Explorer

The Model Library Explorer is used to search the different **model libraries** provided by GAMS and to retrieve their models in a convenient way. It can be opened either by choosing *GAMS > Model Library Explorer* from the menu, by using the shortcut `F6` or by clicking the corresponding icon in the Quick Access Toolbar.

Every library is presented in a separate tab. The search facility in the upper part of the Model Library Explorer allows for dynamic filtering of all model libraries simultaneously. As the search string is entered, the results are applied to the tabs representing the different libraries. If there are no more results on the selected model library tab, the first non-empty tab is automatically selected. This is undone as soon as the originally selected model library contains results again. The parenthesis enclosed numbers indicate the number of models found for the specific library and the current search input. More about the filter can be found in the Filter Section.

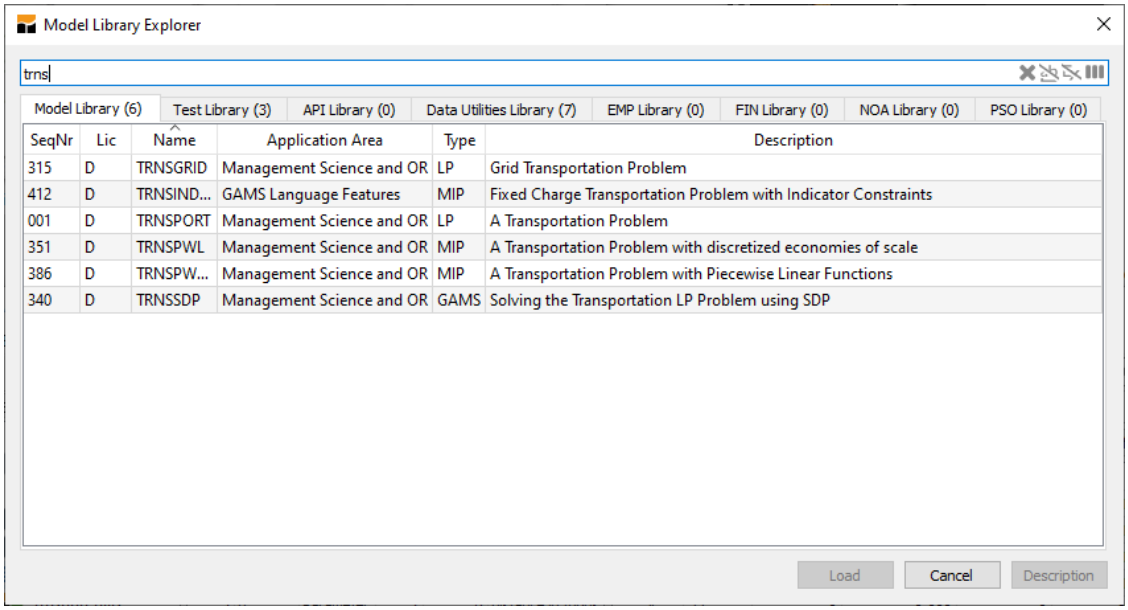

Figure 6.47 Searching for `trns` in the Model Library Explorer

Beside a short description, several models have a longer and more detailed description available. Selecting a model and clicking on the `Description` button in the lower right corner opens a pop-up dialog showing further information about the model. A model can be opened either by clicking on the `Load` button, by double clicking or by selecting the model and pressing the `Enter` key.

User Libraries

Additionally to the model libraries distributed by GAMS, it is possible to access user defined model libraries by providing a GLB file along with the corresponding files belonging to the models in the library. The Model Library Explorer looks into a specific location for user defined model libraries. This location can be accessed or changed by opening the Settings dialog (`File > Settings`) and switching to the `Misc`. tab. The `Arrow` button will show the location where the Model Library Explorer tries to find user defined model libraries, the `Folder` button allows to change the location. Adding a new library is done by copying the required files into a subdirectory in this location. See `Creating a User Library` on how to create a custom model library. Newly added libraries require a restart of the Model Library Explorer to become visible.

6.14.8.5 Settings

The GAMS Studio settings dialog can be accessed via the *File > Settings* menu entry or with the hotkey `F7`. Users can change certain aspects of Studio like behavior or appearance. Settings are categorized loosely on five tab pages.

General page

On the **"General"** tab users control general settings of **Studio**. Some additional hints:

- "Default GAMS Studio workspace". This path is used as a default location for models imported from the Model Library Explorer.
- "Automatically save modified files before running GAMS" is an option that saves all modified files when the user starts a GAMS run. Thereby, previously unsaved changes will be incorporated into that GAMS execution without the need to go through all files and make sure that changes were saved manually.
- "Open .lst file after running GAMS" automatically puts the generated lst file into the foreground after each GAMS run.
- "Jump to first compilation error" is an automatism that aims to make working with Studio a little easier. When compilation errors occur, the editor and the log both jump to the first error detected if this option is activated. This also applies when the option *Open .lst file after running GAMS* is activated. Studio then opens the lst file generated and jumps to the first error in it. If you navigate back to the gms file, the view has also moved to the first error found.
- "Open file in current project by default" switches the menu *File > Open* (`Ctrl-O`) to always open a file in the current project, even if it exists in another project. The alternative open (`Ctrl-Shift-O`) is changed to *File > Open in new project...*.
- "Open file finds or creates new project" switches the menu *File > Open* (`Ctrl-O`) to find the file in any project and open it. If not found, a new project is created. The alternative open (`Ctrl-Shift-O`) is changed to *File > Open in current project...*.
- At the bottom of this tab there is a section to backup all settings. When pressing the **Export** button a dialog pops up, asking for a filename. This name can be chosen freely and the file can than be copied to a USB stick for sharing, or just be saved for later. This is handy if you are planning a fresh install or want to copy your personal settings to a different machine. The button **Import** is used to load a saved settings file. These settings are applied immediately and the settings dialog will be closed automatically.

Editor & Log page

The **"Editor & Log"** tab contains many self explanatory appearance options. Most notably font settings which is used for all monospace fonts like text editors and logs. The font size is used also to calculate the size of proportional fonts (see Zoom Groups)

- "Enable auto-indentation" activates smart line break behavior. When pressing the `Enter` key a line break is inserted and the indentation of the line of origin is copied instead of moving the cursor to the first column.
- "Highlight word under cursor without selection" changes the highlighting behavior of word occurrences. While the default behavior highlights other occurrences of the same word when double clicking or selecting a word, activating this option changes the behavior so that every time there is a word under the text cursor, all of its occurrences will be highlighted. Only full words and no partial matches are highlighted.
- "Tab stop size" lets the user decide how many tabs will be inserted when pressing the Tab-key. GAMS Studio always replaces inserted tabs with spaces.
- "Fold DCO blocks on open" folds all foldable blocks of the types "Text", "Echo", "Put", and "Fold"
- "Syntax Highlight bound" stops highlighting lines with more than the given count of characters. Highlighting long lines is a very time consuming process which can be controlled this way. It's likely that the highlight will get out of sync for one or more lines. By placing syntax relevant characters to the next (shorter) line this side effect can be reduced. To switch off highlighting set this value to 0. To always turn on highlighting set it to -1.
- "Clear process log before GAMS execution" empties the log before running a gms file. If deactivated old log output is kept but colored in a lighter gray so users are still able to identify that they are looking at an old run instead of the most current one. One can also decide if the log should be written to disk as well and if so, how many old versions of the same log should be kept on disk as backup. Note, that in addition to this log file written by Studio, one can instruct GAMS itself to write a log file using the GAMS parameter logOption, which could cause a file naming clash.

GDX Viewer

- "Symbol View" controls if the list view or the table view is used as the default view when a symbol is displayed for the first time.
- "Attributes" allows to control which of the variable and equation attributes should be visible per default.
- "Preferences" controls different default settings for symbol data:
  - "Squeeze Defaults" affects variables and equations only and can be used in order to hide all columns that have the default value of the respective variable or equation type.
  - "Squeeze Trailing Zeroes" allows to turn on/off the truncation of trailing zeroes.
  - "Format" is used to control the default format of numerical values. For detailed information see the corresponding section in the GDX Viewer documentation.
  - "Precision" specifies the number of decimals or the number of significant digits depending on the chosen format. For detailed information see the corresponding section in the GDX Viewer documentation.
- "Decimal Separator in Copied Data" controls the decimal separator used when copying data from a GDX symbol. Note that this setting affects the copied data only but not the diplayed data itself. The following options are available:
  - "Use Studio default": Per default `.` is used as decimal separator in copied data.
  - "Follow system language": Use the decimal separator from the system language settings.
  - "Use custom character": This allows to specify a custom character.

Colors page

The **"Colors"** tab enables you to configure several colors. Studio provides two fixed themes: the "dark" theme and the "light" theme. Depending on the your operating system, this can be selected by the system and/or manually. You can use this to set Studio to use a darker color palette for when you like to work in the dark and don't like to get blinded by bright windows.

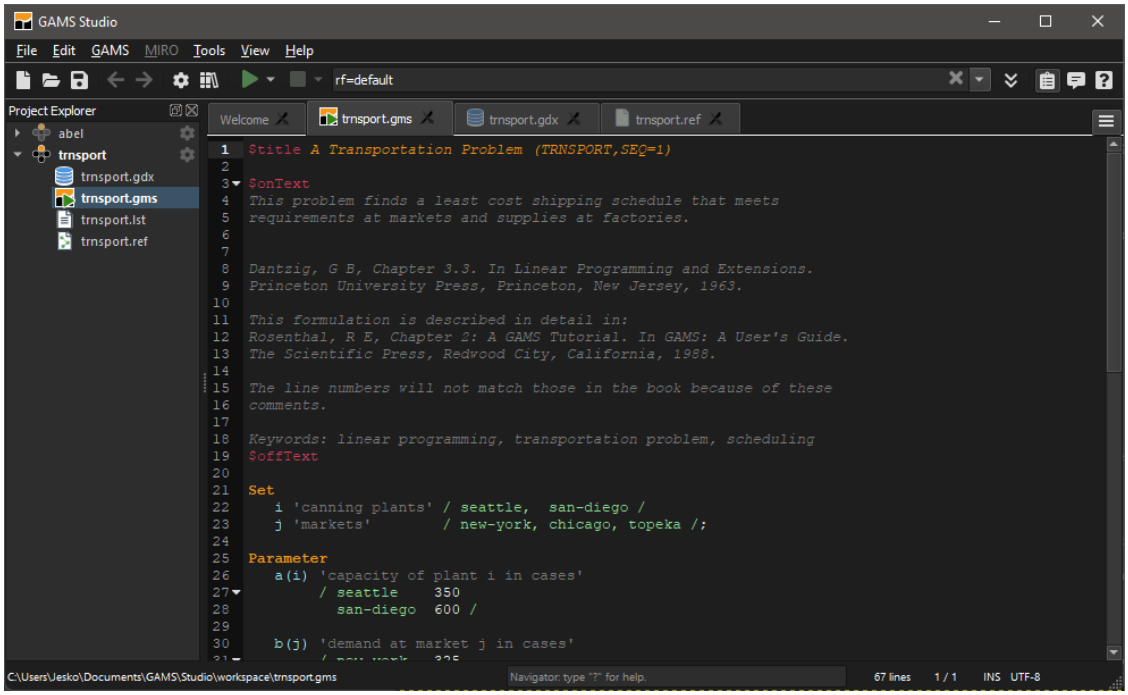

Figure 6.48 Studio using a dark theme

The fixed themes can't be modified, modifying a value implicitly creates a copy of the theme where the changed value is applied. After copying a theme, the new user theme can be adapted to your needs. Additionally these user themes can be exported and imported to a file each.

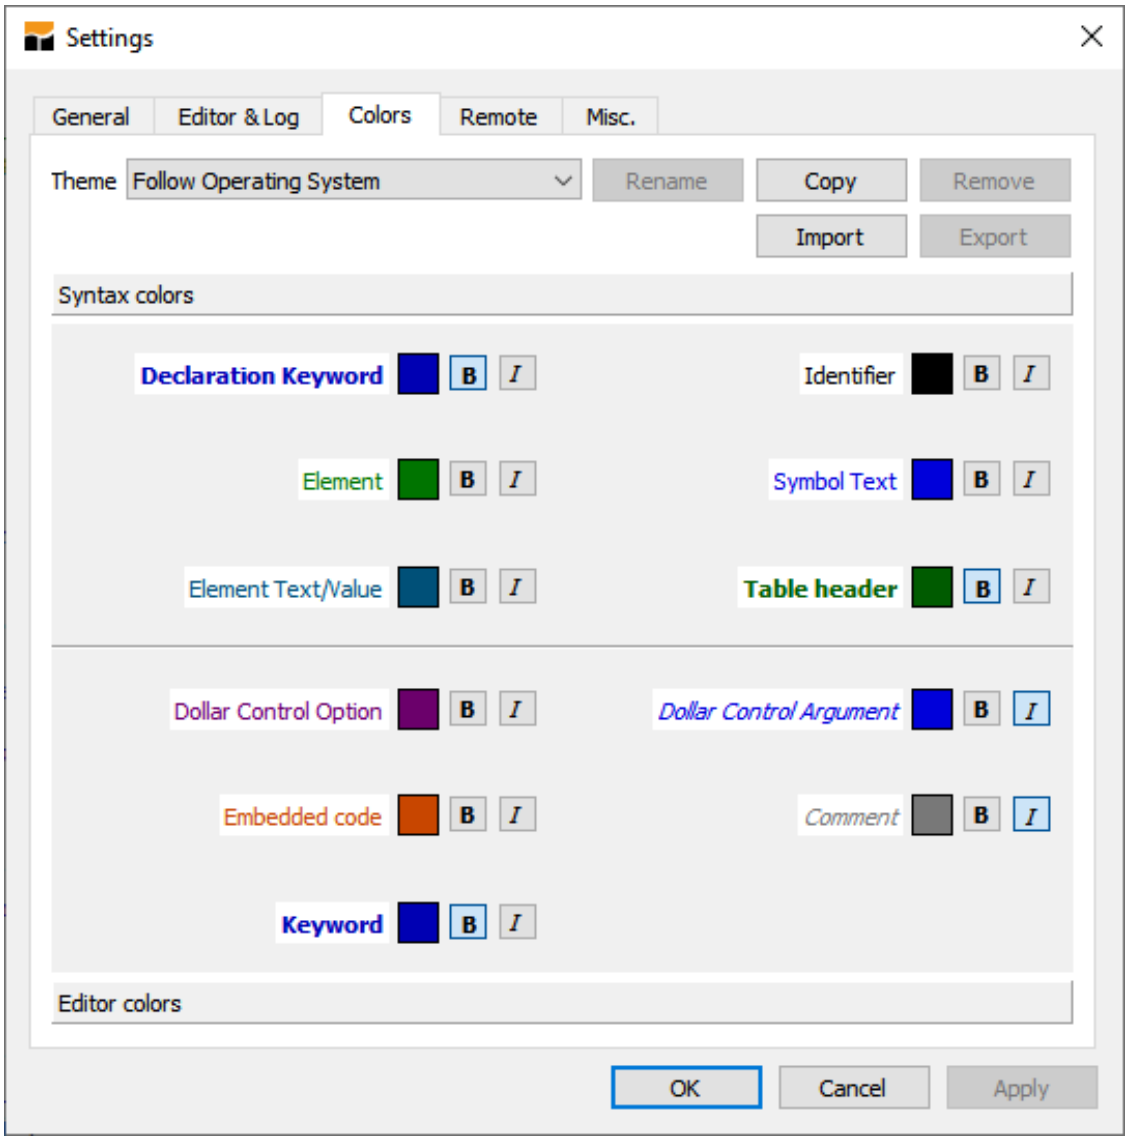

Figure 6.49 Color Settings

The colors are listed in two sections:

- On the "Syntax colors" page you can define a *text color* and the attributes *bold* and *italic*.
- The "Editor colors" page allows to change the colors of *text*, *background*, and *second background* (for blinking). The very first entry on this page, the "Default Text", is the base of the syntax colors.

Remote page

The **"Remote"** tab is used to set various remote settings.

- In the MIRO section the location of your local MIRO installation can be defined.
- The checkbox "Always agree to NEOS" allows to hide the "Terms Of Use" in the submission dialog of NEOS.
- In the GAMS Engine section it can be defined if a login token should be stored to the settings to stay logged in on restarting Studio. The next line allows to define how long the login is valid.
- If the dialog has been switched invisible by clicking "OK, don't ask", the button "Reactivate dialog" switches it on again.

Misc page

The **"Misc"** tab contains some lesser common settings.

- "GAMS source file extensions" allows to add own file extensions that **Studio** counts as *runnable GAMS*. File types added here can be executed, set as main file, and are assigned to the GAMS Syntax Highlighter. The field accepts a comma separated list of file extensions.
- "Auto-reload extensions" Specific extensions that should be *reloaded automatically* can be added here. Files of that type are reloaded into the editor if changed externally. If they also were changed internally, a dialog asks how to proceed. The field expects a comma separated list of file extensions.
- "User model library" shows the folder that is used to find user generated model libraries, see User Libraries. This folder can be changed to a custom location. Up to 10 locations are stored in the history. To remove the current entry from the history use the trash-bin button. The arrow-button opens the file browser in the current folder.
- "Reset History" clears the list of last projects and files used on the Welcome Page
- "Reset Window" resets the appearance of Studio if something went wrong.
- The next group contains a list of options for the Solver Option Editor.

6.14.8.6 Delete scratch directories

GAMS creates working folders for running processes in your working directory. Normally these are automatically removed when a run finishes. However, if a run was interrupted sometimes these working directories remain. That in itself is not a problem as GAMS will pick a new name for the next run if the default name for the working directory is already taken. To automatically clean up the user workspace, Studio offers an action to do this. In the menu under **GAMS > Delete scratch directories** the user has the possibility to remove unwanted, autogenerated directories. Before deleting anything, there will be a popup asking the user for confirmation and also showing the path of the directory that will be cleaned. If the user choses "Yes", all directories that start with 225 followed by one or two letters will be deleted in the given path, which is usually the default workspace. This action is automatically triggered when GAMS has exhausted the pool of possible scratch directory names, but not without asking the user for confirmation first. To avoid any potential errors this action should only be triggered if there are no running GAMS jobs at the moment.

6.14.8.7 Full Screen & Distraction Free Mode

Especially small devices suffer from sparse screen real estate. Studio comes with a few features to make the most of the space that is available on your machine.
The Full Screen mode is activated by pressing `Alt-Enter` on Windows and Linux systems, while on macOS the shortcut is `Command-Control-F`. This enlarges Studio over the whole screen, covering the taskbar and other operating system specific items. The same shortcuts also exit Full Screen mode.
As an alternative, there is also the Distraction Free mode. Some users want to keep their taskbar so with the shortcuts `Ctrl-Alt-Enter` on Windows and Linux or `Cmd-Option-Enter` on macOS hide all Studio widgets and enlarge the central widget to the size of the studio window. You can use this to get the log-, file- and help view out of the way and concentrate writing. Pressing the shortcut again brings everything back. Running your GAMS modell in the Distraction Free mode will also open the log, so you are not missing out on anything.

Action	Shortcut	macOS
Enter/Exit Full Screen	**Alt - Enter**	**Command - Control - F**
Enter/Exit Distraction Free Mode	**Ctrl - Alt - Enter**	**Command - Option - Enter**

6.14.8.8 GDX Diff

The GDX Diff dialog serves as a graphical interface to the command line tool GDXDIFF. It compares the data of two GDX files and writes the differences to a third GDX file. The dialog can be opened by choosing `Tools` > `GDX Diff` from the menu.

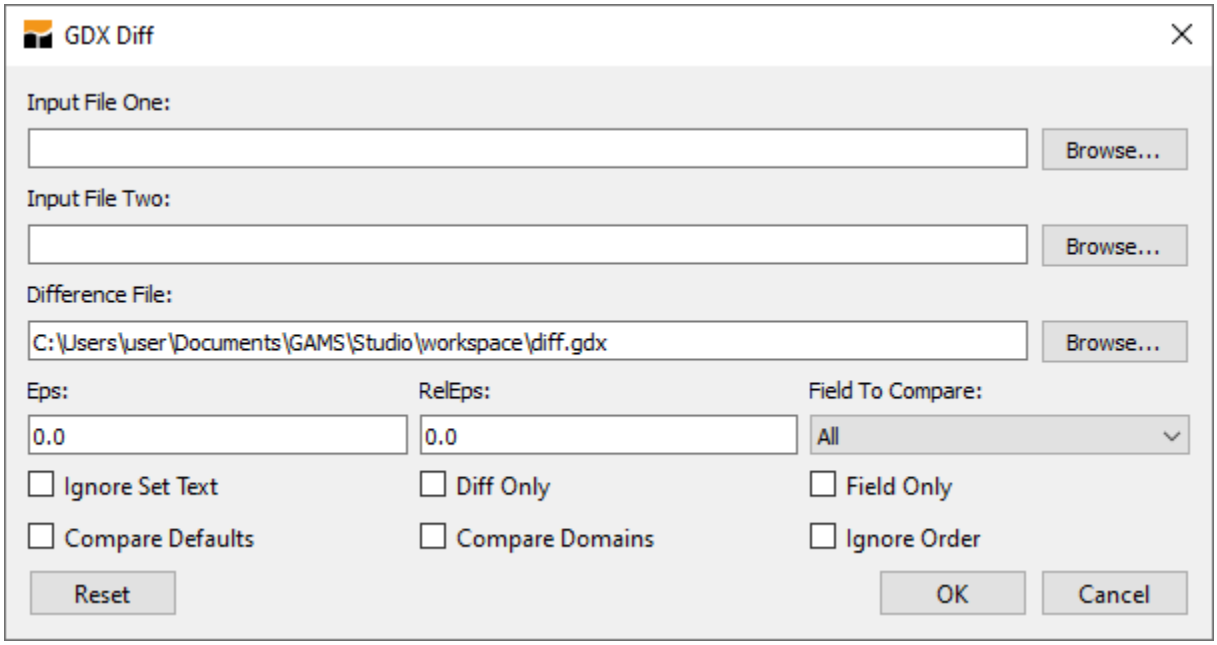

Figure 6.50 GDX Diff dialog

The dialog consists of two parts. The upper part is used to specify the two GDX files for the comparison. The resulting GDX difference file is determined automatically as long as no manual changes have been applied. The default schema for the resulting GDX difference file is the location of the first input GDX file and the file name `diff.gdx`. The difference file will be updated whenever the first input is modified to an existing file. If the GDX Diff dialog gets opened and does not contain a valid first input file, the most recently used directory is used as the location for the resulting difference file instead.

The lower part of the dialog contains different options that can be used in order to control the behavior of the comparison:

- **Eps**: Absolute difference for comparisons. If the difference between two values exceeds Eps, a difference will be reported. Default is `0.0`.
- **RelEps**: Relative difference for comparisons. If the value of RelEps is exceeded, a difference will be reported. Default is `0.0`.
- **Field To Compare**: The specified subfield is the only field used for deciding if a variable or equation is different. List of possible values:
  - **All**: All fields
  - **L**: Level
  - **M**: Marginal
  - **Lo**: Lower Bound
  - **Up**: Upper Bound
  - **Prior**

  - **Scale**

- **Ignore Set Text**: Allows to ignore explanatory text of set elements.
- **Diff Only**: Differences for variables and equations will be written as parameters. Each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option can not be used in combination with `Field Only`.
- **Field Only**: Used in combination with `Field To Compare`. The variables and equations will be written as parameters for the selected subfield. This option can not be used in combination with `Diff Only` and it requires a value for `Field To Compare` other than `All`.
- **Compare Defaults**: Controls if default values for symbols, e.g. 0 for parameters, are reported as differences if they are found in one file and missing in the other or not.
- **Compare Domains**: Controls if different domains for the same symbol are reported as a difference.
- **Ignore Order**: Ignore UEL order of input files. This can reduce the size of the output file.

As soon as the `OK` button is clicked, a validation check on the given input is performed and the two input files are compared. If the specified difference file is already open in a GDX Viewer, the corresponding tab remains open while the underlying GDX file is detached. As soon as the file was updated, the GDX Viewer is reinitialized. In case the GDX file was not open already it gets opened in a new tab. The `Cancel` button closes the dialog and stops a process that has not been finished yet. The dialog needs to be kept open for longer running comparisons of large input files. The `Reset` button can be used to reset the whole dialog to its default state which also enables the automatic pre-population of the difference file path in case it has been disabled before due to a manual change.

The GDX Diff dialog also has an integration in the context menu of the Project Explorer. As soon as either exactly one or two GDX files are selected, the context menu contains an entry for opening the GDX Diff dialog with the file(s). If only one file is selected, the input field that is empty is populated with the corresponding file path. If both fields are filled, the first input file path gets overwritten. In case of two selected GDX files, both input fields get overwritten.

6.14.9 Terminal

GAMS Studio is able to open a native terminal via the main menu `Tools` > `Terminal` or the shortcut `CTRL - T`. Alternatively, a terminal can be opened by right clicking on any entry of the "Project Explorer" and selecting `Open terminal`. The terminal points to the workspace of the current project. On macOS the terminal location is always the user's home directory.

6.14.10 Command Line Options

GAMS Studio can be started with additional command line options that change the behavior or trigger certain functionality at start up time. The syntax for starting GAMS Studio from the command line is

```
studio [options] [files]
```

While `files` is one or more files to be opened by GAMS Studio, the following `options` can be supplied:

- **-?, -h, --help** : Displays the help.
- **-v, --version** : Displays version information.
- **--ignore-settings** : Ignore settings files. Studio will load with default settings without writing them.
- **--reset-settings** : Reset all settings to default. Studio will load with default settings and save them.
- **--reset-view** : Reset studio visually without resetting settings. Useful when a widget got lost or studio started on a disconnected monitor.
- **--gams-dir path_to_gams** : Point Studio to a specific GAMS installation.

6.14.11 General Shortcuts

This section lists any shortcuts that are global to Studio. Shortcuts for more specific areas are mentioned in their corresponding section.

6.14.11.1 Studio Workflow Shortcuts

Shortcut	macOS	Description
Ctrl - 1	**Command - 1**	Set focus to the Project Explorer. After that the arrow keys can be used for file navigation.
Ctrl - 2	**Command - 2**	Set focus to main editor.
Ctrl - 3	**Command - 3**	Set focus to the command line option input field.
Ctrl - 4	**Command - 4**	Opens the tab browser which has a list of all open tabs. Focus is on an input field that can be used to filter tabs. Pressing Return opens the highlighted file.
Ctrl - 5	**Command - 5**	Set focus to log widget.
Shift - Ctrl - 3	**Control - Option - 3**	Opens and closes extended command line option editor.
Ctrl - Tab		Toggles through the open tabs of the central widget from left to right.
Ctrl - Shift - TAB		Toggles through the open tabs of the central widget from right to left.
Alt - Return	**Command - Control - F**	Full Screen
Ctrl - Shift - T	**Command - Shift - T**	Restore recently closed tab
Ctrl - Shift - W	**Command - Shift - W**	Close all tabs
Ctrl - W	**Command - W**	Close current tab. Alternatively, a tab can be closed by clicking the middle mouse button.
Ctrl - Q	**Command - Q**	Close GAMS Studio

6.14.11.2 Studio Dialogs

Shortcut	macOS	Description
F1	**F1**	Open the GAMS Help. If the word under the cursor is a GAMS keyword a search in the documentation document will be started
F6	**F6**	Open GAMS Model Library Explorer
F7	**Command - ,**	Open Studio Settings
Ctrl - F	**Command - F**	Open search and replace widget
Ctrl - G	**Command - G**	Go to specific line number
Ctrl - N	**Command - N**	Open new file dialog
Ctrl - O	**Command - O**	Open file open dialog
Ctrl - Shift - O	**Command - Shift - O**	Open file dialog to open the file(s) in the current (a new) project
Ctrl - P	**Command - P**	Open print dialog
Ctrl - S	**Command - S**	Save the current file. If the file does not exist on disk open the save file dialog
Ctrl - Alt - S	**Command - Option - S**	Open save as dialog
Ctrl - Shift - S	**Command - Shift - S**	Save all open files. Open save file dialog if needed

Shortcut	macOS	Description
Ctrl - K	**Command - K**	Open Navigator widget
Ctrl - T	**Command - T**	Open a terminal for the current project location. On macOS the terminal points to the users home directory

6.14.11.3 Studio Recovery

Shortcut	macOS	Description
Ctrl - F2	**Command - F2**	Reset Studio to default visual settings (window position and -size, widget position and -visibility) Useful when a widget got lost or studio started on a disconnected monitor.

6.14.11.4 Zoom Editor and View

All editors and views can be zoomed in and out. To avoid repeating action a zoom is applied to all editors and views of the same group. Beneath the Integrated Help and the Welcome Page these groups are defined:

- **Text**: contains all editors and views that show flowing text in monospace fonts and appear as Central Widget, like the Code Editor and the Listing Viewer.
- **Log**: contains the Process Logs and the System Log.
- **Table**: contains all editors and viewers that show table and tree elements in proportional fonts as a Central Widget, like the GDX Viewer and the Solver Option Editor. It additionally contains the Command Line Option Editor.

Action	Shortcut	macOS	Description
Zoom In	**Ctrl** - + or **Ctrl** - = or **Ctrl - Wheel Up**	**Command** - + or **Command** - = or **Command - Wheel Up**	Zoom **in** all editors and views of the same group
Zoom Out	**Ctrl** - **-** or **Ctrl - Wheel Down**	**Command** - **-** or **Command - Wheel Down**	Zoom **out** all editors and views of the same group
Reset Zoom	**Ctrl - 0**	**Command - 0**	Reset zoom of all editors and views

6.14.12 Usage Hints

6.14.12.1 Filter in Tables and Trees

To find relevant entries in tables and tree views Studio provides a special line edit containing up to four buttons aligned to the right:

- **Clear** - clears the term in the line edit.
- **Exact Match** - when active, the filter accepts only rows with one cell matching exactly the term regarding wildcard or regular expression setting

- **Regular Expression** - when inactive, the wildcards '∗' (any amount of characters) and '?' (one character) can be used. Otherwise the filter provides full regular expression syntax. Click here for further information about regular expressions.
- **All Columns** - when inactive, the filter checks only the key column. When active, all cells of the table/tree-view are taken into account

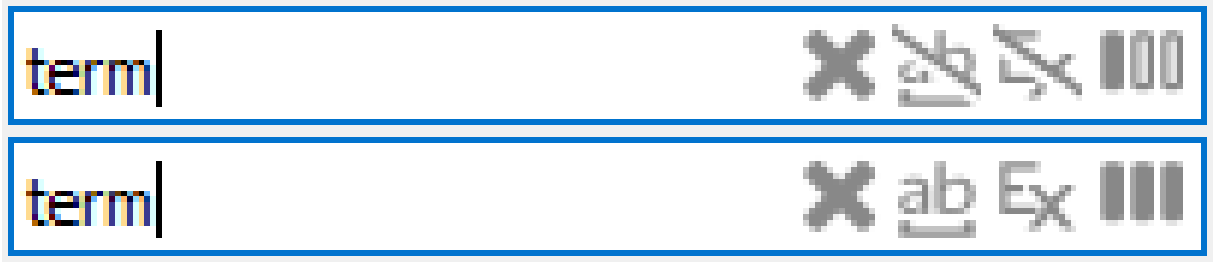

Figure 6.51 Filter LineEdit inactive and active

6.14.13 System Requirements

Compared to most of the GAMS system, GAMS Studio has some additional system requirements, which depend on the platform used. Also, additional information about technical requirements are listed at the GAMS Studio GitHub Wiki.

6.14.13.1 Linux

The Linux version of GAMS Studio is distributed as AppImage and requires glibc 2.30, glibcxx 3.4.28 as well as FUSE to be installed.

The GAMS Studio AppImage was tested and it was verified that it worked for the following Linux distributions (which are all under maintenance). All Linux distributions are under constant development and updates may change the behavior of the AppImage. Please check the Studio issue page if you encounter any issue.

- Debian 12
- Fedora 38
- Manjaro
- openSUSE Tumbleweed
- Ubuntu 22.04 LTS

Other flavors might work as well, but were not tested. If you experience problems with a particular Linux distribution, please let us know.

In some cases the Studio AppImage might not run. If this is the case extract the AppImage by running

```
$ ./studio.AppImage --appimage-extract
```

via the command line and start Studio from the extracted directory.

On some Linux distributions Wayland is used, which can cause issues. If this is the case try to run Studio as shown below.

```
$ QT_QPA_PLATFORM=xcb ./GAMS_Studio-1.12.1-x86_64.AppImage
```

6.14.13.2 macOS

macOS has some special platform requirements related to finding GAMS. Below the steps are listed which are used to link GAMS Studio to GAMS.

- GAMS Studio is going to find GAMS in `/Applications/**` and `/Users/username/Applications/**` if it is part of a GAMS folder. It is required that GAMS Studio gets copied via `Finder` to its target location. This is the case if the GAMS installer is used or if the GAMS Studio DMG is open and GAMS Studio gets copied from there.
- If GAMS Studio could not find GAMS like described previously then it will search `/Applications/**` for a valid GAMS installation, i.e. a GAMS installation which has the minimum required GAMS version or higher.
- GAMS Studio will check the `$PATH` to find GAMS. In almost all cases this will not work on macOS.
- In case of special needs the path to GAMS can be set explicitly by starting GAMS Studio with the command line argument `--gams-dir`.

6.14.13.3 Windows

There are dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio, please run the appropriate installer for these libraries called `vcredist_x64.exe`, which can be found in the GAMS installation folder at `[GAMS system]\studio`.

6.14.14 Comparing GAMS Studio and GAMSIDE

As mentioned above, the classic GAMS IDE has been shipped with the GAMS system for many years and is still the workhorse for many GAMS programmers. So it is still around and an alternative to GAMS Studio, especially since it has features, which are not available in GAMS Studio (yet), but it also lacks some features which are available in GAMS Studio. The following table gives a compact overview about most of the differences.

GAMSIDE only	GAMS Studio only
Supported Platforms	
- Windows	- Windows
	- Linux
	- macOS
GDX Viewer	
- Creating charts	- Filtering (both, symbols and data, labels and values)
- Writing to Html	- Sorting by numerical value
- Heat-map functionality (aka Data Colors)	- Option to change display format of numerical values
Editor	
- Fixed encoding (ISO 8859-1)	- Allow change of encodings and use UTF-8 by default
- Spell checker	- Block edit
- Recognize URLs and open them in the browser	- Help integration (pressing `F1` on a keyword opens the relevant index page of the documentation)
- Different set of keyboard shortcuts	- Tooltips for compilation errors

GAMSIDE only	GAMS Studio only
	- Navigation history
	- Code Completion
	- "Smart typing": Automatic insertion of closing character for brackets and quotes
	- Distraction Free Mode
	- Code Folding
	- Open `$[bat/lib]include` files directly from editor
Execution	
- IDE Projects	- Studio Projects (see below for details)
- Set default options for the IDE only	- Interactive editor for the GAMS User Configuration
- Use different GAMS versions	- Interactive editor of GAMS command line parameters
- Use alternative license	- Interactive editor for GAMS Connect
- Execute program based on extension	- Option to run with GDX creation automatically (`F10` vs. `F9`)
- Solver selection menus	- Integration of GAMS MIRO
	- Remote execution on NEOS Server for Optimization
	- Remote execution with GAMS Engine
	- Support of standard locations, e.g., to detect the license file at a standard path
	- Option to jump to first error automatically
	- Option to not write log to disk
Other	
- Text Diff	- Welcome page
- Script recording	- Project Explorer
- Email file	- Navigator
- Save test files in UNIX format	- Filtering in Model Library Explorer (all model libraries at the same time)
- Link to McCarl chm	- Allow to switch between light, dark or custom themes
	- Reference File Viewer allows to jump to all references etc. and not just the first one
- 32-bit application	- 64-bit application

6.14.14.1 GAMSIDE Projects vs. GAMS Studio Projects

With the GAMSIDE one always started with creating a "Project". This mainly defined a directory used to execute the models added to it (so, it is used to implicitly define the workDir when starting GAMS). When starting the IDE for the first time, one is asked to create a new project. For example, one creates this in directory `a`. After adding models `a/a.gms` and `b/b.gms` both get executed in the project directory `a`, meaning that data sources are expected in `a` (or relative to it) and also output files are generated in `a`, and not necessarily at the location of the `gms` file.

When starting GAMS Studio for the first time, it starts with an empty Project Explorer. Opening a new file creates a new Project per default. Studio Projects also have a "working directory". Initially, this is set automatically to the location of the file that was opened to create the new project. If a model gets executed, it gets executed in this working directory. So, if ones opens `a/a.gms` and `b/b.gms`, by default,

Studio will create two projects: `a` and `b`. When `a` is started input files are expected in directory `a` and output files get generated in `a`. When `b` is started input files are expected in directory `b` and output files get generated in `b`. If one has structured the models so that they rely on the "GAMSIDE way" to execute a model, one can just change the working directory in the project options. Also, it is possible to start with an empty project and just define the working directory explicitly in the way the GAMSIDE did it using the entry `New Project` from the `File` menu.

It is also possible to have multiple files in one project. For example, one could add `b.gms` to project `a` by drag'n'drop in the Project Explorer. Now, the concept of the "main file" of projects becomes important: While the GAMSIDE always executed the currently active `.gms` file, GAMS Studio always executes the main file of the currently active project. So, in our example, you can look at `a.lst` and press `F9` to rerun `a.gms` (the GAMSIDE would not run anything in this case). After adding `b.gms` to project `a`, one would also execute `a.gms` by pressing `F9` while looking at `b.gms`. If you want to execute `b.gms` instead, you can make it the main file of the project. For this, right-click in the Project Explorer at `b.gms` and select "Set as main file". Note that the green arrow indicating the main file of a project in the Project Explorer switches from `a.gms` to `b.gms`. As a reminder: Projects do not know a particular working directory. Pressing `F9` after switching the main file will execute `b.gms` in folder `b`.

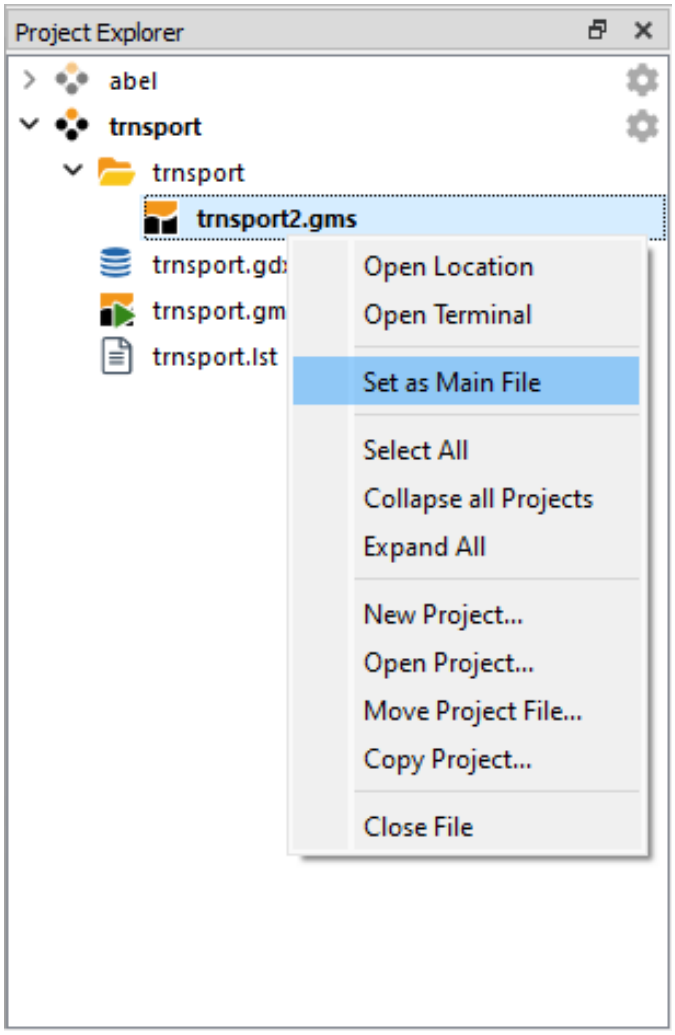

Figure 6.52 Switching the main file

6.15 GDX2ACCESS

6.15.1 Overview

GDX2ACCESS is a tool to dump the contents of a GDX file to an MS Access file (MDB or ACCDB format). Every identifier gets its own table in the database.

Attention

GDX2ACCESS is deprecated (see GAMS 40 GDX2ACCESS release notes). Please use Connect agent SQLWriter instead.

6.15.2 Usage

```
gdx2access inputFile {options}
```

The .gdx file extension of the inputFile can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.15.3 Options

Options are specified in an [INI] (https://en.wikipedia.org/wiki/INI_file) file and not directly on the command line. By default, the file gdx2access.ini located in the same directory as gdx2access.exe is consulted. If this file is not available, the program will continue using default settings (listed in the tables below).

It is also possible to tell the program to use a different INI file. This is done by using an extra argument of the form `@iniFile`. If you want to dump the contents of myFile.gdx to an MS Access file according to the options specified in a file called myIniFile.ini, run the following code:

```
gdx2access myFile.gdx @myIniFile.ini
```

In this case, the program will not read gdx2access.ini located in the same directory as gdx2access.exe, but rather myIniFile.ini in the current directory.

The INI file can contain two sections: [settings] and [debug]. A complete INI file with all possible settings looks like:

```
[settings]
scrdir=c:\tmp
inf=1.0e100
mininf=-1.0e100
eps=0.0
na=0.0
undf=0.0
scalarTable=1
etFlag=1
dbVersion=9
[debug]
method=5
thresholdCount=5
keepFiles=1
```

Note that the values above are not the default values for some options!

Section [settings]

Below some short descriptions for the options in the [settings] section:

Option	Default	Description
scrdir	<windowstemp>	Directory for temporary scratch files.
inf	1.0e100	The value used for GAMS special value `+INF`. See also the example Special value mapping.
mininf	-1.0e100	The value used for GAMS special value `-INF`. See also the example Special value mapping.
eps	0.0	The value used for GAMS special value `EPS`. See also the example Special value mapping.
na	0.0	The value used for GAMS special value `NA`. See also the example Special value mapping.
undf	0.0	The value used for GAMS special value `UNDEF`. See also the example Special value mapping.
scalarTable	0	Possible values: 0 or 1. When set to 1, scalars of the same type are combined in a single table. The names for these tables are fixed: `ScalarParameter`, `ScalarEquation` and `ScalarVariable`. See also the example Special value mapping.
etFlag	0	Possible values: 0 or 1. When set to 1, include the text strings for sets containing element texts. See also the example Writing Explanatory Text to Database.
dbVersion	0	Specify the format of the output database. See also the example Writing Explanatory Text to Database. 0: Create database using current default format. 9: Create a database in the Microsoft Access 2000 (.mdb) file format. 10: Create a database in the Microsoft Access 2002-2003 (.mdb) file format. 12: Create a database in the Microsoft Office Access 2007 (.accdb) file format.

Section [debug]

Below some short descriptions for the options in the [debug] section:

Option	Default	Description
method	5	Select an algorithm to insert data into the Access database. 1: Write a CSV file and use the TransferText action to read this into Access. This is fast, but does not always work when non-US language settings are used. 2: Use recordset.add to add records. This is slow, but does not use intermediate files. 3: Write a tab delimited file with a complete file specification (schema.ini) and use the ISAM Text driver to import the data. This is fast and should work in international settings. 4: For small data use method=2 and for larger data items use method=1. 5: For small data use method=2 and for larger data items use method=3.
thresholdCount	5	When to change between algorithms while using method=4 or method=5. The default is 5 records.
keepFiles	0	Possible values: 0 or 1. When set to 1, the program will not delete intermediate scratch files.

6.15.4 Examples

6.15.4.1 Intro

Suppose we want to write the data of the [**trnsport**] model from the GAMS model library after solving to an MS Access data file. First of all, we solve the model by running the following command. Note that we will save the complete symbol table to a GDX file called trnsport.gdx by adding the command line option `gdx=trnsport`.

```
gams trnsport gdx=trnsport lo=2
```

The option `lo=2` causes GAMS to save the log to an external file (in this case trnsport.log), instead of writing it to the screen. In order to get an idea about the data at this point, we use the GDXDUMP tool to display the contents of the GDX file by running the following command:

```
gdxdump trnsport.gdx symbols
```

By adding the `GDXDUMP` option `symbols`, we will only display the table of contents (shown below) rather than all data stored in trnsport.gdx.

```
*  GDX dump of trnsport.gdx
*  Library in use : C:\GAMS23.3
*  Library version: GDX Library      Nov  1, 2009 23.3.3 WIN 14596.15043 VIS x86/MS Windows
*  File version   : GDX Library      Nov  1, 2009 23.3.3 WIN 14596.15043 VIS x86/MS Windows
*  Producer       : GAMS Base Module Nov  1, 2009 23.3.3 WIN 14929.15043 VIS x86/MS Windows
*  File format    :    7
*  Compression    :    0
*  Symbols        :   12
*  Unique Elements:    5
   Symbol Dim Type  Explanatory text
```

```
 1 a        1  Par  capacity of plant i in cases
 2 b        1  Par  demand at market j in cases
 3 c        2  Par  transport cost in thousands of dollars per case
 4 cost     0  Equ  define objective function
 5 d        2  Par  distance in thousands of miles
 6 demand   1  Equ  satisfy demand at market j
 7 f        0  Par  freight in dollars per case per thousand miles
 8 i        1  Set  canning plants
 9 j        1  Set  markets
10 supply   1  Equ  observe supply limit at plant i
11 x        2  Var  shipment quantities in cases
12 z        0  Var  total transportation costs in thousands of dollars
```

Once we have a GDX file, we can use `GDX2ACCESS` to create a MDB or an ACCDB file. Versions of MicroSoft Office prior to version 2007 use the file extension .mdb, while version 2007 and later versions use the file extension .accdb. We write all the data stored in the GDX file trnsport.gdx to trnsport.mdb resp. trnsport.accdb by running the following code:

```
gdx2access trnsport.gdx
```

Note that we do not referenced an INI file in the previous command in order to specify the options, i.e. `GDX2ACCESS` will consult the file gdx2access.ini located in the same directory as gdx2access.exe or, if the file does not exist, the tool will continue using the default settings (see Options). The information written to the log is shown below, including the identifiers of the symbols which are written to trnsport.accdb and the elapsed time per symbol and in total.

```
GDX Access       ALFA 23Mar10 23.4.0 WIN 16693.16738 VS8 x86/MS Windows
Creating C:\GAMS support\settext\temp1.accdb with Access: 0.48 seconds
Using temp directory C:\Users\Paul\AppData\Local\Temp\
           i.   Insert:  0.00 seconds
           j.   Insert:  0.00 seconds
           a.   Insert:  0.00 seconds
           b.   Insert:  0.00 seconds
           d.   Dump:  0.00 seconds  Load:  0.05 seconds
           f.   Insert:  0.00 seconds
           c.   Dump:  0.00 seconds  Load:  0.05 seconds
           x.   Dump:  0.00 seconds  Load:  0.03 seconds
           z.   Insert:  0.00 seconds
        cost.   Insert:  0.00 seconds
      supply.   Insert:  0.02 seconds
      demand.   Insert:  0.02 seconds
Renaming  C:\GAMS support\settext\temp1.accdb -> trnsport.accdb
Total elapsed time: 0.92 seconds
```

The resulting ACCBD, opened with MS Access, is shown in Figure 1 (limited to the parameter `c` on the left and the variable `x` on the right).

As can be seen, every identifier is stored in its own table. For parameters like `c`, the value is stored in a column named value, while variables like `x` and equations have the columns level, marginal, lowerbound and upperbound. A possible additional field (scale for NLP's, priority for MIP's, stage for stochastic problems) is not exported. If needed, you can assign such a quantity to a parameter in GAMS before writing the GDX file. The complete process shown here can be automated as demonstrated in Example 1.

If no domain information is available for a symbol (like `B` in the code below), each index position gets a column and will be labeled automatically with dim1, dim2, etc. If domain information is available, the columns will use that information but keeping the names unique (like `A` in the code below). The small example below shows how the index positions are made unique using the (relaxed) domain information by adding an ascending number to the identifier.

```
Set i / i1*i5 /;
Alias (i,j,k);

Parameter A(i,i,i) 'domain informations, but the column name would not be unique';
A(i,j,k) = uniform(0,1);

Parameter B 'no domain information' / i1.i1 1, i1.i2 2, i2.i1 3, i2.i2 4 /;

execute_unload 'AB.gdx', A, B;
execute '=gdx2access AB.gdx';
```

The resulting database file, opened with MicroSoft Access, is shown in Figure 2 (parameter `A` on the left, parameter `B` on the right).

6.15.4.2 Example 1 - Dumping the Contents of trnsport.gdx

This example will solve the [**trnsport**] model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Access and MS Access is launched to inspect the results. This is a small example that should run very quickly.

```
execute '=gamslib trnsport';
execute '=gams trnsport lo=3 gdx=trnsport';
execute '=gdx2access trnsport.gdx';
executeTool 'win32.shellExecute trnsport.accdb';
```

Note: the equal signs in front of the external programs indicate we don't go through a shell (e.g. command.com or cmd.exe). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=', such errors go undetected and the GAMS model will continue.

The command 'executeTool 'win32.shellExecute trnsport.accdb';` will launch Access to view the ACCDB file. This assumes that the version of Access installed is a version as recent as version 2007. Earlier versions will generate a database with the extension .mdb and the shellExecute command needs to be changed as follows:

```
* view generated file create
executeTool 'win32.shellExecute trnsport.mdb';
```

The complete example is also part of the GAMS Data Utilities Library, see model [**GDX2ACCESSExample1**] for reference.

6.15.4.3 Example 2 - Writing Explanatory Text to Database

In this example, we write a few sets to a GDX file; two of the sets written have explanatory text for set elements. We use the option etFlag to get this text saved in the Access database file along with the corresponding set elements. Without using the option, only the set tuples are saved in the database.

Running this example on a machine with Access 2007 or a later version installed will create a database with the .accdb file extension that cannot be read by an older version of Access. We use the dbVersion option to save the database in the MDB format. Both options must be specified in an user defined INI file within the settings section, see howToWrite.ini in the code below.

```
Set
   i       / i1 'one', i2 'two', i3 'three', i4 'four' /
   j       / j1*j4 /
   ij(i,j) / i1.j1 'red', i2.(j2,j3) 'green', i3.(j1,j2) 'blue' /;

$gdxOut example2.gdx
$unload i j ij
$gdxOut

$onEcho > howToWrite.ini
[settings]
etFlag=1
dbVersion=10
$offEcho

$call =gdx2access example2.gdx @howToWrite.ini%
```

When we open the database and inspect the table created from the set `ij`, we see the explanatory texts stored along with the corresponding set elements. The column containing the explanatory text will be labeled with `SetText` automatically. The column headers can be renamed as demonstrated in Example 5 - Renaming Fields.

The complete example is also part of the GAMS Data Utilities Library, see model **[GDX2ACCESSExample2]** for reference.

6.15.4.4 Example 3 - Dumping a large Table to Database

This is an artificial example where we generate a large identifier in GAMS: a parameter with a million elements. This parameter will be dumped to an MS Access Database afterwards. Note that the `GDX2ACCESS` execution will last several seconds. The resulting database file has approximately 36MB of size.

```
Set i / i1*i1000 /;
Alias (i,j);
Parameter p(i,j);
p(i,j) = uniform(-100,100);
execute_unload 'example3.gdx', p;
execute '=gdx2access example3.gdx';
```

The complete example is also part of the GAMS Data Utilities Library, see model **[GDX2ACCESSExample3]** for reference.

6.15.4.5 Example 4 - Special Value Mapping

To store special values like +INF, -INF, EPS, NA and UNDF in a numeric field in the database, GDX2ACCESS uses a mapping. This mapping can be changed by using an INI file (for the default values, see Options resp. the comments in the second code below). We will define a scalar for each special value in GAMS in order to demonstrate the scalarTable option in addition. By default, every scalar will be written to a new table. By activating the scalarTable option in the INI file, all scalars will be stored together in a single table.

```
$onEcho > howToWrite.ini
[settings]
inf=1
mininf=2
eps=3
na=4
undf=5
scalarTable=1
$offEcho
```

The usage of our previously customized INI file howToWrite.ini is indicated by the argument @howToWrite.ini within the execute statement.

```
$onUndf
Scalar
   pInf      /  inf /
   mInf      / -inf /
   epsilon   /  eps /
   notAvail  /   na /
   undefined / undf /;

* save scalars in scalars.mdb in a single table named ScalarParameter using
* the scalarTable option
* special values are translated to default values:
*  INF ->  1.0e100
* -INF -> -1.0e100
* EPS,NA,UNDF -> 0

execute_unload 'scalars.gdx', pInf, mInf, epsilon, notAvail, undefined;
execute 'gdx2access scalars.gdx @howToWrite.ini';
```

Note the $onUndf command in order to enter Undf values directly within the definition of the scalars. When we view the generated GDX file in the GAMS IDE or GAMS Studio, the special values are shown (note that the figure shows a parameter actually instead of five single scalars for a more compact presentation):

Viewing the resulting table in Access shows how the mapping for special values was applied (i.e. the GAMS special values have been substituted by our customized values defined in the INI file):

Note that the table will be named ScalarParameter automatically.

The complete example is also part of the GAMS Data Utilities Library, see model **[GDX2ACCESSExample4]** for reference.

6.15.4.6 Example 5 - Renaming Fields

GDX2ACCES will use names like i, j, dim1, dim2, value etc. for the column headers in the resulting database file. In some cases, this may not be convenient, e.g. when more descriptive field names are required. In the following model, we will show how a small script in VBscript[1] can handle this task. The script will rename the columns i, j, and Value in table c to ifrom, jto, and transportcost. At first, the data is defined and dumped to an MicroSoft Access database. The VBscript named access.vbs is written at compile time and later executed at execution time in order to rename the column headers.

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

Parameter
   a(i) 'capacity of plant i in cases'
        / seattle    350
          san-diego  600 /

   b(j) 'demand at market j in cases'
        / new-york   325
          chicago    300
          topeka     275 /;

Table d(i,j) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

* export to gdx file.
execute_unload 'c.gdx', c;

* move to access database
* column names are i and j
execute '=gdx2access c.gdx';

* rename columns
execute '=cscript access.vbs';

* view results
executeTool 'win32.shellExecute c.accdb';

$onEcho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version
Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name
Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name
' rename fields
```

```
oTable.Fields.Item("i").name = "ifrom"
oTable.Fields.Item("j").name = "jto"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"
oDB.Close
Wscript.Echo "Done"
$offEcho
```

The resulting ACCBD, opened with MS Access, is shown in Figure 6 (parameter `c` before executing the VBScript on the left, parameter `c` after renaming the column headers on the right).

The complete example is also part of the GAMS Data Utilities Library, see model **[GDX2ACCESSExample5]** for reference.

6.16 GDX2SQLITE

A Tool to dump GDX contents into SQLite database file.

Author

Erwin Kalvelagen

Date

November 30, 2015

Attention

`GDX2SQLITE` is deprecated (see GAMS 40 GDX2SQLITE release notes). Please use Connect agent SQLWriter instead.

6.16.1 Introduction

`GDX2SQLITE.EXE` is a tool to dump the complete contents of a GAMS GDX file (see GAMS Data eXchange (GDX)) into a SQLite database file (the website http://www.sqlite.org/ contains a wealth of information on SQLite).

A SQLite database is stored in a single file so it can be easily e-mailed or otherwise transmitted. The main advantages of using SQLite over other single file database systems such as MS Access is that SQLite is free and in the public domain and that it does not impose a 2 GB file size limit. For some large data sets this size limit present in MS Access and DBF database files causes problems. Another useful format is CSV files, but typically several CSV files are needed to store a data set stored in a GDX file. Many programs support reading SQLite database files, either through a native database access driver or via a standard ODBC interface. In summary: SQLite is a useful export format for GAMS solution data sets.

6.16.2 Usage

'GDX2SQLITE' is a command line tool that is best called from within a GAMS program using the `$call` or `Execute` statement, e.g.:

```
execute_unload "results.gdx", yield, price;
execute "gdx2sqlite -i results.gdx -o results.db";
```

The following options are available:

Options	Description
`-i gdxinputfile`	Specifies the input GDX file. Typically this is a file with a .gdx extension
`-o sqloutputfile`	Specifies the output SQLite database. Typically this file has a .db extension.
`-debug`	This is an optional flag that will cause gdx2sqlite to print additional debugging information.
`-expltext`	This optional flag will export explanatory text for set elements.
`-append`	Don't delete the database file before processing. This will allow adding new symbols in new tables. We will not allow adding data to existing tables.
`-small`	Write data strings in a separate table. A user-friendly SQL VIEW is created to hide the complexities of the joins.
`-fast`	Try to speed up writing the data using some non-standard pragmas. Using both `-small -fast` will write the data most efficiently.
`-varchar`	String columns will have the type `VARCHAR(255)` instead of `TEXT`.

An example of explanatory text is:

```
Set cty / AFG  'Afghanistan'
          AGO  'Angola'
          ALB  'Albania'     /;
```

In GAMS set elements have a maximum length of 63 characters. Explanatory text has a maximum length of 255 characters.

6.16.3 How data is stored

6.16.3.1 Gams issues

GAMS does not store zero values (or default records for variables and equations). Such non-existing records will not be exported to the GDX file and to the database either. To force a zero to be exported, set it to `EPS` in GAMS. E.g.:

```
p(i)$(p(i)=0) = EPS;
```

In case of doubt you are encouraged to inspect the GDX file.

6.16.3.2 Sets

n-dimensional sets are stored as tables with n text columns. In case the option `-expltext` is used, another column may be added with explanatory text.

GAMS	SQLite
Set month / jan, feb, mar / year / 2013, 2014 / date(year,month) /(2013,2014).(jan,feb,mar) /; execute_unload "sets.gdx"; execute "gdx2sqlite -i sets.gdx -o sets.db";	sqlite>select * from month; month ---------- jan feb mar sqlite>select * from year; year ---------- 2013 2014 sqlite>select * from date; year month ---------- ---------- 2013 jan 2013 feb 2013 mar 2014 jan 2014 feb 2014 mar
Set month / jan 'january' feb 'fabruary' mar 'march' /; execute_unload "sets.gdx"; execute "gdx2sqlite -i sets.gdx -o sets.db -expltext";	sqlite>select * from month; month expltext ---------- ---------- jan january feb fabruary mar march

6.16.3.3 Parameters

n-dimensional parameters will have n index columns plus a value column. Scalars are collected in a separate table.

GAMS	SQLite
Set i / i1*i4 /; Parameter p(i); p(i) = uniform(0,1); Scalar s1 / 10 / s2 / 20 /; execute_unload "data.gdx"; execute "gdx2sqlite -i data.gdx -o data.db";	sqlite>select * from p; i value ---------- ---------- i1 0.171747132 i2 0.843266708 i3 0.550375356 i4 0.301137904 sqlite>select * from scalars; name value ---------- ---------- s1 10.0 s2 20.0

6.16.3.4 Variables and Equations

n-dimensional variables and equations have besides n index columns also columns for the level, the lower and upper-bound and the marginal. Scalars are collected in the tables scalarvariables and scalarequations. Note that INF and -INF are mapped to 1.0e100 and -1.0e100. The special value EPS is exported as zero. To be complete: UNDEF, NA and acronyms are exported as NULLs.

GAMS	SQLite
Set i / i1*i4 /; Positive Variable x(i); x.l(i) = uniform(0,1); Variable z; z.m = 1; execute_unload "data.gdx"; execute "gdx2sqlite -i data.gdx -o data.db";	sqlite>select * from x; i level lo up marginal ---------- ---------- ---------- ---------- ---------- i1 0.171747132 0.0 1.0e+100 0.0 i2 0.843266708 0.0 1.0e+100 0.0 i3 0.550375356 0.0 1.0e+100 0.0 i4 0.301137904 0.0 1.0e+100 0.0 sqlite>select * from scalarvariables; name level lo up marginal ---------- ---------- ---------- ---------- ---------- z 0.0 -1.0e+100 1.0e+100 1.0

6.16.3.5 Fixing up names

A database table is not allowed to have columns with the same name. If a name clash is detected new names may be invented.

GAMS	SQLite
`Set i / i1*i4 /; Parameter p(i,i); p(i,i) = 1;` `execute_unload "data.gdx"; execute "gdx2sqlite -i data.gdx -o data.db";`	`sqlite>select * from p; i i2 value ---------- ---------- ---------- i1 i1 1.0 i2 i2 1.0 i3 i3 1.0 i4 i4 1.0`

6.16.3.6 Speeding up writing data

With the `-small` option we write data in a slightly different format. Instead of using strings for the GAMS indices we write integers. The integers can be looked up in a separate table `UEL$` were the GAMS UELS (Unique Elements) are stored. We export an SQL view for each symbol to hide the complexities of the joins needed to replace the integers by strings.

For more information see: http://yetanothermathprogrammingconsultant.blogspot.com/2014/06/big-data-cube

The `-fast` option will set some SQLite pragmas that can speed up the inserts. Basically they will give up some consistency in case the program crashes, in which case the created database may be invalid.

For more information see: http://yetanothermathprogrammingconsultant.blogspot.com/2014/07/a-little-bit-

6.16.4 SQLite Browsers and compatible software

6.16.4.1 SQLite3.exe

From the distribution on http://www.sqlite.org/download.html a command line tool is available that functions as shell for SQLite. An example session can look like:

```
C:\projects\impact3\sqlite>sqlite3.exe data.db
SQLite version 3.8.0.2 2013-09-03 17:11:13
Enter ".help" for instructions
Enter SQL statements terminated with a ";"
sqlite> .schema
CREATE TABLE [i]([i] TEXT);
CREATE TABLE [p]([i] TEXT,[i2] TEXT,[value] REAL);
sqlite> select * from p;
i1|i1|1.0
i2|i2|1.0
i3|i3|1.0
i4|i4|1.0
sqlite> .quit

C:\projects\impact3\sqlite>
```

6.16.4.2 SQLite Studio

A visual front-end can be downloaded from http://sqlitestudio.pl/.

6.16.4.3 SQLite Database Browser

Another visual browser is available from http://sqlitebrowser.sourceforge.net/.

6.16.4.4 SQLite and R

The statistical software R can conveniently use SQLite data, and can be called from a GAMS environment as follows:

```
$onText
Get data from GAMS into R via SQLite
$offText

$set IMPACTPATH     c:\projects\impact3\impact_3\IMPACTv3.0
$set SCRIPT         script.R
$set RPATH          "C:\Program Files\R\R-3.0.2\bin\R.exe"
$set DB             mapdata.db

Set cty;
$gdxIn %IMPACTPATH%\GDXs\Sets.gdx
$load cty

display cty;

Set maps / data1 'uniform random data between 0 and 1'
           data2 'uniform random data between 0 and 2' /;

Parameter mapdata(cty,maps);
mapdata(cty,"data1") = uniform(0,1);
mapdata(cty,"data2") = uniform(0,2);

execute_unload "mapdata.gdx";
execute "gdx2sqlite -i mapdata.gdx -o %DB% -expltext";
execute '"%RPATH%" --vanilla < %SCRIPT%';

$onEcho > %SCRIPT%
if (!require(RSQLite)) {
   install.packages("RSQLite", repos="http://cran.r-project.org")
   library(RSQLite)
}

sqlite<-dbDriver("SQLite")
db <- dbConnect(sqlite,"%DB%")
dbListTables(db)

maps<-dbGetQuery(db,"select * from maps")
maps

mapdata<-dbGetQuery(db,"select * from mapdata")
mapdata
$offEcho
```

6.16.4.5 SQLite and Python

Python has built-in support for SQLite:

```
import sqlite3

db = sqlite3.connect("turkey.db")

c = db.execute("select * from yieldl")
for row in c:
     print row

db.close()
```

6.16.4.6 SQLite ODBC Driver

ODBC is a database access layer for Windows. It allows many Windows programs that need to talk to databases to do this in a database independent manner. The SQLite ODBC driver can be downloaded from: http://www.ch-werner.de/sqliteodbc/.

6.16.4.7 SQLite and Excel

Excel can read SQLite database files through ODBC.

Import as Table

To import a table from a SQLite database perform the following steps:

1. Select the Data tab and choose Get External Data From Other Sources
2. Choose the Data Connection Wizard
3. Choose ODBC DSN
4. Select SQLite3 Datasource
5. Enter the name and path of the database file and press OK.
6. Choose a table from the database.
7. Give this selection a name.
8. Choose Import as Table

The result is a table:

Import as Pivot Table

The same steps can be used to import as Pivot Table. This way we can easily create summary reports, such as:

6.17 GDX2VEDA

Translates a GDX file into the VEDA format.

6.17.1 Usage

```
gdx2veda gdx vdd [run]
```

gdx

GAMS GDX file

vdd

VEDA Data Definition file

run

VEDA Run identifier (optional)

The VEDA data file name and run identifier are either taken from the gdx file name or specified with the run name. Use "token with blanks" if needed.

6.17.2 Examples

This example dumps the gdx symbols:

```
gdx2veda mygdx
```

This exmaple prints usage and example:

```
gdx2veda
```

To print more detailed help message:

```
gdx2veda --help
```

Add .csv to the run name to write in csv format

6.17.3 Detailed Help Message

6.17.3.1 VDD file Summary

```
[DataBaseName]
 myveda

[Dimensions] cube dimensions
 long_name tuple_element1 tuple_element2 ...

[DataEntries] data for the cube
 long_name gams_name tuple_element1 tuple_element2 ...

[DimensionText] for generating .vde file (only for data in [DataEntries])
 gams_set tuple_element1 tuple_element2 ...

[DimensionTextAll] for generating .vde file (also for data not in [DataEntries])
 gams_set tuple_element1 tuple_element2 ...

[SubSets] for generating .vds file
 sub_name gams_name tuple_element1 tuple_element2 ...

[ParentDimension] defines parent-child structure
 parent_tab  child_tab1 child_tab2 ...

[ParentDimensionTextAll] .vde file definitions with parent-child structure
2d_gams_set  parent_tab child_tab
2d_gams_set  child_tab parent_tab

[ParentSubSets] .vds file definitions with parent-child structure
sub_name 2d_gams_set parent_tab child_tab
sub_name 2d_gams_set child_tab parent_tab

[Options]
TupleSeparator "string"  use a different separator symbol between tuple elements
ShowAllSeparators        don't squeeze unnecessary separators
RelaxDimensionAll        relax strict dimensionality checks in DimensionText(All) sections.
ValueDim n               if n=2 write PV/DV value pairs for VEDA
SetsAllowed dim1 dim2 .. write SetsAllowed specification line to VEDA .vd file
Scenario scenarioSet     specify the scenario set; a record with expl text goes to .vde
Format veda/csv          specify the format of the data files
Not-0 attribute ...      don't write records with zero values for these attributes

[SpecialValues]
EPS "string"             value to be used for EPS
INF "string"             value to be used for +INF
MINF "string"            value to be used for -INF
NA "string"              value to be used for NA
UNDEF "string"           value to be used for UNDEF
```

<myveda>

is usually the application name which will be displayed on the top of the VEDA splash screen. When a new VEDA database is created, a new folder with this name will appear:

`...veda\database\mayveda_date_time.`

Where data and time are the creation time stamp.

<tab_name>

corresponds to the tabs of your VEDA screen

Lines starting with ∗ and empty lines are ignored. Blanks, commas and tabs are delimiters, blanks before and after delimiters are ignored. Quotes around data items are optional. The input data is NOT case sensitive.

6.17.3.2 Veda Data Definition file

Example of a Veda Data Definition file:

```
* Transport model

[DataBaseName]
myveda

[Dimensions]
* tab-name indices
Plants     i
Warehouses j
Links      ii jj

[DataEntries]
* veda_attribute gams_name tab1 tab2 ... for gams index 1, 2, ...
"x(i,j) duals" x.m      i  Warehouses
Shipments      x.l      i  j
SupplyPrice    supply.m i
DemandPrice    demand.m j
TransportCost  c        i  j
Distance       d        ii jj
Supply         a        i
Demand         b        j
TotalCost      z.l
SupplyNodes    i        i
DemandNodes    j        j
Rate           f

[DimensionText]
* gams_set tab
i  i

[DimensionTextAll]
* gams_set tab
j  j

[SubSets]
* sub_name gams_name tab
i1 ic  Plants
i1 id  i
```

Notes:

The long name from the `[Dimensions]` section can be used as a macro that expands to the tuples it defines. E.g. "Links" is identical to "ii jj".

In the `[DataEntries]` section a literal tuple element can be defined as `/element/`.

When `ValueDim=2`, the `[DataEntries]` section can contain `X.LM` entries, indicating both `.L` and `.M` needs to written as a pair.

6.18 GDX2XLS

A Tool to convert GDX data to MS Excel spreadsheets.

Author

Erwin Kalvelagen

Date

June 10, 2005; December 6, 2006

This document describes the GDX2XLS utility which allows to convert data stored in a GDX file into Excel spreadsheets.

6.18.1 Overview

Attention

GDX2XLS is deprecated (see GAMS 42 GDX2XLS release notes). Please use Connect agent ExcelWriter instead.

GDX2XLS is a tool to dump the complete contents of a GDX file to an MS Excel spreadsheet file (.xlsx or .xls file). Every identifier gets its own sheet in the .XLSX file. Excel 2007 or more recent versions will default to an xlsx file; versions before that default to the .xls file format. For instance when we save the results of the trnsport model from the model library:

```
C:\tmp>gamslib trnsport
Model trnsport.gms retrieved

C:\tmp>gams trnsport gdx=trnsport lo=2

C:\tmp>gdxdump trnsport.gdx symbols
   Symbol Dim Type Records  Explanatory text
 1 a        1  Par       2  capacity of plant i in cases
 2 b        1  Par       3  demand at market j in cases
 3 c        2  Par       6  transport cost in thousands of dollars per case
 4 cost     0  Equ       1  define objective function
 5 d        2  Par       6  distance in thousands of miles
 6 demand   1  Equ       3  satisfy demand at market j
 7 f        0  Par       1  freight in dollars per case per thousand miles
 8 i        1  Set       2  canning plants
 9 j        1  Set       3  markets
10 supply   1  Equ       2  observe supply limit at plant i
11 x        2  Var       6  shipment quantities in cases
12 z        0  Var       1  total transportation costs in thousands of dollars

C:\tmp>
```

The example shows how we copy the trnsport.gms model from the model library, and then solve it. The option gdx=filename will save the complete symbol table to a GDX file. The option lo=2 tells GAMS to save the log to a file (in this case trnsport.log) instead of writing it to the screen. The gdxdump will display the contents of the GDX file (the option symbols will only display the table of contents, rather than all data)

Once we have a GDX file we can use GDX2XLS to create an .XLSX file:

```
C:\tmp>gdx2xls trnsport.gdx
GDX2XLS          34.1.0 r644dbd9 Released Jan 29, 2021 WEI x86 64bit/MS Window
Output file: C:\tmp\trnsport.xlsx
C:\tmp>
```

The resulting XLSX file, opened with MS Excel is shown in Figure 1. The first page is the Table of Contents page with all identifiers sorted alphabetically. When clicking on variable `x`, the sheet shown in Figure 2 is displayed.

The table of contents can be reached again by clicking on the `TOC` link in the top left corner. The complete process shown here can be automated as is shown in section Model gdx2xls1: import trnsport.gdx. As can be seen, every identifier is stored in its own sheet. Index positions get a column with labels showing their domains, or `dim1`, `dim2`, etc. if domain information is not available. By default scalar quantities are collected in a single sheet called `scalar`.

6.18.2 AutoFilter

By default the exported tables are organized in `AutoFilter` tables. This will allow you to easily make selections and sort the results.

It is possible to set filters for different columns. Only the rows that meet the criteria will be shown. The columns used in the filter can be recognized by having a blue arrow instead of a black one in the drop down menu header.

Sorting can also be performed on multiple columns: e.g. first sort on one column, then sort on a second column.

The autofilter generation can be turned off using an option in the .ini file.

6.18.3 Options

6.18.3.1 Default ini file

Options are specified in an .INI file. By default, the file `gdx2xls.ini` located in the same directory as `gdx2xls.exe` is consulted. If this file is not available, the program will continue using default settings.

6.18.3.2 Custom ini file

It is also possible to tell the program to use a different .ini file. This is done by using an extra argument of the form `@inifile`. An example would be:

```
C:\TMP> gdx2xls myfile.gdx @myinifile.ini
```

In this case the program will not read `gdx2xls.ini` located in the same directory as `gdx2xls.exe` but rather `myinifile.ini` in the current directory.

The ini file can contain two sections: `[settings]` and `[colors]`. A complete ini file with all possible settings looks like:

```
[settings]
inf=INF
mininf=-INF
eps=EPS
na=NA
undf=INDF
scalarsheet=1
tableformatting=1
toc=1
sorttoc=1
autofilter=1
freezeheader=1
indexformat=
valueformat=

[colors]
header=17
body=19
italics=48

[xmlcolors]
link=#0000FF
header=#9999FF
body=#FFFFCC
italics=#969696
```

6.18.3.3 Settings section

A complete description for the `[settings]` section is:

[settings]	Description
inf	Special values may need to be mapped to numeric values so the values can be used in formula's etc. This setting will specify the value for the GAMS `INF` quantity. The default is the string `INF`.
mininf	This is the mapped value for `-INF`. The default is `-INF`.
eps	This is the mapped value to be used for `EPS`. The default is `EPS`.
na	This is the mapped value to be used for `NA`. The default is `NA`.
undf	This is the mapped value to be used for `UNDF`. The default is `UNDF`.
scalarsheet	When this parameter is set to 1, GDX2XLS will generate a separate sheet to collect scalar parameters, scalar equations and scalar variables. This can reduce the number of sheets created with just a single data item. The name of the sheet is fixed: `scalar`. By default this option is turned on.
tableformatting	If this option is turned on, extra table formatting is used (adding colors, etc.) to make the tables look better. If this is not needed, this option can be turned off. Default: `tableformatting=0`.
toc	Whether or not to add a {*Table* of Contents} sheet. Default is to generate such a table.
sorttoc	Whether or not to sort the table of contents alphabetically. If turned off, the table will be displayed in the order in which the identifiers appear in the GDX file. Default is to sort.
autofilter	Automatically generate `AutoFilter` enabled tables in Excel.
freezeheader	Keep headers fixed so they don't scroll off the screen.
indexformat	Custom format for index columns. By default this is an empty string.
valueformat	Custom format for value columns. By default this is an empty string.

An example of setting special values can be found in section Model gdx2xls4: special value mapping.

6.18.3.4 Colors section

A complete description for the `[colors]` section is:

[colors]	Description
header	The colorindex to be used as background for table headers. Default is 17.
body	The colorindex to be used as background for table bodies. Default is 19.
italics	The colorindex to be used for the font when writing explanatory text. The default is light grey (color index 48).

The `[xmlcolors]` section is used to specify colors in the XML file to be generated.

6.18.3.5 Custom formats

The format strings consists of four pieces:

```
[format for $x>0$];[format for $x<0$];[format for $x=0$];[format for strings]
```

An example given in the Excel help is:

```
#,###.00_);[Red](#,###.00);0.00;"sales "@
```

The codes used here have the following meaning:

Formatting Characters	Description
# (number sign)	displays only significant digits and does not display insignificant zeros.
, (comma)	To display a comma as a thousands separator or to scale a number by a multiple of one thousand, include a comma in the number format.
0 (zero)	displays insignificant zeros if a number has fewer digits than there are zeros in the format.
_ (underscore)	To create a space the width of a character in a number format, include an underscore, followed by the character. For example, when you follow an underscore with a right parenthesis, such as `_)`, positive numbers line up correctly with negative numbers that are enclosed in parentheses.
[color]	One of `[Black]`, `[Blue]`, `[Cyan]`, `[Green]`, `[Magenta]`, `[Red]`, `[White]`, `[Yellow]`.
@ (at sign)	Include an at sign (`@`) in the section where you want to display any text entered in the cell.

Additional formatting characters include:

Formatting Characters	Description
? (question mark)	adds spaces for insignificant zeros on either side of the decimal point so that decimal points align when formatted with a fixed-width font, such as Courier New. You can also use ? for fractions that have varying numbers of digits.
condition	Conditions can be specified as follows: `[Red][<=100];[Blue][>100]`.
exponent	To display numbers in scientific format, use exponent codes in a section, for example, `E-`, `E+`, `e-`, or `e+`.

A useful format is:

```
[settings]
valueformat=#.????
```

which aligns numbers on the decimal point and depicts zero's as dots just as the listing file is doing.

6.18.4 Examples

6.18.4.1 Model gdx2xls1: import trnsport.gdx

This example will solve the `trnsport.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a small example that should run very quickly.

```
$onText
Test of GDX2XLS. Dumps all symbols of
trnsport.gms to trnsport.xlsx.
$offText

execute '=gamslib trnsport';
execute '=gams trnsport lo=3 gdx=trnsport';
execute '=gdx2xls trnsport.gdx';
executeTool 'win32.shellExecute trnsport.xlsx';
```

Notes: the equal signs in from of the external programs indicate we don't go through a shell (e.g. `command.com` or`cmd.exe`). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=' such errors go undetected and the GAMS model will continue.

The command 'executeTool 'win32.shellExecute trnsport.xlsx';` will launch Excel to view the .XLSX file.

6.18.4.2 Model gdx2xls2: import indus89.gdx

This example will solve the `indus89.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a fairly large GDX file, with many identifiers, resulting in many sheets in the workbook.

```
$onText
Test of GDX2XLS. Dumps all symbols of
indus89.gms to indus89.xlsx. This takes
longer as there is a large number of symbols.
$offText

execute '=gamslib indus89';
execute '=gams indus89 lo=3 gdx=indus89';
execute '=gdx2xls indus89.gdx';
executeTool 'win32.shellExecute indus89.xlsx';
```

6.18.4.3 Model gdx2xls3: a large table

This is an artificial example where we generate a large identifier in GAMS: a parameter with as many elements as the number of rows that Excel can handle.

```
$onText
Test of GDX2XLS. Single symbol with 65536-3=65533 records.
Maximum rows that XLS can handle is 65536; an XLSX file allows for slightly more than a million rows
$offText

Set i / i1*i65533 /;

Parameter p(i);
p(i) = uniform(-100,100);
execute_unload 'test.gdx', p;

execute '=gdx2xls test.gdx';
executeTool 'win32.shellExecute test.xlsx';
```

If you create a spreadsheet with too many rows, the XLSX file writer will return `OLE error 800A03EC`. When generating an XML file, an error will occur when Excel loads the file.

6.18.4.4 Model gdx2xls4: special value mapping

To store special values like `INF`, `EPS`, `NA` in a numeric field in the database, GDX2XLS uses a mapping. This mapping can be changed using an INI file.

```
$onText
Test of GDX2XLS.
Check special value mapping.
$offText

$onEcho > m.ini
[settings]
inf=1.0e100
mininf=-1.0e100
eps=0.0
na=#NA!
undf=#UNDF!
$offEcho

Parameter p(*) / i1 inf, i2 -inf, i3 eps, i4 na /;
p('i5') = 1/0;
display p;

* save parameter p in p.xlsx
* special values are translated to default values:
execute_unload "p.gdx", p;
execute '=gdx2xls p.gdx';
executeTool 'win32.shellExecute p.xlsx';

* save parameter p in q.xls using new mapping
* INF -> 1.0e100  (numeric)
```

```
* -INF -> -1.0e100  (numeric)
* EPS -> 0.0  (numeric)
* NA -> #NA! (string)
* UNDF -> #UNDF! (string)
*
execute_unload "q.gdx", p;
execute '=gdx2xls q.gdx @m.ini';
executeTool 'win32.shellExecute q.xlsx';
```

Numeric values are important if you want Excel being able to operate on these numbers.

6.18.4.5 Model gdx2xls8: custom format

We use a custom value format to color the different values `x<0`, `x=0`, `x>0` differently. Also align on the decimal point.

```
$onText
GDX2XLS example: use of custom format
$offText

$onEcho > mexls.ini
[settings]

execute '=gdx2xls mexls.gdx @align.ini';
executeTool 'win32.shellExecute align.xlsx';
```

6.19 GDXCOPY

GDX files from different GAMS version can possibly be incompatible. A current GAMS system can read all older GDX file formats. The GDXCOPY utility provides a mechanism to convert GDX files to a format that different GAMS systems can read.

6.19.1 Usage

```
gdxcopy option inFile outDir
```

or

```
gdxcopy option -Replace inFile
```

The first form copies the converted files to a directory; the second form replaces the original file(s).

inFile

Single file or a file pattern with .gdx file extension.

outDir

The output directory.

Instead of converting the files explicitly using the GDXCOPY utility, files can also be converted by using the environment variable GDXCONVERT with values V5, V6 or V7. The values specified will be used together with the value of the environment variable GDXCOMPRESS to call GDXCOPY as soon as a GDX file is created.

The values of the environment variables can also be set using the GAMS parameters GDXCONVERT and GDXCOMPRESS.

Option:

Option	Target format
-V5	Version 5
-V6U	Version 6 uncompressed
-V6C	Version 6 compressed
-V7U	Version 7 uncompressed
-V7C	Version 7 compressed

A current GAMS system can always handle older GDX file formats. The GDXCOPY utility provides a mechanism to convert GDX files to a prior format, so an older GAMS system can read these files.

Notes:

- Version 7 formatted files were introduced with version 22.6 of GAMS; version 6 formatted files were introduced with version 22.3 of GAMS. Prior versions used version 5.

- Some features introduced in version 7 of the GDX file format cannot be represented in older formats.

Feature	Action taken
Dimension > 10	Symbol is ignored
Identifier longer than 31 characters	Truncated to 31 characters
Unique element longer than 31 characters	Truncated to 31 characters
Domain of a symbol	Domain is ignored
Aliased symbol	Symbol is entered as a set
Additional text for symbol	Additional text is ignored

- The macOS systems do not support GDX conversion into format version 6 and version 5.

6.19.2 Example

In the example below we convert all GDX files to a compressed format for version 6.

```
dir
  1,219 t1.gdx
  1,740 t0.gdx
889,973  i.gdx
  1,740 pv.gdx
894,672 bytes

gdxcopy -v6c *.gdx newdir
dir newdir
  1,219 t1.gdx
  1,219 t0.gdx
203,316  i.gdx
  1,219 pv.gdx
206,973 bytes
```

6.20 GDXDIFF

The GDXDIFF tool compares the data of symbols with identical name, type and dimension in two GDX files and writes the differences to a third GDX file. A summary report will be written to standard output.

6.20.1 Usage

```
gdxdiff file1 file2 {diffile} {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. GDXDIFF requires two parameters, the file names of two GDX files. An optional third parameter is the name of the GDX difference file. Without the third parameter, the difference file will be diffile.gdx in the current directory.

diffile = *fileName* (default = diffile.gdx)

An optional name of the GDX difference file.

6.20.2 Options

The following options can be used when calling GDXDIFF:

Option	Default	Description
Eps	0.0	Epsilon for comparison (absolute).
RelEps	0.0	Epsilon for comparison (relative).
field	all	Specify a single subfield (`l`, `m`, `up`, `lo`, `prior`, `scale`) of a variable or equation to be compared.
fldOnly	disabled	Write variables and equations as parameters for the selected subfield.
id	all	Define specific identifiers of the GDX files to be compared.
diffOnly	disabled	Controls if differences of variables and equations will be written as parameters or not.
cmpDefaults	disabled	Enables the comparison of default values.
cmpDomains	disabled	Enables the comparison of symbol domains.
matrixFile	disabled	Enables the comparison of GAMS matrix files in GDX format.
ignoreOrder	disabled	Ignores UEL order of input files to reduce size of output file.
setDesc	Y	Control if associated text of matching set elements is compared.

Some more detailed remarks on the options:

Eps = *value* (default = 0.0)

Absolute difference for comparisons; see also Comparing numeric values. If the difference between two values exceeds `Eps`, a difference will be reported. The valid range is

RelEps = *value* (default = 0.0)

Relative difference for comparisons; see also Comparing numeric values. If the value of `RelEps` is exceeded, a difference will be reported.

field = *fieldName* (default = all)

The specified subfield is the only field used for deciding if a variable or equation is different. FieldName is one of the following: `l`, `m`, `up`, `lo`, `prior`, `scale` or `all`.

fldOnly (disabled by default)

Used in combination with the field option; The variables and equations will be written as parameters for the selected subfield. This option cannot be used in combination with diffOnly and requires field being set to an actual field name but not to `all`.

id = *identifier* (default = all)

Limits the comparison to one or more symbols; symbols not specified will be ignored. Multiple identifiers can be specified as: `id=id1 id=id2` or as `id="id1 id2"`. When using `GDXDIFF` from the menu bar in the GAMS IDE (Utilities), this option is not available.

diffOnly (disabled by default)

Differences for variables and equations will be written as parameters; each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option cannot be used in combination with `fldOnly`.

cmpDefaults

Enables the comparison of default values. When using `GDXDIFF` from the menu bar in the GAMS IDE (Utilities), this option is not available.

cmpDomains (disabled by default)

Enable the comparison of symbol domains. Note that the difference are not listed in particular in the diffile. When using `GDXDIFF` from the menu bar in the GAMS IDE (Utilities), this option is not available.

matrixFile

This activates a special mode to compare GAMS matrix files in GDX format. This is mostly done for internal use. When using `GDXDIFF` from the menu bar in the GAMS IDE (Utilities), this option is not available.

ignoreOrder

By default, GDXDiff preserves the UEL order of the input files. If this is set, this is disabled so that records in the output file could show up in a different order than in the input files. Doing this, the output file can be reduced in size.

setDesc = *boolean* (default = `Y`)

Enable or disable the comparison of associated texts for set elements.

Criterion for comparing numeric Values
The use of Eps and RelEps is best described by the code fragment below.

```
AbsDiff := Abs(V1 - V2);
if  AbsDiff <= EpsAbsolute
then
  Result := true
else
  if EpsRelative > 0.0
  then
     Result := AbsDiff / (1.0 + DMin(Abs(V1), Abs(V2))) <= EpsRelative
  else
     Result := false;
```

Interpreting the Labels in the diffile
Only symbols with the same name, type and dimension will be compared. Tuples with different values are written to the GDX difference file, and a dimension is added to describe the difference using the following labels:

- `ins1` indicates that the tuple only occurs in the first file.
- `ins2` indicates that the tuple only occurs in the second file.
- `dif1` indicates that the tuple occurs in both files; contains the value from the first file.
- `dif2` indicates that the tuple occurs in both files; contains the value from the second file.

6.20.3 Examples

6.20.3.1 Compares two GDX Files and writes the Differences to a third GDX File

In the following example, the [**trnsport**] model is solved twice with different capacity data. GDX files are saved for each run, and compared afterwards using `GDXDIFF`. The shipments variable is loaded into a new variable used for a display statement. We introduce four new unique elements that are used in the difference file.

```
* solve and write to unmodified.gdx before manipulating the data
solve transport using lp minimizing z;
execute_unload 'unmodified.gdx', a, x;

* manipulate the data and solve again, write to modified.gdx
a('seattle') = 1.2*a('seattle');
solve transport using lp minimizing z;
execute_unload 'modified.gdx', a, x;

execute 'gdxdiff unmodified modified diffile > %system.nullfile%';

* Declare symbols to hold the data for differences
Set difftags / dif1, dif2, ins1, ins2 /;
Variable xdif(i,j,difftags);
Parameter adif(i,difftags);

execute_load 'diffile' adif=a, xdif=x;
display a, xdif.l;
```

The display statement generates the following output in the listing file:

```
----    101 PARAMETER a  capacity of plant i in cases

seattle   420.000,    san-diego 600.000

----    101 VARIABLE xdif.L

                           dif1        dif2

seattle  .new-york       50.000     120.000
san-diego.new-york      275.000     205.000
```

Alternatively, one can open the diffile in GAMS Studio to display the differences.

This example is also part of the GAMS Data Utilities Library, see model [**GDXDIFFExample16**] for reference.

6.21 GDXDUMP

`GDXDUMP` is a tool to write scalars, sets, parameters (tables), variables and equations from a GDX file formatted as a GAMS program with data statements to standard output, GMS or CSV files. To write to a file, use the output redirection '>' provided by the operating system or the output option of `GDXDUMP`.

6.21.1 Usage

```
gdxdump filename {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.21.2 Options

The table summarizes the options of GDXDUMP. Running GDXDUMP without any arguments will write the sets, parameters, scalars etc. to standard output formatted as a GAMS program with data statements.

Option	Default	Description
output	none	Specify the output filename.
version	disabled	Writing version information only.
symb	none	Specify a single identifier to be written from the GDX.
UelTable	none	Write all unique elements in the GDX to a single set.
delim	if format=normal: period if format=csv: comma	Specify a delimiter to separate elements in the output.
decimalSep	period	Specify a decimal separator.
noHeader	disabled	Suppress writing the header information.
header	none	Specify a new header when writing to CSV.
noData	disabled	Only write the headers of the symbols.
CSVAllFields	disabled	Controls the writing of subfields of a variable or equation to CSV.
CSVSetText	disabled	Controls the writing of set element text to CSV.
symbols	disabled	Generate an alphabetical list of all symbols in the GDX file.
symbolsAsSet	disabled	Write some basic information for all symbols in the GDX as set.
symbolsAsSetDI	disabled	Write some basic information including domain information for all symbols in the GDX as set.
domainInfo	disabled	Generate an alphabetical list of all symbols in the GDX file that includes domain information.
setText	disabled	Show the set text (aka the associated text) in the GDX file.
format	normal	Specify the output file format.
dFormat	normal	Specify the numerical format in the output file.
cDim	N	Controls the writing of the column header when using the CSV format.
filterDef	Y	Controls the writing of default values.
EpsOut	EPS	String to be used when writing the value for 'Epsilon'.
NaOut	NA	String to be used when writing the value for 'Not Available'.
pInfOut	+Inf	String to be used when writing the value for 'Positive Infinity'.
mInfOut	-Inf	String to be used when writing the value for 'Negative Infinity'.
UndfOut	Undf	String to be used when writing the value for 'Undefined'.
ZeroOut	0	String to be used when writing the value for 'Zero'.

Some more detailed remarks on the options:

output = *fileName* (default=none)

Write the output to a file. The .gms resp. the .csv file extension must be added when writing to GMS resp. CSV.

This option is demonstrated in Writing GDX to CSV.

-version (disabled by default)

Synonym: -v

Write version information only and terminate; all other options will be ignored.

symb = *identifier* (default=none)

Specify a single identifier in the GDX file to be written to standard output, GMS or CSV. When writing to CSV, one must specify the `symb` option.

This option is demonstrated in Writing GDX to standard output and to GMS.

UelTable = *identifier* (default=none)

Write all unique elements found in the GDX file to a set using the identifier specified as the name for the set.

This option is demonstrated in Writing GDX to standard output and to GMS.

delim = [period, comma, tab, blank, semiColon] (if format=normal: default=period, if format=csv: default=comma)

Selects a different delimiter to separate unique elements; period is the default when writing to standard output or GMS, while comma is the default when writing to CSV.

This option is demonstrated in Writing GDX to CSV.

decimalSep = [period, comma] (default=period)

Specify a decimal separator.

This option is demonstrated in Writing GDX to CSV.

noHeader (disabled by default)

Suppress the header information when writing a single symbol; only the data for the symbol will be written, not its declaration. The option is ignored when writing all symbols. When writing to CSV, the header row can be suppressed by enabling `noHeader`.

This option is demonstrated in Adding double Quotes to an user defined Header when writing to CSV.

header = *string* (default=none)

The string supplied replaces the default header written by the program to a CSV file. If an empty header is desired, the string can be empty; such a string can be written using two single quotes (header=''), while in general it is best to enclose the string with double quotes.

This option is demonstrated in Writing GDX to CSV and Adding double Quotes to an user defined Header whe

noData (disabled by default)

Only write the headers for the symbols; no data is written. The option is ignored when writing to CSV.

CSVAllFields (disabled by default)

When writing a variable or equation to CSV, all fields (level, marginal, lower, upper, and scale) will be written. Without this option, only the level will be written. When writing a set the option control the writing of the element text.

This option is demonstrated in Writing GDX to CSV.

CSVSetText (disabled by default)

When writing a set to CSV, the set element text will be written as the last column in the CSV file in addition to the set elements. Without this option, only the set elements will be written.

This option is demonstrated in Writing GDX to CSV.

symbols (disabled by default)

Generate an alphabetical list of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in Writing GDX to standard output and to GMS.

symbolsAsSet (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, explanatory text) of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in Writing GDX to standard output and to GMS.

symbolsAsSetDI (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, domain information) of all symbols in the GDX file (not valid when writing to CSV).

domainInfo (disabled by default)

Generate an alphabetical list of all symbols in the GDX file that includes domain information (not valid when writing to CSV). The column `DomInf` can have the following values:

`N/A` - The function to get the type of domain information is not available
`None` - No domain was specified (domain is the universe)
`Relaxed` - The domain is relaxed, i.e. the identifiers shown do not necessarily represent one dimensional sets
`Regular` - Regular domain; the identifiers shown are one dimensional sets

This option is demonstrated in Writing GDX to standard output and to GMS.

setText (disabled by default)

Show the set text (aka the associated set text or the set element text) in the GDX file (not valid when writing to CSV).

GDX allows a string of text to be associated with each element of a set. The universe of such strings stored for use in any particular GDX file (i.e. the set text list) can be shown with this option.

format = [normal, gamsbas, CSV] (default=normal)

Change the output format and the symbols written.

When using the gamsbas format, the program will not write the declarations for the symbols and only write the Level and Marginal assignment statements for the variables, and the Marginal assignment statements for equations.

The CSV format adds column headers to the output. By enabling the cDim option the unique elements of the last dimension of the symbol will be used as column headers for the values. If domain information is available, the column headers will be made unique if overlapping names have been used for the names of the index positions. If no domain information is available, the index names used will be of the form `dim1`, `dim2`, ...

In order to run `GDXDUMP`, one must specify a single symbol using the symb option when writing to CSV.

The gamsbas and CSV format is demonstrated in Writing GDX to standard output and to GMS resp. Writing GDX to CSV.

dFormat = [normal, hexponential, hexBytes] (default=normal)

Specify the numerical format in the output file.

cDim = [`Y`, `N`] (default = `N`)

Can be used when writing a CSV file; when enabled, the unique elements of the last dimension will be used as column headers for the values.

This option is demonstrated in Writing GDX to CSV.

filterDef = [`Y`, `N`] (default = `Y`)

When enabled, default values will be filtered and not written. This option is enabled by default. For example, if the Level field (`.L`) of a variable is zero, the value will not be written.

EpsOut = *string* (default = `EPS`)

String to be used when writing the value for 'Epsilon'.

NaOut = *string* (default = `NA`)

String to be used when writing the value for 'Not Available'.

pInfOut = *string* (default = `+Inf`)

String to be used when writing the value for 'Positive Infinity'.

This option is demonstrated in Writing GDX to CSV.

mInfOut = *string* (default = `-Inf`)

String to be used when writing the value for 'Negative Infinity'.

UndfOut = *string* (default = `Undf`)

String to be used when writing the value for 'Undefined'.

zeroOut = *string* (default = 0)

String to be used when writing the value for 'Zero'.

Note that GDX files can also be viewed using the GAMS IDE or GAMS Studio.

6.21.3 Examples

To demonstrate the features of GDXDUMP in the Writing GDX to standard output and to GMS and Writing GDX to CSV examples, we execute the model trnsport.gms ([TRNSPORT] from GAMS Model Library) initially to create the GDX file trnsport.gdx by using the GDX command line option. Afterwards, some important features of GDXDUMP are demonstrated.

```
gams trnsport gdx=trnsport
```

The figure shows the symbol listing of the GDX file in total and the variable x in particular, since those data is used quite often in the following examples:

All subfields of the variable x are shown in the next figure:

6.21.3.1 Writing GDX to standard output and to GMS

In this example, we will demonstrate the effect of some basic features of GDXDUMP.

While we write to standard output in the most sections of this example, one can also write the GDX file contents into a GAMS file using the following command to redirect the output:

```
gdxdump trnsport.gdx > GDXContents.gms
```

Alternatively, the output option can be used to specify an output filename.

Option symbols
This listing shown above can also be written to standard output by using the symbols option of GDXDUMP:

```
gdxdump trnsport symbols
```

The GDXDUMP program writes the following output (except for the numbering and the records column, the content is identical compared to the figure):

```
   Symbol Dim Type Records  Explanatory text
 1 a        1  Par       2  capacity of plant i in cases
 2 b        1  Par       3  demand at market j in cases
 3 c        2  Par       6  transport cost in thousands of dollars per case
 4 cost     0  Equ       1  define objective function
 5 d        2  Par       6  distance in thousands of miles
 6 demand   1  Equ       3  satisfy demand at market j
 7 f        0  Par       1  freight in dollars per case per thousand miles
 8 i        1  Set       2  canning plants
 9 j        1  Set       3  markets
10 supply   1  Equ       2  observe supply limit at plant i
11 x        2  Var       6  shipment quantities in cases
12 z        0  Var       1  total transportation costs in thousands of dollars
```

Option domainInfo
We use the domainInfo option to write some basic information including domain information (column DomInf) to standard output:

```
gdxdump trnsport domainInfo
```

The GDXDUMP program writes the following output:

```
SyNr  Type  DomInf Symbol
  3   Par Regular a(i)
  4   Par Regular b(j)
  7   Par Regular c(i, j)
 10   Equ    None cost
  5   Par Regular d(i, j)
 12   Equ Regular demand(j)
  6   Par    None f
  1   Set    None i(*)
  2   Set    None j(*)
 11   Equ Regular supply(i)
  8   Var Regular x(i, j)
  9   Var    None z
```

Check the domainInfo option explanation linked above to get a full list of possible values for DomInf and their interpretation. In this example, the symbol dimensions were not specified (none) or they are defined on the one dimensional sets i and j (regular).

Option symbolsAsSet
Using the symbolsAsSet option one can write the information displayed by enabling the symbols option to a set declaration:

```
gdxdump trnsport symbolsAsSet
```

The GDXDUMP program writes the following:

```
alias (Symbol, Dim, Type, *)
set    gdxitems(Symbol,Dim,Type)  Items in the GDX file /
"i".1."Set" "canning plants",
"j".1."Set" "markets",
"a".1."Par" "capacity of plant i in cases",
"b".1."Par" "demand at market j in cases",
"d".2."Par" "distance in thousands of miles",
"f".0."Par" "freight in dollars per case per thousand miles",
"c".2."Par" "transport cost in thousands of dollars per case",
"x".2."Var" "shipment quantities in cases",
"z".0."Var" "total transportation costs in thousands of dollars",
"cost".0."Equ" "define objective function",
"supply".1."Equ" "observe supply limit at plant i",
"demand".1."Equ" "satisfy demand at market j"
/;
```

Option symb
One can write a single identifier from the GDX using the symb option:

```
gdxdump trnsport.gdx symb=x
```

The default output includes the declaration header and a data statement when writing a set or parameter. When writing a variable, the output includes the level and marginal subfields:

```
positive Variable x(i,j) shipment quantities in cases /
'seattle'.'new-york'.L 50,
'seattle'.'chicago'.L 300,
'seattle'.'topeka'.M 0.036,
'san-diego'.'new-york'.L 275,
'san-diego'.'chicago'.M 0.00900000000000001,
'san-diego'.'topeka'.L 275 /;
```

Note the default values are not written (for instance, zero values of the level or lower bound subfields are missing).

Option UelTable
Using the UelTable option one can write a set (named `allUELs` in this example) containing all unique elements of the GDX file:

```
gdxdump trnsport output=allUELs.gms UelTable=allUELs
```

The following set declaration will be part of the output file allUELs.gms:

```
Set allUELs /
  'seattle' ,
  'san-diego' ,
  'new-york' ,
  'chicago' ,
  'topeka' /;
```

Format gamsbas
Using the format option one can write a variable or equation in the gamsbas format, i.e. there will be no declaration of the symbol and the level and marginal subfields will be written as assignments.

```
gdxdump trnsport format=gamsbas
```

`GDXDUMP` writes the following to standard output:

```
x.L ('seattle'.'new-york') = 50 ;
x.L ('seattle'.'chicago') = 300 ;
x.M ('seattle'.'topeka') = 0.036 ;
x.L ('san-diego'.'new-york') = 275 ;
x.M ('san-diego'.'chicago') = 0.00900000000000001 ;
x.L ('san-diego'.'topeka') = 275 ;

z.L  = 153.675 ;
cost.M  = 1 ;
supply.M ('seattle') = Eps ;
demand.M ('new-york') = 0.225 ;
demand.M ('chicago') = 0.153 ;
demand.M ('topeka') = 0.126 ;
```

6.21.3.2 Writing GDX to CSV

Next we specify CSV as the output format and demonstrate some simple features available when writing to CSV.

Writing to CSV
One can write to a CSV file by running the following command:

```
gdxdump trnsport.gdx output=varX.csv symb=x format=csv
```

By doing this, the level subfield of the variable `x` is written as a list to the file varX.csv specified in the output statement. The header row contains the domain set identifiers `i` and `j` of `x` and the field "Val":

```
"i","j","Val"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

Option cDim
Using the cDim option one can write the data as a table since the right most dimension is used as the column header:

```
gdxdump trnsport.gdx symb=x format=csv cDim=y
```

We did not specify an output file in this case, so the data will be written to standard output formatted as CSV:

The `GDXDUMP` program writes the following:

```
"i","new-york","chicago","topeka"
"seattle",50,300,0
"san-diego",275,0,275
```

Note the elements new-work, chicago and topeka are written to the header row, since they are elements of the most right dimension `j`.

Customizing the output: CSVAllFields, header, decimalSep, delim, pInfOut etc.
In this section, all subfields of the variable `x` are written to CSV and the representation is customized. The writing of subfields is enabled by CSVAllFields. In addition, the header option is used to overwrite the default header (as seen in the two previous paragraphs). For instance, we want to replace `i` with the term 'canning plants', `j` with the term 'markets' and "Val" with the term 'shipment quantities in cases', while we are fine with the default column labels for the level, marginal etc. subfields, but they will be overwritten, too. Therefore, we must specify them again manually in the `header` option. For some reason, the field separator is changed from comma (default) to semicolon and the decimal separator from period (default) to comma using the delim and decimalSep options. One can define the string written to CSV for special values of GAMS like `+INF` by using the corresponding option pInfOut, which might be useful for further processing of the CSV file.

```
gdxdump trnsport format=csv output=varX.csv symb=x CSVAllFields header="canning plants;markets;shipme
```

GDXDUMP creates the following output:

```
canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale
"seattle";"new-york";50;0;0;1E+100;1
"seattle";"chicago";300;0;0;1E+100;1
"seattle";"topeka";0;0,036;0;1E+100;1
"san-diego";"new-york";275;0;0;1E+100;1
"san-diego";"chicago";0;0,00900000000000001;0;1E+100;1
"san-diego";"topeka";275;0;0;1E+100;1
```

Note that the fields in the header are not enclosed by double quotes. This problem is addressed in the next section Adding double Quotes to an user defined Header when writing to CSV.

Customizing the output: CSVSetText

The set element text is the *value* of a set element. Often this is left out when defining sets, but for descriptive models often set element text is provided. When dumping a set to a CSV file the set element text is not written to the CSV file by default. The option CSVSetText enables the writing of the text. The model mexss.gms ([MEXSS] from GAMS Model Library) has a set i of steel plants with set element text

```
Set i 'steel plants' / ahmsa     'altos hornos - monclova'
                       fundidora 'monterrey'
                       sicartsa  'lazaro cardenas'
                       hylsa     'monterrey'
                       hylsap    'puebla'                  /;
```

When we create a GDX file and dump set i as CSV with defaults via the following commands

```
gamslib mexss
gams mexss a=c gdx=mexss
gdxdump mexss format=csv output=setI.csv symb=i header="steel_plants"
```

GDXDUMP creates the following output:

```
steel_plants
"ahmsa"
"fundidora"
"sicartsa"
"hylsa"
"hylsap"
```

If we add CSVSetText

```
gamslib mexss
gams mexss a=c gdx=mexss
gdxdump mexss format=csv output=setI.csv symb=i CSVSetText header="steel_plants,real_name"
```

GDXDUMP creates the following output:

```
steel_plants,real_name
"ahmsa","altos hornos - monclova"
"fundidora","monterrey"
"sicartsa","lazaro cardenas"
"hylsa","monterrey"
"hylsap","puebla"
```

6.21.4 Adding double Quotes to an user defined Header when writing to CSV

This sections describes a possible workaround for the following problem: Suppose one wish to write a parameter or variable from GDX to CSV, but with a non default header containing double quotes. For this purpose, one might try to use the `header` option of `GDXDUMP` to specify an user defined header. Though, there is no way to add double quotes enclosing the single fields using the `header` option, but this is a quite common standard in CSV files (for instance, if the fields contain reserved characters).

Initially, define the header you want to write to the CSV file and redirect the line to your final CSV file (which will be created at this point, an already existing file will be overwritten!). Note the double quotes enclosing the field content. Adding the single quotes is necessary in order to run the following statement from GAMS IDE (however, they will not be written to the file), while they must be omitted when using the command prompt.

```
$echo '"canning plants","markets","shipment quantities in cases"' > quotedHeader.csv
```

Afterwards, call `GDXDUMP` by specifying the GDX file, the single symbol `x` we want to write, the output format CSV and redirect the output to the file quotedHeader.csv:

```
$call gdxdump trnsport.gdx symb=x format=csv noHeader >> quotedHeader.csv
```

Appending the output of the recent `GDXDUMP` call to the already existing file quotedHeader.csv adds the data of `x` to the file and creates the following CSV file (note that one must prevent `GDXDUMP` to write the default header by using the command noHeader):

```
"canning plants","markets","shipment quantities in cases"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

6.22 GDXEncoding

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This converts the unique elements in the GDX file from one [encoding] (https://docs.python.org/3/library/codecs.ht
to another one. The GDX string (a sequence of bytes) is decoded using *encodingIn* (default `latin_1`) into a proper unicode string and afterwards encoded again into a GDX string (byte array) using *encodingOut* (default `utf_8`). If *verbose* is set to 1 (default is 0) the converted unique elements are printed with new and old GDX strings (byte arrays) to the GAMS log. If the number of conversions is necessary in GAMS, a name of a scalar can be passed via *numConv* (default empty) which will hold the number of unique elements converted.

6.22.1 Usage

Command line:

```
gamstool [gdxservice.]GDXEncoding gdxFile [encodingIn=codeIn] [encodingOut=codeOut] [numConv=id gdxOu
```

Compile time:

```
$callTool [gdxservice.]GDXEncoding gdxFile [encodingIn=codeIn] [encodingOut=codeOut] [numConv=id]
```

Execution time:

```
executeTool '[gdxservice.]GDXEncoding gdxFile [encodingIn=codeIn] [encodingOut=codeOut] [numConv=id]
```

Where:

| gdxFile | Name of GDX file. |

The following named parameters are available:

Argument	Description
encodingIn=codeIn	Input encoding of GDX string. Default is latin_1
encodingOut=codeOut	Output encoding of GDX string. Default is utf_8.
numConv=id	GAMS scalar symbol to store the number of actual conversions.
gdxOut=fileOut.gdx	Name of GDX file that contains symbol numConv after execution. Mandatory if called from the command line with argument numConv set, otherwise optional.

6.22.2 Example

```
* UTF-8 encoding
Set c / "côte d'ivoire-3" , "cote d'ivoire-3" /;
Scalar numConv /0/;
$gdxUnload c.gdx c
* Changes the label encoding from UTF-8 to Latin-1:
$callTool gdxservice.gdxEncoding c.gdx encodingIn=utf_8 encodingOut=latin_1 numConv=numConv trace=1
```

The complete example is also part of the GAMS Test Library, see model [**gdxencoding1**] for reference.

6.23 GDXMERGE

The program GDXMERGE combines multiple GDX files into a single GDX file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.

6.23.1 Usage

```
gdxmerge filepattern1 filepattern2 .... filepatternN {options}
```

Each file pattern represents a file name or a wildcard representation using ? and ∗. A parameter of the form @filename will process the commands from the text file specified. The result of the GDXMERGE execution will be written to a file called merged.gdx, unless this default is overwritten by the output option.

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.23.2 Options

The following options can be specified:

id = <*ident1*>, <*ident2*>... (default = none)

Only merge the symbols `ident1`, `ident2`, ...

exclude = <*ident1*>, <*ident2*>... (default = none)

Merge all symbols except for `ident1`, `ident2`` , ...

big = <*integer*>

The size for big symbols.

strict = true|false (default = false)

The program terminates with an error (non-zero return code) if input files specified cannot be found or a file pattern results in no files. An already existing output file also triggers an error if strict is set to true.

output = *fileName* (default = merged.gdx)

The optional output file name.

All symbols with matching type and dimension will be merged. By specifying the parameter `id=ident1` the merge process will only be performed for the identifier(s) specified, while `exclude=ident1` indicates that all symbols should be merged except for the ones specified in the `exclude` list. Note that the two options `id` and `exclude` are mutually exclusive.

By default, the program reads all GDX once and stores all data in memory before writing the merged.gdx file. The `big` parameter is used to specify a cutoff for symbols that will be written one at a time. Each symbol that exceeds the size will be processed by reading each GDX file and only process the data for that symbol. This can lead to reading the same GDX file many times, but it allows the merging of large data sets. The formula used to calculate the cutoff is:

`dimension ∗ totalNumberOfElements`.

The calculated value is doubled for variables and equations.

In addition to the symbols written, a set is added to the GDX file representing all the files processed during the merge operation. The name of the set is `Merged_set_1`, and is made unique by changing the number. The explanatory text for each set element contains the date and time of the GDX file processed.

Note

- The file merged.gdx, or the file specified with the output parameter, will never be used in a merge operation even if the name matches a file pattern.
- Symbols with dimension 20 cannot be merged, because the resulting symbol will have dimension 21 which exceeds the maximum dimension allowed by GAMS.

6.23.3 Examples

6.23.3.1 Merging several GDX Files

In this example, we solve the [**trnsport**] model from the GAMS Model Library using different LP solvers. After each run, we write all symbols to a GDX file and merge the files into one file. The variable `X` is read from the merged file and displayed.

```
$call gamslib trnsport
$call gams trnsport lp=cplex gdx=cplex
$call gams trnsport lp=xpress gdx=xpress
$call gams trnsport lp=conopt gdx=conopt
$call gams trnsport lp=minos gdx=minos
$call gams trnsport lp=snopt gdx=snopt
$call gdxmerge *.gdx

Variable AllX(*,*,*);
$gdxIn merged.gdx
$load AllX=X
$gdxIn

option  AllX:5:1:2;
display AllX.L;
```

The display statement generates the following output in the listing file:

```
----     22 VARIABLE AllX.L  shipment quantities in cases

           seattle     seattle   san-diego   san-diego
          new-york     chicago    new-york      topeka

conopt                300.00000   325.00000   275.00000
cplex      50.00000   300.00000   275.00000   275.00000
minos      50.00000   300.00000   275.00000   275.00000
snopt      50.00000   300.00000   275.00000   275.00000
xpress                300.00000   325.00000   275.00000
```

Note that the different solutions are combined into a single symbol of a higher dimension. The filenames (resp. the solver used) are added as unique elements.
Instead of using the display statement, we can also use the GAMS IDE or GAMS Studio to display the merged.gdx file. The following figure shows the contents of merged.gdx after selecting the level subfield of the variable to be displayed and arranging the display:

This example is also part of the GAMS Data Utilities Library, see model [**GDXMERGEExample17**] for reference.

6.23.3.2 Recursively Merging GDX Files

Some users generate data scenarios for a model in a hierarchical way and store the results in a directory tree: The following example demonstrates how to use three independent scenario scalars a, b, and c with values *low*, *medium*, and *high* to generate 3∗3∗3=27 scenarios, store these in a directory tree, and merge them recursively. The resulting GDX file has for each scenario scalar a new dimension which makes this data especially suitable for viewing in a pivot table:

```
----     39 PARAMETER p  commodity price

                                new-york     chicago      topeka

a_high.b_high.c_high.report        0.25        0.17        0.14
a_high.b_high.c_low .report        0.20        0.14        0.11
a_high.b_high.c_med .report        0.23        0.15        0.13
a_high.b_low .c_high.report        0.25        0.17        0.14
a_high.b_low .c_low .report        0.20        0.14        0.11
a_high.b_low .c_med .report        0.23        0.15        0.13
a_high.b_med .c_high.report        0.25        0.17        0.14
a_high.b_med .c_low .report        0.20        0.14        0.11
a_high.b_med .c_med .report        0.23        0.15        0.13
a_low .b_high.c_high.report        0.25        0.17        0.14
a_low .b_high.c_low .report        0.20        0.14        0.11
a_low .b_high.c_med .report        0.23        0.15        0.13
...
```

The GAMS program that creates the directory structure and runs the model for all 27 scenarios looks as follows:

```
set a,b,c;
parameter
    ascen(a<) / a_low 0.9, a_med 1.0, a_high 1.1 /
    bscen(b<) / b_low 0.9, b_med 1.0, b_high 1.1 /
    cscen(c<) / c_low 0.9, c_med 1.0, c_high 1.1 /;

loop((a,b,c),
   put_utility 'shell' / 'mkdir ' a.tl:0 '\' b.tl:0 '\' c.tl:0
   put_utility 'exec'  / 'gams t.gms lo=2 -idir "%gams.wdir%" -curdir ' a.tl:0 '/' b.tl:0 '/' c.tl:0
);
```

The program creates the directory tree (by creating the leave nodes of the tree), changes into the leave directory (`curDir`) and calls GAMS (using `iDir` to point to the starting location). The program `t.gms` is almost an identical copy of the [**trnsport**] model with the last few lines changed:

```
* ...
a(i) = %a%*a(i);
b(j) = %b%*b(j);
c(i,j) = %c%*c(i,j);

solve transport using lp minimizing z;

scalar tmodelstat;
tmodelstat = transport.modelstat;
parameter p(j) 'commodity price';
p(j) = demand.m(j);
execute 'test -d results || mkdir results';
execute_unload 'results/input', a, b, c;
execute_unload 'results/report', x, z, p, tmodelstat;
```

This code saves the results of a run in to GDX files `input.gdx` and `report.gdx` in a `results` subdirectory. After the program has executed the 27 runs of `t.gms` it executes some Python code that walks recursively through the directory tree and merges GDX files it finds in a `results` folder in the leaf nodes percolates the results up in the tree by calling `gdxmerge` on each high node level. The Python function `os.walk` with argument `topdown=False` ensure the walking of the tree in the correct order. The complete example can be found in the GAMS Model Library in model [**scenmerge**]:

```
embeddedCode Python:
import os
gd = -1
for root, dirs, files in os.walk(os.path.normpath(r"C:\Users\test\allscen\ ".rstrip()), topdown=Fals
  if 'results' in dirs:
    if gd == -1:
      gd = root.count(os.path.sep)
      gdr = root;
    elif not gd == root.count(os.path.sep):
      raise NameError('results subdirs found at different depths in the tree: ' + root + ' and ' + g
    cmd = 'cd "' + root + '" && gdxmerge results' + os.path.sep + '* output=' + root.split(os.path.s
    print('Merging results in ' + root)
    if not 0 == os.system(cmd + '>' + os.devnull):
      raise NameError('problems running: ' + cmd)
  elif root.count(os.path.sep) < gd:
    input = ''
    for d in dirs:
      if os.path.isfile(os.path.join(root, d, d + '.gdx')):
        input = input + ' ' + os.path.join(d, d + '.gdx')
    if len(input):
      cmd = 'cd "' + root + '" && gdxmerge' + input + ' output=' + root.split(os.path.sep)[-1]
      print('Merging' + input + ' in ' + root)
      print(cmd)
      if not 0 == os.system(cmd + '>' + os.devnull):
        raise NameError('problems running: ' + cmd)
print('All done. Final result file: ' + root.split(os.path.sep)[-1] + '.gdx')
endEmbeddedCode
```

6.24 GDXMRW

Interfacing GAMS and MATLAB. This document briefly describes GDXMRW (GDX-Matlab Read/Write), a suite of utilities to exchange data between GAMS and MATLAB. The software gives MATLAB users the ability to use all the optimization capabilities of GAMS, and allows visualization of GAMS models directly within MATLAB. The most recent version of GDXMRW is included as part of the current GAMS Distribution.

Attention

GDXMRW is deprecated (see GAMS 38 GDXMRW release notes). Please use **GAMS Transfer Matlab** instead.

6.24.1 Introduction

Optimization is becoming widely used in many application areas as can be evidenced by its appearance in software packages such as Excel and MATLAB. While the optimization tools in these packages are useful for small-scale nonlinear models (and to some extent for large linear models), the lack of a capability to compute automatic derivatives makes them impractical for large scale nonlinear optimization. In sharp contrast, modeling languages such as GAMS and AMPL have had such a capability for many years, and have been used in many practical large scale nonlinear applications.

On the other hand, while modeling languages have some capabilities for data manipulation and visualization (e.g., Rutherford's GNUPLOT), specialized software tools like Excel and MATLAB are much better at these tasks.

This paper describes a link between GAMS and MATLAB. The aim of this link is two-fold. Firstly, it is intended to provide MATLAB users with a sophisticated nonlinear optimization capability. Secondly, the visualization tools of MATLAB are made available to a GAMS modeler in an easy and extendable manner so that optimization results can be viewed using any of the wide variety of plots and imaging capabilities that exist in MATLAB.

In order to enable this link between GAMS and MATLAB, we have implemented MATLAB callable functions that can efficiently import and export data to and from GAMS through GDX files. The simplest read and write functions, `irgdx` and `iwgdx`, deal with indexed parameters. Without getting into their precise meaning, these parameters are essentially indexed in each dimension by the sequence of integers from 1 to the size of that dimension. As an example of the read function, the following command in MATLAB will store the matrices `A` and `B` into the caller workspace after reading from the file `foo1.gdx`:

```
>> irgdx('foo1','A','B');
```

Similarly, the call

```
>> iwgdx('foo2','C','D');
```

would write the matrices `C` and `D` (located in the MATLAB workspace) as indexed parameters into a file named `foo2.gdx`. Note that, many of the examples found in this manual are also part of the GAMS data utilities models library, referred to here as **datalib**. The statements above can be found in datalib example `gdxmrw_intro02_init`. For reading and writing more complex data such as sets, variables, equations, and non-indexed parameters, we can use the more sophisticated functions `rgdx` and `wdgx`. Further descriptions of these functions together with advanced use of `irgdx` and `iwgdx` are detailed in the rest of this paper.

In Section Data Transfer, we discuss the data transfer utilities that allow importing and exporting data between MATLAB and GDX files: `irgdx`, `iwgdx`, `rgdx`, `wgdx`. In Section Extended use, we give a few examples of the MATLAB and GAMS interface. In APPENDIX A - Configuring GDXMRW, we provide information about configuring GDXMRW and testing the utilities. In APPENDIX B - Utility functions: gdxWhos and gdxInfo, we describe additional utility functions, `gdxWhos` and `gdxInfo`, that allow viewing contents of GDX files in the MATLAB console. Finally, in APPENDIX C - Calling GAMS model from MATLAB, we discuss the `gams` function that with a single call initializes a GAMS model with MATLAB data, executes GAMS on the model, and returns results back into MATLAB.

6.24.2 Data Transfer

This paper describes a suite of tools for exchanging data between GAMS and MATLAB. This data exchange is accomplished via the GDX (i.e. the GAMS Data eXchange) interface and API. There are many advantages to using GDX, including platform independence, space and time efficiency in storing and accessing data, and a guarantee that all GDX data contains no duplicates and is free from any logical or syntax errors that might prevent it from being read into GAMS. The GDX interface is well tested, available to the public, and is the basis for most if not all of the GAMS data utilities.

In this section we discuss four MATLAB routines. The first two, `irgdx` and `iwgdx`, are the subject of sections irgdx and iwgdx and are used to quickly and simply read indexed parameters from a GDX file into MATLAB and vice versa. For an example use of these functions, a generic quadratic program function that mimics MATLAB's `quadprog` function is provided in datalib example `gdxmrw_qp3`. The `rgdx` and `wgdx` routines (sections rgdx and wgdx) are more sophisticated versions of the first two that can read and write more general GDX data, e.g. sets, variables, equations, and non-indexed parameters. To understand the structure of this GDX data, the material in section Indexing with labels (UELs) is essential.

6.24.2.1 irgdx

`irgdx` is a specialized MATLAB function to do an efficient import of an indexed parameter from a GDX file. The `irgdx` call will not read non-indexed parameters; it can only read data recognized as an indexed data type. If a GDX file consists of both indexed and non-indexed data, `irgdx` can still read the indexed data. To see whether particular parameters in a GDX file are indexed, the `gdxWhos` function described in APPENDIX B - Utility functions: gdxWhos and gdxInfo can be used.

The syntax and functionality of `irgdx` closely resembles that of the MATLAB `load` function to import MATLAB formatted data, i.e data stored in MAT files. In Basic syntax and Load symbols into output structure we describe the basic modes of operation where the data read from GDX are either stored in the caller workspace or into a MATLAB structure on the left-hand side of an assignment. In MATLAB sparse form, we describe an optional specification that allows read results to be stored in MATLAB sparse form. Finally, in Subsection Renaming, we describe a simple syntax that allows the renaming of variables/parameters without the need to make expensive copies.

Basic syntax

The basic syntax for `irgdx` is

```
irgdx('gdxFileName', 'sym1', 'sym2', ...);
```

The above call will read the indexed parameters named sym1, sym2, and so on from the GDX file whose name is specified in the first argument and store the results in the MATLAB caller workspace. Only the GDX name argument is mandatory. If only this argument is specified (i.e. no symbol names are provided) then *all* of the indexed parameters stored in the GDX file will be loaded into the workspace. The GDX name can be specified with or without the `'.gdx'` extension. Note that all of the input arguments must be specified in string form.

As an example of the above syntax, we can read the scalar a0, the vector a1, and the matrix a2 from the file `idx1_.gdx` with the following command:

```
>> irgdx('idx1_','a0','a1','a2');
```

The three symbols are stored as MATLAB variables a0, a1, and a2 in the caller workspace. If we want to read all the symbols from the file `idx1_.gdx`, we simply call `irgdx` with only the file name:

```
>> irgdx('idx1_');
```

Load symbols into output structure

An alternative to storing the results in the MATLAB caller workspace is to return the results in a MATLAB structure. Here, the syntax is:

```
s = irgdx('gdxFileName','sym1','sym2',...);
```

This call will return the indexed parameters named `sym1`, `sym2`, and so on in the structure s, with fields `s.sym1`, `s.sym2`, and so on containing the values of the respective indexed parameters. The input arguments must all be in string form. Only the GDX name is mandatory; if only this argument is specified, all of the indexed parameters stored in the GDX file will be returned in the output structure. The GDX name can be specified with or without the `.gdx` extension.

For example, the following call returns the values of parameter a2 in the structure s:

```
>> s = irgdx('idx1_','a2');
>> s.a2

ans =

    50    50
    50    50
```

To return all the indexed parameters in the fields of the structure `s`, we would simply call `irgdx` with only the GDX name:

```
>> s = irgdx('idx1_');
```

See datalib example `gdxmrw_irgdx01_init`.

MATLAB sparse form

By default, `irgdx` will store results in MATLAB dense form. However, it is possible to use MATLAB sparse form for parameters with dimension less than or equal to 2; MATLAB's sparse storage scheme cannot handle matrices with more than 2 dimensions. Using sparse storage will allow for efficient import of especially large sparse indexed parameters. Note that in this context *sparse* does not refer to data represented in the form [i,j,...,val] but rather to MATLAB's internal sparse storage scheme. To store a particular symbol in MATLAB sparse form, one can simply append ':s' to that symbol's name in the `irgdx` call. For example, the following call will store the parameter a2 into the caller's workspace in sparse form:

```
>> irgdx('idx1_','a2:s');
```

Note that if we want to store *all* the indexed parameters from a specified file in MATLAB sparse form, we would need to specify each symbol individually in order to append the ':s' to each symbol's name.

Renaming

The details of this section are rather involved; it can be skipped without loss of continuity.

While an `irgdx` call will typically store results in the caller workspace or create field names in the output structure using the symbol names from the GDX file, it is possible to rename the outputs in MATLAB without making potentially expensive copies. To rename a symbol, we can take advantage of MATLAB's default copy-on-write mechanism: when an assignment occurs, the values assigned are not actually copied until one of the values (the original or the copy) is actually changed. For example, after executing the following two lines of code, the variable `a2_new` points to the same memory location as a2 and is *not* a separate copy of a2:

```
>> irgdx('idx1_','a2');
>> a2_new = a2;
```

If however the value of `a2_new` were changed after executing the above lines, MATLAB would then need to make a separate copy, at the cost of memory and time. Now, the command

```
>> clear a2;
```

immediately following the above code would complete the rename of `a2` to `a2_new` as desired. Once `a2` is cleared, we can change `a2_new` without needing to make a copy. Similarly, we can do a rename when we have an output structure:

```
>> s = irgdx('idx1_','a2');
>> s.a2_new = s.a2;
>> s = rmfield(s,'a2');
```

To convince ourselves that this code indeed does not require a copy, we can run the commands in the debug output format. That is, immediately after the assignment of `s.a2` to `s.a2_new` in the above code (before using the rmfield function), we can run the following commands:

```
>> format debug;
>> s.a2

ans =

Structure address = 8c1eda0
m = 2
n = 2
pr = 75fa88a0
pi = 0
    50    50
    50    50

>> s.a2_new

ans =

Structure address = 8c1eda0
m = 2
n = 2
pr = 75fa88a0
pi = 0
    50    50
    50    50
```

Note that the pointer pr is the same for both outputs, implying that MATLAB does not make a separate copy prior to a write. A similar test can also be done when parameters are stored in workspace variables rather than a structure.

6.24.2.2 iwgdx

`iwgdx` is a function that creates a GDX file of indexed parameters from MATLAB data. Since `iwgdx` writes only indexed parameters to GDX, the input MATLAB data is simplified: no labels are required or implied. The input matrices can be stored in the usual (dense) scheme or using the MATLAB sparse scheme: `iwgdx` detects and handles the two cases automatically. Note that matrices represented in `[i,j,...,val]` form are not acceptable as `iwgdx` input.

While the `iwgdx` function is patterned after the `save` function in MATLAB, there are important differences. Firstly, if `only` the file name is specified, the `save` function stores all variables in the caller workspace, while `iwgdx` creates an empty GDX file. The behavior of `iwgdx` in this case also differs from that of `irgdx`, which reads all parameters when only the file name is specified. Secondly, `iwgdx` has an additional pass by reference and renaming syntax, in which the parameter string name and values are passed as two consecutive arguments. In Subsection Basic syntax, we describe the basic syntax for `iwgdx`. In Subsection Pass by reference syntax , we introduce the pass by reference and renaming syntax. Finally, in Subsection Dimensionality specification, we describe an optional dimensionality specification that allows symbols to be written with a larger dimensionality than the default.

Basic syntax

The basic syntax for `iwgdx` is:

```
iwgdx('fileName','sym1','sym2',...);
```

The above call will write the values of the variables sym1, sym2, and so on in the MATLAB caller workspace into a GDX file with the name given by the first input argument. The file name can be specified with or without the '.gdx' extension. If a GDX file with the same name already exists, it will be overwritten. Note that a call with a single input argument (the GDX name) will raise a warning and will create an empty GDX file. This contrasts to the MATLAB save function, which writes all of the workspace variables when none are specified. In the basic form described here, all of the `iwgdx` input arguments are strings.

To illustrate, suppose the matrices a2 and a3 exist in the MATLAB caller workspace. We can write the results of these matrices into a file test.gdx with the following call:

```
>> iwgdx('test','a2','a3');
```

If the file test.gdx already exists, it will be overwritten. Specifying only the file name will create an empty GDX file:

```
>> iwgdx('test');
Warning: an empty gdx file was created.
```

Pass by reference syntax

When using the basic `iwgdx` syntax, a copy of the workspace variable to be written to GDX is made as part of the call. This is unavoidable: the MATLAB executable (MEX) interface only provides functions that return *copies* of workspace variables, most likely to avoid overwriting or corrupting data. However, an alternative, more efficient approach is possible by passing the numeric data as an argument. Essentially, the pointer to the data values are passed by reference and no copy is made. This could be especially useful when writing a large amount of data. An additional benefit of this syntax is the ability to write GDX parameters with different names than used in the MATLAB caller workspace. For example:

```
>> iwgdx('test','s1',s1Mat,'s2',s2Mat);
```

In the above command, `s1` and `s2` are strings holding the GDX parameter names, while `s1Mat` and `s2Mat` are matrices containing the values to store. We can also use a mix of the basic syntax with the pass by reference syntax. For example:

```
>> iwgdx('test','anew',a,'b','c',c);
```

This call would save matrix `a` as anew in GDX without making a copy, would internally make a copy of `b` while saving `b` to GDX, and would save `c` to GDX without renaming or making a copy.

We can do a timing test to see the performance difference between the basic syntax and the pass by reference syntax. The following commands create a 5000x5000 dense matrix consisting of random values in the workspace.

```
>> clear;
>> randMat = rand(5000);
```

First, we do a timing test using the basic syntax:

```
>> delete test.gdx; % delete file if it exists
>> tic;
>> iwgdx('test','randMat');
>> t1 = toc

t1 =

    5.3346
```

Now, we do a timing test using the pass by reference syntax:

```
>> delete test.gdx; % delete file if it exists
>> tic;
>> iwgdx('test','randMat',randMat);
>> t2 = toc

t2 =

    5.1636
```

For the above example, the improvement in time performance is about 3%. Of course, the pass by reference call will also use only the half the memory compared to the basic call. We can expect further improvement in performance time and memory use for even larger data.

Dimensionality specification

It is possible to specify the number of dimensions (i.e. dimensionality) for the symbol written to GDX by appending `:n` to the variable/symbol name, where `n` is the desired dimensionality of the GDX symbol. This feature is motivated by two quirks of the MATLAB environment. Firstly, all scalars and vectors are stored in MATLAB as 2-dimensional matrices. For example:

```
>> s0 = 100
>> s1 = [ 100 ]
```

results in two variables with identical storage schemes: 1x1 matrices. In the MATLAB environment this isn't a problem: things behave as you would expect them to, and the `isscalar`, `isvector`, and `ismatrix` calls are available to interrogate MATLAB about how it views variables. However, in GDX there is a distinction between a scalar (something with 0 dimensions), a parameter with 1 dimension and length 1, and a 1x1 parameter. We need to be able to create GDX files containing any or all of these.

Secondly, MATLAB "flattens" all variables by removing trailing dimensions whose size is 1. For example, after executing

```
>> B = ones(2,2,2)
>> C = ones(2,2,2,1,1)
```

`B` and `C` will be identical 3-dimensional MATLAB arrays, yet we need to be able to create a 2x2x2x1x1 indexed parameter in GDX.

By default, `iwgdx` creates GDX parameters that are consistent with the MATLAB view of the data passed in. For example, executing

```
>> d0 = ones(1,1)
>> d1 = ones(3,1)
>> d2 = ones(3,3)
>> iwgdx('dd','d0','d1','d2')
```

results in indexed parameters with 0, 1, and 2 dimensions, respectively, being written to GDX. However, if we want to write d0 as a vector or matrix or higher-dimensional array, we need to use the optional syntax to specify the dimensionality of the resulting symbol in GDX. For example:

```
>> d0 = pi;
>> p1 = d0;
>> d1 = pi*ones(3,1);
>> p2 = d1;
>> d2 = pi*ones(3,3,1)
>> iwgdx('pp','d0','p1:1','d1','p2:2','d2','p3:3',d2)
```

will write the following symbols to GDX:

- The 0-dimensional symbol `d0`. This is the default behavior, consistent with the MATLAB view that `d0` is a scalar.
- The 1-dimensional symbol `p1`. The scalar variable `p1` was promoted to a 1-dimensional symbol by adding an additional singleton dimension.

- The 1-dimensional symbol `d1`. This is the default behavior, consistent with the MATLAB view that `d1` is a vector.
- The 2-dimensional symbol `p2`. The vector variable `p2` was promoted to a 2-dimensional symbol by adding an additional singleton dimension.
- The 2-dimensional symbol `d2`. This is the default behavior, consistent with the MATLAB view that `d2` is a matrix, i.e. the final singleton dimension is just removed.
- The 3-dimensional symbol `p3`. The matrix variable `d2` was promoted to a 3-dimensional symbol by adding an additional singleton dimension. Independently, call-by-reference was used to rename `d2` to `p3`.

Note that the dimensionality specified must always be a promotion, i.e. the dimensionality of the resulting GDX symbol is only increased from what it would be by default.

See datalib example `gdxmrw_iwgdx01_init`.

6.24.2.3 Indexing with labels (UELs)

To this point we have been looking at functions to read (`irgdx`, Section irgdx) and write (`iwgdx`, Section iwgdx) *indexed* parameters from and to GDX. Indexed parameters are convenient since their structure is essentially identical to that of MATLAB matrices. This structure can be encapsulated very simply as the number of dimensions and the size or extent of each dimension. Using indexed parameters, we do not need to be very concerned with the structure of the data since little structure exists. However, there is much more to GDX data than indexed parameters. If we want to read and write GDX data in more generality we will need to understand how labels or strings are used to reference GDX data and how these labels are organized within GDX.

In general, GAMS data is referenced with labels instead of with numbers, so that one references `demand('chicago')` instead of `demand(2)` in a GAMS model. These labels are also called Unique Elements, or UELs. The collection of UELs used in a model or in a GDX file is ordered internally and often referred to as the *universe* of UELs. For efficiency, it is not necessary to use labels internally in GDX or when using the GDX API. Instead, a correspondence or mapping between integers and labels is established initially and/or built up as labels are introduced, so that integers can be used in place of the UELs that reference the data. It is important to keep in mind that the labels are the key thing in referencing GDX data: when integer maps are used the integers are only used to efficiently represent the labels.

A similar scheme mapping integers to labels is used in the `rgdx` and `wgdx` routines for reading and writing general GDX data. In addition to the actual data values being stored, there will be a mapping passed to allow integers to be mapped to labels and vice versa. In some cases, where no mapping is passed and data are written to GDX, a default mapping (`1` to `'1'`, `2` to `'2'`, etc.) may be used. When reading, the default mapping to use when passing back data is the universe mapping from the GDX, but it is possible to apply a filter. A filter can reduce the amount of data returned and also change the order of that data.

6.24.2.4 rgdx

`rgdx` is a MATLAB utility to import data from a GDX file. It takes structural input and returns data back in the form of a structure. This is a very flexible routine as it gives user control over the output data structure. `rgdx` can read a set/parameter/equation/variable from a GDX file and display results in either full/dense or sparse form. A user can also perform a filtered read to read only certain specific elements of a symbol. It can also perform compression to remove extra zeros.

This routine can take up to two arguments. The first argument is a string input containing the GDX file name. It can be with or without the `'.gdx'` file extension. If you call this routine with only the GDX file name as an argument then the `'uels'` field of output structure will be the global UEL of the GDX file and the rest of the fields of the output structure will be NULL. The second argument is a structure input containing information regarding the desired symbol. The syntax for this call looks like this:

```
x = rgdx('fileName', structure);
```

As an example, we read a 3D parameter, `'test3'` from `'sample.gdx'`. Here we display this parameter in full format but without redundant zeros:

```
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)

x =

    name: 'test3'
    type: 'parameter'
     dim: 3
     val: [4x2x2 double]
    form: 'full'
    uels: {{1x4 cell}  {1x2 cell}  {1x2 cell}}

>> x.val

ans(:,:,1) =

     3     4
     4     5
     5     6
     6     7

ans(:,:,2) =

     4     5
     5     6
     6     7
     7     8

>> x.uels{1}

ans =

    '1'    '2'    '3'    '4'

>> x.uels{2}

ans =

    'j1'    'j2'

>> x.uels{3}

ans =

    'k1'    'k2'
```

In the following subsections we will explain the input and output structures. Please note that except for the `'name'` and `'uels'` fields, all other string fields take case insensitive input. All boolean fields can also be entered as string values as well.

Input structure

To read a symbol from a GDX file we just need to know its name in string format. Thus, the only mandatory field of the input structure is 'name'. e.g.

```
>> s.name = 'test3';
```

There are several other optional fields of the input structure that give user more control over the output structure. These optional fields are as follows:

1. form
   This field represents the form of the output data. Output data can be either in `'full'` or `'dense'` form or it can be in `[i, j,.., val]` sparse form. We will label `[i, j,.., val]` as 'sparse'. A user can enter it as string input with value `'full'` or `'sparse'`. e.g.

   ```
   >> s.form = 'full';
   ```

   By default the data will be in 'sparse' format. Note that this sparse format differs from MATLAB's internal sparse storage scheme that we referred to in prior sections for the `irgdx` and `iwgdx` functions.

2. compress
   By default the uels in the output structure will be a global UEL of the GDX file and the `'val'` field data will be indexed to this UEL. The `rgdx` routine allows a user to remove rows and columns with all zeros from the 'val' data matrix and re-indexes the uels accordingly. This is called compression of the data. This can be achieved by setting compress as true in the input structure. Valid values for this field are true and false, either in logical form or in string form. e.g.

   ```
   >> s.compress = 'true';
   ```

   However, we note that compressing the data can be dangerous because the size of the matrix that is read can be incorrect. Essentially, all zero rows and columns are removed, including those that might actually be part of the data values in the symbol matrix.

3. uels
   This input field is used to perform a filtered read, i.e. output data matrix will contain values only corresponding to the entered uels. Filtered read is very useful if user just wants certain specific set of data. Uels should be entered in cell array form. It has to be in 1xN form with each column being a cell array representing the uels for that dimension. Each column can have strings, doubles or combinations of both. It also allows a user to enter double data in shorthand notation or a 1 x N matrix. For example, in the previous example we can perform a filtered read to get data corresponding to only the `'1'`, `'3'` elements of the first index of the parameter `'test3'`. The following function is handy when one needs to generate a UEL listing for the input structure:

   ```
   >> guel = @(s,v) strcat(s,strsplit(num2str(v)));
   ```

   Using the above function, we can create a listing of strings consisting of the string s appended to each number in the array v. Thus, instead of using the command

   ```
   >> s.uels = {{'1','3'},{'j1','j2'},{'k1','k2'}};
   ```

   we can conveniently use the command

   ```
   >> s.uels = {guel('',[1,3]),guel('j',1:2),guel('k',1:2)};
   ```

   The benefit of using the latter command will be more apparent when creating many elements in the listing. Now, as an example, suppose we would like to do a filtered read on the parameter called `test2` in `sample.gdx`. We could use the following commands:

```
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = false;
>> s.uels = {guel('',[1,3]),guel('j',1:2),guel('k',1:2)};
>> x = rgdx('sample',s)

x =

    name: 'test3'
    type: 'parameter'
     dim: 3
     val: [2x2x2 double]
    form: 'full'
    uels: {{1x2 cell}  {1x2 cell}  {1x2 cell}}

>> x.val

ans(:,:,1) =

     3     4
     5     6

ans(:,:,2) =

     4     5
     6     7
```

Here it should be noted that we turned off compression while performing the filtered read. This is necessary because the filtered read will give data in accordance with the entered uels and the output uels will be the same as the input uels; thus compression is not possible.

4. field
   This field is required when variables or equations are to be read from a GDX file. Sets and parameters in the GDX file do not have any field value but variables and equations have 5 fields namely, level, marginal, lower, upper, and scale. Thus, it may be useful to enter field as an input when reading an equation or a variable. A user can enter it as a string with valid values being `'l/m/up/lo/s'`. e.g.

   ```
   >> s.field = 'm';
   ```

   By default, the output will be the level value of a variable or an equation.

5. ts
   This represents the text string associated with the symbol in the GDX file. If a user sets this field to be `'true'`, then the output structure will have one more string field `'ts'` that contains the text string of the symbol. e.g.

   ```
   >> s.ts = true;
   ```

6. te
   GAMS allows a modeler to enter text elements for a set. Similarly to the `'ts'` field, if a user sets `'te'` to be true in the input structure, then the output structure will contain one more field representing the text elements for that symbol. Please note that text elements only exist for `'sets'`. e.g.

   ```
   >> s.te = true;
   ```

Output Structure

As mentioned earlier, output of the `rgdx` routine will be in structure form. This structure is very similar to the input structure. To get information regarding any symbol, we always need to display its basic characteristics, such as its name, type, value, uels, form, etc. An output structure will always have these fields:

1. name
   It is same as that entered in the input structure name field, i.e., the symbol name in the GDX file.
2. val
   It represents the the value matrix of the symbol. To save MATLAB memory by default it will be in `'sparse'` format. e.g.

```
>> s = rmfield(s, 'form');
>> s

s =
        name: 'test3'
    compress: 0

>> x = rgdx('sample', s)

x =

    name: 'test3'
    type: 'parameter'
     dim: 3
     val: [16x4 double]
    form: 'sparse'
    uels: {{1x8 cell}  {1x8 cell}  {1x8 cell}}
```

   Here `val` is a 16x4 double matrix. As it is a parameter; thus the last column of the sparse matrix will represent the value and the rest (i.e. the first three columns) will represent its index. Please note that in the case of a `'set'`, the number of columns in the sparse matrix will be equal to its dimension, i.e., it will not have a column representing its value. Here, the presence of each row in the output `'val'` field corresponds to the existence of a set element at that index. When a `'full'` matrix output is specified, a 1 represents existence of a set element and a 0 otherwise.
3. form
   It represents the format in which the `'val'` field is being displayed. As mentioned earlier it can be either in `'full'` or `'sparse'` form.
4. type
   While reading a symbol from a GDX file it is often very useful to know its type. The `rgdx` routine is designed to read set, parameter, variable and equation. This field will store this information as a string.
5. uels
   This represents the unique element listing of the requested symbol in the form of a cell array. It is a 1 x N cell array, where N is the dimension of the symbol. Each column of this array consists of string elements. By default, the output uels will be the same as the global uel of the GDX file, but it can be reduced to element specific local uels if compress is set to be true in the input structure. If a user is using a filtered read, i.e. calling `rgdx` with input uels, then the output uels will be essentially the same as the input uels.
6. dim
   It is a scalar value representing the dimension of the symbol.

   Apart from these necessary fields there are a few additional fields as well. They are as follows:

7. field
   If we are reading variables or equations, then it becomes useful to know which field we have read, i.e., `l/m/up/lo/s`. This information is displayed via this field in the form of a string.

8. ts
   It display the explanatory text string associated with the symbol. This field only exists in the output structure if the `'ts'` field is set as `'true'` in the input structure.

9. te
   It is an N dimensional cell array representing the text elements associated with each index of the set. This field only exists in the output structure if the `'te'` field is set as true in the input structure and the symbol is a set.

See datalib example `gdxmrw_rgdx01_init`.

6.24.2.5 wgdx

`wgdx` is a MATLAB routine to create a GDX file containing data from MATLAB. Similar to the `rgdx` routine, it takes a structure input and can write multiple symbols into a single GDX file with one call. The first argument is the file name of the GDX file to be created in string format; it can be with or without the `'.gdx'` file extension. The rest of the arguments are structures, each containing data for different symbols to be written into the GDX file. The syntax for the call is:

```
>> wgdx('fileName', s1, s2 ...);
```

If the GDX file already exists in the MATLAB current directory, `wgdx` will overwrite it; otherwise a new file will be created. After a successful run, it doesn't return anything back into MATLAB. Most of the fields of its input structures are the same as those of the `rgdx` output structure. In the example below, we use the `wgdx` routine to create `foo.gdx` containing a set `'l'` and a parameter `'par'`.

```
>> s.name = 'l';
>> s.uels = {{'i1', 'i2', 'i3'}, {'j1',  'j2'}};
>> c.name = 'par';
>> c.type = 'parameter';
>> c.val = eye(3);
>> c.form = 'full';
>> c.ts = '3 x 3 identity';
>> wgdx('foo', s, c)
```

The equivalent code in GAMS to create the above set `'l'` is:

```
Set
   a / i1*i3 /
   b / j1*j2 /
   l(a,b);

l(a,b) = yes;
```

In the next subsection we will explain the input fields in detail.

Input Structure

The necessary fields in an input structure to represent a symbol are given below:

1. name
   It is a string representing the name of the symbol.

2. val
   It represents the value matrix of the parameter or set. It can be entered in either full or sparse format, whichever is convenient to the user; the corresponding format must be specified in the `'form'` field. By default the value matrix is assumed to be in sparse format.

3. type
   It is a string input to specify the type of the symbol. The `wgdx` routine can write a set or parameter into the GDX file. In the previous example, we didn't specify the type for structure `'s'` because by default it is assumed to be a set.

4. form
   This is a string input representing the format in which the val matrix has been entered. By default it is assumed that the data is specified in sparse format.

5. uels
   Similar to the `rgdx` uels field, this represents the local unique element listing of the symbol in an 1 x N cell array form. Each column of this cell array can contain string or double or both. Again we can make use of a handy function to create a UEL listing as mentioned previously in the section about `rgdx`:

   ```
   >> guel = @(s,v) strcat(s,strsplit(num2str(v)));
   ```

   As an example, we create a set using this function and the `wgdx` routine:

   ```
   >> s.name = 'l';
   >> s.uels = {guel('i',1:20),guel('j',1:40)};
   >> wgdx('foo',s);
   ```

   The above code will create `foo.gdx` that contains a 2 dimensional set `'l'` with set elements for each of the specified uels. If a user would like to create a set with set elements only at specified indices, one could do so by entering the indices in the val field. e.g.

   ```
   >> s.val = [1, 1; 2, 1; 3, 6; 4, 7];
   >> wgdx('foo',s);
   ```

   Now the above would result in a set with only elements existing in the indices specified in the `val` field. If a user enters a structure with only two fields, name and uels, as in the example given in the introduction of this section (structure s), then `wgdx` will create a full set corresponding to the global uels.

   The optional fields are:

6. dim
   This field is useful when a user wants to write a zero dimensional or 1 dimensional data in full format. As every data matrix in MATLAB is at least 2D, it becomes necessary to indicate its dimension for writing purposes.

7. ts
   This is the text string that goes with the symbol. If nothing is entered then `'MATLAB data from GDXMRW'` will be written in the GDX file.

See datalib example `gdxmrw_wgdx01_init`.

6.24.3 Extended use

In this section, we will discuss a few examples of the MATLAB and GAMS interface. We will give a simple example of a nonlinear optimization problem that would benefit from this capability and describe the steps that are needed in order to use our interface in this application.

- Special values
  Following example shows how special values are handled by this interface. It can be seen that `rgdx` can retrieve all these values from GDX file and display them appropriately in MATLAB.

```
>> s.name = 'special';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)

x =

    name: 'special'
    type: 'parameter'
     dim: 1
     val: [4x1 double]
    form: 'full'
    uels: {{1x4 cell}}

>> x.val

ans =

                -Inf
                 NaN
   3.141592653589793
                 Inf
```

- Variables and Equations
  In an optimization problem, we are not only interested in level value of variables and equations but also in their marginal values, lower and upper bounds. This interface gives its user ability to read any of these values into MATLAB. By default `rgdx` and `gams` routines will read the level value of equations and variables but this can be changed very easily by using `'field'` in input structure. In `gams` call user can also specify this in `'$set matout'` statement. e.g.

```
$set matout "'matsol.gdx', x.m, dual.lo=dl ";
```

  In this case the marginal value of variable `'x'` will be read and lower bound of dual variable will be read and stored in `'dl'`.

- Text string and Text elements
  GAMS allows its user to enter text string and explanatory text elements and all GDX file contain this information as well. Following example shows how to get these text elements in MATLAB.

```
>> s1.name = 'el';
>> s1.te = true;
>> s1.ts = true;
>> s1.compress = true

s1 =

        name: 'el'
          te: 1
```

```
          ts: 1
    compress: 1

>> z = rgdx('sample', s1)

z =

    name: 'el'
    type: 'set'
     dim: 2
     val: [3x2 double]
    form: 'sparse'
    uels: {{1x2 cell}  {1x2 cell}}
      ts: 'This is 2D set with text elements'
      te: {2x2 cell}

>> z.te

ans =

    'element1'    'element2'
    '2.j1'                []

>> z.val

ans =

     1     1
     1     2
     2     1
```

- String elements
  One piece of information that may be needed within MATLAB is the modelstat and solvestat values generated by GAMS for the solves that it performed. This is easy to generate, and an example is given in `do_status.m`. This example is generated by taking the standard gamslib trnsport example, and adding the following lines to the end:

```
$set matout "'matsol.gdx', returnStat, str ";

Set
   stat / modelstat, solvestat      /
   str  / 'grunt', '%system.title%' /;

Parameter returnStat(stat);
returnStat('modelstat') = transport.modelstat;
returnStat('solvestat') = transport.solvestat;
execute_unload %matout%;
```

  Note that the relevant status numbers are stored in GAMS into the parameter returnStat which is then written to matsol.gdx and read back into MATLAB using the `rgdx` call.

```
>> gamso.output = 'std';
>> gamso.form = 'full';
>> gamso.compress = true;
>> s = gams('trnsport')

s =

     1
     1
```

See datalib example gdxmrw_ext01_init.

- Advanced Use: Plotting
  One of the key features of the GAMS/MATLAB interface is the ability to visualize optimization results obtained via GAMS within MATLAB.
  Some simple examples are contained with the program distribution. For example, a simple two dimensional plot with four lines can be carried out as follows. First create the data in GAMS and export it to MATLAB using the gams routine (see APPENDIX C - Calling GAMS model from MATLAB for a detailed description of this routine).
  We make an assumption that the user will write the plotting routines in the MATLAB environment. To create the plot in MATLAB, the following sequence of MATLAB commands should be input (saved as do_plot.m).

```
gamso.output = 'std';
gamso.compress = true;
gamso.form = 'full';
[a,xlabels,legendset,titlestr] = gams('simple');
figure(1)
% Plot out the four lines contained in a;
% format using the third argument
plot(a,'+-');
% only put labels on x axis at 5 year intervals
xtick = 1:5:length(xlabels{1});
xlabels{1} = xlabels{1}(xtick);
set(gca,'XTick',xtick);
set(gca,'XTickLabel',xlabels{1});
% Add title, labels to axes
title(titlestr{1});
xlabel('Year -- time step annual');
ylabel('Value');
% Add a legend, letting MATLAB choose positioning
legend(legendset{1},0);
% match axes to data, add grid lines to plot
axis tight
grid
```

  The data is created using the following gams code.

```
$title Examples for plotting routines via MATLAB

$set matout "'matsol.gdx', a, t, j, sys ";

Set
   sys / '%system.title%' /
   t   / 1990*2030        /
   j   / a, b, c, d       /;

Parameter a(t,j);
a("1990",j) = 1;

loop(t, a(t+1,j) = a(t,j)*(1 + 0.04*uniform(0.2,1.8)););

Parameter year(*);
year(t) = 1989 + ord(t);

* Omit some data in the middle of the graph:
a(t,j)$((year(t) > 1995)*(year(t) <= 2002)) = na;

execute_unload %matout%;
```

The following figure is an example created using this utility (and the MATLAB command print -djpeg simple).

See datalib example GDXMRWPlotting01.

MATLAB supports extensive hard copy output or formats to transfer data to another application. For example, the clipboard can be used to transfer meta files in the PC environment, or encapsulated postscript files can be generated. The help print command in MATLAB details the possibilities on the current computing platform.

Scaling of pictures is also most effectively carried out in the MATLAB environment. The following code is an example of rescaling printed out. Note that the output of this routine is saved as a jpeg file "rescale.jpg".

```
do_plot;
fpunits = get(gcf,'PaperUnits');
set(gcf,'PaperUnits','inches');
figpos = get(gcf,'Position');
pappos = get(gcf,'PaperPosition');
newpappos(1) = 0.25;
newpappos(2) = 0.25;
newpappos(3) = 4.0;
% get the aspect ratio the same on the print out
newpappos(4) = newpappos(3)*figpos(4)/figpos(3);
set(gcf,'PaperPosition',newpappos),
print -djpeg100 rescale.jpg
set(gcf,'PaperPosition',pappos);
set(gcf,'PaperUnits',fpunits);
```

Other examples of uses of the utility outlined in this paper can be found in the "m" files:

```
do_ehl
plotngon
```

that are contained in the distribution.

6.24.4 Acknowledgements

The authors would like to thank Alexander Meeraus and Michael R. Bussieck of GAMS corporation for constructive comments on the design and improvement of this tool. Thanks to Rishabh Jain for work on an earlier version.

6.24.5 APPENDIX A - Configuring GDXMRW

6.24.5.1 Installation

This section describes the installation procedure for all types of machines. The following section describes the testing procedure for verifying a correct installation.

First of all, you need to install both MATLAB and GAMS on your machine. For brevity, we will assume that the GAMS system (installation) directory is (for Windows)

```
C:\GAMS
```

and for non-Windows systems:

```
/usr/local/gams
```

All of the utilities come as a part of the GAMS distribution, so to use them you have only to add the GAMS directory to the MATLAB path. One way to do this is from the MATLAB command prompt, as follows:

```
>> addpath 'C:\GAMS'; savepath;
```

OR this can be done by following these steps:

1. Start MATLAB
2. Click on 'File' tab.
3. Now click on 'Set Path'
4. Click on 'Add Folder'
5. Select GAMS directory and click 'OK'.
6. Save it and then close it.

6.24.5.2 Testing

The GAMS system comes with some tests that you should run to verify the correct configuration and operation of the GDXMRW utilities. In addition, these tests create a log file that can be useful when things don't work as expected. To run the tests, carry out the following steps.

1. Create a directory to run the tests in, e.g.

   ```
   % mkdir \tmp
   ```

2. Extract the test models and supporting files from the GAMS test library into the test directory.

   ```
   % cd \tmp
   % testlib gdxmrw03
   % testlib gdxmrw04
   % testlib gdxmrw05
   % testlib gdxmrw06
   % testlib gdxmrw07
   ```

3. Execute the GAMS files `gdxmrw03`, `gdxmrw04`, and `gdxmrw06`. The files `gdxmrw03` and `gdxmrw04` test that the `rgdx` and `wgdx` routines are working properly, and `gdxmrw06` test `irgdx` and `iwgdx`. In addition to calling MATLAB in batch mode, they verify that the data are read and written as expected and give a clear indication of success or failure.

4. The GAMS file `gdxmrw05` tests the `gams` MATLAB routine. Like the other tests, it can be run in batch mode. You can also run it interactively by starting MATLAB, making `tmp` the current directory, and running the script `'testinst.m'`.

   ```
   >> testinst
   ```

   In addition to messages indicating success or failure, this test produces a log file `testinstlog.txt` that will be useful in troubleshooting a failed test.

5. The GAMS file `gdxmrw07` helps in basic testing if you find that GDXMRW is not functioning at all.To use this, open Matlab, make `tmp` the current directory and run gdxmrwSupport. You can then look over the outputs and identify if and where any errors or failures are occurring. Re-run the commands that result in failures via cut-and-paste, and examine the tests and the output carefully: perhaps a solution will present itself to you. If the issue persists, send the screen output and the resulting log file gdxmrwSupport.txt (located in the created folder tmp_gdxmrw) to GAMS Support (support@gams.com).

6.24.6 APPENDIX B - Utility functions: gdxWhos and gdxInfo

In this section, we'll describe two utilities, `gdxWhos` and `gdxInfo`, provided with GDXMRW that can be called from the MATLAB command prompt. The `gdxWhos` function is patterned loosely after the MATLAB function `whos` used to query `.mat` files. It provides information about symbols in a specified GDX file. The only input argument is the name of a GDX file, which can be with or without the `'.gdx'` extension. With no output argument, `gdxWhos` lists the symbols in the specified GDX file in the MATLAB command prompt. When used with an output argument, information about the symbols in the GDX file is returned as an array of structures. This meta-data can be used in a variety of ways and is especially useful when programming.

An example GDXWhos call without an output argument is shown below:

```
>> gdxWhos('idx1_.gdx');
Symbol info of GDX idx1_.gdx
  Index Type       Dim       NRecs  Name
      1 Parameter    0           1  a0
      2 Parameter    1           3  a1(5)
      3 Parameter    2           4  a2(2,2)
      4 Parameter    3           6  a3(3,5,2)
      5 Parameter   10         256  a10(3,5,2,2,2,2,2,2,2,2)
```

The above output indicates that there are five indexed parameters in the file `'idx1_.gdx'`. The way we can recognize an indexed parameter is by noticing numbered arguments of the parameters under the `'Name'` column. For non-indexed data, the arguments will appear either as the name of a set or by a '$*$'. For example, the first three symbols are non-indexed and the last symbol is indexed in the output from this call:

```
>> gdxWhos('fake.gdx');
Symbol info of GDX fake.gdx
  Index Type       Dim       NRecs  Name
      1 Set          1           3  i(*)
      2 Parameter    1           3  a(i)
      3 Set          1           3  d_i_m__3(*)
      4 Parameter    1           3  aa(3)
```

The GDXInfo function is patterned after the `gdxdump` utility in GAMS. It lists and dumps all of the data values for each symbol in the specified GDX file to the MATLAB console. The only input argument is the name of a GDX file, which can be with or without the `'.gdx'` extension. It accepts no output arguments. It is especially useful to see the entire contents of smaller GDX files. To use the function, we could simply enter a command such as `gdxInfo('idx1_')` in the MATLAB command prompt, and the entire data contents would be displayed in the console. Further information about what is displayed can be found in the GAMS documentation of the `gdxdump` utility.

6.24.7 APPENDIX C - Calling GAMS model from MATLAB

Until now we have discussed the data Import/Export utility between MATLAB and GAMS. In this section, we will discuss a new MATLAB utility `'gams'` that initializes a GAMS model with MATLAB data then executes GAMS on that model and bring the results back into MATLAB. This `'gams'` routine is based on the same design as `rgdx` and `wgdx` but instead it does everything in one call. This routine can take multiple input arguments and can return multiple output arguments. Its standard syntax is as follows:

```
>>  [x1, x2, x3] = gams('model', s1, s2.., c1, c2..);
```

Here note that the first argument of `gams` is the GAMS model name plus any user specific command line settings. If a user wants to solve the given model (in this case found in `qp.gms`) using a different solver then it can be done by adding that solver to the GAMS model name as `"qp nlp=baron"`. This feature allows a user to change the execution time behavior of the model.

The rest of the input arguments of GAMS are structures. Their positioning is not important. These structures are of two kinds; one is similar to the input structure of `wgdx` and the other structure has just two string fields, name and val. This latter structure is used to set or overwrite values in the model using the `"$set"` variables syntax of GAMS. We will explain it in detail a later section.

The first step is to generate a working GAMS model. For example, we can set up a simple model file to solve a quadratic program that minimizes $\frac{1}{2}$ $x^T Qx + c^T x$ subject to $Ax \geq b$ and $x \geq 0$.

The GAMS model for this quadratic problem is as given in the following code.

```
$set matout "'matsol.gdx', x, dual, obj, returnStat ";

Set
   i / 1*2 /
   j / 1*3 /;

Alias (j1,j);

Parameter
   Q(j,j1) / 1  .1  1.0
             2  .2  1.0
             3  .3  1.0 /
   A(i,j)  / 1  .1  1.0
             1  .2  1.0
             1  .3  1.0
             2  .1 -1.0
             2  .3  1.0 /
   b(i)    / 1 1.0
             2 1.0      /
   c(j)    / 1 2.0      /;

Variable obj;

Positive Variable x(j);

Equation cost, dual(i);

cost..    obj =e= 0.5*sum(j, x(j)*sum(j1, Q(j,j1)*x(j1))) + sum(j, c(j)*x(j));

dual(i).. sum(j, A(i,j)*x(j)) =g= b(i);

Model qp / cost, dual /;

$if exist matdata.gms $include matdata.gms

solve qp using nlp minimizing obj;

Set stat / modelStat, solveStat /;

Parameter returnStat(stat);
```

```
returnStat('modelStat') = qp.modelstat;
returnStat('solveStat') = qp.solvestat;

execute_unload %matout%;
```

This GAMS qp model can be executed directly at the command prompt using the following command

```
gams qp (for Unix/Linux)
```

or

```
gams.exe qp (for Windows)
```

or the user can simply hit the run button in the GAMSIDE. The optimal value is 0.5. In order to run the same model within MATLAB and return the solution vector x back into the MATLAB workspace, no change is required to the GAMS file. In MATLAB, all you have to do is to execute the following command:

```
>>  x = gams('qp');
```

This command will first collect the input structure data and create 'matdata.gdx' and 'matdata.gms' that contains include statements for the symbols written in a file matdata.gdx. In the previous example there is no structural input, so an empty 'matdata.gdx' file will be created and 'matdata.gms' will have just have a load statement for the GDX file but no load statements for any symbol. This is done to prevent any undesirable loading of data in the main model if there had already existed a 'matdata.gdx' or 'matdata.gms file'. After creating these two files then the 'gams' routine will execute "gams qp" using a system call. When this model is executed, another file 'matsol.gdx' will be created because of the execute_unload statement in the last line of the model. Here it should be noted that any model that you want to execute using the MATLAB gams routine should contain something like

```
$set matout "'matsol.gdx', x, dual, obj, returnStat ";
```

either as the first line, or somewhere near the start of the model file. This is a standard gams $set statement, setting the value of the local variable 'matout'. The reason to have this statement near the start of the gms file is that the gams routine searches the file from the beginning for "$set matout" in the gms file. As these files can be very large, it is wise to have this statement near the start of the file. In this statement 'fileName' is the gdx file name that will be created containing symbols 'x1', 'x2', etc. These symbols can then be exported to MATLAB. The last line of the model should always be

```
execute_unload %matout%;
```

The purpose of setting the first and last line of the model in this manner is to specify what data the user wants to export to MATLAB in a "header" of the model. As MATLAB does not give any information about the output arguments except the number of expected arguments, we have to specify what data to export to MATLAB in the GAMS model with minimum modification to the existing model. In the previous example, there is only one output argument, thus the gams routine will get data for its first element from the output gdx file and store it in the MATLAB output argument.

If there is more than one output argument, e.g.,

```
>>  [x, u] = gams('qp');
```

then the gams routine will read the output gdx file and store its first element information of the GDX file as the first output argument of MATLAB, i.e. 'x', and the second element information of the GDX file in the second output argument of MATLAB, i.e. 'u' and so on. If the number of MATLAB output arguments is greater than the number of elements in the GDX file then gams will throw an error.

See datalib example gdxmrw_qp4.

6.24.7.1 Input Structure

As mentioned earlier, the gams routine takes input arguments in structured form. It allows two different types of structure input. One contains the symbol data similar to the wgdx input structure, to be exported to the GDX file. The other structure will just have two string fields 'name' and 'value'. Example use:

```
>> s.name = 'Q';
>> s.val = eye(3);
>> s.form = 'full';
>> m = struct('name','m','val','2');
>> [x] = gams('qpmcp',s, m);
```

In this example both 's' and 'm' are structures but 'm' has only two fields and both are strings. The gams routine will use the 's' structure to create a 'matdata.gdx' file and 'm' to modify the execution command line to include "--m=2" at the end i.e. a command that when executed will be "gams qpmcp --m=2"

The structure 's' is the same as the input structure for wgdx but with two important differences. Firstly, it can be seen in the above example that 's' doesn't have a 'type' field. In wgdx we assume the type to be 'set' by default, but in the gams routine the type is assumed to be 'parameter' by default. The second change is an optional additional input field (in addition to those given in Section Input Structure) called "load".

- load
  It is a string input representing how the corresponding data will be loaded into the GAMS program. Depending on the value of the global option "gamso.input" (see next section) the input data will be read into GAMS in different ways. Suppose the input structure 's' has a 'name' field called 'foo'. By default (where gamso.input = 'compile'), the file matdata.gms will

  ```
  $loadR foo
  ```

  The GAMS parameter (or set) foo will be replaced by the data that is in the 'matdata.gdx' container called 'foo'. If the data has been initialized before in the model, this will replace that initial data with the new data from 'matdata.gdx'. The option can also be explicitly set using

  ```
  s.load = 'replace'
  ```

  There are two other compile time load options, namely 'initialize' and 'merge'. The first is only valid if the parameter values have not been initialized in the GAMS file, otherwise an error is thrown. It uses the GAMS syntax

  ```
  $load foo
  ```

  The merge option is valid when the GAMS file being run has already initialized the parameter values. The new values in the MATLAB structure 's' are merged into the parameter simply overwriting existing values with the new values given. Explicitly, the 'matdata.gms' file contains the statement

  ```
  $loadM foo
  ```

  to direct GAMS accordingly.
  Finally, if gamso.input = 'exec', the loading will occur at execution time. In this case, s.load = 'initialize' is not a valid input, the default setting is s.load = 'replace' which carries out

  ```
  execute_load "matdata.gdx" foo
  ```

  and the alternative setting s.load = 'merge' carries out

  ```
  execute_loadpoint "matdata.gdx" foo
  ```

  In this way, the data is loaded at execution time and performs an appropriate replace or merge.

6.24.7.2 Global input to change default behavior

Until now we have seen how to specify different input to the gams routine and in this section we will see how to change the default behavior of a gams call. This can be done by creating a structure 'gamso' in the current workspace and adding different fields to that structure. There are currently nine fields that can be set in that structure that affect the behavior of the program. Except the uels field, all other string fields take case insensitive data. These are as follows:

- gamso.output
  By default, output of the gams routine will be in structure form but it might be the case that a user is only interested in the data matrix, i.e., the val field of that structure. This can be done by setting gamso.output as 'std'. This will give only the value matrix as output. If this is not set to 'std' then output will be in the structure form described in the wgdx section.

  ```
  >> gamso.output = 'Std';
  >> x = gams('qp nlp=baron')

  x =
      0.5000
  ```

- gamso.input
  By default, the interface updates data at compile time. Thus, if execution time updates are made to the parameters before the line '$include matdata.gms' these may override the data that is provided in 'matdata.gms' (i.e. from the command line). This may not be desirable. If you wish to perform execution time updates to the data, you should set gamso.input to 'exec'.

- gamso.write_data
  If this is set to 'no', then all parameters on the call to gams are ignored, except the program name. This is useful for dealing with large datasets. Consider the following invocation:

  ```
  x = gams('largedata','A');
  y = gams('resolve','A');
  ```

  The first call generates a file 'matdata.gms' containing the elements of the matrix A for use in the largedata.gms program. The second call rewrites a new 'matdata.gms' file that again contains A. If we wish to save writing out A the second time we can use the following invocation:

  ```
  x = gams('largedata','A');
  gamso.write_data = 'no';
  y = gams('resolve','A');
  clear gamso;
  ```

  or the equivalent invocation:

  ```
  x = gams('largedata','A');
  gamso.write_data = 'no';
  y = gams('resolve');
  clear gamso;
  ```

- gamso.show
  This is only relevant on a Windows platform. This controls how the 'command box' that runs GAMS appears on the desktop. The three possible values are:
  - 'minimized' (default): The command prompt appears iconified on the taskbar.
  - 'invisible' : No command prompt is seen.
  - 'normal' : The command prompt appears on the desktop and focus is shifted to this box.

- `gamso.path`
  This option is used to specify fully qualified path for the gams executable. This is very useful if you have multiple versions of GAMS installed on your system and want to make sure which version you are running for the `gams` call. e.g.

  ```
  >> gamso.path = 'C:\Program Files\GAMS23.4GAMS.exe';
  ```

The output of `gams` is similar to `rgdx` but unlike the `rgdx gams` routine it doesn't take input specific to a particular symbol. Thus it becomes important to implement a way to change the default behavior of the output. This can be achieved by adding following field to the global structure `'gamso'`. All these fields behave similar to that described in `rgdx` and take the same input as of `rgdx`.

- `gamso.compress`
- `gamso.form`
- `gamso.uels`
- `gamso.field`

This is a global option however.

6.25 GDXRename

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This renames the labels in the GDX file using a two dimensional `mapSet`. The renaming of the labels only affects the string stored for each label, and does not change the data order for the symbols in the GDX file. Because no data is changing in the GDX file, only the strings for the labels are changed and applied to the GDX file directly and no new GDX file is written. This replaces the labels in the GDX file by the ones in the `mapSet`.

6.25.1 Usage

Command line:

```
gamstool [gdxservice.]GDXRename GDXFile mapSet [reverse=0|1]
```

Compile time:

```
$callTool [gdxservice.]GDXRename [-reverse=0|1] GDXFile mapSet
```

Execution time:

```
executeTool '[gdxservice.]GDXRename [-reverse=0|1] GDXFile mapSet';
```

Where:

Argument	Description
GDXFile	Name of GDX file.
mapSet	Set of labels to be used for renaming mapSet(*,*).

The following named parameter is available:

Argument	Description
reverse=0 or 1	Determines if mapSet with record a.b leads to a replace of a by b or to a replace of b by a (default: 0).

6.25.2 Example

```
Set c / r, g, b, y /;
Parameter A(c) / r 1, g 2, b 3, y 4 /;
$gdxOut color.gdx
$unload c A
$gdxOut

Set map(c,*) / r.red, g.green, b.blue, y.yellow /;
$callTool gdxservice.GDXRename color.gdx map
```

The complete example is also part of the GAMS Test Library, see model [**gdxrename1**] for reference.

6.26 GDXRRW

Interfacing GAMS and R.

Author

Michael C. Ferris [(ferris@cs.wisc.edu)] (ferris@cs.wisc.edu), Computer Sciences Department, University of Wisconsin - Madison, 1210 West Dayton Street, Madison, Wisconsin 53706

Steven Dirkse (sdirkse@gams.com) GAMS Development Corp.

Attention

GDXRRW is deprecated (see GAMS 41 GDXRRW release notes). Please use GAMS Transfer R instead and contact support with any issues about the transition.

GDXRRW is a suite of utilities to import/export data between GAMS and R (both of which the user is assumed to have already) and to call GAMS conveniently from R. The software gives R users the ability to use all the optimization capabilities of GAMS, and allows visualization and other operations on GAMS data directly within R.

The GDXRRW tool is unique among the GDX interface utilities in that it is an R extension made available as an R package. As such, it is run as part of an R session or script, not as part of a GAMS run, and it follows the usual R package conventions.

1. **Installation**: The R software is designed to be easily extended. Thousands of extension packages are freely and conveniently available online and can be installed easily using a simple, standard procedure. The GDXRRW package is one of these. The latest version is available on GitHub in both source and binary form, along with a FAQ list, some hints and tips on common problems and solutions, and other helpful content. For convenience, the source and binary packages are also available in the gdxrrw directory of the GAMS distribution.

2. **Documentation**: The GDXRRW documentation is installed as part of the GDXRRW package and is available from within R in the usual way. See the GDXRRW GitHub page for details and hints.

3. **Examples, tests, and data**: Like many R packages, GDXRRW comes with examples and data that help a user get started using the package. The R help system and the GDXRRW GitHub provide pointers to these. GDXRRW GitHub page also provides hints on finding and running the thousands of lines of tests that come with the GDXRRW package.

6.27 GDXVIEWER

6.27.1 Overview

GDXVIEWER is a tool to view and convert data contained in GDX files.

Attention

GDXVIEWER is deprecated (see GAMS 42 GAMS IDE and GDXVIEWER release notes).

Besides inspecting a GDX file, gdxviewer allows you to export to a large number of data formats, including ASCII text, CSV, HTML, XML, database, and spreadsheet formats.

This tool is designed as an interactive Windows program, but it can also be operated through command line parameters.

6.27.2 Requirements

GDXVIEWER runs only on PC's running Windows (95/98/NT/XP).The DLL **GDXCCLIB.DLL** needs to be in the same location as **GDXVIEWER.EXE**. If XLS files are saved, MS Excel needs to be present. If MDB database files are saved, MS Access needs to be present.

If GDXCCLIB.DLL is not found in the same directory as the executable gdxviewer.exe, the following window will be shown:

A simple way to make sure that GDXVIEWER has access to the GDXCCLIB.DLL dynamic load library is to place **gdxviewer.exe** in the GAMS system directory, e.g. c:\program files\GAMS21.3.

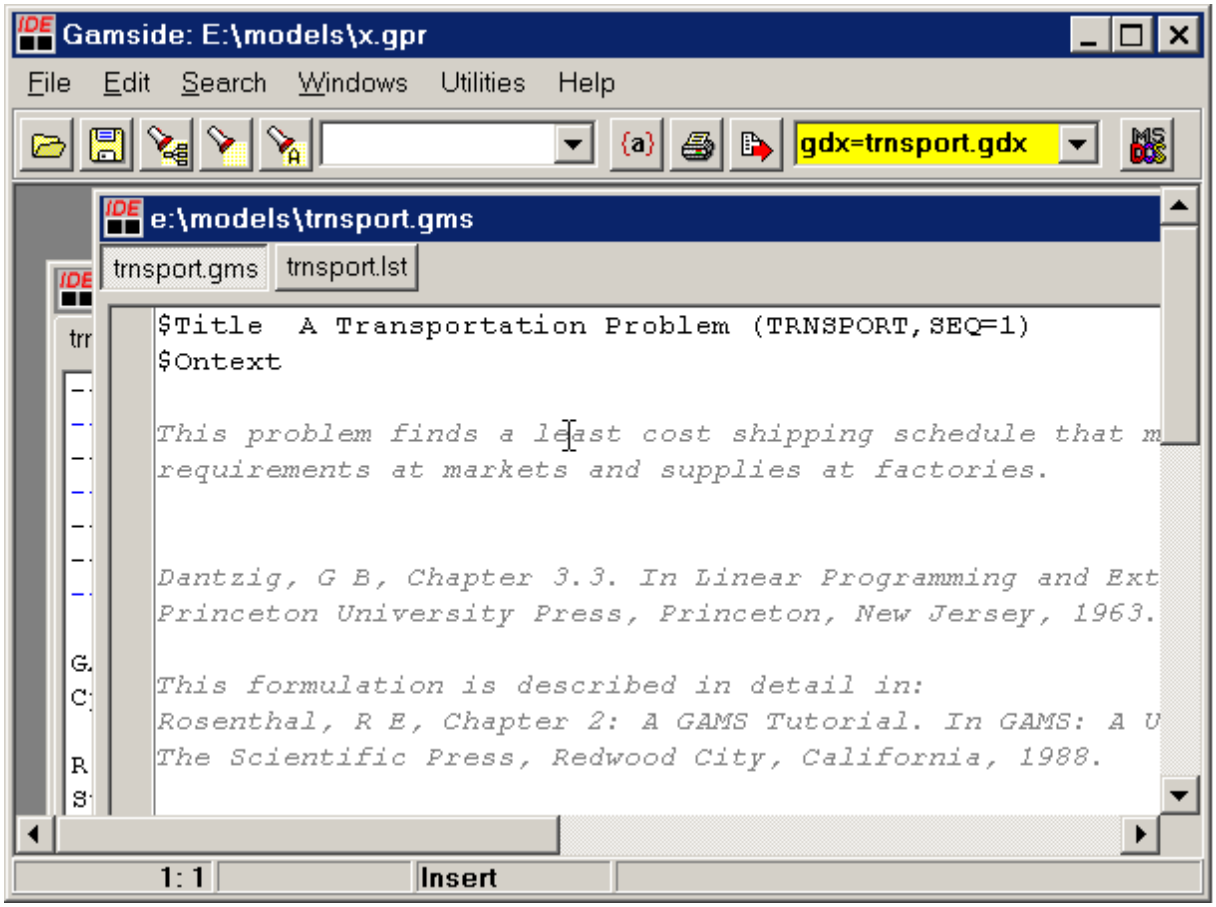
6.27.3 Creating GDX files

GDX files are binary data files. They can contain sets, parameters (including scalars), equations and variables. These files can be generated by a number of tools: by GAMS itself, by utilities such as MDB2GMS, SQL2GMS, GDXXRW.

To save all data from a GAMS model into a GDX file you can use the **GDX=fln** command line parameter:

```
C:\> gams trnsport.gms GDX=trnsport.gdx
```

From the IDE you can specify the command line parameter `GDX=trnsport.gdx` in the parameter edit box:



To selectively place identifiers in a GDX file you can use the **execute_unload** statement:

```
Model transport / all /;
solve transport using lp minimizing z;

display x.l, x.m;

execute_unload 'results.gdx', i, j, x;
```

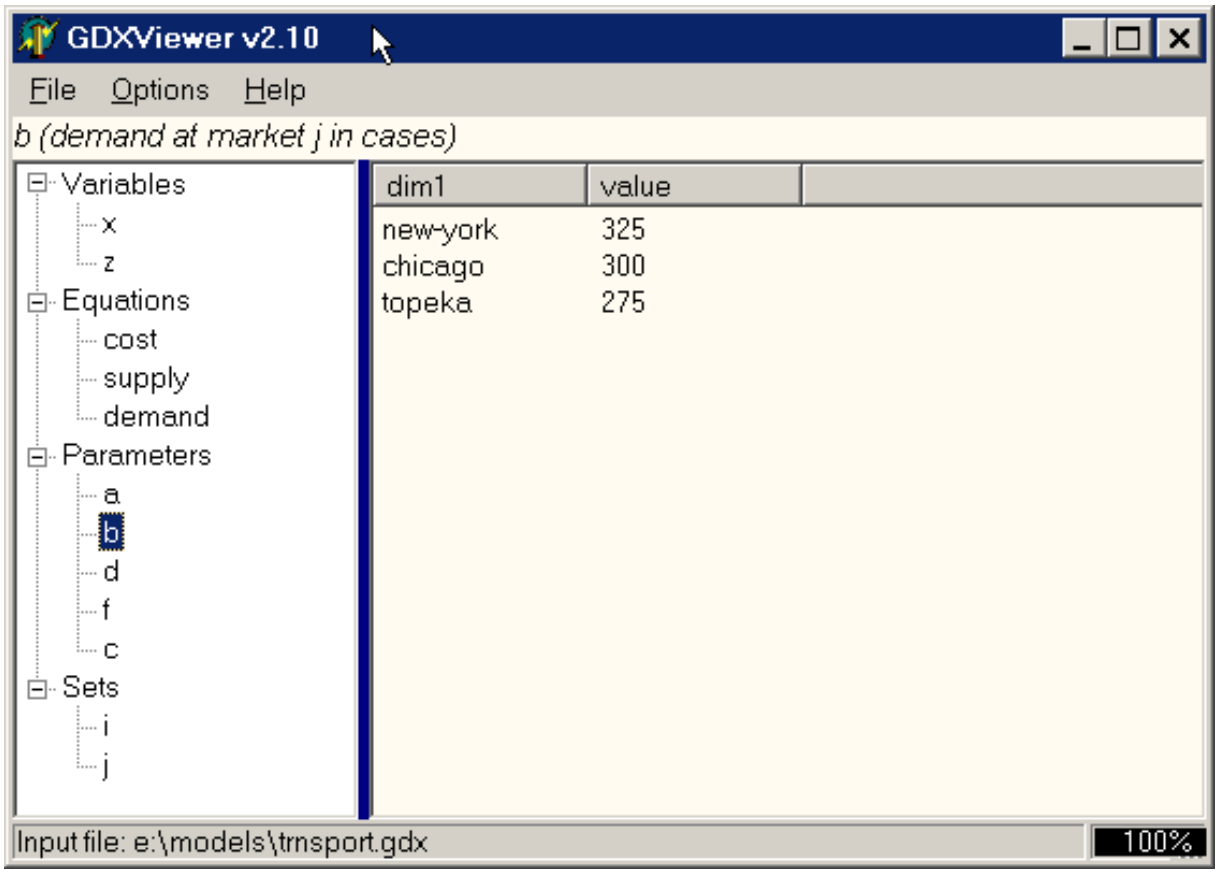
In this example the sets **i** and **j** and the variable **x** are saved to the GDX file **results.gdx**.

Other ways to create GDX files include:

- The MDB2GMS tool can be used to convert data stored in MS Access tables to GDX files
- The SQL2GMS tool can read data from virtually any SQL database (including any ODBC accessible database) and can create GDX files.
- The tool GDXXRW allows data from an Excel spreadsheet to be stored in a GDX file.
- $GDXOUT allows you to write data to a GDX file during GAMS compile time. This is not as useful as execute_unload but may have its use in special cases.
- You can write your own program to write a GDX file. There is an API and bindings for different languages such as Delphi, Kylix, VB6, VBA, VB.NET, C/C++, C#, Java, Fortran.

6.27.4 Viewing GDX files

After loading a GDX file in **gdxviewer** the content of the file is displayed in list view. The left-hand side of the window shows the index of the GDX file organized in a tree structure. When clicking on an identifier, the right-hand-side will display the actual data for the identifier.



When variables are shown, more information is available, such as bounds (lower and upper bounds) and marginals.

The GDX file can be loaded interactively using the `File|Open` menu, or it can be launched from the command line:

```
C:\> gdxviewer e:\models\trnsport.gdx
```

The command line specification can also be used to launch gdxviewer from within a GAMS model as in:

```
Model transport / all /;
solve transport using lp minimizing z;

display x.l, x.m;

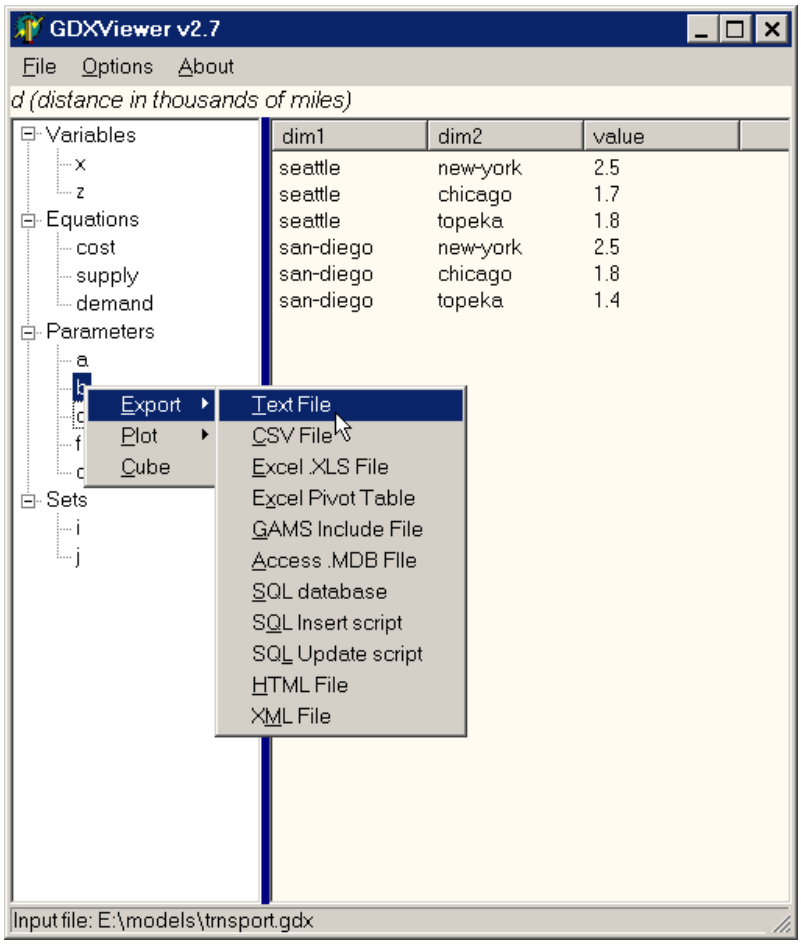
execute_unload 'results.gdx', i, j, x;
execute '=gdxviewer results.gdx';
```

In this case **gdxviewer.exe** was located in the GAMS system directory, such that **execute** had no problems in finding it.

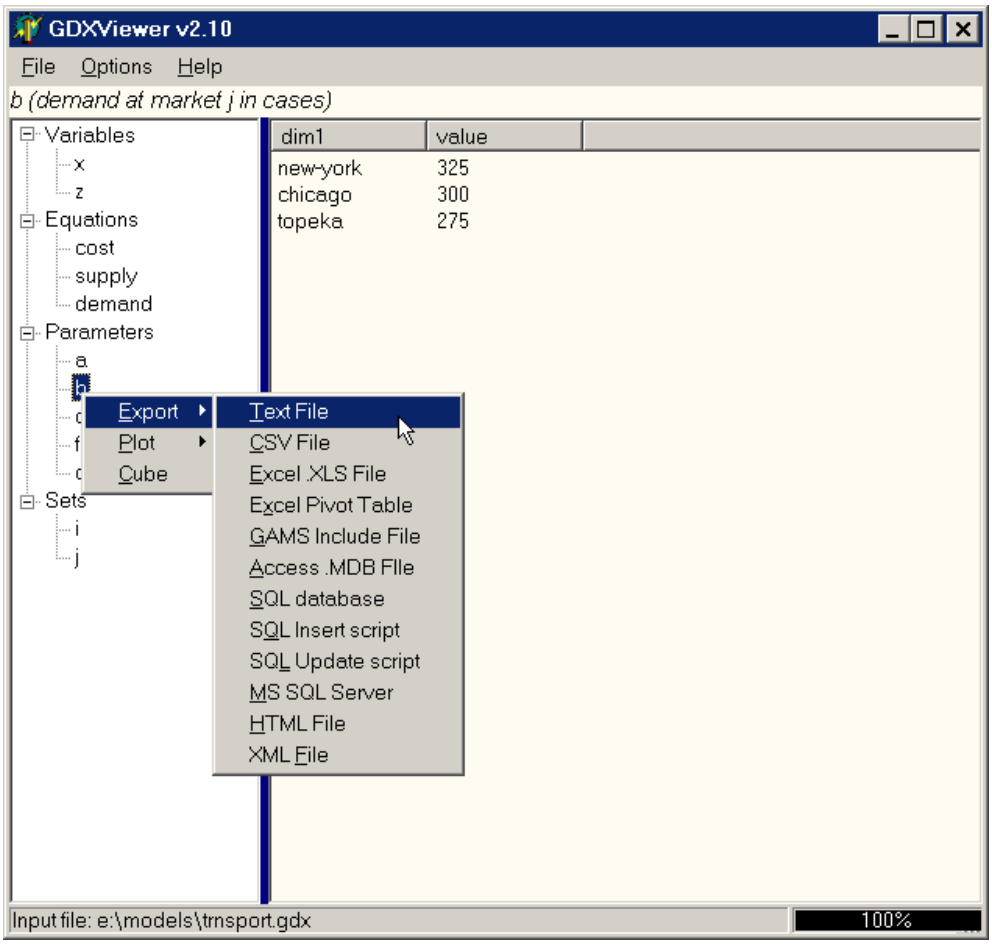
Note: there are alternative tools to view GDX files. The GAMS IDE has a built-in GDX file viewer (use `File|Open`) and there is a command line utility called GDXDUMP.

6.27.5 Exporting an identifier

When the right mouse button is clicked on an identifier a pop-up menu is presented that allows you to export an identifier to a number of target formats.



The same operation can be invoked from the `File|Export` menu:

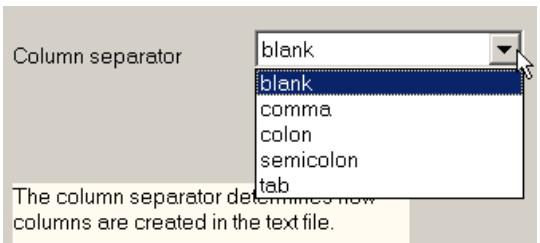


6.27.6 Exporting to a Text File

The text file export facility (`File`|`Export`|`Text File`) will write a GAMS identifier to a standard ASCII text file. Such a text file can look like:

```
seattle new-york 2.5
seattle chicago 1.7
seattle topeka 1.8
san-diego new-york 2.5
san-diego chicago 1.8
san-diego topeka 1.4
```

The separator symbol can be set using the menu `Options`|`Configuration`|`Text File`:



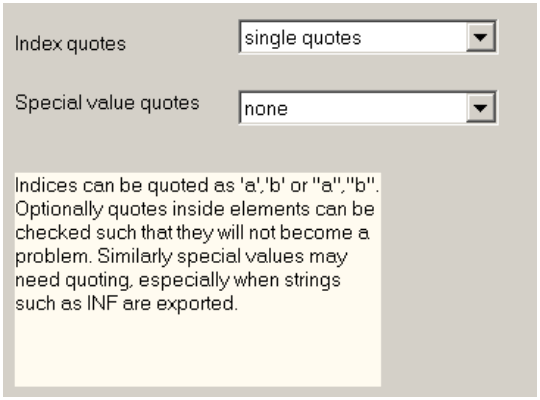
Other options that involve the format of the text file being written are: Options|Configuration|Export and Options|Configuration|Special Values. Currently there are no facilities to write fixed format text files. If you need to write fixed format text files you can use the GAMS PUT statement.

6.27.7 Exporting to a CSV files

Comma-separated Values (`File`|`Export`|`CSV File`) is a popular format to exchange data between applications. An example of such a file is:

```
'new-york',325
'chicago',300
'topeka',275
```

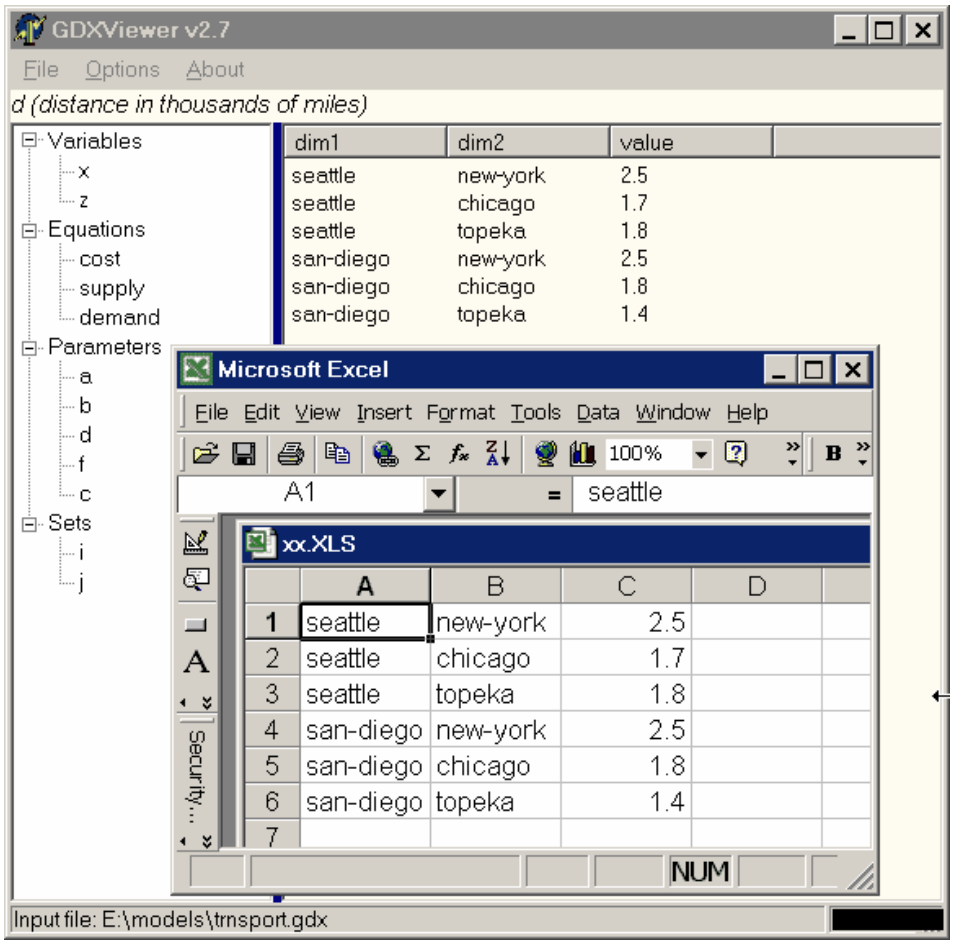
Strings are surrounded by quotes and each field is separated by a comma. The precise format can be specified using the menu `Options`|`Configuration`|`CSV File`:



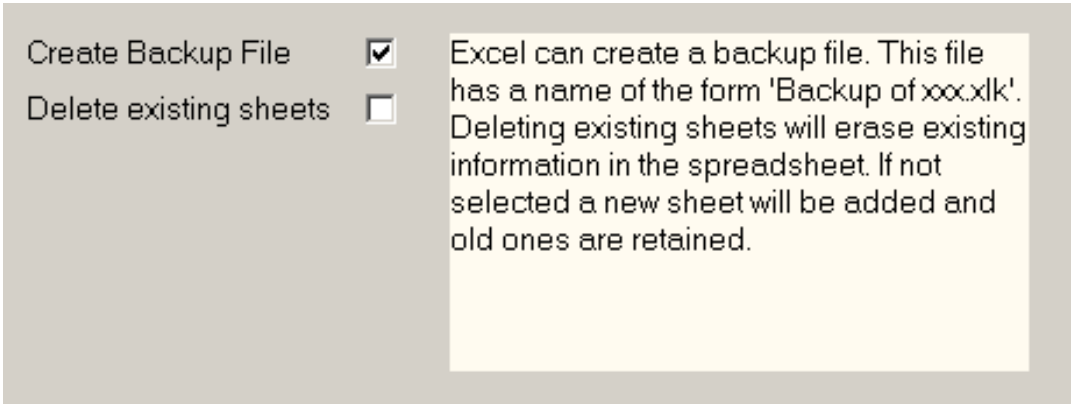
Other options that involve the format of the CSV file being written are: Options|Configuration|Export and Options|Configuration|Special Values.

6.27.8 Exporting to an XLS file

A GAMS identifier can be exported directly to an MS Excel spreadsheet using `File`|`Export`|`Excel XLS File`:



There are a few options available for this operation. Under `Options|Configuration|Excel` the following settings can be changed:

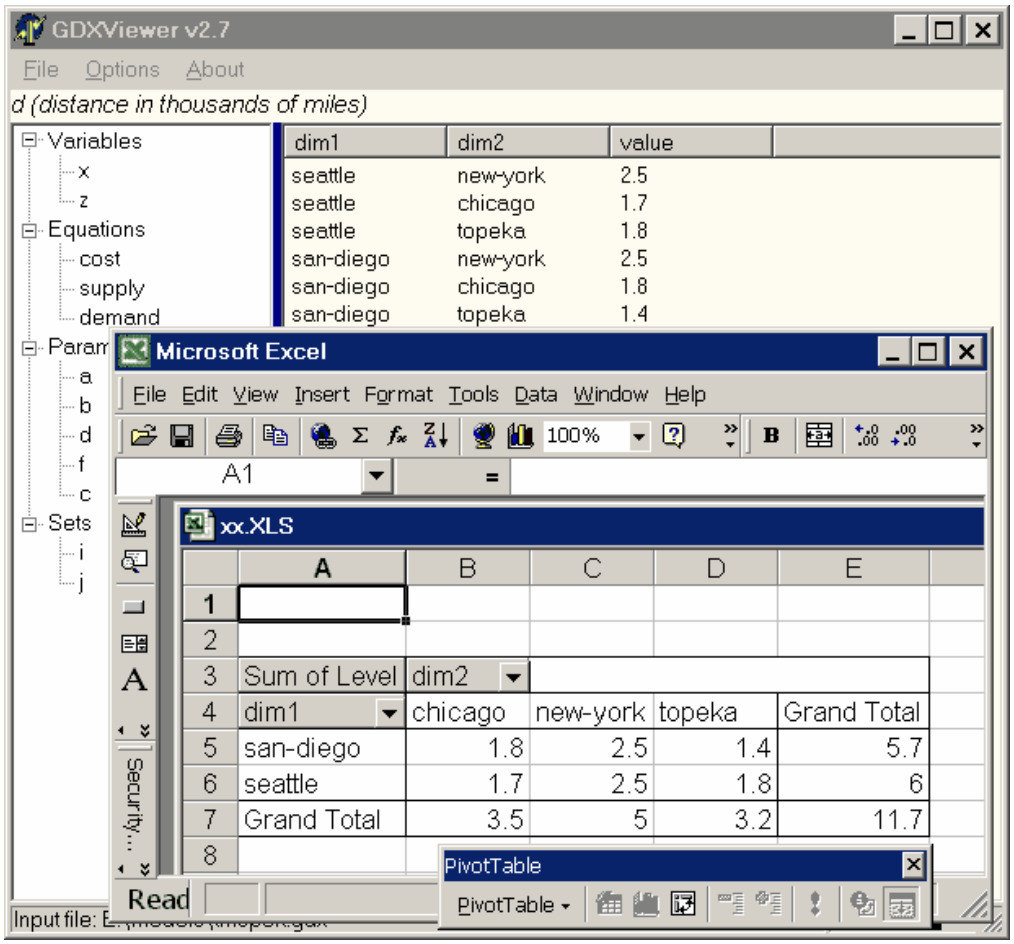


Other options that involve the format of the CSV file being written are: Options|Configuration|Export and Options|Configuration|Special Values. Exporting to Excel is only available if you have Microsoft Excel installed on your machine.

Note: We can write all symbols in the gdx file to Excel by specifying `ID=*` on the command line.

6.27.9 Exporting to an XLS Pivot Table

We can export to an XLS file and create a Pivot Table automatically (`File|Export|Excel Pivot Table`):



Pivot tables are a very convenient way to analyze multi-dimensional data.

The following options are available: Options|Configuration|Excel, Options|Configuration|Export and Options|Configuration|Special Values.

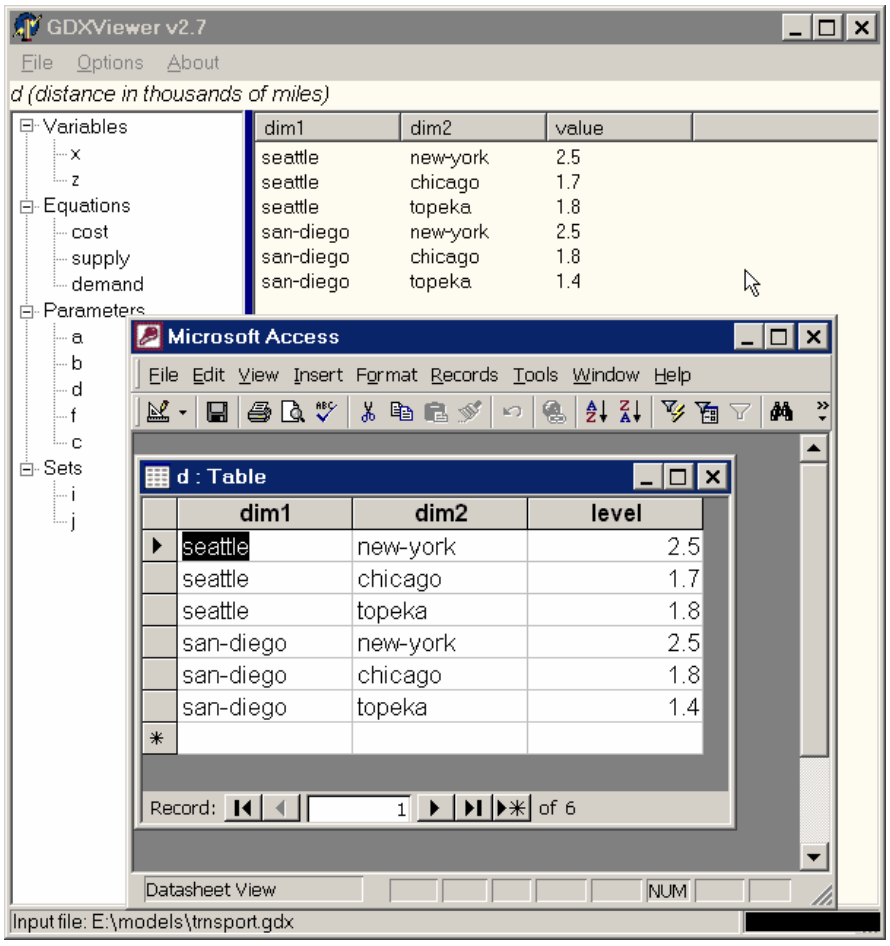
6.27.10 Exporting to a GAMS Include Files

The option `File|Export|GAMS` Include file will export an identifier to a GAMS include file format. An example of such an exported include file can look like:

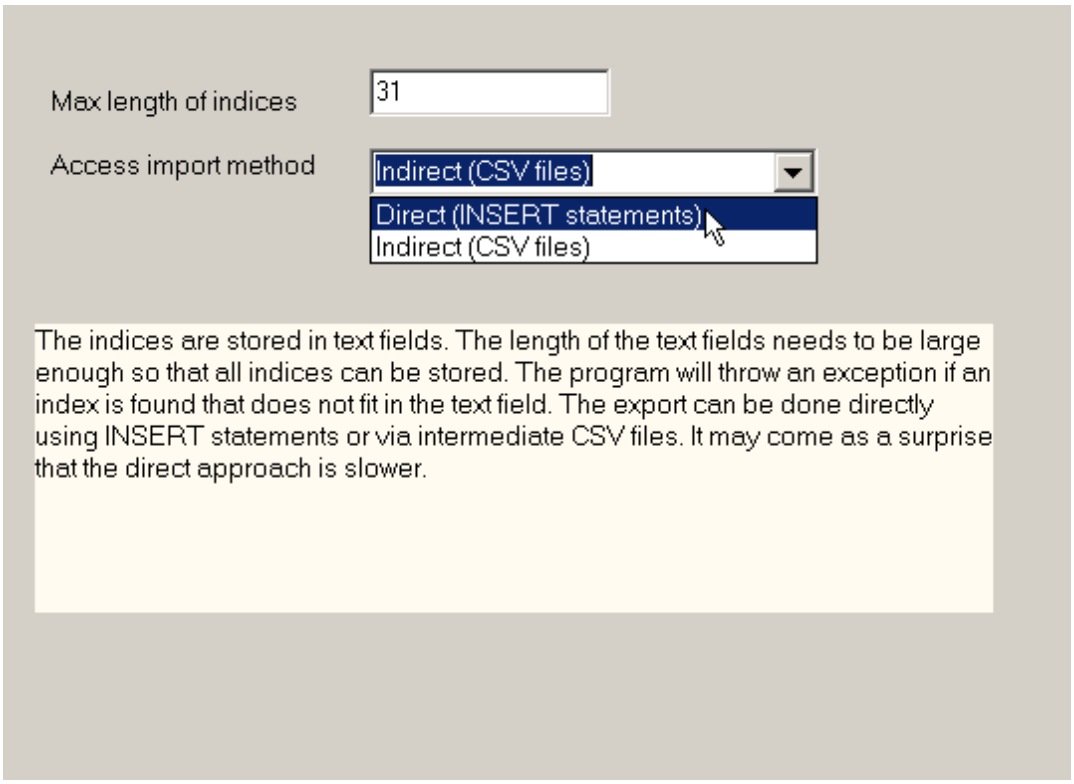
```
Parameter d 'distance in thousands of miles'
            / seattle.new-york 2.5, san-diego.new-york 2.5
              seattle.chicago  1.7, san-diego.chicago  1.8
              seattle.topeka   1.8, san-diego.topeka   1.4 /;
```

6.27.11 Exporting to an Access Tables

GDXVIEWER can export data directly to a table in an Access database using `File|Export|Access (MDB or ACCDB) File`. The name of the table will be the name of the parameter. If the table already exists, GDXVIEWER will try to create a new table with a slightly different name (e.g. d2, d3,...).



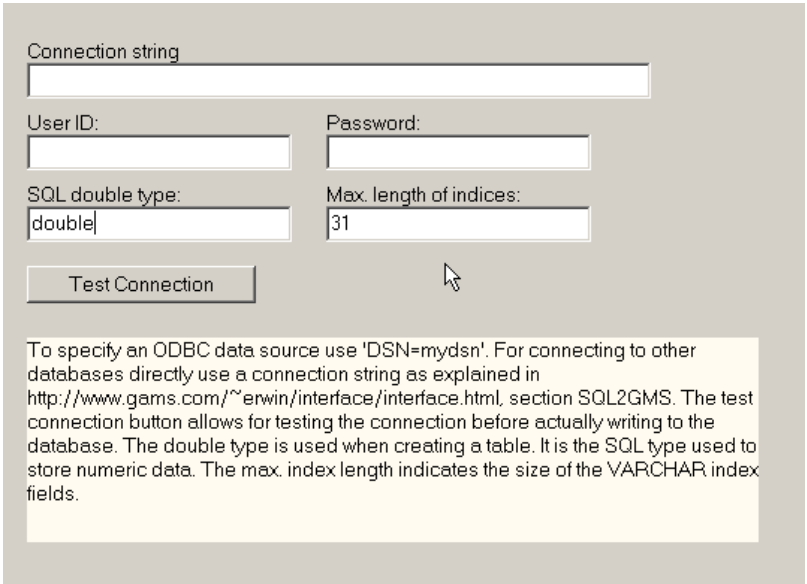
An option `Options|Configuration|Access` allows you to set the length of the text fields where the GAMS indices are stored. This length is used when creating the table.



A feature added in version 2.9 is the possibility to use intermediate CSV (comma separated value) files instead of using direct SQL INSERT statements. The CSV files can be read into Access using a bulk operation and is therefore faster for large datasets. When using CSV files make sure double quotes are used (if single quotes are used they will become part of the data). The temporary CSV files will be written to the Windows TEMP directory (e.g. `C:\WINDOWS\TEMP`). When the import is done, these scratch files will be removed automatically. If you want to look at the CSV files that are being fed into Access, export the data to a CSV file.

6.27.12 Exporting to an SQL Table

It is possible to export data to SQL databases through ADO which includes all databases accessible through ODBC. The configuration information can be specified in `Options`|`Configuration`|`SQL Database`.



The **Test Connection** button will allow you to check the configuration and see if the database can be connected to.

The SQL data for double precision number is no always the same for each database. E.g. for MS Access you can use **double** while for MS SQL server you can use **float**.

When exporting data a new table is created with the name of the identifier. If such a table already exists, names like **name2**, **name3**, are tried.

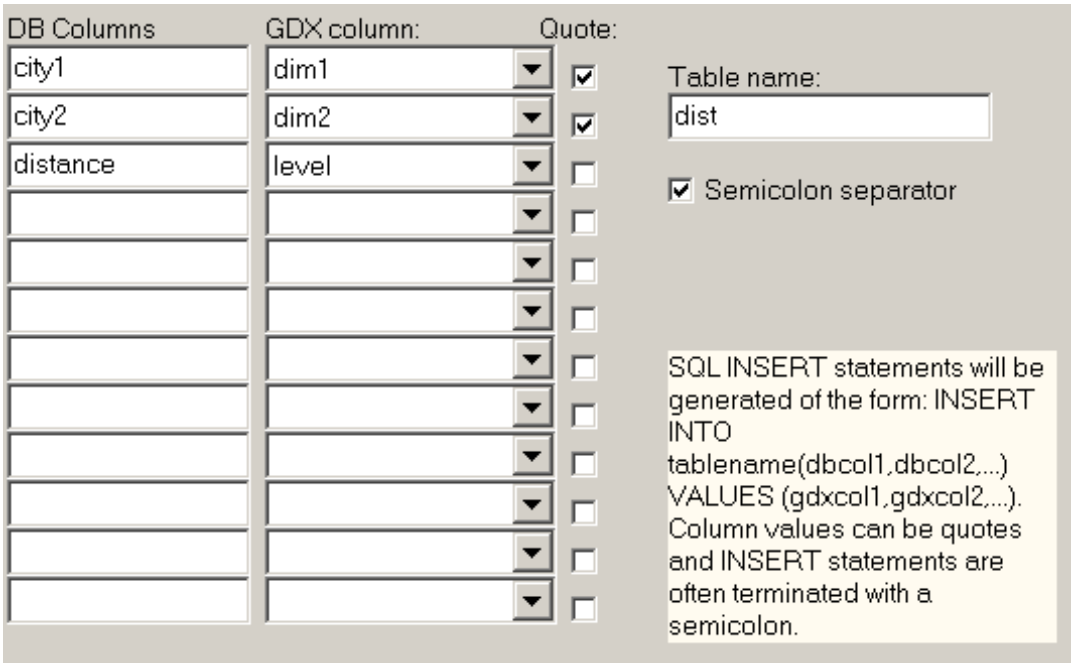
6.27.13 Exporting to MS SQL Server

We can export to Microsoft SQL Server through the standard SQL export facility. However a special facility called BULK INSERT is only available through the specialized SQL Server export tool. BULK INSERT writes a TAB delimited text file to the Windows TEMP directory and subsequently calls BULK INSERT to load that file. This way is often much faster that using individual INSERT statements for each record.

6.27.14 Exporting to SQL Insert script

An SQL script with INSERT statements like:

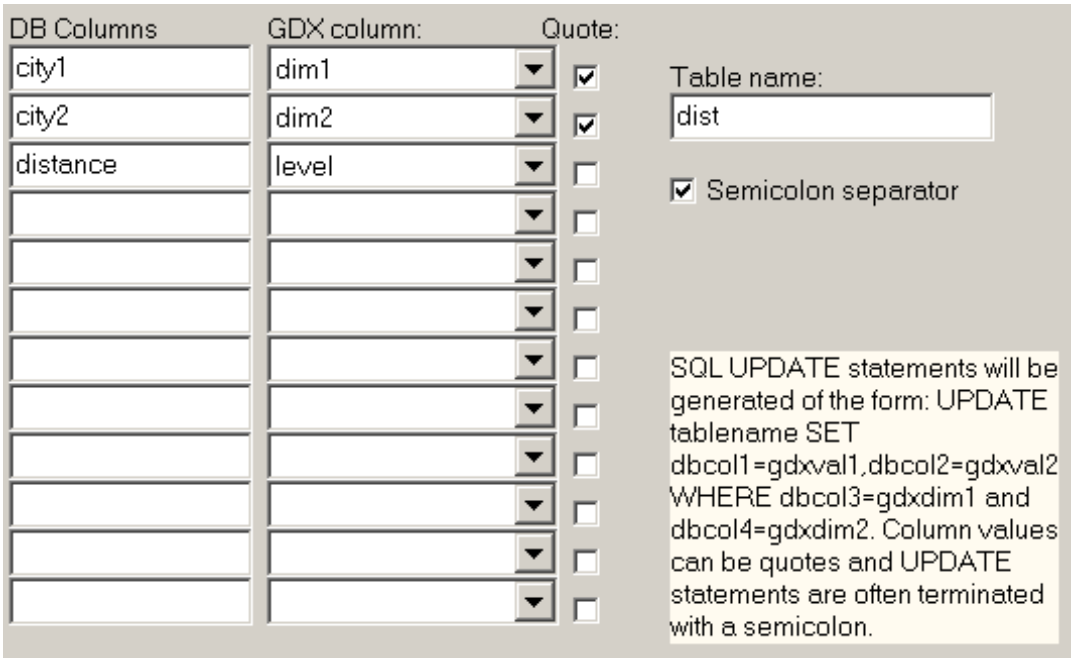
can be generated with `File`|`Export`|`SQL Insert script`. The following settings in `Options`|`Configuration`|`SQL Insert` were used:



6.27.15 Exporting to SQL Update script

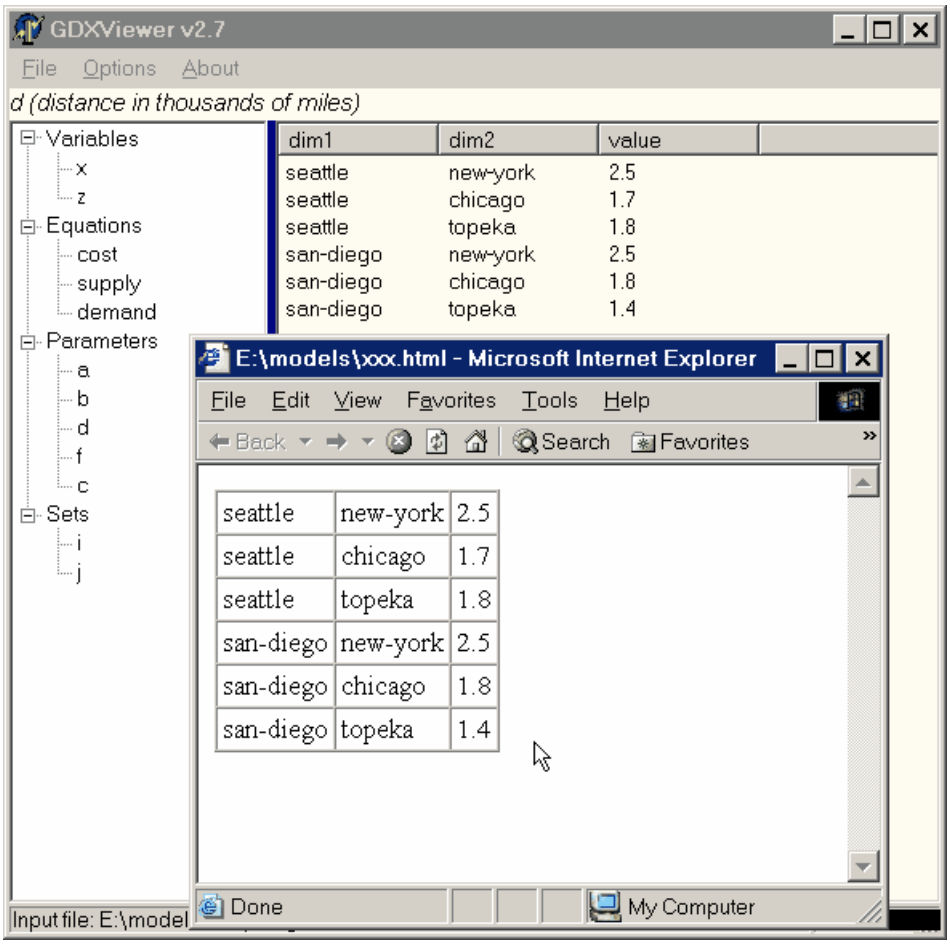
An SQL script with UPDATE statements like:

can be generated with `File`|`Export`|`SQL Update script`. The following settings in `Options`|`Configuration`|`SQL Update` were used:

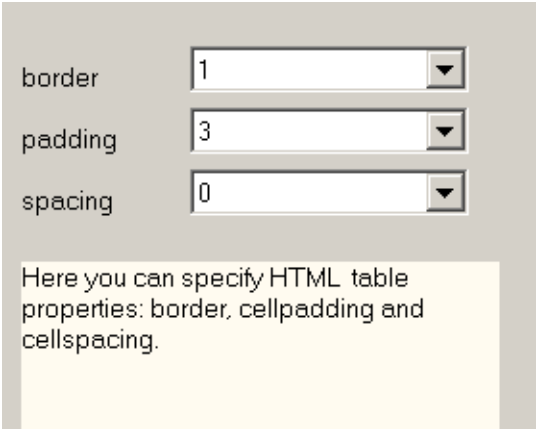


6.27.16 Exporting HTML

GDXVIEWER can write an identifier to an HTML file using `File`|`Export`|`HTML` File.

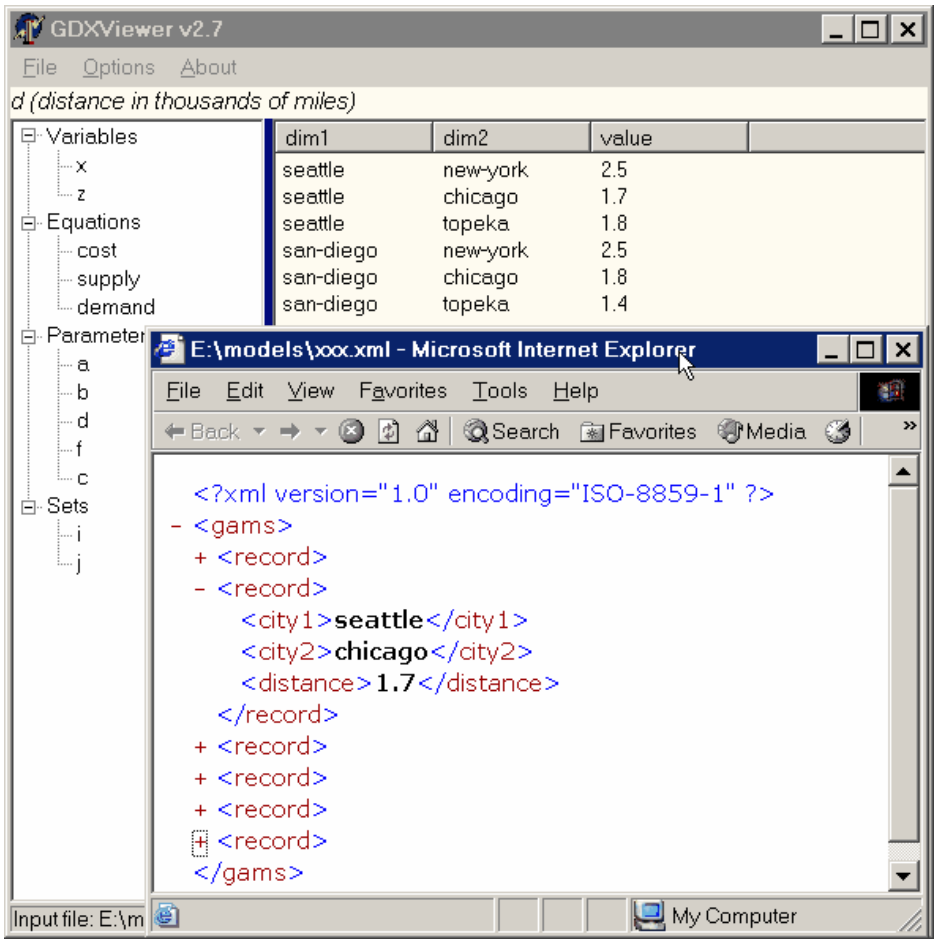


The options relevant to this format are specified in `Options`|`Configuration`|`HTML`.

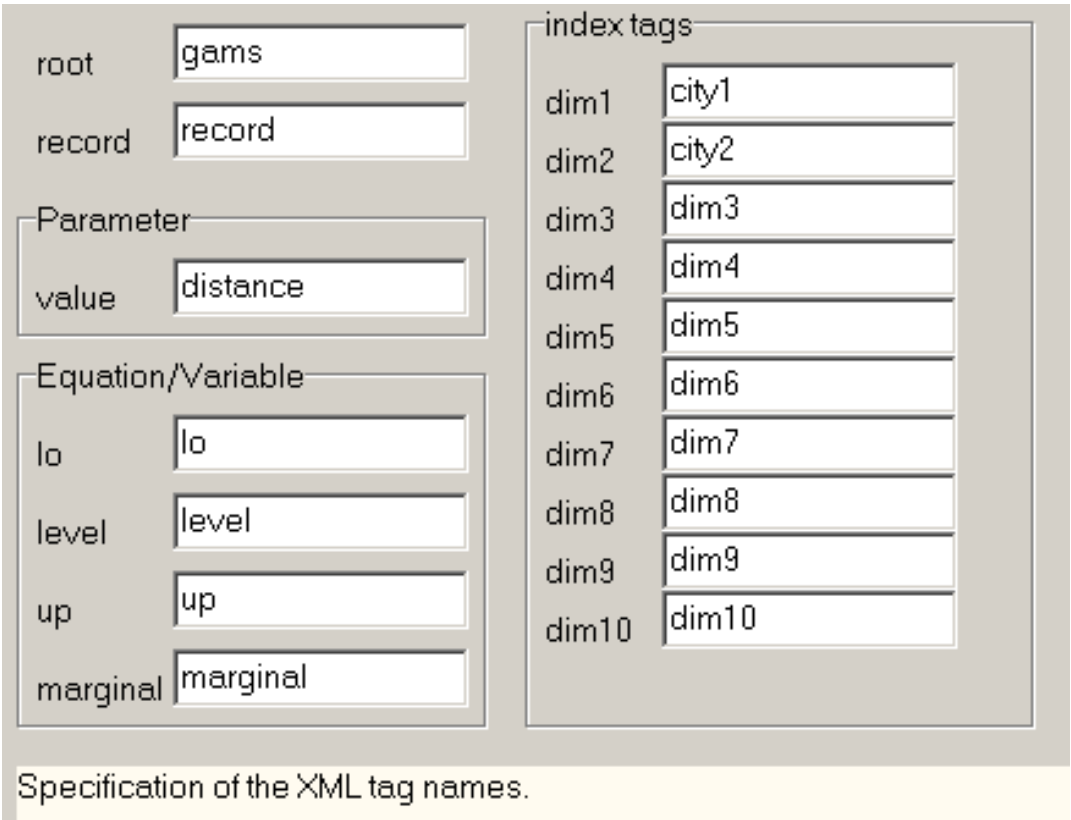


6.27.17 Exporting XML

GDXVIEWER can write an identifier to an XML file using `File`|`Export`|`XML File`.



The XML tags can be specified in `Options`|`Configuration`|`XML`.



6.27.18 Exporting fields

The menu `Options`|`Configuration`|`Export` allows you to set which fields are exported.

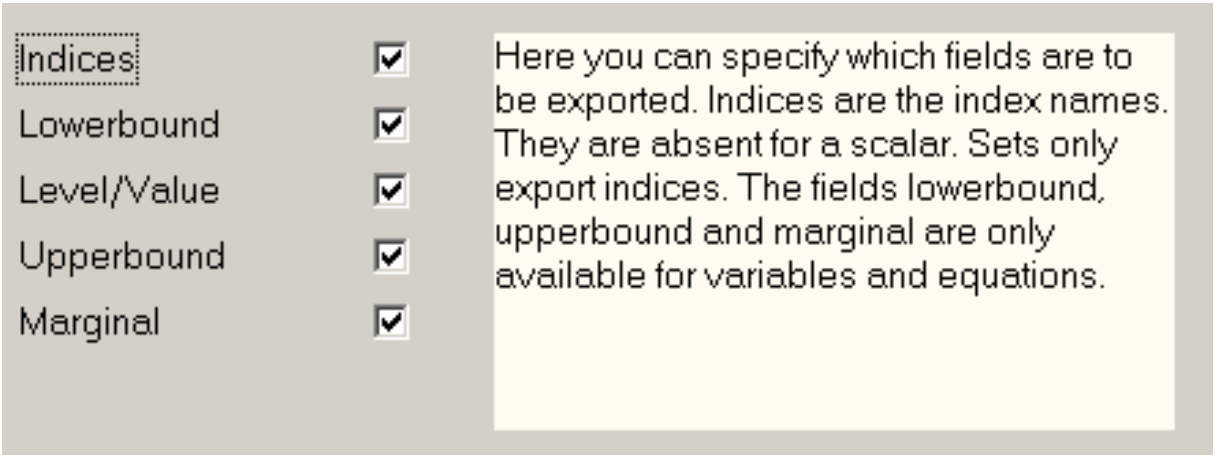


Figure 6.53 400px

The following table gives the possibilities for exports:

	set	scalar	parameter	variable	equation
Indices	+		+	+	+
Lower bound				+	+
Level/Value		+	+	+	+
Upper bound				+	+
Marginal				+	+

6.27.19 Special Values

GAMS data can assume so called special values: `-INF`, `+INF`, `EPS`, `NA`, and `UNDF`. The meaning of these special values is as follows:

Value	Description
-INF	Minus infinity. Mostly used for non-binding lowerbounds.
+INF	Plus infinity. Mostly used for non-binding upperbounds.
EPS	Mostly used for marginals where it can indicate non-basic but numerically zero.
NA	Not available. Not often used.
UNDF	Undefined. Not often used.

When exporting GAMS identifiers we need to map such values to strings that the receiving program can understand. E.g. we could map `{INF` to `{1.0e10` and `+INF` to `+1.0e10`. A good choice for `EPS` would be `0.0`.

The mapping can be specified in `Options`|`Configuration`|`Special Values`:

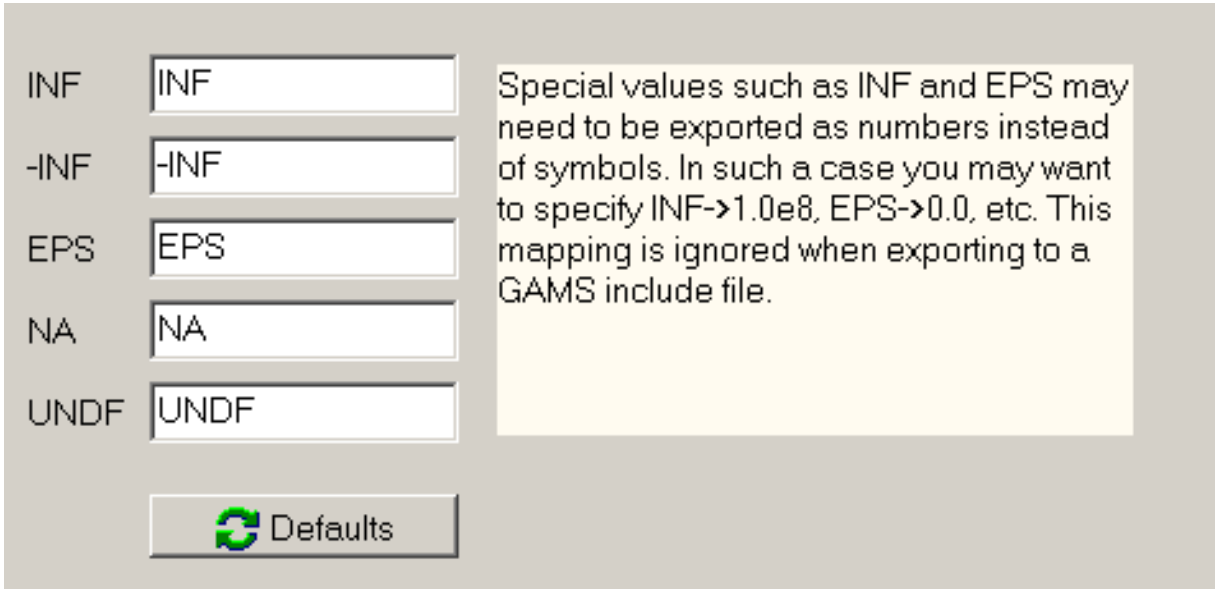

Figure 6.54 400px

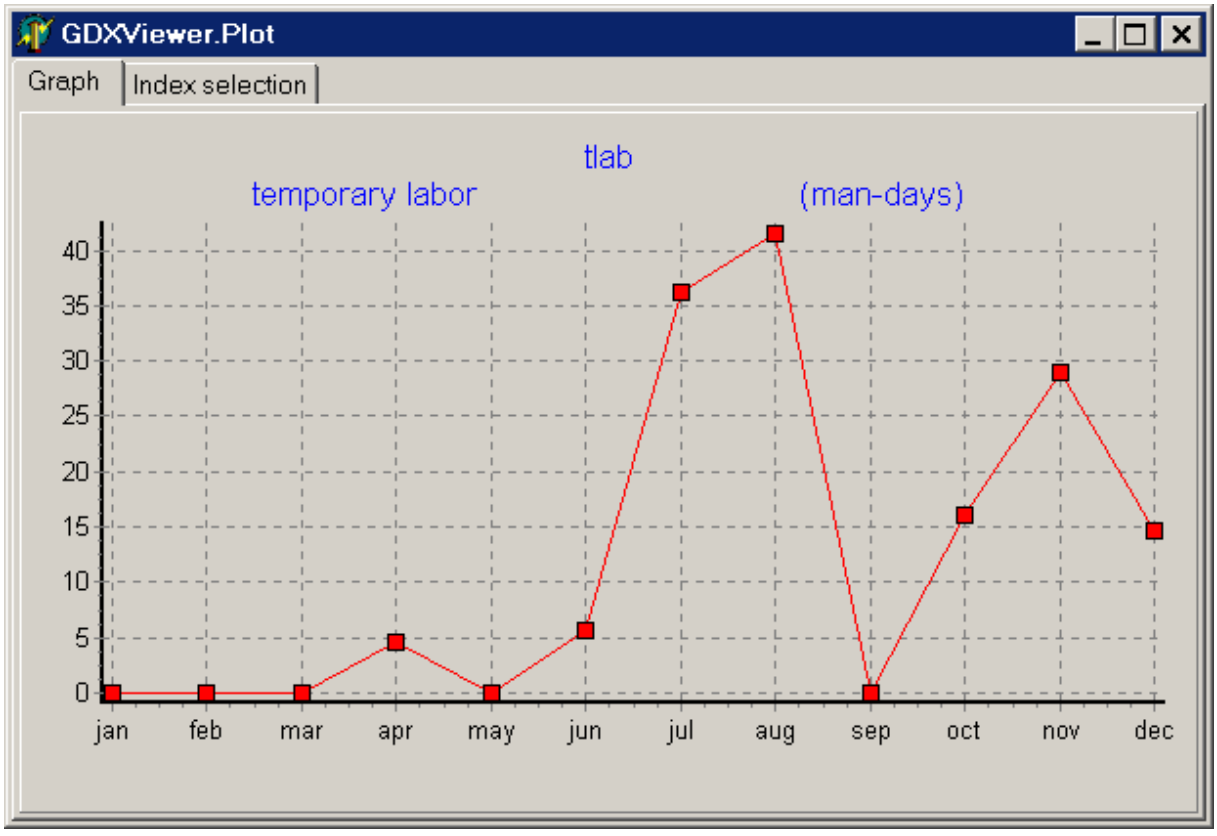
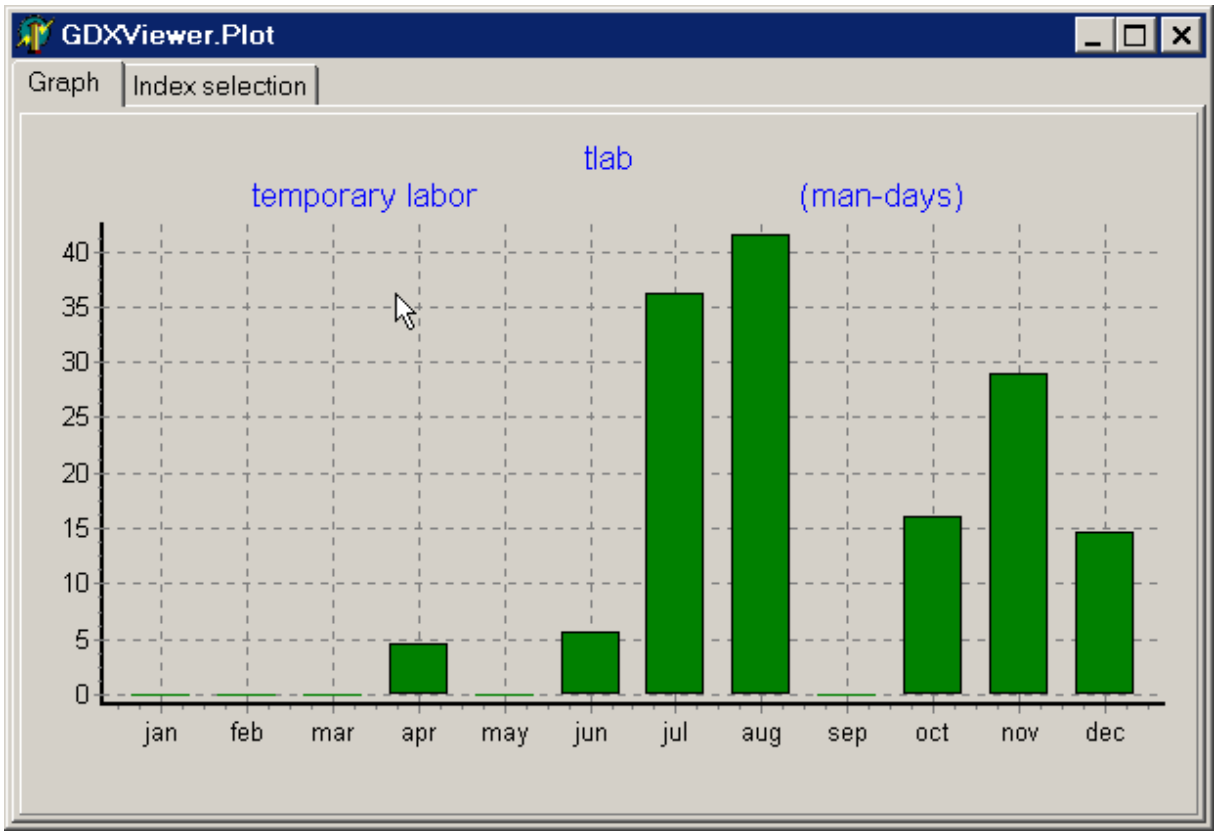
When we export to a GAMS include file all special values are understood, so the mapping is not used. The defaults button will reset the mapping to their default values.

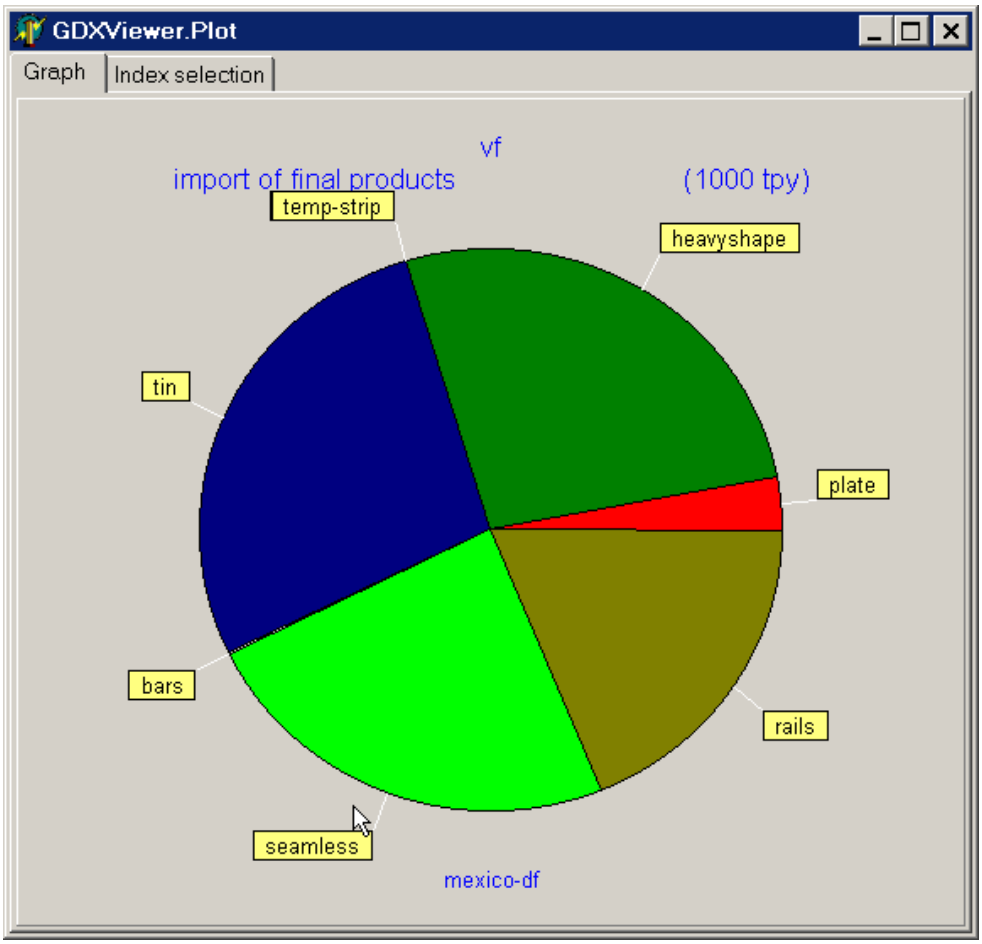
6.27.20 Plotting Data

GDXVIEWER has a built-in facility to quickly plot data. It includes LINE, BAR and PIE charts, examples are shown below. The plots can be made through the menu `File|Plot`.

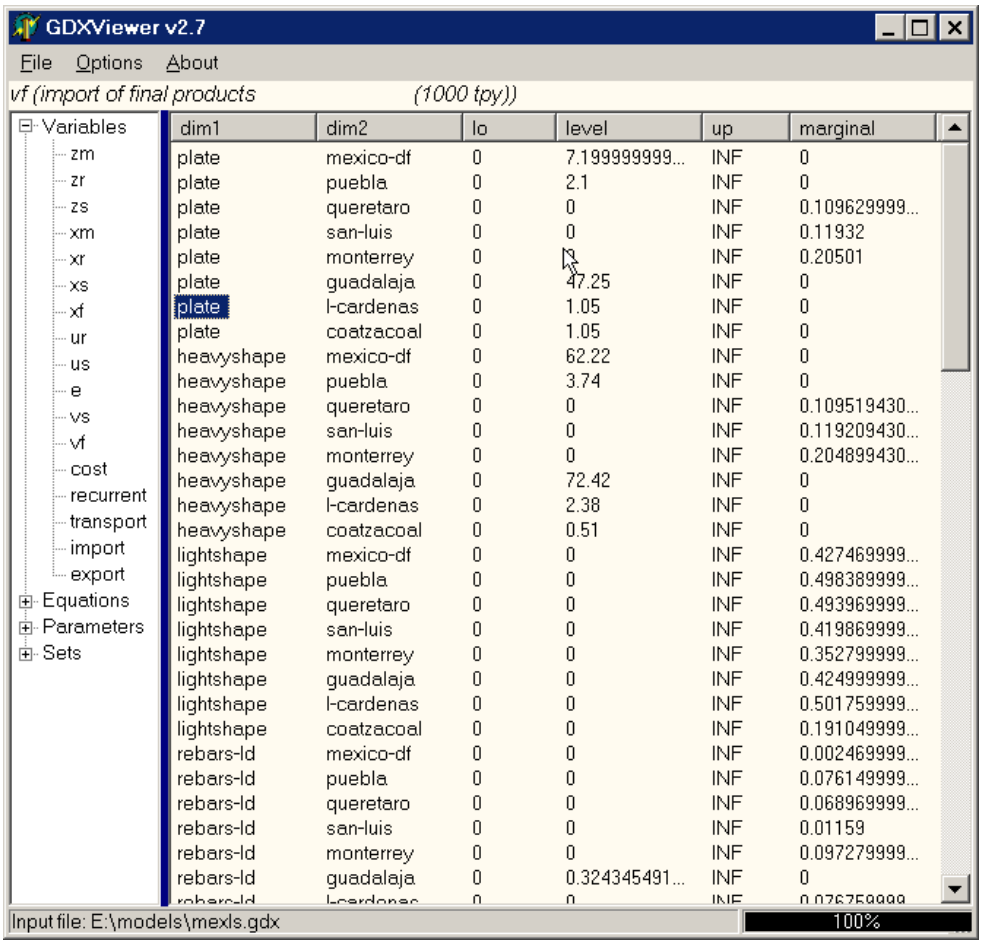




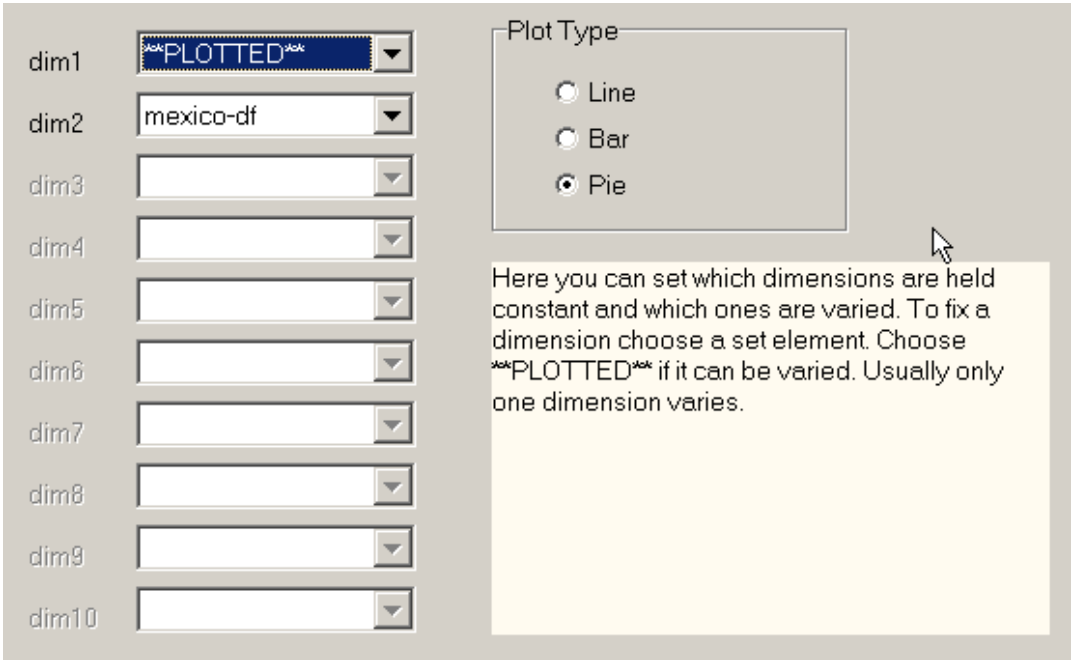
GDXViewer.Plot
Graph
Index selection
tlab
temporary labor
(man-days)
40
35
30
25
20
15
10
5
0
jan
feb
mar
apr
may
jun
jul
aug
sep
oct
nov
dec



For multi-dimensional data it may be needed to take a "slice" of the data to make meaningful graphs. In the example above we plotted a two dimensional quantity **vf** which looks like:

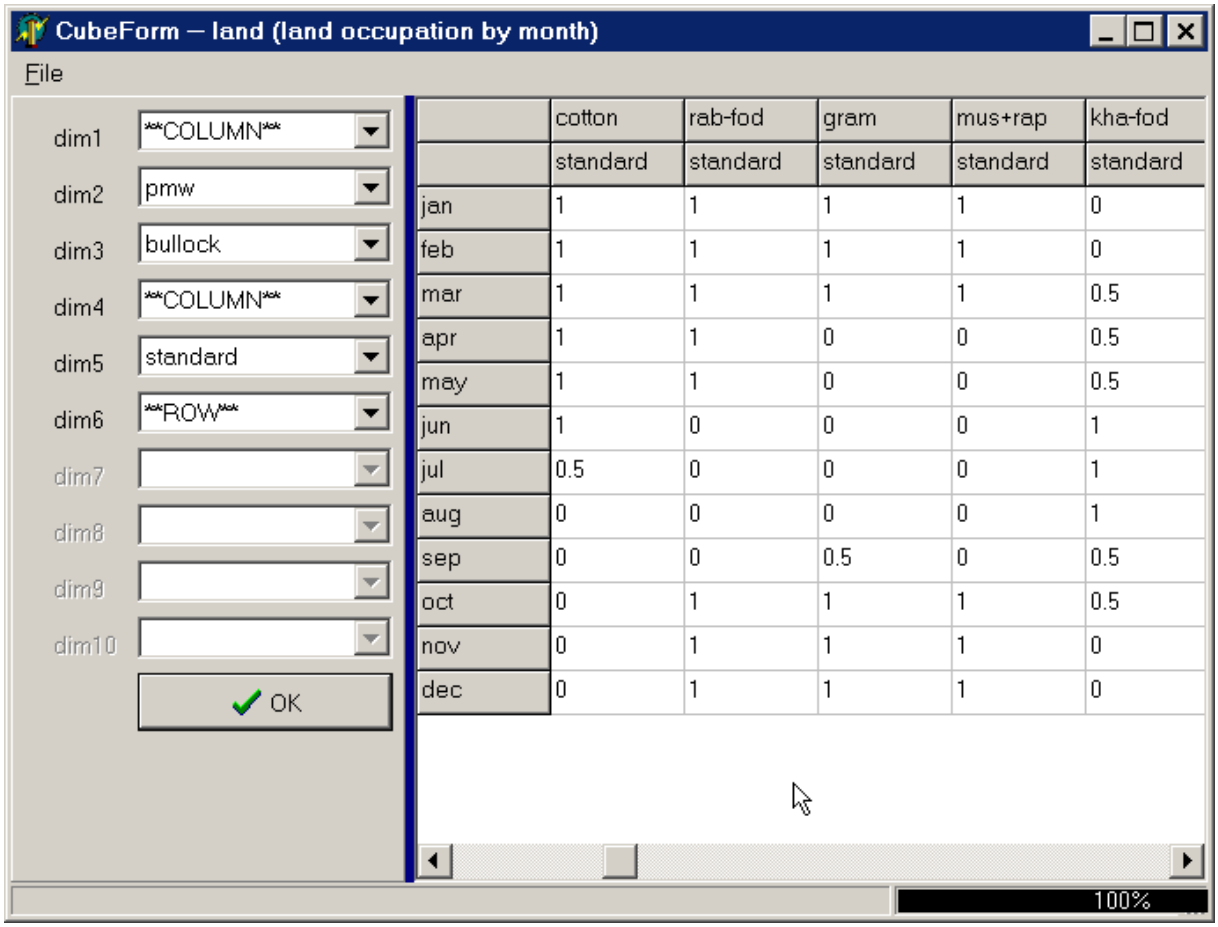


In this case we want to plot a pie graph of **vf(∗,'mexico-df')** which can be specified in the index-selection tab:



6.27.21 Cube View

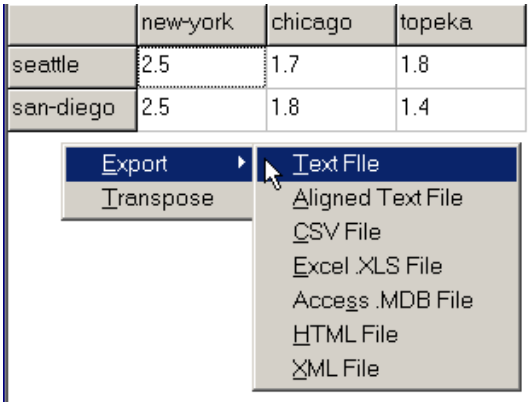
GDXVIEWER has a Cube View which allows to select rows and columns in a flexible way. In the example below we show a six dimensional variable where three dimensions are fixed, one dimension is chosen for the rows and two dimensions are chosen for the columns.



Below are some of the possibilities using parameter **d(i,j)** from the **trnsport.gms** model:

6.27.22 Exporting cubes

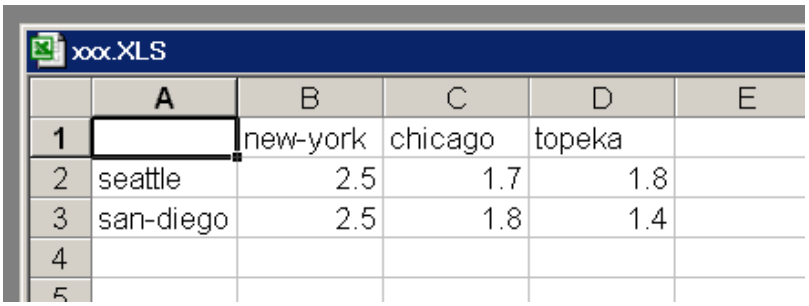
After creating a cube view, we can export that configuration by a right mouse click:



Exporting a cube will only export the selected slice (if certain dimensions are held fixed) and depending on the target format it will preserve the layout, e.g. an exported aligned text file can look like:

```
          new-york chicago topeka
  seattle      2.5     1.7    1.8
san-diego      2.5     1.8    1.4
```

Simarly, the XLS file can look like:



6.27.23 Commandline operation

The GDXViewer utility from version 2.3 accepts several command line parameters, so it can be used in a batch environment. When running in batch mode, the same configuration and option settings are used as for the interactive system and they can be changed by running GDXviewer interactively using the Options menu (the settings are saved in an INI file). It is advised to first run the program interactively until the results are as intended.

- **Single parameter** A single parameter is the filename of the GDX file. GDXViewer will load this file, and will continue to run interactively. Example: .

  ```
  Gdxviewer.exe test.gdx
  ```

- **XLS writing** To write an XLS file, one can use the syntax `i=inputfile.gdx xls=outputfile.xls id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is: @verbatim execute_unload 'd:\tmp\result.gdx',x; execute 'gdxviewer.exe i=d:\tmp\result.gdx xls=d:\tmp\result.xls id=x'; \endverbatim - Text file writing To write a text file, one can use the syntax <tt>i=inputfile.gdx txt=outputfile.txt id=x</tt>. If a path or filename contains blanks, the name can be surrounded by quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx txt=d:\tmp\result.txt id=x';
  ```

- **CSV file writing** To write a CSV file, one can use the syntax `i=inputfile.gdx csv=outputfile.csv id=x`. If a path or filename contains blanks, the name can be surrounded by quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is: @verbatim execute_unload 'd:\tmp\result.gdx',x; execute 'gdxviewer.exe i=d:\tmp\result.gdx csv=d:\tmp\result.csv id=x'; \endverbatim - HTML file writing To write an HTML file, one can use the syntax <tt>i=inputfile.gdx html=outputfile.html id=x</tt>. If a path or filename contains blanks, the name can be surrounded by quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx html=d:\tmp\result.html id=x';
```

- **XML file writing** To write an XML file, one can use the syntax `i=inputfile.gdx xml=outputfile.xml id=x`. If a path or filename contains blanks, the name can be surrounded by quotes ("). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is: @verbatim execute_unload 'd:\tmp\result.gdx',x; execute 'gdxviewer.exe i=d:\tmp\result.gdx xml=d:\tmp\result.xml id=x'; \endverbatim - GAMS include file writing To write a GAMS include file, one can use the syntax <tt>i=inputfile.gdx inc=outputfile.inc id=x</tt>. If a path or filename contains blanks, the name can be surrounded by quotes ("). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx inc=d:\tmp\result.inc id=x';
  ```

- **Access MDB file writing** To write a Access MDB file, one can use the syntax `i=inputfile.gdx mdb=outputfile.mdb id=x`. If a path or filename contains blanks, the name can be surrounded by quotes ("). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is: @verbatim execute_unload 'd:\tmp\result.gdx',x; execute 'gdxviewer.exe i=d:\tmp\result.gdx mdb=d:\tmp\result.mdb id=x'; \endverbatim - Excel Pivot Table writing To write a file containing a pivot table, one can use the syntax <tt>i=inputfile.gdx pivot=outputfile.xls id=x</tt>. If a path or filename contains blanks, the name can be surrounded by quotes ("). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
  ```

- **SQL Database Table writing** To write a table to an SQL database, first interactively configure the connection to the database. The Export SQL Database option allows you to see if a connection succeeded and if the correct database was accessed. The configuration information is written to the SQLVIEWER.INI configuration file. The information in this file is used also when performing a batch command-line operation. The syntax is: `i=inputfile.gdx sql id=x`. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx sql id=x';
  ```

If you need to access several different databases, you can copy the file `SQLVIEWER.INI` (located in the directory where `SQLVIEWER.EXE` is placed). To tell `GDXVIEWER` to read a different INI file, you can say:

```
execute_unload 'd:\tmp\result.gdx',x;
execute 'gdxviewer.exe i=d:\tmp\result.gdx ini=copy.ini sql id=x';
```

GDXVIEWER uses the MS Access and MS Excel applications as COM Object to write files in XLS (both XLS and PIVOT commands) or MDB format. Those applications may write to `C:\My Documents` in case no full path is specified. Other formats use the default GAMS working directory. In case when running under the IDE this is the location of the project file (∗.GPR).

If a path or file name contains a blank, then it is possible to surround the name by double quotes as in:

```
execute_unload 'result.gdx',x;
execute 'gdxviewer.exe i=result.gdx csv="c:\my documents\result.csv" id=x';
```

Under windows 98 ME the call

```
execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
```

will cause GAMS to continue while GDXVIEWER is executing. If we use:

```
execute '=gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';
```

GAMS will wait until **gdxviewer.exe** is terminated before executing more statements. This situation is different under other operating systems such as XP and NT.

6.27.24 Notes

GDX

GDX stands for **Gams Data** Exchange. It is a binary file format to get data in and out of GAMS.

6.28 GDXXRW

`GDXXRW` is a utility to read and write Excel spreadsheet data. `GDXXRW` can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet.

Note

- GDXXRW is available on Windows only. This is an important factor to consider when moving an existing code to GAMS Engine.
- GDXXRW can also be used to read csv files. Please be aware that Excel files have a row and column number limit and that rows and columns in csv files beyond this limit may be ignored.

6.28.1 Usage

```
gdxxrw inputFile {outputFile} {options} [symbols]
```

Options and symbol specifications can also be read from a text file; the use of an option file is indicated by preceding the file name with a `@` (At sign.). When reading from a text file, lines starting with an asterisk (∗) will be ignored and act as a comment.

Options and symbol specifications can also be read from an area in a spreadsheet; see index below.

Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. The use of file names with embedded blanks is allowed as long as the file name is enclosed in double-quotes (").

Note

A libinclude tool is available to see if Excel is installed, to close an Excel file etc. See Windows Only Tools (win32) for more details. To read data from an Excel file without Excel installed see XLSDUMP.

6.28.2 Options

Describing the actions to be taken by GDXXRW requires passing a number of options and symbol specifications to the program. The ability of GDXXRW to process multiple actions in a single call makes the option passing and interpretation more complex.

There are four kinds of options:

1. **Immediate** Immediate options are recognized and processed before any other actions are taken and can only be specified once. Examples are:

   ```
   input= output= trace=
   ```

2. **Global** Global options are interpreted from left to right and affect every action that follows. The same option can be used multiple times to affect the actions that follow. Examples are:

   ```
   skipEmpty= epsOut=
   ```

3. **Symbol** A symbol definition introduces a new action for reading or writing a symbol. Examples are:

   ```
   par= set= dSet=
   ```

4. **Symbol attributes** Attributes specify additional information for the last symbol defined. Examples are:

   ```
   dim= cDim= merge clear
   ```

6.28.2.1 Immediate Options

Immediate options are recognized independent of their position on the command line. They are global and they can only be specified once.

Option	Default	Description
input	none	Specify the input filename (required).
output	inputFileName	Specify the output filename.
log	none	Specify the log filename.
logAppend	none	Appending the log information to the file specified.
index	none	Indicates reading the options and symbols directly from the spreadsheet.
password	none	Password for an encrypted input file.
rWait	0	Delay after opening a spreadsheet.
checkDate	disabled	Write GDX file only if the input file is more recent than the GDX file.
useRC	disabled	Use Row-Column notation to specify cells and ranges.
reCalc	N	Controls if recalculations of cells inside Excel are executed after writing to the spreadsheet.
trace	1	Controls the amount of information written to the log.
maxDupeErrors	0	Maximum number of duplicate records allowed for a symbol.
updLinks	0	Updating of cells that refer to other spreadsheets.
runMarcos	0	Execution of Excel Auto macros.

Some more detailed remarks on the immediate options:

input = *fileName* (required, default = none)

Synonym: i

Either use the keywords `input` or `i` to specify the input file name anywhere on the command line or just specify the input file name without keyword at the first position behind `GDXXRW`. The file extension of the input file is required and determines the action taken by the program.

The extension .gdx for the input file will read data from a GDX file and write data to a spreadsheet. The extension .xls, .xlsx, .xlsm, or .xlsb for the input file will read a spreadsheet and write the data to a .gdx file. In addition to the .xls, .xlsx, .xlsm, or .xlsb input file extension, the following file extensions are also valid for spreadsheet input files: .wk1, .wk2, .wk3 and .dbf.

A file sharing conflict will arise when writing to a spreadsheet with the target file open in Excel. Either close the file in Excel before executing `GDXXRW`, or mark the spreadsheet as a shared workbook in Excel. To change the shared status of a workbook, use the Excel commands available under: `Tools`|`Share Workbook`.

Writing to a shared workbook can be painfully slow; simply closing the file and reopen the file after `GDXXRW` has finished is often a better option.

output = *fileName* (default = inputFileName)

Synonym: o

When an output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. The file type, i.e. the file extension, depends on the installed version of Excel. Versions prior to Excel 2007 use the .xls file extension, later version use .xlsx, .xlsm, and .xlsb. Excel 2007 can write .xls files, but in that case the output file has to be specified with an .xls file extension.

log = *fileName* (default = none)

Specifies the filename of the log file. When omitted, log information will be written to standard output. When using `GDXXRW` in a GAMS model that is started from the GAMS IDE, the output will be written to the IDE process window.

logAppend = *fileName* (default = none)

Using `logAppend` will add the log information to the end of the file specified. If the file does not exist yet, a new one will be created.

index = *Excel Range*

The `index` option is used to obtain the global options, symbols and symbol attributes specified by reading them from the spreadsheet directly. The parameters are read using the specified range, and treated as if they were specified directly on the command line. The first three columns of the range have a fixed interpretation: dataType, Symbol identifier and dataRange. The fourth and following columns can be used for additional parameters. The column header contains the keyword when necessary, and the cell content is used as the parameter value. See Reading Spreadsheet using the Index Option for instance.

password = *string* (default = none)

Specifies a password for a protected spreadsheet file.

rWait = *integer* (default = 0)

Introduce a delay (in milliseconds) after opening a spreadsheet before accessing the data. This parameter can be used to work around an issue we encountered that Excel indicated it was not ready. The issue can arise during the data exchange with Excel Sheets that contain macros, plots or pivot tables where `GDXXRW` attempts to access a sheet while Excel is busy updating macros, graphs, and pivot tables.

checkDate (disabled by default)

When specified, no data will be written if the output file already exists and the file date for the output file is more recent than the file date for the input file. Provides a simple check to update the output file only if the input file has changed to save resources.

useRC (disabled by default)

Specify that all cell and range references use RC notation. So, instead of specifying the range Sheet1!A1:D6, one specifies Sheet1!R1C1:R6C4. When tracing is enabled, ranges will be reported in RC notation. This is a global option and applies to all cell references.

reCalc = *flag* (default = `N`)

Enable or disable the recalculations of cells inside Excel after writing to the spreadsheet. If there are many formulas in the spreadsheet the recalculation of cells can become very expensive and slowing down the writing process. By default, the recalculation is disabled and can be enabled via this option.

trace = *integer* (default = 1)

Sets the amount of information written to the log (for a better debugging). Higher values will generate more output. Valid range is `0..4`.

0 Minimal information is included in the output
1 Message appears telling about each `GDXXRW` call indicating input file, output file and execution time
2 Message appears giving the level 1 output plus a listing for each symbol specified, indicating the type, sheet name, dimension, data range and the range of the row and column headers
3 Message appears giving the level 2 output plus cell ranges affected by reading, writing and clearing
4 Message appears giving the level 3 output plus cell addresses, and numerical or string values for every cell worked with

maxDupeErrors = *integer* (default = 0)

Sets the maximum number of duplicate records that is allowed when reading a spreadsheet and writing to a GDX file. The duplicate records for each symbol will be reported in the logfile, and if their accumulated number does not exceed the maximum specified using this option, the GDX file will not be deleted. This is a global option and applies to each symbol read from the spreadsheet.

The option is demonstrated in Reading Set from Lists with Duplication.

updLinks = *integer* (default = 0)

Specifies how links in a spreadsheet should be updated. The valid range is `0..3`.

0 Doesn't update any references
1 Updates external references but not remote references
2 Updates remote references but not external references
3 Updates both remote and external references

runMacros = *integer* (default = 0)

This option controls the execution of the 'Auto_open' and the 'Auto_close' macros when opening or closing a spreadsheet. Valid range is `0..3`.

0 Doesn't execute any macros
1 Executes Auto_open macro
2 Executes Auto_close macro
3 Executes Auto_open and Auto_close macro

6.28.2.2 Global Options

The following options affect the symbols that follow the option. They remain in effect unless they are redefined and used again for another symbol.

Option	Default	Description
acronyms	0	Controls the handling of acronyms.
cMerge	0	Controls the handling of merged Excel ranges.
dSetText	`N`	Read explanatory text for set elements of domain sets.
epsOut	`Eps`	String to be used when writing the value for 'Epsilon'.
filter	0	Set the Excel filter for symbols written to Excel.
incRC	`N`	Include Excel row and column indices when a symbol is written to the GDX file.
mInfOut	`-Inf`	String to be used when writing the value for 'Negative infinity'.
NaIn	none	String to be used when reading a value for 'Not available'.
nameConv	`N`	Controls the interpretation of an Excel range.
NaOut	`NA`	String to be used when writing the value for 'Not available'.
pInfOut	`+Inf`	String to be used when writing the value for 'Positive infinity'.
resetOut	disabled	Reset the output strings for special values to their defaults.
squeeze	`Y`	Controls writing of default values of sub-fields of variables and equations resp. the handling of zero values within parameters when reading from spreadsheet.
skipEmpty	1	Number of empty row or column cells to ignore before the next empty row or column indicates the end of a block when reading from spreadsheet using the top left cell specification.
UndfOut	`Undf`	String to be used when writing the value for 'Undefined'.
allUELs	`Y`	Controls the handling of UELs without associated values in the data range.
zeroOut	0	String to be used when writing the value for 'Zero'.

Some more detailed remarks on the global options:

acronyms = *integer* (default = `0`)

A non-zero value indicates that acronyms can be expected and should be processed.

If no acronym processing takes place, reading an identifier in the data section of a sheet will generate an error. Writing an acronym to a sheet will write the internal numerical representation of the acronym.

Processing acronyms:

When reading a spreadsheet, an identifier in the data section of the sheet will be interpreted as an acronym and will be written to the GDX file.

When writing to a spreadsheet, a data tuple containing an acronym will be stored using the corresponding identifier of the acronym.

cMerge = *integer* (default = `0`)

Option indicating how to read an empty cell that is part of a merged Excel range. See Reading merged Excel Ranges with cMerge. Possible values and their interpretation are:

0 Leave the cell empty
1 Use merged value in row and column headers only
2 Use merged value in all cells

dSetText = *flag* (default = `N`)

Valid only when reading a spreadsheet.

This controls the reading of explanatory text for set elements of domain sets. By default, no text is read for domain sets. If this option is activated this is changed. If an element appears more than once, the first one defines the explanatory text read.

epsOut = *string* (default = `Eps`)

String to be used when writing the value for 'Epsilon'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet and Writing Parameter to Spreadsheet including Zero Values.

filter = *integer* (default = `0`)

Adds basic Excel filter to the columns of the spreadsheet to display only those values matching some conditions. Using this option when reading an Excel file will result in an error. Specifying `filter=1` will set an Excel filter for the row of labels that are closest to the data values. When there are multiple rows in a column header (`cDim > 1`) we can specify `filter=x` where `x` is a number of the range `2..cDim`, indicating to use a row farther away from the data values. See also Writing to Spreadsheet using a Filter.

incRC = *flag* (default = `N`)

Valid only when reading a spreadsheet.

Include Excel row and column indices when a symbol is written to the GDX file. For example, when we write a parameter `P` with indices `I` and `J`, without this option it will be written as `P(I, J)`. When `incRC` is enabled, the parameter will be written as `P(Excel_Rows, I, Excel_Columns, J)`. Note that the sets `Excel_Rows` and `Excel_Columns` will be added to the GDX file automatically.

mInfOut = *string* (default = `-Inf`)

String to be used when writing the value for 'Negative infinity'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

NaIn = *string* (default = none)

String to be used when reading a value for 'Not available'; this string is recognized in addition to the string 'NA' and is not case-sensitive. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

nameConv = *flag* (default = `N`)

Synonym: nC

The naming convention parameter is used to change the interpretation of an Excel range that does not contain an '!' (exclamation mark). For details see Excel Ranges below.

NaOut = *string* (default = `NA`)

String to be used when writing the value for 'Not available'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

pInfOut = *string* (default = `+Inf`)

String to be used when writing the value for 'Positive infinity'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

resetOut (disabled by default)

Reset the output strings for special values to their defaults. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

squeeze = *flag* (default = `Y`)

Synonym: sq

Writing to a spreadsheet:

The `squeeze` option affects the writing of sub-fields of variables and equations. A value for the field that is the default value for that type of variable or equation will not be written to the spreadsheet. For example, the default for `.l` (level value) is `0.0`, and therefore zero will not be written to the spreadsheet. When we set `squeeze=n`, all values will be written to the spreadsheet.

The `squeeze` option for writing data is demonstrated in Reading Data from Spreadsheet and writing Data t and Writing Parameter to Spreadsheet including Zero Values.

Reading a spreadsheet:

When the `squeeze` option is enabled, zero values for parameters will not be written to the GDX file. When the `squeeze` option is disabled, zero values will be written to the GDX file. In either case, empty cells, or cells containing blanks only, will never be written to the GDX file.

The `squeeze` option for reading data is demonstrated in Reading Special Values from Spreadsheet and writi

skipEmpty = *integer* (default = `1`)

Synonym: sE

The `skipEmpty` option can be used when reading a spreadsheet and the range is specified using the top left corner instead of a block range. The value defines the number of empty row or column cells to ignore before the next empty row or column signals the end of a block. Valid values are `0..n`. If the range is specified using a block range, `skipEmpty` will be ignored. Blank rows or columns will be skipped automatically.

Note that `skipEmpty` is also valid when using the merge resp. clear options in order to write data to spreadsheet (in a specific order determined by matching row and column labels already stored in the spreadsheet).

See Skipping Empty Rows and Columns or Reading Multi-dimensional Parameter from Spreadsheet for instance.

UndfOut = *string* (default = `Undf`)

String to be used when writing the value for 'Undefined'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

allUELs = *flag* (default = `Y`)

Valid only when reading a spreadsheet.

When enabled, all unique elements found in a range will be entered in the GDX file. When disabled, only those unique elements that are used in conjunction with a value will be entered in the GDX file.

zeroOut = *string* (default = `0`)

String to be used when writing the value for 'Zero'; by default this is '0'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

6.28.2.3 Symbols

To write data to a spreadsheet or to a GDX file, one or more symbols and their associated Excel range need to be specified. See also Excel Ranges.

The general syntax for a symbol specification is:

dataType=*symbolName* {symbolAttributes}

dataTyp	Description

Among the symbolAttributes, one specifies the dataRange, the dimensions of the symbol and some additional symbolOptions in general.

dataType

dataTyp	Description
par	Declare the symbol as parameter and define a individual name when reading from spreadsheet, or specify a parameter from a GDX file when writing to spreadsheet.
equ	Specify a sub-field of a equation from a GDX file when writing to spreadsheet.
var	Specify a sub-field of a variable from a GDX file when writing to spreadsheet.
set	Declare the symbol as set and define a individual name when reading from spreadsheet, or specify a set from a GDX file when writing to spreadsheet.
dSet	Declare the symbol as domain set and define a individual name when reading from spreadsheet, or specify a domain set from a GDX file when writing to spreadsheet.
text	Write the text specified to spreadsheet. One can also create hyperlinks, using the link resp. linkID statement.
textID	Write the explanatory text of an identifier stored in the GDX file to spreadsheet.
hText	Write sections of the text specified to different cells in the horizontal direction (row).
vText	Write sections of the text specified to different cells in the vertical direction (column).

par = *GAMS_Parameter*

Specify a GAMS parameter to be read from a GDX file and written to spreadsheet, or to be read from a spreadsheet and written to a GDX file.

When writing to a spreadsheet, special values such as `Eps`, `NA` and `Inf` will be written in ASCII. When reading data from a spreadsheet, the ASCII strings will be used to write the corresponding special values to the GDX file.

This datatype is used in the most examples. Reading parameters is demonstrated in Reading Parameter from Spreadsheet or Reading Multi-dimensional Parameter from Spreadsheet. Writing parameters from GDX to spreadsheet is demonstrated in Writing Parameter to Spreadsheet.

equ = *GAMS_Equation*
var = *GAMS_Variable*

A sub-field of a variable or equation can be written to a spreadsheet and should be specified as part of the symbolName. The fields recognized are `.l` (level), `.m` (marginal), `.lo` (lower bound), `.up` (upper bound), `.prior` (priority), and `.scale` (scale). The sub-field names are not case-sensitive. See also Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve.

A sub-field of a variable or equation cannot be read from a spreadsheet and written to a GDX file.

set = *GAMS_Set* [values = *valueType*]

In GAMS we can define a set by specifying all its elements. In addition, each tuple can have an associated text. To read a set from a spreadsheet, the values option is used to indicate if there is any data, and if there is, if the data should be interpreted as associated text or as an indicator whether the tuple should be included in the set or not.

Reading sets is demonstrated in Reading Set from Spreadsheet or Reading Set Elements associated with Data o (focusing on the `values` option) for instance. Writing sets from GDX to spreadsheet is demonstrated in Writing Set to Spreadsheet.

valueType	Interpretation
auto	Based on the range, row and column dimensions for the set, the program decides on the valueType to be used. This is the default for `values`.
noData	There is no data range for the set; all tuples will be included.
YN	Only those tuples will be included that have a data cell that is not empty and does not contain '0', 'N' or 'No'.
sparse	Only those tuples will be included that have a data cell that is not empty. The string in the data cell will be used as the associated text for the tuple.
dense	All tuples will be included. A string in the data cell will be used as the associated text for the tuple.

Due to backward compatibility, `valueType=string` or `all` are also recognized and are synonyms for `valueType=dense`. The following table summarizes which valueType will be used when reading a set, if a valueType was not specified:

Range specification	rDim = 0 Or cDim = 0	rDim > 0 And cDim > 0
Top left corner only	dense	YN
A block, but the data range is empty	dense	YN
A block, and there is a data range	dense	YN

When writing to a spreadsheet, the entire set is written to the spreadsheet and the writing of the associated text is governed by the values option:

valueType	Interpretation
auto	If `rDim=0` or `cDim=0`, auto means string, otherwise auto means YN.
noData	Neither associated text nor 'Y' is written for a set element.
YN	A 'Y' is written for a set element.
string	The associated text is written for a set element. If no text is stored with set element the cell will be empty.

Due to backward compatibility, `valueType=dense`, `sparse` or `all` are also recognized and are synonyms for `valueType=string`.

dSet = *GAMS_Set*

A domain set is used to read the domain of a set from a spreadsheet row or column. Either the row or the column dimension (`rDim` or `cDim`) should be set to '1' to specify a row or column for the set, resulting in a one-dimensional set. Duplicate labels in the range specified do not generate an error message. For instance, see also Reading Set from Lists with Duplication.

Note that reading explanatory text of set elements is not supported by `dSet`. In order to read explanatory text, use set instead. If there are duplicate set element labels in your data, use the `set` symbol specification while increasing the value of the immediate option maxDupeErrors to oppress an error message when reading duplicates.

text = *"String of characters"* {dataRange}
textID = *Identifier* {dataRange}

Write the text to the cell specified in the DataRange. In addition, `textID` will write the explanatory text of the Identifier in the cell to the right of the dataRange.

A Text directive can be followed by a link=*Address* or linkID=*identifier* directive. Using `link` will create a hyperlink to an external page or to a cell in the spreadsheet, while `linkID` will create a hyperlink to the top left corner of the symbol specified. See Writing to Spreadsheet adding Text and Hyperlinks for instance.

hText = *"String of characters"* {dataRange}
vText = *"String of characters"* {dataRange}

Write a string of characters in the horizontal direction for `hText` or vertical direction for `vText`. Text for the next cell is indicated by a comma. In order to write a comma as part of the text, the comma needs to be preceded by a backslash. See Writing Set to Spreadsheet for instance.

Symbol Attributes

The following options apply to the symbol preceding the option, and only affect that symbol:

Parameter	Default	Description
dataRange	Cell A1 of the first sheet	Specify the Exel range of the symbol for reading from spreadsheet or for writing to spreadsheet.
dim	2 when reading from spreadsheet Defined by the symbol dimension stored in the GDX file when writing to spreadsheet	Total dimension of the symbol. Please also refer to section More about dimensions.
cDim	`1`	Column dimension of the symbol. Please also refer to section More about dimensions.
rDim	`dim-1`	Row dimension of the symbol. Please also refer to section More about dimensions.
merge	disabled	When enabled, the data will be written in a specific order determined by matching row and column labels already stored in the spreadsheet.
clear	disabled	In addition to the effect of `merge`, already existing values in the data range of the spreadsheet are removed before writing.
colMerge	0	Determines the columns for which non-empty content of the previous cell will be used as content for the empty cell of a column.
intAsText	`Y`	Determines the cell format when writing unique elements that are a proper integers to spreadsheet.
ignoreRows/Cols	none	Specify rows and columns to be ignored when reading from spreadsheet.

Some more detailed remarks on the symbol attributes:

dataRange

rng = *Excel Range*

The Excel Range for the data for the symbol. Note that an empty range is equivalent to the first cell of the first sheet.

dimensions

dim = *integer*

The total dimension for the symbol.

cDim = *integer*

Column dimension: the number of rows in the data range that will be used to define the labels for the columns. The first `cDim` rows of the data range will be used for labels.

rDim = *integer*

Row dimension: the number of columns in the data range that will be used to define the labels for the rows. The first `rDim` columns of the data range will be used for the labels.

More about dimensions:

The sum of `cDim` and `rDim` determine the dimension of the symbol: `dim = cDim + rDim`.

Reading data from a GDX file and writing to a spreadsheet:
In this case, the dimension of the symbol is stored in the GDX file and therefore known. `cDim` and/or `rDim` can be omitted. If both `cDim` and `rDim` are omitted, the program assumes that `cDim=1` and `rDim=dim-1`.

Reading a spreadsheet and writing data to a GDX file:
In this case, the dimension of the symbol is not known. If neither `cdim` nor `rdim` are known, both default to `1` (hence the default value for `dim` is `2`). If `dim` and either `cdim` or `rdim` are known, the missing dimension is calculated using `dim = cDim + rDim`. If only `cdim` or `rdim` are known, but `dim` is not, the missing dimension is set to `0`.

symbolOptions

The options below are only valid when reading a GDX file and writing to a spreadsheet.

By default, writing data to a spreadsheet will include the row and column labels in addition to the data. The row and column labels will appear in the same order as they appear in the GDX file.

merge (disabled by default)

Using the `merge` option assumes that the row and column labels are in the spreadsheet already. For each value read from the GDX file, the location of the row and column labels is used to update the spreadsheet. Using the `merge` option will force the data to be presented in a given order using the row and column labels. Spreadsheet cells for which there is no matching row/column pair will not be changed. The matching of labels is not case-sensitive. See also Writing to Spreadsheet with merge Option Example.

Note that the skipEmpty option value affects the reading of the row and column labels from spreadsheet in case of top left range specification (while `skipEmpty` is ignored in case of block range specification).

Warning: The `merge` or `clear` option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.

clear (disabled by default)

The `clear` option is similar as the `merge` option, except that the data range will be cleared before any data is written. See also Writing to Spreadsheet with clear Option Example.

colMerge = *integer* (default = 0)

The number of columns that will use a previous value in that column if the cell is empty. Can only be used when reading from a spreadsheet. See Reading empty Cells with colMerge.

intAsText = *flag* (default = `Y`)

Unique elements that are a proper integer can be written as text or as an integer value. The default is `Y`, which will write the unique element as a string. Note that this impacts the sorting order and can be used when using an Excel filter on a data range.

Ignoring Rows and Columns when reading from a spreadsheet

ignoreRows = *rownr, rownr, rownr:rownr*
ignoreColumns = *colnr, colnr, colnr:colnr*

Row numbers are represented by integers. Column numbers are represented by Excel column numbers, like A, CD, IV etc, or by integers.

Note

- Ignoring rows or columns is only allowed when reading a spreadsheet.
- The specification of ignored rows or columns follows the symbol specification and only applies to that symbol.
- When ignoring a column that would be part of an index if the column was not ignored, the range for the index will be extended for each column that is ignored. The same holds for ignored rows that are part of an index.

See also Ignoring Rows and Columns.

6.28.2.4 Syntax Elements

The most options are specified by using an integer, a string or a flag. Note that the options `useRC`, `resetOut`, `checkDate`, `merge` and `clear` are enabled or disabled by simply adding the keyword to your `GDXXRW` statement.

Element	Description
integer	An unsigned integer
string	A string of characters; a string can be quoted with single or double quotation marks.
flag	True values: `1`, `Y` or `Yes` False values: `0`, `N` or `No` (not case-sensitive)

6.28.2.5 Excel Ranges

An Excel Range is specified using the standard Excel notation: `SheetName!CellRange`.

When the `SheetName!` is omitted, the first sheet will be used. A CellRange is specified by using the `TopLeft:BottomRight` cell notation like `A1:C12`. When `:BottomRight` is omitted, the program will extend the range as far down and to the right as possible. (Using '..' in stead of ':' is supported.)

Excel also allows for named ranges; a named range includes a sheet name and a cell range. Before interpreting a range parameter, the string will be used to search for a pre-defined Excel range with that name. See Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges for instance.

When writing to a spreadsheet and a sheet name has been specified that does not exist, a new sheet will be added to the workbook with that name. Reading a spreadsheet and using an unknown range or sheet name will result in an error.

The following table summarizes all possible input combinations and their interpretation:

Input	Sheet used	Cell(s) used	Condition
	First sheet	A1	
!	First sheet	A1	
Name	First sheet	Name	When nc=0
Name	Name	A1	When nc=1
Name!	Name	A1	
!Name	First sheet	Name	
Name1!Name2	Name1	Name2	

The term `nc=` refers to the nameConv option.

6.28.3 Return Codes

On success, `GDXXRW` will return 0 as error code. However, there might be an error which will be signaled with a specific return code in addition to an error message.

Return Code	Interpretation
0	No error

Return Code	Interpretation
1	Cannot write log
2	GDX error
3	No input file
4	Input file not found
5	Bad parameter
6	Read error
7	Problem loading GDX DLL
8	Symbol not found
9	Dimension different
10	Types different
11	Bad UELs
12	Bad output file
13	Problem opening Excel
14	Problem writing to Excel
15	Problem reading from Excel
16	Duplicate entry
17	Cannot add sheet
18	Bad cell value
19	Dimension conflict
20	Data exceeds range
21	Exceeds range or memory problem
22	Deprecated
23	Program aborted
24	Merge range empty
25	Too many columns skipped
26	Too many rows skipped

6.28.4 Warning

When executing `GDXXRW` twice and redirecting output to the same log file may result in a fatal error.

For example:

```
gdxxrw step1 parameters > logfile
gdxxrw step2 parameters > logfile
```

The execution of step2 may fail, because Excel will close the logfile in step1 in a delayed fashion, but return control to `GDXXRW` immediately. Using the log or logAppend parameter will avoid this problem.

6.28.5 Reading from Spreadsheet - Examples:

6.28.5.1 Reading Set from Spreadsheet

Assuming we want to read set elements from the first sheet of the spreadsheet file exampleData.xlsx and write the data to exampleData.gdx.

Either of the following two statements below reads the second row of set elements from the spreadsheet above:

```
gdxxrw exampleData.xlsx  set=i1  rng=readingSets!A2:C2 cDim=1
gdxxrw exampleData.xlsx dSet=i1a rng=readingSets!A2:C2 cDim=1
```

When the output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. Since all elements in the second row are unique, there is no need of increasing the maxDupeErrors parameter to avoid an error message when defining the symbol as set. By specifying the symbol directly as a dSet (domain set) in the second statement, duplicate labels would be removed without throwing an error. We set cDim to one so that the first row of the range is used for the labels of the set.

On the other hand if we want to read set elements listed in a column:

Either of the following two statements reads column A of set elements from the spreadsheet above:

```
gdxxrw exampleData.xlsx  set=j1  rng=readingSets!A35:A37 rDim=1
gdxxrw exampleData.xlsx dSet=j1a rng=readingSets!A35:A37 rDim=1
```

Besides the range we also had to change the parameter rDim to indicate that the first column of the range is to be used for the labels.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample18**] for reference.

6.28.5.2 Reading Set and Explanatory Text

Suppose we want to read the set elements in the ninth row and their associated text in the tenth row of the following spreadsheet:

We can read the set elements and their explanatory text by executing the command:

```
gdxxrw exampleData.xlsx set=i3 rng=readingSets!A9:E10 cDim=1
```

To read the explanatory text, we simple include the tenth row within the range of the symbol `i3` and specify `cDim=1`. By doing this, the first row of the range, i.e. the elements of the ninth row, will be used as the set elements, while the tenth row will be interpreted as their associated text (depending on the values option specified. By default, the `values` option is set to `dense` in this example, i.e. all elements will be included and the string in the associated data cell will be used as explanatory text. See also Reading set elements associated with Data or Text for instance.).

Note here the explanatory text of the set element `skipme2` is just a `Y` as it has a blank entry for the explanatory text.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample18**] for reference.

6.28.5.3 Reading Set Elements associated with Data or Text using the values Option

When reading set elements from spreadsheet, the values option can be used to control whether elements and associated text are included in the set or not. We use the data displayed in the spreadsheet below to demonstrate the `yn`, `dense`, `sparse` and `noData` specifications:

The set element names are stored in the first row, the associated data cells in the second row.

1. values=yn
Run the following command to load those element names associated with nonzero data or yes without storing the data as explanatory text:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=yn
```

The set `A` will contain the elements `a`, `b`, `e`, `f`, `h`, `i`, `k` and `m`, since the elements `c`, `d`, `g`, `j` and `l` are associated with a zero, a blank or a no resp. N (case insensitive).

2. values=dense
This option must be specified, if we want to read all elements while using the strings in the data cells as explanatory text.

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=dense
```

3. values=sparse
To read in all elements having a non-empty data cell while interpreting the string in the data cell as explanatory text, run the following command:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=sparse
```

The set `A` will contain all elements except for `j`, since the associated data cell is empty.

4. values=noData
This option must be used, if we want to read all set elements while ignoring the data range. Especially, the data cells will not be interpreted as explanatory text. To read the elements from the range A1:M1, one could run the following command:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1
```

While all elements `a` - `m` will be included this way, the second row will be automatically interpreted as explanatory text (even though we specified only the first row within the `rng` statement). This might be not desirable at all in some situations, e.g. when reading the city names in the next example Reading Set from Data Tables, we do not want to have the numbers 5000, 6000 and 0 to be explanatory text for the city names. Run the following command to include all elements in your set without interpreting the cells in the second row as explanatory text:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1 values=noData
```

5. values=auto (default)
The second table within the description of the values options indicates which value type will be used by default based on the `rng`, `cDim` and `rDim` specifications for the set. For instance, when running the following command:

```
gdxxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1
```

the value type used is `dense`, since we specified a block range with a data row and `rDim` equals zero.

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample9]** for reference.

6.28.5.4 Reading Set from Data Tables

One may wish to load set elements from a data table. Given a spreadsheet segment like the following:

We can take the set across the top containing the elements cleveland, chicago and dallas with any of the following commands:

```
gdxxrw exampleData.xlsx  set=i6  rng=readingSets!B20:D20 cDim=1 values=noData
gdxxrw exampleData.xlsx dSet=i6a rng=readingSets!B20:D20 cDim=1
gdxxrw exampleData.xlsx  set=i6c rng=readingSets!B20:D21 cDim=1 values=noData
```

Note the usage of the values option in order to avoid reading the numbers as explanatory text. See also Reading set elements associated with Data or Text. However, this can also be avoided by declaring the symbol as a domain set using the symbol declaration dSet.
We can also take a set vertically from column A as follows:

```
gdxxrw exampleData.xlsx dSet=j4 rng=readingSets!A21:A23 rDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample18**] for reference.

6.28.5.5 Reading Set from Lists with Duplication

One may wish to extract set elements from a spreadsheet where there is no unique list of elements that can be read but rather a list where some names are repeated. In the example below note that in rows 26 and 27 there are set element names but they are duplicated:

One can read this using dSet as follows:

```
gdxxrw exampleData.xlsx dSet=i7 rng=readingSets!B26:E26 cDim=1 dSet=i8 rng=readingSets!B27:E27 cDim=
```

Both domain sets will be read within a single `GDXXRW` call. The `rng` and `cDim` specifications affect only the symbol that they are following directly.

It may be favored in some situation to use the set symbol instead (e.g. for reading explanatory text). To oppress an error message when reading sets with duplication, one must specify a sufficient large number within the maxDupeErrors option.

```
gdxxrw exampleData.xlsx maxDupeErrors=4 set=i7 rng=readingSets!B26:E26 cDim=1 values=noData set=i8 r
```

For the data in this example, four is a sufficient large number since there are two duplicates for the first and two duplicates for the second set within each range. Note the usage of the values option in order to avoid reading 'cleveland' as explanatory text for the elements of set `i7` and to avoid reading the numbers as explanatory text for the elements of `i8`. See also Reading set elements associated with Data or Text for more informations about the `values` option.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample18**] for reference.

6.28.5.6 Reading Parameter from Spreadsheet

Assuming we want to read parameter `data1` from the file Test1.xlsx and write the data to Test1.gdx.

The following statement reads parameter `data1` from the spreadsheet above (using the par data type):

```
gdxxrw Test1.xlsx par=data1 rng=A1:D3 cDim=1 rDim=1
```

The sheet name in a range can be omitted when it refers to the first sheet. The elements in the first row and first column of the data range will be used as labels for the two dimensional parameter `data1` by defining `cDim=1` and `rDim=1` (see also cDim resp. rDim).

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample5]** for reference.

6.28.5.7 Reading Parameter from Spreadsheet with Duplication

The same data as in the previous example, but organized differently. We use the dSet symbol specification instead of set to read set `I` (in column A) and set `A` (in column B), since there are duplicate entries in column A resp. column B.

The following statement reads parameter `data2` from the spreadsheet above:

```
gdxxrw Test1.xlsx par=data2 rng=EX2!A1 rDim=2 dSet=I rng=EX2!A1 rDim=1 dSet=A rng=EX2!B1 rDim=1
```

By setting `rDim=2` for the parameter `data2` we indicate to use the first two columns of the data range as the labels for the parameter values. Since the sheet does not contain further data, one can specify the ranges using the top left cell notation without hesitation.
When using a few symbols, the command line can become too long to be practical. In such case, use a text file to hold the parameters. A parameter file can contain multiple lines to increase readability and a line starting with a '*' will be ignored.

```
* file example6.txt
par =data2 rng=EX2!A1 rDim=2
dSet=I     rng=EX2!A1 rDim=1
dSet=A     rng=EX2!B1 rDim=1
```

An option file is indicated by preceding the file name with a @ (At sign.).

```
gdxxrw Test1.xlsx @example6.txt
```

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample6]** for reference.

Note

- An option file can contain multiple lines to increase readability.
- When reading parameters from a text file, lines starting with an asterisk (*) will be ignored and act as a comment.
- An option file can also be written during the execution of a GAMS model using the GAMS Put Facility and the subsequent `GDXXRW` commands must use execute command so the put file is written before it is to be read (this would happen when using the compile time command `$call` to run `GDXXRW`).
- Using an option file can be useful in reducing execution time by combining the options and symbols from multiple `GDXXRW` calls in a single option file used in a single `GDXXRW` call.

6.28.5.8 Reading Multi-dimensional Parameter from Spreadsheet

This example illustrates how to read a four dimensional parameter from spreadsheet:

The strings in the first two columns and the first two rows of the data range A1:F6 shall be used as labels for the parameter values. Therefore, we define `rDim=2` and `cDim=2` (see also rDim and cDim). The parameter will be named `data3` (within the par declaration). Run the following command to read the data with `GDXXRW`:

```
gdxxrw Test1.xlsx par=data3 rng=EX3!A1:F6 rDim=2 cDim=2
```

Note that the data range was specified using the block range notation. However, it might be more comfortable to specify only the top left corner sometimes, but empty rows or columns may affect the reading process, i.e. `GDXXRW` might stop to early when encountering empty rows or columns or it will try to read data separated by empty rows or columns not being part of the data you wish to read. When we specify the range as a block, an empty row or column will always be ignored. When we specify the top left cell only, the skipEmpty option can be used to ignore one or more empty rows or columns. However, for the data in this example, we do not need to ignore empty rows or columns within the data range, but suppose there is non-relevant data starting in column H. By default (`skipEmpty=1`), `GDXXRW` would try to read the data starting in H. When we specify `skipEmpty=0` and cells A7, B7, G1 and G2 are empty, the range can be specified with the top left cell only in this example:

```
gdxxrw Test1.xlsx skipEmpty=0 par=data3 rng=EX3!A1 rDim=2 cDim=2
```

Since `skipEmpty` is a global option, affecting every symbol that follows, we define it before declaring the parameter `data3`.

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample7]** for reference.

6.28.5.9 Reading Spreadsheet using the Index Option

The index option is used to read a number of parameters and sets based on information stored in the spreadsheet itself. By doing this, the `GDXXRW` command becomes quit short and the informations on how to read the data can be written directly within the spreadsheet to increase readability. The first row of the range is used for column headings indicating additional parameters. We will discuss the results only briefly, because all other options used in this example were demonstrated before.

Suppose we want to read the parameters and sets from the following spreadsheet:

The informations about all parameters and sets are stored within the sheet index in the same spreadsheet file exampleData.xlsx as testIndex above:

The following statement reads parameters and sets from the spreadsheets using the `index` option:

```
gdxxrw exampleData.xlsx output=gdxAll.gdx index=index!A1
```

We use the `output` option to write the data to gdxAll.gdx for demonstration here. By default, `GDXXRW` would write to testIndex.gdx. Some brief remarks on the results:

- Elements of set i1 and i1a: trains, cars and planes. There is no explanatory text, since the data range (third row) is empty. We can use dim=1 equivalently to cDim=1 in this example, because by default, cDim=1 and rDim=dim-1. See also dimensions.
- When reading the sets i2 and i3, we are defining which elements and explanatory text will be stored by specifying the values option.
- The set i4 will contain all elements of the thirteenth row. Afterwards, skipEmpty is set to zero, affecting the reading of i4a and i5. Unlike i4, the sets i4a and i5 will not contain the element houston, since skipEmpty=0 and the empty column signals GDXXRW to stop reading (note that the range is not defined using the block range specification). Since there is a data range for i5, the strings city1 - city5 will be used as explanatory text by default. After reading i4a and i5, skipEmpty is reset to one (default).
- Each of the sets i6, i6a and i6b will contain the elements cleveland, chicago and dallas. There is no explanatory text for any of the sets in the GDX file, however, one must enforce this for the set i6 with values=noData.

There are no interesting details for the remaining sets and parameters to discuss here. The complete example and the results displayed within GAMS can be found in the GAMS Data Utilities Library, see model **[GDXXRWExample10]** for reference.

Note

- The parameters and sets are read using the specifications within the myIndex sheet. They are treated as if they appeared directly on the command line.
- In the spreadsheet, the first three columns of the range have a fixed interpretation: DataType (par, set, dSet, equ, or var), Item name identifier and spreadsheet data range. The fourth and following columns can be used for additional parameters like dim, rDim, cDim, merge, clear and skipEmpty. The column header contains the keyword when necessary, and the cell content is used as the option value.
- When an entry appears in a column without a heading then it is directly copied into the GDXXRW option file. Thus in the example above the items in column G are directly copied into the file.
- Rows do not need to have entries in the first three columns if one just wants to enter persistent options such as skipEmpty or some of the special character string re-definitions (as in row seven and ten from the spreadsheet above).

6.28.5.10 Reading Data from Spreadsheet and Loading into GAMS

One can use $call to execute the GDXXRW command in the GAMS code to read from spreadsheet at compilation time (the data is taken from the previous example):

```
$call gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
```

Getting a set from the spreadsheet into a GDX file is only half the battle. One must also use commands in GAMS to load the data as discussed in the chapter Using GAMS Data Exchange or GDX Files. At compile time this is done using:

```
Set i9;
* read/load set from data at compile time
$call gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
$gdxIn testIndex.gdx
$load i9
```

where the set must be declared in a set statement then one can if needed create the GDX file using `GDXXRW`, then one uses a `$gdxIn` to identify the source file and a `$load` to bring in the data.

Some users may wish to load sets at execution time. However, this is limited to subsets that are dynamic sets and cannot be used in domains. To do this one simply uses the statements as above, but substitutes `execute` in place of `$call` as follows:

```
Set i9(i6a);
* read/load set from data at execution time
execute 'gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData'
execute_load 'testIndex' i9;
```

where the set `i9` must be declared as a subset in a set statement (of `i6a` in this case), then one can if needed create the GDX file using execution time `GDXXRW`, and an `execute_load` to bring in the data with an identification of the GDX source file name. Note that we used the set `i6a` as superset, fitting best to the data from the previous example. However, one could also use the statement `Set i9(*);`.

One can load the universe of labels from a GDX file into a set at run-time using the syntax:

```
execute_load 'someFile', someSet=*;
```

Note

In doing this, only labels known to the GAMS program will be loaded.

6.28.5.11 Reading empty Cells with colMerge

Suppose we want to read the four dimensional parameter from the following spreadsheet:

The cells B4, B5, C4 and D5 might be empty to avoid duplication, i.e., the non-empty content of the previous cell in the same column shall be used as content for the empty cell. In particular: the content of B3 shall be used for the content of B4 and B5, the content of C3 for C4 and the content of D4 for cell D5. Reading the above spreadsheet using the following GAMS statement:

```
gdxxrw exampleData.xlsx par=A_d rng=colMerge!B2 rDim=3 cDim=1
```

results in empty cells B4, B5, C4 and D5, causing troubles if you want to declare the parameter as `A(number,number,number,color)` certainly:

Adding the symbol attribute colMerge, we use the non-empty content of the previous cell in the same column as the content for the empty cell. Specifying `colMerge=2` will do this for the first two columns for instance.

```
gdxxrw exampleData.xlsx par=A_2 rng=colMerge!B2 rDim=3 cDim=1 colMerge=2
```

Only the two entries corresponding to the cell D5 are still empty, since we do not specify all three columns within `colMerge`:

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an <empty> entry instead.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample20**] for reference.

6.28.5.12 Reading merged Excel Ranges with cMerge

Suppose we want to read the three dimensional parameter from the following spreadsheet:

Note that the label 'red' is centered over the merged cells B1, C1 and D1 and label 'green' over the merged cells E1 and F1. Additionally, in the data range, the cells B3:C3 and B4:C4 are merged, too. The option cMerge can be used to control the way merged cells are handled. We will discuss the effect of the possible values for `cMerge` on the data presented above by running the following commands (an option file is used to increase readability):

```
$onEcho > howToRead.txt
cMerge=0 par=B_d rng=cMerge!A1 rDim=1 cDim=2
cMerge=1 par=B_1 rng=cMerge!A1 rDim=1 cDim=2
cMerge=2 par=B_2 rng=cMerge!A1 rDim=1 cDim=2
$offEcho

$call gdxxrw exampleData.xlsx output=cMerge.gdx @howToRead.txt
```

We specify `cMerge` in advance, since it is a global option affecting every symbol that follows. Executing the three statements will create three different output files, all displayed in GAMS Studio:

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an <empty> entry instead.

Some remarks on the results:

cMerge=0 (default)
Empty cells being part of a merged Excel range will remain empty. Thus, the cells C1, D1, F1, C3 and C4 from the spreadsheet above will remain empty when reading with `GDXXRW`. Since C3 and C4 are empty while being part of the data range, they won't show up in the GDX file. The values in the last column of the GDX file are useful to compare the results with the spreadsheet. For instance, the UELs of the value `5` are `a`, <empty> and `two`, since the cell F1 is empty, while A3 contains the string `a` and F2 the string `two`.

cMerge=1
The value of a merged range within a row or column header will be used for all cells being part of the merged range. Thus, the string 'red' will be used for the cells in the column header C1 and D1 and the string 'green' for the cell F1. Since C3 and C4 are part of the data range, they will remain empty and are not displayed in the GDX file. As you can see, there is no longer an empty UEL.

cMerge=2
The value of a merged range will be used for all cells being part of the merged range, i.e. `cMerge=1` is extended to the data range. Therefore, the value 1 resp. 11 will be also used for the cell C3 resp. C4, appearing in the GDX file for the first time. Since there is no change in handling merged cells within the row or column header, all values have non-empty labels.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample20**] for reference.

6.28.5.13 Skipping Empty Rows and Columns

By using the skipEmpty option, we can control the way blank rows or columns are handled and causes `GDXXRW` to either stop or skip over if a blank row or column is encountered when using the top left corner range specification instead of a block range. If the range is specified using the `TopLeft:BottomRight` cell notation (often refered as block range notation), empty rows or columns will be skipped automatically. Suppose the data is stored in the following spreadsheet:

We can read this spreadsheet and skip blank rows and columns with the following command:

```
gdxxrw exampleData.xlsx      par=A_d rng=skippingRC!A2 rDim=2 cDim=1
```

or

```
gdxxrw exampleData.xlsx se=1 par=A_1 rng=skippingRC!A2 rDim=2 cDim=1
```

Note that there will be no difference concerning the generated GDX files, since `skipEmpty` is set to one by default. On the other hand, if `skipEmpty` is set to zero

```
gdxxrw exampleData.xlsx se=0 par=A_0 rng=skippingRC!A2 rDim=2 cDim=1
```

the blanks terminate the read not reading the `rail` column and the `san francisco.chicago` row. After loading into GAMS the data become:

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample21**] for reference.

Note

> The `skipEmpty` option must appear before any `par`, `set`, `dSet` etc statements that use it and will persist for the rest of the statements in a command unless it is set to another value.

6.28.5.14 Ignoring Rows and Columns

We can use the options ignoreColumns and ignoreRows to ignore columns and rows when reading data for a symbol. Suppose we want to ignore the red colored rows and columns of the following spreadsheet, when reading the four dimensional parameter:

We can read this spreadsheet and ignore the red colored columns and rows with `GDXXRW` by running the following command:

```
gdxxrw exampleData.xlsx par=A rng=ignoringRCC1 cDim=2 rDim=2 ignoreRows=2,6 ignoreColumns=D,G
```

The options `ignoreRows` and `ignoreColumns` are symbol options and therefore must appear after the symbol specification, affecting only this particular symbol.

In the example above we ignored column D which would have been part of the index for the rows. So the range for the row index was extended with column E. The E column is no longer part of the data range. The treatment of the column index is similar. The second row would have been part of the column index, and now that the row is ignored, the next row becomes part of the column index and the third row is no longer part of the data range.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample21**] for reference.

Note

The `ignoreColumns` and `ignoreRows` options appear after any `par`, `set`, `dSet` etc `GDXXRW` command instruction and only affect reading of that item.

6.28.5.15 Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges

As mentioned in section Excel Ranges, the range of a symbol to be read can be defined by using named ranges. To name a cell range within Excel, simply select the cell range and type in the name you want to assign to this particular range by using the name-box next to the top left corner of your spreadsheet. Suppose we want to read the data in the range A1:D3 taken from the example Reading Parameter from Spreadsheet:

Instead of specifying the range explicitly by `rng=A1:D3`, we use the pre-defined named range 'parRange', i.e. `rng=parRange`. `GDXXRW` uses the string specified to search for a matching pre-defined named range first. In summary, run the following command to read the parameter `data4` from the file Test1.xlsx:

```
gdxxrw Test1.xlsx par=data4 rng=parRange rDim=1 cDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample5**] for reference.

Note

In Excel, one can assign a single name to several separated block ranges, e.g. assign the name 'disconnected' to the block ranges A1:D3 and F4:H5 (by holding 'Strg' while selecting the second block range and using the name-box to assign the name). However, such disconnected data cannot be read using the named-range specification.

6.28.6 Writing to Spreadsheet - Examples:

6.28.6.1 Unloading Data from GAMS before Writing to Spreadsheet

When writing to spreadsheet with GDXXRW, one must use commands in GAMS to place the data into the GDX file at first (see also Using GAMS Data Exchange or GDX files). When reading data, it is often desirable to use a $call command to run GDXXRW and the statements $gdxIn and $load afterwards to load the data, allowing also domain definitions (at compile time) for instance. This is hardly ever desirable or realizable when unloading and writing to a spreadsheet, for example, if one wish to write the solution after solving a model to spreadsheet. This should generally not be done at compile time so one should only use the execute and execute_unload commands at execution time as follows:

```
execute_unload 'test.gdx' someParameter;
execute 'gdxxrw test.gdx par=someParameter rng=A1'
```

where the execute_unload tells what data to place in the GDX file and determines the GDX source file name. The matching GDXXRW execution tells the name of the GDX file, the name of the spreadsheet (optional) and identifies the data to write.

See also Writing Set to Spreadsheet and Writing Parameter to Spreadsheet for demonstration.

Note

- One must be careful when using GDXXRW as each time the command is executed the GDX file is erased and only has the current contents and thus should be written just before if reusing the name.
- One also obtains output of sets using the command execute_unloaddi where the GDX file automatically includes all sets associated with unloaded parameters, variables and equations without need to list the set element names.

6.28.6.2 Writing Set to Spreadsheet

At fist, we will create a GDX file containing a simple set using the execute and execute_unloading directives. Most of the elements have an explanatory text:

```
Set x / element1 'explanatory text'
        element2
        element3 'previous element does not have explanatory text' /;

execute_unload 'writingSet.gdx' x;
```

Of course, in this particular code section above, one could also use $gdxOut and $unload. The values option can be used to control whether explanatory text is written to the spreadsheet. We'll demonstrate all three possible values explicitly within a single GDXXRW execution:

```
$onEcho > howToWrite.txt
hText="values: noData,,,values: yn,,,values: string" rng=Sheet1!A1
set=x rng=Sheet1!A2 rDim=1 values=noData
set=x rng=Sheet1!D2 rDim=1 values=yn
set=x rng=Sheet1!G2 rDim=1 values=string
$offEcho

execute 'gdxxrw writingSet.gdx output=writingSet.xlsx @howToWrite.txt'
```

Before executing this example, check if the Excel file (writingSet.xlsx) is open. If you run `GDXXRW` for writing a file sharing conflict will arise. To avoid this problem, either close the Excel file or use the Excel Tools menu to make this a shared notebook. After writing to the spreadsheet (still opened), use the Excel "File Save" command to verify the changes made.

By adding two additional commas within the hText statement, the cells B1, C1 and E1, F1 will be skipped when writing the text to the first row of the spreadsheet. If `values=noData`, neither explanatory text nor a `Y` are written to spreadsheet for the set elements. If `values=yn`, `GDXXRW` writes a `Y` for each set element to spreadsheet. To write the explanatory text, specify `values=string`.

Since `cDim=0`, the default option is `string` (see values). Imagine a two dimensional set, one could write the set in a table format, i.e. `cDim=1` and `rDim=1`. By default, `GDXXRW` would write this set using the `values=yn` format.

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample11b]** for reference.

Note

- A workbook cannot in general be open unless you have made special provisions with an error signaled indicating a file sharing conflict will arise when the target file is open in Excel.
- To avoid the sharing conflict error the user must either close the file or indicate that the spreadsheet is a shared Excel workbook by using the Excel Tools Share Workbook dialogue.
- In an open shared workbook the contents are not updated until you have done a file save in Excel.
- Writing to a shared workbook can be painfully slow.
- In general, it is best to close the workbook.

6.28.6.3 Writing Parameter to Spreadsheet

At first, we create a GDX file, containing some random data:

```
* file makeData.gms
Set
   i / i1*i4 /
   j / j1*j4 /
   k / k1*k4 /;

Parameter V(i,j,k);
V(i,j,k)$(uniform(0,1) < 0.30) = uniform(0,1);
```

When we run this GAMS model from the command prompt using the following statement, the file writingPar.gdx will be created at the end of the run.

```
GAMS makeData gdx=writingPar
```

Using the file writingPar.gdx, we can write to a spreadsheet:

> Write parameter V to the first cell in the first sheet; because we only specify the top left corner of the sheet, the complete sheet can be used to store the data. We do not specify the row and column dimension, so they will be set to rDim=2 and cDim=1 by default. (See also dimensions)

By using the following command (remember to close an already existing file writingPar.xlsx in advance or make it a shared notebook as discussed in the previous example):

```
gdxxrw writingPar.gdx output=writingPar.xlsx par=V rng=A1
```

The steps above can be combined in a single GAMS model using the execute_unload and execute statements as follows:

```
Set
   i / i1*i4 /
   j / j1*j4 /
   k / k1*k4 /;

Parameter V(i,j,k);
V(i,j,k)$(uniform(0,1) < 0.30) = uniform(0,1);

execute_unload 'writingPar.gdx', i, j, k, V;
execute 'gdxxrw writingPar.gdx par=V rng=A1';
```

The resultant spreadsheet looks like:

Note that if we only want to write the parameter V, there is no need to unload the sets i, j and k explicitly. The labels written to the columns A and B and to the first row are stored directly together with V in the GDX file.

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample11b]** for reference.

6.28.6.4 Writing to Spreadsheet with merge Option

When writing to a spreadsheet one can control data handling and matching using the merge command line option. When `merge` is active, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already. Also under `merge`, spreadsheet cells for which there is no matching row/column pair will not be changed. This option might be very useful, e.g., if there is a fixed report layout/framework already in your spreadsheet file which should not be changed when writing the data from GAMS.

Suppose we want to write the parameter `A`, already stored in data.gdx, to an existing spreadsheet:

In the following spreadsheet, there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non existing row labels 'san francisco.chicago':

Use the following commands to write the data from GDX to spreadsheet twice to different ranges for comparison:

```
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B1:G4 rDim=2 cDim=1 merge
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B8    rDim=2 cDim=1
```

Note that `merge` is a symbol option affecting only the symbol `A`. The resultant spreadsheet looks like:

The parameter is written to the range B8-F12 without `merge` enabled, while the option is enabled when writing to the range B1:G4, respecting the data arrangement already existing. Note that the column and row orders vary and the san francisco - chicago row is missing since it is not mentioned in the labels within the spreadsheet before the merge operation, while the horse column is still present with it's data left alone, not being overwritten by the parameter.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample12**] for reference.

Note

- Using the `merge` option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a `merge` option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements at all.
- The matching of labels is not case-sensitive.
- Warning: Enabling the `merge` option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.

6.28.6.5 Writing to Spreadsheet with clear Option

When writing to a spreadsheet one can also use the clear option to control data handling and matching. When `clear` is enabled, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already but all data and formulas in the target range will be removed.

Suppose the parameter `A` from the previous example is stored in data.gdx and there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non existing row labels 'san francisco.chicago':

Use the following command to write to exampleData.xlsx with `clear` enabled:

```
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!I1 rDim=2 cDim=1 clear
```

then the result is

The results are similar to those under merge but the old data in the column labeled 'horse' has been removed.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample12**] for reference.

Note

- Using the `clear` option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a `clear` option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements.
- The matching of labels is not case-sensitive.
- Warning: The `clear` option will clear all Excel formulas and values in the rectangle used, even if the cells do not have matching row/column labels in the GDX file.

6.28.6.6 Writing to Spreadsheet using a Filter

In Excel, you can filter the data by some specified conditions so that only the data matching the conditions is displayed. This might be useful in some cases, e.g. it helps you to focus on the most relevant data within a large table of data. With `GDXXRW` you can add some basic filter to your spreadsheet when writing data from a GDX file.
The following example creates a small GDX file with some random data, which is used to write the symbol `A` to a spreadsheet later on with the filter option enabled.

```
Set
   i / i1*i2 /
   j / j1*j2 /
   k / k1*k2 /;

Parameter A(i,j,k);
A(i,j,k) = uniform(0,1);

execute_unload 'test.gdx', A;
execute 'gdxxrw test.gdx filter=1 par=A rDim=1 cDim=2 rng=Sheet1!A1';
```

Since `filter` is a global option, it must be specified in advance of the symbols for which you want to add a filter. The default value is zero, i.e. no filter will be added. If there are multiple rows in the column header, i.e. `cDim` is greater than zero, the valid range for the filter option is `1..cDim`.

The screenshot above shows the filter in Excel. When we specify `filter=2` in this example with two dimensions for the column header, the row with the filter moves away from the data range as illustrated below:

One could now filter the data, e.g. displaying only the values where the label of the first dimension is `i1` by selecting this value exclusively within the drop down menu of column A.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample15**] for reference.

6.28.6.7 Writing to Spreadsheet adding Text and Hyperlinks

The following example illustrates the use of the text directive. Adding text and hyperlinks to your spreadsheet is useful to customize the output and to navigate more quickly through the data.

First, we write some data to a GDX file and we use the text directive to write text to various cells in the spreadsheet; some of the cells are hyperlinks to other locations. To increase readability, we'll use a parameter file howToWrite.txt to shorten the `GDXXRW` statement.

```
Set
   i / i1*i9 /
   j / j1*j9 /;

Parameter A(i,j);
A(i,j) = 10*ord(i) + ord(j);

execute_unload 'pv.gdx' A;

$onEcho > howToWrite.txt
text="Link to data" rng=Index!A2 linkID=A
text="Below the data for symbol A" rng=data!C2
par=A rng=data!C4
text="Back to index" rng=data!A1 link=Index!A1
text="For more information visit GAMS" rng=data!C1 link=http://www.gams.com
$offEcho

execute 'gdxxrw pv.gdx output=pv.xlsx @howToWrite.txt'
```

We will write the text "Link to data" to the cell A2 of sheet Index. The option `linkID` is used to add a hyperlink to the range of the symbol `A`. In addition, we create a hyperlink "Back to index" in the cell A1 of sheet data using the `link` option pointing to the cell A1 of sheet Index. One can also specify links to external sources. For demonstration, we add a link to the GAMS homepage.

Below a screen shot showing both sheets data and Index created by the commands above:

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample16**] for reference.

6.28.7 Reading and Writing, Extended Use - Examples:

6.28.7.1 Reads a Table from Spreadsheet, manipulates the Data and writes back to Spreadsheet

In the following example, we read data from a spreadsheet and save the data in a GDX file. Using the `$gdxIn` and `$load` GAMS directives, we load the data from the GDX file into GAMS afterwards. The GAMS program modifies the data and at the end of the run the data is saved in a new GDX file (tmp.gdx). The last step updates the spreadsheet with the modified parameter.

We read the spreadsheet and load the data from the resultant GDX file at compile time. The data modification and the unloading and writing process are done at execution time, using the `execute_unload` and `execute` directives:

```
$call gdxxrw test1.xlsx dSet=I rng=A2:A3 rDim=1 dSet=A rng=B1:D1 cDim=1 par=X rng=A1:D3 rDim=1 cDim=
$gdxIn test1.gdx

Set I(*), A(*);
$load I A

Parameter X(I,A);
$load X

display I, A, X;
$gdxIn
X(I,A) = - X(I,A);

execute_unload 'tmp.gdx', I, A, X;
execute 'gdxxrw tmp.gdx output=test1.xlsx par=X rng=EX6!A1:D3 rDim=1 cDim=1';
```

The parameter is written to the sheet EX6. However, since we only write the parameter `X`, we do not necessarily have to unload the set `I` and `A`.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample13**] for reference.

6.28.7.2 Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve

In this example, we use a modified version of the [**trnsport**] model from the GAMS model library to demonstrate the process of reading data, defining and solving the model and writing a solution report to spreadsheet altogether. This example illustrates in particular:

- Compilation phase
- Read data from a spreadsheet and create a GDX file
- Loading sets from the GDX file
- Using the sets as a domain for additional declarations
- Reading additional data elements

- Execution phase
- Solve the model
- Write solution to a GDX file
- Use GDX file to update spreadsheet

A parameter file howToRead.txt is used to increase the readability of the GDXXRW call. Note that the dimension of the scalar we want to read is set to zero. The range of each parameter can be specified by using the top left corner only, since there are two empty rows separating the data blocks from each other and the default value of skipEmpty signals to stop reading if two empty rows occur.

```
$onEcho > howToRead.txt
dSet=i rng=A3:A4 rDim=1
dSet=j rng=B2:D2        cDim=1
par =d rng=A2    rDim=1 cDim=1
par =a rng=A8    rDim=1
par =b rng=A13   rDim=1
par =f rng=A19    dim=0
$offEcho
$call gdxxrw TrnsportData.xlsx @howToRead.txt
$gdxIn TrnsportData.gdx

Set
   i(*) 'canning plants'
   j(*) 'markets';

$load i j

display i, j;

Parameter
   a(i)   'capacity of plant i in cases'
   b(j)   'demand at market j in cases'
   d(i,j) 'distance in thousands of miles';

Scalar f 'freight in dollars per case per thousand miles';
$load d a b f
$gdxIn

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

Variable
   x(i,j) 'shipment quantities in cases'
   z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
   cost      'define objective function'
   supply(i) 'observe supply limit at plant i'
   demand(j) 'satisfy demand at market j';

cost..      z =e= sum((i,j), c(i,j)*x(i,j));
supply(i).. sum(j, x(i,j)) =l= a(i);
demand(j).. sum(i, x(i,j)) =g= b(j);
```

```
Model transport / all /;

solve transport using lp minimizing z;

display x.l, x.m;

execute_unload 'TrnsportData.gdx', x;
execute 'gdxxrw TrnsportData.gdx output=TrnsportData.xlsx squeeze=n var=x.l rng=Sheet2!A1';
```

The solution is written to Sheet2 of the input file TrnsportData.xlsx by executing GDXXRW at execution time. The var statement is used in the symbol specification to write out the level of variable x. In order to write zero values, the squeeze option is disabled. Otherwise, the cells C4 and D3 remain blank.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample14**] for reference.

6.28.7.3 Reading Special Values from Spreadsheet and writing to Spreadsheet

This example demonstrates the reading and writing of special values with GDXXRW.

Reading Special Values
Assuming we want to read the special values stored in the spreadsheet below:

The following statement reads parameter vIN from the spreadsheet above:

```
gdxxrw exampleData.xlsx output=specialValues.gdx NaIn=N/A squeeze=n par=vIN cDim=1 rng=specialValues
```

To affect the parameter vIN, the global options NaIn and squeeze (to display zero values in the GDX file) must be specified in advance.

The cells containing the strings Eps, +Inf, -Inf, Inf, NA and Undf are read in correctly. The division by zero error in the spreadsheet will be written as Undf. We defined a new string - 'N/A' - within the option NaIn to be recognized as NA additionally. Within GAMS, there is no directly comparable data type for 'None' and 'Null', so these strings will be interpreted as Undf. Note the importance of the cell format specified within Excel. For instance, the values for v13 and v14 are different, although both fields contain a Dollar sign, since the cell format of M2 is 'General', while the cell format of N2 is 'Currency'.
The boolean 'False' turns into zero after reading, while 'True' turns into -1. Note here, that this is independent whether the booleans are written as plain text within Excel or by using the formulas '=True()' resp. '=False()'. We disabled squeeze in order to display the zero values for the elements v16, v18 and v19 in the GDX file.

Writing Special Values
Initially, we declare a parameter with special values and generate a GDX file from it:

```
$onUndf
Set v / v1*v7 /;
Parameter vOUT(v) / v1 Eps, v2 +Inf, v3 -Inf, v4 Inf, v5 Undf, v6 0.0, v7 NA /;
Scalar S / 0 /;

execute_unload 'specialValues.gdx', v, vOUT, S;
```

We will write the parameter vOUT to spreadsheet twice. At first to demonstrate the usage of EpsOut, pInfOut, mInfOut, UndfOut, zeroOut and NaOut, the second time to show the default settings when writing. Those output string options may be useful, if the GAMS default settings are not appropriate for your Excel calculations later on or to customize the representation of the values in Excel in general. Note that there is also a scalar declaration in order to demonstrate the different behavior when writing scalars and parameter with zero values to Excel while using the zeroOut option.

```
$onEcho > howToWrite.txt
* defining new strings to be used when writing special values:
EpsOut=0 pInfOut=+1E+100 mInfOut=-1E+100 UndfOut=undefined zeroOut=zero NaOut=notAvailible

* now write parameter vOUT with merge to force the column F containing set element "v6" and vOUT("v6"
set=v    rng=specialValues!A6:G6 cDim=1
par=vOUT rng=specialValues!A6:G7 cDim=1 merge
text="Special values of Parameter vOUT written with user defined output strings:" rng=specialValues!A
text="Scalar S / 0 /:" rng=specialValues!I6
par=S rng=specialValues!I7

* reset the strings for special values back to default und write vOUT again
resetOut
set=v    rng=specialValues!A10:G10 cDim=1
par=vOUT rng=specialValues!A10:G11 cDim=1 merge
text="Special values of Parameter vOUT written with default output strings:" rng=specialValues!A9
text="Scalar S / 0 /:" rng=specialValues!I10
par=S rng=specialValues!I11
$offEcho

execute 'gdxxrw specialValues.gdx output=exampleData.xlsx @howToWrite.txt';
```

In order to increase readability when executing GDXXRW, we use a parameter file named howToWrite.txt and additionally, we write some text out to structure the Excel file. The range for the non-default values is A6:G7. We define the new strings to be used for the special values first, affecting the following symbols. To write the default values to the range A10:G11, we use the resetOut option to reset the output strings to default, otherwise, the new strings remain in effect, since they are global options.

As mentioned briefly above, the zeroOut option affects the scalar S and the parameter vOUT differently. While we get the expected result - 'zero' - for the scalar S, the cell F7 for the zero value of vOUT remains empty, since zero values of parameters are not even part of the GDX file in general (and cannot be added from your GAMS model; Note here, that the squeeze options only affects the writing of sub-fields of variables and equations). Therefore, cell F11 has no value, too. Though scalars with zero values are stored in the GDX file. We'll present a workaround for writing zero values of a parameter to spreadsheet in the next example Writing Parameter to Spreadsheet including Zero Values.

The complete example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample8]** for reference.

Note

- When writing to a spreadsheet, special values such as Eps, NA, Undf and Inf will be written but this can be changed. When reading data from a spreadsheet, the ASCII strings for these special character strings will be used to write corresponding special values to the GDX file.
- Cells that are empty or zero will not be written to the GDX file.

6.28.7.4 Writing Parameter to Spreadsheet including Zero Values

There is no straight way to write zero values of a GAMS parameter to spreadsheet from your model using GDXXRW, since zero values of a parameter are not stored in the GDX file (see also the previous example Reading Special Values from Spreadsheet and writing to Spreadsheet). However, instead of the zero values one can store an EPS in the GDX file and instruct GDXXRW to use a zero when writing the value for EPS using the epsOut option afterwards as demonstrated below:

```
Set i / i1*i9 /;
Parameter A(i), Amod(i);
A(i) = uniformInt(0,1);

* Amod(i) = A(i) if A(i) <> 0 and Amod(i) = EPS if A(i) = 0
Amod(i) = EPS$(not A(i)) + A(i);

* Unload the unmodified and modified parameter and write to spreadsheet using an option file
execute_unload 'zeroPar1.gdx' A Amod;

$onEcho > howToWrite1.txt
text="Parameter A" rng=A1
par=A rng=A2
text="Modified Parameter Amod written with epsOut: 0" rng=A5
epsOut=0 par=Amod rng=A6
$offEcho
execute 'gdxxrw zeroPar1.gdx output=writingZeros.xlsx @howToWrite1.txt';
```

This approach is impracticable in the unlikely event that there are already EPS values in your parameter and you want to write these as EPS to your spreadsheet.

An alternate approach regarding variables while exploiting the squeeze option is demonstrated below (parameter A and set i refer to the data above):

```
Variable dummyPar(i);
dummyPar.l(i) = A(i);

* In order to write every entry of dummyPar in the spreadsheet, one must allocate
* a non-zero value to one of the variable attributes .m, .lo or .up
dummyPar.up(i) = 1;

* Unload the dummy variable and write the .l subfield to spreadsheet while disabling squeeze
execute_unload 'zeroPar2.gdx' dummyPar;

$onEcho > howToWrite2.txt
text="Variable dummyPar written with squeeze: n" rng=A9
squeeze=n var=dummyPar.l rng=A10
$offEcho
execute 'gdxxrw zeroPar2.gdx output=writingZeros.xlsx @howToWrite2.txt';
```

Creating the additional variable and the allocation of a non-zero value to one of the other variable attributes are the drawbacks of this approach. Note that we only declared the parameter Amod to keep the original data of A untouched in order to run the code in a single model and to write A to spreadsheet, too.

This example is also part of the GAMS Data Utilities Library, see model [**GDXXRWExample19**] for reference.

6.28.7.5 Reading several Scalars from Spreadsheet

Suppose you want to read a large number of scalars (i.e. scalar names and their associated values) for your model from a spreadsheet file as shown below. Originally, the data was taken from the model **[indus89]** of the GAMS Model Library.

Natively, one could declare all scalars directly inside the model and read every single one of them with GDXXRW afterwards (the following code is shortened for representation):

```
Scalar baseyear, repco;

$call gdxxrw exampleData.xlsx output=indus89Scalars.gdx par=baseyear rng=indus89Scalars!B2 dim=0 par
$gdxIn indus89Scalars.gdx
$load baseyear repco
```

However, the code would become quit long and circumstantially for this example, especially the GDXXRW statement, because every scalar must be specified individually. Therefore, we present a more sneaky way to tackle the problem. At first, the file mkScalar.gms is written. We declare a set and a parameter to hold the scalar names and their values. A simple GDXXRW call is used to read the names and values from the file exampleData.xlsx. Afterwards, we load the data using $gdxIn and $load. The result of this is a single parameter containing the scalar values defined over a set containing the scalar names. However, this is not exactly what we are looking for. To transform this representation into several single scalar definitions, we use a simple loop over the set scalarNames and the Put Writing Facility to generate a file scalars.gms, containing those single scalar statements.

```
$onEchoV > mkScalar.gms
Set scalarNames;
Parameter scalarValues(scalarNames);

$call gdxxrw exampleData.xlsx output=indus89Scalars.gdx set=scalarNames rng=indus89Scalars!A2:A22 rD
$ifE errorLevel<>0 $abort Problems reading sheet indus89Scalars with GDXXRW
$gdxIn indus89Scalars.gdx
$load scalarNames scalarValues

File fs / 'scalars.gms' /;
put  fs;
loop(scalarNames, put / 'Scalar ' scalarNames.tl ' / ' scalarValues(scalarNames):>20:10 ' /;';);
$offEcho

$call gams mkScalar
$include scalars.gms
```

Calling the file mkScalar.gms will create the file scalars.gms, containing all those scalar statements (shortened for representation):

```
Scalar baseyear     /      1988.0000000000 /;
Scalar repco        /         2.5000000000 /;
```

Finally, the file scalars.gms is included to your model.

This example is also part of the GAMS Data Utilities Library, see model **[GDXXRWExample17]** for reference.

6.28.8 Changes in the Set Values Parameter

The following documents some changes that were made when reading a set using the `values=string` option. Reading a domain or a parameter was not affected by these changes.

To illustrate the various behaviors in different versions of `GDXXRW`, we are using the spreadsheet data as shown below, using the following call:

```
$call gdxxrw test.xlsx set=one rng=B2 rDim=1 values=string set=two rng=B1 rDim=1 cDim=1 values=string
```

We read the one dimensional set in column B by specifying the top-left corner of the data (cell B2) or the full range (B2..B5). A two dimensional set is read using the top-left corner of the data (cell B1) or the full range (B1..E5). Variations are introduced by specifying options for `values` to be `string` or `yn` or `noData`. The option value `all` is only available in later versions of `GDXXRW` and was used to introduce the same behavior as `strings` in earlier versions.

6.28.8.1 Chronological description of the changes made to the Values option:

- **GAMS versions prior to version 24.3:**

  `values=string` results in reading the data dense. The contents of a cell is used for the set associated text and an element is included even if the data cell is empty.

- **GAMS version 24.3.1**

  We changed the interpretation of `string` to mean that the set element was only to be included when the string data was not empty. Note below that element a4 is missing from the one-dimensional set and so are a1.b1, a2.b2 etc from the two-dimensional set. For the two-dimensional case this looked more or less how the GAMS compiler interprets a table statement. Unfortunately, the interpretation of empty data cells was also applied to one-dimensional sets leading to undesired results.

- **GAMS version 24.4.1**

  Recognizing that reading a set dense was no longer available, we introduced a new option `values=all`. This allowed us to read Excel data the same way as was possible before version 24.3.1 using the `values=string` i.e. reading the data dense and including all cells whether the data cell is empty or not and use the content of the data cell for the set associated texts.

- **GAMS version 24.4.6 (Current status)**

  We decided to remove some confusion with the interpretation of the `values` option by introducing the options `dense` and `sparse` and flagging the options `strings` and `all` as deprecated. Both `strings` and `all` are replaced with `dense`.

Backward compatibility issues.

With these changes we broke our in house rule not to introduce changes that break backward compatibility. Because of this, the user needs to change the parameters for the `GDXXRW` call or change the workbook data. The parameters for the call should be changed from `values=string` to `values=dense` for one-dimensional sets where we specify the top-left corner only. In case the data in the workbook needs to be changed, inserting a string to in the data cell will address the issue. In the example on the top of the page, inserting a 'Y' in cell C5.

6.29 Invert

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This calculates the inverse of a square matrix A: `A*AInv = I`. The matrices `A` and `AInv` are indexed over `(i,i)`.

6.29.1 Usage

Command line:

```
gamstool [linalg.]Invert i A AInv gdxIn=fileIn.gdx gdxOut=fileOut.gdx
```

Compile time:

```
$callTool [linalg.]Invert i A AInv [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]
```

Execution time:

```
executeTool '[linalg.]Invert i A AInv [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]';
```

Where:

Argument	Description
`i`	Name of set used in matrix `i(*)`.
`A`	Name of two-dimensional matrix parameter `A(i,i)`.
`AInv`	Name of two-dimensional parameter containing the inverse `AInv(i,i)`.

The following parameters are available:

Parameter	Description
`gdxIn=fileIn.gdx`	Name of GDX file that contains symbols `i` and `A`. Mandatory if called from the command line, otherwise optional.
`gdxOut=fileOut.gdx`	Name of GDX file that contains symbol `AInv` after execution. Mandatory if called from the command line, otherwise optional.

6.29.2 Example

```
Set i /i1*i3 /;

Alias (i,j);

Table a(i,j) 'original matrix'
        i1   i2   i3
   i1    1    2    3
   i2    1    3    4
   i3    1    4    3;

Parameter inva(i,j) 'inverse of a';

execute_unload 'a.gdx', i, a;
executeTool.checkErrorLevel 'linalg.invert i a inva -gdxIn=a.gdx -gdxOut=b.gdx';
execute_load 'b.gdx', inva;

display a, inva;
```

6.30 MDB2GMS

Author

Erwin Kalvelagen

Attention

`MDB2GMS` is deprecated (see GAMS 40 MDB2GMS release notes). Please use Connect agent SQLReader instead.

6.30.1 Overview

`MDB2GMS` is a tool to convert data from an Microsoft Access database into GAMS readable format. The source is an MS Access database file (.mdb or .accdb) and the target is a GAMS Include File (.inc) or a GAMS GDX File (.gdx).

When running the executable mdb2gms.exe without command-line arguments, the tool will run interactively with a built-in GUI interface. Alternatively `MDB2GMS` can be run in batch mode, which is useful when running it directly from a GAMS model without user intervention using the `$call` command at compile time or the `execute` command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL's should not be allowed to get into a GAMS data structure. The handling of NULL's can be specified in an option.

Besides parameters it is also possible to generate set data.

6.30.2 Requirements

MDB2GMS runs only on Windows PC's and with MS Access installed. MS Access comes with certain versions of MS Office, but some MS Office versions will not include Access. The actual retrieval of the database records is performed by [DAO] (https://en.wikipedia.org/wiki/Data_access_object) or Data Access Objects, an object layer for accessing the database. The actual database is the Jet engine, which performs the queries and retrieves the data. Also consider to use SQL2GMS instead of MDB2GMS, if MS Access is not installed on your system.

To use this tool effectively you will need to have a working knowledge of [SQL] (https://en.wikipedia.org/wiki/SQL) in order to formulate proper database queries.

6.30.3 Batch Usage

MDB2GMS can be run in batch mode without user intervention from within the GAMS model by using the $call resp. execute statements or directly from command prompt while specifying all arguments in the command-line. A MDB2GMS batch call is of the following form:

```
mdb2gms inputFile outputFile queryString
```

A proper batch call will at least contain the following three command-line arguments:

1. The name of the MS Access database inputFile must be specified (.mdb or .accbd format). Use the I argument to enter the file name, i.e. I=inputFile.
2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option O, i.e. O=outputFile.inc, while the use of a GDX file is indicated by the option X, i.e. X=outputFile.gdx.
3. The SQL queryString, containing the SQL statement to be executed on the database, must be specified within the option Q, i.e. Q=queryString.

See also Command-line Arguments below for a complete list of all possible command-line arguments. Consider that the $call or execute usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the interactive built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a @ (At sign).

Also consider to take a look at the section Strategies, mentioning some of the drawbacks of the batch usage and how to overcome them.

If you only specify I=inputFile then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command-line argument. Only if an input file, an output file and a query string is provided, the call will be considered as batch invocation.

6.30.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using MDB2GMS directly from the GAMS model or command prompt.

Argument	Interpretation	Default	Description
I	inputFile	none	Specify the name of the input file (required).
O	outputIncludeFile	none	Specify the name of the output file (.inc). Either `O=` or `X=` must be specified (or both).
On	n-th outputIncludeFile	none	Match the nth query with the nth output file (.inc format) if multiple queries are used.
X	outputGDXFile	none	Specify the name of the output file (.gdx). Either `O=` or `X=` must be specified (or both).
Q	Query	none	This option can be used to specify a SQL query (required).
Qn	n-th Query	none	Match the nth query with the nth output file (.inc) format or with the nth set- or parameter name when writing to GDX if multiple queries are used.
S	setName	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.
Sn	n-th setName	none	Match the nth query with the nth set in the GDX file if multiple queries are used.
Y	setName (with expl. text)	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. Use this argument to store a set with explanatory text.
Yn	n-th setName (with expl. text)	none	Match the nth query with the nth set (with explanatory text) in the GDX file if multiple queries are used.
P	parameterName	none	If we write to a GDX file, use this option to specify the name of a parameter to be used inside the GDX file.
Pn	n-th parameterName	none	Match the nth query with the nth parameter in the GDX file if multiple queries are used.
D	Debug	disabled	Generate debug information.
B	Quote Blanks	disabled	Quote strings if they contain blanks or embedded quotes.
M	Mute	disabled	Controls if additional information is written to the log and include file.
L	Listing	disabled	Controls if the data is embedded in the listing file.
@fileName	ext. options file	none	Causes the program to read options from an external text file.
N	iniFileName	mdb2gms.ini	Indicates the usage of a different INI file.
F	formatString	none	Specify a format string.

Argument	Interpretation	Default	Description
W	Wiring	none	Maps database columns to GAMS index positions.
R	rowBatchSize	100	Row batch size; the default is 100 records.

Some more detailed remarks on the command-line arguments:

I = *string* (inputFile, default = none)

This option is required and specifies the name of the .mdb or .accbd file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. On a network UNC Names can be used, and files from another computer can be accessed, e.g.

```
"\\hostname\c\my documents\a.mdb."
```

This option is required for batch processing. To specify a path equal to the location where the .gms file is located, you can use:

```
I=system.fpmydb.mdb
```

This option is demonstrated in most examples, see Example 1 - Reading a single valued Table for instance.

O = *string* (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is writable. UNC Names can be used. An output file must be specified for batch operation: i.e. either `O=` or `X=` needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the $include command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in most examples, see Example 1 - Reading a single valued Table for instance.

On = *string* (outputIncludeFile, default = none)

When using multiple queries in a single `MDB2GMS` call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

X = *string* (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS GDX file. Make sure the directory is writable. UNC names can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either `O=` or `X=` needs to be specified (or both). This option is demonstrated in Example 5 - Reading Set with Explanatory Text or Example 7 - Multi-Query Batch Example for instance.

Q = *string* (Query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by Access we refer to the documentation that comes with MS Access. The query is passed on directly to the Jet database engine, so the complete power and expressiveness of Access SQL is available. For an exact description of allowed expressions consult a text on MS Access.

One notable syntax feature is that when field names or table names contain blanks, they can be specified in square brackets. Examples:

```
Q="SELECT * FROM mytable"
Q="SELECT year, production FROM [production table]"
Q="SELECT [GAMS City], value FROM [example table], CityMapper
WHERE [Access City]=city"
```

This option is demonstrated in Example 1 - Reading a single valued Table for instance

Qn = *string* (Query, default = none)

When using multiple queries in a single `MDB2GMS` call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

or (GDX output file format - where several sets and parameters can be stored in a single file):

```
Q1="SELECT a, b FROM table"
P1=abParameter
Q2="SELECT c FROM table"
S2=cSet
```

Note the usage of the arguments Pn resp. Sn in order to store the results as parameter resp. set and to specify the name of the symbols. See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

S = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in Example 4 - Reading a multi dimensional Set.

Sn = *string* (setName, default = none)

If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet
```

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

Y = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in Example 5 - Reading Sets with Explanatory Text for instance.

Yn = *string* (setName, default = none)

If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet
```

The last column specified within the select clause in the SQL statements will be used as explanatory text.

P = *string* (parameterName, default = none)

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).

Pn = *string* (parameterName, default = none)

If multiple queries are used in a single MDB2GMS call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i, j, value FROM table"
A1=ijValue
Q2="SELECT n, m, value FROM table"
A2=nmValue
```

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

D (Debug, default = disabled)

This option can be used for debugging purposes. If specified the import filter will not run minimized but "restored", i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of MDB2GMS.

B (Quote Blanks, default = disabled)

If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off. For more information see subsection Quotes. This option only applies to an output include file.

M (Mute, default = disabled)

Run in modest or mute mode: no additional information, such as version number, number of rows in the data, elapsed time, used query etc. is written to the log and include file.

L (Listing, default = disabled)

Embed the data between the `$offListing` and `$onListing` dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

@fileName = *string* (fileName, default = none)

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also Command Files for some further details.

N = *string* (fileName, default = mdb2gms.ini)

Use a different INI file than the standard mdb2gms.ini located in the same directory as the executable mdb2gms.exe.

F = *string* (formatString, default = none)

In special cases we can apply a format string on the include file output (not for GDX output). Each column in the result set is a string and can be represented by a s in the format string.

W = *string* (wiring, default = none)

By using the `W` option, one can map database columns to GAMS index positions. See model **[Wiring]** for reference.

R = *integer* (rowBatchSize, default = 100)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of `MDB2GMS`.

6.30.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the [**trnsport**] model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.mdb).

Distances

City1	City2	Distance
SEATTLE	CHICAGO	1,7
SAN-DIEGO	CHICAGO	1,8
SEATTLE	NEW-YORK	2,5
SAN-DIEGO	NEW-YORK	2,5
SEATTLE	TOPEKA	1,8
SAN-DIEGO	TOPEKA	1,4

Figure 6.55 Table: distances

The data can be queried with a simple SQL statement:

```
SELECT city1, city2, distance
FROM   distances
```

By running the following `MDB2GMS` statement, the connection to the database Sample.mdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

```
mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
```

The MS Access database file name is specified using the argument I. Note that the string is enclosed by quotes, as the string contains blanks. The arguments Q and O are used to specify the query and the output file name (and format).

The generated include file distances.inc looks like:

```
* -----------------------------------------------------
* MDB2GMS          24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* DAO version: 14.0
* Jet version: 4.0
* Database:    F:\datalib\Sample.mdb
* Query:       SELECT city1, city2, distance FROM distances
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------
```

The commented header section summarizes some information about the `MDB2GMS` resp. GAMS version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your GAMS model.

Retrieving the data using `MDB2GMS` from the database and including the queried data in your GAMS model within the parameter declaration statement (at compile time) can be combined in the following way:

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

$call mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i,j) 'distance in thousands of miles' /
$include distances.inc
/;

display d;
```

Finally, the values of the parameter `d` are displayed:

```
             new-york      chicago       topeka

seattle         2.500        1.700        1.800
san-diego       2.500        1.800        1.400
```

This example is also part of the GAMS Data Utilities Library, see model [**Distances1**] for reference. Note that the query results are written to a GDX file in addition.

6.30.3.3 Example 2 - Reading a multi valued Table

In this scenario, we want two read the three index columns `year`, `loc`, `prod` and the value columns `sales` and `profit` from the database file Sample.mdb. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for `sales` resp. `profit`) and a UNION select.

Consider the table with two value columns `sales` and `profit`:

data

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.56 Table: data (shortened for presentation)

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```
SELECT year, loc, prod, sales
FROM   data
SELECT year, loc, prod, profit
FROM   data
```

We can generate a include file sales.inc by running the following command:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
```

Note that we specify the first query in order to select the sales and the relevant index columns within the Q argument. The query results are written to sales.inc using the O argument. Analogously we generate a include file profit.inc by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
```

Retrieving the data using MDB2GMS from the database Sample.mdb and including the queried data in your GAMS model within the parameter declaration statements of sales and profit (at compile time) can be combined in the following way:

```
Set
   year 'years'     / 1997*1998 /
   loc  'locations' / nyc, was, la, sfo  /
   prd  'products'  / hardware, software /;

$call mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
Parameter sales(year,loc,prd) /
$include sales.inc
/;

$call mdb2gms I=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
Parameter profit(year,loc,prd) /
$include profit.inc
/;
```

This example is also part of the GAMS Data Utilities Library, see model [**SalesProfitDB1**] for reference.

Single Parameter with extra Index Position

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index type to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

```
SELECT year, loc, prod, 'sales', sales
FROM   data
UNION
SELECT year, loc, prod, 'profit', profit
FROM   data
```

The data is accessed, queried and written to data.inc by running the following command:

```
mdb2gms @howToRead.txt
```

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

```
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FR
O=data.inc
```

The generated include file data.inc looks like (shortened for presentation):

```
* ------------------------------------------------------
* MDB2GMS          24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* ------------------------------------------------------
* DAO version: 14.0
* Jet version: 4.0
* Database:    F:\datalib\Sample.mdb
* Query:       SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit
* ------------------------------------------------------
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
1997.was.hardware.profit 7
1997.was.hardware.sales 120
1997.was.software.profit 20
1997.was.software.sales 70
1998.la.hardware.profit 6
1998.la.hardware.sales 70
* ------------------------------------------------------
```

Retrieving the data using `MDB2GMS` from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index `type` in order to access the data type `sales` resp. `profit`):

```
$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FR
O=data.inc
$offEcho

Set
   year 'years'     / 1997*1998 /
   loc  'locations' / nyc, was, la, sfo  /
   prd  'products'  / hardware, software /
   type 'data type' / sales, profit      /;

$call mdb2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
/;
```

This example is also part of the GAMS Data Utilities Library, see model [**SalesProfitDB2c**] for reference.

6.30.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a MS Access database file. Suppose we want to read the column City1 (see table distances) in order to define the set `i` in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```
SELECT distinct(City1)
FROM   distances
```

The include file city1.inc looks like (header informations are removed in order to shorten the representation):

```
* ----------------------------------------------------
 SAN-DIEGO
 SEATTLE
* ----------------------------------------------------
```

All steps (data access via `MDB2GMS`, set definition) can be combined:

```
$call mdb2gms I=Sample.mdb Q="SELECT distinct(city1) FROM distances" O=city_i.inc
Set i 'canning plants' /
$include city_i.inc
/;

display i;
```

The display statement generates the following output in the listing file:

```
----     56 SET i

seattle  ,    san-diego
```

6.30.3.5 Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the O argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing `a b c` is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. `a.b.c` will be interpreted correctly.

There are different ways to add these periods explicitly within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some placeholders):

```
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (|| or & depending on DBMS):

```
SELECT index1&'.'&index2&'.'&index3 FROM dataTable
SELECT index1||'.'||index2||'.'||index3 FROM dataTable
```

For instance, suppose we want to define a two dimensional set

```
Set ij(i,j) 'canning plants - markets';
```

based on the data of the table distances stored in Sample.mdb. The following MDB2GMS statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

```
mdb2gms I=Sample.mdb Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc
```

The include file city_ij.inc looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
SEATTLE.NEW-YORK ' '
SAN-DIEGO.NEW-YORK ' '
SEATTLE.CHICAGO ' '
SAN-DIEGO.CHICAGO ' '
SEATTLE.TOPEKA ' '
SAN-DIEGO.TOPEKA ' '
* -----------------------------------------------------
```

Without adding the empty value field, the resulting include file would look like (shortened):

```
* -----------------------------------------------------
SEATTLE NEW-YORK
SAN-DIEGO NEW-YORK
* -----------------------------------------------------
```

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

$call mdb2gms I=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc

Set ij(i,j) 'two dimensional set' /
$include city_ij.inc
/;

display ij;
```

The display statement generates the following output in the listing file:

```
----     75 SET ij  two dimensional set

             new-york     chicago      topeka

SAN-DIEGO         YES         YES         YES
SEATTLE           YES         YES         YES
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the X and S resp. Y arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

when using MDB2GMS in the following way:

```
mdb2gms I=Sample.mdb Q="SELECT index1, index2, index3 FROM datatable" X=setData.gdx S=setName
```

which will generate the file setData.gdx with a three dimensional set named setName containing the results of the query.

6.30.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a MS Access database file using MDB2GMS. In the first place, we are going to write the query results to an include file, afterwards we use the Y argument in order to store the query results as a set with explanatory text in a GDX file.

setData

setElement	explText
firstSetElement	Explanatory text for the first 'set element'
secondSetElement	Explanatory text for the second "set element"
thirdSetElement	Explanatory text for the third 'set element"
fourthSetElement	Explanatory text for the fourth set element

Figure 6.57 Table: setData

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```
SELECT setElement, explText
FROM   setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument B in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file setData.inc:

```
$call mdb2gms I=Sample.mdb B Q="SELECT setElement, explText FROM setData" O=setData.inc

Set a /
$include setData.inc
/;
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
firstSetElement "Explanatory text for the first 'set element'"
secondSetElement 'Explanatory text for the second "set element"'
thirdSetElement "Explanatory text for the third 'set element'"
fourthSetElement 'Explanatory text for the fourth set element'
* -----------------------------------------------------
```

Note the handling of the quotes according to the description in B.

Writing the Query Results in a GDX File
When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the Y argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

```
$call mdb2gms I=Sample.mdb Q="SELECT setElement, explText FROM setData" X=setData.gdx Y=set_b

Set b;
$gdxIn setData.gdx
$load b = set_b
$gdxIn
```

Note that the name of the set in the GDX file is `set_b` (specified within the `Y` argument), while the name of the GDX file was specified within the X argument.

6.30.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

```
Set i / NY, DC, LA, SF /;
```

Now assume a data table looks like:

example table

city	value
new york	100
los angeles	120
san francisco	105
washington dc	102

Figure 6.58 Table: example table

This means we have to map 'new york' to 'NY' etc. This mapping can be done in two places: either in GAMS or in the database.

Index Mapping done in GAMS

When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
'new york' 100
'los angeles' 120
'san francisco' 105
'washington dc' 102
* -----------------------------------------------------
```

Note that the single quotes are added by activating the option B (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

```
Set i / NY, DC, LA, SF /;

Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;

$call mdb2gms I=Sample.mdb B O="city1.inc" Q="SELECT city, value FROM [example table]"
Parameter dbdata(idb) /
$include city1.inc
/;

Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;

Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;
```

The display statement generates the following output in the listing file:

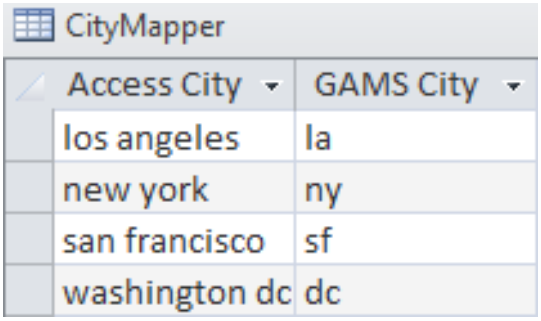
```
----     47 PARAMETER data

NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

This example is also part of the GAMS Data Utilities Library, see model [**IndexMapping1**] for reference.

Index mapping done in Database

The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:



CityMapper

Access City	GAMS City
los angeles	la
new york	ny
san francisco	sf
washington dc	dc

Figure 6.59 Table: CityMapper

This table can be used in a join to export the data in a format we can use by executing the query:

```
SELECT [GAMS City], value
FROM    example_table, CityMapper
WHERE   CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
la 120
ny 100
sf 105
dc 102
* -----------------------------------------------------
```

All steps can be combined in the GAMS model:

```
Set i / NY, DC, LA, SF /;

$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_
O=city2.inc
$offEcho

$call mdb2gms @howToRead.txt
Parameter data(i) /
$include city2.inc
/;
display data;
```

The display statement generates the following output in the listing file:

```
----     38 PARAMETER data

NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

Note: MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [**IndexMapping2**] for reference.

6.30.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual MDB2GMS execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single MDB2GMS call and write several GAMS include files containing the results of the queries, we can use the command-line arguments Qn and On. The structure of a multi-query call looks like:

```
I=sample.mdb

Q1=firstQuery
O1=outputFileName.inc

Q2=secondQuery
O2=outputFileName.inc

Q3=thirdQuery
O3=outputFileName.inc
```

The terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. We see that the argument `Qn` is matched by an argument `On`. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments Qn, Sn, Pn and Yn. The structure of a multi-query call when writing to a GDX file looks like:

```
I=sample.mdb
X=sample.gdx

Q1=firstQuery
S1=setName

Q2=secondQuery
S2=setName

Q3=thirdQuery
A3=parameterName

Q4=fourthQuery
A4=setName
```

Again, the terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. Here we see that a query `Qn` is matched by either a set name `Sn` or a parameter name `Pn`, i.e. the results of the first query will be stored as a set whose name is specified within the `S1` argument, the results of the third query will be stored as a parameter whose name is specified within the `P3` argument etc. The `X` argument is used to specify the name of the GDX file.

For a complete example see section Example 7 - Multi-Query Batch Example.

6.30.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file Sample.mdb):

data

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.60 Table: data (shortened for presentation)

We want to extract the following information:

- The set **year**
- The set **loc**
- The set **prd**
- The parameter **sales**
- The parameter **profit**

Output: Several include Files

This can be accomplished using the following GAMS code with multiple queries in a single `MDB2GMS` call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):

```
$onEcho > howToRead.txt
I=Sample.mdb

Q1=SELECT distinct(year) FROM data
O1=year.inc

Q2=SELECT distinct(loc) FROM data
O2=loc.inc

Q3=SELECT distinct(prod) FROM data
O3=prod.inc
```

```
Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc

Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
$offEcho

$call =mdb2gms @howToRead.txt

Set y 'years' /
$include year.inc
/;
Set loc 'locations' /
$include loc.inc
/;
Set prd 'products' /
$include prod.inc
/;

Parameter sales(prd,loc,y) /
$include sales.inc
/;
display sales;

Parameter profit(prd,loc,y) /
$include profit.inc
/;
display profit;
```

This example is also part of the GAMS Data Utilities Library, see model [**SalesProfitDB3**] for reference.

Output: A single GDX File

The same example imported through a GDX file can look like:

```
$onEcho > howToRead.txt
I=Sample.mdb
X=Sample.gdx

Q1=SELECT distinct(year) FROM data
S1=year

Q2=SELECT distinct(loc) FROM data
S2=loc

Q3=SELECT distinct(prod) FROM data
S3=prd

Q4=SELECT prod, loc, year, sales FROM data
P4=sales

Q5=SELECT prod, loc, year, profit FROM data
P5=profit
$offEcho
```

```
$call =mdb2gms @howToRead.txt

Set
   y   'years'
   loc 'locations'
   prd 'products';

Parameter
   sales(prd,loc,y)
   profit(prd,loc,y);

$gdxIn Sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;
```

The call of the GDXViewer will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model **[SalesProfitDB4]** for reference.

6.30.5 Interactive Usage

When the tool is called without command-line parameters, it will startup interactively. Using it this way, one can specify the database file (.mdb or .accbd file), the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.

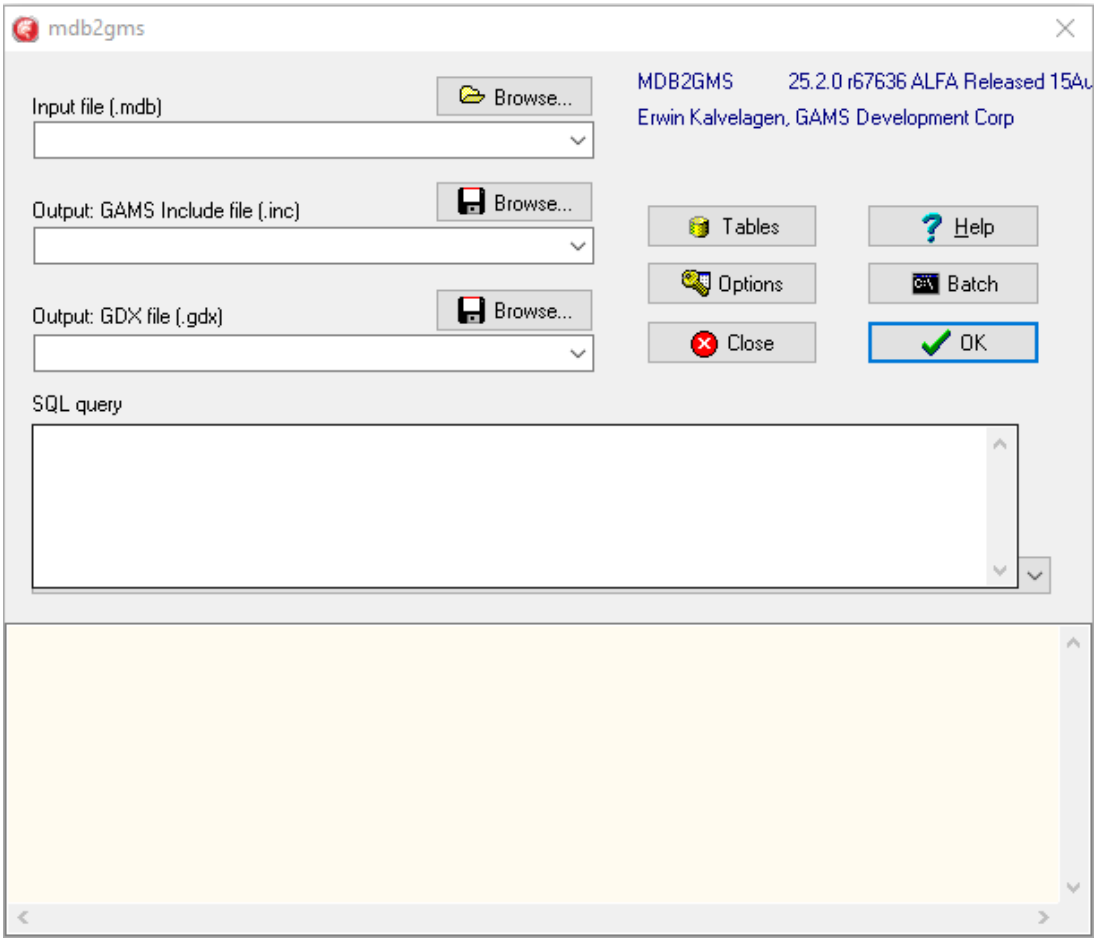


Figure 6.61 MDB2GMS - Graphical User Interface

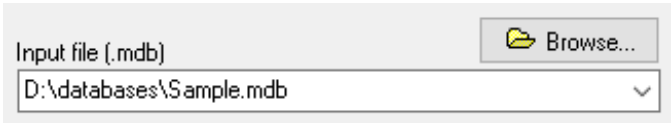
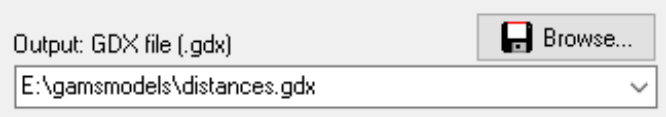
- **Input file (.mdb or .accbd)**. This is the combo box to specify the input file. See also inputFile for some more detailed remarks. The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation `\\machine\directory\file.mdb`.

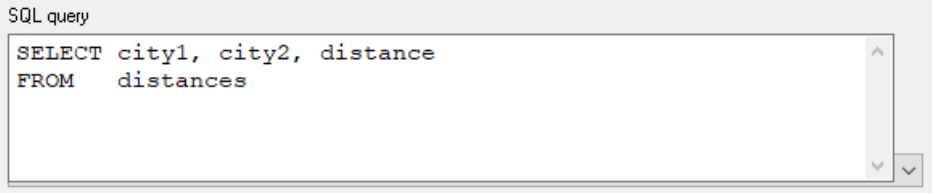


- **Output GAMS Include file (∗.inc)**. If you want to create a GAMS include file, then specify here the destination file. See also outputIncludeFile for some more detailed remarks.

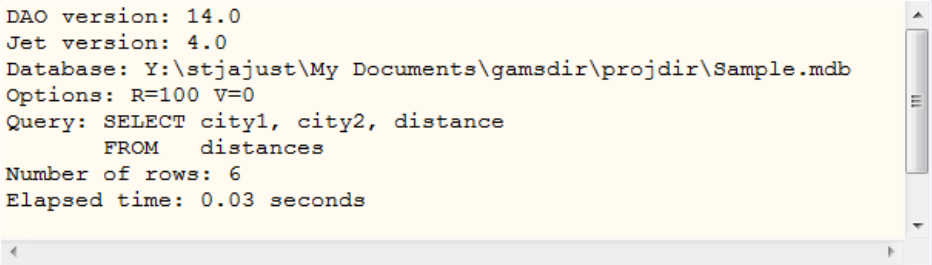
- **Output GDX file (∗.gdx)**. As an alternative to a GAMS include file, the tool can also generate a GDX file. One or both of the output files need to be specified. See also outputGDXFile for some more detailed notes.



- **SQL Query**. The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also Q for some more detailed remarks. For an exact description of allowed expressions consult a text on MS Access.



- **Progress Memo**. This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.



- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

- The **Options button** will pop up a window where you can specify a number of options.

- Pressing the **Help button** will show this documentation.

- Pressing the **OK button** will execute the query and an include file or GDX file will be generated.

- Pressing the **Batch button** will give information on how the current query can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied to the clipboard. In the IDE press `Ctrl-C` or choose `Edit|Paste` to copy the contents of the clipboard to a GAMS text file.

- Pressing **Close button** will exit the application. The current settings will be saved in an INI file so when you run `MDB2GMS` again all current settings will be restored.

6.30.5.1 Options

The **Options** window can be created by pressing the options button:

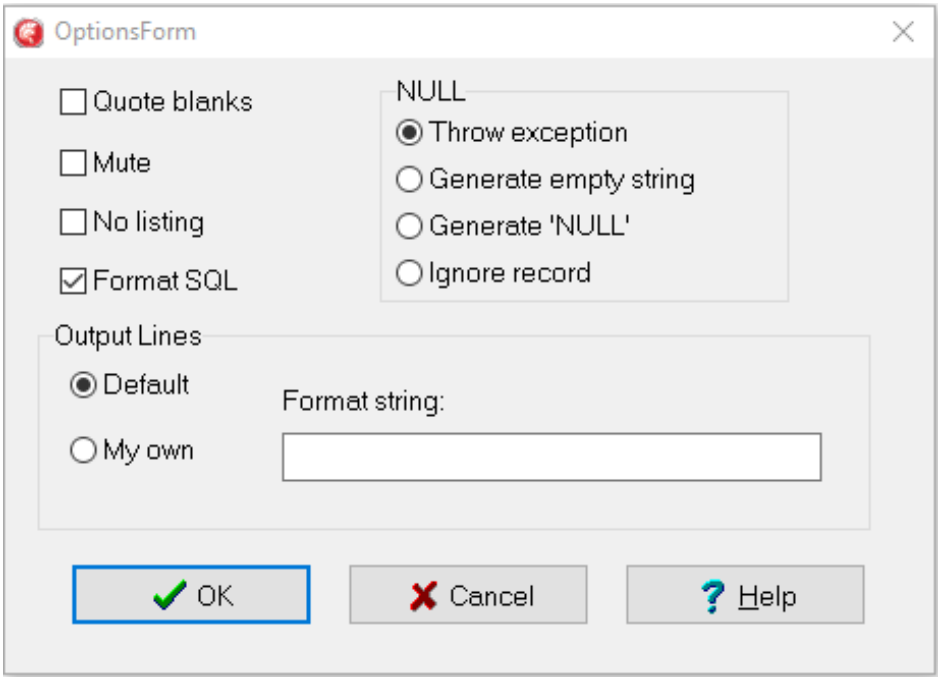


Figure 6.62 Options Menu of the Graphical User Interface

The following options are available in the options window:

- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also B for some more detailed notes.

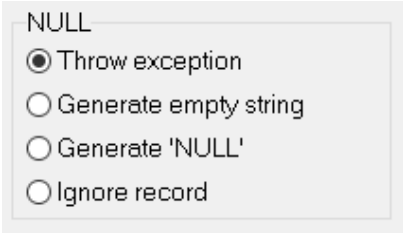
- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file.

- **No listing:** Surround the include file by `$offListing` and `$onListing` so that the data will not be echoed to the listing file. The equivalent command-line argument is L.

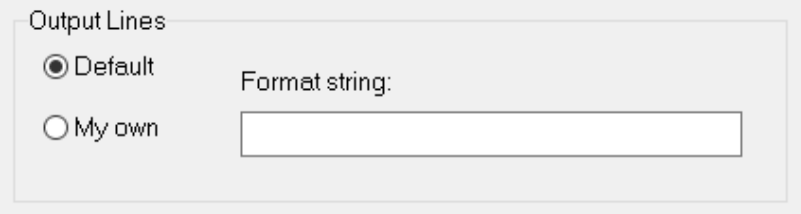
- **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

The following options are only needed in special cases:

- **NULL:** This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.



- **Output Lines:** By default output lines are created as follows: all first n-1 fields are considered indices and the last n-th column is the value. The format corresponding to this situation is '%s.%s.%s %s'` (for a three dimensional parameter). In special cases you may want to tinker with the format string being used. The fields are all considered strings, so only use s as format placeholder. Make sure you specify exactly the same number of s's as there are columns in the result set.



The buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** wil ignore the changes made, and all option settings will revert to their previous values.

- **Help button** will show this help text.

6.30.6 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.
- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.
- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

```
Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing
```

we can conveniently use the save/restart facility. The individual submodel are coded as:

- **Step 0: sr0.gms**

```
$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText

Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';
```

```
$onEcho > howtoRead.txt
I=transportation.mdb

Q1=select name from suppliers
O1=i.inc

Q2=select name from demandcenters
O2=j.inc

Q3=select name,demand from demandcenters
O3=demand.inc

Q4=select name,supply from suppliers
O4=supply.inc

Q5=select supplier,demandcenter,distance from distances
O5=dist.inc
$offEcho

$call =mdb2gms.exe @howtoRead.txt

Set i /
$include i.inc
/;

Set j /
$include j.inc
/;

Parameter demand /
$include demand.inc
/;

Parameter supply /
$include supply.inc
/;

Parameter dist /
$include dist.inc
/;

display i, j, demand, supply, dist;
```

- **Step 1: sr1.gms**

```
$onText
step 1: data manipulation step
execute as: > gams sr1 restart=s0 save=s1
$offText

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;
```

- **Step 2: sr2.gms**

```
$onText
step 2: model definition
```

```
execute as: > gams sr2 restart=s1 save=s2
$offText

Variable
   x(i,j) 'shipment quantities in cases'
   z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
   ecost      'define objective function'
   esupply(i) 'observe supply limit at plant i'
   edemand(j) 'satisfy demand at market j';

ecost..      z =e= sum((i,j), c(i,j)*x(i,j));

esupply(i).. sum(j, x(i,j)) =l= supply(i);

edemand(j).. sum(i, x(i,j)) =g= demand(j);
```

- **Step 3: sr3.gms**

```
$onText
step 3: model solution
execute as: > gams sr3 restart=s2 save=s3
$offText

option lp = cplex;

Model transport / all /;
solve transport using lp minimizing z;
```

- **Step 4: sr4.gms**

```
$onText
step 4: report writing
execute as: > gams sr4 restart=s3
$offText

abort$(transport.modelStat <> 1) "model not solved to optimality";

display x.l, z.l;
```

A model that executes all steps can be written as:

```
execute '=gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute '=gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute '=gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute '=gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute '=gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";
```

If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [**MDBSr5**] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

MDB2GDX1.gms

```
execute '=gams.exe sr0 lo=3 gdx=trnsport.gdx';
abort$errorLevel "step 0 failed";

execute '=gdxviewer.exe trnsport.gdx';
```

The model [**MDB2GDX1**] is also part of the GAMS Data Utilities Library.

We can also let MDB2GMS create the GDX file:

MDB2GDX2.gms

This model demonstrates how to store data from Access database (file Transportation.mdb) into a GDX file.

```
$onEcho > howToRead.txt
I=Transportation.mdb
X=Transportation.gdx

Q1=SELECT name FROM suppliers
S1=i

Q2=SELECT name FROM demandcenters
S2=j

Q3=SELECT name, demand FROM demandcenters
P3=demand

Q4=SELECT name, supply FROM suppliers
P4=supply

Q5=SELECT supplier, demandcenter, distance FROM distances
P5=dist
$offEcho

$call =mdb2gms.exe @howToRead.txt
```

The first approach has the advantage that a complete audit record is available from the data moved from the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the database and how this was stored in the GDX file, that file gives the answer.

The model [**MDB2GDX2**] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

GDXTRNSPORT.gms

This model demonstrates how to load the transportation data from GDX file at compile time.

```
Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist

display i, j, demand, supply, dist;
```

DBTimestamp1.gms

In one application I had to retrieve data from the database each morning, at the first run of the model. The rest of the day, the data extracted that morning could be used. The following logic can implement this:

```
$onText
Retrieve data from data base first run each morning.
$offText

$onEcho > getdate.txt
I=%system.fp%transportation.mdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho

$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/;

Scalar currentday 'day of this run';
currentday = gday(jnow);

display "compare", dbtimestamp, currentday;

if(dbtimestamp <> currentday,
   execute '=gams.exe sr0 lo=3 gdx=transportation.gdx';
   abort$errorLevel "step 0 (database access) failed";
   execute '=mdb2gms.exe @getdate.txt'
);
```

The include file dbtimestamp.inc contains the day of the month (1,..,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the dbtimestamp.inc file. This last operation could be done using a `PUT` statement, but in this case we used an SQL statement.

The model [**DBTimestamp1**] is also part of the GAMS Data Utilities Library.

6.30.7 Command Files

Parameters can be specified in a command file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command-line as in:

```
$call =mdb2gms I="c:\My Documents\test.mdb" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command-line like:

```
$call =mdb2gms @"c:\My Documents\options.txt"
```

The command file

```
c:\My Documents\options.txt
```

can look like:

```
I=c:\My Documents\test.mdb
O=c:\My Documents\data.inc
Q=SELECT * FROM mytable
```

It is possible to write the command file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```
$set cmdfile "c:\windows\temp\commands.txt"
$echo "I=E:\models\labordata.mdb" >  "%cmdfile%"
$echo "O=E:\models\labor.INC"     >> "%cmdfile%"
$echo "Q=SELECT * FROM labor"     >> "%cmdfile%"
$call =mdb2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;

display p;
```

Newer versions of GAMS allow the usage of the `$onEcho` and `$offEcho` commands:

```
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho > "%cmdfile%"
I=E:\models\labordata.mdb
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho
$call =mdb2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;

display p;
```

Note that the quotes enclosing strings with blanks like `Q=SELECT * FROM labor` can be omitted when using an external parameter file.

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character \ as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data \
UNION \
SELECT prod, loc, year, 'profit', profit FROM data
```

6.30.8 Notes

6.30.8.1 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: $gdxIn, $load, execute_load, execute_unload. The GDX=filename command-line argument will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using `File|Open`.

6.30.8.2 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\\<server>\<share>\<path>\<file>
```

Examples:

```
\\athlon\c\My Documents\MDB2GMS.rtf
```

6.30.8.3 Quotes

Examples of handling of indices when the option B for quoting strings containing blanks is used:

6.30.8.4 $CALL Command

The `$call` command in GAMS will execute an external program at compile time. There are two forms:

The `$call` command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalProgram
```

```
$call =externalProgram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form `$call externalProgram` which uses the command processor.
2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form `$call externalProgram`.
3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form `$call =externalProgram`. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: `$call =externalProgram`.
4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the `START` command, as in: `$call start /w externalWindowsProgram`. Otherwise, it is preferred to use: `$call =externalWindowsProgram`.

Attention

In general it is recommended to use the `$call =externalProgram` version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2
```

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call '"external program" "parameter 1" "parameter 2"'
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes *only if* the = appears outside the double quotes.

6.30.8.5 Compile Time Commands

All $ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed **before** an execution time command, even if it is below. As an example consider:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
$call x.bat
```

This fragment does not work correctly as already during compilation, the `$call` is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

```
$echo "dir" > x.bat
$call x.bat
```

or by moving the external program invocation to execution time:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;
```

Notice that all $ commands do not include a semi-colon but are terminated by the end-of-line.

6.31 MessageReceiverWindow

6.31.1 Introduction

`MessageReceiverWindow` is a graphical tool that receives and displays Windows messages. The tool can either be used with the put_utility feature or with an arbitrary client (e.g. a Python program) that sends messages to a previously spawned instance of `MessageReceiverWindow.exe`.

6.31.2 Usage

An instance of `MessageReceiverWindow.exe` can be started as follows:

```
MessageReceiverWindow <title>
```

The optional argument `title` specifies the title of the `MessageReceiverWindow` instance. If the argument is omitted, the instance gets the default title `Form1`. Windows messages of type `WM_COPYDATA` that are send to the spawned instance, appear in its message log. The `Copy To Clipboard` button allows to copy the content of the message log to the clipboard. The `Save As ...` button can be used to save the content to a file.

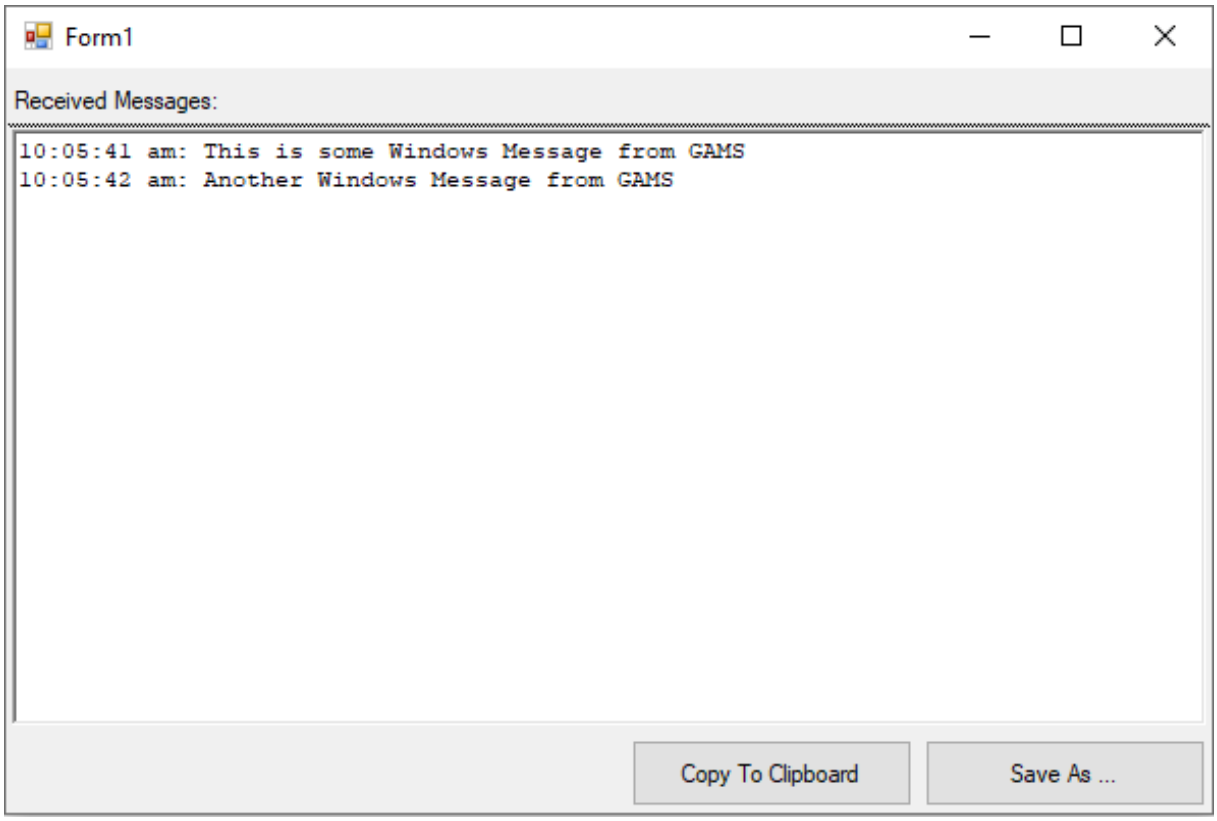


Figure 6.63 MessageReceiverWindow during the execution of Test Library model `MRW01`.

6.31.3 Special Commands

While arbitrary text messages are diplayed in the message log, there are special commands for controlling special behavior of an instance of `MessageReceiverWindow`:

Message	Action
@CopyToClipboard	Copies the content of the message log to the clipboard
@SaveAs [file]	Writes the content of the message log to [file]
@Terminate	Terminates the MessageReceiverWindow executable

6.31.4 Usage With put_utility

The put_utility feature offers a convenient integration of `MessageReceiverWindow`. The example **MRW01** shows how this works. First of all, an instance of MessagereceiverWindow needs to be spawned from within GAMS:

```
$set title Form1
Execute.Async "MessageReceiverWindow.exe %title%";
```

As soon as the window is ready, text messages or special commands can be sent by using put_utility with the command winMsg:

```
file f;
put_utility f 'WinMsg' / '%title%' / 'This is some Windows Message from GAMS';
```

By sending @Terminate, the instance can be terminated:

```
put_utility f 'WinMsg' / '%title%' / '@Terminate';
```

6.31.5 Usage With Python

The example **MRW02** from the GAMS Test Library demonstrates the use of MessageReceiverWindow from within Python. While it uses the Python programming language from within an Embedded Code section, other programming languages can be used as long as they provide access to Windows messages.

First of all, a ctypes.Structure derived class is defined which is used for sending Windows message to a MessageReceiverWindow instance:

```
class _CopyDataStruct(ctypes.Structure):
    _fields_ = [('dwData', ctypes.c_char_p),
                ('cbData', ctypes.c_ulong),
                ('lpData', ctypes.c_char_p)]
```

The function sendMessage() sends a message to the window with the title windowName. It makes use of functions FindWindowA and SendMessageA from ctypes.windll.user32:

```
def sendMessage(windowName, message):
    cs = _CopyDataStruct()
    receiver = ctypes.windll.user32.FindWindowA(None, bytes(windowName, 'utf-8'))
    cmd = bytes(message, 'utf-8')
    cs.dwData = 1
    cs.cbData = len(cmd)+1
    cs.lpData = cmd
    WM_COPYDATA = 0x4A
    ctypes.windll.user32.SendMessageA(receiver, WM_COPYDATA, 0, ctypes.byref(cs))
```

Popen from the subprocess module is used in order to start an instance of MessageReceiverWindow. The system_directory property of a GamsWorkspace instance from the GAMS Python API is used for finding a GAMS system directory:

```
windowName = 'MRW Python'
p = Popen([os.path.join(GamsWorkspace().system_directory, 'MessageReceiverWindow.exe'), windowName])
```

As soon as the window is ready, text messages or special commands can be sent by using the previously defined sendMessage function:

```
sendMessage(windowName, "This is some Windows Message from Python")
```

Sending @Terminate will terminate the running MessageReceiverWindow instance:

```
sendMessage(windowName, "@Terminate")
```

6.32 MODEL2TEX

A Tool to generate a documentation from GAMS source code in LaTeX format.

Author

Clemens Westphal

Special thanks to Ingmar Schlecht for supporting us and sharing his gamsToLatex implementation.

6.32.1 Introduction

MODEL2TEX is a tool to generate a documentation from GAMS source code in LaTeX format. This LaTeX output can then be further processed in order to generate pretty output files like PDF. The tool can be found in the root directory of GAMS. The tool allows to document one specific model symbol inside of a GAMS program. The resulting documentation contains two parts. The first part shows a list of symbols that are used by the model. The second part shows the actual algebra of the used equations and information about the types of used variables. An optional third part can contain additional notes.

6.32.2 Usage

MODEL2TEX is a command line tool. The general command line usage is as follows:

```
model2tex baseName [-h] [-m MODEL] [-f] [-o OUTPUT]
```

Since it operates on output files generated by GAMS, the first step is to generate the required files using the docfile option. In order to to that, execute the following command line:

```
gams myModel.gms docfile=myModel
```

The second step is to call MODEL2TEX: model2tex is distributed as Python source code (model2tex.py) and is executed via model2tex.cmd on Windows and model2tex.sh on all other platforms.

Windows:

```
model2tex myModel [-m MODEL] [-f] [-o OUTPUT]
```

Linux/macOS:

```
model2tex.sh myModel [-m MODEL] [-f] [-o OUTPUT]
```

The output file myModel.tex can be further processed for example by calling pdflatex in order to generate a PDF file.

```
pdflatex myModel.tex
```

6.32.3 Options

The following parameters can be used when calling MODEL2TEX:

Parameter	Description
-m model	Since MODEL2TEX generates documentation for one model symbol, the model name needs to be specified explicitly, if the GAMS file contains more than one model symbol
-f	MODEL2TEX does not allow the occurrence of suffixes in equations. This option can be used in order to force the creation of the tex file by skipping the checks for suffixes.
-o output	Use this name for the generated TeX file instead of the base name.

6.32.4 Using a JSON style file

MODEL2TEX automatically creates a JSON file that can be modified in order to customize the output. If you want to get the default settings back, just delete the generated JSON file and let MODEL2TEX create it again. The following list shows the available options in the JSON file:

Parameter	Default	Description
fontSize	11	The size of the used font
hrules	true	Horizontal rules are added between equations.
colors	black	Specifies the used colors in equations for variables, parameters, and sets.
landscape	false	Allows to change the page format to landscape.
noPowerFunc	false	Beside a power operator, GAMS offers several power functions. Setting this option to true will replace all power functions with the power operator.
reduceFrac	false	Try to resolve unbalanced fractions. This means that fractions with an unbalanced length of denominator and numerator will be changed in order to shrink the fraction.
reduceFracRatio	5.0	This number has only effect when reduceFrac is set to true. It specifies the ratio between denominator and numerator that is used as a threshold for reduceFrac.
latexDescription	false	Explanatory text for symbols is expected to be arbitrary text. In order to display the text correctly in LaTeX, some automatic adjustments are applied. If all explanatory text already contains valid LaTeX strings, this option can be enabled.
nameMap	the original names	This map allows to specify alternative names for symbols.
extraSymbols	empty list	On default, only the required symbols in a GAMS model symbol are contained in the generated LaTeX file. This list can be used in order to specify further symbols that should be included as well.
notes	empty list	Allows to specify additional notes for the documentation. Each list element will result in a new line.

6.32.5 Example

This example creates a PDF file for the pump model from the GAMS Model Library.

1. Retrieve model pump from GAMS Model Library

   ```
   gamslib pump
   ```

2. Generate required doc files

   ```
   gams pump.gms docfile=pump
   ```

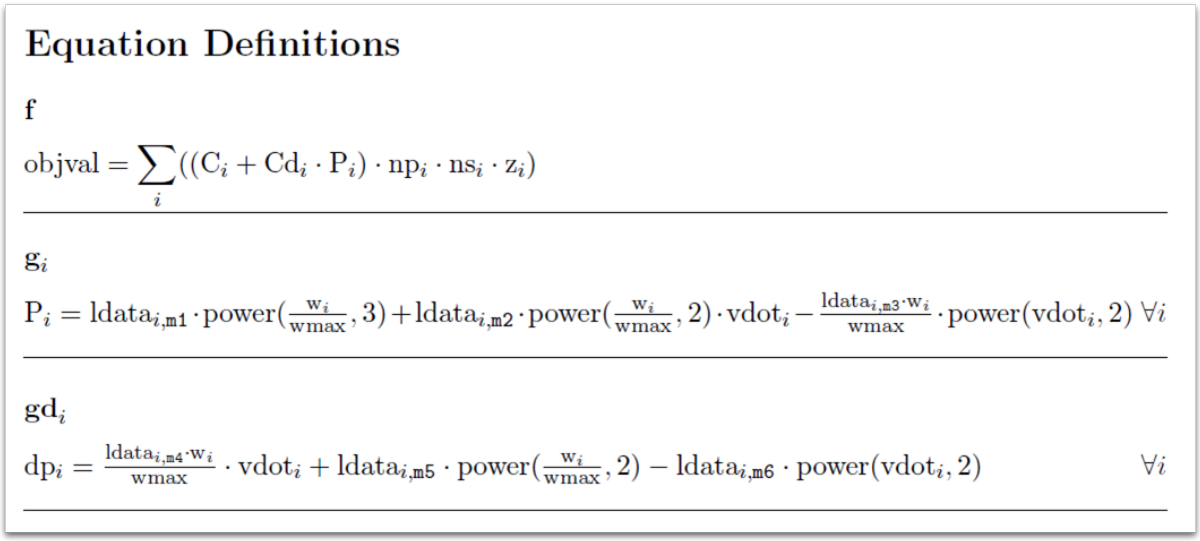
3. Generate the LaTex files

   ```
   model2tex pump -m=pump
   ```

4. Generate PDF documentation

   ```
   pdflatex pump.tex
   ```

The following pictures show snippets from the resulting PDF file:



Equation Definitions

f

$$\text{objval} = \sum_i ((\text{C}_i + \text{Cd}_i \cdot \text{P}_i) \cdot \text{np}_i \cdot \text{ns}_i \cdot \text{z}_i)$$

---

g_i

$$\text{P}_i = \text{ldata}_{i,\texttt{m1}} \cdot \text{power}(\tfrac{\text{w}_i}{\text{wmax}}, 3) + \text{ldata}_{i,\texttt{m2}} \cdot \text{power}(\tfrac{\text{w}_i}{\text{wmax}}, 2) \cdot \text{vdot}_i - \tfrac{\text{ldata}_{i,\texttt{m3}} \cdot \text{w}_i}{\text{wmax}} \cdot \text{power}(\text{vdot}_i, 2) \;\forall i$$

---

gd_i

$$\text{dp}_i = \tfrac{\text{ldata}_{i,\texttt{m4}} \cdot \text{w}_i}{\text{wmax}} \cdot \text{vdot}_i + \text{ldata}_{i,\texttt{m5}} \cdot \text{power}(\tfrac{\text{w}_i}{\text{wmax}}, 2) - \text{ldata}_{i,\texttt{m6}} \cdot \text{power}(\text{vdot}_i, 2) \qquad \forall i$$

---

5. Customizing the JSON style file In order to change the appearance of the PDF file, the generated JSON file `pump.json` can be modified. Changing the options in `pump.json` according to the picture and executing the commands from step 3 and 4 again will result in a customized PDF output.

6.33 MPS2GMS

Translates an MPS or LP file into an equivalent short generic GAMS program using a GDX file to store data. A number of solver specific extensions are recognized.

The MPS file is first attempted to be read in free format (no spaces in names). If it seems that row or column names have spaces but have at most 8 characters, parsing in fixed format is attempted. The MPS and LP readers of the HiGHS solver are utilized. GAMS Data Exchange (GDX) files and matching GAMS source is written.

Notes:

- Row, column, SOS (special ordered sets), and cone names can have up to 63 characters and are tested for case sensitivity and uniqueness because these names become GAMS set members. If the test fails, the tool attempts to modify the names.
- MPS files may contain multiple N rows. The first one will be used as objective function and remaining ones will be ignored.
- If no optimization direction is given in a MPS file, minimization will be assumed.
- Variables in SOS must be continuous.
- SOS must not overlap. A variable cannot appear multiple times in the same SOS.

The MPS and LP formats have been extended in different forms by several solver vendors. Not all extensions are supported by MPS2GMS.

The following MPS sections are recognized by the free format parser:

- NAME
- OBJSENSE, MAX, MIN
- ROWS
- COLUMNS
- RHS
- BOUNDS
- RANGES
- QUADOBJ, QMATRIX
- QSECTION, QCMATRIX
- CSECTION with cone types QUAD and RQUAD
- SETS, SOS
- ENDATA

The fixed format parser also recognizes these sections except for QMATRIX, QSECTION, QCMATRIX, CSECTION, SETS, and SOS.

For a description of the MPS format, see also

- the CPLEX manual,
- the FICO Xpress manual,
- the GUROBI manual,
- the MOSEK manual.

The following LP format features are recognized:

- Comments
- Single objective function: linear or quadratic only
- Constraints (`Subject To` section): linear or quadratic only
- Variable bounds and types (`Bounds`, `Binaries`, `Generals`, `Semis` section); to specify semi-integer variables, they need to appear in sections `Generals` and `Semis`
- Special ordered sets (`SOS` section)

For a description of the LP format, see also

- the CPLEX manual
- the FICO Xpress manual
- the GUROBI manual
- the MOSEK manual

6.33.1 Usage

```
mps2gms mpsfile | lpfile [ gdxfile [ gmsfile ] ] { key=value }
```

If the first parameter is not of the form key=value and ends with `.lp` or `.lp.gz`, it is assumed to be the name of an LP file, otherwise it is assumed to be the name of an MPS file. If no GDX filename is given, the name of the MPS or LP file is used, with `.mps`/`.lp` (or `.mps.gz`/`.lp.gz`) extension replaced by `.gdx`, or `.gdx` appended. If no GMS filename is given, the name of the GDX file is used, with `.gdx` extension replaced by `.gms`, or `.gms` appended.

Guide to parameters:

Key	Description
MPS	Name of MPS input file, can be compressed with GZIP
LP	Name of LP input file, can be compressed with GZIP
GDX	Name of GDX output file
GMS	Name of GAMS program output file
CEQUATIONS	Whether to write quadratic cones from CSECTION sections into deprecated =C= equations. Possible values: 0, N, 1, Y. Default: 0
COLUMNINTVARSAREBINARY	Whether integer variables that appear first in COLUMNS section should be assumed to be binary variables. Possible values: 0, N, 1, Y. Default: 0. Note that modern solvers assume binary variables, but for backward compatibility the default is set to the original IBM interpretation.
DUPLICATES	Whether to check and how to handle multiple coefficients for the same variable or product in LP files. If set to NOCHECK, then no checks for multiple coefficients are done. In this case, writing the GDX file may fail. For performance reasons, this is the default. If set to ADD, then coefficient are added up. If set to IGNORE, then additional coefficients are ignored and a warning is printed to the log. If set to ERROR, then warnings are printed to the log and MPS2GMS terminates with a nonzero return code.

6.34 MSAppAvail

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

Checks if a MS Office Application is available. The return code (errorLevel) signals if the application is available (0) or not (not 0).

6.34.1 Usage

Command line:

```
gamstool [win32.]MSAppAvail Application
```

Compile time:

```
$callTool [win32.]MSAppAvail Application
```

Execution time:

```
executeTool '[win32.]MSAppAvail Application';
```

Argument	Description
Application	MS Office application to check.

6.34.2 Example: Checking whether MS Access is available

This example checks if Microsoft Access is available on the system and quit without error if this is not the case.

```
$callTool win32.msappavail Access
$if errorlevel 1 $abort.noError "No MS Access available"
```

6.35 Ordinary Least Squares (OLS)

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This estimates the unknown parameters in a linear regression model. The set `i` are the observations, the set `p` are the estimates. The matrix `A(i,p)` contains the explanatory variable and `y(i)` the dependent variable. On return the symbol `estimate(p)` will contain the estimated statistical coefficients. Other statistical information parameters are available.

6.35.1 Usage

Command line:

```
gamstool [linalg.]OLS i p A y est [covar=id] [df=id] [fitted=id] [r2=id] [resid=id] [resvar=id] [rss=
```

Compile time:

```
$callTool [linalg.]OLS i p A y est [covar=id] [df=id] [fitted=id] [r2=id] [resid=id] [resvar=id] [rs
```

Execution time:

```
executeTool '[linalg.]OLS i p A y est [covar=id] [df=id] [fitted=id] [r2=id] [resid=id] [resvar=id]
```

Where:

Argument	Description
i	Name of set of observations i(*).
p	Name of set of estimates p(*).
A	Name of two-dimensional explanatory variable matrix A(i,p).
y	Name of one-dimensional dependent variable y(i).
est	Name of one-dimensional estimated statistical coefficients est(p).

The following names parameters are available:

Parameter	Description
covar=id	Statistical info: variance-covariance matrix CoVar(p,p)
df=id	Statistical info: degrees of freedom (scalar)
fitted=id	Statistical info: fitted values for dependent variable fitted(i)
r2=id	Statistical info: R squared (scalar)
resid=id	Statistical info: residuals resid(i)
resvar=id	Statistical info: residual variance (scalar)
rss=id	Statistical info: residual sum of squares (scalar)
se=id	Statistical info: standard errors se(p)
sigma=id	Statistical info: standard error (scalar)
tval=id	Statistical info: standard errors se(p)
gdxIn=fileIn.gdx	Name of GDX file that contains symbols i, p, A, and y. Mandatory if called from the command line, otherwise optional.
gdxOut=fileOut.gdx	Name of GDX file that contains symbol est and statistical information parameters after execution. Mandatory if called from the command line, otherwise optional.

6.35.2 Example

For an example see model [**LeastSquares**] in the GAMS Data Utilities Library.

6.36 GAMS Posix Utilities

Starting with distribution 20.6 the GAMS system for Windows includes a collection of Posix utilities which are usually available for the different Unix systems and therefore help to write platform independent scripts. The following utilities are available:

- awk - Pattern scanning and processing language (1)
- cat - Concatenate and print files
- cksum - Write file checksums and sizes
- cmp - Compare two files

- comm - Select or reject lines common to two files
- cp - Copy files
- cut - Cut out selected fields of each line of a file
- diff - Compare two files
- expr - Evaluate arguments as an expression
- fold - Fold lines
- gsort - Sort, merge, or sequence check text files (1)
- grep - File pattern searcher
- gdate - Write the date and time (1)
- gunzip - File decompression
- gzip - File compression
- head - Copy the first part of files
- join - Relational database operator
- make - Build automation tool
- mkdir - Create a new directory
- mv - Move files
- od - Dump files in various formats
- paste - Merge corresponding or subsequent lines of files
- printf - Write formatted output
- rm - Remove directory entries
- sed - Stream editor
- sleep - Suspend execution for an interval
- tail - Copy the last part of a file
- tar - Collect files into one archive file
- tee - Duplicate standard input
- test - Evaluate expression
- touch - Update access date and/or modification date of a file or directory
- tr - Translate characters
- uniq - Report or filter out repeated lines in a file
- wc - Word, line, and byte count
- xargs - Construct argument list(s) and invoke utility

(1) Please note that the utilities "date" and "sort" have been renamed to "gdate" and "gsort" to avoid conflicts with the Windows commands "date" and "sort". For compatibility reasons the GNU implementation of awk called "gawk" has been renamed to "awk".

The collection consists of native Windows ports of GNU implementation of these utilities taken from the Sourceforge. Detailed descriptions of the utilities can be found at the GNU website.

The Posix tools and in particular the awk utility can be used to transform a variety of different text inputs into GAMS readable input files. Examples can be found in the **GAMS Model Library** (Subject "GAMS Tools").

6.37 Rank

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This sorts one dimensional symbol `sym` and stores sorted indices in one dimensional parameter `symIdx`.

6.37.1 Usage

Command line:

```
gamstool [alg.]Rank sym symIdx gdxIn=fileIn.gdx gdxOut=fileOut.gdx
```

Compile time:

```
$callTool [alg.]Rank sym symIdx [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]
```

Execution time:

```
executeTool '[alg.]Rank sym symIdx [gdxIn=fileIn.gdx] [gdxOut=fileOut.gdx]';
```

Where:

Argument	Description
`sym`	Name of parameter or set to be sorted `sym(*)`
`symIdx`	Name of parameter containing sort indexes `symIdx(*)`

The following named parameters are available:

Parameter	Description
`gdxIn=fileIn.gdx`	Name of GDX file that contains symbol sym. Mandatory if called from the command line, otherwise optional.
`gdxOut=fileOut.gdx`	Name of GDX file that contains symbol symIdx after execution. Mandatory if called from the command line, otherwise optional.

6.37.2 Example

```
set I /i1 * i6/;
```

```
parameter A(I) /i1=+Inf, i2=-Inf, i3=Eps, i4= 10, i5=30, i6=20/;
parameter AIndex(i) 'permutation index';

* sort symbol; result in parameter AIndex
$callTool.checkErrorLevel 'alg.Rank A AIndex';
display AIndex;
```

The complete example is also part of the GAMS Data Utilities Library, see model [**GDXRANKExample18**] for reference. The libInclude rank.gms uses this tool internally.

6.38 SCENRED

6.38.1 Release Notes

- May, 2002: Level 001 (GAMS Distribution 20.6)
  - GAMS/SCENRED introduced.

6.38.2 Introduction

Stochastic programs with recourse employing a discrete distribution of the random parameters become a deterministic programming problem. They can be solved by an appropriate optimization algorithm, ignoring the stochastic nature of (some or all) parameters.

SCENRED is a tool for the reduction of scenarios modeling the random data processes. The scenario reduction algorithms provided by SCENRED determine a scenario subset (of prescribed cardinality or accuracy) and assign optimal probabilities to the preserved scenarios. The reduced problem is then solved by a deterministic optimization algorithm provided by GAMS.

6.38.3 Scenario Reduction Algorithms

Many solution methods for stochastic programs employ discrete approximations of the uncertain data processes by a set of scenarios (i.e., possible outcomes of the uncertain parameters) with corresponding probabilities.

For most practical problems the optimization problem that contains all possible scenarios (the so-called deterministic equivalent program) is too large. Due to computational complexity and to time limitations this program is often approximated by a model involving a (much) smaller number of scenarios.

The reduction algorithms developed in [1,2] determine a subset of the initial scenario set and assign new probabilities to the preserved scenarios. All deleted scenarios have probability zero.

SCENRED contains three reduction algorithms: The Fast Backward method, a mix of Fast Backward/Forward methods and a mix of Fast Backward/Backward methods. In general, the computational performance (accuracy, running time) of the methods differ. For huge scenario trees the Fast Backward method has the best expected performance with respect to running time. The results of the Forward and Backward methods are more accurate, but at the expense of higher computing time. The Forward method is the best algorithm when comparing accuracy, but it can only be recommended if the number of preserved scenarios is small (strong reduction). The combined methods improve the result of the Fast Backward method if the Forward or Backward method, respectively, can be completed within the running

time limit. If no reduction method is selected, the method with the best expected performance with respect to running time is chosen.

The reduction algorithms exploit a certain probability distance of the original and the reduced probability measure. The probability distance trades off scenario probabilities and distances of scenario values. Therefore, deletion will occur if scenarios are close or have small probabilities.

The reduction concept is general and universal. No requirements on the stochastic data processes (e.g. the dependency or correlation structure of the scenarios, the scenario probabilities or the dimension of the process) or on the structure of the scenarios (e.g. tree-structured or not) are imposed. The reduction algorithms can be tailored to the stochastic model if the user provides additional information (How many decision stages are involved? Where do the random parameters enter the model – in objective and/or right hand sides and/or technology matrices?) The information is used to choose the probability distances (cf. Remark 1 in [1]).

6.38.4 Using GAMS/SCENRED

The reduction algorithms require additional data preparation and reformulation of the GAMS program for the stochastic programming model.

GAMS offers great flexibility with respect to the organization of data specification, model definition and solve statements. The most common way to organize GAMS/SCENRED programs is shown below. Since the initial scenarios and a number of input parameters have to be passed to SCENRED, the corresponding components of the GAMS program have to be defined before the SCENRED call. The reduced scenarios have to be defined before the equations of the (reduced) stochastic programming model are used in a solve statement. Therefore the SCENRED call can be placed anywhere between the definitions of the GAMS parameters and the solve statement of the reduced stochastic programming model.

When building or modifying a model for use with GAMS/SCENRED the following steps should be taken:

- Analyse the GAMS program of the stochastic programming model.
  Since the initial scenarios and a number of input parameters have to be passed to SCENRED (see Section The SCENRED Input File), one must identify the corresponding components of the GAMS model and create or calculate them if they do not already exist.
- Reformulate the GAMS program.
  Check if the model can handle varying scenario or node probabilities, and whether the equations are defined in terms of a (possibly reduced) tree. If the model doesn't already contain a scenario tree, one should be added. If it does, it is a simple task to rewrite the equation definitions (and possibly other statements too) in terms of a subset of the original nodes or tree.
- Add the statements for passing the initial set of scenarios to SCENRED, for the execution of SCENRED and for the import of the reduced scenarios from SCENRED.

A reduction of the initial scenarios makes sense only if we are able to generate that part of the model that corresponds to the preserved scenarios (i.e. the reduced subtree). This is done by declaring a subset of the nodes in the original tree. The parameters and equations are declared over the original node set, but are defined over only the subtree. This will be illustrated by an example later in the section.

Further, one should verify that the model can handle changing probabilities. Many practical models involve scenarios with equal probabilities. This property will not be maintained by the probabilities in the reduced subtree.

ORGANIZATION OF GAMS/SCENRED PROGRAMS

Component	Contents
1. DATA	* set & parameter declarations and definitions * $libinclude scenred.gms * assignments displays
2. SCENRED CALL	* export the initial scenarios from GAMS to SCENRED * execute SCENRED * import the reduced scenarios from SCENRED to GAMS
3. MODEL	* variable declaration * equation declarations * equation definitions (using sets from reduced tree) * model definition & solution

Prior to calling SCENRED, you should include the declaration of the SCENRED input and output parameters and the definition of the sets they are indexed by from the GAMS include library:

```
$libinclude scenred.gms
```

Once you have created all the inputs to SCENRED and assigned values to them, you are ready to write the SCENRED GDX data input file, write the SCENRED options file, call SCENRED, and read the reduced tree data from the SCENRED GDX data output file (see Section The SCENRED Input File, Section SCENRED Options and the Option File, and Section The SCENRED Output File). Assuming your model is formulated to use a subtree of the original, you can now continue with the solve and any subsequent reporting.

SCENRED is executed by issuing the statement

```
execute 'scenred optfilename';
```

where `optfilename` is the name of the SCENRED option file.

As an example, consider the `srkandw` model in the GAMS model library, and the `kand` model upon which it is based (get these from the modlib now!). To produce `srkandw` from `kand`, we first reformulate the original to allow for solution over a reduced tree. To do this, we introduce a subset of the node set: `set sn(n) 'nodes in reduced tree';` For convenience and clarity, we introduce a second subset at the same time, the set of leaf nodes: `set leaf(n) 'leaf nodes in original tree';` as well as some code to compute this set based on the existing time-node mapping. We also declare a new parameter, the probabilities for the reduced tree: `parameter sprob(n) 'node probability in reduced tree';` Once these are declared, we can quickly edit the equation *definitions* so that they run only over the reduced subtree: we simply substitute the reduced probabilities `sprob` for the original `prob`, and the reduced node set `sn` for the original node set `n`. Note that the *declaration* of the equations does not change.

This example illustrates one other change that may be required: the stochastic data must be in parameters having the node set as their last index. This is not the case in the `kand` model, so we simply reversed the indices in the `dem` parameter to meet the requirement in `srkandw`. It is also possible to create a transposed copy of the original data and pass that the SCENRED if the original data cannot be changed conveniently.

6.38.5 The SCENRED Input File

The SCENRED input file contains the initial scenarios and their stochastic parameter data, as well as statistics describing this input and (possibly) options to control the SCENRED run. This input file has a special binary format; it is a GDX (GAMS Data Exchange) file. The name of the SCENRED input file is assigned in the option file (see Section SCENRED Options and the Option File).

The scalar inputs to SCENRED are collected in the one-dimensional parameter `ScenRedParms`, the first parameter stored in the SCENRED input file. Some of the elements of `ScenRedParms` are required (e.g. statistics for the input tree) while others are optional (e.g. the run time limit). SCENRED will stop if a required element is missing or out of range.

Table 1 Required `ScenRedParms` elements

Element	Description
num_leaves	the number of initial scenarios or leaves of the scenario tree (i.e., before the reduction)
num_nodes	number of nodes in the initial tree (the number of scenarios if not tree-structured)
num_random	Number of random variables assigned to a scenario or node, i.e., the dimension of the random data process
num_time_steps	Length of a path from the root node to a leaf of the scenario tree, i.e., the number of time steps involved

Table 2 Optional ScenRedParms elements

Element	Description	Default
red_num_leaves	specifies the desired number of preserved scenarios or leaves	none
red_percentage	specifies the desired reduction in terms of the relative distance between the initial and reduced scenario trees (a real between 0.0 and 1.0)	none
num_stages	Set the number of branching levels of the scenario tree, i.e., the number of stages of the model -1. Hence num_stages=1 if no branching occurs, i.e., the values of the scenarios differ for all time steps	1
where_random	An integer indicating where the randomness enters the model. The value is interpreted as a digit map computed using the formula 100∗inObj + 10∗inRHS + inMatrix, where inObj is 1 if the objective contains random parameters and 0 otherwise, inRHS is 1 if the right-hand side contains random parameters and 0 otherwise, and inMatrix is 1 if the constraint matrix contains random coefficients and 0 otherwise.	10 (random right-hand side)
reduction_method	Select a reduction method: 0: automatic (best expected performance with respect to running time) 1: Fast Backward method 2: Mix of Fast Backward/Forward methods 3: Mix of Fast Backward/Backward methods	0
run_time_limit	Defines a limit on the running time in seconds	none
report_level	Control the content of the SCENRED log file: 0: Standard SCENRED log file 1: Additional information about the tree	0

A few comments on the parameters red_percentage and red_num_leaves are in order. At least one of these values must be set. The value of red_percentage will be ignored if the parameter red_num_leaves is non-zero. Otherwise, the tree will not be reduced if red_percentage=0, while the reduction of the tree will be maximal (i.e. only one scenario will be kept) if red_percentage=1. A numeric value of 0.5 means that the reduced tree maintains 50% of the information contained in the original tree. The reduction algorithms are skipped if red_num_leaves=num_leaves or if red_num_leaves=0 and red_percentage=0. These values can be assigned if the user wishes to run the scenario tree diagnostic.

The second data element in the input file is the set of nodes making up the scenario tree. Note that the cardinality of this set is part of ScenRedParms.

The third data element is the ancestor mapping between the nodes. This mapping determines the scenario tree. Note that the mapping can be either an ancestor mapping (i.e. child-parent) or a successor mapping

(parent-child). By default, SCENRED expects an ancestor mapping. If the check for this fails, it looks for a successor mapping.

The fourth data element is the parameter of probabilities for the nodes in the original tree. It is only required that probabilities for the scenarios (i.e. the leaf nodes) be provided, but the parameter can contain probabilities for the non-leaf nodes as well.

The remaining elements in the input data file specify the parameter(s) that comprise the random values assigned to the initial scenarios, or to the nodes of the scenario tree. There can be more than one such parameter, included in any order. The only requirement is that the node set be the final index in each of these parameters.

Table 3 summarizes the content of the SCENRED input file. Please keep in mind that the order of the entries must not be altered!

Table 3 Content of the SCENRED Input File

No.	Symbol	Type	Dimension	Content
1	`ScenRedParms`	Parameter	1	scalar SCENRED input
2	(any name)	Set	1	nodes in the scenario tree
3	(any name)	Set	2	the ancestor set
4	(any name)	Parameter	1	node probabilities; at least for the leaves
≥ 5	(any name)	Parameter	≥ 1	random values assigned to the nodes

To create the SCENRED data input file, the GAMS `execute_unload` statement is used. This statement is used to transfer GAMS data to a GDX file at execution time. As an example, to create a GDX file with the 4 required input parameters and one parameter `demand` containing the stochastic data, you might have the following statement:

```
execute_unload 'sr_input.gdx', ScenRedParms, node, ancestor, prob, demand;
```

6.38.6 SCENRED Options and the Option File

When the SCENRED executable is run, it takes only one argument on the command line: the name of the SCENRED option file. The option file is a plain text file. Typically, it is used to specify at least the names of the SCENRED data input and output files. The option file must be created by the SCENRED user (typically via the GAMS put facility during the GAMS run). The syntax for the SCENRED option file is

`optname value` or `optname = value`

with one option on each line. Comment lines start with an asterix and are ignored.

Some of the SCENRED options may be specified in two places: as elements of the `ScenRedParms` parameter of the SCENRED input file, or as entries in the options file. These parameters have been summarized in Table 2. If an option is set in both these places, the value in the option file takes precedence of over the value from `ScenRedParms`. In addition, the parameters in Table 4 can only be specified in the option file.

Table 4 Options - optfile only

Option	Description	Default
`input_gdx`	Name of the SCENRED data input file	`xllink.gdx`
`output_gdx`	Name of the SCENRED data output file	`scenred.gdx`
`log_file`	Name of the SCENRED log file	`scenred.log`

6.38.7 The SCENRED Output File

The SCENRED output file contains the reduced scenario tree and the `ScenRedReport` parameter. Like the input file, the output file has a special binary format; it is a GDX (GAMS Data Exchange) file.

The first data element in the output file is the `ScenRedReport` parameter containing the scalar outputs and statistics from the SCENRED run. The elements of this parameter are summarized in Table 5. The second data element is the parameter containing the probabilities of the nodes in the reduced scenario tree. These node probabilities are required to construct the reduced tree. The third and final data element is the ancestor map for the reduced scenario tree. This map can be read from the GDX file, or the reduced tree can be built from the original one by using the reduced probabilities. The content of the data output file is summarized in Table 6.

Table 5 `ScenRedReport` elements

Element	Description
`ScenRedWarnings`	number of SCENRED warnings
`ScenRedErrors`	number of SCENRED errors
`run_time`	running time of SCENRED in sec.
`orig_nodes`	number of nodes in the initial scenario tree
`orig_leaves`	number of leaves (scenarios) in the initial scenario tree
`red_nodes`	number of nodes in the reduced scenario tree
`red_leaves`	number of leaves(scenarios) in the reduced tree
`red_percentage`	relative distance of initial and reduced scenario tree
`red_absolute`	absolute distance between initial and reduced scenario tree
`reduction_method`	reduction method used: 0: the program stopped before it could select a method 1: Fast Backward method 2: Mix of Fast Backward/Forward methods 3: Mix of Fast Backward/Backward methods

Table 6 Content of the SCENRED Output File

No.	Symbol	Type	Dimension	Content
1	`ScenRedReport`	Parameter	1	report of the SCENRED run
2	`red_prob`	Parameter	1	node probabilities for the reduced scenarios
3	`red_ancestor`	Set	2	the ancestor map for the reduced scenarios

To read the SCENRED data output file, the GAMS `execute_load` statement is used. This statement is used to transfer GDX data to GAMS at execution time. As an example, to read a GDX file named `sr_output.gdx` created by SCENRED, you might have the following statement:

```
execute_load 'sr_output.gdx', ScenRedReport, sprob=red_prob, sanc=red_ancestor;
```

In the statement above, the equal sign `=` is used to indicate that the data in the GDX parameter `red_prob` should be read into the GAMS parameter `sprob`, and the data in the GDX set `red_ancestor` should be read into the GAMS set `sanc`.

6.38.8 Diagnostic Check of Scenario Trees

When SCENRED reads its input data, it performs a number of checks to verify that the data is correct. The diagnostic checks of the input parameters include:

- consistency of the desired input parameters with the contents of the SCENRED input file (number of nodes, number of leaves, number of time steps, number of random values assigned to a node)
- range check of desired input parameters and options
- check of scenario and node probabilities
- check of the ancestor matrix (check the orientation of the graph, check if the graph contains a cycle, check if the graph contains incomplete forests or scenarios, check the consistency of the parameter `num_time_steps` with the ancestor matrix)

The following errors in the specification of the scenario tree cause SCENRED to skip the reduction algorithms:

- The input files cannot be opened.
- Not all required input parameters are given.
- The required input parameters are not consistent with the contents of the SCENRED input file.
- The required input parameters are out of range.
- Missing or negative scenario probabilities (probabilities of leaves).
- The ancestor set contains too many entries (more than `2*num_nodes`).
- SCENRED detects a cycle in the ancestor set.
- SCENRED detects incomplete scenarios in the ancestor set.
- Run time limit reached

6.38.9 SCENRED Errors and Error Numbers

When SCENRED encounters a serious error in the input files or in the scenario tree, it sends an error message to the screen and to the log file. These messages always start with

```
**** SCENRED run-time error ...
```

The number of SCENRED errors are contained in the parameter `ScenRedReport` of the SCENRED output file (if it could be created). The occurrence of an error can also be detected from the last line that SCENRED sends to the screen:

```
**** SCENRED ErrCode=...
```

The numerical values of `ErrCode` and their meaning are given below.

ErrCode	Meaning
1	(for internal use)
2	fatal error while reading from SCENRED input file
3	fatal error while writing to SCENRED output file
4	fatal error while reading from SCENRED option file

ErrCode	Meaning
5	log file cannot be opened
6	a memory allocation error occurred
7	there are missing input parameters
8	could not access the GAMS names for the nodes
9	(for internal use)
10	ancestor set not given or contains too many entries
11	node probabilities cannot be not read or are wrong
12	random values for the nodes cannot be read
13	input parameters are out of range
14	ancestor set contains a cycle
15	incomplete scenarios or forests detected
16	fatal error in reduction algorithm (not enough memory)
17	running time limit reached

6.38.10 SCENRED Warnings

SCENRED warnings are caused by misspecification of the initial scenarios that can be possibly fixed. When SCENRED encounters such an error in the input files or in the scenario tree, it sends a message to the screen and to the log file. These messages always start with

```
**** SCENRED Warning ...
```

The following list gives an overview of the cases that produce warnings, and the action taken by SCENRED in these cases.

- The user assigned an option value that is out of range.
  Action: Assign the default value.

- Both parameters `red_num_leaves` and `red_percentage` are assigned nontrivial values.
  Action: The value of `red_percentage` will be ignored.

- The scenario probabilities (probabilities of leaves) do not sum up to 1.
  Action: The scenario probabilities are rescaled. Assign new probabilities to the remaining (inner) nodes that are consistent with the scenario probabilities.

- Missing probabilities of inner nodes.
  Action: Assign node probabilities that are consistent with the scenario probabilities.

- The ancestor set contains more than one ancestor for a node.
  Action: SCENRED assumes to be given a successor set instead of an ancestor set (i.e., the transpose of an ancestor matrix. This means that the graph corresponding to the ancestor set has the wrong orientation). SCENRED starts the tree diagnostic for the successor set. The reduced tree will be defined in terms of a successor set as well (if the successor set passes the tree diagnostic and if SCENRED locates no fatal error during the run).

- The fast backward method delivered a result, but the result cannot be improved by the forward or backward method (running time limit reached).
  Action: Use the result of the fast backward method.

6.39 SCENRED2

6.39.1 Introduction

Scenred2 is a fundamental update of the well-known scenario reduction software Scenred. A lot of new features come along with the latest release version. Beside updates and extensions concerning the control of the scenario reduction action an all new device for scenario tree construction has been implemented in Scenred2. Moreover, a lot of visualization functions to plot scenario trees and scenario processes linked to the free Gnuplot plotting software are available with Scenred2 now.

Table: Summary of basic new functions in Scenred2

Description	Section
Additional options for controlling the scenario reduction	Scenario Reduction
New device of scenario tree construction	Scenario Tree Construction
Visualization of scenario trees and processes	Visualization
Command line interface and data export	Command Line Interface

6.39.2 Using Gams/Scenred2

Successful applying Scenred or Scenred2 requires a special formulation of the stochastic programming model within the Gams program. Probabilistic information must be given by a set of nodes implying a certain ancestor structure including a well-defined root node. Note that the usage of Gams/Scenred2 is basically the same as the usage of Gams/Scenred. Hence, it is recommended for new users to look at the Scenred documentation first. All details about how to organize your Gams program, how to run Scenred from the Gams program by using the gdx interface, and, of course, examples can be found in that documentation.

The Gams/Scenred2 link provides the same gdx interface. But, due to new features some small changes in controlling the options are needed. Scenred2 supports now two types of option files. The first one is the SR-Command-File which must be passed to Scenred2 together with the Scenred2 call. The second one, the SR-Option-File includes more specific options to control the selected scenario reduction or scenario construction methods and can be declared in the SR-Command-File.

6.39.2.1 SR-Command-File

The command file includes the basic specifications. These are input/output gdx file names, the log file name, all other file names which are needed for diverse visualization and output options. It also includes the name of the SR-Option-File.

Option	Description	Required
`log_file`	specify a log file name	yes
`input_gdx`	specify the gdx input file for Scenred	yes
`output_gdx`	specify the gdx output file of Scenred	yes
`sr_option`	specify a SR-Option-File	no
`visual_init`	specify a name for visualization of input tree	no
`visual_red`	specify a name for visualization of reduced/constructed tree	no
`plot_scen`	specify a name for visualization of scenario processes	no
`out_scen`	specify a file for scenario data output in fan format	no
`out_tree`	specify a file for scenario data output in tree format	no

Example:

Scenred2 must be called together with a command file, which contains at least all required options. The data exchange via the gdx interface and the Scenred2 call from the Gams program is of the form (be careful with the meanings and right order of gdx symbols):

```
execute_unload 'srin.gdx', ScenRedParms, n, ancestor, prob, random;
execute 'scenred2 scenred.cmd';
execute_load 'srout.gdx', ScenRedReport, ancestor=red_ancestor, prob=red_prob;
```

For example, the command file could be the following (note the compatible gdx file names):

```
* scenred command file 'scenred.cmd'

log_file    sr.log
input_gdx   srin.gdx
output_gdx  srout.gdx
sr_option   scenred.opt
visual_red  tree
out_scen    raw.dat
```

6.39.2.2 ScenRedParms

With the symbol list of the parameter ScenRedParms and the SR-Option-File all necessary information regarding the Scenred2 run can be assigned. The Gams parameter ScenRedParms can easily included to the Gams program by the statement:

```
$libInclude scenred2
```

Of course, the include must be stated before calling Scenred2. After that statement all supported parameters can be assigned, but at least all required parameters regarding the input scenarios. By the symbols of the parameter ScenRedParms you make also the decision of what features you exactly want to use with Scenred2. Moreover, some other usefull parameters for the Scenred2 run are included in the symbol list of the parameter ScenRedParms.

Table: Supported Scenred2 parameters in ScenRedParms

Symbol	Description	Required
num_time_steps	path length from root to leaf	yes
num_leaves	leaves/scenarios in the initial tree	yes
num_nodes	nodes in the initial tree	yes
num_random	random variables assigned to a scenario or node	yes
red_num_leaves	desired number of preserved scenarios or leaves	no
red_percentage	desired relative distance (accuracy)	no
reduction_method	desired reduction method	no
construction_method	desired tree construction method	no
num_stages	number stages	no
run_time_limit	time limit in seconds	no
report_level	report level: more messages by higher values	no
scen_red	scenario reduction command	no
tree_con	tree construction command	no
visual_init	visualization initial tree	no
visual_red	visualization reduced (constructed) tree	no
plot_scen	visualization scenario processes	no
out_scen	output of scenario raw data	no

To enable some options assign a value to the parameter. A parameter value of zero (default) disables an option. Note that when running Scenred2 either scenario reduction or scenario tree construction can be performed. Hence, only `scen_red` or `tree_con` should be used at once.

Example:

The following statements describe a possible example setup for proceeding the scenario tree construction with visualization of the scenario tree and output of the scenarios to a raw data file afterwards. Note that for the visualization and the scenario output the name of output files must be specified in the SR-Command-File. Otherwise a warning will inform you about not selected file names.

```
* general parameters
ScenRedParms('num_leaves') = 100;
ScenRedParms('num_nodes') = 200;
ScenRedParms('num_time_steps') = 5;
ScenRedParms('num_random') = 2;
ScenRedParms('report_level') = 2;
ScenRedParms('run_time_limit') = 30;

* execution commands
ScenRedParms('tree_con') = 1;
ScenRedParms('visual_red') = 1;
ScenRedParms('out_scen') = 1;
```

Scenred2 can also be used for plotting tasks only. Disable both the `scen_red` and `tree_con` option and use one ore more visualization options only (see also Section Visualization for more details regarding visualizations).

6.39.2.3 SR-Option-File

The SR-Option-File is the more specific option file and will be passed to Scenred2 by the`sr_option` statement specified in the SR-Command-File. It serves as control unit for available methods provided by Scenred2. The supported options depend on what kind of method is called with Scenred2. A detailed list of all options together with examples are given below for both the scenario reduction and the scenario construction devices (see Sections Scenario Reduction and Scenario Tree Construction, respectively). Note that certain parameters can be assigned by using both ScenRedParms and the SR-Option-File. In case of having parameters defined twice a warning by Scenred2 will generated to inform you.

6.39.3 Scenario Reduction

The scenario reduction device consists of approved methods for reducing the model size by reducing the number of scenarios in an optimal way. Here it doesn't make any difference whether the input data is structured as scenario tree or not. But note, the classical scenario reduction approach is actually developed for two-stage models. Extensions for the multistage case are planed in the near future. To learn more about the mathematical theory see, for example,

- H. Heitsch, W. Römisch, and C. Strugarek. Stability of multistage stochastic programs. SIAM Journal on Optimization, 17, 2006.
- H. Heitsch and W. Römisch. A note on scenario reduction for two-stage stochastic programs. Operations Research Letters, 35:731-738, 2007.
- H. Heitsch and W. Römisch. Scenario tree reduction for multistage stochastic programs. Computational Management Science, 6:117-133, 2009.

With Scenred2 the most popular and accurate reduction algorithms of forward and backward type are maintained further on. New options make it possible to proceed with the scenario reduction more individual. The most important new parameter is given by the option `metric_type` which allows to control the reduction process by different type of probability distances. Altogether three distances can be selected (see Table below). All probability distances are associated with a special order specification which can be set by the new option `order`. Both options replace the old option `where_random` which is not used any longer.

Table: SR Options - Scenario Reduction

Option	Description
`red_num_leaves`	desired number of scenarios (integer)
`red_percentage`	relative accuracy (number from 0.0 to 1.0)
`reduction_method`	1 - Forward, 2 - Backward, 0 - Default
`metric_type`	1 - Transport (default), 2 - Fortet-Mourier, 3 - Wasserstein
`p_norm`	choice of norm (example: 0 - max, 1 - sum, 2 - Euclidian)
`scaling`	0 - scaling off, 1 - scaling on (default)
`order`	metric order (integer, default is 1)

Example:

For example, a valid SR-Option-File is the following:

```
* scenred option file

reduction_method  1
red_percentage    0.3
metric_type       2
order             2
p_norm            1
scaling           0
```

Lines starting with the star symbol (route symbol can be used too) provide comment lines. The star symbol can also be used to out comment and disable certain options.

6.39.4 Scenario Tree Construction

Scenario tree construction is the outstanding all new device of Scenred2. It allows to construct scenario trees as accurate input for multistage stochastic programs (cf. H. Heitsch and W. Römisch, Scenario tree modeling for multistage stochastic programs, Mathematical Programming, 118:371–406, 2009). The input are individual scenarios in form of a fan which must be allocated before calling Scenred2. A lot of options are offered to control the tree construction process. Note that in some cases due to sensibility of certain parameters some tuning is indispensable for producing good results.

Table: SR Options (basic) - Scenario Tree Construction

Option	Description
`construction_method`	1 - forward, 2 - backward
`reduction_method`	1 - forward, 2 - backward, used within the iteration
`first_branch`	time period of first branch (integer)
`red_percentage`	relative accuracy (level from 0.0 to 1.0)
`eps_growth`	1 - linear, 2 - exponential
`eps_evolution`	tree structure parameter (from 0.0 to 1.0)
`scaling`	0 - scaling off, 1 - scaling on (default)
`order`	order of metric

The Table above displays the main options to control the tree construction process. They are very similar to the reduction options. The role of the option `red_percentage` is here to prescribe a total epsilon accuracy (level) for the approximation scheme. But the approximation scheme is based on stagewise approximations which requires a splitting of the total level to the stages. Two strategies are offered by Scenred2 a linear and an exponential mapping of the total level to the intermediate levels. Use option `eps_growth` to select one of them. Both strategies allow a second tuning parameter `eps_evolution` which effects the slope of the epsilon splitting.

Even though this kind of control may generate good results for many applications, sometimes a more individual control can be needed. For example, some applications require a localization of branching stages. Moreover, to setup approximation bounds directly to stages can be very useful. To this end the standard options are extended by a new section environment.

6.39.4.1 Additional options - The section environment

An alternative control for the accurate constructions is provided by using the section environment. The section environment aims to establish a better monitoring of the construction process. There are overall three section types supported by Scenred2 with the same syntax.

Branching control:

This section environment allows to specify branching points, i.e., an explicit selection of stages serving for branching. For example, use

```
section branching
  2
  4
  6
end
```

to allow branching only at time period 2, 4, and 6. Note that each stage statement must be placed in one line. But stages can be merged. A shorter formulation of the same contents can be written in closed form

```
section branching
  2*6  2
end
```

This statement reads branching within time periods from period 2 to period 6 with increment 2 steps. Both assignments can be combined and should be used together with the `red_percentage` option.

Epsilon control:

In the similar way by the epsilon section it is possible to assign epsilon tolerances for the stage approximations explicitly. This environment overcomes difficulties at times coming across with the automatic epsilon control. Note that this environment disables the option `red_percentage`. For example, use

```
section epsilon
  2    0.04
  3*4  0.03
  5    0.02
  6    0.01
end
```

to control the approximation scheme by assigning different epsilon values per stage. Note that the value 0.03 is assigned to time period 3 and 4 in the example.

Node control:

The node control is the most specific control you have over the tree construction. With this environment the number of nodes of the tree which will generated can be assigned for each time stage explicitly. For example, use

```
section num_nodes
  1    1
  2*3  5
  4*5  10
  6    15
end
```

The syntax is the same as before. Note that only one section environment can be use at once. In particular, only the first section environment detected in the option file is used. The section environment can be out commented like a standard option too.

Experimental option:

There is one other useful option to speed up computations when building different scenario trees from exactly the same input data. In this case the scenario distances needed to compute the trees could be saved to a external file at the first run and reloaded at later runs. Hence, the distances must be calculated only once. For example, use the option

```
write_distance  dist.sr2
```

to save the computed distances to the file 'dist.sr2'. To reload them at next run use the option

```
read_distance  dist.sr2
```

The option is classified as experimental since no validation of the input file takes place. Before using this option, please ensure that the distances loaded with the `read_distance` option are the right ones.

Example:

Finally, look at the following example to see a valid SR-Option-File which can be passed to the scenario tree construction:

```
* tree construction option file

construction_method  2
reduction_method     1
order                1
scaling              0

section epsilon
  2*4    0.1
  5      0.2
  6      0.1
end
```

6.39.4.2 Example problems 'srtree.gms' and 'srpchase.gms'

Small example problems has been included to the GAMS Model Library.

The implementation can be found in the Gams programs 'srtree.gms' and 'srpchase.gms'. It might help you to practice in building scenario trees using Gams/Scenred2. The problem 'srtree.gms' converts a fan format scenario representation into a tree format representation and then reduces the tree size. The problem 'srpchase.gms' is to solve a simple stochastic purchase problem involving three stages. Sample scenarios which are generated from a fixed distribution using a random value generator serve as input for the tree construction.

6.39.5 Visualization

Visualization is another all new feature of Scenred2. In this section an easy way for making plots of scenario processes and tree structures is described. To this end you need the free Gnuplot software or any other plotting software which allows plotting directly from simple data files.

The concept of plotting tasks is the following. For each plot two files are generated, a Gnuplot access file (name.plt) and a raw data file (name.dat). The access file contains basic Gnuplot options and it can be adjusted for individual liking afterwards. The default output is the display. The supported plotting commands are

```
visual_init, visual_red, plot_scen
```

for plotting the initial tree structure, the reduced/constructed tree structure, and the scenario process(es), respectively.

Example:

For example, to visualize the constructed tree use the option

```
visual_red tree
```

within the SR-Command-File to specify the name for the output and activate the ScenRedParms parameter

```
ScenRedParms('visual_red') = 1;
```

in the Gams program. The result are the output files 'tree.plt' and 'tree.dat'. To compute the picture now you simply open the file 'tree.plt' with Gnuplot from the directory, where both output files are located (that should be the working directory). Alternatively, from the command line prompt call

```
>gnuplot tree.plt
```

Gnuplot will automatically generate the picture. Feel free to change any option in the Gnuplot access file for individual requirements. See also the Gnuplot manual for more details. In particular, to compute a well-scaled encapsulated postscript picture (eps), you simply have to uncomment a few lines in the Gnuplot option file above and to open it with Gnuplot once again.

With the command `plot_scen` the scenario process(es) can be visualized. Note that Scenred2 generates Gnuplot access and data files according to the number of random values.

6.39.6 Command Line Interface

The command line interface allows to run Scenred2 stand alone without using Gams. In this case the input for scenario reduction and scenario tree construction is handled by special input data files. The command file will be extended by the parameters having with the ScenRedParms otherwise.

To execute Scenred2 from the command line prompt together with a specified command file (which is required again), for example, call

```
>scenred2 command.file -nogams
```

To avoid diverse error messages do not forget the '-nogams' option to switch off the Gams interface. The command file can include some of the following options.

```
report_level  <integer>
runtime_limit <integer>
read_scen     <input file>
scen_red      <option file>
tree_con      <option file>
visual_init   <name>
visual_red    <name>
plot_scen     <name>
out_scen      <file name>
out_tree      <file name>
```

The denotation is not accidental the same as in case of using the Gams interface. The meaning of a certain option is maintained for the command line interface. To compute any scenario reduction or scenario tree construction the same SR-Option-Files are supported. It remains to clarify the data input format which comes across with the new `read_scen` command.

6.39.6.1 Data input format

To feed Scenred2 with data the scenario parameters must be passed by the `read_scen` command. Two types of input file formats are accepted.

a) The tree format:

This file is a formated data file including all information of the input scenarios tree. It must have a header with dimension information and the scenario data separated for each node. The header includes the type declaration, the number of nodes, and the number of random values.

The data part starts with the key word `DATA` (do not forget). The tree data has to be ordered node by node. For every node the following information is expected separated by white spaces: The unique predecessor node (root node points to itself) followed by the node probability and followed by the assigned number of random data values. All information to one node should be written to one line (only for clearness reasons). Comment lines are allowed.

Match the following conventions:

- Nodes are identified by a sequence of integer numbers.
- The root node is expected to be the node '1'.
- The predecessor of root is '1' too, i.e., the root points to itself.

- All nodes numbers require a canonical order by stages and scenarios (see example).

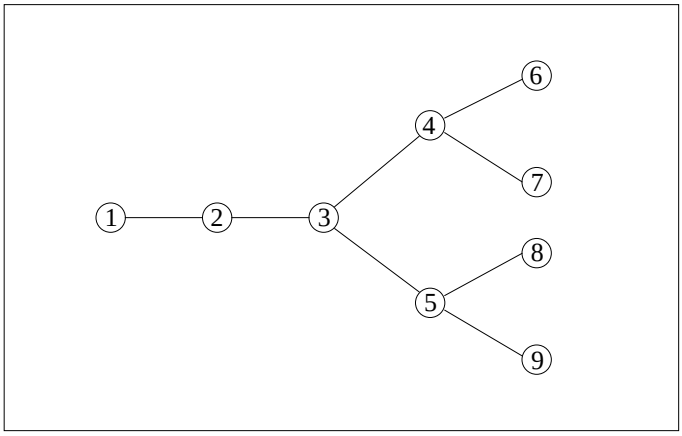
Example:

```
# input tree example for scenred

TYPE TREE

NODES   9
RANDOM  4

DATA
* PRED PROB  RAND-1 RAND-2 RAND-3 RAND-4
   1    1.0    42.5    9.1    7.5  120.0
   1    1.0    39.8   11.2    8.4   90.0
   2    1.0    37.6   14.0    6.3  110.0
   3    0.5    38.9   12.4    8.1  130.0
   3    0.5    35.7   13.8    7.5  120.0
   4   0.25    40.3   14.9    7.2  120.0
   4   0.25    38.4   15.2    8.9  100.0
   5    0.3    37.6   14.9    9.3   80.0
   5    0.2    36.3   12.8   10.3   90.0
END
```



b) The fan format:

A scenario fan serves as input for the scenario tree construction but it can be used also for the scenario reduction. The scenario fan represents a special form of a scenario tree, where we consider individual scenarios merged to a collective root node (the root node can also be viewed here as some kind of artificial node).

Accordingly, the fan input file is a formated data file including all information of the scenarios in individual form now. It must have a similar header with dimension information and the scenario data separated now for each scenario. The header gets the type declaration `FAN` instead of `TREE` and includes the number of scenarios, the number of time periods, and the number of random values. The data part is opened again with the `DATA` key word.

Every scenario is specified by a dataset including the scenario probability first followed by the different random values in ascending order w.r.t. time periods. All entries must be separated by a white space. Comment lines can be placed by the star and route symbols again. Note that in case of having an undetermined root node the mean of random values will taken for the first time period to appoint a unique root node. The example tree represented as input in scenario fan format is displayed in the next example.

Example:

```
# input fan example for scenred

TYPE  FAN

TIME    5
SCEN    4
RANDOM  4

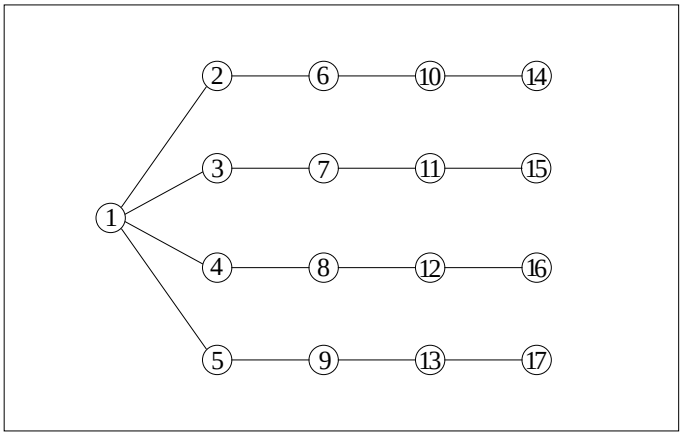
DATA
0.2500
42.5      9.1      7.5     120.0
39.8     11.2      8.4      90.0
37.6     14.0      6.3     110.0
38.9     12.4      8.1     130.0
40.3     14.9      7.2     120.0

0.2500
42.5      9.1      7.5     120.0
39.8     11.2      8.4      90.0
37.6     14.0      6.3     110.0
38.9     12.4      8.1     130.0
38.4     15.2      8.9     100.0

0.3000
42.5      9.1      7.5     120.0
39.8     11.2      8.4      90.0
37.6     14.0      6.3     110.0
35.7     13.8      7.5     120.0
37.6     14.9      9.3      80.0

0.2000
42.5      9.1      7.5     120.0
39.8     11.2      8.4      90.0
37.6     14.0      6.3     110.0
35.7     13.8      7.5     120.0
36.3     12.8     10.3      90.0
END
```

Note that even though all scenarios coincide at the first three time periods, in this example, the scenarios will represented by one node each for every time period by the fan input format. The exception is the first time period, where a unique root node is expected in general and, therefore, only one node is assigned. The following picture shows the structure of the scenario fan which is generated by the example input.



6.39.6.2 Data Export

Scenred2 allows to export scenario data after computing the scenario reduction or scenario tree construction to external data files. Data export is available for both the Gams and the command line interface. To export data from Scenred2 two output options `out_tree` and `out_scen` can be use. These options generate data files according to the tree and fan format, respectively. The name of the data files will be specified in the SR-Command-File. When using the Gams interface the options must be connected by activating the corresponding ScenRedParms parameter, additionally.

6.39.7 A Simplified Interface to Scenred2: $libinclude runscenred2

While the previously described interface between GAMS and Scenred2 provides a maximum of flexibility, it also is rather complex and error-prone. The GAMS utility `runscenred2` tries to hide most of the mechanics of the GAMS/Scenred2 interface. The call to `runscenred2` looks as follows:

```
$libInclude runscenred2 myprefix tree_con n tree p rtree rp rv1 rv2
```

Table: runscenred2 Arguments:

	Argument	Description
1	`myprefix`	base name for files used with Scenred2
2	`tree_con` or `scen_red`	select Scenred2 action: tree construction or scenario reduction
3	`n`	the set of nodes in the tree
4	`tree`	the set of ancestor relations describing the tree
5	`p`	the parameter containing the node probabilities
6	`rtree`	the set of ancestor relations of the reduced tree (output)
7	`rp`	the parameter containing the node probabilities for the reduced tree (output)
8	`rv1`, `rv2`, ...	parameters containing random values of the nodes

The table above describes the arguments of the `runscenred2` call. Arguments 3, 4, 5, 8 and following correspond to the symbols that need to be exported to the Scenred2 data input file (done with the `execute_unload` call in the complex interface). The output arguments 6 and 7 correspond to the symbols imported from te Scenred2 data output file (done with the `execute_load` call in the complex interface). The parameters `ScenRedParms` and `ScenRedReport` are invisibly communicated with Scenred2.

The second argument instructs Scenred2 either to construct a tree (`tree_con`) or to reduce a tree (`scen_red`).

Instead of providing an explicit name for all the different files in the Scenred2 command file, the first argument determines the name of all files using a simple naming scheme. The following name scheme is observed:

Filename	Command option	Description
`sr2`*myprefix*`.log`	`log_file`	log file name
`sr2`*myprefix*`_in.gdx`	`input_gdx`	gdx input file name
`sr2`*myprefix*`_out.gdx`	`output_gdx`	gdx output file name
`sr2`*myprefix*`.opt`	`sr_option`	option file name
`sr2`*myprefix*`_vi.plt`	`visual_init`	file name for visualization of input tree

Filename	Command option	Description
sr2*myprefix*_vr.plt	visual_red	file name for visualization of reduced/constructed tree
sr2*myprefix*_plot.plt	plot_scen	file name for visualization of scenario process
sr2*myprefix*_raw.dat	out_scen	file name for scenario data output in fan format
sr2*myprefix*_tree.dat	out_tree	file name for scenario data output in tree format

The first three files (log_file, input_gdx and output_gdx) are always used. The only optional input file sr_option is read by Scenred2 if ScenRedParms('sroption')=1. When you create this file, make sure to use the proper file name. The output files are created by Scenred2 if the corresponding option is set to 1 in ScenRedParms, e.g. ScenRedParms('out_tree')=1.

In addition to a simpler communication of data between GAMS and Scenred2, the newer versions of GAMS/Scenred2 (starting with GAMS distribution 23.1) release the user of setting required fields in the ScenRedParms parameter: num_time_steps, num_leaves, num_nodes, and num_random. GAMS/Scenred2 calculates these numbers from its input data. In case the user still sets these fields, Scenred2 will ensure that the internally calculated numbers and the user provided numbers match.

6.40 ShellExecute

Note

This tool is part of the GAMS Tools Library. Please inspect the general information about GAMS Tools.

This allows you to spawn an external program based on the file type of the document to open.

6.40.1 Usage

Command line:

```
gamstool [win32.]ShellExecute filename [arguments] [dir=workdir] [verb=open|edit|find|print|...] [sh
```

Compile time:

```
$callTool [win32.]ShellExecute filename [arguments] [dir=workdir] [verb=open|edit|find|print|...] [s
```

Execution time:

```
executeTool '[win32.]ShellExecute filename [arguments] [dir=workdir] [verb=open|edit|find|print|...]
```

Where

Argument	Description
filename	Name of the file to open.
arguments	Additional arguments, if needed.

Argument	Description
dir=workdir	This specifies the directory where the file to be opened is located. Default: current directory.
verb=open or ...	This specifies the action to be performed (default open). The allowed actions are application dependent. Some commonly available verbs include: • edit: Launches an editor and opens the document for editing. • find: Initiates a search starting from the specified directory. • open: Launches an application. If this file is not an executable file, its associated application is launched. • print: Prints the document file. • properties: Displays the object's properties.
-showcmd	The optional argument showcmd specifies how an application is to be displayed when it is opened. The map between numerical values 0 to 11 and symbolic names can be found here: https://docs.microsoft.com/en-us/windows/win32/api/winuser/nf-winuser-showwi

6.40.2 Example: Opening MS Access database

This example uses the [**trnsport**] model from the model library. After solving the model, a couple of symbols is exported to a Microsoft Access database using GAMS Connect. MS Access is then launched to inspect the results. This is a small example that should run very quickly.

```
$call.checkErrorLevel gamslib -q trnsport
$call.checkErrorLevel gams trnsport gdx=trnsport.gdx
$onEmbeddedCode Connect:
- GDXReader:
    file: trnsport.gdx
    readAll: True
- SQLWriter:
    connection: {'DRIVER':'Microsoft Access Driver (*.mdb, *.accdb)', 'DBQ': '%system.fp%trnsport.ac
    connectionType: access
    symbols:
      - name: a
        tableName: capacity
        ifExists: replace
      - name: b
        tableName: demand
        ifExists: replace
      - name: d
```

```
        tableName: distance
        ifExists: replace
$offEmbeddedCode
$callTool win32.ShellExecute trnsport.accdb
```

The command `$callTool win32.ShellExecute trnsport.accdb` will launch Access to view the ACCDB file.

6.41 SQL2GMS

Author

Erwin Kalvelagen

Attention

`SQL2GMS` is deprecated (see GAMS 40 SQL2GMS release notes). Please use Connect agent SQLReader instead.

6.41.1 Overview

`SQL2GMS` is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File (.inc) or a GAMS GDX File (.gdx).

When running the executable sql2gms.exe without command line arguments, the tool will run interactively with a built-in GUI interface. Alternatively `SQL2GMS` can be run in batch mode, which is useful when running it directly from a GAMS model without user intervention using the `$call` command at compile time or the `execute` command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL's should not be allowed to get into a GAMS data structure. The handling of NULL's can be specified in an option.

Besides parameters it is also possible to generate set data.

If you need to read data from an MS Access database or MS Excel spreadsheet, the accompanying tools MDB2GMS or XLS2GMS resp. GDXXRW may be more appropriate. In some cases it may be more useful to use `SQL2GMS` to read from Access and Excel data sources.

6.41.2 Requirements

SQL2GMS runs only on Windows PC's with [MDAC] (https://en.wikipedia.org/wiki/Microsoft_Data_Access_Compon
(Microsoft Data Objects) installed. In many cases this will be installed on your computer. Otherwise it can
be downloaded from the [Microsoft Download Center] (https://www.microsoft.com/en-in/download/details.aspx?i
(direct link to MDAC).

In order to use SQL2GMS effectively, you will need to have a working knowledge of [SQL] (https://en.wikipedia.org/wiki/SQL) in order to formulate proper database queries. In addition you will need some knowledge on how to connect to your database using ODBC or ADO.

6.41.3 Batch Usage

SQL2GMS can be run in batch mode without user intervention from within the GAMS model by using the $call resp. execute statements or directly from command prompt while specifying all arguments in the command-line. A SQL2GMS batch call is of the following form:

```
sql2gms connectionString outputFile queryString
```

A proper call will at least contain the following three command-line arguments:

1. The name of the database and the instruction for connecting to the database must be specified within the connectionString, which is indicated by the option C. i.e. C=connectionString.
2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option O, i.e. O=outputFile.inc, while the use of a GDX file is indicated by the option X, i.e. X=outputFile.gdx.
3. The SQL queryString, containing the SQL statement to be executed on the database, must be specified within the option Q, i.e. Q=queryString.

See also Command-line Arguments below for a complete list of all possible command-line arguments. Consider that the $call or execute usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the interactive built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a @ (At sign).

Also consider to take a look at the section Strategies, mentioning some of the drawbacks of the batch usage and how to overcome them.

6.41.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using SQL2GMS directly from the GAMS model or command prompt.

Argument	Interpretation	Default	Description
C	connectionString	none	Specify the connectionString (required).
O	outputIncludeFile	none	Specify the name of the output file (.inc). Either `O=` or `X=` must be specified (or both).
On	nth outputIncludeFile	none	Match the nth query with the nth output file (.inc format) if multiple queries are used.
X	outputGDXFile	none	Specify the name of the output file (.gdx). Either `O=` or `X=` must be specified (or both).
Q	Query	none	This option can be used to specify a SQL query (required).
Qn	nth query	none	Match the nth query with the nth output file (.inc) format or with the nth set- or parameter name when writing to GDX if multiple queries are used.
S	setName	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.
Sn	nth setName	none	Match the nth query with the nth set in the GDX file if multiple queries are used.
Y	setName (with expl. text)	none	If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. Use this argument to store a set with explanatory text.
Yn	nth setName (with expl. text)	none	Match the nth query with the nth set (with explanatory text) in the GDX file if multiple queries are used.
A	parameterName	none	If we write to a GDX file, use this option to specify the name of a parameter to be used inside the GDX file.
An	nth parameterName	none	Match the nth query with the nth parameter in the GDX file if multiple queries are used.
L	Listing	disabled	Controls if the data is embedded in the listing file.
M	Mute	disabled	Controls if additional information is written to the log and include file.
B	Quote Blanks	disabled	Quote strings if they contain blanks or embedded quotes.
@fileName	ext. options file	none	Causes the program to read options from an external text file.
N	iniFileName	sql2gms.ini	Indicates the usage of a different INI file.
T1	connectionTimeOut	15	Indicates how long to wait while establishing a connection before terminating the attempt and generating an error.
T2	commandTimeOut	30	Indicates how long to wait while executing a command before terminating the attempt and generating an error.
T	timeOut	none	Sets both `T1` and `T2`.
D	Debug	disabled	Generate debug information.

Argument	Interpretation	Default	Description
E	Empty sets	disabled	Allow an empty result set; without this option an empty result set will generate an error.
R	rowBatchSize	100	Row batch size; the default is 100 records.
P	Password	none	Specify a password for the database.
W	Wiring	none	Maps database columns to GAMS index positions.

Some more detailed remarks on the command-line arguments:

C = *string* (connectionString, default = none)

This option is required and specifies which database is to be used and how `SQl2GMS` talks to the database. A collection of valid connection strings can be found in section Connection Strings. Often the connection string will need to be surrounded by quotes, as in: `C="DSN=sample"`. This option is demonstrated in all examples, see Example 1 - Reading a single valued Table for instance.

O = *string* (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is writable. UNC names can be used. An output file must be specified for batch operation: i.e. either `O=` or `X=` needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the $include command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in Example 1 - Reading a single valued Table for instance.

On = *string* (outputIncludeFile, default = none)

When using multiple queries in a single `SQL2GMS` call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

X = *string* (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS GDX file. Make sure the directory is writable. UNC names can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either `O=` or `X=` needs to be specified (or both). This option is demonstrated in Example 5 - Reading Set with Explanatory Text or Example 7 - Multi-Query Batch Example for instance.

Q = *string* (query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by the database we refer to the documentation that comes with your RDBMS (Relational DataBase Management System). The query is passed on directly to the RDBMS so the complete power and expressiveness of SQL is available including stored procedures etc. For an exact description of allowed expressions consult a text on your database system. This option is demonstrated in Example 1 - Reading a single valued Table for instance.

Qn = *string* (query, default = none)

When using multiple queries in a single `SQL2GMS` call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

```
Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc
```

or (GDX output file format - where several sets and parameters can be stored in a single file):

```
Q1="SELECT a, b FROM table"
A1=abParameter
Q2="SELECT c FROM table"
S2=cSet
```

Note the usage of the arguments An resp. Sn in order to store the results as parameter resp. set and to specify the name of the symbols. See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

S = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in Example 4 - Reading a multi dimensional Set.

Sn = *string* (setName, default = none)

If multiple queries are used in a single `SQL2GMS` call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet
```

See section Multi-Query Batch Usage and Example 7 - Multi-Query Batch Example for instance.

Y = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in Example 5 - Reading Sets with Explanatory Text for instance.

Yn = *string* (setName, default = none)

If multiple queries are used in a single `SQL2GMS` call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet
```

The last column specified within the select clause in the SQL statements will be used as explanatory text.

A = *string* (parameterName, default = none)

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).
Note: `MDB2GMS` uses `P`, but `P` was already taken in `SQL2GMS` for specifying the password.

An = *string* (parameterName, default = none)

If multiple queries are used in a single `SQL2GMS` call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i, j, value FROM table"
A1=ijValue
Q2="SELECT n, m, value FROM table"
A2=nmValue
```

See section Multi-Query Batch Usage and Example 7 - Multi-Query Batch Example for instance. for instance.

L (Listing, disabled by default)

Embed the data between the `$offListing` and `$onListing` dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

M (Mute, disabled by default)

Controls if additional information (GAMS and `SQL2GMS` version numbers, number of rows in the data, elapsed time, used query etc.) is written to the log and include file.

B (Quote Blanks, disabled by default)

Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. In the special case that the string contains both, the double quotes are replaced by single quotes. For more information see subsection Quotes. This option only applies to an output include file.

@fileName = *string* (fileName, default = none)

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also Parameter Files for some further details.

N = *string* (fileName, default = none)

Use a different INI file than the standard sql2gms.ini located in the same directory as the executable sql2gms.exe.

T1 = *integer* (connectionTimeOut, default = 15)

Indicates how long to wait while establishing a connection before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for the connection to open. Default is 15. If you set the property to zero, ADO will wait indefinitely until the connection is opened. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

T2 = *integer* (commandTimeOut, default = 30)

Indicates how long to wait while executing a command before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for a command to execute. Default is 30. If you set the property to zero, ADO will wait indefinitely until the execution is complete. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

T = *integer* (timeOut, default = none)

Sets both T1 and T2.

D (Debug, disabled by default)

Generate debug information. This option must be specified in an INI file when using the interactive mode of `SQL2GMS`.

E (Empty sets, disabled by default)

Allow an empty result set; without this option an empty result set will generate an error. This option must be specified in an INI file when using the interactive mode of `SQL2GMS`.

R = *integer* (rowBatchSize, default = 100)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of `SQL2GMS`.

P = *string* (password, default = none)

Specify a password for the database.

W = *string* (wiring, default = none)

By using the `W` option, one can map database columns to GAMS index positions. See model **[Wiring]** for reference (note that `MDB2GMS` is used to access the MS Access database instead of `SQL2GMS`, however this does not affect the `wiring` specification).

6.41.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the [**trnsport**] model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.accdb).

Distances

City1	City2	Distance
SEATTLE	CHICAGO	1,7
SAN-DIEGO	CHICAGO	1,8
SEATTLE	NEW-YORK	2,5
SAN-DIEGO	NEW-YORK	2,5
SEATTLE	TOPEKA	1,8
SAN-DIEGO	TOPEKA	1,4

Figure 6.64 Table: distances

The data can be queried with a simple SQL statement:

```
SELECT city1, city2, distance
FROM   distances
```

By running the following `SQL2GMS` statement, the connection to the database Sample.accdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

```
sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2, distar
```

The connection string is specified using the argument C. Note that the string is enclosed by quotes, as the string contains blanks. The database file name Sample.accdb is also specified within the connection string. For more information on how to connect to your database, see section Connection Strings. The arguments Q and O are used to specify the query and the output file name (and format).

The generated include file distances.inc looks like:

```
* ------------------------------------------------------
* SQL2GMS 3.0      25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* ------------------------------------------------------
* ADO version: 10.0
* Connection string: Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb
* Provider: MSDASQL
* Query: SELECT city1, city2, distance FROM distances
* ------------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* ------------------------------------------------------
```

The commented header section summarizes some information about the SQl2GMS resp. GAMS version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your GAMS model.

Retrieving the data using SQL2GMS from the database and including the queried data in your GAMS model within the parameter declaration statement (at compile time) can be combined in the following way:

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2,
Parameter d(i,j) 'distance in thousands of miles' /
$include distances.inc
/;

display d;
```

Finally, the values of the parameter d are displayed:

```
             new-york      chicago       topeka

seattle         2.500        1.700        1.800
san-diego       2.500        1.800        1.400
```

This example is also part of the GAMS Data Utilities Library, see model [**Distances2**] for reference. Note that the query results are written to a GDX file in addition.

6.41.3.3 Example 2 - Reading a multi valued Table

In this scenario, we want two read the three index columns year, loc, prod and the value columns sales and profit from the database file Sample.accdb. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for sales resp. profit) and a UNION select.

Consider the table with two value columns sales and profit:

data

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.65 Table: data (shortened for presentation)

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```
SELECT year, loc, prod, sales
FROM   data
SELECT year, loc, prod, profit
FROM   data
```

We can generate a include file sales.inc by running the following command:

```
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year, loc,
```

Note that we specify the first query in order to select the sales and the relevant index columns within the Q argument. The query results are written to sales.inc using the O argument. Analogously we generate a include file profit.inc by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year, loc,
```

Retrieving the data using `SQL2GMS` from the database Sample.accdb and including the queried data in your GAMS model within the parameter declaration statements of `sales` and `profit` (at compile time) can be combined in the following way:

```
Set
   year 'years'     / 1997*1998 /
   loc  'locations' / nyc, was, la, sfo  /
   prd  'products'  / hardware, software /;

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year,
Parameter sales(year,loc,prd) /
$include sales.inc
/;

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" Q="SELECT year,
Parameter profit(year,loc,prd) /
$include profit.inc
/;
```

Single Parameter with extra Index Position

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index `type` to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

```
SELECT year, loc, prod, 'sales', sales
FROM   data
UNION
SELECT year, loc, prod, 'profit', profit
FROM   data
```

The data is accessed, queried and written to data.inc by running the following command:

```
sql2gms @howToRead.txt
```

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

```
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FR
O=data.inc
```

The generated include file data.inc looks like (shortened for presentation):

```
* -----------------------------------------------------
* SQL2GMS 3.0      25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version: 10.0

* -----------------------------------------------------
```

Retrieving the data using `SQL2GMS` from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index `type` in order to access the data type `sales` resp. `profit`):

```
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FR
O=data.inc
$offEcho

Set
   year 'years'     / 1997*1998 /
   loc  'locations' / nyc, was, la, sfo  /
   prd  'products'  / hardware, software /
   type 'data type' / sales, profit      /;

$call sql2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
/;
```

This example is also part of the GAMS Data Utilities Library, see model **[SalesProfitDB5]** for reference.

6.41.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a database file. Suppose we want to read the column City1 (see table distances) in order to define the set i in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```
SELECT distinct(City1)
FROM   distances
```

The include file city1.inc looks like (header informations are removed in order to shorten the representation):

```
* ----------------------------------------------------
SAN-DIEGO
SEATTLE
* ----------------------------------------------------
```

All steps (data access via SQL2GMS, set definition) can be combined:

```
$call sql2gms C="Provider=MMicrosoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT distinct(city
Set i 'canning plants' /
$include city_i.inc
/;

display i;
```

The display statement generates the following output in the listing file:

```
----     56 SET i

seattle  ,    san-diego
```

6.41.3.5 Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the O argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing a b c is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. a.b.c will be interpreted correctly.

Depending on your DBMS (DataBase Management System), these periods must be added explicitly in a different way within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some placeholders):

```
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (|| or & depending on DBMS):

```
SELECT index1&'.'&index2&'.'&index3 FROM dataTable
SELECT index1||'.'||index2||'.'||index3 FROM dataTable
```

For instance, suppose we want to define a two dimensional set

```
Set ij(i,j) 'canning plants - markets';
```

based on the data of the table distances stored in Sample.accdb. The following SQL2GMS statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

```
sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2, ' ' FI
```

The include file city_ij.inc looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
SEATTLE.NEW-YORK ' '
SAN-DIEGO.NEW-YORK ' '
SEATTLE.CHICAGO ' '
SAN-DIEGO.CHICAGO ' '
SEATTLE.TOPEKA ' '
SAN-DIEGO.TOPEKA ' '
* -----------------------------------------------------
```

Without adding the empty value field, the resulting include file would look like (shortened):

```
* -----------------------------------------------------
SEATTLE NEW-YORK
SAN-DIEGO NEW-YORK
* -----------------------------------------------------
```

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT city1, city2,

Set ij(i,j) 'two dimensional set' /
$include city_ij.inc
/;

display ij;
```

The display statement generates the following output in the listing file:

```
----     75 SET ij  two dimensional set

             new-york     chicago      topeka

SAN-DIEGO         YES         YES         YES
SEATTLE           YES         YES         YES
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the X and S resp. Y arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

when using SQL2GMS in the following way:

```
sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT index1, index2, inde
```

which will generate the file setData.gdx with a three dimensional set named setName containing the results of the query.

6.41.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a database file using SQL2GMS. In the first place, we are going to write the query results to an include file, afterwards we use the Y argument in order to store the query results as a set with explanatory text in a GDX file.

setData

setElement	explText
firstSetElement	Explanatory text for the first 'set element'
secondSetElement	Explanatory text for the second "set element"
thirdSetElement	Explanatory text for the third 'set element"
fourthSetElement	Explanatory text for the fourth set element

Figure 6.66 Table: setData

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```
SELECT setElement, explText
FROM   setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument B in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file setData.inc:

```
$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" B Q="SELECT setElement,

Set a /
$include setData.inc
/;
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
firstSetElement "Explanatory text for the first 'set element'"
secondSetElement 'Explanatory text for the second "set element"'
thirdSetElement "Explanatory text for the third 'set element'"
fourthSetElement 'Explanatory text for the fourth set element'
* -----------------------------------------------------
```

Note the handling of the quotes according to the description in B.

Writing the Query Results in a GDX File
When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the Y argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

```
$call sql2gms C="Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb" Q="SELECT setElement, e

Set b;
$gdxIn setData.gdx
$load b = set_b
$gdxIn
```

Note that the name of the set in the GDX file is `set_b` (specified within the `Y` argument), while the name of the GDX file was specified within the X argument.

6.41.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

```
Set i / NY, DC, LA, SF /;
```

Now assume a data table looks like:

example table

city	value
new york	100
los angeles	120
san francisco	105
washington dc	102

Figure 6.67 Table: example table

This means we have to map 'new york' to 'NY' etc. This mapping can be done in two places: either in GAMS or in the database.

Index Mapping done in GAMS

When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
'new york' 100
'los angeles' 120
'san francisco' 105
'washington dc' 102
* -----------------------------------------------------
```

Note that the single quotes are added by activating the option B (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

```
Set i / NY, DC, LA, SF /;

Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb" B O="city1.inc"
Parameter dbdata(idb) /
$include city1.inc
/;

Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;

Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;
```

The display statement generates the following output in the listing file:

```
----     47 PARAMETER data

NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

This example is also part of the GAMS Data Utilities Library, see model [**IndexMapping3**] for reference.

Index mapping done in Database

The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

CityMapper

Access City	GAMS City
los angeles	la
new york	ny
san francisco	sf
washington dc	dc

Figure 6.68 Table: CityMapper

This table can be used in a join to export the data in a format we can use by executing the query:

```
SELECT [GAMS City], value
FROM    example_table, CityMapper
WHERE   CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
la 120
ny 100
sf 105
dc 102
* -----------------------------------------------------
```

All steps can be combined in the GAMS model:

```
Set i / NY, DC, LA, SF /;

$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_
O=city2.inc
$offEcho

$call sql2gms @howToRead.txt
Parameter data(i) /
$include city2.inc
/;
display data;
```

The display statement generates the following output in the listing file:

```
----     38 PARAMETER data

NY 100.000,    DC 102.000,    LA 120.000,    SF 105.000
```

Note: MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [**IndexMapping4**] for reference.

6.41.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual `SQL2GMS` execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single `SQL2GMS` call and write several GAMS include files containing the results of the queries, we can use the command-line arguments Qn and On. The structure of a multi-query call looks like:

```
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=sample.accdb

Q1=firstQuery
O1=outputFileName.inc

Q2=secondQuery
O2=outputFileName.inc

Q3=thirdQuery
O3=outputFileName.inc
```

The terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. We see that the argument `Qn` is matched by an argument `On`. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments Qn, Sn, An and Yn. The structure of a multi-query call when writing to a GDX file looks like:

```
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=sample.accdb
X=sample.gdx

Q1=firstQuery
S1=setName

Q2=secondQuery
S2=setName

Q3=thirdQuery
A3=parameterName

Q4=fourthQuery
A4=setName
```

Again, the terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. Here we see that a query `Qn` is matched by either a set name `Sn` or a parameter name `An` (the letter `P` was taken already: it is used to specify a password), i.e. the results of the first query will be stored as a set whose name is specified within the `S1` argument, the results of the third query will be stored as a parameter whose name is specified within the `A3` argument etc. The `X` argument is used to specify the name of the GDX file.

For a complete example see section Example 7 - Multi-Query Batch Example .

6.41.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file Sample.mdb):

data

year	loc	prod	sales	profit
1997	la	hardware	80	8
1997	la	software	60	16
1997	nyc	hardware	110	5
1997	nyc	software	100	10
1997	sfo	hardware	80	9
1997	sfo	software	50	10
1997	was	hardware	120	7
1997	was	software	70	20
1998	la	hardware	70	6
1998	la	software	70	10

Figure 6.69 Table: data (shortened for presentation)

We want to extract the following information:

- The set **year**
- The set **loc**
- The set **prd**
- The parameter **sales**
- The parameter **profit**

Output: Several include Files

This can be accomplished using the following GAMS code with multiple queries in a single `SQL2GMS` call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):

```
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};dbq=Sample.accdb

Q1=SELECT distinct(year) FROM data
O1=year.inc

Q2=SELECT distinct(loc) FROM data
O2=loc.inc

Q3=SELECT distinct(prod) FROM data
O3=prod.inc

Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc

Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
```

```
$offEcho

$call =sql2gms @howToRead.txt

Set y 'years' /
$include year.inc
/;
Set loc 'locations' /
$include loc.inc
/;
Set prd 'products' /
$include prod.inc
/;

Parameter sales(prd,loc,y) /
$include sales.inc
/;
display sales;

Parameter profit(prd,loc,y) /
$include profit.inc
/;
display profit;
```

This example is also part of the GAMS Data Utilities Library, see model [**SalesProfitDB6**] for reference.

Output: A single GDX File

The same example imported through a GDX file can look like:

```
$onEcho > howToRead.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=Sample.accdb
X=Sample.gdx

Q1=SELECT distinct(year) FROM data
S1=year

Q2=SELECT distinct(loc) FROM data
S2=loc

Q3=SELECT distinct(prod) FROM data
S3=prd

Q4=SELECT prod, loc, year, sales FROM data
A4=sales

Q5=SELECT prod, loc, year, profit FROM data
A5=profit
$offEcho

$call =sql2gms @howToRead.txt
$call ="%gams.sysdir%studio/studio" Sample.gdx

Set
   y   'years'
   loc 'locations'
```

```
   prd 'products';

Parameter
   sales(prd,loc,y)
   profit(prd,loc,y);

$gdxIn sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;
```

The call of the GDXViewer will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [**SalesProfitDB7**] for reference.

6.41.5 Interactive Usage

When the tool is called without command-line arguments, it will startup interactively. Using it this way, one can specify options such as the connection string, the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.

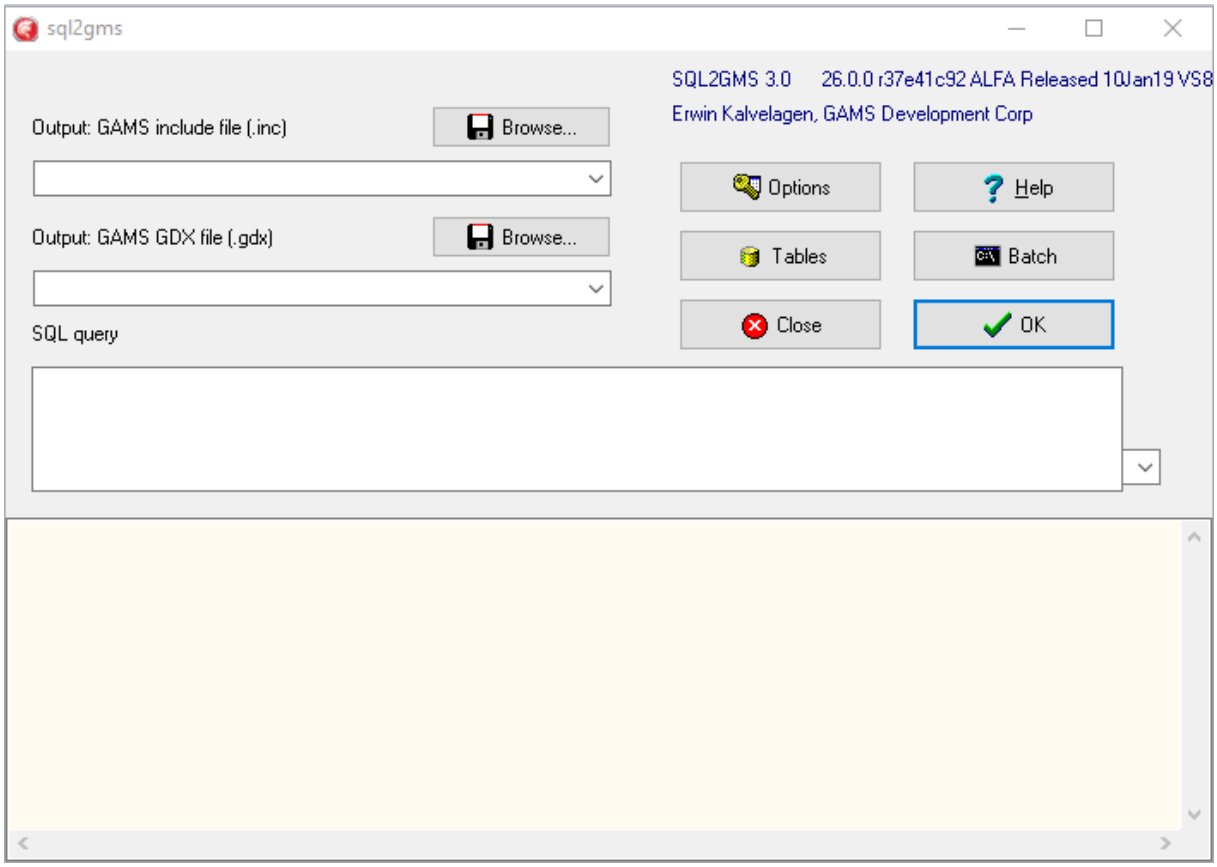

Figure 6.70 SQL2GMS - Graphical User Interface

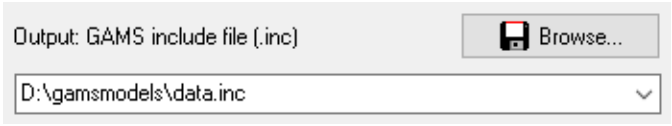
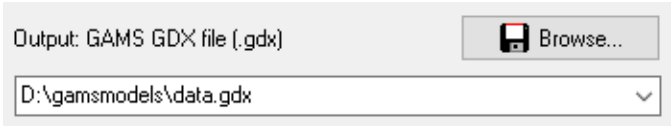
- **Output GAMS Include file (∗.inc)**. If you want to create a GAMS include file, then specify here the destination file. See also outputIncludeFile for some more detailed remarks.

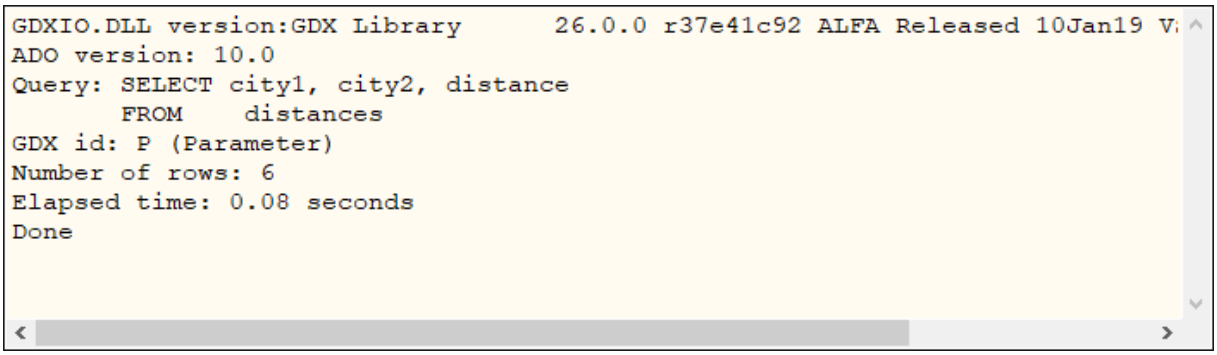


- **Output GDX file (∗.gdx)**. As an alternative to a GAMS include file, the tool can also generate a GDX file. One or both of the output files need to be specified. See also outputGDXFile for some more detailed notes.



- **SQL Query**. The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also Q for some more detailed notes.

- **Progress Memo**. This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.



- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

- The **Options button** will pop up a window where you can specify a number of options. The connection string is an important option, which needs to be set correctly before a query can be submitted successfully.

- Pressing the **Help button** will show this documentation.

- Pressing the **OK button** will execute the query and an output file will be generated.

- The **Batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press `Ctrl-C` or choose `Edit|Paste` to copy the contents of the clipboard to a GAMS text file.

- Pressing the **Close button** will exit the application. The current settings will be saved in an INI file so when you run `SQL2GMS` again all current settings will be restored.

6.41.5.1 Options

The **Options** window can be created by pressing the options button:

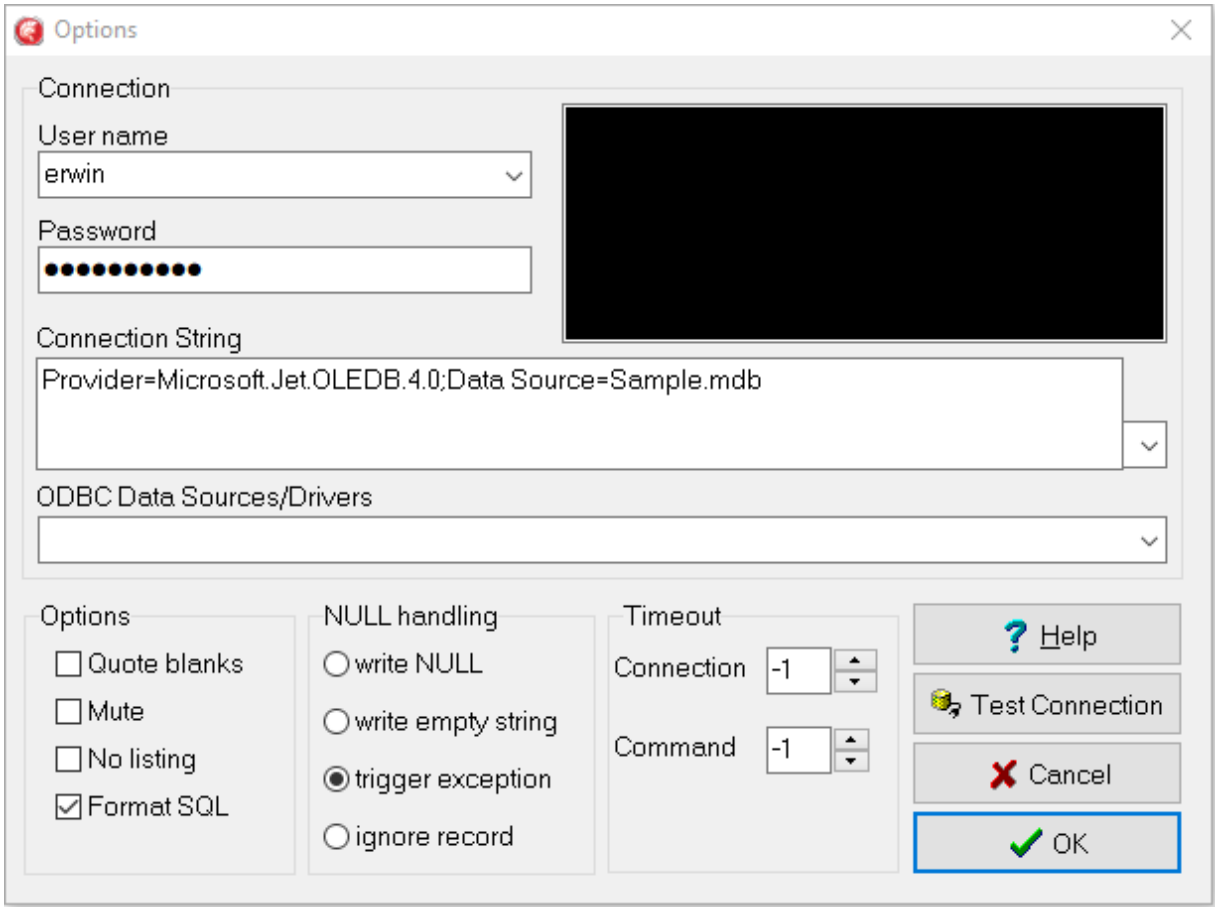


Figure 6.71 Options Menu of the Graphical User Interface

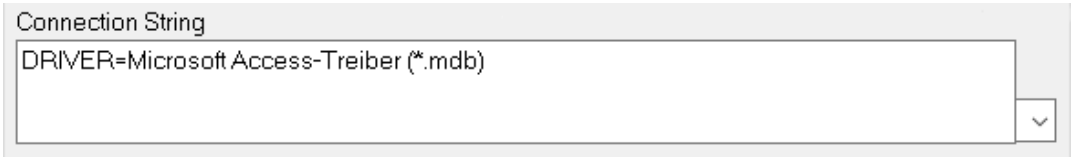
The following options are available in the options window:

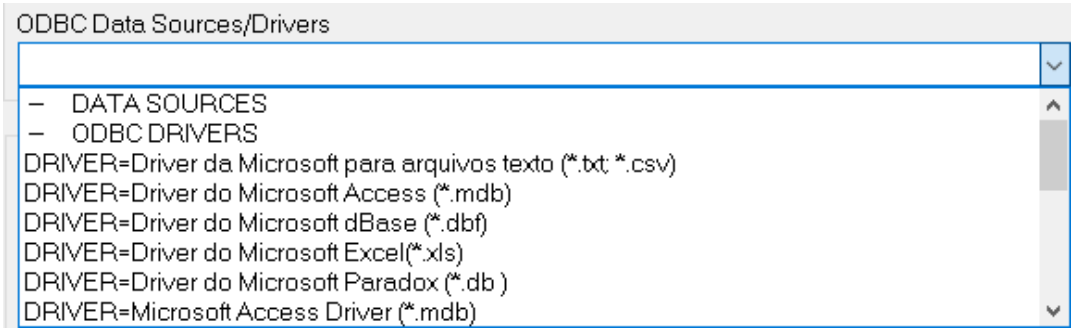
- **User name:** Here you can specify the user name for logging in to the RDBMS. For databases without user authentication, this can be left empty.

- **Password:** This edit box allows you to specify the password for the database system. The characters are echoed as a '∗'.

- **Connection String:** The connection string determines how `SQL2GMS` talks to the database. For more informations see Connection Strings.



- **ODBC Data Sources/Drivers:** This drop down list can be used to compose a connection string when an ODBC data source or driver is involved. The list will show all configured data sources and all available ODBC drivers.



- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also B for some more detailed notes.

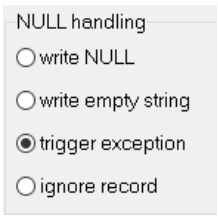
- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file. The equivalent command-line argument is M.

- **No listing:** Surround the include file by `$offListing` and `$onListing` so that the data will not be echoed to the listing file. The equivalent command-line argument is L.

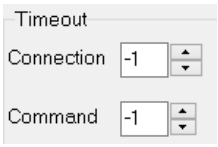
- **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

The following options are only needed in special cases:

- **NULL:** This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.



- **Time-out** values for connection time and command execution time expressed in seconds. If -1 is specified then it will use the default value which is 15 seconds for the connection and 30 for the commands. See also T1, T2 resp. T for some more detailed notes.



The following buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made and all option settings will revert to their previous values.

- **Help button** will show this documentation.

- **Test Connection** will try to make a connection to the database using the given connection string.

If the settings are correct you will see something like:

The following options can only be specified in an INI file; there is no interactive equivalent:

Key	Type	Meaning
D		Generate debug output
E		Allow an empty result set; without this option an empty result set will generate an error
R	integer	Row batch size; the default is 100 records

6.41.6 Connection Strings

The connection string determines to which database the tool will try to connect. You can give simply the name of an ODBC Data Source or provide much more elaborate connection strings. Here is an example list:

- ODBC Examples
- **OLE DB Examples**
- **MS Remote Examples**

For more information consult the documentation with your database driver. ODBC drivers can be had from several sources: Microsoft delivers ODBC with a number of drivers; database providers may have likely an ODBC driver for their RDBMS available and finally there are a number of third party ODBC drivers available (e.g. from `http://www.easysoft.com`).

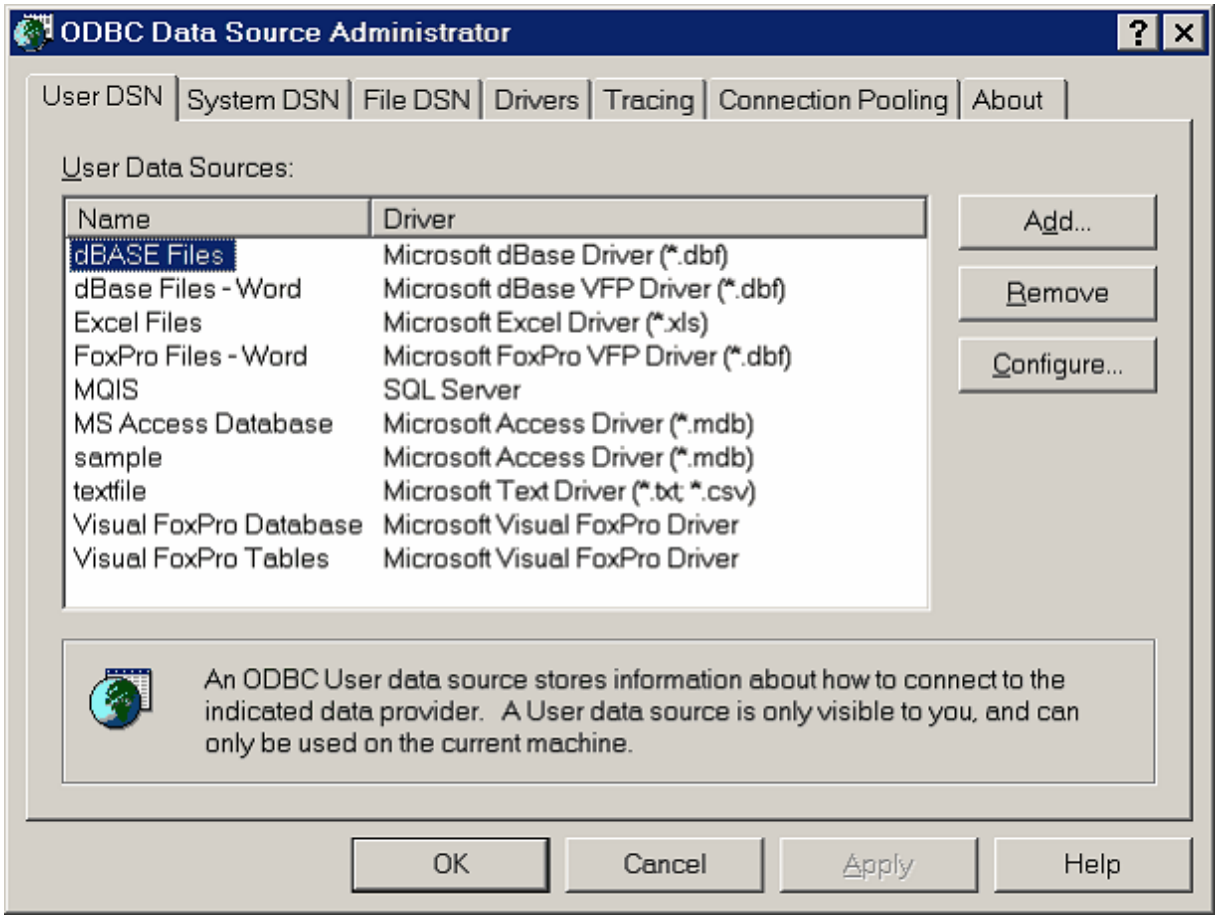
6.41.7 ODBC Examples

In this section we show a few examples using `SQL2GMS` with ODBC data sources.

6.41.7.1 ODBC Driver Manager

To configure ODBC data sources use the `ODBC Data Source Administrator`. This tool can be invoked from the Start button menu: `Settings`|`Control Panel`, and click on the `ODBC Data Sources` icon:

Under Windows XP the sequence is: `Control Panel`|`Performance` and `Maintenance`|`Administrative Tools` and click on the `Data Sources (ODBC)` icon. Under Windows 10, access the `Control Panel` at first, type 'odbc' in the top right box and select either 'Set up ODBC data sources (32-bit)' or 'Set up ODBC data sources (64-bit)'. The ODBC Data Source Administrator tool looks like:



To create a new data source, click the Add button, select a driver, give it a name (this is the DSN name) and configure the data source.

6.41.7.2 Example 8 - Reading from an MS Access Database

There are several ways to export data from an SQL database into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Access Export. See also CSV Files.
2. Use the MDB2GMS tool.
3. Use `SQL2GMS` with a configured ODBC data source. The connection string will look like:

   ```
   "DSN=mydsn".
   ```

4. Use `SQL2GMS` with a DSN-less ODBC connection. In this case we need to specify both the driver and the location of the database file explicitly in the connection string. The connection string will look like:

   ```
   "Driver=Microsoft Access Driver (*.mdb, *.accdb);dbq=D:\data\mydata.accdb".
   ```

5. Use `SQL2GMS` with an OLE DB driver. The connection string can look like:

   ```
   "Microsoft.ACE.OLEDB.12.0;Data Source=D:\data\mydata.accdb"
   ```

6.41.7.3 Example 9 - Reading from an MS Excel Spreadsheet

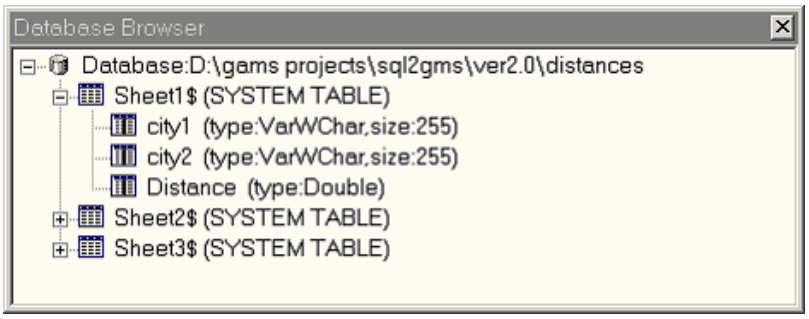
There are numerous ways to export data from an Excel spreadsheet into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Excel Export.
2. Use the XLS2GMS tool.
3. Use the GDXXRW tool.
4. Use `SQL2GMS` with an Excel ODBC connection. An example is shown below.

Consider the spreadsheet ExcelDist.xls:

	A	B	C	D	E
1					
2		city1	city2	Distance	
3		SEATTLE	NEW-YORK	2.5	
4		SAN-DIEGO	NEW-YORK	2.5	
5		SEATTLE	CHICAGO	1.7	
6		SAN-DIEGO	CHICAGO	1.8	
7		SEATTLE	TOPEKA	1.8	
8		SAN-DIEGO	TOPEKA	1.4	
9					

After configuring a data source ExcelDist that uses the Excel ODBC driver and points to the .xls file containing the above sheet, we can use the connection string: `"DSN=ExcelDist"`. With the database browser we see:



I.e. the table name is `Sheet1$`. We now can formulate the query: `SELECT city1, city2, distance FROM [Sheet1$]`. We need the brackets to protect the funny table name. The result is (header removed in order to shorten the presentation=:

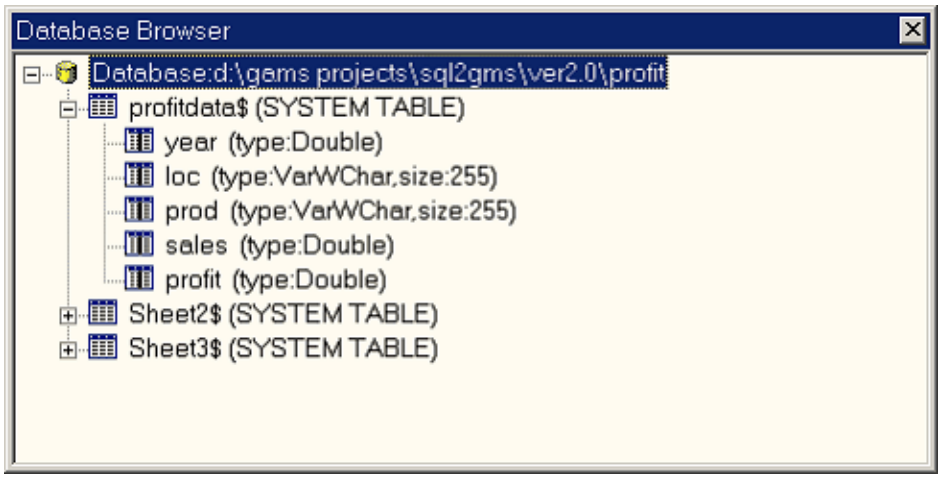
```
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------
```

Although other tools are often more convenient to use, this approach is useful if you need to select a subsection of the spreadsheet table. It is easy to select just a few columns or rows from a table using a properly formulated SQL query. The skeleton would be: `SELECT columns_to_extract FROM [sheet1$] WHERE rows_to_extract`.

An example of a more complex spreadsheet is (profit.xls):

	A	B	C	D	E	F
1	year	loc	prod	sales	profit	
2	1997	la	hardwar	80	8	
3	1997	la	software	60	16	
4	1997	nyc	hardwar	110	5	
5	1997	nyc	software	100	10	
6	1997	sfo	hardwar	80	9	
7	1997	sfo	software	50	10	
8	1997	was	hardwar	120	7	
9	1997	was	software	70	20	
10	1998	la	hardwar	70	6	
11	1998	la	software	70	10	
12	1998	nyc	hardwar	120	7	
13	1998	nyc	software	120	14	
14	1998	sfo	hardwar	90	12	
15	1998	sfo	software	70	15	
16	1998	was	hardwar	130	12	
17	1998	was	software	80	15	
18						

A DSN-less connection string would be: `"DRIVER=Microsoft Excel Driver (*.xls); DBQ=d:\gams projects\sql2gms\ver2.0\profit.xls"`. The browser will show:



A possible query that maps the two value columns into a GAMS parameter is:

```
SELECT year, loc, prod, 'sales', sales
FROM  [profitdata$]
UNION
SELECT year, loc, prod, 'profit', profit
FROM  [profitdata$]
```

The result is (shortened for presentation):

```
* -----------------------------------------------------
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
1997.was.hardware.profit 7
1997.was.hardware.sales 120
1997.was.software.profit 20
1997.was.software.sales 70
1998.la.hardware.profit 6
1998.la.hardware.sales 70
* -----------------------------------------------------
```

This example is also part of the GAMS Data Utilities Library, see model [**Excel**] for reference.

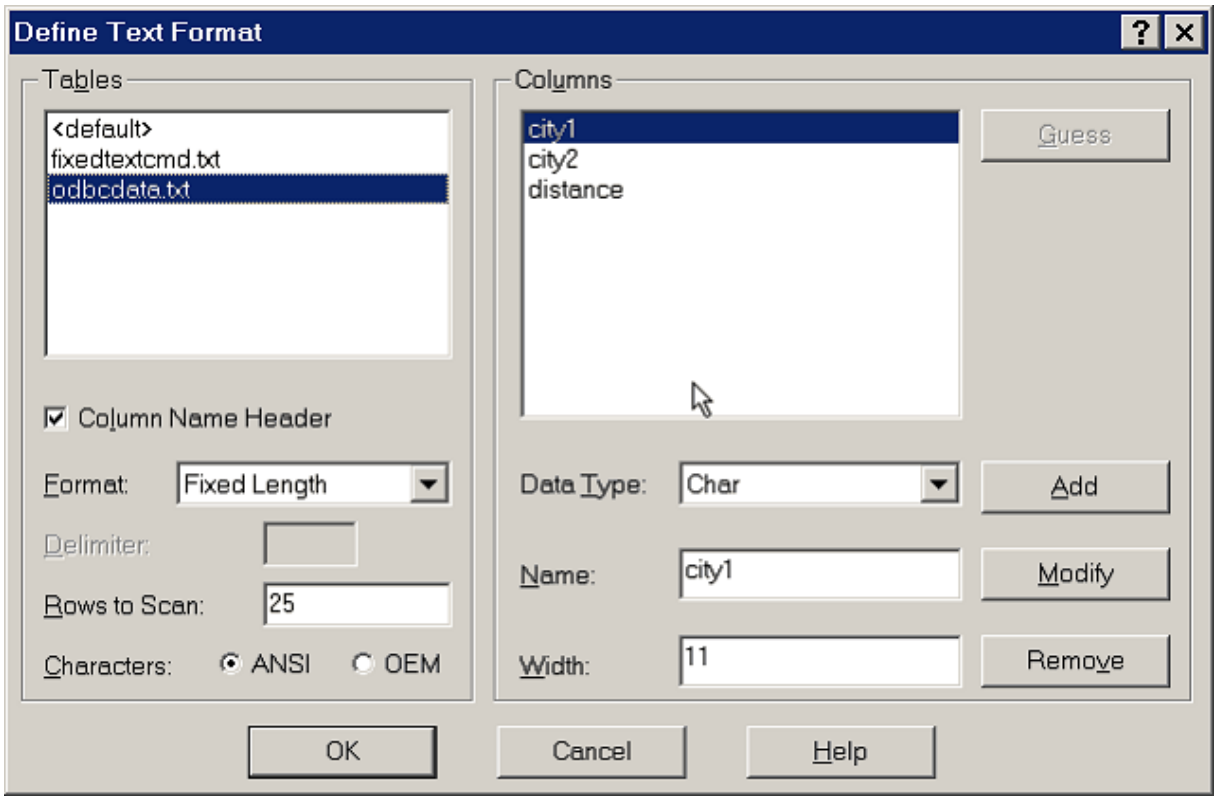
6.41.7.4 Example 10 - Reading from a Text File

Microsoft delivers ODBC with a text file driver which allows you to read a text file as if it is a database table.

A fixed format file such as:

```
City1      City2     Distance
SEATTLE    NEW-YORK  2.5
SAN-DIEGO  NEW-YORK  2.5
SEATTLE    CHICAGO   1.7
SAN-DIEGO  CHICAGO   1.8
SEATTLE    TOPEKA    1.8
SAN-DIEGO  TOPEKA    1.4
```

can be read using Fixed Length setting of the text driver:



The resulting include file will look like:

```
* ----------------------------------------------------
* SQL2GMS Version 2.0, January 2004
* Erwin Kalvelagen, GAMS Development Corp
* ----------------------------------------------------
* ADO version:       2.7
* Connection string: DSN=text
* Query:             SELECT city1, city2, distance FROM odbcdata.txt
* Provider:          MSDASQL
* ----------------------------------------------------
```

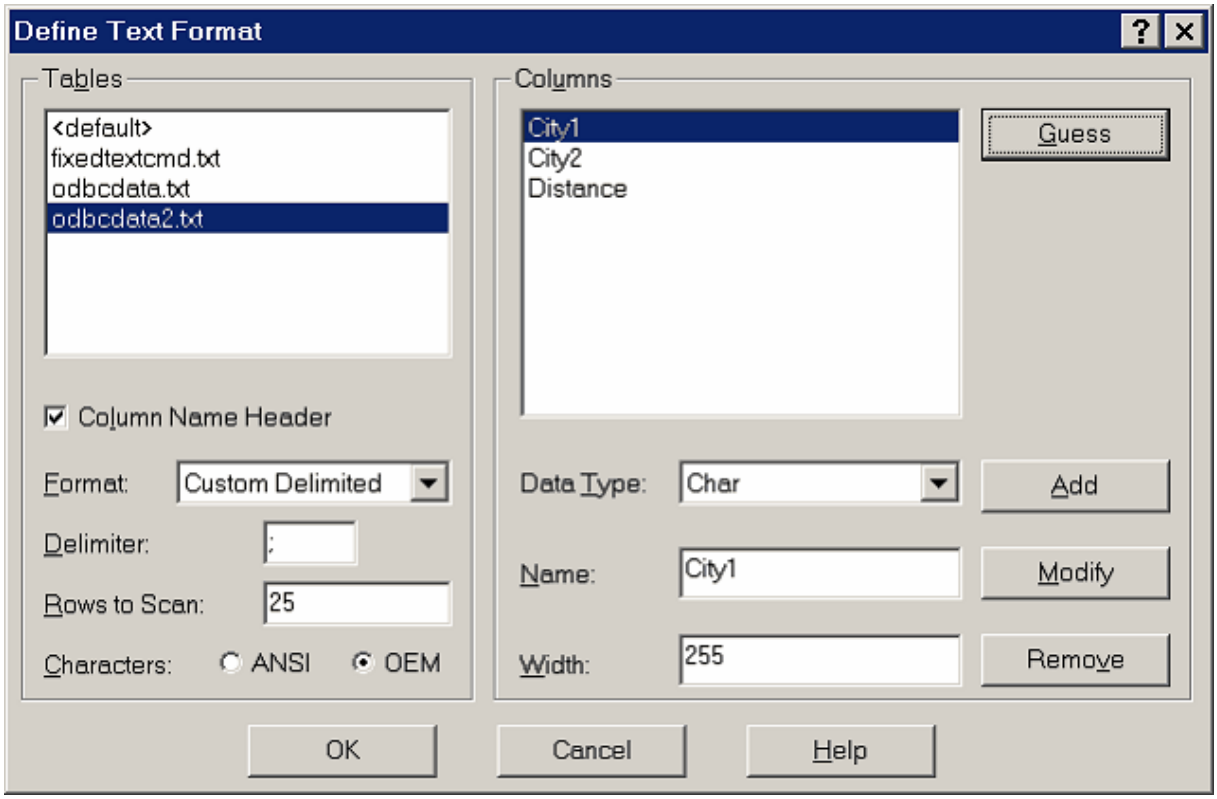
```
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* ------------------------------------------------------
```

Note that the text file is specified directly within the FROM clause.

A CSV file can be interpreted as a table as well, or any other separated format. We will try to read:

```
City1;City2;Distance
SEATTLE;NEW-YORK;2.5
SAN-DIEGO;NEW-YORK;2.5
SEATTLE;CHICAGO;1.7
SAN-DIEGO;CHICAGO;1.8
SEATTLE;TOPEKA;1.8
SAN-DIEGO;TOPEKA;1.4
```

This can be read using:



The actual formats used are stored by ODBC in an INI file schema.ini (located in the directory of the data files) which can be inspected directly:

```
[odbcdata.txt]
ColNameHeader=True
Format=FixedLength
MaxScanRows=25
CharacterSet=ANSI
Col1=city1 Char Width 11
Col2=city2 Char Width 11
Col3=distance Float Width 10

[odbcdata2.txt]
ColNameHeader=True
Format=Delimited(;)
MaxScanRows=25
CharacterSet=OEM
Col1=City1 Char Width 255
Col2=City2 Char Width 255
Col3=Distance Float
```

This example is also part of the GAMS Data Utilities Library, see model [**Text**] for reference.

6.41.8 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.
- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.
- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

```
Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing
```

we can conveniently use the save/restart facility. The individual submodel are coded as:

- **Step 0 - Data Extraction: sr0.gms**

```
$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText

Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';

$onEcho > howtoRead.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=%system.fp%transportation.accdb

Q1=SELECT name FROM suppliers
O1=i.inc

Q2=SELECT name FROM demandcenters
O2=j.inc

Q3=SELECT name,demand FROM demandcenters
O3=demand.inc

Q4=SELECT name, supply FROM suppliers
O4=supply.inc

Q5=SELECT supplier, demandcenter, distance FROM distances
O5=dist.inc
$offEcho

$call =sql2gms.exe @howtoRead.txt

Set i /
$include i.inc
/;

Set j /
$include j.inc
/;

Parameter demand /
$include demand.inc
/;

Parameter supply /
$include supply.inc
/;

Parameter dist /
$include dist.inc
/;

display i, j, demand, supply, dist;
```

- **Step 1 - Data Manipulation: sr1.gms**

```
$onText
step 1: data manipulation step
execute as: > gams sr1 restart=s0 save=s1
$offText

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;
```

- **Step 2 - Model Definition: sr2.gms**

```
$onText
step 2: model definition
execute as: > gams sr2 restart=s1 save=s2
$offText

Variable
   x(i,j) 'shipment quantities in cases'
   z      'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
   ecost      'define objective function'
   esupply(i) 'observe supply limit at plant i'
   edemand(j) 'satisfy demand at market j';

ecost..      z  =e= sum((i,j), c(i,j)*x(i,j));

esupply(i).. sum(j, x(i,j)) =l= supply(i);

edemand(j).. sum(i, x(i,j)) =g= demand(j);
```

- **Step 3 - Model Solution: sr3.gms**

```
$onText
step 3: model solution
execute as: > gams sr3 restart=s2 save=s3
$offText

option lp = cplex;

Model transport / all /;
solve transport using lp minimizing z;
```

- **Step 4 - Report Writing: sr4.gms**

```
$onText
step 4: report writing
execute as: > gams sr4 restart=s3
$offtext

abort$(transport.modelStat <> 1) "model not solved to optimality";

display x.l, z.l;
```

A model that executes all steps can be written as:

```
execute '=gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute '=gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute '=gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute '=gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute '=gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";
```

If you only change the reporting step, i.e. generating some output using `PUT` statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [**SQLSr5**] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

SQL2GDX1.gms

```
$onText
Store data from Access database into a GDX file.
$offText

execute '=gams.exe sr0 lo=3 gdx=trnsport.gdx';
abort$errorLevel "step 0 failed";

execute '=gdxviewer.exe trnsport.gdx';
```

The model [**SQL2GDX1**] is also part of the GAMS Data Utilities Library.

We can also let `SQL2GMS` create the GDX file:

SQL2GDX2.gms

```
$onText
Store data from Access database into a GDX file.
$offText

$onEcho > howToRead.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=%system.fp%transportation.accdb
X=%system.fp%transportation.gdx

Q1=SELECT name FROM suppliers
S1=i

Q2=SELECT name FROM demandcenters
```

```
S2=j

Q3=SELECT name, demand FROM demandcenters
A3=demand

Q4=SELECT name, supply FROM suppliers
A4=supply

Q5=SELECT supplier, demandcenter, distance FROM distances
A5=dist
$offEcho

$call =sql2gms.exe @howToRead.txt
```

The first approach has the advantage that a complete audit record is available from the data moved from the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the database and how this was stored in the GDX file, that file gives the answer.

The model [**SQL2GDX2**] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

GDXTRNSPORT.gms

This model demonstrates how to load the transportation data from GDX file at compile time.

```
Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist
$gdxIn

display i, j, demand, supply, dist;
```

DBTimestamp2.gms

In one application I had to retrieve data from the database each morning, at the first run of the model. The rest of the day, the data extracted that morning could be used. The following logic can implement this:

```
$onText
Retrieve data from data base first run each morning.
$offText

$onEcho > getdate.txt
C=Provider=Microsoft.ACE.OLEDB.12.0;Data Source=%system.fp%transportation.accdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho
```

```
$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/;

Scalar currentday 'day of this run';
currentday = gday(jnow);

display "compare", dbtimestamp, currentday;

if(dbtimestamp<>currentday,
   execute '=gams.exe sr0 lo=3 gdx=transportation.gdx';
   abort$errorLevel "step 0 (database access) failed";

   execute '=sql2gms.exe @getdate.txt'
);
```

The include file dbtimestamp.inc contains the day of the month (1,..,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the dbtimestamp.inc file. This last operation could be done using a `PUT` statement, but in this case we used an SQL statement.

The model [**DBTimestamp2**] is also part of the GAMS Data Utilities Library.

6.41.9 Parameter Files

Parameters can be specified in an external parameter file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command line as in:

```
$call =sql2gms C="DSN=sample" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command line like:

```
$call =sql2gms @"c:\My Documents\options.txt"
```

The parameter file

```
c:\My Documents\options.txt
```

can look like:

```
C=DSN=sample
O=c:\My Documents\data.inc
Q=SELECT * FROM mytable
```

It is possible to write the parameter file from inside a GAMS model using the $echo command. The following example will illustrate this:

```
$set cmdfile "c:\windows\temp\commands.txt"
$echo "C=DSN=sample"              >  "%cmdfile%"
$echo "O=E:\models\labor.INC"     >> "%cmdfile%"
$echo "Q=SELECT * FROM labor"     >> "%cmdfile%"
$call =sql2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

Newer versions of GAMS allow the usage of the $onEcho and $offEcho commands:

```
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho  >  "%cmdfile%"
C=DSN=sample
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho

$call =sql2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character \ as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data \
UNION \
SELECT prod, loc, year, 'profit', profit FROM data
```

6.41.10 Notes

6.41.10.1 ADO

ActiveX Data Objects. Microsoft's data-access object model. An object-oriented architecture for accessing data stored in SQL databases and related data sources. Accessible from a large number of host languages such as VB, C++, Delphi. Supersedes ODBC. Many SQL databases provide ADO access through either OLEDB or ODBC.

6.41.10.2 ODBC

An API and driver manager system for accessing data stored in an RDBMS. The API provides applications a way to talk to databases while the driver manager application allows users to install, configure and manage ODBC drivers for different databases.

6.41.10.3 OLEDB

Driver architecture for SQL databases. A driver is called a OLE DB provider. This is used from ADO.

6.41.10.4 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\\<server>\<share>\<path>\<file>
```

Examples:

```
\\athlon\c\My Documents\sql2gms.rtf
```

6.41.10.5 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: $gdxIn, $load, execute_load, execute_unload. The GDX=filename command-line option will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using `File|Open`.

6.41.10.6 MDB2GMS

`MDB2GMS` is a tool to import tables from MS Access databases. This utility directly uses MS Access and DAO (Data Access Objects) resulting in a somewhat simpler interface. It is not needed to specify a connection string, but just a .accdb or .mdb file. The query mechanism is similar: a query is sent as it is to the database server and the result set is translated into a GAMS representation. For more information see MDB2GMS.

6.41.10.7 XLS2GMS

`XLS2GMS` is a tool to import data from an Excel spreadsheet. It considers the content of a selected range as GAMS source code. For more information XLS2GMS.

6.41.10.8 GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet. For more information GDXXRW.

6.41.10.9 Quotes

Examples of handling of indices when the option B for quoting strings containing blanks is used:

6.41.10.10 $CALL Command

The $call command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalProgram
```

```
$call =externalProgram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form $call externalProgram which uses the command processor.
2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call externalProgram.
3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalProgram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalProgram.
4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /w externalWindowsProgram. Otherwise, it is preferred to use: $call =externalWindowsProgram.

Attention

In general it is recommended to use the $call =externalProgram version for its better error-handling.

When command-line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2
```

The total length of the command-line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call '"external program" "parameter 1" "parameter 2"'
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command-line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes *only if* the = appears outside the double quotes.

6.41.10.11 Compile Time Commands

All $ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed **before** an execution time command, even if it is below. As an example consider:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
$call x.bat
```

This fragment does not work correctly as already during compilation, the $call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

```
$echo "dir" > x.bat
$call x.bat
```

or by moving the external program invocation to execution time:

```
File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;
```

Notice that all $ commands do not include a semi-colon but are terminated by the end-of-line.

6.42 XLS2GMS

Author

Erwin Kalvelagen, GAMS Development Corp

Version

2.4

Date

May 2004

6.42.1 Overview

Attention

XLS2GMS is deprecated (see GAMS 42 XLS2GMS release notes). Please use Connect agent ExcelReader instead.

XLS2GMS is a tool to convert spreadsheet data from a Microsoft Excel spreadsheet into GAMS readable format. The source is a MS Excel spreadsheet file (∗.XLS) and the target is a GAMS Include File.

When running the executable **XLS2GMS.EXE** without command line parameters the tool will run interactively with a built-in GUI interface. Alternatively XLS2GMS can be run in batch mode which is useful when calling it directly from a GAMS model using the $call command.

The philosophy of the tool is to consider the content of a spreadsheet as **Text**. This text can contain GAMS statements, or parts of GAMS statements (e.g. the data part of a table statement). The text is exported to a GAMS include file where some spacing is introduced to maintain cell boundaries. This allows tables to be exported directly to GAMS include files.

6.42.2 Requirements

XLS2GMS runs only on PC's running Windows (95/98/NT/XP) and with MS Excel installed. Microsoft Excel is included in the MS Office suite.

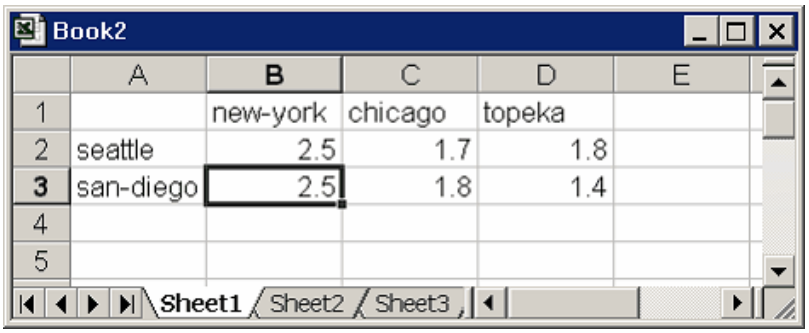
6.42.3 Converting spreadsheet data to GAMS data

Spreadsheet data are often differently organized than is suitable for import into a GAMS model. In some cases the data is scattered around different sheets, and in a format that is not compatible with a more structured multi-dimensional parameter as are used in a GAMS model. To export spreadsheet data to GAMS parameters, tools will either require a strict format to be used inside the spreadsheet or they will need to offer a complex specification step where the data representation in the spreadsheet is described so that it can be understood by the tool. This tool will use the first approach: the modeler is required to lay-out the data in the spreadsheet in a well defined format. Instead of defining a new format, we use the GAMS language syntax as the required representation. In effect the spreadsheet is considered as an alternative editor for GAMS source code.

As an example consider the GAMS table in the model [TRNSPORT] which is part of the GAMS model library:

```
Table d(i,j) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;
```

This table can be expressed comfortably in a spreadsheet as follows:



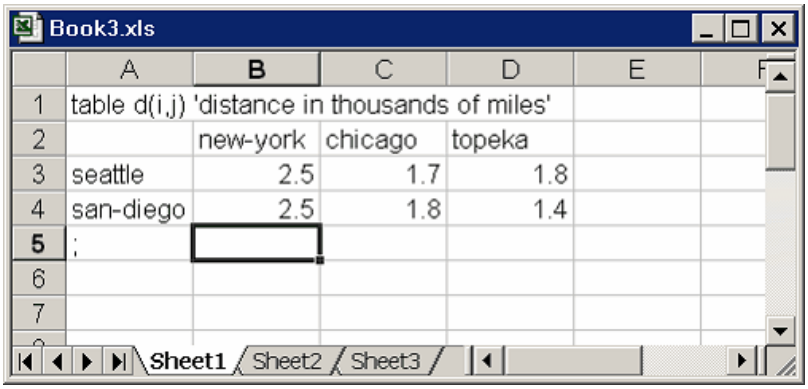
XLS2GMS can convert this table into a GAMS include file, which results in:

```
* ------------------------------------------------------
* XLS2GMS Version 2.4,  May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* ------------------------------------------------------
* Application: Microsoft Excel
* Version:     9.0
* Workbook:    D:\gams projects\xls2gms\ver2.0\Book2.xls
* Sheet:       Sheet1
* Range:       $A$1:$D$3
* ------------------------------------------------------
        new-york chicago topeka
seattle   2.5      1.7     1.8
san-diego 2.5      1.8     1.4
* ------------------------------------------------------
```

The tool will try to keep cells in a column aligned so that table statements can be used in the GAMS model. The above file **book2.inc** can be imported directly into a GAMS model by:

```
Table d(i,j) 'distance in thousands of miles'
$include book2.inc
;
```

As the tool does not expect any special formatting, we could have include the table statement in the spreadsheet, as in:



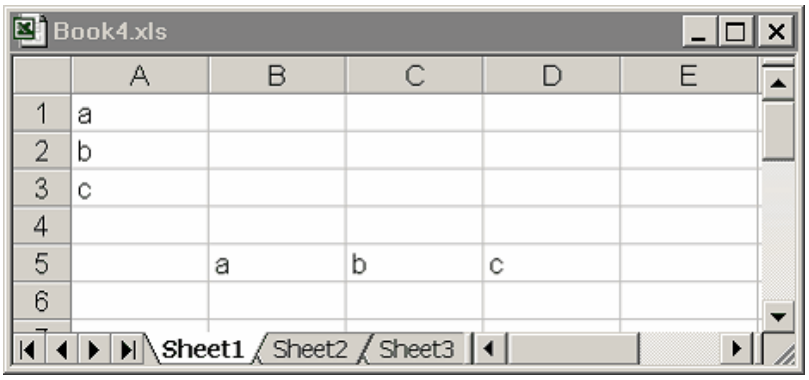
This would result in:

```
* ---------------------------------------------------
* XLS2GMS Version 2.4,  May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* ---------------------------------------------------
* Application: Microsoft Excel
* Version:     9.0
* Workbook:    D:\gams projects\xls2gms\ver2.0\Book3.xls
* Sheet:       Sheet1
* Range:       $A$1:$D$5
* ---------------------------------------------------
table d(i,j) 'distance in thousands of miles'
        new-york chicago topeka
seattle   2.5      1.7     1.8
san-diego 2.5      1.8     1.4
;
* ---------------------------------------------------
```

In some cases the data will need to be copied and massaged to fit into the above format. It is convenient to add a sheet dedicated for this purpose to your workbook. This interface sheet can be filled either manually, with formulas that automatically update values, or by macro's (either recorded or programmed in VBA).

6.42.4 Importing sets

Sets can be directly imported if they are organized vertically. The following picture shows a spreadsheet with two sets with elements {a,b,c} organized vertically (A1:A3) and horizontally (B5:D5).



The first set can be imported directly using:

```
Set i /
$call =xls2gms r=a1:a3 i=book4.xls o=set1.inc
$include set1.inc
/;

display i;
```

The second set is somewhat more difficult, as we need to add a separating comma between the elements. This can be accomplished by:

```
Set j /
$call =xls2gms r=b5:d5 s="," i=book4.xls o=set2.inc
$include set2.inc
/;

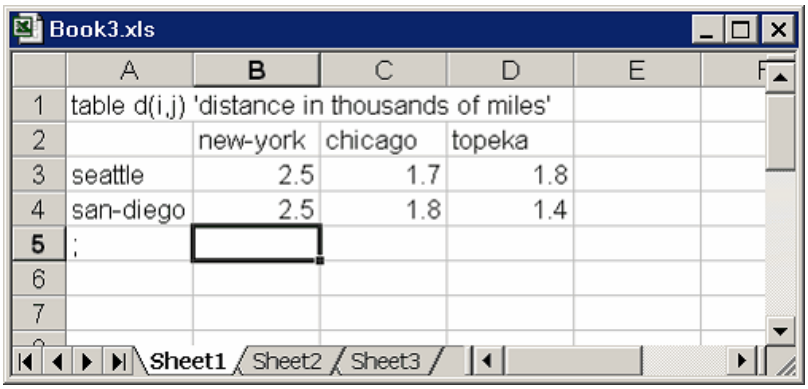
display j;
```

This will generate the include file:

```
* ------------------------------------------------------
* XLS2GMS Version 2.4,  May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* ------------------------------------------------------
* Application: Microsoft Excel
* Version:     9.0
* Workbook:    D:\gams projects\xls2gms\ver2.0\Book4.xls
* Sheet:       Sheet1
* Range:       $B$5:$D$5
* ------------------------------------------------------
a,b,c
* ------------------------------------------------------
```

6.42.5 Importing sets and tables

The table



can be considered to contain three pieces of GAMS data:

- The `set i (seattle, san-diego)`
- The `set j (new-york, chicago, topeka)`
- The `distances`

All this information can be read as follows:

```
Set i /
$call =xls2gms r=a3:a4 i=book3.xls o=seti.inc
$include seti.inc
/;

Set j /
$call =xls2gms r=b2:d2 s="," i=book3.xls o=setj.inc
$include setj.inc
/;

Table d(i,j)
$call =xls2gms r=a2:d4 i=book3.xls o=pard.inc
$include pard.inc
;

display i, j, d;
```

The above $call statements can be combined onto one as follows:

```
$onEcho > book3a.txt
i=%system.fp%book3.xls
r1=a3:a4
o1=seti.inc
r2=b2:d2
o2=setj.inc
s2=","
r3=a2:d4
o3=pard.inc
$offEcho

$call =xls2gms @book3a.txt

Set i /
```

```
$include seti.inc
/;

Set j /
$include setj.inc
/;

Table d(i,j)
$include pard.inc
;

display i, j, d;
```

The command file generated by the $onecho statement looks like:

```
i=E:\wtools\ver000\examples\book3.xls
r1=a3:a4
o1=seti.inc
r2=b2:d2
o2=setj.inc
s2=","
r3=a2:d4
o3=pard.inc
```

6.42.6 Multidimensional parameters

Consider the data table:

data.txt

	A	B	C	D	E	F	G	H	I	J
1	livestock yield time series (kg per head)									
2					1974	1975	1976	1977	1978	1979
3										
4		sheep	.	meat	10.6	11.42	10.6	9.38	8.97	6.93
5		sheep	.	milk	23.7	24.1	24.2	24.2	24	23.9
6		sheep	.	wool	1.3	1.3	1.3	1.3	1.3	1.3
7		sheep	.	hide	0.5	0.6	0.6	0.5	0.6	0.4
8		goat	.	meat	6.39	7.31	8.68	7.31	6.39	6.85
9		goat	.	milk	37.7	38.1	38.2	38.2	38.3	37.8
10		goat	.	wool	0.6	0.6	0.6	0.6	0.6	0.6
11		goat	.	hide	0.2	0.3	0.3	0.3	0.2	0.3
12		angora	.	meat	1.77	1.77	2.66	2.21	1.77	1.77
13		angora	.	milk	14.9	15.2	14.8	15.2	14.8	15
14		angora	.	wool	1.6	1.6	1.6	1.6	1.6	1.4
15		angora	.	hide	0.1	0.1	0.1	0.1	0.1	0.1
16		cattle	.	meat	24.59	25.12	21.42	23	18.25	25.12
17		cattle	.	milk	210	208.1	219.8	213.8	214.8	217.5
18		cattle	.	hide	3.3	3.4	2.9	3	2.6	3.3
19		buffalo	.	meat	43.73	45.42	40.61	37.21	32.2	32.68
20		buffalo	.	milk	267.1	269.2	263.8	219.6	275.5	285.1
21		buffalo	.	hide	4.1	3.4	3	2.4	2.5	2.6
22		poultry	.	meat	2.24	2.24	2.24	2.24	2.24	2.24
23		poultry	.	egg	62.4	62.2	64.2	78.3	76.4	73.3
24										

data

In this spreadsheet the first two columns are index columns. To make this valid GAMS syntax we need to insert a dot between the index elements. A simple way is to insert a (narrow) column with a dot in each cell. This way we can import this table as:

```
Set
   l  'livestock types'      / sheep, goat, angora, cattle, buffalo, mule, poultry /
   cl 'livestk comm'         / meat, milk, wool, hide, egg /
   ty 'time periods - years' / 1974*1979 /;

$onEcho > yield.txt
I="%system.fp%yield.xls"
R=data!B2:J23
O=yield.inc
$offEcho

$call =xls2gms @yield.txt

Table yieldtl(l,cl,ty) 'livestock "yield" time series (kg per head)'
$include yield.inc
;

display yieldtl;
```

6.42.7 Interactive use

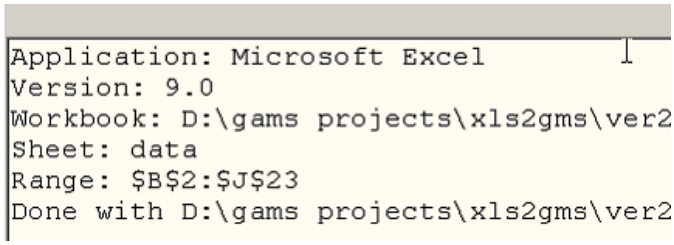
When the tool is called without command line parameters, it will startup interactively. Using it this way, one can specify the spreadsheet file (.XLS file), the range and the final destination file (a GAMS include file) using the built-in interactive environment. The main screen contains a number of buttons and edit boxes, which are explained below.

- **Input file (∗.XLS)**. This is the combo box to specify the input file. The file must be a valid MS Excel spreadsheet file (∗.XLS). The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation `\machine\directory\file.xls`.

- **Range**. The range can be left empty in which case the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). The range can also be a name if the spreadsheet contains named ranges. The browse button will start Excel allowing you to interactively select a range.

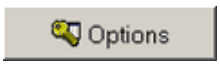
- **Output GAMS Include file (∗.INC)**. If you want to create a GAMS include file, then specify here the destination file. The include file will be an ASCII file that can be read by GAMS using the $include command. If the include file already exists, it will be overwritten.

- **Progress Memo**. This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.



- The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

- **options button** will pop up a window where you can specify a number of options.



- **help button** will show this help.

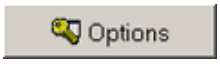
- the **OK button** is pressed the query will be executed and an include file will be generated.

- the **batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press Ctrl-C or choose Edit|Paste to copy the contents of the clipboard to a GAMS text file.

- **close button** will exit the application. The current settings will be saved in an INI file so when you run XLS2GMS again all current settings will be restored.

6.42.8 Options

The **Options** window can be created by pressing the options button:



The following options are available in the options window:

- **Quote blanks:** Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. (In the special case the string contains both, double quotes are replaced by single quotes). For more information see this example.

- **Mute:** Don't include the extra informational text (such as used query etc.) in the include file.

- **No listing:** Surround the include file by `$offlisting` and `$onlisting` so that the data will not be echoed to the listing file. This can be useful for very large data files, where the listing file would become too large to be handled comfortably.

- **Separator.** This option allows you to set a separator string to be written between cell entries. By default this is a blank. In some cases it can be useful to make this a comma. See example for an example where this is used to import sets. Note: when this option is set to an empty string, the results may not be syntactically correct for GAMS. As it is difficult to see the difference between a single blank and an empty string, the user interface will give some feedback for these cases. When an empty string is used, a warning is written to the include file.

- **Range Seperator.** Multiple ranges can be separated by a range separator symbol. By default this is a semi-colon. When certain non-US locales are used, the semi-colon is a list separator symbol which can be used in multi-area ranges. In case of such a conflict, it is possible to change the range separator symbol.

- **Append.** Append to the output file.

- **Browse Read-Only.** When the Browse Range button is pressed, we launch Excel and try to load the currently specified input file. If this option is checked then the input file is loaded as read-only. If this option is not checked the file is loaded normally, in which case you can change and save it.

The buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made, and all option settings will revert to their previous values.

- **Help button** will show this help text.

6.42.9 Batch use

When calling **XLS2GMS** directly from GAMS we want to specify all command and options directly from the command line or from a command file. An example is:

```
C:\tmp>xls2gms "I=c:\My Documents\test.xls" O=test.inc
```

This call will perform its task without user intervention. The batch facility can be used from inside a GAMS model, e.g.:

```
Table c(i,j) 'data from spreadsheet' /
$call =xls2gms I=C:\tmp\test.xls O=C:\tmp\data.inc R=B1:E10
$include C:\tmp\data.inc
/;
```

The $call statement is rather error prone and you will need to spend a little it of time to get the call correct and reliable.

All the possible command line options are listed in command line arguments section. A proper batch call will at least contain the following command line parameters:

1. I=inputfilename
2. O=outputincludefile

If you only specify **I=inputfilename** then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command line argument. Only if an input file and an output file is provided, the call will be considered a batch invocation.

6.42.10 Command-line Arguments

Argument	Description
I=inputfile	This option is required and specifies the name of the .XLS file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. If only the file name is used without a path, the file is searched in the current directory (this is the project directory when running under the IDE). On a network UNC names can be used, and files from another computer can be accessed, e.g. `"\\hostname\c\my documents\a.xls."` This option is required for batch processing.
O=outputincludefile	option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter statement. Make sure the directory is writable. UNC names can be used. An output file must be specified for batch operation.
R=range	range is an optional argument. If not specified the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). To specify a whole sheet use: Sheet2!. The range can also be a name if the spreadsheet contains named ranges. Both global names (e.g. R=rangename) and sheet specific range names (e.g. R=Sheet2!rangename) are recognized. To select multiple ranges in one go, you can specify: R=range1;range2;range3. This is just a short-hand for three separate invocations of xls2gms. A multiple-area range can be specified by R=area1,area2,area3. Before exporting, a new range is created consisting of the union of the areas. This can be used to drop certain rows or columns from a table.
D	Debug. This option can be used for debugging purposes. If specified the import filter will no run minimized but "restored", i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of **xls2gms**.
B	If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off.
M	Run in modest or mute mode: no additional information, such as version number etc. is written to the listing file.
L	Embed the data in $offlisting, $onlisting. A quick way to reduce the size of the listing file.
@filename @"file name"	Causes the program to read options from a file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if it were specified on the command line.
N=inifilename	Use a different Inifile than the standard **xls2gms.ini** located in the same directory as the executable **xls2gms.exe**.
A	Append to output files instead of overwriting them.
G="x"	Sets the range separator symbol
S="x"	Sets the output separator symbol

As invocations of **xls2gms** are reasonably expensive (a copy of Excel is started), there is a way to optimize related calls. From version 1.4, xls2gms allows multiple ranges to be read and multiple include files to be written in one swoop. The syntax is best explained by showing an illustrative example:

```
$call =xls2gms I=c:\tmp\x.xls R1=range1 R1=range2 R2=range3 O1=c:\tmp\f1.inc O2=c:\tmp\f2.inc
```

In this example the ranges 'range1' and 'range2' are written to the file 'f1.inc' while the range 'range3' will go to file 'f2.inc'. In general the ranges specified with Rn will be written to the file specified with On. If multiple ranges are specified, they are written sequentially to the output file.

```
$call =xls2gms I=c:\tmp\x.xls R=range1 R=range2 O=c:\tmp\f1.inc
```

In this example the ranges 'range1' and 'range2' are written to 'f1.inc'.

6.42.11 $CALL command

The **$CALL** command in GAMS will execute an external program at compile time. There are two forms:

```
$call externalprogram
```

```
$call =externalprogram
```

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=', bypasses the command processor and directly executes the external program. We mention some of the differences:

- Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE.
- If you want to execute these commands you will need to use the form `$call externalprogram` which uses the command processor. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form `$call externalprogram`.
- If it is important to stop with an appropriate error message if the external program does not exist, only use the form `$call =externalprogram`. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: `$call =externalprogram`.
- When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: `$call start /w externalwindowsprogram`. Otherwise, it is preferred to use: `$call =externalwindowsprogram`.

Attention

> In general it is recommended to use the `$call =externalprogram` version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

```
$call externalprogram parameter1 parameter2
```

```
$call =externalprogram parameter1 parameter2
```

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

```
$call '"external program" "parameter 1" "parameter 2"'
```

```
$call ="external program" "parameter 1" "parameter 2"
```

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes `only if` the = appears outside the double quotes.

6.42.12 Command files

Parameters can be specified in a command file. This is important if the length of the command line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command lines. Instead of specifying a long command line as in:

```
$call =xls2gms I="c:\My Documents\test.xls" O="c:\My Documents\data.inc" R="Sheet2!A1:F15"
```

we can use a command line like:

```
$call =xls2gms @"c:\My Documents\options.txt"
```

The command file `c:\My Documents\options.txt` can look like:

```
I=c:\My Documents\test.xls
O=c:\My Documents\data.inc
R=Sheet2!A1:F15
```

It is possible to write the command file from inside a GAMS model using the $echo command. The following example will illustrate this:

```
$set cmdfile "trnsport.txt"
$echo "I=trnsport.xls" > "%cmdfile%"
$echo "O=trnsport.inc" >> "%cmdfile%"
$call =xls2gms @"%cmdfile%"

$include trnsport.inc
```

Newer versions of GAMS allow:

```
$set cmdfile trnsport.txt
$onEcho > "%cmdfile%"
I=trnsport.xls
O=trnsport.inc
$offEcho
$call =xls2gms @"%cmdfile%"

$include trnsport.inc
```

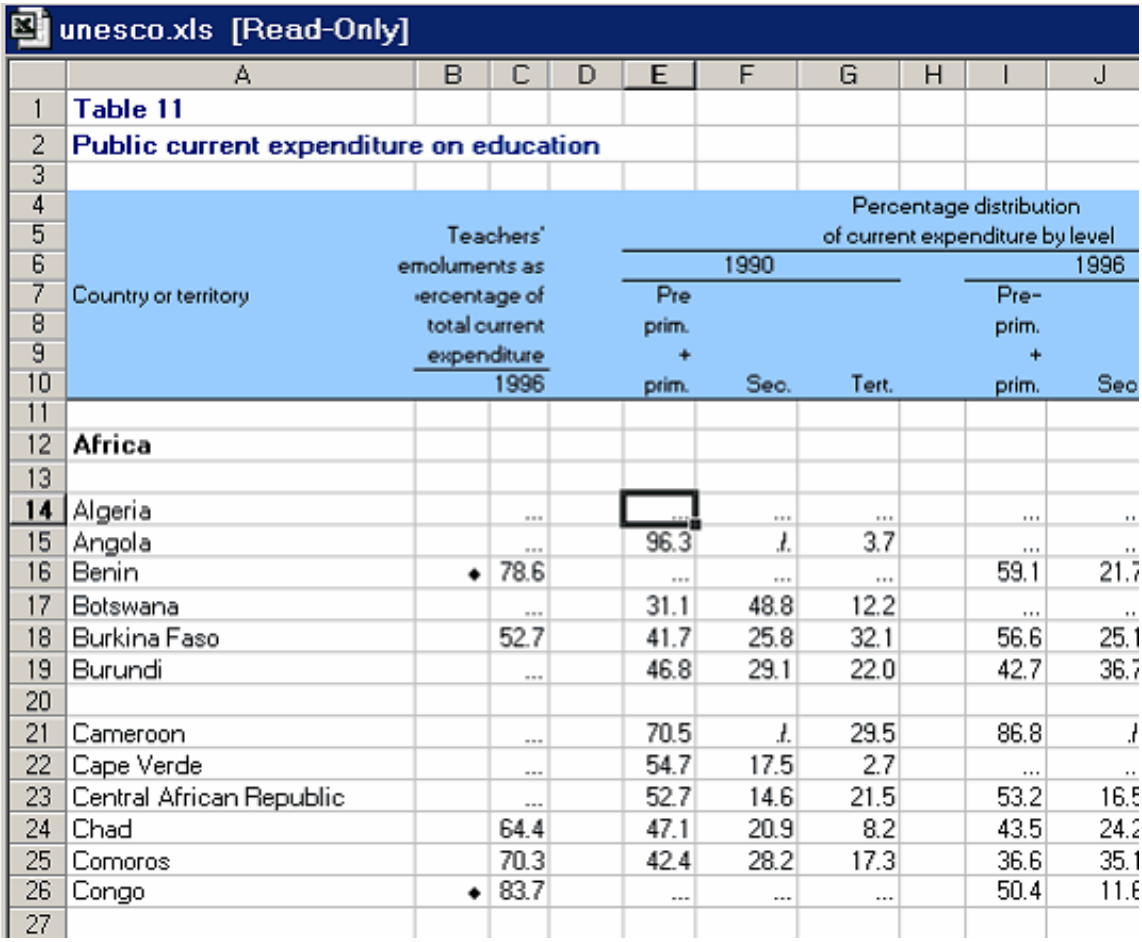
6.42.13 Multiple-area ranges and post-processing

The following fragment is from a spreadsheet from Unesco:

unesco.xls [Read-Only]

	A	B	C	D	E	F	G	H	I	J
1	**Table 11**									
2	**Public current expenditure on education**									
3										
4					Percentage distribution of current expenditure by level					
5		Teachers' emoluments as ercentage of total current expenditure			1990				1996	
6	Country or territory		1996		Pre prim. + prim.	Sec.	Tert.		Pre-prim. + prim.	Sec
7										
8	**Africa**									
9										
10	Algeria		...		...	...	...		...	..
11	Angola		...		96.3	.I.	3.7		...	..
12	Benin	◆	78.6		...	...	...		59.1	21.7
13	Botswana		...		31.1	48.8	12.2		...	..
14	Burkina Faso		52.7		41.7	25.8	32.1		56.6	25.1
15	Burundi		...		46.8	29.1	22.0		42.7	36.7
16										
17	Cameroon		...		70.5	.I.	29.5		86.8	.I
18	Cape Verde		...		54.7	17.5	2.7		...	..
19	Central African Republic		...		52.7	14.6	21.5		53.2	16.5
20	Chad		64.4		47.1	20.9	8.2		43.5	24.2
21	Comoros		70.3		42.4	28.2	17.3		36.6	35.1
22	Congo	◆	83.7		...	...	...		50.4	11.6
23										

Assume we want to extract the 1990 percentage distribution of current expenditure for the countries Algeria through Congo. The range to select is not a contiguous area but consists of several pieces. In Excel we can use the mouse and the Ctrl key to make a multiple selection:



unesco.xls [Read-Only]

	A	B	C	D	E	F	G	H	I	J
1	**Table 11**									
2	**Public current expenditure on education**									
3										
4					Percentage distribution of current expenditure by level					
5		Teachers'								
6		emoluments as			1990				1996	
7	Country or territory	ercentage of			Pre				Pre-	
8		total current			prim.				prim.	
9		expenditure			+				+	
10		1996			prim.	Sec.	Tert.		prim.	Sec
11										
12	**Africa**									
13										
14	Algeria		...		...	...	...		...	..
15	Angola		...		96.3	./.	3.7		...	..
16	Benin	◆	78.6		...	...	...		59.1	21.7
17	Botswana		...		31.1	48.8	12.2		...	..
18	Burkina Faso		52.7		41.7	25.8	32.1		56.6	25.1
19	Burundi		...		46.8	29.1	22.0		42.7	36.7
20										
21	Cameroon		...		70.5	./.	29.5		86.8	./
22	Cape Verde		...		54.7	17.5	2.7		...	..
23	Central African Republic		...		52.7	14.6	21.5		53.2	16.5
24	Chad		64.4		47.1	20.9	8.2		43.5	24.2
25	Comoros		70.3		42.4	28.2	17.3		36.6	35.1
26	Congo	◆	83.7		...	...	...		50.4	11.6
27										

The range is `A10,E10:G10,A14:A19,E14:G19,A21:A26,E21:G26,` where the comma's indicate the range is a multiple-area range. In this case we have six pieces. It is important that Excel understands that the union of the pieces forms a rectangular area. If this is not the case an error will be raised. (You can check this yourself by selecting a multi-area range and copying it to a new sheet: this operation will fail if the areas together don't form a rectangle).

The extracted text file will look like:

```
* -----------------------------------------------------
* XLS2GMS Version 2.3,  March 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----------------------------------------------------
* Application: Microsoft Excel
* Version:     9.0
* Workbook:    D:\gams projects\xls2gms\ver2.0\unesco.xls
* Sheet:       Sheet1
* Range:       $A$10,$E$10:$G$10,$A$14:$A$19,$E$14:$G$19,$A$21:$A$26,$E$21:$G$26
* -----------------------------------------------------
                          prim. Sec. Tert.
Algeria                    ...   ...  ...
Angola                    96.3  ./.  3.7
Benin                      ...   ...  ...
Botswana                  31.1  48.8 12.2
'Burkina Faso'            41.7  25.8 32.1
Burundi                   46.8  29.1 22
Cameroon                  70.5  ./.  29.5
'Cape Verde'              54.7  17.5 2.7
```

```
'Central African Republic' 52.7  14.6 21.5
Chad                        47.1  20.9 8.2
Comoros                     42.4  28.2 17.3
Congo                       ...   ...  ...
* ---------------------------------------------------
```

This file is not completely suitable for using in a GAMS model. The following edits would need to be made:

1. The header labels should get rid of the trailing dot.
2. Cells with ... should be replaced by blanks.
3. Cells with ./. should be replaced by blanks

In the GAMS distribution a subdirectory **gbin** contains lots of interesting Unix utilities. Some of these are very suited to do string processing on text files, such as **sed** and **awk**. In this case we can use sed with some substitution commands:

Command	Description
`s/prim\./prim /`	Replace "prim." by "prim ". We need to be careful to keep the table alignment correctly, so we replace the dot by a blank instead of just removing the dot. A dot is a special character in sed (it means "any character") so we escape it by specifying "\.".
`s/Sec\./sec /`	Replace "Sec." by "sec ".
`s/Tert\./tert /`	Replace "Tert." by "tert ".
`s/\.\.\./ /g`	Replace "..." by " ". The dots are escaped. We add g to indicate there there may be multiple instances on a line that must be replaced.
`s/\.\/\./ /g`	Replace "./." by " ". Both dots and '/' needs to be escaped.

The complete GAMS formulation can look like:

```
$onText
New version XLS2GMS ver 2.1 can handle
multiple-area ranges.
$offText

Set
   c   'countries'
       / Algeria, Angola, Benin, Botswana, 'Burkina Faso', Burundi, Cameroon
        'Cape Verde', 'Central African Republic', Chad, Comoros, Congo       /
   exp 'percentage distribution of current expenditure'
       / prim, sec, tert /;

$onEcho > commands.txt
I=%system.fp%unesco.xls
R=A10,E10:G10,A14:A19,E14:G19
O=unesco.inc
B
$offEcho

$call =xls2gms @commands.txt

$onEcho > sedcommands.txt
```

```
s/prim\./prim /
s/Sec\./sec /
s/Tert\./tert /
s/\.\.\./   /g
s/\.\/\./   /g
$offEcho

$call sed.exe -f sedcommands.txt unesco.inc > unescox.inc

Table distr(c,exp)
$include unescox.inc
;

display distr;
```

6.43 XLSDUMP

Attention

> `XLSDump` is deprecated (see GAMS 42 XLSDump release notes). Please use Connect agent RawExcelReader instead.

This program will write all worksheets of an Excel workbook to a gdx file. Unlike GDXXRW, the program does not require that Excel is installed. Windows platforms only.

6.43.1 Usage

```
XLSDump infile outfile
```

where

infile

> A valid Excel workbook

outfile

> Optional. The output gdx file. If no output file is specified, the name of the input file will be used to construct the name the output file.

6.43.2 Example

Consider the following working file 'test2.xlsx'.

Converting this workbook using xlsdump:

```
xlsdump test2.xlsx
```

Will generate the file `test2.gdx`. Showing this gdx file in the GAMS IDE:

The parameter VF:

6.44 Multi-Objective Optimization (MOO)

6.44.1 Introduction

In Multi-Objective Optimization (MOO) there is more than one objective function and there is no single optimal solution that simultaneously optimizes all the objective functions. In MOO the concept of optimality is replaced by *Pareto* efficiency or optimality. Pareto efficient (or optimal, nondominated, etc.) solutions are solutions that cannot be improved in one objective without deteriorating in at least one of the other objectives. The mathematical definition of an efficient solution is the following:

Without loss of generality assume that all objective functions f_k with $k = 1, ..., p$ are for minimization. A feasible solution x of a MOO problem is (strongly) efficient if there is no feasible solution x' such as $f_k(x') \leq; f_k(x)$ for $k = 1, ..., p$ with at least one strict inequality. A feasible solution x is weakly efficient if there is no feasible solution x' such as $f_k(x') < f_k(x)$ for $k = 1, ..., p$.

In case of a non-convex feasible objective and decision space (e.g. MIP), the set of efficient solutions can be further partitioned into supported and non-supported efficient solutions. Supported efficient solutions are optimal solutions of the weighted sum single objective problem for any non-negative weights (corner solutions of the feasible space). See the following graph that illustrates the difference between supported and non-supported efficient solutions:

A simple MOO method is *lexicographic optimization*. Lexicographic optimization presumes that the decision-maker has *lexicographic preferences*, ranking the efficient solutions to a *lexicographic order* of the objective functions. A lexicographic minimization problem can be written as:

$lex\ min\ f_1(x), f_2(x), ..., f_p(x)$
s.t.
$x \in S$

where x is the vector of decision variables, S is the feasible region, and $f_1(x), f_2(x), ..., f_p(x)$ are the p objective functions ordered from the most to the least important. A lexicographic minimization problem with p objective functions can be solved using a sequence of p single-objective optimization problems as follows:

For $i = 1, ..., p$ **do**

- Solve single-objective optimization problem:

  $min\ z_i$
  s.t.
  $f_k(x) = z_k\ \forall k = 1, ..., i-1$
  $x \in S$

  where z_k are the objective function variables
- Fix the value of objective function variable z_i for the following iterations

End for

The MOO methods provided by this LibInclude file use lexicographic optimization to calculate a *payoff* table to obtain e.g. ranges for the objectives. The $p \times p$ payoff table contains the results of p lexicographic optimizations with orders $\{f_1(x), f_2(x), ..., f_p(x)\}, \{f_2(x), f_3(x), ..., f_p(x), f_1(x)\}, ..., \{f_p(x), f_1(x), ..., f_{p-1}(x)\}$.

This LibInclude file provides a collection of methods to generate Pareto efficient solutions for MOO models. All implemented methods are so-called a-posteriori (or generation) methods for generating Pareto efficient solutions. After the Pareto efficient set or a representative subset of the Pareto efficient set has been generated, it is returned to the user, who then analyses the solutions and selects the most preferred among the alternatives.

6.44.2 Usage

LibInclude file `moo.gms` provides methods for multi-objective optimization in GAMS and can be used as follows:

```
$libinclude moo method modelName modelType objectiveSet direction objectiveVar points paretoPoints [
```

Where:

Argument	Description
`method`	Specify the name of the method to use. Available methods are `EpsConstraint`, `RandomWeighting`, and `Sandwiching`. See Methods for details.
`modelName`	Specify the name of the multi-objective optimization model that should be solved.
`modelType`	Specify the corresponding model type, e.g. `LP`.
`objectiveSet`	Specify the set of objectives.
`direction`	One-dimensional parameter that contains the optimization direction for each `objectiveSet` element - min (-1) or max (+1).
`objectiveVar`	Specify the objective function variable. Compared to the traditional scalar objective function variable with a single objective optimization problem in GAMS, this objective function variable is one-dimensional.
`points`	Specify the set of pareto points. The number of members in the set defines the maximum number of returned pareto points. Therefore, make sure to define the set large enough.
`paretoPoints`	Specify the two-dimensional (`points`,`objectiveSet`) parameter that will be used to save the objective values of pareto points.
`optList`	Optional list of `-optkey=optval` option pairs, e.g. `-savepoint=1 -optfile_main=99`. See available options below.

Method	Option	Description
All:	`debug`	Set to 1 to activate debugging. This will create additional information being written to the log as well as creating files to support debugging, e.g. if savepoint is activated a file `savepoint_iteration_map.csv` is written to the `savepoint_dir` that contains the mapping of savepoint files to the corresponding iteration. Default: 0.
	`optfile_init`	Solver option file for initial solves. In particular, solves to calculate the payoff table. Default: 0.
	`optfile_main`	Solver option file for main solves, i.e. the main part of the methods. Default: 0.
	`plot`	Set to 1 to activate plots for multi objective problems with two or three objective functions, e.g. a plot of the pareto points. Python package `matplotlib` needs to be installed. Default: 0.

Method	Option	Description
	plot_dir	Set the directory where plots should be saved. Per default the GAMS working directory will be used.
	pre	Prefix for names of GAMS symbols used in moo.gms. Allows to make GAMS symbol names unique and avoids problems with redefined symbols. The default is MOO_<MOO___COUNTER>, where MOO___COUNTER is a (global) compile-time variable that counts the MOO runs in the GAMS program, so each run has unique GAMS symbol names. This option allows to change the default.
	savepoint	If set to 1, a point format GDX file that contains information on the solution point will be saved for each pareto point. Default is 0, where no solution points will be saved.
	savepoint_dir	Set the directory where save point files should be saved. Per default the GAMS working directory will be used.
	savepoint_filename	Set the (base) name of the save point files. The file name gets extended by the points set to generate unique file names as follows: <savepoint_filename>_<points>.gdx. Per default this option is set to the name of the method. If an empty string is provided the file name matches exactly with the points set: <points>.gdx.
	solver	Default solver for all model types that the solver is capable to process.
EpsConstraint:	gridpoints	Specify the number of grid points per objective function used as a constraint (default: 10). As an example, consider a model with three objective functions, the Epsilon Constraint method will optimize one objective function using the other two as contraints. With 10 grid points (default) the maximum number of runs will therefore be 10x10. In general, increasing the number of grid points increases the density of the approximation.
RandomWeighting:	iterations	Terminating condition in terms of iterations. Default: inf.
	seed	Set the seed for the pseudo random number generator that generates the weights. Set to None to set the seed to a random number. Default: 3141.
	time	Terminating condition in terms of time in seconds. Default: 3600.

Method	Option	Description
Sandwiching:	`gap`	Terminating condition in terms of a gap (default: 0.01). The gap is calculated by the current maximum distance between the inner and outer approximation divided by the initial maximum distance.
	`time`	Terminating condition in terms of time in seconds. Default: 3600.

6.44.3 Methods

This section gives an introduction and details on the implemented methods for MOO. The implemented methods are so-called a-posteriori (or generation) methods for generating Pareto efficient solutions. After the Pareto efficient set or a representative subset of the Pareto efficient set has been generated, it is returned to the user, who then analyses the solutions and selects the most preferred among the alternatives.

6.44.3.1 Augmented Epsilon Constraint [EpsConstraint]

The Epsilon Constraint method optimizes one of the objective functions using the other objective functions as constraints. By parametrical variation in the Right-Hand Side (RHS) of the constrained objective functions the efficient solutions of the problem are obtained. The implemented Augmented Epsilon Constraint method is based on:

> Mavrotas, G., Effective implementation of the eps-constraint method in Multi-Objective Mathematical Programming problems. Applied Mathematics and Computation 213, 2 (2009), 455-465.

> Mavrotas, G., and Florios, K., An improved version of the augmented eps-constraint method (AUGMECON2) for finding the exact Pareto set in Multi-Objective Integer Programming problems. Applied Mathematics and Computation 219, 18 (2013), 9652-9669

The Augmented Epsilon Constraint method is a variation of the Epsilon Constraint method that produces only efficient solutions (no weakly efficient solutions) and also avoids redundant iterations as it can perform early exit from the relevant loops (that lead to infeasible solutions) and exploits information from slack variables in every iteration.

Compared to the Random Weighting method the runs are exploited more efficiently and almost every run produces a different efficient solution, thus obtaining a better representation of the efficient set. Allowed model types: **LP**, **MIP** as well as corresponding **Non Linear** cases. The method is able to find the exact Pareto set for integer programming problems by appropriately tuning the number of grid points. The Augmented Epsilon Constraint method is able to produce supported and unsupported efficient solutions.

Implementation details:

- The Augmented Epsilon Constraint method optimizes one of the objective functions using the other objective functions as constraints, incorporating the constraint part of the model as follows:

  $max(f_1(x) + eps \times (s_2/r_2 + 10^{-1} \times s_3/r_3 + ... + 10^{-(p-2)} \times s_p/r_p))$

  s.t.
  $f_2(x) - s_2 = e_2$
  $f_3(x) - s_3 = e_3$
  ...
  $f_p(x) - s_p = e_p$
  $x \in S$ and $s_k \in \mathbb{R}^+$

  where x is the vector of decision variables, S is the feasible region, and $f_1(x), f_2(x), ..., f_p(x)$ are the p objective functions. e_k are the parameters for the RHS for the specific iteration drawn from the grid points of the objective functions k ($k = 2, 3, ..., p$). s_k are slack or surplus variables, r_k is the range of the k-th objective function (calculated from the payoff table), and $eps \in [10^{-6}, 10^{-3}]$.

- The method is implemented as follows: From the payoff table we obtain the range of the $p-1$ objective functions that are used as constraints. The range of the k-th objective function is divided into q_k equal intervals using $(q_k - 1)$ intermediate equidistant grid points. Thus, we have in total $(q_k + 1)$ **grid points** that are used to vary parametrically the RHS (e_k) of the k-th objective. The total number of runs becomes $(q_2 + 1) \times (q_3 + 1) \times ... \times (q_p + 1)$.

  The discretization step for objective function k:

  $step_k = r_k/q_k$

  The RHS of the corresponding constraint in the i-th iteration in the specific objective function will be:

  $e_{ki} = fmin_k + i_k \times step_k$

  where $fmin_k$ is the minimum obtained from the payoff table and i_k the counter for the specific objective function.

- At each iteration we check the surplus variable that corresponds to the innermost objective function (in this case $p = 2$) and calculate the bypass coefficient as:

  $b = floor(s_2/step_2)$

  Where $floor()$ is a function that always rounds down and returns the largest integer less than or equal to a given number. When the surplus variable s_2 is larger than the $step_2$ it is implied that in the next iteration the same solution will be obtained with the surplus variable being $s_2 - step_2$. Therefore, the bypass coefficient actually indicates how many consecutive iterations can be bypassed.

- Early exit from the loop when the problem becomes infeasible for some combination of e_k. The bounding strategy for each one of the objective functions starts from the more relaxed formulation (lower bound for maximization objective function or upper bound for a minimization) and move to the most strict. If we arrive to an infeasible solution there is no need to perform the remaining runs of the loop, as the problem will become even stricter.

6.44.3.2 Random Weighting [RandomWeighting]

With the Random Weighting method, the weighted sum of the objective functions is optimized. By randomly varying the weights different pareto points are obtained.

Allowed model types: All model types with an objective variable, in particular **LP**, **MIP**, **NLP**, and **MINLP**. Note that the Random Weighting method may spend a lot of runs that are redundant in the sense that there can be a lot of combinations of weights that result in the same efficient point. Also note that the Random Weighting method cannot produce unsupported efficient solutions.

Implementation details:

- For Random Weighting the scaling of the objective functions has a strong influence on the obtained results. Therefore, the objective functions are scaled between 0 and 1 using the objective function ranges obtained from the payoff table.

6.44.3.3 Sandwiching

Sandwiching algorithms are used to approximate the pareto front by sandwiching the nondominated set between an inner and outer approximation. Sandwiching algorithms iteratively improve both the Inner and Outer approximation of the Pareto Set (IPS and OPS) to minimize the distance between the approximations. The implemented Sandwiching method is based on:

> Koenen, M., Balvert, M., and Fleuren, HA. (2023). A Renewed Take on Weighted Sum in Sandwich Algorithms: Modification of the Criterion Space. (Center Discussion Paper; Vol. 2023-012). CentER, Center for Economic Research.

An advantage of the Sandwiching method is that the distance between the IPS and OPS provides an upper bound on the approximation error which can also be used as a termination criterion for the algorithm. Please be aware that for more than two objectives the distance using the definition of the Koenen et al. (2023) can sometimes increase over the iterations. Allowed model type: **LP**.

Implementation details:

- The Sandwiching algorithm of Koenen et al. (2023) is based on a weighted sum approach, i.e. the weighted sum of the objective functions is optimized. By varying the weights at each iteration the efficient points are obtained. The algorithm selects weights derived from the IPS that have the potential to reduce the approximation error the most.
- The IPS is a convex hull encompassed in the objective space formed by a set of efficient points and the OPS is formed by supporting halfspaces of those efficient points.
- The basic procedure of the algorithm can be described as follows:
  1. **Initialize the IPS and OPS** using the pseudo nadir point and so called anchor points. The pseudo nadir point and anchor points are obtained from the payoff table and also define the initial bounding box of the objective space.
  2. **Expand the IPS based on its distance to the OPS**. For each relevant hyperplane of the convex hull of the IPS determine the distance to the OPS and find the hyperplane for which the current distance from the IPS to the OPS is maximal. The normal of this hyperplane will be used as weights in the current iteration. If a new efficient point is found, update the IPS and OPS, otherwise set the distance of the current hyperplane to zero. The procedure is repeated until a stopping criterion is met (see options `gap` or `time`).
- The calculation of the distance between IPS and OPS is based on SUB (see Koenen et al. (2023)).
- The scaling of the objective functions has a strong influence on the obtained results. Therefore, the objective functions are scaled between 0 and 1 using the objective function ranges obtained from the payoff table.

6.44.4 Examples

6.44.4.1 Example 1: Solve scalable multi-objective knapsack model

The following example demonstrates how to solve a multi-objective knapsack model (MIP) using the `moo` LibInclude:

```
$if not set NBITM $set NBITM 50
$if not set NBDIM $set NBDIM  2
$if not set NBOBJ $set NBOBJ  2

Set
   i 'items'                / i1*i%NBITM% /
   j 'weight dimensions'    / j1*j%NBDIM% /
   k 'value dimensions'     / k1*k%NBOBJ% /
   p 'pareto points'        / point1*point1000 /;

Parameter
   a(i,j)           'weights of item i'
   c(i,k)           'values of item i'
   b(j)             'knapsack capacity for weight j'
   dir(k)           'direction of the objective functions 1 for max and -1 for min' / #k 1/
   pareto_obj(p,k)  'objective values of the pareto points'
;
a(i,j) = UniformInt(1,100);
c(i,k) = UniformInt(1,100);
b(j)   = UniformInt(1,100) * %NBITM%/4;

Variable
   Z(k) 'objective variables'
   X(i) 'decision variables';

Binary Variable X;

Equation
   objfun(k) 'objective functions'
   con(j)    'capacity constraints';

objfun(k).. sum(i, c(i,k)*X(i)) =e= Z(k);

con(j)..    sum(i, a(i,j)*X(i)) =l= b(j);

Model example / all /;

$libinclude moo EpsConstraint example MIP k dir Z p pareto_obj -gridpoints=20

display pareto_obj;
```

The example is easily scalable by allowing to set the number of items, the number of weight dimensions and the number of objectives through double dash parameters. This example is also part of the GAMS Data Utilities Library, see model **[moo01]** for reference. The model is solved using `EpsConstraint` method with 20 `gridpoints`. The objective function values of the pareto points found are saved in parameter `pareto_obj`:

```
----    618 PARAMETER pareto_obj  objective values of the pareto points

                k1          k2

point1     953.000    1076.000
point2     956.000    1062.000
point3     972.000    1052.000
point4    1005.000    1037.000
point5    1030.000    1024.000
point6    1049.000    1004.000
```

```
point7     1063.000     990.000
point8     1088.000     955.000
point9     1091.000     946.000
point10    1105.000     932.000
point11    1121.000     876.000
point12    1130.000     827.000
point13    1137.000     783.000
```

If `plot` is set to 1 and Python package `matplotlib` is installed, a plot of the pareto points is generated:

Setting `--NBOBJ=3` with model [**moo01**] allows to solve a knapsack problem with three objectives. These are the resulting pareto points:

6.44.4.2 Example 2: Solve multi-objective power generation model

The following example demonstrates how to solve a multi-objective power generation model (LP) using the `moo` LibInclude:

```
$inlineCom [ ]

$if not set NBOBJ $set NBOBJ  2
$if not set METHOD $set METHOD Sandwiching

Set
   p       'power generation units' / Lignite, Oil, Gas, RES /
   i       'load areas'             / base, middle, peak     /
   pi(p,i) 'availability of unit for load types' / Lignite.(base,middle)
                                                   Oil.(middle,peak), Gas.set.i
                                                   RES.(base, peak)            /
   es(p)   'endogenous sources'  / Lignite, RES /
   k       'objective functions' / cost, CO2emission, endogenous /
   points  'pareto points' / point1*point1000 /;

$set min -1
$set max +1

Parameter dir(k) 'direction of the objective functions 1 for max and -1 for min'
                 / cost %min%, CO2emission %min%, endogenous %max% /
          pareto_obj(points,k) 'objective values of the pareto points';

Set pheader / capacity, cost, CO2emission /;

Table pdata(pheader,p)
                          Lignite    Oil    Gas    RES
   capacity [GWh]           61000  25000  42000  20000
   cost [$/MWh]                30     75     60     90
   CO2emission [t/MWh]       1.44   0.72   0.45      0;

Parameter
   ad        'annual demand in GWh'          / 64000 /
   df(i)     'demand fraction for load type' / base 0.6, middle 0.3, peak 0.1 /
   demand(i) 'demand for load type in GWh';

demand(i) = ad*df(i);
```

```
Variable
   z(k)      'objective function variables';

Positive Variable
   x(p,i)    'production level of unit in load area in GWh';

Equation
   objcost   'objective for minimizing cost in K$'
   objco2    'objective for minimizing CO2 emissions in Kt'
   objes     'objective for maximizing endogenous sources in GWh'
   defcap(p) 'capacity constraint'
   defdem(i) 'demand satisfaction';

objcost..   sum(pi(p,i), pdata('cost',p)*x(pi)) =e= z('cost');

objco2..    sum(pi(p,i), pdata('CO2emission',p)*x(pi)) =e= z('CO2emission');

objes..     sum(pi(es,i), x(pi)) =e= z('endogenous');

defcap(p).. sum(pi(p,i), x(pi))  =l= pdata('capacity',p);

defdem(i).. sum(pi(p,i), x(pi))  =g= demand(i);

Model example / all /;

Set kk(k) 'active objective functions';
kk(k) = yes;
$if %NBOBJ%==2 kk('endogenous') = no;

$libinclude moo %METHOD% example LP kk dir z points pareto_obj -iterations=20 -gridpoints=5 -savepoi
execute 'gdxmerge savepoints%system.DirSep%*.gdx > %system.NullFile%';

display pareto_obj;
```

This example is also part of the GAMS Data Utilities Library, see model **[moo02]** for reference. The model is solved using the `Sandwiching` method with a `gap` of 0.01 (default). The objective function values of the pareto points found are saved in parameter `pareto_obj`:

```
----   1164 PARAMETER pareto_obj  objective values of the pareto points

              cost  CO2emissi~

point1 2112000.000   85824.000
point2 3180000.000   50580.000
point3 4470000.000   20340.000
```

In addition, `savepoint` is activated and thus, for each pareto point a point format GDX file that contains information on the solution point will be written. Using `gdxmerge` all savepoint GDX files can be merged into a single GDX file.

If `plot` is set to 1 and Python package `matplotlib` is installed, a plot of the pareto front is generated:

The plot shows the pareto efficient extreme points as well as the lines connecting these points (the IPS). An animation of the algorithm shows how the IPS and OPS are updated at each iteration:

Starting with the initial points from the payoff table, the IPS and the OPS are constructed (iteration 0). In iteration 1, a new point is found and the IPS and OPS are updated. In the last two iterations no new

point is found but the OPS is updated so the upper bound on the approximation error (distance between the IPS and OPS) decreases and the gap of 0.01 is reached.

Setting --NBOBJ=3 with model [**moo02**] allows to solve a power generation problem with three objectives. This is the resulting pareto front:

6.45 Model Instances (pyEmbMI)

Libinclude file pyembpy.gms for the GAMS Python API class GAMSModelInstance. An instance of this class provides access to a model instance that can be modified and resolved without regenerating the model over and over.

Usage:

```
$libinclude pyEmbMI myPyMI 'solve statement' [optlist] updateList
```

Where:

Argument	Description
myPyMI	Name of the GAMSModelInstance Python identifier.
solve statement	Part of the solve statment that gives model name, solver type and optimization direction / variable, e.g. transport minimize z us lp.
optlist	Optional list of -optkey=optval option pairs, e.g. -reslim=100 -all_model_types=cplex that build update a GamsOption object used in the instantiate call. See **gams.control.options.GamsOptions Class Reference** for details.
updateList	List of update tuples (see details below): Variable update tuples: gmsModelVar.Lower|Upper|Fixed|Primal|Dual.gmsPar.Zero|BaseCa Parameter update pairs: gmsModelPar.Zero|BaseCase|Accumulate

The update tuples contain instructions how to deal with updating variable/equation attributes (mostly bounds) and parameters: If you want to change a parameter the entries holds the syntax: x.action where x is the GAMS name of the parameter and action is the update type of the parameter. This identifies how a parameter is updated if there is no data corresponding to the set intersection defining the parameter.

- parametername.Zero will set all parameter values that are not explicitly set to zero.
- parametername.BaseCase will set all parameter values that are not explicitly set to the value from the first model instantiation.
- parametername.Accumulate will keep all parameter values that are not explicitly set to their last known value.

To update an attribute of a variable/equation 4 things need to be considered:

- What variable or equation to work with

- What attribute to change (e.g. upper and lower corresponding bounds)
- What parameter contains the new values
- What to do with zeros which is the `Zero`, `BaseCase`, and `Accumulate` from above. This is expressed in the `tuple variableName.attribute.parameterWithNewValues.zeroKeyword`. For example `x.Upper.xUp.BaseCase` would reset upper bounds for `x` to the values in the parameter `xup` and set the values that are not explicitly set to their last known value.

Hence a call to this include might look like this:

```
$libinclude pyEmbMI miTransport 'transport minimizing z using lp' -all_model_types=cplex  x.Upper.xU
```

Embedded Code Model Instance Example

The GAMS Embedded Code facility allows to execute foreign code (e.g. Python) while GAMS runs and to exchange data with GAMS without any disk access (e.g. GDX).

In this example we combine the power of the embedded code facility with the GAMS Python OO-API class `GAMSModelInstance`. An instance of this class provides access to a model instance that can be modified and resolved without regenerating the model over and over.

Here we generate the model instance once by using the libinclude `pyEmbMI`. The arguments to this call provide all necessary information to instantiate an instance of a `GAMSModelInstance`. In particular we provide the relevant part of the solve statement as well as a list of modifiers. These are the parameters in the model that are subject to change. In addition we can provide some options belonging to a GAMS/Python OO-API class `GAMSOptions` via the `-key=value` pairs. See more about the use of `GAMSModelInstance` and `GAMSOptions` in the GAMS/Python OO-API.

Background:

A traditional GAMS implemenation of a scenario loop looks like this:

```
loop(ScenariosToRun,
   a(i) = newsupply(ScenariosToRun,i);
   b(j) = newdemand(ScenariosToRun,j);
   solve transport using lp minimizing z;
   resultantx(ScenariosToRun,i,j) = x.l(i,j)
);
```

With the embedded code/GAMSModelInstance solution this loop looks as follows:

```
$libInclude pyEmbMI tMI 'transport us lp min z' -all_model_types=cplex a.Zero b.Zero
loop(ScenariosToRun,
   a(i) = newsupply(ScenariosToRun,i);
   b(j) = newdemand(ScenariosToRun,j);
   continueEmbeddedCode:
   gams.db['a'].copy_symbol(tMI.sync_db['a'])
   gams.db['b'].copy_symbol(tMI.sync_db['b'])
   tMI.solve()
   tMI.sync_db['x'].copy_symbol(gams.db['x'])
   pauseEmbeddedCode x
   resultantx(ScenariosToRun,i,j) = x.l(i,j);
);
```

With a little helper function `solveMI` (see below) this code becomes even more similar:

```
$libInclude pyEmbMI tMI 'transport us lp min z' -all_model_types=cplex a.Zero b.Zero
loop(ScenariosToRun,
   a(i) = newsupply(ScenariosToRun,i);
   b(j) = newdemand(ScenariosToRun,j);
   continueEmbeddedCode:
   solveMI(tMI,['a','b'],['x'])
   pauseEmbeddedCode x
   resultantx(ScenariosToRun,i,j) = x.l(i,j);
);
```

In contrast to GUSS/Scenario Solver here we implement the loop logic in GAMS and execute in the loop body the solve method of the `GAMSModelInstance` class inside the embedded Python code. Rather than using the `gams.get|set` method of the embedded code facility we use `GAMSDatabase.copy_symbol` to move data between GAMS (`gams.db`) and the `GAMSModelInstance.sync_db`.

Note

Even though we don't exercise the ability in this example, the combination of `GAMSModelInstance` and embedded code provides a way of defining the scenario n+1 based on the result (primal and dual) of the nth scenario. This is not possible in GUSS/Scenario Solver.

Example:

```
* GMSPYTHONLIB gets automatically set to use the internal Python installation in sysdir/GMSPython.
$if not setEnv GMSPYTHONLIB $abort.noError Embedded code Python not ready to be used
$log --- Using Python library %sysEnv.GMSPYTHONLIB%

```

The complete example is also part of the GAMS Model Library, see model [**embmiex1**] for reference.

6.46 Sorting (rank)

Libinclude file `rank.gms` for ranking one-dimensional numeric data.

Developed by Thomas F. Rutherford, Department of Economics, University of Colorado

Usage:

```
$libInclude rank v s r [p]
```

Where:

Type	Argument	Description
Input:	*v(s)*	Array of values to be ranked.
	s	A one-dimensional set, the domain of array *v*.
Output:	*r(s)*	Rank order of element *v(s)*, an integer between 1 and card(s), ranking from smallest to largest.
Optional: (input and output)	*p(*)*	On input this vector specifies percentile levels to be computed. On output, it returns the linearly interpolated percentiles.

Note:

- `rank` only works for numeric data. You cannot sort sets.
- The first invocation must be outside of a loop or if block. This routine may be used within a `loop` or `if` block only if it is first initialized with blank invocations (`"$libInclude rank"` in a context where set and parameter declarations are permitted (See Example 3).
- The following names are used within these routines and may not be used in the calling program:

  `rank_tmp` `rank_u` `rank_p`

- This routine returns rank values and does not return `sorted vectors`, however rank values are easily used to produce a sorted array. This can be done using computed "leads" and "lags" in GAMS' ordered set syntax, as illustrated in examples 1 and 3 below.

6.46.1 Examples

6.46.1.1 Example 1: Rank a vector, and display the data in sorted order

```
Set
   i 'Set on which random data are defined'   / a, b, d, c, e, f /
   k 'Ordered set for displaying sorted data' / 1*6 /;

Parameter
   x(i)   'Random data to be sorted'
   r(i)   'Rank values'
   s(k,i) 'Sorted data';

x(i) = uniform(0,1);

$libInclude rank x i r
display x;

* Generate a sorted list using the ordered set k.

* This assignment statement illustrates how the rank orders
* can be used to sort output for display in proper order.  This
* statement uses GAMS support for computed "leads" and "lags"
* on the ordered set k.  The loop is used to improve execution
* speed for larger dimensional sets:

loop(k$sameas(k,"1"),
   s(k+(r(i)-1),i) = x(i);
);

option  s:3:0:1;
display s;
```

This example is also part of the GAMS Data Utilities Library, see model **[rank01]** for reference. It writes the following lines to ex1.lst:

```
----     11 PARAMETER x  Random data to be sorted

a 0.172,    b 0.843,    d 0.550,    c 0.301,    e 0.292,    f 0.224

----     75 PARAMETER s  Sorted data

1.a 0.172
2.f 0.224
3.e 0.292
4.c 0.301
5.d 0.550
6.b 0.843
```

The `rank` libinclude can be used to also sort variable levels as the following example shows:

```
Set
   i 'Set on which random data are defined'   / a, b, d, c, e, f /
```

```
   k 'Ordered set for displaying sorted data' / 1*6 /;

Variable
   x(i)   'Random data to be sorted'
Parameter
   r(i)   'Rank values'
   s(k,i) 'Sorted data';

x.l(i) = uniform(0,1);

$onDotL
$libInclude rank x i r
display x.l;

loop(k$sameas(k,"1"),
   s(k+(r(i)-1),i) = x(i);
);

option  s:3:0:1;
display s;
```

Before the "`$libInclude rank`" the dollar control option $onDotL needs to be activated.

6.46.1.2 Example 2: Generate percentiles for a random vector

```
Set
   i 'Set on which random data are defined' / a, b, d, c, e /
   p 'Percentiles (all of them)'            / 0*100 /;

Parameter x(i) 'Random data to be sorted';

* Generate the random data on set i:
x(i) = uniform(0,1);
display x;

Parameter
   r(i)   'Rank values'
   pct(*) 'Percentiles to be computed' / 20 20.0, median 50.0, 75 75.0 /;

* Generate ranks and compute the specified percentiles (Note that
* the rank array, r, is required, even if the values are not used.)

$libInclude rank x i r pct

* Display three percentiles:
display pct;
```

This example is also part of the GAMS Data Utilities Library, see model [**rank02**] for reference. The random data are displayed as follows in the listing file:

```
----     11 PARAMETER x  Random data to be sorted

a 0.172,    b 0.843,    d 0.550,    c 0.301,    e 0.292
```

The interpolated percentiles are computed as follows:

```
----    103 PARAMETER pct  Percentiles

20     0.268,    75     0.550,    median 0.301
```

The following code evaluates a full set of percentiles, from 1 to 100. The GAMS special value of EPS is used to represent zero in the percentile calculation. (Percentiles between zero and one are not permitted to avoid misunderstandings about how percentiles are scaled.) The code makes use of Tom Rutherfords plot libInclude available at http://www.mpsge.org/gnuplot/index.html

```
pct(p) = (ord(p) - 1) + eps;
pct("median") = 0;
display pct;

$libInclude rank x i r pct
display pct;

* Plot the results using GNUPLOT:

Set pl(p) / 20, 40, 60, 80, 100 /;
$setGlobal domain p
$setGlobal labels pl
$libInclude plot pct
```

This is the generated plot:

6.46.1.3 Example 3: Use RANK to report multisectoral Monte Carlo results

One of the most perplexing challenges in economic modeling with GAMS is to present multisectoral results in an easily interpreted format. One simple idea is to present sectoral results in a sorted sequence to make it easier to identify the most seriously affected sectors. The presentation of results in a multisectoral model is made even more challenging when model results are generated for a randomized set of scenarios. A summary of Monte Carlo results involves reporting both mean results and their sensitivity. One means of characterizing the sensitivity of model results is to report functions of the sample distribution such as the upper and lower quartiles.

This example illustrates how `rank` can be used to help report results from the Monte Carlo analysis of a multisectoral model.

The complete model used as example here is part of the GAMS Data Utilities Library, see model **[rank03]** for reference. The following extract of that model generates the result we want to look at.

```
* Determine ranking of sectors by mean impact:
mean(i) = qvalue(i,"mean");
$libInclude rank mean i meanrank

* The following statement creates a tuple matching the ordered
* set, ki, to the set of sectors, i.  In this tuple, the sequence of
* assignments corresponds to increasing mean impacts:
imap(ki+(meanrank(i)-ord(ki)),i) = yes;

* Evaluate quartiles of sectoral impacts for each sector:
```

```
loop(i,
   x(s) = v(s,i);

*  Load quartile with the perctiles to be
*  evaluated (25th, 50th and 75th):
   quartile(qtl) = qv(qtl);

$  libInclude rank x s r quartile

*  Save the quartile values:
   qvalue(i,qtl) = quartile(qtl);
);
display qvalue;

Parameter results(ki,i,*) 'Summary of impacts (sorted)';
results(ki,i,"mean")$imap(ki,i) = mean(i);
results(ki,i,qtl)$imap(ki,i)    = qvalue(i,qtl);
display results;
```

The program produces the following display output:

```
              q25         q50         q75        mean

25.TRD       5.694       6.454       7.250       6.476
26.AIR       5.227       7.182       9.276       7.320
27.FIN       4.919       7.301      10.175       7.640
28.COA       6.581       7.818       9.125       7.878
29.TMS       5.668       8.530      11.086       8.591
30.CHM       8.071       9.299      10.534       9.319
31.TRK       7.031       9.367      11.851       9.577
32.MAR       9.485      13.072      16.424      13.049
33.GAS       4.437      13.183      22.311      13.462
34.FME      14.794      16.617      18.382      16.642
35.NFM      23.299      26.398      29.281      26.263
```

The tabular report is helpful, but it does not convey the results as immediately as a picture. GNUPLOT's errorbar plot format is a convenient graphical format for portraying this information. The libinclude interface to GNUPLOT does not support this type of plot, so the continuation of the program produces the GNUPLOT command and data files before invoking the GNUPLOT program:

```
* Write out a GNUPLOT file to generate a chart of the results:

File kplt / ex3.gnu /;
put  kplt;
kplt.lw = 0;

put "reset"/;
put 'set title "Sectoral Impacts with Quartiles"'/;
put "set linestyle 1 lt 8 lw 1 pt 8 ps 0.5"/;
put "set grid"/;
put 'set ylabel "% change"'/;
put "set xzeroaxis"/;
put "set bmargin 4"/;
put "set xlabel 'sector'"/;
put 'set xrange [1:',card(i),']'/;
put 'set xtics rotate (';
loop(ki, loop(i$imap(ki,i), put '\'/' "',i.tl,'" ', ord(ki):0,',';));
put @(file.cc-1) ')'/;
put "plot 'ex3.dat' notitle with errorbars ls 1"/;
putClose;

File kpltdata / ex3.dat /;
put  kpltdata;
kpltdata.nr =  2;
kpltdata.nw = 14;
kpltdata.nd =  6;
loop(ki, loop(i$imap(ki,i), put ord(ki):0,qvalue(i,"mean"), qvalue(i,"q25"), qvalue(i,"q75")/;));
putClose;
execute 'wgnupl32 ex3.gnu -';
```

This is the generated plot:

6.46.1.4 Example 4: Repeated computation of percentiles within a loop

The following code extract shows how to do repeated computation of percentiles within a loop while the data is changing. This is an extract of the model **[rank04]** from the GAMS Data Utilities Library.

```
* Do several iterations, computing percentiles in each step:

loop(iter,
*  Substitute a call to the NLP solver by a call to the random
*  number generator.  In many applications, this substitution
*  produces profoundly more sensible results.
*
*  solve catchment using nlp maximizing max;

   z(week) = uniform(0,1);

*  If you want to retrieve percentile values, you need to reassign
```

```
*  the percentiles that you wish to retrieve at this point in the
*  program.  If pct() were not reassigned at this point, the INPUT
*  values would correspond to the OUTPUTs from the previous call.

   pct(pctl) = pct0(pctl);

$  libInclude rank z week rnk pct

   pctval(iter,pctl) = pct(pctl);
);

display pctval;
```

Output:

```
----     58 Here are the INPUT values of PCT0 and PCT prior to the call to rank:

----     58 PARAMETER pct0  Percentiles to be computed

50 50.000,    75 75.000,    80 80.000,    95 95.000

----     58 PARAMETER pct  Percentiles to be computed (input) and those values (output)

50 50.000,    75 75.000,    80 80.000,    95 95.000

----    153 Here are the values of PCT0 and PCT after the call to rank:

----    153 PARAMETER pct0  Percentiles to be computed

50 50.000,    75 75.000,    80 80.000,    95 95.000

----    153 Note that rank has changed the OUTPUT value of pct

----    153 PARAMETER pct  Percentiles to be computed (input) and those values (output)

50 0.424,    75 0.662,    80 0.712,    95 0.864

----    273 PARAMETER pctval  Percentile values in successive iterations

               50          75          80          95

iter1       0.345       0.594       0.638       0.922
iter2       0.385       0.633       0.672       0.941
iter3       0.474       0.705       0.766       0.962
iter4       0.627       0.796       0.823       0.978
iter5       0.428       0.682       0.793       0.904
iter6       0.422       0.690       0.729       0.958
iter7       0.558       0.716       0.756       0.902
iter8       0.451       0.638       0.726       0.942
iter9       0.464       0.704       0.755       0.916
iter10      0.564       0.805       0.831       0.974
```

6.46.1.5 Example 5: Generating percentiles for heterogenous households.

```
$title Percentile ranking of household expenditure data with heterogenous household size

Set h / 0*100 /;

Parameter
   y(h)    'Aggregate expenditure associated with household type h'
   n(h)    'Number of persons associated with household type h'
   ypc(h)  'Per-capita expenditure of household type h'
   rank(h) 'Rank of household in per-capita expenditure';

* Assign some random values:
y(h)   = uniform(0.2,1.2);
n(h)   = uniform(1,6);
ypc(h) = y(h)/n(h);

* Assign ranks to household based on per-capita expenditures:
$libInclude rank ypc h rank

* Now determine percentile ranking of the households taking into account
* differences in numbers of members and household representation:
Set r 'Temporary set used for ranking' / r0*r100 /;

Parameter
   pcttmp(r) 'Temporary array for computing percentiles'
   pct(h)    'Percentile rankings for households';

Set r0(r) / r0 /;

* First, create an array with households assigned
loop((r0(r),h), pcttmp(r+(rank(h)-1)) = n(h););
loop(r,         pcttmp(r) = pcttmp(r) + pcttmp(r-1););
pcttmp(r) = pcttmp(r)/sum(h, n(h));

loop((r0(r),h), pct(h) = pcttmp(r+(rank(h)-1)););

Parameter ranking 'Ranking of households and expenditures';

loop((r0(r),h),
   ranking(r+(rank(h)-1),h,"n")   = n(h);
   ranking(r+(rank(h)-1),h,"ypc") = ypc(h);
   ranking(r+(rank(h)-1),h,"pct") = pct(h);
);

display ranking;
```

This example is also part of the GAMS Data Utilities Library, see model [**rank05**] for reference. It produces the following output:

```
                    n         ypc         pct
r0  .43         5.662       0.044       0.018
r1  .8          5.682       0.047       0.036
r2  .58         4.477       0.052       0.050
r3  .14         5.742       0.058       0.068
r4  .55         4.815       0.063       0.083
```

```
r5   .65        3.702       0.063       0.094
r6   .61        5.880       0.064       0.113
r7   .54        4.463       0.064       0.127
....
r98  .62        1.134       0.640       0.991

```

Chapter 7

Application Programming Interfaces

The Application Programing Interfaces (APIs) to GAMS allow the seamless integration of GAMS into an application. The APIs by provides appropriate classes for the interaction with GAMS. The `GAMSDatabase` class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the `GAMSJob` class and by using the `GAMSModelInstance` class a sequence of closely related model instances can be solved in the most efficient way. Note that the GAMS object-oriented API was not designed to offer modeling capability. The model needs to be formulated in GAMS and passed on to the `GAMSJob` class.

Five versions of object-oriented GAMS APIs :

- **.NET API** with Target Framework Version 4.6.2,
- C++ API works with C++17 or later,
- Java API works with Java SE 11 or later. The non-mainstream version of Java API that works with Java SE 8 is still available with maintenance support, but the functionality that is newer than GAMS 43 will be not available in this version. See Java Release Notes and Java Tutorial for more details.
- Python API works with Python 3.8 to 3.12.
- Matlab API works with Matlab 2017b (or later) and Octave 5.2 (or later).

In addition to the object-oriented GAMS APIs, there exist an R API and expert-level (or low-level) GAMS APIs in which its usage requires advanced knowledge of GAMS component libraries.

See Executing GAMS from other Environments if you want to execute GAMS directly from an application without using APIs.

7.1 Object-oriented APIs

The Reference Manuals give an overview of the features provides by GAMS APIs, release notes, and a list of all classes with descriptions. The Tutorials provide an overview of the basic functionality of the GAMS APIs and the Examples provides a list of examples available with GAMS distribution with detailed description. See also Release Notes and Supported Platforms.

7.1.1 Reference Manuals

The GAMS APIs reference manuals give an overview of the features provides by GAMS APIs, release notes, and a list of all classes with descriptions.

- .NET API
- C++ API
- Java API
- Python API
- Matlab API

7.1.2 Tutorials

GAMS API Tutorials provide an overview of basic functionalities of GAMS APIs and allow a user to get started to work with the GAMS API.

- .NET API Tutorial
- C++ API Tutorial
- Java API Tutorial
- Python API Tutorial
- Matlab API Tutorial

7.1.3 Examples

There are several examples avaiable for the different programming languages: .NET, C++, Java, and Python. Below we give a description of each example together with its link to the detailed page in different languages.

Examples	.NET	C++	Java	Python
Alias	Alias		Alias	alias.py
Benders2Stage	Benders2Stage, Benders2StageMT		Benders2Stage, Benders2StageMT	benders_2stage.py, benders_2stage_mt.py
Clad	Clad		Clad	clad.py
CutStock	Cutstock, SimpleCutstock		CutstockModel, SimpleCutstock, Cutstock	cutstock_class.py, simple_cutstock.py, cutstock.py
Domain Checking	DomainChecking	domainchecking.cpp	DomainCheck	domain_checking.py
Graphical User Interface (GUI)				
- CutstockGUI	CutStockGUI			

Examples	.NET	C++	Java	Python
- FarmGUI	FarmGUI			
- InterruptGUI	InterruptGui		InterruptGUI	interrupt_gui.py
- TransportGUI	TransportGUI		TransportGUI	
GAMS Remote Object	GAMSServer, GAMSClient			
Interrupt	Interrupt		ConsoleInterrupt	interrupt.py
Markowitz	Markowitz			markowitz.py
MessageReceiver Window	MessageReceiverWindow			
Special Values	SpecialValues		SpecialValues	special_values.py
Transport Model Sequence	Transport, Transport1 - Transport14	transport.cpp, transport1.cpp - transport14.cpp	TransportModel, Transport1 - Transport14	transport_class.py, transport1.py - transport14.py
Traveling Salesman Problem	Tsp		Tsp	tsp.py
Warehouse	Warehouse	warehouse.cpp	Warehouse	warehouse.py
Unit Test	NUnitTest			

These examples are available with the GAMS distribution in `[Path/To/GAMS]/apifiles/` directory. In that directory, the file `readme.txt` describes how to build and execute these examples. A GAMS script to compile and execute each example is available in `[Path/To/GAMS]/apilib_ml/` directory with a **table of contents**.

7.1.3.1 Alias

The Object-oriented API does not have the concept of a GAMS alias. An alias cannot be entered into a GAMSDatabase by API methods. Nevertheless, if the GAMSDatabase is loaded from a GDX container (e.g. the GAMSJob.OutDB), the database can contain aliases. Such an alias can be retrieved as a GAMSSet and consists of the elements of the aliased set. The method to find out if a GAMSSet in a GAMSDatabase is indeed an alias is to check if the symbol name is different from the lookup name (i.e. bool isAlias = db.GetSet("ii").Name != "ii"). This example model goes through the logic of how aliases are handled in the Object-oriented API.

See Alias example in [**.NET**, **Java**, **Python**].

7.1.3.2 Benders2Stage

This example implements a simple Benders decomposition method for a stochastic linear program. The underlying model implements a simple distribution system with stochastic demand data. This example actually consists of two programs: A sequential and a parallel implementation. In the sequential version, the master and the subproblems are implemented with the GAMSModelInstance object which allows resolving the model with modified input without regenerating the model. A GAMSModelInstance has a fixed model rim, so this provides a challenge for Benders master problem because every iteration adds new constraints (the Benders cuts) to the master. We get around this limitation of GAMSModelInstance by initializing the GAMSModelInstance of the master with a fixed number of empty (i.e. non-binding) placeholders constraints and during the run of the algorithm turn these placeholder constraints into valid Benders cuts. The parallel version extends the Benders2Stage example by solving the independent subproblems in parallel. For that we need to instantiate a separate GAMSModelInstance for each parallel

worker. We use the efficient GAMSModelInstance. CopyInstance method to accomplish this in the most effective way. The number of demand scenarios can be larger than the number of parallel workers. The distribution of work is handles through a work queue. The parallel execution of the subproblems is done in separate threads (the MT in the name of the example stands for Multi Threading), so there is very little overhead from disk activity.

See Bender2Stage example in [**.NET**, **Java**, **Python**] and Bender2StageMT example in [**.NET**, **Java**, **Python**].

7.1.3.3 Clad

This example demonstrates how to implement a complex termination criterion for a difficult MIP using GAMS/Cplex. We would like to achieve a globally optimal solution (relative gap 0%) but if solution time becomes larger than n1 seconds, we can compromise for a 10% gap, and if this is not achieved after n2 seconds, we compromise for a 20% gap, and again if this is not accomplished in n3 seconds we take whatever the solver has done so far and terminate the solve. This is implemented by executing GAMSJob.run in an independent thread and providing new tolerances for the relative gap in the main thread by supplying new GAMS/Cplex option files and triggers the processing of the new tolerance option by GAMS/Cplex through the GAMSJob.Interrupt method.

See Clad example in [**.NET**, **Java**, **Python**].

7.1.3.4 CutStock

This example contains two programs that implement a column generation approach to solve the cutting stock problem. In the program SimpleCutsock, the column generation scheme has been implemented in GAMS. Moreover the GAMS model with the input and output data has been wrapped in a class that separates all interaction with GAMS from the driving application. In the second example, the column generation approach has been entirely implemented in the program using GAMSJob for the master and GAMSModelInstance for the pricing problem. GAMS is used to build the master and pricing problems. The logic of the column generation method is in the application program.

See Cutstock Model example in [**.NET**, **Java**, **Python**], SimpleCustock example in [**.NET**, **Java**, **Python**], and Custock example in [**.NET**, **Java**, **Python**].

7.1.3.5 Domain Checking

Enforcing referential integrity also known in the GAMS lingo as domain checking is an essential and important part of GAMS. The Object-oriented API does a delayed domain checking of symbols. So you can add records to a domain controlled parameter (e.g. p(i)) even though the GAMSSet i does not contain the label (yet). The user can trigger an explicit check of the referential integrity by calling the GAMSDatabase.CheckDomains (or GAMSSymbol.CheckDomains). The Object-oriented API provides methods to access the records that violate the referential integrity (see GAMSDatabaseDomainViolation for details). Domain checking is implicitly done when the GAMSDatabase is exported to a GDX file via the GAMSDatabase.Export method or for databases provided in the GAMSJob.Run method. The implicit domain check can be suppressed (and left to GAMS when importing data) via the GAMSDatabase.SuppressAutoDomainChecking property. This example demonstrates how to trigger domain checking and how to access the records that violate the referential integrity.

See Domain checking example in [**.NET**, **C++**, **Java**, **Python**].

7.1.3.6 GUI Examples

Modern development frameworks like Microsoft's Visual Studio, Python, and Java allow to quickly build graphical user interfaces. Every example consists of a simple GUI that provides data entry, executing of a GAMSJob and graphically represents the results of a GAMS model.

- **CutstockGUI**: This example allows to either load data from a database or to enter data manually. A cutting stock problem is solved by using both the GAMSJob and the GAMSModelInstance class in order to implement a decomposition approach. See also CutStock Example. See this example in [**.NET**].
- **InterruptGUI**: This small example demonstrates how to run a GAMS model in a graphical user interface. This has all rudimentary features we know from the GAMS IDE: starting a job, capture the GAMS log in a window, and providing a button to interrupt. The underlying mechanism to interrupt the job is similar to the Interrupt Example (GAMSJob.Interrupt), but the trigger mechanism is very different. See this example in [**.NET**, **Java**, **Python**].
- **FarmGUI**: For this farming model, the input data can be entered directly into several tables. The GAMS model itself is executed by using one single GAMSJob instance. Results are displayed in different charts and tables. See this example in [**.NET**].
- **TransportGUI**: In this example a series of transportation problems is solved using GAMSModelInstance. Data can be entered into tables or can be loaded from a database. When data is entered into a table, related tables are updated automatically. Results are shown in tables and/or a bar chart. See also Transport Model Sequence Example. See this example in [**.NET**, **Java**].

7.1.3.7 GAMS Remote Object

This example demonstrates how to implement a simple GAMS Server. The example has two parts: GAMSServer and GAMSClient. The example is configured to run the client and server on the same machine, but can easily be altered to run on different machines. Both client and server need access to the GAMSRemoteClass that implements the server. The method to communicate is very simple. The client sets up the ingredients for a GAMSJob (model text, GDX input, parameters) and sends them serialized (via a byte representation of the GDX and parameter file) to the server. The server recreates the GAMS objects from the serialized representations, runs the model, and ships GAMSJob.OutDB serialized back to the client for further processing.

See GAMSServer example in [**.NET**] and GAMSClient in [**.NET**].

7.1.3.8 Interrupt

Ctrl-C in a regular console application results in the interrupt of the entire job. GAMS users are used to the fact that Ctrl-C interrupts a solve but then continues with the execution of the remaining GAMS job. The example demonstrates how to alter some console properties to get this behavior of Ctrl-C.

See Interrupt example in [**.NET**, **Java**, **Python**].

7.1.3.9 Markowitz

This is a small graphical program that plots the efficient frontier of Markowitz' portfolio selection problem with the two objectives return and risk. The example utilizes the GAMSModelInstance class to solve the parameterized objective max lambda∗return - (1-lambda)∗risk in the most efficient way.

See Markowitz example in [**.NET**, **Python**].

7.1.3.10 MessageReceiver Window

The little example demonstrates how to implement a custom visual log. From GAMS one can send messages to the form started by this program via the put_utility "winmsg". The form also understands some commands (a message that starts with @) to save the content of the form, to put the content into the clipboard, or to terminate the program. The MessageReceiverWindow is also distributed as an executable in the GAMS system directory ready to be used. The model mrw01 in the GAMS Test Library demonstrates the use of the program.

See MessageReceiver Window example in [**.NET**].

7.1.3.11 Special Values

This example shows how special values of the programming language (e.g. infinity) percolate down to GAMS. Infinity and NaN (not a number) are well defined. The GAMS Undefined and EPS need special considerations.

See Special Values example in [**.NET**, **Java**, **Python**].

7.1.3.12 Transport Model Sequence

This set of examples demonstrates the use of the Object-oriented API on the simple transport model **trnsport.gms : A Transportation Problem** [trnsport]. The detailed description of the various examples is provided in the Object-oriented API tutorials in the GAMS documentation.

See Transport Model example in [**.NET**, **C++**, **Java**, **Python**].

7.1.3.13 Traveling Salesman Problem

This example demonstrates how to use a GAMSModelInstance to implement the subtour elimination algorithm for the Traveling Salesman Problem (TSP) problem. Similar to Benders2Stage example, we have a placeholder for the subtour elimination constraint that gets generated in each iteration of the algorithm. In contrast to the Benders example, here we regenerate the GAMSModelInstance if the original number of placeholders was not big enough. We continue this process until all subtours are eliminated.

See Traveling Salesman Problem example in [**.NET**, **Java**, **Python**].

7.1.3.14 Unit Test

This example contains all the unit tests we run on the .Net Object-oriented API. See Unit Test example in [**.NET**].

7.1.3.15 Warehouse

This example demonstrates how to solve a simple GAMS model to assign stores to warehouses for different data sets in parallel. The model has been parameterized. The data can be derived from a few numbers namely the number of warehouses, stores, and some fixed cost scalar. The results of the model are written into a single result database that is protected across the parallel threads via a mutex.

See Warehouse example in [**.NET**, **C++**, **Java**, **Python**].

7.1.4 Release Notes

GAMS API Release Notes provide an overview of changes to the GAMS APIs in releases of the GAMS distribution.

- Java API Release Notes

7.1.5 Supported Platforms

	x86 64bit MS Windows	x86 64bit Linux	x86 64bit macOS	arm 64bit macOS
GAMS C++	✓	✓	✓	✓
GAMS Java	✓	✓	✓	✓
GAMS.NET	✓	✓	✓	✓
GAMS Python	✓	✓	✓	✓
GAMS Matlab	✓	✓	✓	✓

7.2 Expert-Level APIs

In addition to the object-oriented GAMS API, there exist expert-level (or low-level) APIs to some component libraries of the GAMS system. These APIs are used internally in GAMS for a long time and help in the deployment of GAMS models. While they offer high performance and flexibility, they also require advanced knowledge and it is recommended that the object-oriented GAMS API is used if possible. The expert-level APIs are offered for *C*, *C#*, *Delphi*, *Fortran*, *Java*, *Python*, and *Visual Basic*.

The DCT, GEV, and GMO components are mainly used to build solver links to GAMS (see, e.g., the `GAMSLinks project`. In fact, all professional GAMS solver links are based on these components. They provide access to an instance of a model generated by a `solve` statement. If you plan to build advanced algorithms for models or need to solve a sequence of very similar models these components might represent an alternative to an implementing using the GAMS language.

While we also strive for backward compatibility with our component libraries, but programming interfaces are commonly subject to change, so programs based on these APIs might require adjustment when updating to a new GAMS version. The Release Notes have a section on these API changes.

Overviews of the exported function in pseudo code are available in the following summary pages:

- `CFG API` (GAMS Configuration Object)
- `DCT API` (GAMS Dictionary Object)
- `GDX API` (GAMS Data Exchange Object) which is also available as `open source project on GitHub` with `additional documentation`.
- `GEV API` (GAMS Environment Object) with additional GAMS Environment Object Options.

- GMO API (GAMS Modeling Object) with additional information on philosophy and design.
- IDX API (GAMS IDX Object)
- OPT API (GAMS Option Object)
- PAL API (GAMS Auditing and Licensing Object)

Note

Without having a GAMS system directory in the PATH environment variable, the xyzCreateD functions (e.g. gdxCreateD, optCreateD, ...) might cause some issues finding libraries that are only in the GAMS system directory on Windows.

7.2.1 Supported Platforms

	x86 64bit MS Windows	x86 64bit Linux	x86 64bit macOS	arm 64bit macOS
C	✓	✓	✓	✓
C#	✓			
Delphi	✓			
Fortran∗	✓	✓	✓	✓
Java	✓	✓	✓	✓
Python	✓	✓	✓	✓
VBA	✓			
VB.NET	✓			

∗ Fortran API files are based on C code to load dynamic libraries. For Windows pure Fortran API files for Intel and Lahey Fortran compilers are included

7.3 C++ API

GAMS C++ API provides a convenient way to exchange input data and model results with in-memory representation of data (**GAMSDatabase**), and to create and run GAMS models (**GAMSJob**) that can be customized by GAMS options (**GAMSOptions**). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (**GAMSModelInstance**).

7.4 Java API

GAMS Java API provides a Java programming interface to the General Algebraic Model System (GAMS). GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be

customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. The use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute_load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object GAMSWorkspace manages the anchor to the file system.

With the exception of GAMSWorkspace the objects in the gams namespace cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GAMSModelInstance class).

Note

If you use multiple instances of the GAMSWorkspace in parallel, you should avoid using the same WorkingDirectory. Otherwise you may end up with conflicting file names.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GAMSModelInstances. Some solvers will not work in a multi-threaded application using GAMSModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GAMSModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Java API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.

7.5 Python API

The GAMS API is a Python package that contains several sub-modules that enable the control of the GAMS system as well as the movement of data between GAMS and Python. Currently the API supports the Python versions 3.8 to 3.12. The following table gives an overview of all available sub-modules:

Sub-Module	Description
connect (beta)	Used primarily by GMSPython to digest YAML syntax to Extract, Transform and Load (ETL) data into GAMS, but can be used in native Python environments.
control	Enables full control of the GAMS System
core	Core GAMS API tools used to connect to GDX, GMD, GMO and other GAMS objects. Requires expert level knowledge.
engine	GAMS Engine API (OpenAPI compliant), manages jobs with GAMS Engine
magic (beta)	Enables the use of GAMS from within Jupyter notebooks
tools (beta)	Code base for the GAMS tools library
transfer	Data Only API – Allows GAMS data to be maintained outside a GAMS script

Note

Due to compatibility issues the GAMS Python API does not work with the Python interpreter from the Microsoft Store.

To install the API please visit: Getting Started.

7.5.1 Migrate import statements

With the release of GAMS 42 the GAMS Python ecosystem has been restructured – the new structure has many benefits (easier/safer (un)installs, cleaner module namespaces, etc.).

Attention

The new API structure cannot be used to simply "update" previous versions – users should build new python environments from scratch before attempting to install.

Restructuring of the GAMS python API ecosystem was confined to the creation of the new nested structure – class, method and other variables names were not modified. The import statements in legacy code will need to be updated if using the new system. Best practice will be to use the new package structure to import different sub-modules as needed (and avoid `from <module_name> import *` syntax). We provide a mapping between the old syntax and the new to aid in the transition to the new API structure:

Old `import` statement	New `import` recommendation(s)
`from gams import GamsWorkspace`	`from gams import GamsWorkspace`
`from gams import *`	`import gams`

`from gdxcc import *`	`from gams.core import gdx`
	-or-
	`import gams.core.gdx as gdx`

`from optcc import *`	`from gams.core import opt`
	-or-
	`import gams.core.opt as opt`

`import gamstransfer as gt`	`from gams import transfer as gt`
	-or-
	`import gams.transfer as gt`

`import gams_engine`	'import gams.engine'

Note

Jupyter users will need to migrate their `reload_ext gams_magic` -> `reload_ext gams.magic` and `load_ext gams_magic` -> `load_ext gams.magic`

7.5.1.1 Testing for Old vs New API

Users may be running the same python code with different versions of the Python API. If this is the case, it might be beneficial to include conditional import statements. It is possible to test for the GAMS major version number with the `GamsWorkspace.api_major_rel_number` property:

```
from gams import GamsWorkspace
if GamsWorkspace.api_major_rel_number<42:  # old API structure
    import gdxcc as gdx
    from gams import *
    import gamstransfer as gt
else:  # new API structure
    import gams.core.gdx as gdx
    from gams.control import *
    import gams.transfer as gt
```

Attention

While conditional import statements can be helpful, users are strongly encouraged to modify their code to use the new structure.

7.5.2 GAMS Python API Structure

7.5.3 Magic (Jupyter Notebooks)

Note

This feature is currently in beta status.

7.5.3.1 Introduction

GAMS Jupyter Notebooks allow to use notebook technology in combination with GAMS. If you just want to learn GAMS there are probably better ways doing this. Notebooks allow you to combine GAMS and Python. The former works great with well structured data and optimization models, while the latter is very rich in features to retrieve, manipulate, and visualize data that comes in all sort of ways. Combining GAMS and Python in a notebook it is relatively easy to tell an optimization story with text, data, graphs, math, and models.

7.5.3.2 Getting Started

The first step in getting started with GAMS Jupyter Notebooks is to make your Python 3 installation aware of the GAMS Python API described in the Getting Started section of the API tutorial. We recommend to follow the steps below which are specifically tailored for getting started with GAMS Jupyter notebooks. While any Python 3.8 to 3.12 installation is supported, we recommend the use of `miniconda` Python distributions.

Attention

All core third party dependencies will be installed if the user supplies the optional `pip` syntax (`pip install gamsapi[magic]`).

In addition to the GAMS Python API collection (and the core `magic` dependencies), the examples located in `[PATH TO GAMS]/api/python/examples/magic` will require the additional packages: `jupyterlab`, `matplotlib`, and `tabulate`. The following code section shows how to create and set up a `conda` environment for GAMS Jupyter notebooks:

The notebooks `Millco.ipynb` and `Introduction.ipynb` located in `api/python/examples/magic` are good starting points to get familiar with Jupyter notebooks and GAMS. The remainder of this section gives the dialog of the `Introduction.ipynb` notebook. Please see also the other notebook examples:

- `PickStock Example`
- `Filling grids with (distinct) polyominos`
- `DICE Model from 2018 Nobel laureate William D. Nordhaus`
- `PickStock Analysis using R`

7.5.3.3 Tutorial

7.5.3.4 Converting GAMS Jupyter Notebooks into Python Scripts

Sometimes it can be useful to execute the logic of a GAMS Jupyter notebook in a standalone Python script. This can be achieved by using the `gams.magic.GamsInteractive` class which implements the back-end logic of `gams.magic` and does require neither `IPython` nor `jupyter`. Translating GAMS magic commands into Python method equivalents is stright forward. First, the Python equivalent of `%reload_ext gams.magic` needs to be added to the beginning of a Python script:

```
from gams.magic import GamsInteractive
gams = GamsInteractive()
```

Afterwards, each magic command or method available in GAMS Jupyter notebooks has an equivalent in `GamsInteractive` with the same name. GAMS magic commands like `%gams` or `%gams_reset` can be translated into methods of the exact same name - in this case `GamsInteractive.gams()` and `GamsInteractive.gams_reset()`. Methods and properties which are accessed directly (without GAMS magic command) in a Jupyter notebook like `gams.exchange_container` or `gams.activate()` can be used in the exact same way from within `GamsInteractive`. Options and parameters of GAMS magic commands can be used with corresponding arguments of the equivalent methods.

While GAMS magic commands can be translated very easily, certain interactive functionality like chart plotting might require a different mechanism when being translated. Also `display()` might need to be changed into `print()` or similar to be working in a standalone Python script. In addition, Jupyter notebooks display data which is returned by the last command of a Python cell. In Python we need to use another `print()` of the return value to get it as output.

For a complete example of a translated GAMS Jupyter notebook see `[PATH TO GAMS]/api/python/examples/magic/millc` which is a translation of the `Millco.ipynb` notebook.

7.5.4 Transfer

`transfer` is a tool to maintain GAMS data outside a GAMS script in a programming language like Python or Matlab. It allows the user to add GAMS symbols (Sets, Aliases, Parameters, Variables and Equations), to manipulate GAMS symbols, as well as read/write symbols to different data endpoints. `transfer`'s main focus is the highly efficient transfer of data between GAMS and the target programming language, while keeping those operations as simple as possible for the user. In order to achieve this, symbol records – the actual and potentially large-scale data sets – are stored in native data structures of the corresponding programming languages. The benefits of this approach are threefold: (1) The user is usually very familiar with these data structures, (2) these data structures come with a large tool box for various data operations, and (3) optimized methods for reading from and writing to GAMS can transfer the data as a bulk – resulting in the high performance of this package. This documentation describes, in detail, the use of `transfer` within a Python environment.

Data within `transfer` will be stored as Pandas DataFrame. The flexible nature of Pandas DataFrames makes them ideal for storing/manipulating sparse data. Pandas includes advanced operations for `indexing and slicing`, `reshaping`, `merging` and even `visualization`.

Pandas also includes a number of advanced data `I/O tools` that allow users to generate DataFrames directly from CSV (`.csv`), JSON (`.json`), HTML (`.html`), Microsoft Excel (`.xls`, `.xlsx`), SQL , pickle (`.pkl`), SPSS (`.sav`, `.zsav`), SAS (`.xpt`, `.sas7bdat`), etc.

Centering `transfer` around the Pandas DataFrame gives GAMS users (on a variety of platforms – macOS, Windows, Linux) access to tools to move data back and forth between their favorite environments for use in their GAMS models.

The goal of this documentation is to introduce the user to `transfer` and its functionality. This documentation is not designed to teach the user how to effectively manipulate Pandas DataFrames; users seeking a deeper understanding of Pandas are referred to the extensive `documentation`.

Experienced GAMS API users seeking detailed documentation and examples are directed to Main Classes and Additional Topics.

7.5.4.1 Recommended Import

Users can access the `transfer` sub-module with either of the following (equivalent) import statements once the GAMS Python API has been installed:

```
import gams.transfer as gt
from gams import transfer as gt
```

7.5.4.2 Design

Storing, manipulating, and transforming sparse data requires that it lives within an environment – this data can then be linked together to enable various operations. In `transfer` we refer to this "environment" as the `Container`, it is the main repository for storing and linking our sparse data. Symbols can be added to the `Container` from a variety of GAMS starting points but they can also be generated directly within the Python environment using convenient function calls that are part of the `transfer` package; a symbol can only belong to one container at a time.

The process of linking symbols together within a container was inspired by typical GAMS workflows but leverages aspects of object oriented programming to make linking data a natural process. Linking data enables data operations like implicit set growth, domain checking, data format transformations (to dense/sparse matrix formats), etc – all of these features are enabled by the use of ordered `pandas.CategoricalDtype` data types. All of these details will be discussed in the following sections.

7.5.4.3 Naming Conventions

Methods – functions that operate on a object – are all verbs (i.e., `getMaxAbsValue()`, `getUELs()`, etc.) and use camel case for identification purposes. Methods are, by convention, tools that "do things"; that is they involve some, potentially expensive, computations. Some `transfer` methods accept arguments, while others are simply called using the `()` notation. Plural arguments (`columns`) hint that they can accept lists of inputs (i.e., a list of symbol names) while singular arguments (`column`) will only accept one input at a time.

Properties – inherent attributes of an object – are all nouns (i.e., `name`, `number_records`, etc.) and use snake case (lower case words separated by underscores) for identification purposes. Object properties (or "object attributes") are fundamental to the object and therefore they are not called like methods; object properties are simply accessed by other methods or user calls. By convention, properties only require trival amounts of computation to access.

Classes – the basic structure of an object – are all singular nouns and use camel case (starting with a capital first letter) for identification purposes.

7.5.4.4 Install

The user must download and install the latest version of GAMS in order to install `transfer`. `transfer` is installed when the GAMS Python API is built and installed. The user is referred HERE for instructions on how to install the Python API files. `transfer` and all GAMS Python API files are compatible with environment managers such as Anaconda.

7.5.4.5 Examples

GDX Read

Reading in all symbols can be accomplished with one line of code (we reference data from the **`trnsport.gms`** example).

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
```

All symbol data is organized in the data attribute – `m.data[<symbol_name>].records` (the `Container` is also subscriptable, `m[<symbol_name>].records` is an equivalent statement) – records are stored as Pandas DataFrames.

Write Symbol to CSV

Writing symbol records to a CSV can also be accomplished with one line.

```
m["x"].records.to_csv("x.csv")
```

Write a New GDX

There are six symbol classes within `transfer`: 1) Sets, 2) Parameters, 3) Variables, 4) Equations, 5) Aliases and 6) UniverseAliases. For purposes of this quick start, we show how to recreate the `distance` data structure from the **`trnsport.gms`** model (the parameter `d`). This brief example shows how users can achieve "GAMS-like" functionality, but within a Python environment – `transfer` leverages the object oriented programming to simplify syntax.

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
# create the sets i, j
i = gt.Set(m, "i", records=["seattle", "san-diego"], description="supply")
j = gt.Set(m, "j", records=["new-york", "chicago", "topeka"], description="markets")
# add "d" parameter -- domain linked to set objects i and j
d = gt.Parameter(m, "d", [i, j], description="distance in thousands of miles")
# create some data as a generic DataFrame
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
# setRecords will automatically convert the dist DataFrame into a standard DataFrame format
d.setRecords(dist)
# write the GDX
m.write("out.gdx")
```

This example shows a few fundamental features of `transfer`:

1. An empty Container is analogous to an empty GDX file
2. Symbols will always be linked to a Container (notice that we always pass the Container reference `m` to the symbol constructor)
3. Records can be added to a symbol with the `setRecords()` method or through the `records` constructor argument (internally calls `setRecords()`). `transfer` will convert many common Python data structures into a standard format.
4. Domain linking is possible by passing domain set objects to other symbols
5. Writing a GDX file can be accomplished in one line with the `write()` method.

Full Example

It is possible to use everything we now know about `transfer` to recreate the **`trnsport.gms`** results in GDX form. As part of this example we also introduce the `write` method (and generate `new.gdx`). We will discuss it in more detail in the following section: GDX Read/Write.

```
import gams.transfer as gt
# create an empty Container object
m = gt.Container()
# add sets
i = gt.Set(m, "i", records=["seattle", "san-diego"], description="supply")
j = gt.Set(m, "j", records=["new-york", "chicago", "topeka"], description="markets")
# add parameters
a = gt.Parameter(m, "a", ["*"], description="capacity of plant i in cases")
b = gt.Parameter(m, "b", j, description="demand at market j in cases")
d = gt.Parameter(m, "d", [i, j], description="distance in thousands of miles")
```

```
f = gt.Parameter(
    m, "f", records=90, description="freight in dollars per case per thousand miles"
)
c = gt.Parameter(
    m, "c", [i, j], description="transport cost in thousands of dollars per case"
)
# set parameter records
cap = pd.DataFrame([("seattle", 350), ("san-diego", 600)], columns=["plant", "n_cases"])
a.setRecords(cap)
dem = pd.DataFrame(
    [("new-york", 325), ("chicago", 300), ("topeka", 275)],
    columns=["market", "n_cases"],
)
b.setRecords(dem)
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
d.setRecords(dist)
# c(i,j) = f * d(i,j) / 1000;
cost = d.records.copy(deep=True)
cost["value"] = f.records.loc[0, "value"] * cost["value"] / 1000
c.setRecords(cost)
# add variables
q = pd.DataFrame(
    [
        ("seattle", "new-york", 50, 0),
        ("seattle", "chicago", 300, 0),
        ("seattle", "topeka", 0, 0.036),
        ("san-diego", "new-york", 275, 0),
        ("san-diego", "chicago", 0, 0.009),
        ("san-diego", "topeka", 275, 0),
    ],
    columns=["from", "to", "level", "marginal"],
)
x = gt.Variable(
    m, "x", "positive", [i, j], records=q, description="shipment quantities in cases",
)
z = gt.Variable(
    m,
    "z",
    records=pd.DataFrame(data=[153.675], columns=["level"]),
    description="total transportation costs in thousands of dollars",
)
# add equations
cost = gt.Equation(m, "cost", "eq", description="define objective function")
supply = gt.Equation(m, "supply", "leq", i, description="observe supply limit at plant i")
demand = gt.Equation(m, "demand", "geq", j, description="satisfy demand at market j")
# set equation records
cost.setRecords(
    pd.DataFrame(data=[[0, 1, 0, 0]], columns=["level", "marginal", "lower", "upper"])
)
supplies = pd.DataFrame(
    [
        ("seattle", 350, "eps", float("-inf"), 350),
        ("san-diego", 550, 0, float("-inf"), 600),
    ],
    columns=["from", "level", "marginal", "lower", "upper"],
)
supply.setRecords(supplies)
demands = pd.DataFrame(
    [
        ("new-york", 325, 0.225, 325),
        ("chicago", 300, 0.153, 300),
        ("topeka", 275, 0.126, 275),
    ],
    columns=["from", "level", "marginal", "lower"],
)
demand.setRecords(demands)
m.write("new.gdx")
```

7.5.4.6 Extended Examples

Get HTML data

```
import gams.transfer as gt
```

```
import pandas as pd
url = "https://www.fdic.gov/resources/resolutions/bank-failures/failed-bank-list"
dfs = pd.read_html(url)
# pandas will create a list of dataframes depending on the target URL, we just need the first one
df = dfs[0]
m = gt.Container()
b = gt.Set(m, "b", ["*"], records=df["Bank NameBank"].unique(), description="Bank Name")
s = gt.Set(
    m,
    "s",
    ["*"],
    records=df["StateSt"].sort_values().unique(),
    description="States (alphabetical order)",
)
c = gt.Set(
    m,
    "c",
    ["*"],
    records=df["CityCity"].sort_values().unique(),
    description="Cities (alphabetical order)",
)
c_to_s = gt.Set(
    m,
    "c_to_s",
    [c, s],
    records=df[["CityCity", "StateSt"]]
    .drop_duplicates()
    .sort_values(by=["StateSt", "CityCity"]),
    description="City/State pair",
)
bf = gt.Parameter(
    m,
    "bf",
    b,
    records=df[["Bank NameBank", "FundFund"]]
    .drop_duplicates(subset="Bank NameBank")
    .sort_values(by=["Bank NameBank"]),
    description="Bank Namd & Fund #",
)
In [1]: m.isValid()
Out[1]: True
```

Note

Users can chain Pandas operations together and pass those operations through to the `records` argument or the `setRecords` method.

Get PostgreSQL data (w/ sqlalchemy)

```
import gams.transfer as gt
from sqlalchemy import create_engine
import pandas as pd
# connect to postgres (assuming a localhost)
engine = create_engine("postgresql://localhost:5432/" + <database_name>)
df = pd.read_sql(<sql_table_name>, con=engine, index_col=0)
# create the Container and add symbol
m = Container()
p = Parameter(m, <sql_table_name>)
# we need to figure out the symbol dimensionality (potentially from the shape of the dataframe)
r, c = df.shape
p.dimension = c - 1
# set the records
p.setRecords(df)
# write out the GDX file
m.write("out.gdx")
```

7.5.4.7 Main Classes

Container

The main object class within `transfer` is called `Container`. The `Container` is the vessel that allows symbols to be linked together (through their domain definitions), it enables implicit set definitions, it enables structural manipulations of the data (matrix generation), and it allows the user to perform different read/write operations.

Constructor

Constructor Arguments

Argument	Type	Description	Required	Default
load_from	str or PathLike object, GMD Object Handle, GamsDatabase object, Container	Points to the source of the data being read into the Container	No	None
system_directory	str	Absolute path to GAMS system directory	No	Attempts to find the GAMS installation by creating a GamsWorkspace object and loading the system_directory attribute.

Creating a Container is a simple matter of initializing an object. For example:

```
import gams.transfer as gt
m = gt.Container()
```

This new Container object, here called m, contains a number of convenient properties and methods that allow the user to interact with the symbols that are in the Container. Some of these methods are used to filter out different types of symbols, other methods are used to numerically characterize the data within each symbol.

Properties

Property	Description	Type	Special Setter Behavior
data	main dictionary that is used to store all symbol data (case preserving)	CasePreservingDict	-
modified	Flag that identifies if the Container has been modified in some way. Container.modifed=False will reset this flag for all symbols in the container as well as the container itself.	bool	-
summary	returns a brief summary of the Container	dict	-

Symbols are organized in the Container under the data Container attribute. The dot notation (m.data) is used to access the underlying dictionary. Symbols in this dictionary can then be retrieved with the standard bracket notation (m.data[<symbol_name>]). The Container is also subscriptable (i.e., m["i"] will return the i Set object just as if the user called m.data["i"]). The behavior of the data dictionary is has been customized to be case-insensitive (which mimics the behavior of GAMS) – m["i"] and m["I"] will return the same object.

```
In [1]: m.data
Out[1]:
{'i': <Set 'i' (0x7f95b8d63e80)>,
```

```
 'j': <Set 'j' (0x7f95b8d63a60)>,
 'a': <Parameter 'a' (0x7f95b8d63ee0)>,
 'b': <Parameter 'b' (0x7f95b8d63d00)>,
 'd': <Parameter 'd' (0x7f95b8da86a0)>,
 'f': <Parameter 'f' (0x7f95b8da8670)>,
 'c': <Parameter 'c' (0x7f95b8da83d0)>,
 'x': <Positive Variable 'x' (0x7f95b8da83a0)>,
 'z': <Free Variable 'z' (0x7f95b8da8400)>,
 'cost': <Eq Equation 'cost' (0x7f95b8da82b0)>,
 'supply': <Leq Equation 'supply' (0x7f95b8da8280)>,
 'demand': <Geq Equation 'demand' (0x7f95b8da8580)>}
```

Symbol existence in the `Container` can be tested with an overloaded Python `in` operator. The following (case-insensitive) syntax is possible:

```
In [1]: 'i' in m
Out[1]: True
In [2]: 'I' in m
Out[2]: True
In [3]: i in m
Out[3]: True
```

Note

The final example assumes the existence of a separate symbol object called `i`.

The `Container` can also iterate through the symbols (will return a tuple of `(symbol_name, symbol_object)` using a `for-loop` as in the following example. The `list` and `dict` methods can be useful in creating lists and dictionaries of all symbols in the `Container`.

```
In [1]: m = gt.Container("out.gdx")
In [2]: for name, obj in m:
   ...:     print(name, obj)
   ...:
i <Set 'i' (0x7f9038533fa0)>
j <Set 'j' (0x7f9038533fd0)>
a <Parameter 'a' (0x7f9038533340)>
b <Parameter 'b' (0x7f9038533f10)>
d <Parameter 'd' (0x7f9038533f70)>
f <Parameter 'f' (0x7f9038533160)>
c <Parameter 'c' (0x7f90583b4bb0)>
x <Positive Variable 'x' (0x7f90583b4070)>
z <Free Variable 'z' (0x7f90583b5570)>
cost <Eq Equation 'cost' (0x7f90583b44f0)>
supply <Leq Equation 'supply' (0x7f9008c33df0)>
demand <Geq Equation 'demand' (0x7f9008c33b80)>
In [3]: list(m)
Out[3]:
[('i', <Set 'i' (0x7fced87d3790)>),
 ('j', <Set 'j' (0x7fced882e530)>),
 ('a', <Parameter 'a' (0x7fced882e9b0)>),
 ('b', <Parameter 'b' (0x7fced882ebf0)>),
 ('d', <Parameter 'd' (0x7fced882e800)>),
 ('f', <Parameter 'f' (0x7fced882e9e0)>),
 ('c', <Parameter 'c' (0x7fced882e320)>),
 ('x', <Positive Variable 'x' (0x7fced882e650)>),
 ('z', <Free Variable 'z' (0x7fced882e410)>),
 ('cost', <Eq Equation 'cost' (0x7fcec8918640)>),
 ('supply', <Leq Equation 'supply' (0x7fcec8918610)>),
 ('demand', <Geq Equation 'demand' (0x7fcec89183a0)>)]
In [5]: dict(m)
Out[5]:
{'i': <Set 'i' (0x7fced87d3790)>,
 'j': <Set 'j' (0x7fced882e530)>,
 'a': <Parameter 'a' (0x7fced882e9b0)>,
 'b': <Parameter 'b' (0x7fced882ebf0)>,
 'd': <Parameter 'd' (0x7fced882e800)>,
 'f': <Parameter 'f' (0x7fced882e9e0)>,
 'c': <Parameter 'c' (0x7fced882e320)>,
 'x': <Positive Variable 'x' (0x7fced882e650)>,
 'z': <Free Variable 'z' (0x7fced882e410)>,
 'cost': <Eq Equation 'cost' (0x7fcec8918640)>,
 'supply': <Leq Equation 'supply' (0x7fcec8918610)>,
 'demand': <Geq Equation 'demand' (0x7fcec89183a0)>}
```

Note

The `len` (length) function can be used to quickly find out how many symbols exist in the `Container` (`len(m)`).

Methods

Method	Description	Arguments/Defaults	Returns
addAlias	Container method to add an Alias	name (str) alias_with (Set, Alias)	Alias object
addEquation	Container method to add an Equation	name (str) type (str) domain=[] (str, list) records=None (pandas.DataFrame, numpy.ndarry, None) domain_forwarding=False (bool) description="" (str) uels_on_axes=False (bool)	Equation object
addParameter	Container method to add a Parameter	name (str) domain=None (str, list, None) records=None (pandas.DataFrame, numpy.ndarry, None) domain_forwarding=False (bool) description="" (str) uels_on_axes=False (bool)	Parameter object
addSet	Container method to add a Set	name (str) domain=None (str, list, None) is_singleton=False (bool) records=None (pandas.DataFrame, numpy.ndarry, None) domain_forwarding=False (bool) description="" (str) uels_on_axes=False (bool)	Set object
addUniverseAlias	Container method to add a UniverseAlias	name (str)	UniverseAlias object

Method	Description	Arguments/Defaults	Returns
addVariable	Container method to add an Variable	name (str) type="free" (str) domain=[] (str, list) records=None (pandas.DataFrame, numpy.ndarry, None) domain_forwarding=False (bool) description="" (str) uels_on_axes=False (bool)	Variable object
capitalizeUELs	will capitalize all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	symbols=None (str, list, None) - if None, assumes all symbols	self
casefoldUELs	will casefold all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	symbols=None (str, list, None) - if None, assumes all symbols	self
countDomainViolations	get the count of how many records contain at least one domain violation for symbols (if symbols=None assume all symbols)	symbols=None (str, list, None)	dict
countDuplicateRecords	returns the count of how many duplicate records exist for symbols (if symbols=None assume all symbols)	symbols=None (str, list, None)	dict
describeAliases	create a summary table with descriptive statistics for Aliases	symbols=None (None, str, list) - if None, assumes all aliases	pandas.DataFrame
describEquations	create a summary table with descriptive statistics for Equations	symbols=None (None, str, list) - if None, assumes all equations	pandas.DataFrame
describeParameters	create a summary table with descriptive statistics for Parameters	symbols=None (None, str, list) - if None, assumes all parameters	pandas.DataFrame
describeSets	create a summary table with descriptive statistics for Sets	symbols=None (None, str, list) - if None, assumes all sets	pandas.DataFrame
describeVariables	create a summary table with descriptive statistics for Variables	symbols=None (None, str, list) - if None, assumes all variables	pandas.DataFrame

Method	Description	Arguments/Defaults	Returns
dropDomainViolations	drop records that have domain violations for symbols (if symbols=None assume all symbols)	symbols=None (str, list, None)	None
dropDuplicateRecords	drop records with duplicate domains from symbols in the Container – keep argument can take values of "first" (keeps the first instance of a duplicate record), "last" (keeps the last instance of a record), or False (drops all duplicates including the first and last)	symbols=None (str, list, None) - if None, assumes all symbols keep="first" (str, False)	None
getAliases	return all alias objects in the container (is_valid=None), return all valid alias objects (is_valid=True), return all invalid alias objects (is_valid=False) in the container	is_valid=None (bool, None)	list
getDomainViolations	gets domain violations that exist in the data for symbols (if symbols=None assume all symbols); returns a list of DomainViolation objects (or None if no violations)	symbols=None (str, list, None)	list or None
getEquations	return all equation objects (is_valid=None), return all valid equation objects (is_valid=True), return all invalid equation objects (is_valid=False) in the container	is_valid=None (bool, None) types=None (list of equation types) - if None, assumes all types	list
getParameters	return all parameter objects in the container (is_valid=None), return all valid parameter objects (is_valid=True), return all invalid parameter objects (is_valid=False) in the container	is_valid=None (bool, None)	list

Method	Description	Arguments/Defaults	Returns
getSets	return all set objects in the container (is_valid=None), return all valid set objects (is_valid=True), return all invalid set objects (is_valid=False) in the container	is_valid=None (bool, None)	list
getSymbols	returns a list of object references for symbols	symbols (str, list)	list
getUELs	gets UELs from all symbols. If symbols=None and ignore_unused=False, return the full universe set. If symbols=None and ignore_unused=True, return a universe set that contains UELs that only appear in data.	symbols=None (str, list, None) ignore_unused=False (bool)	list
getVariables	return all variable objects (is_valid=None), return all valid variable objects (is_valid=True), return all invalid variable objects (is_valid=False) in the container	is_valid=None (bool, None) types=None (list of variable types) - if None, assumes all types	list
hasDomainViolations	returns True if there are domain violations in the records for symbols (if symbols=None assume all symbols), returns False if not.	symbols=None (str, list, None)	bool
hasDuplicateRecords	returns True if there are duplicate records for symbols (if symbols=None assume all symbols), False if not.	symbols=None (str, list, None)	bool
isValid	True if symbols in the Container are valid (if symbols=None assume all symbols)	symbols=None (str, list, None)	bool
ljustUELs	will left justify all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " symbols=None (int, list, or None) - if None, assumes all symbols	self

Method	Description	Arguments/Defaults	Returns
`listAliases`	list all aliases (`is_valid=None`), list all valid aliases (`is_valid=True`), list all invalid aliases (`is_valid=False`) in the container	`is_valid=None` (`bool`, `None`)	`list`
`listEquations`	list all equations (`is_valid=None`), list all valid equations (`is_valid=True`), list all invalid equations (`is_valid=False`) in the container	`is_valid=None` (`bool`, `None`) `types=None` (`list` of equation types) - if `None`, assumes all types	`list`
`listParameters`	list all parameters (`is_valid=None`), list all valid parameters (`is_valid=True`), list all invalid parameters (`is_valid=False`) in the container	`is_valid=None` (`bool`, `None`)	`list`
`listSets`	list all sets (`is_valid=None`), list all valid sets (`is_valid=True`), list all invalid sets (`is_valid=False`) in the container	`is_valid=None` (`bool`, `None`)	`list`
`listSymbols`	list all symbols (`is_valid=None`), list all valid symbols (`is_valid=True`), list all invalid symbols (`is_valid=False`) in the container	`is_valid=None` (`bool`, `None`)	`list`
`listVariables`	list all variables (`is_valid=None`), list all valid variables (`is_valid=True`), list all invalid variables (`is_valid=False`) in the container	`is_valid=None` (`bool`, `None`) `types=None` (`list` of variable types) - if `None`, assumes all types	`list`
`lowerUELs`	will lowercase all UELs in the `Container` or a subset of specified `symbols`, can be chained with other `*UELs` string operations	`symbols=None` (`str`, `list`, `None`) - if `None`, assumes all symbols	`self`
`lstripUELs`	will left strip whitespace from all UELs in the `Container` or a subset of specified `symbols`, can be chained with other `*UELs` string operations	`symbols=None` (`str`, `list`, `None`) - if `None`, assumes all symbols	`self`

Method	Description	Arguments/Defaults	Returns
read	main method to read load_from, can be provided with a list of symbols to read in subsets, records controls if symbol records are loaded or just metadata, mode controls if data is first read into categorical data structures or object type structures, encoding specifies the original file encoding and to properly decode special characters	load_from (str or PathLike object, GMD Object Handle, GamsDatabase object, Container) symbols="all" (str, list) records=True (bool) mode="category" (category or string) encoding=None (str or None)	None
removeSymbols	symbols to remove from the Container, also sets the symbols container to None. If symbols=None, will remove all symbols.	symbols=None (str, list, None)	None
removeUELs	removes UELs from all symbols in all dimensions. If uels is None only unused UELs will be removed. If symbols is None UELs will be removed from all symbols.	uels (str, list, None) symbols=None (str, list, None)	None
renameSymbol	rename a symbol in the Container	old_name (str), new_name (str)	None
renameUELs	renames UELs (case-sensitive) that appear in symbols (for all dimensions). If symbols=None, rename UELs in all symbols. If allow_merge=True, the categorical object will be re-created to offer additional data flexibility. ** All trailing whitespace is trimmed **	uels (dict) symbols=None (str, list, None) allow_merge=False (bool)	None
reorderSymbols	reorder symbols in order to avoid domain violations	-	None
rjustUELs	will right justify all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " symbols=None (int, list, or None) - if None, assumes all symbols	self

Method	Description	Arguments/Defaults	Returns
rstripUELs	will right strip whitespace from all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	symbols=None (str, list, None) - if None, assumes all symbols	self
stripUELs	will strip whitespace from all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	symbols=None (str, list, None) - if None, assumes all symbols	self
titleUELs	will title (capitalize all individual words) in all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	symbols=None (str, list, None) - if None, assumes all symbols	self
upperUELs	will uppercase all UELs in the Container or a subset of specified symbols, can be chained with other *UELs string operations	symbols=None (str, list, None) - if None, assumes all symbols	self
write	main bulk write method to a write_to target	write_to (str, PathLike object, GamsDatabase object, GMD Object) symbols=None (None, str, list) - if None, assumes all symbols compress=False (bool) uel_priority=None (str, list) merge_symbols=None (None, str, list) mode=None (None, string, category) - if None, assumes string mode writing eps_to_zero=True (bool) - default behavior will convert all -0.0 (EPS) values into 0.0 (drop the sign bit)	None

Set

There are two different ways to create a GAMS set and add it to a Container.

1. Use `Set` constructor
2. Use the `Container` method `addSet` (which internally calls the `Set` constructor)

Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the `Container` object that the symbol is being added to	Yes	-
`description`	`str`	Description of symbol	No	""
`domain`	`list`, `str`, or `Set/Alias`	List of domains given either as string ('*' for universe set) or as reference to a Set/Alias object	No	`["*"]`
`domain_forwarding`	`bool` or `list`	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of `bool` to control which domains to forward.	No	False
`is_singleton`	`bool`	Indicates if set is a singleton set (`True`) or not (`False`)	No	False
`name`	`str`	Name of symbol	Yes	-
`records`	many	Symbol records	No	None
`uels_on_axes`	`bool`	Instructs `setRecords` to assume symbol domain information is contained in the axes of the Pandas object	No	False

Note

Set records can be updated through the object constructor (a new object will not be created) if a symbol of the same name already exists in the container, has the same domain, and has the same `is_singleton` and `domain_forwarding` state. The symbol description will only be updated if new text is provided.

Properties

Property	Description	Type	Special Setter Behavior
`container`	reference to the `Container` that the symbol belongs to	`Container`	-
`description`	description of symbol	`str`	-

Property	Description	Type	Special Setter Behavior
`dimension`	dimension of symbol	`int`	setting is a shorthand notation to create `["*"] * n` domains in symbol
`domain`	list of domains given either as string (* for universe set) or as reference to the Set/Alias object	`list`, `str`, or `Set/Alias`	-
`domain_forwarding`	flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of `bool` to control which domains to forward.	`bool` or `list`	no effect after records have been set
`domain_labels`	column headings for the `records` DataFrame	`list` of `str`	will add a `_<dimension>` tag to user supplied column names (if not unique)
`domain_names`	string version of domain names	`list` of `str`	-
`domain_type`	`none`, `relaxed` or `regular` depending on state of domain links	`str`	-
`is_singleton`	`bool` if symbol is a singleton set	`bool`	-
`modified`	Flag that identifies if the `Set` has been modified	`bool`	-
`name`	name of symbol	`str`	sets the GAMS name of the symbol
`number_records`	number of symbol records (i.e., returns `len(self.records)` if not `None`)	`int`	-
`records`	the main symbol records	`pandas.DataFrame`	responsive to `domain_forwarding` state
`summary`	output a `dict` of only the metadata	`dict`	-

Methods

Method	Description	Arguments/Defaults	Returns
`addUELs`	adds UELs to the symbol `dimensions`. If `dimensions` is `None` then add UELs to all dimensions. ** All trailing whitespace is trimmed **	`uels` (`str`, `list`) `dimensions=None` (`int`, `list`, `None`)	`None`

Method	Description	Arguments/Defaults	Returns
capitalizeUELs	will capitalize all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
casefoldUELs	will casefold all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
countDomainViolations	returns the count of how many records contain at least one domain violation	-	int
countDuplicateRecords	returns the count of how many (case insensitive) duplicate records exist	-	int
dropDomainViolations	drop records from the symbol that contain a domain violation	-	None
dropDuplicateRecords	drop records with (case insensitive) duplicate domains from the symbol – keep argument can take values of "first" (keeps the first instance of a duplicate record), "last" (keeps the last instance of a record), or False (drops all duplicates including the first and last)	keep="first" (str, False)	None
equals	Used to compare the symbol to another symbol. If check_uels=True then check both used and unused UELs and confirm same order, otherwise only check used UELs in data and do not check UEL order. If check_element_text=True then check that all set elements have the same descriptive element text, otherwise skip. If check_meta_data=True then check that symbol name and description are the same, otherwise skip. If verbose=True will return an exception from the asserter describing the nature of the difference.	check_uels=True (bool) check_element_text=True (bool) check_meta_data=True (bool) verbose=False (bool)	bool

Method	Description	Arguments/Defaults	Returns
`findDomainViolations`	get a view of the records DataFrame that contain any domain violations	-	`pandas.DataFrame`
`findDuplicateRecords`	get a view of the records DataFrame that contain any (case insensitive) duplicate domains – `keep` argument can take values of "first" (finds all duplicates while keeping the first instance as unique), "last" (finds all duplicates while keeping the last instance as unique), or `False` (finds all duplicates)	`keep="first"` (str, `False`)	`pandas.DataFrame`
`generateRecords`	convenience method to set standard `pandas.DataFrame` formatted records given domain set information. Will generate records with the Cartesian product of all domain sets. The `density` argument can take any value on the interval `[0,1]`. If `density` is <1 then randomly selected records will be removed. `density` will accept a `list` of length `dimension` -- allows users to specify a density per symbol dimension. Random number state can be set with `seed` argument.	`density=1.0` (`float`, `list`) `seed=None` (`int`, `None`)	`None`
`getDomainViolations`	returns a `list` of `DomainViolation` objects if any (`None` otherwise)	-	`list` or `None`
`getSparsity`	get the sparsity of the symbol w.r.t the cardinality	-	`float`

Method	Description	Arguments/Defaults	Returns
getUELs	gets UELs from symbol dimensions. If dimensions is None then get UELs from all dimensions (maintains order). The argument codes accepts a list of str UELs and will return the corresponding int; must specify a single dimension if passing codes. Returns only UELs in the data if ignore_unused=True, otherwise return all UELs.	dimensions=None (int, list, None) codes=None (int, list, None) ignore_unused=False (bool)	list
hasDomainViolations	returns True if there are domain violations in the records, returns False if not.	-	bool
hasDuplicateRecords	returns True if there are (case insensitive) duplicate records in the symbol, returns False if not.	-	bool
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=True, recheck a symbol if force=True	verbose=False force=True	bool
ljustUELs	will left justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
lowerUELs	will lowercase all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
lstripUELs	will left strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self

Method	Description	Arguments/Defaults	Returns
pivot	Convenience function to pivot records into a new shape (only symbols with >1D can be pivoted). If index is None then it is set to dimensions [0..dimension-1]. If columns is None then it is set to the last dimension. Missing values in the pivot will take the value provided by fill_value	index=None (str, list, None) columns=None (str, list, None) fill_value=None (int, float, str)	pd.DataFrame
renameUELs	renames UELs (case-sensitive) that appear in the symbol dimensions. If dimensions is None then operate on all dimensions of the symbol. If allow_merge=True, the categorical object will be re-created to offer additional data flexibility. ** All trailing whitespace is trimmed **	uels (str, list, dict) dimensions (int, list, None) allow_merge=False (bool)	None
reorderUELs	reorders the UELs in the symbol dimensions. If uels is None, reorder UELs to data order and append any unused categories. If dimensions is None then reorder UELs in all dimensions of the symbol.	uels (str, list, dict, None) dimensions (int, list, None)	None
removeUELs	removes UELs that appear in the symbol dimensions, If uels is None then remove all unused UELs (categories). If dimensions is None then operate on all dimensions.	uels=None (str, list, None) dimensions=None (int, list, None)	bool
rjustUELs	will right justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
rstripUELs	will right strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self

Method	Description	Arguments/Defaults	Returns
`setRecords`	main convenience method to set standard `pandas.DataFrame` formatted records. If `uels_on_axes=True` `setRecords` will assume that all domain information is contained in the axes of the pandas object – data will be flattened (if necessary).	`records` (many types)	`None`
`setUELs`	set the UELs for symbol `dimensions`. If `dimensions` is `None` then set UELs for all dimensions. If `rename=True`, then the old UEL names will be renamed with the new UEL names. ** All trailing whitespace is trimmed **	`uels` (`str`, `list`) `dimensions=None` (`int`, `list`, `None`) `rename=False` (`bool`)	`None`
`stripUELs`	will strip whitespace from all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`titleUELs`	will title (capitalize all individual words) in all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`toList`	convenience method to return symbol records as a Python list	`include_element_text=False` (bool)	`list`
`upperUELs`	will uppercase all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`

Adding Set Records

Three possibilities exist to assign symbol records to a set (roughly ordered in complexity):

1. Setting the argument `records` in the set constructor/container method (internally calls `setRecords`) - creates a data copy
2. Using the symbol method `setRecords` - creates a data copy

3. Setting the property `records` directly - does not create a data copy

If the data is in a convenient format, a user may want to pass the records directly within the set constructor. This is an optional keyword argument and internally the set constructor will simply call the `setRecords` method. The symbol method `setRecords` is a convenience method that transforms the given data into an approved Pandas DataFrame format (see Standard Data Formats). Many native Python data types can be easily transformed into DataFrames, so the `setRecords` method for `Set` objects will accept a number of different types for input. The `setRecords` method is called internally on any data structure that is passed through the `records` argument. We show a few examples of ways to create differently structured sets:

Example #1 - Create a 1D set from a list

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego"])
# NOTE: the above syntax is equivalent to -
# i = gt.Set(m, "i")
# i.setRecords(["seattle", "san-diego"])
# NOTE: the above syntax is also equivalent to -
# m.addSet("i", records=["seattle", "san-diego"])
# NOTE: the above syntax is also equivalent to -
# i = m.addSet("i")
# i.setRecords(["seattle", "san-diego"])
# NOTE: the above syntax is also equivalent to -
# m.addSet("i")
# m["i"].setRecords(["seattle", "san-diego"])
In [1]: i.records
Out[1]:
       uni   element_text
0    seattle
1  san-diego
```

Example #2 - Create a 1D set from a tuple

```
import gams.transfer as gt
m = gt.Container()
j = gt.Set(m, "j", records=("seattle", "san-diego"))
# NOTE: the above syntax is equivalent to -
# j = gt.Set(m, "j")
# j.setRecords(("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# m.addSet("j", records=("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# j = m.addSet("j")
# j.setRecords(("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# m.addSet("j")
# m["j"].setRecords(("seattle", "san-diego"))
In [1]: j.records
Out[1]:
       uni   element_text
0    seattle
1  san-diego
```

Example #3 - Create a 2D set from a list of tuples

```
import gams.transfer as gt
m = gt.Container()
k = gt.Set(m, "k", ["*", "*"], records=[("seattle", "san-diego")])
# NOTE: the above syntax is equivalent to -
# k = gt.Set(m, "k", ["*", "*"])
# k.setRecords([("seattle", "san-diego")])
# NOTE: the above syntax is also equivalent to -
# m.addSet("k", ["*","*"], records=[("seattle", "san-diego")])
# NOTE: the above syntax is also equivalent to -
# k = m.addSet("k", ["*","*"])
# k.setRecords([("seattle", "san-diego")])
# NOTE: the above syntax is also equivalent to -
# m.addSet("k", ["*","*"])
# m["k"].setRecords([("seattle", "san-diego")])
In [1]: k.records
Out[1]:
     uni_0      uni_1 element_text
0  seattle  san-diego
```

Example #4 - Create a 1D set from a DataFrame slice + .unique()

```
import gams.transfer as gt
m = gt.Container()
# note that the raw data is convenient to hold in a DataFrame
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
l = gt.Set(m, "l", records=dist["from"].unique())
# NOTE: the above syntax is equivalent to -
# l = gt.Set(m, "l")
# l.setRecords(dist["from"].unique())
# NOTE: the above syntax is also equivalent to -
# m.addSet("l", records=dist["from"].unique())
# NOTE: the above syntax is also equivalent to -
# l = m.addSet("l")
# l.setRecords(dist["from"].unique())
# NOTE: the above syntax is also equivalent to -
# m.addSet("l")
# m["l"].setRecords(dist["from"].unique())
In [1]: l.records
Out[1]:
       uni   element_text
0    seattle
1  san-diego
```

Note

The `.unique()` method preserves the order of appearance, unlike `set()`.

Set element text is very handy when labeling specific set elements within a set. A user can add a set element text directly with a set element. Note that it is not required to label all set elements, as can be seen in the following example.

Example #5 - Add set element text

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(
    m,
    "i",
    records=[
        ("seattle", "home of sub pop records"),
        ("san-diego",),
        ("washington_dc", "former gams hq"),
    ],
)
# NOTE: the above syntax is equivalent to -
#
# i = gt.Set(m, "i")
# i_recs = [
#     ("seattle", "home of sub pop records"),
#     ("san-diego",),
#     ("washington_dc", "former gams hq"),
# ]
#
# i.setRecords(i_recs)
# NOTE: the above syntax is also equivalent to -
# m.addSet("i", records=i_recs)
# NOTE: the above syntax is also equivalent to -
# i = m.addSet("i")
# i.setRecords(i_recs)
# NOTE: the above syntax is also equivalent to -
# m.addSet("i")
# m["i"].setRecords(i_recs)
In [1]: i.records
Out[1]:
           uni               element_text
0        seattle  home of sub pop records
1      san-diego
2  washington_dc           former gams hq
```

Example #6 - Create a 1D set from a Pandas Series

```
import gams.transfer as gt
import pandas as pd
s = pd.Series(index=["a", "b"])
m = gt.Container()
i = gt.Set(m, "i", records=s, uels_on_axes=True)
# NOTE: We pass the uels_on_axes=True argument in order to tell setRecords to reshape the data
In [1]: i.records
Out[1]:
  uni element_text
0   a
1   b
# Now let's add in some element_text
s = pd.Series(index=["a", "b"], data=["node_1", "node_2"])
m = gt.Container()
i = gt.Set(m, "i", records=s, uels_on_axes=True)
In [2]: i.records
Out[2]:
  uni element_text
0   a       node_1
1   b       node_2
# If uels_on_axes=False, setRecords will attempt to create a categorical data structure from s.values -- which cannot be
      done successfully if there are NaN values in s.values.
s = pd.Series(index=["a", "b"])
m = gt.Container()
i = gt.Set(m, "i", records=s)
ValueError: Categorical categories cannot be null
```

Example #7 - Create a 2D set from a Pandas Series

```
s = pd.Series(
   index=pd.MultiIndex.from_tuples([("a", "b"), ("c", "d")]),
   data=["link_1", "link_2"],
)
m = gt.Container()
i = gt.Set(m, "i", ["*", "*"], records=s, uels_on_axes=True)
# Here is the raw pandas.Series object
In [1]: s
Out[1]:
a  b    link_1
c  d    link_2
dtype: object
# When setting records the pandas.Series object will get converted into a pandas.DataFrame
In [2]: i.records
Out[2]:
  uni_0 uni_1 element_text
0     a     b       link_1
1     c     d       link_2
```

Attention

> The order of the set element could be surprising depending on how the pandas MultiIndex is created. Users should take care that the order of the elements returned from the `getUELs` method is correct.

Example #8 - Create a 2D set from a Pandas DataFrame with uels_on_axes=True

```
import gams.transfer as gt
import pandas as pd
# Create some data first
dim1 = ["a", "b"]
dim2 = ["e", "f"]
dim3 = ["z", "x", "y"]
df = pd.DataFrame(
    index=dim1, columns=pd.MultiIndex.from_product([dim2, dim3]), dtype=bool
)
# now remove all set elements that contain the "z" element in the 3rd dimension
df.loc[:, (slice(None), "z")] = False
# now remove all set elements that contain the "a" element in the 1st dimension
df.loc["a", :] = False
In [1]: df
Out[1]:
       e                   f
```

```
       z      x      y      z      x      y
a  False  False  False  False  False  False
b  False   True   True  False   True   True
# create the Container and add records
m = gt.Container()
i = gt.Set(m, "i", ["*"] * 3, records=df, uels_on_axes=True)
In [2]: i.records
Out[2]:
  uni_0 uni_1 uni_2 element_text
0     b     e     x
1     b     e     y
2     b     f     x
3     b     f     y
```

Note

It not possible to set `element_text` when `uels_on_axes=True`

Directly Set Records

The primary advantage of the `setRecords` method is that `transfer` will convert many different (and convenient) data types into the standard data format (a Pandas DataFrame). Users that require higher performance will want to directly pass the `Container` a reference to a valid Pandas DataFrame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process and it avoids making a copy of the data in memory. In this section we walk the user through an example of how to set records directly.

Example #1 - Directly set records (1D set)

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
i = gt.Set(m, "i", description="supply")
# create a standard format dataframe
df_i = pd.DataFrame(
    data=[("seattle", ""), ("san-diego", "")], columns=["uni", "element_text"]
)
# need to create categorical column type, referencing elements already in df_i
df_i["uni"] = df_i["uni"].astype(
    pd.CategoricalDtype(categories=df_i["uni"].unique(), ordered=True)
)
# set the records directly
i.records = df_i
In [1]: i.isValid()
Out[1]: True
```

Stepping through this example we take the following steps:

1. Create an empty `Container`
2. Create a GAMS set `i` in the Container, but do not set the `records`
3. Create a Pandas DataFrame (manually, in this example) taking care to follow the standard format
4. The DataFrame has the right shape and column labels so we can proceed to set the records.
5. We need to cast the `uni` column as a `categorical` data type, so we create a custom ordered categorty type using `pandas.CategoricalDtype`
6. Finally, we set the records directly by passing a reference to `df_i` into the symbol records attribute. The setter function of `.records` checks that a DataFrame is being set, but does not check validity. Thus, as a final step we call the `.isValid()` method to verify that the symbol is valid.

Attention

> Users can debug their DataFrames by running `<symbol_name>.isValid(verbose=True)` to get feedback about their data.

Example #2 - Directly set records (1D subset)

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego"], description="supply")
j = gt.Set(m, "j", i, description="supply")
# create a standard format dataframe
df_j = pd.DataFrame(data=[("seattle", "")], columns=["i", "element_text"])
# create the categorical column type
df_j["i"] = df_j["i"].astype(i.records["uni"].dtype)
# set the records
j.records = df_j
In [1]: j.isValid()
Out[1]: True
```

This example is more subtle in that we want to create a set `j` that is a subset of `i`. We create the set `i` using the `setRecords` method but then set the records directly for `j`. There are two important details to note: 1) the column labels in `df_j` now reflect the standard format for a symbol with a domain set (as opposed to the universe) and 2) we create the categorical dtype by referencing the parent set (`i`) for the categories (instead of referencing itself).

Generate Set Records

Generating the initial `pandas.DataFrame` object could be difficult for `Set` symbols that have a large number of records and a small number of UELs – these higher dimensional symbols will benefit from the `generateRecords` convenience function. Internally, `generateRecords` computes the dense Cartesian product of all the domain sets that define a symbol (`generateRecords` will only work on symbols where `<symbol>.domain_type == "regular"`).

Example #1 - Create a large (dense) 4D set

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Set(m, "a", [i, j, k, l])
# generate the records
a.generateRecords()
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
         i    j    k    l   element_text
0         i0   j0   k0   l0
1         i0   j0   k0   l1
2         i0   j0   k0   l2
3         i0   j0   k0   l3
4         i0   j0   k0   l4
...      ...  ...  ...  ...          ...
6249995  i49  j49  k49  l45
6249996  i49  j49  k49  l46
6249997  i49  j49  k49  l47
6249998  i49  j49  k49  l48
6249999  i49  j49  k49  l49
[6250000 rows x 5 columns]
```

It is also possible to generate a sparse set (randomly selected rows are removed from the dense dataframe) with the `density` argument to `generateRecords`.

Example #2 - Create a large (sparse) 4D set

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Set(m, "a", [i, j, k, l])
# generate the records
a.generateRecords(density=0.05)
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
        i    j    k    l   element_text
0        i0   j0   k1   l4
1        i0   j0   k1  l13
2        i0   j0   k1  l19
3        i0   j0   k1  l23
4        i0   j0   k2   l1
...     ...  ...  ...  ...          ...
312495  i49  j49  k48  l27
312496  i49  j49  k48  l30
312497  i49  j49  k49   l7
312498  i49  j49  k49  l32
312499  i49  j49  k49  l42
[312500 rows x 5 columns]
```

Example #3 - Create a large 4D set w/ only 1 sparse dimension

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Set(m, "a", [i, j, k, l])
# generate the records
a.generateRecords(density=[1, 0.05, 1, 1])
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
        i    j    k    l   element_text
0        i0  j22   k0   l0
1        i0  j22   k0   l1
2        i0  j22   k0   l2
3        i0  j22   k0   l3
4        i0  j22   k0   l4
...     ...  ...  ...  ...          ...
249995  i49  j36  k49  l45
249996  i49  j36  k49  l46
249997  i49  j36  k49  l47
249998  i49  j36  k49  l48
249999  i49  j36  k49  l49
[250000 rows x 5 columns]
```

Parameter

There are two different ways to create a GAMS parameter and add it to a `Container`.

1. Use `Parameter` constructor
2. Use the `Container` method `addParameter` (which internally calls the `Parameter` constructor)

Constructor

Constructor Arguments

Argument	Type	Description	Required	Default
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
description	str	Description of symbol	No	""
domain	list, str, or Set/Alias	List of domains given either as string ('*' for universe set) or as reference to a Set/Alias object, an empty domain list will create a scalar parameter	No	[]
domain_forwarding	bool or list	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of bool to control which domains to forward.	No	False
name	str	Name of symbol	Yes	-
records	many	Symbol records	No	None
uels_on_axes	bool	Instructs setRecords to assume symbol domain information is contained in the axes of the Pandas object	No	False

Note

Parameter records can be updated through the object constructor (a new object will not be created) if a symbol of the same name already exists in the container, has the same domain, and has the same domain_forwarding state. The symbol description will only be updated if new text is provided.

Properties

Property	Description	Type	Special Setter Behavior
container	reference to the Container that the symbol belongs to	Container	-
description	description of symbol	str	-
dimension	dimension of symbol	int	setting is a shorthand notation to create ["*"] * n domains in symbol
domain	list of domains given either as string (* for universe set) or as reference to the Set/Alias object	list, str, or Set/Alias	-

Property	Description	Type	Special Setter Behavior
`domain_forwarding`	flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of `bool` to control which domains to forward.	`bool` or `list`	no effect after records have been set
`domain_labels`	column headings for the `records` DataFrame	`list` of `str`	will add a `_<dimension>` tag to user supplied column names (if not unique)
`domain_names`	string version of domain names	`list` of `str`	-
`domain_type`	`none`, `relaxed` or `regular` depending on state of domain links	`str`	-
`is_scalar`	True if the `len(self.domain) = 0`	`bool`	-
`modified`	Flag that identifies if the `Parameter` has been modified	`bool`	-
`name`	name of symbol	`str`	sets the GAMS name of the symbol
`number_records`	number of symbol records (i.e., returns `len(self.records)` if not `None`)	`int`	-
`records`	the main symbol records	`pandas.DataFrame`	responsive to `domain_forwarding` state
`shape`	a tuple describing the array dimensions if `records` were converted with `.toDense()`	`tuple`	-
`summary`	output a `dict` of only the metadata	`dict`	-

Methods

Method	Description	Arguments/Defaults	Returns
`addUELs`	adds UELs to the symbol `dimensions`. If `dimensions` is `None` then add UELs to all dimensions. ** All trailing whitespace is trimmed **	`uels` (`str`, `list`) `dimensions=None` (`int`, `list`, `None`)	`None`

Method	Description	Arguments/Defaults	Returns
`capitalizeUELs`	will capitalize all UELs in the symbol or a subset of specified `dimensions`, can be chained with other `*UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`casefoldUELs`	will casefold all UELs in the symbol or a subset of specified `dimensions`, can be chained with other `*UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`countDomainViolations`	returns the count of how many records contain at least one domain violation	-	`int`
`countDuplicateRecords`	returns the count of how many (case insensitive) duplicate records exist	-	`int`
`countEps`	total number of `SpecialValues.EPS` in `value` column	-	`int` or `None`
`countNA`	total number of `SpecialValues.NA` in `value` column	-	`int` or `None`
`countNegInf`	total number of `SpecialValues.NEGINF` in `value` column	-	`int` or `None`
`countPosInf`	total number of `SpecialValues.POSINF` in `value` column	-	`int` or `None`
`countUndef`	total number of `SpecialValues.UNDEF` in `value` column	-	`int` or `None`
`dropDefaults`	an alias to `dropZeros`	-	`None`
`dropDomainViolations`	drop records from the symbol that contain a domain violation	-	`None`
`dropDuplicateRecords`	drop records with (case insensitive) duplicate domains from the symbol – `keep` argument can take values of "first" (keeps the first instance of a duplicate record), "last" (keeps the last instance of a record), or `False` (drops all duplicates including the first and last)	`keep="first"` (str, `False`)	`None`
`dropEps`	drop records from the symbol that are `GAMS EPS` (zero `0.0` records will be retained)	-	`None`

Method	Description	Arguments/Defaults	Returns
`dropMissing`	drop records from the symbol that are `NaN` (includes both `NA` and `Undef` special values)	-	`None`
`dropNA`	drop records from the symbol that are `GAMS NA`	-	`None`
`dropUndef`	drop records from the symbol that are `GAMS Undef`	-	`None`
`dropZeros`	drop records from the symbol that are zero (GAMS EPS (`-0.0`) will not be dropped)	-	`None`
`equals`	Used to compare the symbol to another symbol. If `check_uels=True` then check both used and unused UELs and confirm same order, otherwise only check used UELs in data and do not check UEL order. If `check_meta_data=True` then check that symbol name and description are the same, otherwise skip. `rtol` (relative tolerance) and `atol` (absolute tolerance) set equality tolerances. If `verbose=True` will return an exception from the asserter describing the nature of the difference.	`check_uels=True` (`bool`) `check_meta_data=True` (`bool`) `rtol=0.0` (`float`, `None`) `atol=0.0` (`float`, `None`) `verbose=False` (`bool`)	`bool`
`findDomainViolations`	get a view of the records DataFrame that contain any domain violations	-	`pandas.DataFrame`
`findDuplicateRecords`	get a view of the records DataFrame that contain any (case insensitive) duplicate domains – `keep` argument can take values of "first" (finds all duplicates while keeping the first instance as unique), "last" (finds all duplicates while keeping the last instance as unique), or `False` (finds all duplicates)	`keep="first"` (str, `False`)	`pandas.DataFrame`

Method	Description	Arguments/Defaults	Returns
`findEps`	find positions of `SpecialValues.EPS` in `value` column	-	`pandas.DataFrame` or `None`
`findNA`	find positions of `SpecialValues.NA` in `value` column	-	`pandas.DataFrame` or `None`
`findNegInf`	find positions of `SpecialValues.NEGINF` in `value` column	-	`pandas.DataFrame` or `None`
`findPosInf`	find positions of `SpecialValues.POSINF` in `value` column	-	`pandas.DataFrame` or `None`
`findUndef`	find positions of `SpecialValues.Undef` in `value` column	-	`pandas.DataFrame` or `None`
`generateRecords`	convenience method to set standard `pandas.DataFrame` formatted records given domain set information. Will generate records with the Cartesian product of all domain sets. The `density` argument can take any value on the interval `[0,1]`. If `density` is <1 then randomly selected records will be removed. `density` will accept a `list` of length `dimension` -- allows users to specify a density per symbol dimension. Random number state can be set with `seed` argument.	`density=1.0` (`float`, `list`) `func=numpy.random.uniform(0,1)` (callable) `seed=None` (`int`, `None`)	`None`
`getMaxAbsValue`	get the maximum absolute value in `value` column	-	`float` or `None`
`getMaxValue`	get the maximum value in `value` column	-	`float` or `None`
`getMeanValue`	get the mean value in `value` column	-	`float` or `None`
`getMinValue`	get the minimum value in `value` column	-	`float` or `None`
`getSparsity`	get the sparsity of the symbol w.r.t the cardinality	-	`float`

Method	Description	Arguments/Defaults	Returns
getUELs	gets UELs from symbol dimensions. If dimensions is None then get UELs from all dimensions (maintains order). The argument codes accepts a list of str UELs and will return the corresponding int; must specify a single dimension if passing codes. Returns only UELs in the data if ignore_unused=True, otherwise return all UELs.	dimensions=None (int, list, None) codes=None (int, list, None) ignore_unused=False (bool)	list
hasDomainViolations	returns True if there are domain violations in the records, returns False if not.	-	bool
hasDuplicateRecords	returns True if there are (case insensitive) duplicate records in the symbol, returns False if not.	-	bool
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=True, recheck a symbol if force=True	verbose=False force=True	bool
ljustUELs	will left justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
lowerUELs	will lowercase all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
lstripUELs	will left strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self

Method	Description	Arguments/Defaults	Returns
pivot	Convenience function to pivot records into a new shape (only symbols with >1D can be pivoted). If index is None then it is set to dimensions [0..dimension-1]. If columns is None then it is set to the last dimension. Missing values in the pivot will take the value provided by fill_value	index=None (str, list, None) columns=None (str, list, None) fill_value=None (int, float, str)	pd.DataFrame
removeUELs	removes UELs that appear in the symbol dimensions, If uels is None then remove all unused UELs (categories). If dimensions is None then operate on all dimensions.	uels=None (str, list, None) dimensions=None (int, list, None)	bool
renameUELs	renames UELs (case-sensitive) that appear in the symbol dimensions. If dimensions is None then operate on all dimensions of the symbol. If allow_merge=True, the categorical object will be re-created to offer additional data flexibility. ** All trailing whitespace is trimmed **	uels (str, list, dict) dimensions (int, list, None) allow_merge=False (bool)	None
reorderUELs	reorders the UELs in the symbol dimensions. If uels is None, reorder UELs to data order and append any unused categories. If dimensions is None then reorder UELs in all dimensions of the symbol.	uels (str, list, dict, None) dimensions (int, list, None)	None
rjustUELs	will right justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self

Method	Description	Arguments/Defaults	Returns
`rstripUELs`	will right strip whitespace from all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`setRecords`	main convenience method to set standard `pandas.DataFrame` records. If `uels_on_axes=True` `setRecords` will assume that all domain information is contained in the axes of the pandas object – data will be flattened (if necessary).	`records` (many types).	`None`
`setUELs`	set the UELs for symbol `dimensions`. If `dimensions` is `None` then set UELs for all dimensions. If `rename=True`, then the old UEL names will be renamed with the new UEL names. ** All trailing whitespace is trimmed **	`uels` (`str`, `list`) `dimensions=None` (`int`, `list`, `None`) `rename=False` (`bool`)	`None`
`stripUELs`	will strip whitespace from all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`titleUELs`	will title (capitalize all individual words) in all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`toDense`	convert symbol to a dense `numpy.array` format	-	`numpy.array` or `None`

Method	Description	Arguments/Defaults	Returns
`toDict`	convenience method to return symbol records as a Python dictionary, `orient` can take values `natural` or `columns` and will control the shape of the `dict`. Must use `orient="columns"` if attempting to set symbol records with `setRecords`	`orient="natural"`	`dict`
`toList`	convenience method to return symbol records as a Python list	-	`list`
`toSparseCoo`	convert symbol to a sparse COOrdinate `numpy.array` format	-	sparse matrix format or `None`
`toValue`	convenience method to return symbol records as a Python float. Only possible with scalar symbols.	-	`float`
`upperUELs`	will uppercase all UELs in the symbol or a subset of specified `dimensions`, can be chained with other `*UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`whereMax`	find the domain entry of records with a maximum value (return first instance only)	-	`list` of `str` or `None`
`whereMaxAbs`	find the domain entry of records with a maximum absolute value (return first instance only)	-	`list` of `str` or `None`
`whereMin`	find the domain entry of records with a minimum value (return first instance only)	-	`list` of `str` or `None`

Adding Parameter Records

Three possibilities exist to assign symbol records to a parameter (roughly ordered in complexity):

1. Setting the argument `records` in the set constructor/container method (internally calls `setRecords`) - creates a data copy
2. Using the symbol method `setRecords` - creates a data copy
3. Setting the property `records` directly - does not create a data copy

If the data is in a convenient format, a user may want to pass the records directly within the parameter constructor. This is an optional keyword argument and internally the parameter constructor will simply call the `setRecords` method. The symbol method `setRecords` is a convenience method that transforms the given data into an approved Pandas DataFrame format (see Standard Data Formats). Many native Python data types can be easily transformed into DataFrames, so the `setRecords` method for `Set` objects will accept a number of different types for input. The `setRecords` method is called internally on any data structure that is passed through the `records` argument. We show a few examples of ways to create differently structured parameters:

Example #1 - Create a GAMS scalar

```
import gams.transfer as gt
m = gt.Container()
pi = gt.Parameter(m, "pi", records=3.14159)
# NOTE: the above syntax is equivalent to -
# pi = gt.Parameter(m, "pi")
# pi.setRecords(3.14159)
# NOTE: the above syntax is also equivalent to -
# m.addParameter("pi", records=3.14159)
# NOTE: the above syntax is also equivalent to -
# pi = m.addParameter("pi")
# pi.setRecords(3.14159)
# NOTE: the above syntax is also equivalent to -
# m.addParameter("pi")
# m["pi"].setRecords(3.14159)
In [14]: pi.records
Out[14]:
     value
0  3.14159
```

Note

> `transfer` will still convert scalar values to a standard format (i.e., a Pandas DataFrame with a single row and column).

Example #2 - Create a 1D parameter (defined over $*$) from a list of tuples

```
import gams.transfer as gt
m = gt.Container()
i = gt.Parameter(m, "i", ["*"], records=[("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is equivalent to -
# i = gt.Parameter(m, "i")
# i.setRecords([("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is also equivalent to -
# m.addParameter("i", records=[("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is also equivalent to -
# i = m.addParameter("i")
# i.setRecords([("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is also equivalent to -
# m.addParameter("i")
# m["i"].setRecords([("i" + str(i), i) for i in range(5)])
In [1]: i.records
Out[1]:
  uni  value
0   i0    0.0
1   i1    1.0
2   i2    2.0
3   i3    3.0
4   i4    4.0
```

Example #3 - Create a 1D parameter (defined over a set) from a list of tuples

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=["i" + str(i) for i in range(5)])
a = gt.Parameter(m, "a", i, records=[("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is equivalent to -
# i = gt.Set(m, "i")
# i.setRecords(["i" + str(i) for i in range(5)])
# a = gt.Parameter(m, "a", i)
# a.setRecords([("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is also equivalent to -
# m.addSet("i", records=["i" + str(i) for i in range(5)])
# m.addParameter("a", i, records=[("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is also equivalent to -
# i = m.addSet("i")
# i.setRecords(["i" + str(i) for i in range(5)])
# a = m.addParameter("a", i)
# a.setRecords([("i" + str(i), i) for i in range(5)])
# NOTE: the above syntax is also equivalent to -
# m.addSet("i")
# m["i"].setRecords(["i" + str(i) for i in range(5)])
# m.addParameter("a", i)
# m["a"].setRecords([("i" + str(i), i) for i in range(5)])
In [1]: a.records
Out[1]:
  i  value
0  i0    0.0
1  i1    1.0
2  i2    2.0
3  i3    3.0
4  i4    4.0
```

Example #4 - Create a 2D parameter (defined over a set) from a DataFrame slice

```
import gams.transfer as gt
import pandas as pd
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=dist["from"].unique())
j = gt.Set(m, "j", ["*"], records=dist["to"].unique())
a = gt.Parameter(m, "a", [i, j], records=dist.loc[[0, 3], :])
# NOTE: the above syntax is equivalent to -
# i = gt.Set(m, "i")
# i.setRecords(dist["from"].unique())
# j = gt.Set(m, "j")
# j.setRecords(dist["to"].unique())
# a = gt.Parameter(m, "a", [i, j])
# a.setRecords(dist.loc[[0, 3], :])
# NOTE: the above syntax is also equivalent to -
# m.addSet("i", records=dist["from"].unique())
# m.addSet("j", records=dist["to"].unique())
# m.addParameter("a", i, records=dist.loc[[0, 3], :])
In [1]: a.records
Out[1]:
         i         j    value
0    seattle  new-york    2.5
3  san-diego  new-york    2.5
```

Note

The original indexing is preserved when a user slices rows out of a reference dataframe.

Example #5 - Create a 2D parameter (defined over a set) from a matrix

```
import gams.transfer as gt
import pandas as pd
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=dist["from"].unique())
j = gt.Set(m, "j", ["*"], records=dist["to"].unique())
a = gt.Parameter(m, "a", [i, j], records=dist)
In [1]: a.toDense()
Out[1]:
array([[2.5, 1.7, 1.8],
       [2.5, 1.8, 1.4]])
# use a.toDense() to create a new (and identical) parameter a2
a2 = gt.Parameter(m, "a2", [i, j], records=a.toDense())
# check that a is identical to a2
In [1]: a.equals(a2, check_meta_data=False)
Out[1]: True
```

Example #6 - Create a 2D parameter from an array using setRecords

```
import gams.transfer as gt
import numpy as np
import pandas as pd
m = gt.Container()
i = gt.Set(m, "i", records=["i" + str(i) for i in range(5)])
j = gt.Set(m, "j", records=["j" + str(j) for j in range(5)])
# create the parameter with linked domains (these will control the .shape of the symbol)
a = gt.Parameter(m, "a", [i, j])
# here we use the .shape property to easily generate a dense random array in numpy
a.setRecords(np.random.uniform(low=1, high=10, size=a.shape))
In [1]: a.toDense()
Out[1]:
array([[3.6694495 , 5.17395381, 1.99129484, 3.28315433, 1.44793791],
       [1.06953243, 6.56331121, 5.26162554, 5.98098795, 8.30006   ],
       [3.77213221, 5.82144901, 9.30035479, 9.12534285, 8.51970747],
       [8.47965504, 7.84426304, 5.2442471 , 6.96666622, 6.55194415],
       [5.62682779, 4.92509183, 8.94579609, 2.7724934 , 9.99576081]])
```

Example #7 - Create a 1D parameter from a pandas Series

```
import gams.transfer as gt
import pandas as pd
s = pd.Series(index=["a", "b", "c"], data=[i + 1 for i in range(3)])
m = gt.Container()
i = gt.Parameter(m, "i", ["*"], records=s, uels_on_axes=True)
In [1]: i.records

15    d1    d1    d1    d1  0.535248
```

Directly Set Records

As with sets, the primary advantage of the `setRecords` method is that `transfer` will convert many different (and convenient) data types into the standard data format (a Pandas DataFrame). Users that require higher performance will want to directly pass the `Container` a reference to a valid Pandas DataFrame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process and it avoids making a copy of the data in memory. In this section we walk the user through an example of how to set records directly.

Example #1 - Correctly set records (directly)

```
import gams.transfer as gt
import pandas as pd
import numpy as np
df = pd.DataFrame(
    data=[
        ("h" + str(h), "m" + str(m), "s" + str(s))
        for h in range(8760)
        for m in range(60)
        for s in range(60)
    ],
    columns=["h", "m", "s"],
)
df["value"] = np.random.uniform(0, 100, len(df))
m = gt.Container()
hrs = gt.Set(m, "h", records=df["h"].unique())
mins = gt.Set(m, "m", records=df["m"].unique())
secs = gt.Set(m, "s", records=df["s"].unique())
df["h"] = df["h"].astype(hrs.records["uni"].dtype)
df["m"] = df["m"].astype(mins.records["uni"].dtype)
df["s"] = df["s"].astype(secs.records["uni"].dtype)
a = gt.Parameter(m, "a", [hrs, mins, secs])
# set records
a.records = df
In [1]: a.isValid()
Out[1]: True
```

In this example we create a large parameter (31,536,000 records and 8880 unique domain elements – we mimic data that is labeled for every second in one year) and assign it to a parameter with `a.records`. `transfer` requires that all domain columns must be a categorical data type, furthermore, this categorical must be ordered. The `records` setter function does very little work other than checking if the object being set is a DataFrame. This places more responsibility on the user to create a DataFrame that complies with the standard format. In Example #1 we take care to properly reference the categorical data types from the domain sets – and in the end `a.isValid() = True`.

Users will need to use the `.isValid(verbose=True)` method to debug any structural issues. As an example we incorrectly generate categorical data types by passing the DataFrame constructor the generic `dtype="category"` argument. This creates categorical column types but they are not ordered and they do not reference the underlying domain set. These errors result in `a` being invalid.

Example #2 - Incorrectly set records (directly)

```
import gams.transfer as gt
import pandas as pd
import numpy as np
df = pd.DataFrame(
    data=[
        ("h" + str(h), "m" + str(m), "s" + str(s))
        for h in range(8760)
```

```
        for m in range(60)
        for s in range(60)
    ],
    columns=["h", "m", "s"],
    dtype="category"
)
df["value"] = np.random.uniform(0, 100, len(df))
m = gt.Container()
hrs = gt.Set(m, "h", records=df["h"].unique())
mins = gt.Set(m, "m", records=df["m"].unique())
secs = gt.Set(m, "s", records=df["s"].unique())
a = gt.Parameter(m, "a", [hrs, mins, secs])
# set the records directly
a.records = df
In [1]: a.isValid()
Out[1]: False
In [2]: a.isValid(verbose=True)
Out[2]: Exception: Domain information in column 'h' for 'records' must be an ORDERED categorical type (i.e.,
      <symbol_object>.records["h"].dtype.ordered = True)
```

Generate Parameter Records

Generating the initial `pandas.DataFrame` object could be difficult for `Parameter` symbols that have a large number of records and a small number of UELs – these higher dimensional symbols will benefit from the `generateRecords` convenience function. Internally, `generateRecords` computes the dense Cartesian product of all the domain sets that define a symbol (`generateRecords` will only work on symbols where `<symbol>.domain_type == "regular"`).

Example #1 - Create a large (dense) 4D parameter

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Parameter(m, "a", [i, j, k, l])
# generate the records
a.generateRecords()
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
         i    j    k    l       value
0         i0   j0   k0   l0  0.386390
1         i0   j0   k0   l1  0.671253
2         i0   j0   k0   l2  0.522057
3         i0   j0   k0   l3  0.037694
4         i0   j0   k0   l4  0.564205
...      ...  ...  ...  ...       ...
6249995  i49  j49  k49  l45  0.573354
6249996  i49  j49  k49  l46  0.033717
6249997  i49  j49  k49  l47  0.410322
6249998  i49  j49  k49  l48  0.758310
6249999  i49  j49  k49  l49  0.920708
[6250000 rows x 5 columns]
```

Note

> In Example #1 a large 4D parameter was generated – by default, the value of these records are randomly drawn numbers from the interval `[0,1]` (uniform distribution).

As with `Sets`, it is possible to generate a sparse parameter with the `density` argument to `generateRecords`. We extend this example by passing our own custom `func` argument that will control the behavior of the `value` columns. The `func` argument accepts a `callable` (i.e., a reference to a function).

Example #2 - Create a large (sparse) 4D parameter with normally distributed values

```
import gams.transfer as gt
import numpy as np
# create a custom function to pass to ‘generateRecords‘
def value_dist(size):
    return np.random.normal(loc=10.0, scale=2.3, size=size)
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Parameter(m, "a", [i, j, k, l])
# generate the records
a.generateRecords(density=0.05, func=value_dist)
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
        i    j    k    l        value
0        i0   j0   k0  133  12.490579
1        i0   j0   k0  143   9.460560
2        i0   j0   k0  144   7.660337
3        i0   j0   k0  147   8.811967
4        i0   j0   k1   l5  11.103291
...     ...  ...  ...  ...        ...
312495  i49  j49  k48  138  10.619791
312496  i49  j49  k48  141  14.208250
312497  i49  j49  k48  147   6.104145
312498  i49  j49  k49   10  10.216812
312499  i49  j49  k49  139   9.739771
[312500 rows x 5 columns]
In [3]: a.records["value"].mean()
Out[3]: 10.004072307451391
In [4]: a.records["value"].std()
Out[4]: 2.292569938350144
```

Note

> The custom `callable` function reference must expose a `size` argument. It might be tedious to know the exact number of the records that will be generated, especially if a fractional density is specified; therefore, the `generateRecords` method will pass in the correct size automatically. Users are encouraged to use the Numpy suite of random distributions when generating samples – custom functions have the potential to be computationally burdensome if a symbol has a large number of records.

Example #3 - Create a large 4D parameter with 1 sparse dimension

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Parameter(m, "a", [i, j, k, l])
# generate the records
a.generateRecords(density=[1, 0.05, 1, 1])
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
        i    j    k    l       value
0        i0  j30   k0   10  0.473084
1        i0  j30   k0   11  0.192571
2        i0  j30   k0   12  0.060711
3        i0  j30   k0   13  0.655477
4        i0  j30   k0   14  0.629535
...     ...  ...  ...  ...       ...
249995  i49  j32  k49  145  0.442380
249996  i49  j32  k49  146  0.002444
249997  i49  j32  k49  147  0.332731
249998  i49  j32  k49  148  0.983800
249999  i49  j32  k49  149  0.984322
[250000 rows x 5 columns]
```

Example #4 - Create a large 4D parameter with a random number seed

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Parameter(m, "a", [i, j, k, l])
a2 = gt.Parameter(m, "a2", [i, j, k, l])
# generate the records
a.generateRecords(density=0.05, seed=123)
a2.generateRecords(density=0.05)
In [1]: a.equals(a2, check_meta_data=False)
Out[1]: False
In [2]: a2.generateRecords(density=0.05, seed=123)
In [3]: a.equals(a2, check_meta_data=False)
Out[3]: True
```

Note

The `seed` is an `int` that will set the random number generator state (enables reproducible sequences of random numbers).

Variable

There are two different ways to create a GAMS variable and add it to a `Container`.

1. Use `Variable` constructor
2. Use the `Container` method `addVariable` (which internally calls the `Variable` constructor)

Constructor

Constructor Arguments

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the `Container` object that the symbol is being added to	Yes	-
`description`	`str`	Description of symbol	No	""
`domain`	`list`, `str`, or `Set/Alias`	List of domains given either as string (∗ for universe set) or as reference to a Set/Alias object, an empty domain list will create a scalar variable	No	[]
`domain_forwarding`	`bool` or `list`	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of `bool` to control which domains to forward.	No	False

Argument	Type	Description	Required	Default
`name`	`str`	Name of symbol	Yes	-
`records`	many	Symbol records	No	None
`type`	`str`	Type of variable being created [`binary`, `integer`, `positive`, `negative`, `free`, `sos1`, `sos2`, `semicont`, `semiint`]	No	`free`
`uels_on_axes`	`bool`	Instructs `setRecords` to assume symbol domain information is contained in the axes of the Pandas object	No	False

Note

Variable records can be updated through the object constructor (a new object will not be created) if a symbol of the same name already exists in the container, has the same domain, has the same `type`, and has the same `domain_forwarding` state. The symbol description will only be updated if new text is provided.

Properties

Property	Description	Type	Special Setter Behavior
`container`	reference to the `Container` that the symbol belongs to	`Container`	-
`description`	description of symbol	`str`	-
`dimension`	dimension of symbol	`int`	setting is a shorthand notation to create `["*"] * n` domains in symbol
`domain`	list of domains given either as string (* for universe set) or as reference to the Set/Alias object	`list`, `str`, or `Set/Alias`	-
`domain_forwarding`	flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of `bool` to control which domains to forward.	`bool` or `list`	no effect after records have been set
`domain_labels`	column headings for the `records` DataFrame	`list` of `str`	will add a `_<dimension>` tag to user supplied column names (if not unique)
`domain_names`	string version of domain names	`list` of `str`	-

Property	Description	Type	Special Setter Behavior
domain_type	none, relaxed or regular depending on state of domain links	str	-
is_scalar	True if the len(self.domain) = 0	bool	-
modified	Flag that identifies if the Variable has been modified	bool	-
name	name of symbol	str	sets the GAMS name of the symbol
number_records	number of symbol records (i.e., returns len(self.records) if not None)	int	-
records	the main symbol records	pandas.DataFrame	responsive to domain_forwarding state
shape	a tuple describing the array dimensions if records were converted with .toDense()	tuple	-
summary	output a dict of only the metadata	dict	-
type	str type of variable	str	-

Methods

Method	Description	Arguments/Defaults	Returns
addUELs	adds UELs to the symbol dimensions. If dimensions is None then add UELs to all dimensions. ** All trailing whitespace is trimmed **	uels (str, list) dimensions=None (int, list, None)	None
capitalizeUELs	will capitalize all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
casefoldUELs	will casefold all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
countDomainViolations	returns the count of how many records contain at least one domain violation	-	int

Method	Description	Arguments/Defaults	Returns
countDuplicateRecords	returns the count of how many (case insensitive) duplicate records exist	-	int
countEps	total number of SpecialValues.EPS across all columns	columns="level" (str, list)	int or None
countNA	total number of SpecialValues.NA across all columns	columns="level" (str, list)	int or None
countNegInf	total number of SpecialValues.NEGINF across all columns	columns="level" (str, list)	int or None
countPosInf	total number of SpecialValues.POSINF across all columns	columns="level" (str, list)	int or None
countUndef	total number of SpecialValues.UNDEF across all columns	columns="level" (str, list)	int or None
dropDefaults	drop records that are set to GAMS default records (check .default_records property for values)	-	None
dropDomainViolations	drop records from the symbol that contain a domain violation	-	None
dropDuplicateRecords	drop records with (case insensitive) duplicate domains from the symbol – keep argument can take values of "first" (keeps the first instance of a duplicate record), "last" (keeps the last instance of a record), or False (drops all duplicates including the first and last)	keep="first" (str, False)	None
dropEps	drop records from the symbol that are GAMS EPS (zero 0.0 records will be retained)	-	None
dropMissing	drop records from the symbol that are NaN (includes both NA and Undef special values)	-	None
dropNA	drop records from the symbol that are GAMS NA	-	None
dropUndef	drop records from the symbol that are GAMS Undef	-	None

Method	Description	Arguments/Defaults	Returns
equals	Used to compare the symbol to another symbol. The columns argument allows the user to numerically compare only specified variable attributes (default is to compare all). If check_uels=True then check both used and unused UELs and confirm same order, otherwise only check used UELs in data and do not check UEL order. If check_meta_data=True then check that symbol name, description and variable type are the same, otherwise skip. rtol (relative tolerance) and atol (absolute tolerance) set equality tolerances; can be different tolerances for different variable attributes (if specified as a dict). If verbose=True will return an exception from the asserter describing the nature of the difference.	columns=["level", "marginal", "lower", "upper", "scale"] check_uels=True (bool) check_meta_data=True (bool) rtol=0.0 (int, float, None) atol=0.0 (int, float, None) verbose=False (bool)	bool
findDomainViolations	get a view of the records DataFrame that contain any domain violations	-	pandas.DataFrame
findDuplicateRecords	get a view of the records DataFrame that contain any (case insensitive) duplicate domains – keep argument can take values of "first" (finds all duplicates while keeping the first instance as unique), "last" (finds all duplicates while keeping the last instance as unique), or False (finds all duplicates)	keep="first" (str, False)	pandas.DataFrame
findEps	find positions of SpecialValues.EPS in column	column="level" (str)	pandas.DataFrame or None

Method	Description	Arguments/Defaults	Returns
`findNA`	find positions of `SpecialValues.NA` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`findNegInf`	find positions of `SpecialValues.NEGINF` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`findPosInf`	find positions of `SpecialValues.POSINF` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`findUndef`	find positions of `SpecialValues.Undef` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`generateRecords`	convenience method to set standard `pandas.DataFrame` formatted records given domain set information. Will generate records with the Cartesian product of all domain sets. The `density` argument can take any value on the interval `[0,1]`. If `density` is <1 then randomly selected records will be removed. `density` will accept a `list` of length `dimension` -- allows users to specify a density per symbol dimension. Random number state can be set with `seed` argument.	`density=1.0` (`float`, `list`) `func=numpy.random.uniform(0,1)` (`dict` of `callables`) `seed=None` (`int`, `None`)	`None`
`getMaxValue`	get the maximum value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getMinValue`	get the minimum value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getMeanValue`	get the mean value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getMaxAbsValue`	get the maximum absolute value across all `columns`	`columns="level"` (`str`, `list`)	`float`
`getSparsity`	get the sparsity of the symbol w.r.t the cardinality	-	`float`

Method	Description	Arguments/Defaults	Returns
`getUELs`	gets UELs from symbol `dimensions`. If `dimensions` is `None` then get UELs from all dimensions (maintains order). The argument `codes` accepts a list of `str` UELs and will return the corresponding `int`; must specify a single dimension if passing `codes`. Returns only UELs in the data if `ignore_unused=True`, otherwise return all UELs.	`dimensions=None` (`int`, `list`, `None`) `codes=None` (`int`, `list`, `None`) `ignore_unused=False` (`bool`)	`list`
`hasDomainViolations`	returns `True` if there are domain violations in the records, returns `False` if not.	-	`bool`
`hasDuplicateRecords`	returns `True` if there are (case insensitive) duplicate records in the symbol, returns `False` if not.	-	`bool`
`isValid`	checks if the symbol is in a valid format, throw exceptions if `verbose=True`, recheck a symbol if `force=True`	`verbose=False` `force=True`	`bool`
`ljustUELs`	will left justify all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`length` (`int`) `fill_character=None` - if `None`, assumes `" "` `dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`lowerUELs`	will lowercase all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`lstripUELs`	will left strip whitespace from all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`

Method	Description	Arguments/Defaults	Returns
pivot	Convenience function to pivot records into a new shape (only symbols with >1D can be pivoted). If index is None then it is set to dimensions [0..dimension-1]. If columns is None then it is set to the last dimension. If value is None then the level values will be pivoted. Missing values in the pivot will take the value provided by fill_value	index=None (str, list, None) columns=None (str, list, None) value (str) fill_value=None (int, float, str)	pd.DataFrame
removeUELs	removes UELs that appear in the symbol dimensions, If uels is None then remove all unused UELs (categories). If dimensions is None then operate on all dimensions.	uels=None (str, list, None) dimensions=None (int, list, None)	bool
renameUELs	renames UELs (case-sensitive) that appear in the symbol dimensions. If dimensions is None then operate on all dimensions of the symbol. If allow_merge=True, the categorical object will be re-created to offer additional data flexibility. ** All trailing whitespace is trimmed **	uels (str, list, dict) dimensions (int, list, None) allow_merge=False (bool)	None
reorderUELs	reorders the UELs in the symbol dimensions. If uels is None, reorder UELs to data order and append any unused categories. If dimensions is None then reorder UELs in all dimensions of the symbol.	uels (str, list, dict, None) dimensions (int, list, None)	None

Method	Description	Arguments/Defaults	Returns
rjustUELs	will right justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
rstripUELs	will right strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
setRecords	main convenience method to set standard pandas.DataFrame records. If uels_on_axes=True setRecords will assume that all domain information is contained in the axes of the pandas object – data will be flattened (if necessary).	records (many types)	None
setUELs	set the UELs for symbol dimensions. If dimensions is None then set UELs for all dimensions. If rename=True, then the old UEL names will be renamed with the new UEL names. ** All trailing whitespace is trimmed **	uels (str, list) dimensions=None (int, list, None) rename=False (bool)	None
stripUELs	will strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
titleUELs	will title (capitalize all individual words) in all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
toDense	convert column to a dense numpy.array format	column="level" (str)	numpy.array or None

Method	Description	Arguments/Defaults	Returns
`toDict`	convenience method to return symbol records as a Python dictionary. `columns` will control which attributes to include in the `dict`. `orient` can take values `natural` or `columns` and will control the shape of the `dict`. Must use `orient="columns"` if attempting to set symbol records with `setRecords`.	`columns="level"` (str) `orient="natural"` (str)	`dict`
`toList`	convenience method to return symbol records as a Python list, the `columns` argument will control with attributes to include in the list	`columns="level"` (str)	`list`
`toSparseCoo`	convert `column` to a sparse COOrdinate `numpy.array` format	`column="level"` (`str`)	sparse matrix format or `None`
`toValue`	convenience method to return symbol records as a Python float. Only possible with scalar symbols. Attribute can be specified with `column` argument.	`column="level"` (str)	`float`
`upperUELs`	will uppercase all UELs in the symbol or a subset of specified `dimensions`, can be chained with other `*UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`whereMax`	find the domain entry of records with a maximum value (return first instance only)	`column="level"` (`str`)	`list` of `str` or `None`
`whereMaxAbs`	find the domain entry of records with a maximum absolute value (return first instance only)	`column="level"` (`str`)	`list` of `str` or `None`
`whereMin`	find the domain entry of records with a minimum value (return first instance only)	`column="level"` (`str`)	`list` of `str` or `None`

Adding Variable Records

Three possibilities exist to assign symbol records to a variable (roughly ordered in complexity):

1. Setting the argument `records` in the set constructor/container method (internally calls `setRecords`) - creates a data copy
2. Using the symbol method `setRecords` - creates a data copy
3. Setting the property `records` directly - does not create a data copy

If the data is in a convenient format, a user may want to pass the records directly within the variable constructor. This is an optional keyword argument and internally the variable constructor will simply call the `setRecords` method. In contrast to the `setRecords` methods in in either the Set or Parameter classes the `setRecords` method for variables will only accept Pandas DataFrames and specially structured `dict` for creating records from matrices. This restriction is out of necessity because to properly set a record for a Variable the user must pass data for the `level`, `marginal`, `lower`, `upper` and `scale` attributes. That said, any missing attributes will be filled in with the GAMS default record values (see: Variable Types), default `scale` value is always 1, and the default `level` and `marginal` values are 0 for all variable types). We show a few examples of ways to create differently structured variables:

Example #1 - Create a GAMS scalar variable

```
import gams.transfer as gt
m = gt.Container()
pi = gt.Variable(m, "pi", records=pd.DataFrame(data=[3.14159], columns=["level"]))
# NOTE: the above syntax is equivalent to -
# pi = gt.Variable(m, "pi", "free")
# pi.setRecords(pd.DataFrame(data=[3.14159], columns=["level"]))
# NOTE: the above syntax is also equivalent to -
# m.addVariable("pi", "free", records=pd.DataFrame(data=[3.14159], columns=["level"]))
In [1]: pi.records
Out[1]:
     level  marginal  lower  upper  scale
0  3.14159       0.0   -inf    inf    1.0
```

Example #2 - Create a 1D variable (defined over $*$) from a list of tuples

In this example we only set the `marginal` values.

```
import gams.transfer as gt
m = gt.Container()
v = gt.Variable(
    m,
    "v",
    "free",
    domain=["*"],
    records=pd.DataFrame(
        data=[("i" + str(i), i) for i in range(5)], columns=["domain", "marginal"]
    ),
)
In [1]: v.records
Out[1]:
  uni    level  marginal  lower  upper  scale
0    i0    0.0       0.0   -inf    inf    1.0
1    i1    0.0       1.0   -inf    inf    1.0
2    i2    0.0       2.0   -inf    inf    1.0
3    i3    0.0       3.0   -inf    inf    1.0
4    i4    0.0       4.0   -inf    inf    1.0
```

Example #3 - Create a 1D variable (defined over a set) from a list of tuples

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=["i" + str(i) for i in range(5)])
v = gt.Variable(
    m,
    "v",
    "free",
    domain=i,
```

```
    records=pd.DataFrame(
        data=[("i" + str(i), i) for i in range(5)], columns=["domain", "marginal"]
    ),
)
In [1]: v.records
Out[1]:
  i    level  marginal  lower  upper  scale
0  i0    0.0       0.0   -inf    inf    1.0
1  i1    0.0       1.0   -inf    inf    1.0
2  i2    0.0       2.0   -inf    inf    1.0
3  i3    0.0       3.0   -inf    inf    1.0
4  i4    0.0       4.0   -inf    inf    1.0
```

Example #4 - Create a 2D positive variable, specifying no numerical data

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
v = gt.Variable(
    m,
    "v",
    "positive",
    ["*", "*"],
    records=pd.DataFrame([("seattle", "san-diego"), ("chicago", "madison")]),
)
In [1]: v.records
Out[1]:
     uni_0      uni_1  level  marginal  lower  upper  scale
0  seattle  san-diego    0.0       0.0    0.0    inf    1.0
1  chicago    madison    0.0       0.0    0.0    inf    1.0
```

Example #5 - Create a 2D variable (defined over a set) from a matrix

```
import gams.transfer as gt
import pandas as pd
import numpy as np
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=["i" + str(i) for i in range(5)])
j = gt.Set(m, "j", ["*"], records=["j" + str(i) for i in range(5)])
a = gt.Parameter(
    m,
    "a",
    [i, j],
    records=[("i" + str(i), "j" + str(j), i + j) for i in range(5) for j in range(5)],
)
# create a free variable and set the level and marginal attributes from matricies
v = gt.Variable(
    m, "v", domain=[i, j], records={"level": a.toDense(), "marginal": a.toDense()}
)
# if not specified, the toDense() method will convert the level values to a matrix
In [1]: v.toDense()
Out[1]:
array([[0., 1., 2., 3., 4.],
       [1., 2., 3., 4., 5.],
       [2., 3., 4., 5., 6.],
       [3., 4., 5., 6., 7.],
       [4., 5., 6., 7., 8.]])
```

Example #6 - Create a 1D variable from a pandas Series

```
import gams.transfer as gt
import pandas as pd
s = pd.Series(index=["a", "b", "c"], data=[i + 1 for i in range(3)])
m = gt.Container()
v = gt.Variable(m, "v", domain=["*"], records=s, uels_on_axes=True)
In [1]: v.records
Out[1]:
  uni  level  marginal  lower  upper  scale
0   a    1.0       0.0   -inf    inf    1.0
1   b    2.0       0.0   -inf    inf    1.0
2   c    3.0       0.0   -inf    inf    1.0
```

Note

`transfer` will assume that the `level` value is being set if attributes cannot be found in the axes

Example #7 - Create a 1D variable from a pandas Series (set only the marginal)

```
import gams.transfer as gt
import pandas as pd
# NOTE: we include the "marginal" label in level 1 of the MultiIndex
s = pd.Series(
    index=pd.MultiIndex.from_product([["a", "b", "c"], ["marginal"]]),
    data=[i + 1 for i in range(3)],
)
m = gt.Container()
v = gt.Variable(m, "v", domain=["*"], records=s, uels_on_axes=True)
In [1]: v.records
Out[1]:
  uni  level  marginal  lower  upper  scale
0   a    0.0       1.0   -inf    inf    1.0
1   b    0.0       2.0   -inf    inf    1.0
2   c    0.0       3.0   -inf    inf    1.0
```

Note

`transfer` will search the axes for any variable attributes and set those attributes provided. It is necessary to include all attributes into the same axes level (if a MultiIndex) without any other UELs – if other UELs are found in the same level then all element will be interpreted as UELs and could result in GAMS domain violations.

Example #8 - Create a 2D variable from a DataFrame (uels_on_axes=True)

```
import gams.transfer as gt
import pandas as pd
import numpy as np
dim1 = [f"d{i}" for i in range(2)]
dim2 = [f"e{i}" for i in range(2)]
dim3 = [f"f{i}" for i in range(2)]
dim4 = [f"g{i}" for i in range(2)]
rng = np.random.default_rng(seed=100)
df = pd.DataFrame(
    data=rng.uniform(size=(4, 4)),
    index=pd.MultiIndex.from_product([dim1, dim2]),
    columns=pd.MultiIndex.from_product([dim3, dim4]),
)
In [1]: df
Out[1]:
             f0                  f1
             g0        g1        g0        g1
d0 e0  0.834982  0.596554  0.288863  0.042952
   e1  0.973654  0.596472  0.790263  0.910339
d1 e0  0.688154  0.189991  0.981479  0.284740
   e1  0.629273  0.581036  0.599912  0.535248
m = gt.Container()
v = gt.Variable(m, "v", domain=["*"] * 4, records=df, uels_on_axes=True)
In [8]: v.records
Out[8]:
   uni_0 uni_1 uni_2 uni_3     level  marginal  lower  upper  scale
0     d0    e0    f0    g0  0.834982       0.0   -inf    inf    1.0
1     d0    e0    f0    g1  0.596554       0.0   -inf    inf    1.0
2     d0    e0    f1    g0  0.288863       0.0   -inf    inf    1.0
3     d0    e0    f1    g1  0.042952       0.0   -inf    inf    1.0
4     d0    e1    f0    g0  0.973654       0.0   -inf    inf    1.0
5     d0    e1    f0    g1  0.596472       0.0   -inf    inf    1.0
6     d0    e1    f1    g0  0.790263       0.0   -inf    inf    1.0
7     d0    e1    f1    g1  0.910339       0.0   -inf    inf    1.0
8     d1    e0    f0    g0  0.688154       0.0   -inf    inf    1.0
9     d1    e0    f0    g1  0.189991       0.0   -inf    inf    1.0
10    d1    e0    f1    g0  0.981479       0.0   -inf    inf    1.0
11    d1    e0    f1    g1  0.284740       0.0   -inf    inf    1.0
12    d1    e1    f0    g0  0.629273       0.0   -inf    inf    1.0
13    d1    e1    f0    g1  0.581036       0.0   -inf    inf    1.0
14    d1    e1    f1    g0  0.599912       0.0   -inf    inf    1.0
15    d1    e1    f1    g1  0.535248       0.0   -inf    inf    1.0
```

Directly Set Records

As with sets, the primary advantage of the `setRecords` method is that `transfer` will convert many different (and convenient) data types into the standard data format (a Pandas DataFrame). Users that require higher performance will want to directly pass the `Container` a reference to a valid Pandas DataFrame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process and it avoids making a copy of the data in memory. In this section we walk the user through an example of how to set records directly.

Example #1 - Correctly set records (directly)

```
import gams.transfer as gt
import pandas as pd
import numpy as np
df = pd.DataFrame(
    data=[
        ("h" + str(h), "m" + str(m), "s" + str(s))
        for h in range(8760)
        for m in range(60)
        for s in range(60)
    ],
    columns=["h", "m", "s"],
)
# it is necessary to specify all variable attributes if setting records directly
# NOTE: all numeric data must be type float
df["level"] = np.random.uniform(0, 100, len(df))
df["marginal"] = 0.0
df["lower"] = gt.SpecialValues.NEGINF
df["upper"] = gt.SpecialValues.POSINF
df["scale"] = 1.0
m = gt.Container()
hrs = gt.Set(m, "h", records=df["h"].unique())
mins = gt.Set(m, "m", records=df["m"].unique())
secs = gt.Set(m, "s", records=df["s"].unique())
df["h"] = df["h"].astype(hrs.records["uni"].dtype)
df["m"] = df["m"].astype(mins.records["uni"].dtype)
df["s"] = df["s"].astype(secs.records["uni"].dtype)
a = gt.Variable(m, "a", domain=[hrs, mins, secs])
# set records
a.records = df
In [1]: a.isValid()
Out[1]: True
```

Attention

All numeric data in the records will need to be type `float` in order to maintain a valid symbol.

In this example we create a large variable (31,536,000 records and 8880 unique domain elements – we mimic data that is labeled for every second in one year) and assign it to a variable with `a.records`. `transfer` requires that all domain columns must be a categorical data type, furthermore this categorical must be ordered. The `records` setter function does very little work other than checking if the object being set is a DataFrame. This places more responsibility on the user to create a DataFrame that complies with the standard format. In Example #1 we take care to properly reference the categorical data types from the domain sets – and in the end `a.isValid() = True`. As with Set and Parameters, users can use the `.isValid(verbose=True)` method to debug any structural issues.

Generate Variable Records

Generating the initial `pandas.DataFrame` object could be difficult for `Variable` symbols that have a large number of records and a small number of UELs – these higher dimensional symbols will benefit from the `generateRecords` convenience function. Internally, `generateRecords` computes the dense Cartesian product of all the domain sets that define a symbol (`generateRecords` will only work on symbols where `<symbol>.domain_type == "regular"`).

Example #1 - Create a large (dense) 4D variable

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Variable(m, "a", "free", [i, j, k, l])
# generate the records
a.generateRecords()
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
         i    j    k    l       level  marginal  lower  upper  scale
0         i0   j0   k0   l0  0.470248       0.0   -inf    inf    1.0
1         i0   j0   k0   l1  0.924286       0.0   -inf    inf    1.0
2         i0   j0   k0   l2  0.347550       0.0   -inf    inf    1.0
3         i0   j0   k0   l3  0.937009       0.0   -inf    inf    1.0
4         i0   j0   k0   l4  0.050716       0.0   -inf    inf    1.0
...      ...  ...  ...  ...       ...       ...    ...    ...    ...
6249995  i49  j49  k49  l45  0.385032       0.0   -inf    inf    1.0
6249996  i49  j49  k49  l46  0.029305       0.0   -inf    inf    1.0
6249997  i49  j49  k49  l47  0.440716       0.0   -inf    inf    1.0
6249998  i49  j49  k49  l48  0.432931       0.0   -inf    inf    1.0
6249999  i49  j49  k49  l49  0.157107       0.0   -inf    inf    1.0
[6250000 rows x 9 columns]
```

Note

> In Example #1 a large 4D variable was generated – by default, only the `level` value of these records are randomly drawn from the interval `[0,1]` (uniform distribution). Other variable attributes take the default record value.

As with `Parameters`, it is possible to generate a sparse variable with the `density` argument to `generateRecords`. We extend this example by passing our own custom `func` argument that will control the behavior of the `value` columns. The `func` argument accepts a `dict` of `callables` (i.e., a reference to a function).

Example #2 - Create a large (sparse) 4D variable with normally distributed values

```
import gams.transfer as gt
import numpy as np
# create a custom function to pass to ‘generateRecords‘
def level_dist(size):
    return np.random.normal(loc=10.0, scale=2.3, size=size)
def marginal_dist(size):
    return np.random.normal(loc=0.5, scale=0.1, size=size)
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Variable(m, "a", "free", [i, j, k, l])
# generate the records
a.generateRecords(density=0.05, func={"level":level_dist, "marginal":marginal_dist})
In [1]: a.isValid()
Out[1]: True
In [12]: a.records
Out[12]:
        i    j    k    l        level  marginal  lower  upper  scale
0        i0   j0   k0  l36  11.105235  0.468989   -inf    inf    1.0
1        i0   j0   k0  l40   5.697361  0.478019   -inf    inf    1.0
2        i0   j0   k1  l17  11.900784  0.473814   -inf    inf    1.0
3        i0   j0   k1  l24  10.105931  0.456925   -inf    inf    1.0
4        i0   j0   k1  l31   8.444142  0.490966   -inf    inf    1.0
...     ...  ...  ...  ...        ...       ...    ...    ...    ...
312495  i49  j49  k47  l17  11.523186  0.508001   -inf    inf    1.0
312496  i49  j49  k47  l20   9.341183  0.739237   -inf    inf    1.0
312497  i49  j49  k47  l26  10.705808  0.581103   -inf    inf    1.0
312498  i49  j49  k47  l32   7.910963  0.479655   -inf    inf    1.0
```

```
312499  i49  j49  k49   l8  11.800414  0.628040   -inf    inf    1.0
[312500 rows x 9 columns]
In [3]: a.records["level"].mean()
Out[3]: 10.004072307451391
In [4]: a.records["level"].std()
Out[4]: 2.292569938350144
In [5]: a.records["marginal"].mean()
Out[5]: 0.49970172269778
In [6]: a.records["marginal"].std()
Out[6]: 0.09998772109802055
```

Note

The custom `callable` function reference must expose a `size` argument. It might be tedious to know the exact number of the records that will be generated, especially if a fractional density is specified; therefore, the `generateRecords` method will pass in the correct size automatically. Users are encouraged to use the Numpy suite of random distributions when generating samples – custom functions have the potential to be computationally burdensome if a symbol has a large number of records.

Equation

There are two different ways to create a GAMS equation and add it to a `Container`.

1. Use `Equation` constructor
2. Use the `Container` method `addEquation` (which internally calls the `Equation` constructor)

Constructor

Constructor Arguments

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the `Container` object that the symbol is being added to	Yes	-
`description`	`str`	Description of symbol	No	""
`domain`	`list`, `str`, or `Set/Alias`	List of domains given either as string (∗ for universe set) or as reference to a Set/Alias object, an empty domain list will create a scalar equation	No	[]
`domain_forwarding`	`bool` or `list`	Flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of `bool` to control which domains to forward.	No	False
`name`	`str`	Name of symbol	Yes	-
`records`	many	Symbol records	No	None

Argument	Type	Description	Required	Default
type	str	Type of equation being created [eq (or E/e), geq (or G/g), leq (or L/l), nonbinding (or N/n), external (or X/x)]	Yes	-
uels_on_axes	bool	Instructs setRecords to assume symbol domain information is contained in the axes of the Pandas object	No	False

Note

Equation records can be updated through the object constructor (a new object will not be created) if a symbol of the same name already exists in the container, has the same domain, has the same type, and has the same domain_forwarding state. The symbol description will only be updated if new text is provided.

Properties

Property	Description	Type	Special Setter Behavior
container	reference to the Container that the symbol belongs to	Container	-
description	description of symbol	str	-
dimension	dimension of symbol	int	setting is a shorthand notation to create ["*"] * n domains in symbol
domain	list of domains given either as string (* for universe set) or as reference to the Set/Alias object	list, str, or Set/Alias	-
domain_forwarding	flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of bool to control which domains to forward.	bool or list	no effect after records have been set
domain_labels	column headings for the records DataFrame	list of str	will add a _<dimension> tag to user supplied column names (if not unique)
domain_names	string version of domain names	list of str	-
domain_type	none, relaxed or regular depending on state of domain links	str	-

Property	Description	Type	Special Setter Behavior
is_scalar	True if the len(self.domain) = 0	bool	-
modified	Flag that identifies if the Equation has been modified	bool	-
name	name of symbol	str	sets the GAMS name of the symbol
number_records	number of symbol records (i.e., returns len(self.records) if not None)	int	-
records	the main symbol records	pandas.DataFrame	responsive to domain_forwarding state
shape	a tuple describing the array dimensions if records were converted with .toDense()	tuple	-
summary	output a dict of only the metadata	dict	-
type	str type of variable	str	-

Methods

Method	Description	Arguments/Defaults	Returns
addUELs	adds UELs to the symbol dimensions. If dimensions is None then add UELs to all dimensions. ** All trailing whitespace is trimmed **	uels (str, list) dimensions=None (int, list, None)	None
capitalizeUELs	will capitalize all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
casefoldUELs	will casefold all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
countDomainViolations	returns the count of how many records contain at least one domain violation	-	int

Method	Description	Arguments/Defaults	Returns
countDuplicateRecords	returns the count of how many (case insensitive) duplicate records exist	-	int
countEps	total number of SpecialValues.EPS across all columns	columns="level" (str, list)	int or None
countNA	total number of SpecialValues.NA across all columns	columns="level" (str, list)	int or None
countNegInf	total number of SpecialValues.NEGINF across all columns	columns="level" (str, list)	int or None
countPosInf	total number of SpecialValues.POSINF across all columns	columns="level" (str, list)	int or None
countUndef	total number of SpecialValues.UNDEF across all columns	columns="level" (str, list)	int or None
dropDefaults	drop records that are set to GAMS default records (check .default_records property for values)	-	None
dropDomainViolations	drop records from the symbol that contain a domain violation	-	None
dropDuplicateRecords	drop records with (case insensitive) duplicate domains from the symbol – keep argument can take values of "first" (keeps the first instance of a duplicate record), "last" (keeps the last instance of a record), or False (drops all duplicates including the first and last)	keep="first" (str, False)	None
dropEps	drop records from the symbol that are GAMS EPS (zero 0.0 records will be retained)	-	None
dropMissing	drop records from the symbol that are NaN (includes both NA and Undef special values)	-	None
dropNA	drop records from the symbol that are GAMS NA	-	None
dropUndef	drop records from the symbol that are GAMS Undef	-	None

Method	Description	Arguments/Defaults	Returns
`equals`	Used to compare the symbol to another symbol. The `columns` argument allows the user to numerically compare only specified equation attributes (default is to compare all). If `check_uels=True` then check both used and unused UELs and confirm same order, otherwise only check used UELs in data and do not check UEL order. If `check_meta_data=True` then check that symbol name, description and equation type are the same, otherwise skip. `rtol` (relative tolerance) and `atol` (absolute tolerance) set equality tolerances; can be different tolerances for different equation attributes (if specified as a `dict`). If `verbose=True` will return an exception from the asserter describing the nature of the difference.	`columns=["level", "marginal", "lower", "upper", "scale"]` `check_uels=True` (`bool`) `check_meta_data=True` (`bool`) `rtol=0.0` (`int`, `float`, `None`) `atol=0.0` (`int`, `float`, `None`) `verbose=False` (`bool`)	`bool`
`findDomainViolations`	get a view of the records DataFrame that contain any domain violations	-	`pandas.DataFrame`
`findDuplicateRecords`	get a view of the records DataFrame that contain any (case insensitive) duplicate domains – `keep` argument can take values of "first" (finds all duplicates while keeping the first instance as unique), "last" (finds all duplicates while keeping the last instance as unique), or `False` (finds all duplicates)	`keep="first"` (str, `False`)	`pandas.DataFrame`
`findEps`	find positions of `SpecialValues.EPS` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`

Method	Description	Arguments/Defaults	Returns
`findNA`	find positions of `SpecialValues.NA` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`findNegInf`	find positions of `SpecialValues.NEGINF` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`findPosInf`	find positions of `SpecialValues.POSINF` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`findUndef`	find positions of `SpecialValues.Undef` in `column`	`column="level"` (`str`)	`pandas.DataFrame` or `None`
`generateRecords`	convenience method to set standard `pandas.DataFrame` formatted records given domain set information. Will generate records with the Cartesian product of all domain sets. The `density` argument can take any value on the interval `[0,1]`. If `density` is <1 then randomly selected records will be removed. `density` will accept a `list` of length `dimension` -- allows users to specify a density per symbol dimension. Random number state can be set with `seed` argument.	`density=1.0` (`float`, `list`) `func=numpy.random.uniform(0,1)` (`dict` of `callables`) `seed=None` (`int`, `None`)	`None`
`getMaxAbsValue`	get the maximum absolute value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getMaxValue`	get the maximum value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getMeanValue`	get the mean value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getMinValue`	get the minimum value across all `columns`	`columns="level"` (`str`, `list`)	`float` or `None`
`getSparsity`	get the sparsity of the symbol w.r.t the cardinality	-	`float`

Method	Description	Arguments/Defaults	Returns
`getUELs`	gets UELs from symbol `dimensions`. If `dimensions` is `None` then get UELs from all dimensions (maintains order). The argument `codes` accepts a list of `str` UELs and will return the corresponding `int`; must specify a single dimension if passing `codes`. Returns only UELs in the data if `ignore_unused=True`, otherwise return all UELs.	`dimensions=None` (`int`, `list`, `None`) `codes=None` (`int`, `list`, `None`) `ignore_unused=False` (`bool`)	`list`
`hasDomainViolations`	returns `True` if there are domain violations in the records, returns `False` if not.	-	`bool`
`hasDuplicateRecords`	returns `True` if there are (case insensitive) duplicate records in the symbol, returns `False` if not.	-	`bool`
`isValid`	checks if the symbol is in a valid format, throw exceptions if `verbose=True`, recheck a symbol if `force=True`	`verbose=False` `force=True`	`bool`
`ljustUELs`	will left justify all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`length` (`int`) `fill_character=None` - if `None`, assumes `" "` `dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`lowerUELs`	will lowercase all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`lstripUELs`	will left strip whitespace from all UELs in the symbol or a subset of specified `dimensions`, can be chained with other *`UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`

Method	Description	Arguments/Defaults	Returns
pivot	Convenience function to pivot records into a new shape (only symbols with >1D can be pivoted). If index is None then it is set to dimensions [0..dimension-1]. If columns is None then it is set to the last dimension. If value is None then the level values will be pivoted. Missing values in the pivot will take the value provided by fill_value	index=None (str, list, None) columns=None (str, list, None) value (str) fill_value=None (int, float, str)	pd.DataFrame
removeUELs	removes UELs that appear in the symbol dimensions, If uels is None then remove all unused UELs (categories). If dimensions is None then operate on all dimensions.	uels=None (str, list, None) dimensions=None (int, list, None)	bool
renameUELs	renames UELs (case-sensitive) that appear in the symbol dimensions. If dimensions is None then operate on all dimensions of the symbol. If allow_merge=True, the categorical object will be re-created to offer additional data flexibility. ** All trailing whitespace is trimmed **	uels (str, list, dict) dimensions (int, list, None) allow_merge=False (bool)	None
reorderUELs	reorders the UELs in the symbol dimensions. If uels is None, reorder UELs to data order and append any unused categories. If dimensions is None then reorder UELs in all dimensions of the symbol.	uels (str, list, dict, None) dimensions (int, list, None)	None

Method	Description	Arguments/Defaults	Returns
rjustUELs	will right justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
rstripUELs	will right strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
setRecords	main convenience method to set standard pandas.DataFrame records. If uels_on_axes=True setRecords will assume that all domain information is contained in the axes of the pandas object – data will be flattened (if necessary).	records (many types)	None
setUELs	set the UELs for symbol dimensions. If dimensions is None then set UELs for all dimensions. If rename=True, then the old UEL names will be renamed with the new UEL names. ** All trailing whitespace is trimmed **	uels (str, list) dimensions=None (int, list, None) rename=False (bool)	None
stripUELs	will strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
titleUELs	will title (capitalize all individual words) in all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
toDense	convert column to a dense numpy.array format	column="level" (str)	numpy.array or None

Method	Description	Arguments/Defaults	Returns
`toDict`	convenience method to return symbol records as a Python dictionary. `columns` will control which attributes to include in the `dict`. `orient` can take values `natural` or `columns` and will control the shape of the `dict`. Must use `orient="columns"` if attempting to set symbol records with `setRecords`.	`columns="level"` (str) `orient="natural"` (str)	`dict`
`toList`	convenience method to return symbol records as a Python list, the `columns` argument will control with attributes to include in the list	`columns="level"` (str)	`list`
`toSparseCoo`	convert `column` to a sparse COOrdinate `numpy.array` format	`column="level"` (`str`)	sparse matrix format or `None`
`toValue`	convenience method to return symbol records as a Python float. Only possible with scalar symbols. Attribute can be specified with `column` argument.	`column="level"` (str)	`float`
`upperUELs`	will uppercase all UELs in the symbol or a subset of specified `dimensions`, can be chained with other `*UELs` string operations	`dimensions=None` (`int`, `list`, or `None`) - if `None`, assumes all symbols	`self`
`whereMax`	find the domain entry of records with a maximum value (return first instance only)	`column="level"` (`str`)	`list` of `str` or `None`
`whereMaxAbs`	find the domain entry of records with a maximum absolute value (return first instance only)	`column="level"` (`str`)	`list` of `str` or `None`
`whereMin`	find the domain entry of records with a minimum value (return first instance only)	`column="level"` (`str`)	`list` of `str` or `None`

Adding Equation Records

Adding equation records mimics that of variables – three possibilities exist to assign symbol records to an equation (roughly ordered in complexity):

1. Setting the argument `records` in the set constructor/container method (internally calls `setRecords`) - creates a data copy
2. Using the symbol method `setRecords` - creates a data copy
3. Setting the property `records` directly - does not create a data copy

Setting equation records require the user to be explicit with the type of equation that is being created; in contrast to setting variable records (where the default variable is considered to be `free`).

If the data is in a convenient format, a user may want to pass the records directly within the equation constructor. This is an optional keyword argument and internally the equation constructor will simply call the `setRecords` method. In contrast to the `setRecords` methods in in either the Set or Parameter classes the `setRecords` method for variables will only accept Pandas DataFrames and specially structured `dict` for creating records from matrices. This restriction is out of necessity because to properly set a record for an Equation the user must pass data for the `level`, `marginal`, `lower`, `upper` and `scale` attributes. That said, any missing attributes will be filled in with the GAMS default record values (`level = 0.0`, `marginal = 0.0`, `lower = -inf`, `upper = inf`, `scale = 1.0`). We show a few examples of ways to create differently structured variables:

Example #1 - Create a GAMS scalar equation

```
import gams.transfer as gt
m = gt.Container()
# here we create an equality (=E=) equation
z = gt.Equation(m, "z", "eq", records=pd.DataFrame(data=[3.14159], columns=["level"]))
# NOTE: the above syntax is equivalent to -
# pi = gt.Equation(m, "pi", "eq")
# pi.setRecords(pd.DataFrame(data=[3.14159], columns=["level"]))
# NOTE: the above syntax is also equivalent to -
# m.addEquation("pi", "eq", records=pd.DataFrame(data=[3.14159], columns=["level"]))
In [1]: pi.records
Out[1]:
     level  marginal  lower  upper  scale
0  3.14159       0.0   -inf    inf    1.0
```

Example #2 - Create a 1D Equation (defined over $*$) from a list of tuples

In this example we only set the `marginal` values.

```
import gams.transfer as gt
m = gt.Container()
# here we define a greater than or equal (=G=) equation
i = gt.Equation(
    m,
    "i",
    "geq",
    domain=["*"],
    records=pd.DataFrame(
        data=[("i" + str(i), i) for i in range(5)], columns=["domain", "marginal"]
    ),
)
In [1]: i.type
Out[1]: 'geq'
In [2]: i.records
Out[2]:
  uni    level  marginal  lower  upper  scale
0    i0    0.0       0.0   -inf    inf    1.0
1    i1    0.0       1.0   -inf    inf    1.0
2    i2    0.0       2.0   -inf    inf    1.0
3    i3    0.0       3.0   -inf    inf    1.0
4    i4    0.0       4.0   -inf    inf    1.0
```

Example #3 - Create a 1D Equation (defined over a set) from a list of tuples

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=["i" + str(i) for i in range(5)])
# here we define a less than or equal (=L=) equation
e = gt.Equation(
    m,
    "e",
    "leq",
    domain=i,
    records=pd.DataFrame(
        data=[("i" + str(i), i) for i in range(5)], columns=["domain", "marginal"]
    ),
)
In [1]: i.type
Out[1]: 'leq'
In [5]: e.records
Out[5]:
  i    level  marginal  lower  upper  scale
0  i0    0.0       0.0   -inf    inf    1.0
1  i1    0.0       1.0   -inf    inf    1.0
2  i2    0.0       2.0   -inf    inf    1.0
3  i3    0.0       3.0   -inf    inf    1.0
4  i4    0.0       4.0   -inf    inf    1.0
```

Example #4 - Create a 2D equation, specifying no numerical data

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
e = gt.Equation(
    m,
    "e",
    "eq",
    ["*", "*"],
    records=pd.DataFrame([("seattle", "san-diego"), ("chicago", "madison")]),
)
In [1]: e.records
Out[1]:
     uni_0      uni_1  level  marginal  lower  upper  scale
0  seattle  san-diego    0.0       0.0   -inf    inf    1.0
1  chicago    madison    0.0       0.0   -inf    inf    1.0
```

Example #5 - Create a 2D equation (defined over a set) from a matrix

```
import gams.transfer as gt
import pandas as pd
import numpy as np
m = gt.Container()
i = gt.Set(m, "i", ["*"], records=["i" + str(i) for i in range(5)])
j = gt.Set(m, "j", ["*"], records=["j" + str(i) for i in range(5)])
a = gt.Parameter(
    m,
    "a",
    [i, j],
    records=[("i" + str(i), "j" + str(j), i + j) for i in range(5) for j in range(5)],
)
# create a nonbinding (=N=) equation and set the level and marginal attributes from matricies
e = gt.Equation(
    m, "e", "nonbinding", domain=[i, j], records={"level": a.toDense(), "marginal": a.toDense()}
)
In [1]: e.records
Out[1]:
   i   j    level  marginal  lower  upper  scale
0   i0  j1    1.0       1.0   -inf    inf    1.0
1   i0  j2    2.0       2.0   -inf    inf    1.0
2   i0  j3    3.0       3.0   -inf    inf    1.0
3   i0  j4    4.0       4.0   -inf    inf    1.0
4   i1  j0    1.0       1.0   -inf    inf    1.0
5   i1  j1    2.0       2.0   -inf    inf    1.0
6   i1  j2    3.0       3.0   -inf    inf    1.0
7   i1  j3    4.0       4.0   -inf    inf    1.0
8   i1  j4    5.0       5.0   -inf    inf    1.0
9   i2  j0    2.0       2.0   -inf    inf    1.0
10  i2  j1    3.0       3.0   -inf    inf    1.0
```

```
11  i2  j2    4.0       4.0   -inf    inf    1.0
12  i2  j3    5.0       5.0   -inf    inf    1.0
13  i2  j4    6.0       6.0   -inf    inf    1.0

23  i4  j4    8.0       8.0   -inf    inf    1.0
# if not specified, the toDense() method will convert the level values to a matrix
In [2]: e.toDense()
Out[2]:
array([[0., 1., 2., 3., 4.],
       [1., 2., 3., 4., 5.],
       [2., 3., 4., 5., 6.],
       [3., 4., 5., 6., 7.],
       [4., 5., 6., 7., 8.]])
```

Example #6 - Create a 1D equation from a pandas Series

```
import gams.transfer as gt
import pandas as pd
s = pd.Series(index=["a", "b", "c"], data=[i + 1 for i in range(3)])
m = gt.Container()
e = gt.Equation(m, "e", "eq", domain=["*"], records=s, uels_on_axes=True)
In [1]: e.records
Out[1]:
  uni  level  marginal  lower  upper  scale
0   a    1.0       0.0   -inf    inf    1.0
1   b    2.0       0.0   -inf    inf    1.0
2   c    3.0       0.0   -inf    inf    1.0
```

Note

> `transfer` will assume that the `level` value is being set if attributes cannot be found in the axes (same behavior when setting `Variables`)

Example #7 - Create a 1D equation from a pandas Series (set only the marginal)

```
import gams.transfer as gt
import pandas as pd
# NOTE: we include the "marginal" label in level 1 of the MultiIndex
s = pd.Series(
    index=pd.MultiIndex.from_product([["a", "b", "c"], ["marginal"]]),
    data=[i + 1 for i in range(3)],
)
m = gt.Container()
e = gt.Equation(m, "e", "eq", domain=["*"], records=s, uels_on_axes=True)
In [1]: v.records
Out[1]:

```

Directly Set Records

As with set, parameters and variables, the primary advantage of the `setRecords` method is that `transfer` will convert many different (and convenient) data types into the standard data format (a Pandas DataFrame). Users that require higher performance will want to directly pass the `Container` a reference to a valid Pandas DataFrame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process and it avoids making a copy of the data in memory. In this section we walk the user through an example of how to set records directly.

Example #1 - Correctly set records (directly)

```
import gams.transfer as gt
import pandas as pd
import numpy as np
df = pd.DataFrame(
    data=[
        ("h" + str(h), "m" + str(m), "s" + str(s))
        for h in range(8760)
        for m in range(60)
        for s in range(60)
    ],
    columns=["h", "m", "s"],
)
# it is necessary to specify all variable attributes if setting records directly
# NOTE: all numeric data must be type float
df["level"] = np.random.uniform(0, 100, len(df))
df["marginal"] = 0.0
df["lower"] = gt.SpecialValues.NEGINF
df["upper"] = gt.SpecialValues.POSINF
df["scale"] = 1.0
m = gt.Container()
hrs = gt.Set(m, "h", records=df["h"].unique())
mins = gt.Set(m, "m", records=df["m"].unique())
secs = gt.Set(m, "s", records=df["s"].unique())
df["h"] = df["h"].astype(hrs.records["uni"].dtype)
df["m"] = df["m"].astype(mins.records["uni"].dtype)
df["s"] = df["s"].astype(secs.records["uni"].dtype)
a = gt.Equation(m, "a", "eq", domain=[hrs, mins, secs])
# set records
a.records = df
In [1]: e.isValid()
Out[1]: True
```

Attention

All numeric data in the records will need to be type `float` in order to maintain a valid symbol.

In this example we create a large equation (31,536,000 records and 8880 unique domain elements) and assign it to a variable with `a.records`. `transfer` requires that all domain columns must be a categorical data type, furthermore this categorical must be ordered. The `records` setter function does very little work other than checking if the object being set is a DataFrame. This places more responsibility on the user to create a DataFrame that complies with the standard format. In Example #1 we take care to properly reference the categorical data types from the domain sets – and in the end `a.isValid() = True`. As with Set and Parameters, users can use the `.isValid(verbose=True)` method to debug any structural issues.

Generate Equation Records

Generating the initial `pandas.DataFrame` object could be difficult for `Equation` symbols that have a large number of records and a small number of UELs – these higher dimensional symbols will benefit from the `generateRecords` convenience function. Internally, `generateRecords` computes the dense Cartesian product of all the domain sets that define a symbol (`generateRecords` will only work on symbols where `<symbol>.domain_type == "regular"`).

Example #1 - Create a large (dense) 4D equation

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Equation(m, "a", "eq", [i, j, k, l])
# generate the records
a.generateRecords()
In [1]: a.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
         i    j    k    l       level  marginal  lower  upper  scale
0         i0   j0   k0   l0  0.470248       0.0   -inf    inf    1.0
1         i0   j0   k0   l1  0.924286       0.0   -inf    inf    1.0
2         i0   j0   k0   l2  0.347550       0.0   -inf    inf    1.0
3         i0   j0   k0   l3  0.937009       0.0   -inf    inf    1.0
4         i0   j0   k0   l4  0.050716       0.0   -inf    inf    1.0
...      ...  ...  ...  ...       ...       ...    ...    ...    ...
6249995  i49  j49  k49  l45  0.385032       0.0   -inf    inf    1.0
6249996  i49  j49  k49  l46  0.029305       0.0   -inf    inf    1.0
6249997  i49  j49  k49  l47  0.440716       0.0   -inf    inf    1.0
6249998  i49  j49  k49  l48  0.432931       0.0   -inf    inf    1.0
6249999  i49  j49  k49  l49  0.157107       0.0   -inf    inf    1.0
[6250000 rows x 9 columns]
```

Note

In Example #1 a large 4D equation was generated – by default, only the `level` value of these records are randomly drawn from the interval `[0,1]` (uniform distribution). Other variable attributes take the default record value.

As with `Variables`, it is possible to generate a sparse variable with the `density` argument to `generateRecords`. We extend this example by passing our own custom `func` argument that will control the behavior of the `value` columns. The `func` argument accepts a `dict` of `callables` (i.e., a reference to a function).

Example #2 - Create a large (sparse) 4D equation with normally distributed values

```
import gams.transfer as gt
import numpy as np
# create a custom function to pass to ‘generateRecords‘
def level_dist(size):
    return np.random.normal(loc=10.0, scale=2.3, size=size)
def marginal_dist(size):
    return np.random.normal(loc=0.5, scale=0.1, size=size)
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(50)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(50)])
k = gt.Set(m, "k", records=[f"k{i}" for i in range(50)])
l = gt.Set(m, "l", records=[f"l{i}" for i in range(50)])
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = gt.Equation(m, "a", "eq", [i, j, k, l])
# generate the records
a.generateRecords(density=0.05, func={"level":level_dist, "marginal":marginal_dist})
In [1]: a.isValid()
Out[1]: True
In [12]: a.records
Out[12]:
        i    j    k    l        level  marginal  lower  upper  scale
0        i0   j0   k0  136  11.105235  0.468989   -inf    inf    1.0

```

Note

> The custom `callable` function reference must expose a `size` argument. It might be tedious to know the exact number of the records that will be generated, especially if a fractional density is specified; therefore, the `generateRecords` method will pass in the correct size automatically. Users are encouraged to use the Numpy suite of random distributions when generating samples – custom functions have the potential to be computationally burdensome if a symbol has a large number of records.

Alias

There are two different ways to create a GAMS alias and add it to a `Container`.

1. Use `Alias` constructor
2. Use the `Container` method `addAlias` (which internally calls the `Alias` constructor)

Constructor

Constructor Arguments

Argument	Type	Description	Required	Default
alias_with	Set object	set object from which to create an alias	Yes	-
container	Container	A reference to the Container object that the symbol is being added to	Yes	-
name	str	Name of symbol	Yes	-

Note

The Alias property alias_with can be updated through the object constructor (a new object will not be created) if a symbol of the same name already exists in the container.

Example - Creating an alias from a set

transfer only stores the reference to the parent set as part of the alias structure – most properties that are called from an alias object simply point to the properties of the parent set (with the exception of container, name, and alias_with). It is possible to create an alias from another alias object. In this case a recursive search will be performed to find the root parent set – this is the set that will ultimately be stored as the alias_with property. We can see this behavior in the following example:

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i" + str(i) for i in range(5)])
ip = gt.Alias(m, "ip", i)
ipp = gt.Alias(m, "ipp", ip)
In [1]: ip.alias_with.name
Out[1]: 'i'
In [2]: ipp.alias_with.name
Out[2]: 'i'
```

Properties

Property	Description	Type	Special Setter Behavior
alias_with	aliased object	Set	-
container	reference to the Container that the symbol belongs to	Container	-
description	description of symbol	str	-
dimension	dimension of symbol	int	setting is a shorthand notation to create ["*"] * n domains in symbol
domain	list of domains given either as string (* for universe set) or as reference to the Set/Alias object	list, str, or Set/Alias	-
domain_forwarding	flag that forces set elements to be recursively included in all parent sets (i.e., implicit set growth). Can pass as a list of bool to control which domains to forward.	bool or list	no effect after records have been set

Property	Description	Type	Special Setter Behavior
domain_labels	column headings for the records DataFrame	list of str	will add a _<dimension> tag to user supplied column names (if not unique)
domain_names	string version of domain names	list of str	-
domain_type	none, relaxed or regular depending on state of domain links	str	-
is_singleton	if symbol is a singleton set	bool	-
modified	Flag that identifies if the Alias has been modified	bool	-
name	name of symbol	str	sets the GAMS name of the symbol
number_records	number of symbol records (i.e., returns len(self.records) if not None)	int	-
records	the main symbol records	pandas.DataFrame	responsive to domain_forwarding state
summary	output a dict of only the metadata	dict	-

Methods

Method	Description	Arguments/Defaults	Returns
addUELs	adds UELs to the parent set dimensions. If dimensions is None then add UELs to all dimensions. ** All trailing whitespace is trimmed **	uels (str, list) dimensions=None (int, list, None)	None

Method	Description	Arguments/Defaults	Returns
equals	Used to compare the symbol to another symbol. If check_uels=True then check both used and unused UELs and confirm same order, otherwise only check used UELs in data and do not check UEL order. If check_element_text=True then check that all set elements have the same descriptive element text, otherwise skip. If check_meta_data=True then check that symbol name and description are the same, otherwise skip. If verbose=True will return an exception from the asserter describing the nature of the difference.	check_uels=True (bool) check_element_text=True (bool) check_meta_data=True (bool) verbose=False (bool)	bool
capitalizeUELs	will capitalize all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
casefoldUELs	will casefold all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
countDomainViolations	returns the count of how many records in the parent set contain at least one domain violation	-	int
countDuplicateRecords	returns the count of how many (case insensitive) duplicate records exist in the parent set	-	int
dropDomainViolations	drop records from the parent set that contain a domain violation	-	None

Method	Description	Arguments/Defaults	Returns
`dropDuplicateRecords`	drop records with (case insensitive) duplicate domains from the parent set – `keep` argument can take values of "first" (keeps the first instance of a duplicate record), "last" (keeps the last instance of a record), or `False` (drops all duplicates including the first and last)	`keep="first"` (str, `False`)	`None`
`findDomainViolations`	get a view of the records DataFrame that contain any domain violations	-	`pandas.DataFrame`
`findDuplicateRecords`	get a view of the records DataFrame from the parent set that contain any (case insensitive) duplicate domains – `keep` argument can take values of "first" (finds all duplicates while keeping the first instance as unique), "last" (finds all duplicates while keeping the last instance as unique), or `False` (finds all duplicates)	`keep="first"` (str, `False`)	`pandas.DataFrame`
`getDomainViolations`	returns a `list` of `DomainViolation` objects if any (`None` otherwise)	-	`list` or `None`
`getSparsity`	get the sparsity of the symbol w.r.t the cardinality	-	`float`
`getUELs`	gets UELs from the parent set `dimensions`. If `dimensions` is `None` then get UELs from all dimensions (maintains order). The argument `codes` accepts a list of `str` UELs and will return the corresponding `int`; must specify a single dimension if passing `codes`. Returns only UELs in the data if `ignore_unused=True`, otherwise return all UELs.	`dimensions=None` (`int`, `list`, `None`) `codes=None` (`int`, `list`, `None`) `ignore_unused=False` (`bool`)	`list`
`hasDomainViolations`	returns `True` if there are domain violations in the records of the parent set, returns `False` if not.	-	`bool`

Method	Description	Arguments/Defaults	Returns
hasDuplicateRecords	returns True if there are (case insensitive) duplicate records in the parent set, returns False if not.	-	bool
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=True, re-check a symbol if force=True	verbose=False force=True	bool
ljustUELs	will left justify all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
lowerUELs	will lowercase all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
lstripUELs	will left strip whitespace from all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
pivot	Convenience function to pivot records into a new shape (only symbols with >1D can be pivoted). If index is None then it is set to dimensions [0..dimension-1]. If columns is None then it is set to the last dimension. Missing values in the pivot will take the value provided by fill_value	index=None (str, list, None) columns=None (str, list, None) fill_value=None (int, float, str)	pd.DataFrame
removeUELs	removes UELs that appear in the parent set dimensions, If uels is None then remove all unused UELs (categories). If dimensions is None then operate on all dimensions.	uels=None (str, list, None) dimensions=None (int, list, None)	bool

Method	Description	Arguments/Defaults	Returns
renameUELs	renames UELs (case-sensitive) that appear in the parent set dimensions. If dimensions is None then operate on all dimensions of the symbol. If allow_merge=True, the categorical object will be re-created to offer additional data flexibility. ** All trailing whitespace is trimmed **	uels (str, list, dict) dimensions (int, list, None) allow_merge=False (bool)	None
reorderUELs	reorders the UELs in the parent set dimensions. If uels is None, reorder UELs to data order and append any unused categories. If dimensions is None then reorder UELs in all dimensions of the parent set.	uels (str, list, dict, None) dimensions (int, list, None)	None
rjustUELs	will right justify all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	length (int) fill_character=None - if None, assumes " " dimensions=None (int, list, or None) - if None, assumes all symbols	self
rstripUELs	will right strip whitespace from all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
setRecords	main convenience method to set standard pandas.DataFrame formatted records. If uels_on_axes=True setRecords will assume that all domain information is contained in the axes of the pandas object – data will be flattened (if necessary).	records (many types)	None

Method	Description	Arguments/Defaults	Returns
setUELs	set the UELs for parent set dimensions. If dimensions is None then set UELs for all dimensions. If rename=True, then the old UEL names will be renamed with the new UEL names. ** All trailing whitespace is trimmed **	uels (str, list) dimensions=None (int, list, None) rename=False (bool)	None
stripUELs	will strip whitespace from all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
titleUELs	will title (capitalize all individual words) in all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self
toList	convenience method to return symbol records as a Python list	include_element_text=False (bool)	list
upperUELs	will uppercase all UELs in the parent set or a subset of specified dimensions in the parent set, can be chain with other *UELs string operations	dimensions=None (int, list, or None) - if None, assumes all symbols	self

Adding Alias Records

The linked structure of Aliases offers some unique opportunities to access some of the setter functionality of the parent set. Specifically, transfer allows the user to change the domain, description, dimension, and records of the underlying parent set as a shorthand notation. We can see this behavior if we look at a modified Example #1 from Adding Set Records.

Example - Creating set records through an alias link

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i")
ip = gt.Alias(m, "ip",i)
ip.description = "adding new descriptive set text"
ip.domain = ["*", "*"]
ip.setRecords([("i" + str(i), "j" + str(j)) for i in range(3) for j in range(3)])
In [1]: i.description
Out[1]: 'adding new descriptive set text'
In [2]: i.domain
Out[2]: ['*', '*']
In [3]: i.records
```

```
Out[3]:
  uni_0 uni_1 element_text
0    i0    j0
1    i0    j1
2    i0    j2
3    i1    j0
4    i1    j1
5    i1    j2
6    i2    j0
7    i2    j1
8    i2    j2
```

Note

An alias `.isValid()=True` when the underlying parent set is also valid – if the parent set is removed from the Container the alias will no longer be valid.

UniverseAlias

There are two different ways to create a GAMS UniverseAlias (an alias to the universe) and add it to a `Container`.

1. Use `UniverseAlias` constructor
2. Use the `Container` method `addUniverseAlias` (which internally calls the `UniverseAlias` constructor)

Constructor

Constructor Arguments

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the `Container` object that the symbol is being added to	Yes	-
`name`	`str`	Name of symbol	Yes	-

Example - Creating an alias to the universe

In GAMS it is possible to create aliases to the universe (i.e., the entire list of UELs) with the syntax:

```
set i / i1, i2 /;
alias(h,*);
set j / j1, j2 /;
```

In this small example, `h` would be associated with all four UELs (`i1`, `i2`, `j1` and `j2`) even though set `j` was defined after the alias declaration. `transfer` mimics this behavior with the `UniverseAlias` class. Internally, the `records` attribute will always call the <`Container`>`.getUELs()` and build the Pandas `DataFrame` on the fly. The `UniverseAlias` class is fundamentally different from the `Alias` class because it does not point to a parent set at all; it is not possible to perform operations (like `setRecords` or

`findDomainViolations`) on the parent set through a `UniverseAlias` (because there is no parent set). This means that a `UniverseAlias` can be created by only defining the symbol name. We can see this behavior in the following example:

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2"])
h = gt.UniverseAlias(m, "h")
j = gt.Set(m, "j", records=["j1", "j2"])
# -- alternative syntax --
# m = gt.Container()
# m.addSet("i", records=["i1", "i2"])
# m.addUniverseAlias("h")
# m.addSet("j", records=["j1", "j2"])
In [1]: m.data
Out[1]:
{'i': <Set `i` (0x7f9598a3bd90)>,
 'h': <UniverseAlias `h` (0x7f9598a61690)>,
 'j': <Set `j` (0x7f95b9359cc0)>}
In [2]: h.records
Out[2]:
   uni
0  i1
1  i2
2  j1
3  j2
```

Note

Unlike other sets, the universe does not hold on to set `element_text`, thus the returned `DataFrame` for the `UniverseAlias` will only have 1 column.

Properties

Property	Description	Type	Special Setter Behavior
`alias_with`	always $*$	`str`	-
`container`	reference to the `Container` that the symbol belongs to	`Container`	-
`description`	always `Aliased with` $*$	`str`	-
`dimension`	always `1`	`int`	-
`domain`	always `["*"]`	`list` of `str`	-
`domain_labels`	always `["*"]`	`list` of `str`	-
`domain_names`	always `["*"]`	`list` of `str`	-
`domain_type`	always `none`	`str`	-
`is_singleton`	always `False`	`bool`	-
`modified`	flag that identifies if the `UniverseAlias` has been modified	`bool`	-
`name`	name of symbol	`str`	sets the GAMS name of the symbol
`number_records`	number of symbol records (i.e., returns `len(records)` if not `None`)	`int`	-
`records`	the main symbol records	`pandas.DataFrame`	-
`summary`	output a `dict` of only the metadata	`dict`	-

Methods

Method	Description	Arguments/Defaults	Returns
equals	Used to compare the symbol to another symbol. If check_uels=True then check both used and unused UELs and confirm same order, otherwise only check used UELs in data and do not check UEL order. If check_element_text=True then check that all set elements have the same descriptive element text, otherwise skip. If check_meta_data=True then check that symbol name and description are the same, otherwise skip. If verbose=True will return an exception from the asserter describing the nature of the difference.	check_uels=True (bool) check_element_text=True (bool) check_meta_data=True (bool) verbose=False (bool)	bool
getSparsity	always 0.0	-	float
getUELs	gets UELs from the Container. Returns only UELs in the data if ignore_unused=True, otherwise return all UELs.	ignore_unused=False (bool)	list
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=True, re-check a symbol if force=True	verbose=False force=True	bool
pivot	Convenience function to pivot records into a new shape (only symbols with >1D can be pivoted). If index is None then it is set to dimensions [0..dimension-1]. If columns is None then it is set to the last dimension. Missing values in the pivot will take the value provided by fill_value	index=None (str, list, None) columns=None (str, list, None) fill_value=None (int, float, str)	pd.DataFrame
toList	convenience method to return symbol records as a Python list	-	list

DomainViolation

DomainViolation objects are convenient containers that store information about the location of domain violations in a symbol. These objects are computed dynamically with the getDomainViolations method and should not be instantiated by the user (they are read-only, to the extent that this is possible in Python). However, the user may be interested in some of the information that they contain.

Constructor

Constructor Arguments/Properties

Argument	Type	Description	Required	Default
`symbol`	`_Symbol`	A reference to the `_Symbol` object that has a domain violation	Yes	-
`dimension`	`int`	An index to the dimension of the `symbol` where the domain violation exists	Yes	-
`domain`	`Set`, `Alias` or `UniverseAlias`	A reference to the symbol domain that is the source of the domain violation	Yes	-
`violations`	`list`	A list of all the domain elements that are causing violations	Yes	-

7.5.4.8 Additional Topics

Validating Data

`transfer` requires that the records for all symbols exist in a standard format (Standard Data Formats) in order for them to be understood by the `Container`. It is certainly possible that the data could end up in a state that is inconsistent with the standard format (especially if setting symbol attributes directly). `transfer` includes the `.isValid()` method in order to determine if a symbol is structurally valid – this method returns a `bool`. This method does not guarantee that a symbol will be successfully written to either GDX or GMD, other data errors (duplicate records, long UEL names, or domain violations) could exist that are not tested in `.isValid()`.

For example, we create two valid sets and then check them with `.isValid()` to be sure.

Note

It is possible to run `.isValid()` on both the `Container` as well as the symbol object – `.isValid()` will also return a `bool` if there are any invalid symbols in the `Container` object.

Example (valid data)

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego", "washington_dc"])
j = gt.Set(m, "j", i, records=["san-diego", "washington_dc"])
In [1]: i.isValid()
Out[1]: True
In [2]: j.isValid()
Out[2]: True
In [3]: m.isValid()
Out[3]: True
```

The `.isValid()` method checks:

1. If the symbol belongs to a Container
2. If all domain set symbols exist in the Container
3. If all domain set symbols objects are valid
4. If any domain set is also a singleton set (not allowed in GAMS)
5. If records are a DataFrame (or `None`)

6. If the records DataFrame is the right number of columns (based on symbol dimension)
7. If the symbol is a scalar, then ensure there is only one record (row) in the DataFrame
8. If records column headings are unique
9. If any symbol attribute columns are missing or out of order
10. If all domain columns are type `category`
11. If all domain categories are type `str`
12. If all data columns are type `float`

Custom Column Headings

The names of the domain columns are flexible, but `transfer` requires unique column names. Users are encouraged to change the column headings of the underlying dataframe by using the `domain_labels` property. Using this property will ensure that unique column names are generated by adding a `_<dimension>` tag to the end of any user supplied column names. The following examples show this behavior.

Attention

> All $*$ domains are recast as `uni`. This allows users to access the column data with both the Pandas bracket and/or dot notation (i.e., `df["uni"]` or `df.uni`).

Column heading behavior at symbol instantiation

The `setRecords` (which is called internally at symbol instantiation) method will set default `domain_labels` if they were not provided by the user. The only way for a user to provide domain labels with `setRecords` is by passing in a Pandas DataFrame object. The `_<dimension>` tag will be added to all domain labels in order to make all domain names unique – this tag is added to all dimensions if any subset of the domain names are non-unique.

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
# define a symbol with unique domain names
a = gt.Parameter(
    m, "a", [i, "*"], records=[("i1", "u1", 1), ("i2", "u2", 1), ("i3", "u3", 1)]
)
# define a symbol with NON-unique domain names
b = gt.Parameter(
    m, "b", [i, i], records=[("i1", "i1", 1), ("i2", "i2", 1), ("i3", "i3", 1)]
)
# define a symbol from a dataframe that already has column names
df = pd.DataFrame(
    [("i1", "i1", 1), ("i2", "i2", 1), ("i3", "i3", 1)],
    columns=["from", "to", "distance"],
)
c = gt.Parameter(m, "c", [i, i], records=df)
In [1]: m.isValid()
Out[1]: True
In [2]: i.records
Out[2]:
  uni element_text
0  i1
1  i2
2  i3
In [3]: a.records
Out[3]:
    i uni  value
0  i1  u1    1.0
1  i2  u2    1.0
2  i3  u3    1.0
In [4]: b.records
```

```
Out[4]:
  i_0 i_1  value
0  i1  i1    1.0
1  i2  i2    1.0
2  i3  i3    1.0
In [5]: c.records
Out[5]:
  from  to  value
0   i1  i1    1.0
1   i2  i2    1.0
2   i3  i3    1.0
```

Customizing column headings

Many users may want to output the GAMS DataFrame directly to another format (CSV, etc.) and may wish to create customized DataFrame column headings for readability. User can do this by directly setting the `domain_labels` property, as seen in the following example.

Attention

> Users are encouraged to use the `<symbol>.domain_labels` property instead of setting the `<DataFrame>.columns` directly. The avoids the possibility of out-of-sync symbol validity. The `domain_labels` property does not store anything, calling this property simply returns the exact domain labels from the DataFrame.

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
# define a symbol with unique domain names
a = gt.Parameter(
    m, "a", [i, "*"], records=[("i1", "u1", 1), ("i2", "u2", 1), ("i3", "u3", 1)]
)
# customize the headings to allow more friendly output (to csv, etc.)
a.domain_labels = ["start", "destination"]
In [1]: m.isValid()
Out[1]: True
In [2]: a.records
Out[2]:
  start destination  value
0    i1          u1    1.0
1    i2          u2    1.0
2    i3          u3    1.0
```

Converting Records

All data in `transfer` will be stored as a Pandas DataFrame – however, it is desirable to have easy access to data without the additional infrastructure that comes with the DataFrame object. We include `to*` methods (available for all symbol types) that will return other data structures. The following examples show the behavior of `toValue`, `toList`, and `toDict` (previous examples showed examples of `toDense` and `toSparseCoo`).

Examples of toList

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
i = gt.Set(m, "i", records=["i0", "i1", "i2"])
ii = gt.Set(
    m, "ii", ["*", "*"], records=[(f"i{i}", f"i{i}", f"element_text for i{i}") for i in range(3)]
)
s = gt.Set(m, "s", i, is_singleton=True, records="i1")
u = gt.UniverseAlias(m, "u")
ip = gt.Alias(m, "ip", i)
a0 = gt.Parameter(m, "a0", records=1)
a1 = gt.Parameter(m, "a1", i, records=[("i1", 1), ("i2", 2)])
```

```
a2 = gt.Parameter(m, "a2", [i, i], records=[("i1", "i1", 1), ("i2", "i1", 2)])
v0 = gt.Variable(m, "v0", "free", records=1)
v1 = gt.Variable(
    m,
    "v1",
    "free",
    i,
    records=pd.DataFrame([("i1", 1), ("i2", 2)], columns=["i", "level"]),
)
v2 = gt.Variable(
    m,
    "v2",
    "free",
    [i, i],
    records=(
        pd.DataFrame(
            [("i1", "i1", 1), ("i2", "i1", 2)],
            columns=["i", "i", "level"],
        )
    ),
)
In [1]: i.toList()
Out[1]: ['i0', 'i1', 'i2']
In [2]: ii.toList()
Out[2]: [('i0', 'i0'), ('i1', 'i1'), ('i2', 'i2')]
In [3]: ii.toList(include_element_text=True)
Out[3]:
[('i0', 'i0', 'element_text for i0'),
 ('i1', 'i1', 'element_text for i1'),
 ('i2', 'i2', 'element_text for i2')]
In [4]: s.toList()
Out[4]: ['i1']
In [5]: u.toList()
Out[5]: ['i0', 'i1', 'i2']
In [6]: ip.toList()
Out[6]: ['i0', 'i1', 'i2']
In [7]: a0.toList()
Out[7]: [1.0]
In [8]: a1.toList()
Out[8]: [('i1', 1.0), ('i2', 2.0)]
In [9]: a2.toList()
Out[9]: [('i1', 'i1', 1.0), ('i2', 'i1', 2.0)]
In [10]: v0.toList() # default is to include only the "level"
Out[10]: [1.0]
In [11]: v0.toList("marginal")
Out[11]: [0.0]
In [12]: v1.toList() # default is to include only the "level"
Out[12]: [('i1', 1.0), ('i2', 2.0)]
In [13]: v1.toList(["level", "marginal"])
Out[13]: [('i1', 1.0, 0.0), ('i2', 2.0, 0.0)]
```

Examples of toValue

```
In [1]: a0.toValue()
Out[1]: 1.0
In [2]: a1.toValue()
Out[2]: TypeError: Cannot extract value data for non-scalar symbols (symbol dimension is 1)
In [3]: v0.toValue() # default is to only include the "level"
Out[3]: 1.0
In [4]: v0.toValue("marginal")
Out[4]: 0.0
```

Examples of toDict

```
In [1]: i.toDict()
Out[1]: AttributeError: 'Set' object has no attribute 'toDict'
In [2]: a0.toDict()
Out[2]: TypeError: Symbol `a0` is a scalar and cannot be converted into a dict.
In [3]: a1.toDict()
Out[3]: {'i1': 1.0, 'i2': 2.0}
In [4]: a2.toDict()
Out[4]: {('i1', 'i1'): 1.0, ('i2', 'i1'): 2.0}
In [5]: v1.toDict() # default is to only include the "level"
Out[5]: {'i1': 1.0, 'i2': 2.0}
In [6]: v1.toDict(["level","marginal"])
Out[6]: {'i1': {'level': 1.0, 'marginal': 0.0}, 'i2': {'level': 2.0, 'marginal': 0.0}}
In [7]: v1.toDict(orient="columns") # this format is useful for recreating Pandas DataFrames
Out[7]: {'i': {0: 'i1', 1: 'i2'}, 'level': {0: 1.0, 1: 2.0}}
```

Comparing Symbols

Sparse GAMS data is inherently unordered. The concept of order is GAMS is governed by the order of the UELs in the universe set not the order of the records. This differs from the sparse data structures that we use in `transfer` (Pandas DataFrames) because each record (i.e., DataFrame row) has an index (typically `0..n`) and can be sorted by this index. Said a slightly different way, two GDX files will be equivalent if their universe order is the same and the records are the same, however when creating the GDX file, it is of no consequence what order the records are written in. Therefore, in order to calculate an equality between two symbols in `transfer` we must perform a merge operation on the symbol domain labels – an operation that could be computationally expensive for large symbols.

Attention

> The nature of symbol equality in `transfer` means that a potentially expensive merge operation is performed, we do not recommend that the `equals` method be used inside loops or when speed is critical. It is, however, very useful for data debugging.

A quick example shows the syntax of `equals`:

```
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(5)], description="set i")
j = gt.Set(m, "j", records=[f"i{i}" for i in range(5)], description="set j")
In [1]: i.equals(j)
Out[1]: False
```

By default, `equals` takes the strictest view of symbol "equality" – everything must be the same. In this case, the symbol names and descriptions differ between the two sets `i` and `j`. We can relax the view of equality with a combination of argument flags. Comparing the two symbols again, but ignoring the meta data (i.e., ignoring the symbol name, description and type (if a Variable or Equation)):

```
In [1]: i.equals(j, check_meta_data=False)
Out[1]: True
```

It is also possible to ignore the set element text in `equals`:

```
m = gt.Container()
i = gt.Set(m, "i", records=[(f"i{i}", "arlington") for i in range(5)])
j = gt.Set(m, "j", records=[f"i{i}" for i in range(5)])
In [1]: i.records
Out[1]:
  uni   element_text
0    i0    arlington
1    i1    arlington
2    i2    arlington
3    i3    arlington
4    i4    arlington
In [2]: j.records
Out[2]:
  uni   element_text
0    i0
1    i1
2    i2
3    i3
4    i4
In [3]: i.equals(j, check_meta_data=False, check_element_text=False)
Out[3]: True
```

The `check_uels` argument will ensure that the symbol "universe" is the same (in order and content) between two symbols, as illustrated in the following example:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
ip = gt.Set(m, "ip", records=["i3", "i2", "i1"])
```

Clearly, the two sets `i` and `ip` have the same records, but the UEL order is different. If `check_uels=True` the resulting symbols will not be considered equal – turning this flag off results in equality.

```
In [1]: i.getUELs()
Out[1]: ['i1', 'i2', 'i3']
In [2]: ip.getUELs()
Out[2]: ['i3', 'i2', 'i1']
In [3]: i.equals(ip, check_meta_data=False)
Out[3]: False
In [4]: i.equals(ip, check_meta_data=False, check_uels=False)
Out[4]: True
```

Numerical comparisons are enabled for `Parameters`, `Variables` and `Equations` – equality can be flexibly defined through the `equals` method arguments. Again, the strictest view of equality is taken as the default behavior of `equals` (no numerical tolerances, some limitations exist – see: `numpy.isclose` for more details).

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
a = gt.Parameter(m, "a", i, records=[("i1", 1), ("i2", 2), ("i3", 3)])
ap = gt.Parameter(m, "ap", i, records=[("i1", 1 + 1e-9), ("i2", 2), ("i3", 3)])
In [1]: a.equals(ap, check_meta_data=False)
Out[1]: False
In [2]: a.equals(ap, check_meta_data=False, atol=1e-8)
Out[2]: True
```

Attention

> The numerical comparison is handled by `numpy.isclose`, more details can be found in the Numpy documentation.

In the case of variables and equations, it is possible for the user to confine the numerical comparison to certain certain attributes (`level`, `marginal`, `lower`, `upper` and `scale`) by specifying the `columns` argument as the following example illustrates:

```
m = gt.Container()
a = gt.Variable(m, "a", "free", records=100)
ap = gt.Variable(m, "ap", "free", records=101)
In [1]: a.records
Out[1]:
   level  marginal  lower  upper  scale
0  100.0       0.0   -inf    inf    1.0
In [2]: ap.records
Out[2]:
   level  marginal  lower  upper  scale
0  101.0       0.0   -inf    inf    1.0
In [3]: a.equals(ap, check_meta_data=False)
Out[3]: False
In [4]: a.equals(ap, check_meta_data=False, columns="level")
Out[4]: False
In [5]: a.equals(ap, check_meta_data=False, columns="marginal")
Out[5]: True
```

Domain Forwarding

GAMS includes the ability to define sets directly from data using the implicit set notation (see: Implicit Set Definition (or: Domain Defining Symbol Declarations)). This notation has an analogue in `transfer` called `domain_forwarding`.

Note

> It is possible to recursively update a subset tree in `transfer`.

Domain forwarding is available as an argument to all symbol object constructors; the user would simply need to pass `domain_forwarding=True`.

In this example we have raw data that in the `dist` DataFrame and we want to send the domain information into the `i` and `j` sets – we take care to pass the set objects as the domain for parameter `c`.

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i")
j = gt.Set(m, "j")
dist = pd.DataFrame(
    [
        ("seattle", "new-york", 2.5),
        ("seattle", "chicago", 1.7),
        ("seattle", "topeka", 1.8),
        ("san-diego", "new-york", 2.5),
        ("san-diego", "chicago", 1.8),
        ("san-diego", "topeka", 1.4),
    ],
    columns=["from", "to", "thousand_miles"],
)
```

```
c = gt.Parameter(m, "c", [i, j], records=dist, domain_forwarding=True)
In [1]: i.records
Out[1]:
       uni   element_text
0    seattle
1  san-diego
In [2]: j.records
Out[2]:
      uni   element_text
0  new-york
1   chicago
2    topeka
In [3]: c.records
Out[3]:
         i         j    value
0    seattle  new-york    2.5
1    seattle   chicago    1.7
2    seattle    topeka    1.8
3  san-diego  new-york    2.5
4  san-diego   chicago    1.8
5  san-diego    topeka    1.4
```

Note

The element order in the sets `i` and `j` mirrors that in the raw data.

In this example we show that domain forwarding will also work recursively to update the entire set lineage – the domain forwarding occurs at the creation of every symbol object. The correct order of elements in set `i` is `[z, a, b, c]` because the records from `j` are forwarded first, and then the records from `k` are propagated through (back to `i`).

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i")
j = gt.Set(m, "j", i, records=["z"], domain_forwarding=True)
k = gt.Set(m, "k", j, records=["a", "b", "c"], domain_forwarding=True)
In [1]: i.records
Out[1]:
  uni   element_text
0     z
1     a
2     b
3     c
In [2]: j.records
Out[2]:
  i   element_text
0   z
1   a
2   b
3   c
In [3]: k.records
Out[3]:
  j   element_text
0   a
1   b
2   c
```

It is also possible to forward to specific domain sets by passing a `list` of `bool` to the `domain_forwarding` property, as seen in the following example:

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i")
j = gt.Set(m, "j")
k = gt.Set(m, "k")
ijk = gt.Parameter(
    m,
    "ijk",
    [i, j, k],
    records=[("i", "j", "k", 1)],
domain_forwarding=[True, False, True],
)
In [1]: i.records
Out[1]:
  uni element_text
0   i
In [2]: j.records is None
Out[2]: True
In [3]: k.records
Out[3]:
  uni element_text
0   k
```

Domain Violations

Domain violations occur when domain labels appear in symbol data but they do not appear in the parent set which the symbol is defined over – attempting to execute a GAMS model when there domain violations will lead to compilation errors. Domain violations are found dynamically with the <Symbol>.findDomainViolations() method.

Note

the findDomainViolations method can be computationally expensive – UELs in GAMS are case preserving (just like symbol names); additionally, GAMS ignores all trailing white space in UELs (leading white space is considered significant). As a result, transfer must lowercase all UELs and then strip any trailing white space before doing the set comparison to locate (and create) any DomainViolation objects. findDomainViolations should not be used in a loop (nor should any of its related methods: hasDomainViolations, countDomainViolations, getDomainViolations, or dropDomainViolations).

In the following example we intentionally create data with domain violations in the a parameter:

```
m = gt.Container()
i = gt.Set(m, "i", records=["a", "b", "c"])
a = gt.Parameter(m, "a", i, records=[("aa", 1), ("c", 2)])
In [1]: a.findDomainViolations()
Out[1]:
  i    value
0  aa    1.0
In [2]: a.hasDomainViolations()
Out[2]: True
In [3]: a.countDomainViolations()
Out[3]: 1
In [4]: a.getDomainViolations()
Out[4]: [<DomainViolation at 0x7fb6b83d9630>]
```

Dynamically locating domain violations allows transfer to return a view of the underlying pandas dataframe with the problematic domain labels still intact – at this point the user is free to correct issues in the UELs with any of the *UELs methods or by simply dropping any domain violations from the dataframe completely (the dropDomainViolations method is a convenience function for this operation).

Attention

It is not possible to create a GDX file if symbols have domain violations.

Unused UELs will not result in domain violations.

Attempting to write this container to a GDX file will result in an exception.

```
m = gt.Container()
i = gt.Set(m, "i", records=["a", "b", "c"])
a = gt.Parameter(m, "a", i, records=[("aa", 1), ("c", 2)])
m.write("out.gdx")
Exception: Encountered data errors with symbol ‘a‘. Possible causes are from duplicate records and/or domain violations.
Use ’hasDuplicateRecords’, ’findDuplicateRecords’, ’dropDuplicateRecords’, and/or ’countDuplicateRecords’ to find/resolve
      duplicate records.
Use ’hasDomainViolations’, ’findDomainViolations’, ’dropDomainViolations’, and/or ’countDomainViolations’ to find/resolve
      domain violations.
GDX file was not created successfully.
```

Duplicate Records

Duplicate records can easily appear in large datasets – locating and fixing these records is straightforward with transfer. transfer includes find*, has*, count* and drop* methods for duplicate records, just as it has for domain violations.

Note

the `findDuplicateRecords` method can be computationally expensive – UELs in GAMS are case preserving (just like symbol names); additionally, GAMS ignores all trailing white space in UELs (leading white space is considered significant). As a result, `transfer` must lowercase all UELs and then strip any trailing white space before doing the set comparison to locate duplicate records. `findDuplicateRecords` should not be used in a loop (nor should any of its related methods: `hasDuplicateRecords`, `countDuplicateRecords`, or `dropDuplicateRecords`).

Dynamically locating duplicate records allows `transfer` to return a view of the underlying pandas dataframe with the problematic domain labels still intact – at this point the user is free to correct issues in the UELs with any of the `*UELs` methods or by simply dropping any duplicate records from the dataframe completely (the `dropDuplicateRecords` method is a convenience function for this operation).

```
m = gt.Container()
a = gt.Parameter(
    m,
    "a",
    ["*"],
    records=[("i" + str(i), float(i)) for i in range(4)]
    + [("j" + str(i), i) for i in range(4)]
    + [("I" + str(i), i) for i in range(4)],
)
```

Note

The user can decide which duplicate records they would like `keep` with `keep="first"` (default), `keep="last"`, or `keep=False` (which returns all duplicate records)

```
In [1]: a.records
Out[1]:
   uni    value
0     i0    0.0
1     i1    1.0
2     i2    2.0
3     i3    3.0
4     j0    0.0
5     j1    1.0
6     j2    2.0
7     j3    3.0
8     I0    0.0
9     I1    1.0
10    I2    2.0
11    I3    3.0
In [2]: a.findDuplicateRecords()
Out[2]:
   uni    value
8     I0    0.0
9     I1    1.0
10    I2    2.0
11    I3    3.0
In [3]: a.findDuplicateRecords(keep="last")
Out[3]:
  uni    value
0    i0    0.0
1    i1    1.0
2    i2    2.0
3    i3    3.0
In [4]: a.findDuplicateRecords(keep=False)
Out[4]:
   uni    value
0     i0    0.0
1     i1    1.0
2     i2    2.0
3     i3    3.0
8     I0    0.0
9     I1    1.0
10    I2    2.0
11    I3    3.0
```

Attention

It is not possible to create a GDX file if symbols have duplicate records.

Attempting to write this container to a GDX file will result in an exception.

```
m = gt.Container()
```

```
a = gt.Parameter(
    m,
    "a",
    ["*"],
    records=[("i" + str(i), float(i)) for i in range(4)]
    + [("j" + str(i), i) for i in range(4)]
    + [("I" + str(i), i) for i in range(4)],
)
m.write("out.gdx")
Exception: Encountered data errors with symbol 'a'. Possible causes are from duplicate records and/or domain violations.
Use 'hasDuplicateRecords', 'findDuplicateRecords', 'dropDuplicateRecords', and/or 'countDuplicateRecords' to find/resolve
      duplicate records.
Use 'hasDomainViolations', 'findDomainViolations', 'dropDomainViolations', and/or 'countDomainViolations' to find/resolve
      domain violations.
GDX file was not created successfully.
```

Pivoting Data

It might be convenient to pivot data into a multi-dimensional data structure rather than maintaining the flat structure in `records`. A convenience method called `pivot` is provided for all symbol classes and will return a pivoted `pandas.DataFrame`. Pivoting is only available for symbols with more than one dimension.

Example #1 - Pivot a 2D Set

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(5)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(5)])
ij = gt.Set(m, "ij", [i, j])
ij.generateRecords(density=0.25, seed=123)
In [1]: ij.pivot()
Out[1]:
       j0     j1     j3     j4
i0   True   True  False  False
i1   True  False  False  False
i2  False  False   True   True
i4  False   True  False  False
```

Example #2 - Pivot a 3D Set

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(5)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(5)])
iji = gt.Set(m, "iji", [i, j, i])
iji.generateRecords(density=0.25, seed=123)
In [1]: iji.pivot()
Out[1]:
          i0     i1     i2     i3     i4
i0 j0  False   True   True  False  False
   j1   True  False  False  False  False
   j3  False  False  False   True  False
   j4  False  False   True  False  False
i1 j0   True   True  False   True  False
   j1   True   True  False  False   True
   j2  False   True  False  False  False
   j4  False  False  False   True  False
i2 j0   True  False  False  False  False
   j1  False  False   True  False   True
   j3   True  False  False  False  False
i3 j2  False   True   True  False   True
   j3  False   True  False  False  False
   j4   True  False   True   True   True
i4 j0  False   True  False   True  False
   j1  False  False  False   True  False
   j3  False  False  False   True  False
   j4  False  False  False   True   True
In [2]: iji.pivot(fill_value="")
Out[2]:
         i0    i1    i2    i3    i4
i0 j0        True  True
   j1  True
   j3                   True
```

```
   j4             True
i1 j0  True  True       True
   j1  True  True             True
   j2       True
   j4                 True
i2 j0  True
   j1             True       True
   j3  True
i3 j2       True  True       True
   j3       True
   j4  True       True  True  True
i4 j0       True       True
   j1                  True
   j3                  True
   j4                  True  True
```

Note

When pivoting symbols with >2 dimensions, the first [0..(dimension-1)] dimensions will be set to the index and the last dimension will be pivoted into the columns. This behavior can be customized with the `index` and `columns` arguments.

Example #3 - Pivot a 3D Parameter w/ a fill_value

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(5)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(5)])
iji = gt.Parameter(m, "iji", [i, j, i])
iji.generateRecords(density=0.05, seed=123)
In [1]: iji.pivot(fill_value="NONE")
Out[1]:
             i1        i2        i3        i4
i0 j1  0.682352      NONE      NONE      NONE
   j2  0.053821      NONE   0.22036      NONE
i1 j1      NONE      NONE      NONE  0.184372
i2 j0      NONE  0.175906      NONE      NONE
i3 j4      NONE      NONE  0.812095      NONE
In [2]: iji.pivot(fill_value=0)
Out[2]:
             i1        i2        i3        i4
i0 j1  0.682352  0.000000  0.000000  0.000000
   j2  0.053821  0.000000  0.220360  0.000000
i1 j1  0.000000  0.000000  0.000000  0.184372
i2 j0  0.000000  0.175906  0.000000  0.000000
i3 j4  0.000000  0.000000  0.812095  0.000000
In [3]: iji.pivot(fill_value=gt.SpecialValues.EPS)
Out[3]:
             i1        i2        i3        i4
i0 j1  0.682352 -0.000000 -0.000000 -0.000000
   j2  0.053821 -0.000000  0.220360 -0.000000
i1 j1 -0.000000 -0.000000 -0.000000  0.184372
i2 j0 -0.000000  0.175906 -0.000000 -0.000000
i3 j4 -0.000000 -0.000000  0.812095 -0.000000
```

Example #4 - Pivot (only the marginal values) of a 3D Variable

```
import gams.transfer as gt
# NOTE: custom functions should expose a 'seed' argument
def marginal_values(seed, size):
    rng = np.random.default_rng(seed)
    return rng.normal(5, 1.2, size=size)
m = gt.Container()
i = gt.Set(m, "i", records=[f"i{i}" for i in range(5)])
j = gt.Set(m, "j", records=[f"j{i}" for i in range(5)])
iji = gt.Variable(m, "iji", "free", [i, j, i])
iji.generateRecords(density=0.05, func={"marginal": marginal_values}, seed=123)
In [1]: iji.records
Out[1]:
  i_0 j_1 i_2  level  marginal  lower  upper  scale
0  i0  j1  i1    0.0  3.813054   -inf    inf    1.0
1  i0  j2  i1    0.0  4.558656   -inf    inf    1.0
2  i0  j2  i3    0.0  6.545510   -inf    inf    1.0
3  i1  j1  i4    0.0  5.232769   -inf    inf    1.0
```

```
4  i2  j0  i2    0.0  6.104277   -inf    inf    1.0
5  i3  j4  i3    0.0  5.692525   -inf    inf    1.0
In [2]: iji.pivot(value="marginal")
Out[2]:
             i1        i3        i4        i2
i0 j1  3.813054  0.000000  0.000000  0.000000
   j2  4.558656  6.545510  0.000000  0.000000
i1 j1  0.000000  0.000000  5.232769  0.000000
i2 j0  0.000000  0.000000  0.000000  6.104277
i3 j4  0.000000  5.692525  0.000000  0.000000
```

Describing Data

The methods `describeSets`, `describeParameters`, `describeVariables`, and `describeEquations` allow the user to get a summary view of key data statistics. The returned DataFrame aggregates the output for a number of other methods (depending on symbol type). A description of each `Container` method is provided in the following subsections:

describeSets

Argument	Type	Description	Required	Default
`symbols`	`list`, `str`, NoneType	A list of sets in the `Container` to include in the output. describeSets will include aliases if they are explicitly passed by the user.	No	`None` (if `None` specified, will assume all sets – not aliases)

Returns: `pandas.DataFrame`

The following table includes a short description of the column headings in the return.

Property / Statistic	Description
`name`	name of the symbol
`is_singleton`	`bool` if the set/alias is a singleton set (or an alias of a singleton set)
`alias_with`	[OPTIONAL if users passes an alias name as part of `symbols`] name of the parent set (for alias only), None otherwise
`domain`	domain labels for the symbol
`domain_type`	`none`, `relaxed` or `regular` depending on the symbol state
`dimension`	dimension
`number_records`	number of records in the symbol
`sparsity`	`1 - number_records/cardinality`

Example #1

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
In [1]: m.describeSets()
Out[1]:
  name  is_singleton domain domain_type  dimension  number_records sparsity
0    i         False    [*]        none          1               2     None
1    j         False    [*]        none          1               3     None
```

Example #2 – with aliases

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i" + str(i) for i in range(1, 10)])
j = gt.Set(m, "j", records=["j" + str(i) for i in range(1, 10)])
ip = gt.Alias(m, "ip", i)
jp = gt.Alias(m, "jp", j)
In [1]: m.describeSets()
Out[1]:
  name  is_singleton domain domain_type  dimension  number_records sparsity
0    i         False    [*]        none          1               9     None
1    j         False    [*]        none          1               9     None
In [2]: m.describeSets(m.listSets() + m.listAliases())
Out[2]:
  name  is_singleton  is_alias alias_with domain domain_type  dimension  number_records sparsity
0    i         False     False       None    [*]        none          1               9     None
1   ip         False      True          i    [*]        none          1               9     None
2    j         False     False       None    [*]        none          1               9     None
3   jp         False      True          j    [*]        none          1               9     None
```

describeParameters

Argument	Type	Description	Required	Default
`symbols`	`list`, `str`, NoneType	A list of parameters in the `Container` to include in the output	No	`None` (if `None` specified, will assume all parameters)

Returns: `pandas.DataFrame`

The following table includes a short description of the column headings in the return.

Property / Statistic	Description
`name`	name of the symbol
`domain`	domain labels for the symbol
`domain_type`	`none`, `relaxed` or `regular` depending on the symbol state
`dimension`	dimension
`number_records`	number of records in the symbol
`min`	min value in data
`mean`	mean value in data
`max`	max value in data
`where_min`	domain of min value (if multiple, returns only first occurrence)
`where_max`	domain of max value (if multiple, returns only first occurrence)
`sparsity`	`1 - number_records/cardinality`

Example

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
In [1]: m.describeParameters()
Out[1]:
  name  domain domain_type  dimension  number_records      min     mean      max           where_min           where_max
     sparsity
0    a     [i]     regular          1               2  350.000  475.000  600.000           [seattle]          [san-diego]
      0.0
1    b     [j]     regular          1               3  275.000  300.000  325.000            [topeka]           [new-york]
      0.0
```

```
2    c  [i, j]     regular          2              6    0.126    0.176    0.225  [san-diego, topeka]  [seattle, new-york]
      0.0
3    d  [i, j]     regular          2              6    1.400    1.950    2.500  [san-diego, topeka]  [seattle, new-york]
      0.0

describeVariables

Argument	Type	Description	Required	Default
`symbols`	`list`, `str`, NoneType	A list of variables in the `Container` to include in the output	No	`None` (if `None` specified, will assume all variables)

Returns: `pandas.DataFrame`

The following table includes a short description of the column headings in the return.

Property / Statistic	Description
`name`	name of the symbol
`type`	type of variable (i.e., `binary`, `integer`, `positive`, `negative`, `free`, `sos1`, `sos2`, `semicont`, `semiint`)
`domain`	domain labels for the symbol
`domain_type`	`none`, `relaxed` or `regular` depending on the symbol state
`dimension`	dimension
`number_records`	number of records in the symbol
`sparsity`	`1 - number_records/cardinality`
`min_level`	min value in the `level`
`mean_level`	mean value in the `level`
`max_level`	max value in the `level`
`where_max_abs_level`	domain of max(abs(`level`)) in data

Example

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
In [1]: m.describeVariables()
Out[1]:
  name      type  domain domain_type  dimension  number_records sparsity  min_level  mean_level  max_level
      where_max_abs_level
0    x  positive  [i, j]     regular          2              6      0.0      0.000     150.000    300.000  [seattle,
      chicago]
1    z      free      []        none          0              1     None    153.675     153.675    153.675
      None
```

describeEquations

Argument	Type	Description	Required	Default
`symbols`	`list`, `str`, NoneType	A list of equations in the `Container` to include in the output	No	`None` (if `None` specified, will assume all equations)

Returns: `pandas.DataFrame`

The following table includes a short description of the column headings in the return.

Property / Statistic	Description
`name`	name of the symbol
`type`	type of variable (i.e., `binary`, `integer`, `positive`, `negative`, `free`, `sos1`, `sos2`, `semicont`, `semiint`)
`domain`	domain labels for the symbol
`domain_type`	`none`, `relaxed` or `regular` depending on the symbol state
`dimension`	dimension
`number_records`	number of records in the symbol
`sparsity`	`1 - number_records/cardinality`
`min_level`	min value in the `level`
`mean_level`	mean value in the `level`
`max_level`	max value in the `level`
`where_max_abs_level`	domain of max(abs(`level`)) in data

Example

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
In [1]: m.describeEquations()
Out[1]:
     name type domain domain_type  dimension  number_records sparsity  min_level  mean_level  max_level where_max_abs_level
0    cost   eq     []         none          0               1     None       -0.0         0.0       -0.0
      None
1  demand  geq    [j]      regular          1               3      0.0      275.0       300.0      325.0
      [new-york]
2  supply  leq    [i]      regular          1               2      0.0      350.0       450.0      550.0
      [san-diego]
```

describeAliases

Argument	Type	Description	Required	Default
`symbols`	`list`, `str`, NoneType	A list of alias (only) symbols in the `Container` to include in the output	No	`None` (if `None` specified, will assume all aliases – not sets)

Returns: `pandas.DataFrame`

The following table includes a short description of the column headings in the return. All data is referenced from the parent set that the alias is created from.

Property / Statistic	Description
`name`	name of the symbol
`alias_with`	name of the parent set (for alias only), None otherwise
`is_singleton`	`bool` if the set/alias is a singleton set (or an alias of a singleton set)
`domain`	domain labels for the symbol
`domain_type`	`none`, `relaxed` or `regular` depending on the symbol state

Property / Statistic	Description
`dimension`	dimension
`number_records`	number of records in the symbol
`sparsity`	`1 - number_records/cardinality`

Example

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i" + str(i) for i in range(5)])
j = gt.Set(m, "j", records=["j" + str(j) for j in range(10)])
ip = gt.Alias(m, "ip", i)
ipp = gt.Alias(m, "ipp", ip)
jp = gt.Alias(m, "jp", j)
In [1]: m.describeAliases()
Out[1]:
  name alias_with  is_singleton domain domain_type  dimension  number_records sparsity
0   ip          i         False    [*]        none          1               5     None
1  ipp          i         False    [*]        none          1               5     None
2   jp          j         False    [*]        none          1              10     None
```

Matrix Generation

`transfer` stores data in a "flat" format, that is, one record entry per DataFrame row. However, it is often necessary to convert this data format into a matrix format – `transfer` enables users to do this with relative ease using the `toDense` and the `toSparseCoo` symbol methods. The `toDense` method will return a dense N-dimensional numpy array with each dimension corresponding to the GAMS symbol dimension; it is possible to output an array up to 20 dimensions (a GAMS limit). The `toSparseCoo` method will return the data in a sparse scipy COOrdinate format, which can then be efficiently converted into other sparse matrix formats.

Attention

Both the `toDense` and `toSparseCoo` methods do not transform the underlying DataFrame in any way, they only return the transformed data.

Note

`toSparseCoo` will only convert 2-dimensional data to the scipy COOrdinate format. A user interested in sparse data for an N-dimensional symbol will need to decide how to reshape the dense array in order to generate the 2D sparse format.

Attention

In order to use the `toSparseCoo` method the user will need to install the scipy package. Scipy is not provided with GMSPython.

Both the `toDense` and `toSparseCoo` method leverage the indexing that comes along with using `categorical` data types to store domain information. This means that linking symbols together (by passing symbol objects as domain information) impacts the size of the matrix. This is best demonstrated by a few examples.

Example (1D data w/o domain linking (i.e., a relaxed domain))

```
import gams.transfer as gt
m = gt.Container()
a = gt.Parameter(m, "a", "i", records=[("a", 1), ("c", 3)])
In [1]: a.records
Out[1]:
  i    value
0   a    1.0
1   c    3.0
In [2]: a.toDense()
Out[2]: array([1., 3.])
In [3]: a.toSparseCoo()
Out[3]:
<1x2 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in COOrdinate format>
```

Note that the parameter `a` is not linked to another symbol, so when converting to a matrix, the indexing is referenced to the data structure in `a.records`. Defining a sparse parameter `a` over a set `i` allows us to extract information from the `i` domain and construct a very different dense matrix, as the following example shows:

Example (1D data w/ domain linking (i.e., a regular domain))

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["a", "b", "c", "d"])
a = gt.Parameter(m, "a", i, records=[("a", 1), ("c", 3)])
In [1]: i.records
Out[1]:
  uni   element_text
0     a
1     b
2     c
3     d
In [2]: a.records
Out[2]:
  i    value
0   a    1.0
1   c    3.0
In [3]: a.toDense()
Out[3]: array([1., 0., 3., 0.])
In [4]: a.toSparseCoo()
Out[4]:
<1x4 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in COOrdinate format>
```

Example (2D data w/ domain linking)

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["a", "b", "c", "d"])
a = gt.Parameter(m, "a", [i, i], records=[("a", "a", 1), ("c", "c", 3)])
In [1]: i.records
Out[1]:
  uni   element_text
0     a
1     b
2     c
3     d
In [2]: a.records
Out[2]:
  i_0 i_1  value
0   a   a    1.0
1   c   c    3.0
In [3]: a.toDense()
Out[3]:
array([[1., 0., 0., 0.],
       [0., 0., 0., 0.],
       [0., 0., 3., 0.],
       [0., 0., 0., 0.]])
In [4]: a.toSparseCoo()
Out[4]:
<4x4 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in COOrdinate format>
```

The Universe Set

A Unique Element (UEL) is an `(i,s)` pair where `i` (or index) is an identification number for a (string) label `s`. GAMS uses UELs to efficiently store domain entries of a record by storing the UEL ID `i` of a domain entry instead of the actual string `s`. This avoids storing the same string multiple times. The concept of UELs also exists in Python/Pandas and is called a "categorical series". `transfer` leverages these types in order to efficiently store strings and enable domain checking within the Python environment.

Each domain column in a DataFrame can be assigned a unique categorical type, the effect is that each symbol maintains its own list of UELs per dimension. It is possible to convert a categorical column to its ID number representation by using the categorical accessor `x.records[<domain_column_label>].cat.codes`; however, this type of data manipulation is not necessary within `transfer`, but could be handy when debugging data.

Pandas offers the possibility to create categorical column types that are `ordered` or not; `transfer` relies exclusively on `ordered` categorical data types (in order for a symbol to be valid it must have only `ordered` categories). By using ordered categories, `transfer` will order the UEL such that elements appear in the order in which they appeared in the data (which is how GAMS defines the UEL). `transfer` allows the user to reorder the UELs with the `uel_priority` argument in the `.write()` method.

`transfer` does not actually keep track of the UEL separately from other symbols in the `Container`, it will be created internal to the `.write()` method and is based on the order in which data is added to the container. The user can access the current state of the UEL with the `.getUELs()` container method. For example, we set a two dimensional set:

```
import gams.transfer as gt
m = gt.Container()
j = gt.Set(m, "j", ["*", "*"], records=[("i" + str(n), "j" + str(n)) for n in range(2)])
In [1]: j.records
Out[1]:
  uni_0 uni_1 element_text
0    i0    j0
1    i1    j1
In [2]: m.getUELs()
Out[2]: ['i0', 'i1', 'j0', 'j1']
```

Pandas also includes a number of methods that allow categories to be renamed, appended, etc. These methods may be useful for advanced users, but most users will probably find that modifying the original data structures and resetting the symbol records provides a simpler solution. The design of `transfer` should enable the user to quickly move data back and forth, without worrying about the deeper mechanics of categorical data.

Customize the Universe Set

The concept of a universe set is fundamental to GAMS and has consequences in many areas of GAMS programming including the order of loop execution. For example:

```
set final_model_year / 2030 /;
set t "all model years" / 2022*2030 /;

singleton set my(t) "model solve year";

loop(t,
  my(t) = yes;
  display my;
  );
```

The loop will execute model solve year `2030` first because the UEL `2030` was defined in the set `final_model_year` before it was used again in the definition of set `t`. This could lead to some surprising behavior if model time periods are linked together. Many GAMS users would create a dummy set (perhaps the first line of their model file) that contained all the UELs that had a significant order tom combat this behavior. `transfer` allows for full control (renaming as well as ordering) over the universe set through the `*UELS` methods, briefly described here:

Quick summary table of UELs functions

Method	Brief Description
addUELs	Adds UELS to a symbol dimension(s). This function does not have a container level implementation.
capitalizeUELs	Capitalize all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
casefoldUELs	Casefold all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
getUELs	Gets the UELs in a over either a symbol dimension, the entire symbol or the entire container. Unused UELs do not show up in symbol data but will show up in the GAMS UEL list.
ljustUELs	Left justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
lowerUELs	Lowercase all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
lstripUELs	Left strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
removeUELs	Removes UELs from a symbol dimension, the entire symbol, the entire container (or just a subset of symbols). If a used UEL is removed the DataFrame record will show a NaN.
renameUELs	Renames UELs in a symbol dimension, the entire symbol, the entire container (or just a subset of symbols). Very handy for harmonizing UEL labeling of data that might have originated from different sources.
reorderUELs	Reorders UELs in a symbol dimension(s). This function does not have a container level implementation.
rjustUELs	Right justify all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
rstripUELs	Right strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
setUELs	Sets UELs for a symbol dimension(s). Equivalent results could be obtained with a combination of renameUELs and reorderUELs, but this one call may have some performance advantage.
stripUELs	Strip whitespace from all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
titleUELs	Title (capitalize all individual words) in all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations
upperUELs	Uppercase all UELs in the symbol or a subset of specified dimensions, can be chained with other *UELs string operations

These tools are extremely useful when data is arriving at a model from a variety of data sources. We will describe each of these functions in detail and provide examples in the following sections.

Attention

GAMS is insensitive to trailing whitespaces, the *UELs methods will automatically trim any trailing whitespace when creating the new UELs.

getUELs Examples

getUELs is a method of all GAMS symbol classes as well as the Container class. This allows the user to retrieve (ordered) UELs from the entire container or just a specific symbol dimension. For example:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
j = gt.Set(m, "j", i, records=["j1", "j2", "j3"])
```

```
a = gt.Parameter(m, "a", [i, j], records=[(f"i{i}", f"j{i}", i) for i in range(4)])
In [1]: i.getUELs()
Out[1]: ['i1', 'i2', 'i3']
In [2]: m.getUELs()
Out[2]: ['i1', 'i2', 'i3', 'j1', 'j2', 'j3', 'i0', 'j0']
In [3]: m.getUELs("j")
Out[3]: ['j1', 'j2', 'j3']
```

addUELs Examples

`addUELs` is a method of all GAMS symbol classes. This method allows the user to add in new UELs labels to a specific dimension of a symbol – the user can add UELs that do not exist in the symbol `records`. For example:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
j = gt.Set(m, "j", i, records=["j1", "j2", "j3"])
a = gt.Parameter(m, "a", [i, j], records=[(f"i{i}", f"j{i}", i) for i in range(1,4)])
i.addUELs("ham")
a.addUELs("and", 0)
a.addUELs("cheese", 1)
In [1]: i.getUELs()
Out[1]: ['i1', 'i2', 'i3', 'ham']
In [2]: a.getUELs()
Out[2]: ['i1', 'i2', 'i3', 'and', 'j1', 'j2', 'j3', 'cheese']
```

In this example we have added three new (unused) UELs: `ham`, `and`, `cheese`. These three UELs will now appear in the GAMS universe set (accessible with `m.getUELs()`). The addition of unused UELs does not impact the validity of the symbols (i.e., unused UELs will not trigger domain violations).

removeUELs Examples

`removeUELs` is a method of all GAMS symbol classes as well as the `Container` class. As a result, this method allows the user to clean up unwanted or simply unused UELs in a symbol dimension(s), over several symbols, or over the entire container. The previous example added three unused UELs (`ham`, `and`, `cheese`), but now we want to remove these UELs in order to clean up the GAMS universe set. We can accomplish this several ways:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
j = gt.Set(m, "j", i, records=["j1", "j2", "j3"])
a = gt.Parameter(m, "a", [i, j], records=[(f"i{i}", f"j{i}", i) for i in range(1,4)])
i.addUELs("ham")
a.addUELs("and", 0)
a.addUELs("cheese", 1)
# remove symbol UELs explicitly by dimension
i.removeUELs("ham", 0)
a.removeUELs("and", 0)
a.removeUELs("cheese", 1)
# remove symbol UELs for the entire symbol
i.removeUELs("ham")
a.removeUELs(["and", "cheese"])
# remove ONLY unused UELs from each symbol, independently
i.removeUELs()
a.removeUELs()
# remove ONLY unused UELs from the entire container (all symbols)
m.removeUELs()
```

In all cases the resulting universe set will be:

```
In [1]: m.getUELs()
Out[1]: ['i1', 'i2', 'i3', 'j1', 'j2', 'j3']
```

If a user removes a UEL that appears in data, that data will be lost permanently. The domain label will be transformed into an `NaN` as seen in this example:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
j = gt.Set(m, "j", i, records=["j1", "j2", "j3"])
a = gt.Parameter(m, "a", [i, j], records=[(f"i{i}", f"j{i}", i) for i in range(1,4)])
m.removeUELs("i1")
In [1]: i.records
Out[1]:
  uni   element_text
0   NaN
```

```
1    i2
2    i3
In [2]: a.records
Out[2]:
   i   j    value
0  NaN  j1    1.0
1   i2  j2    2.0
2   i3  j3    3.0
```

Attention

A container cannot be written if there are `NaN` entries in any of the domain columns (in any symbol) – an Exception is raised if there are missing domain labels.

renameUELs Examples

`renameUELs` is a method of all GAMS symbol classes as well as the `Container` class. This method allows the user to rename UELs in a symbol dimension(s), over several symbols, or over the entire container. This particular method is very handy when attempting to harmonize labeling schemes between data structures that originated from different sources. For example:

```
m = gt.Container()
a = gt.Parameter(
    m,
    "a",
    ["*", "*"],
    records=[("WI", "IL", 10), ("IL", "IN", 12.5), ("WI", "IN", 8.7)],
    description="shipment quantities",
)
b = gt.Parameter(
    m,
    "b",
    ["*"],
    records=[("wisconsin", 1.2), ("illinois", 1.7), ("indiana", 1.2)],
    description="multipliers",
)
```

...results in the following records:

```
In [1]: a.records
Out[1]:
  uni_0 uni_1  value
0    WI    IL   10.0
1    IL    IN   12.5
2    WI    IN    8.7
In [2]: b.records
Out[2]:
       uni    value
0  wisconsin    1.2
1   illinois    1.7
2    indiana    1.2
```

However, two different data sources were used to generate the parameters `a` and `b` – one data source used the uppercase postal abbreviation of the state name and the other source used a lowercase full state name as the unique identifier. With the following syntax the user would be able to harmonize to a mixed case postal code labeling scheme (without losing any of the original UEL ordering).

```
m.renameUELs(
    {
        "WI": "Wi",
        "IL": "Il",
        "IN": "In",
        "wisconsin": "Wi",
        "illinois": "Il",
        "indiana": "In",
    }
)
```

...results in the following records (and the universe set):

```
In [1]: a.records
Out[1]:
  uni_0 uni_1  value
0    Wi    Il   10.0
1    Il    In   12.5
2    Wi    In    8.7
In [2]: b.records
Out[2]:
```

```
  uni    value
0    Wi    1.2
1    Il    1.7
2    In    1.2
```

The universe set will now be:

```
In [1]: m.getUELs()
Out[1]: ['Wi', 'Il', 'In']
```

It is possible that some data needs to be cleaned and multiple UELs need to be mapped to a single label (within a single dimension). This is not allowed under default behavior because `transfer` assumes that the provided UELs are truly unique (logically and lexicographically) – however, it might be necessary recreate the underlying categorical object to combine `n` (previously unique) UELs into one to establish the necessary logical set links. For example:

```
m = gt.Container()
a = gt.Parameter(
    m,
    "a",
    ["*", "*"],
    records=[("WISCONSIN", "iowa", 10), ("WI", "illinois", 12)],
)
In [1]: a.records
Out[1]:
      uni_0     uni_1  value
0  WISCONSIN      iowa   10.0
1         WI  illinois   12.0
```

The records are unique for `a`, but logically, there might be a need to rename `WI` to `WISCONSIN`.

```
In [1]: a.renameUELs({"WI": "WISCONSIN"})
Out[1]: Exception: Could not rename UELs (categories) in ‘a‘ dimension ‘0‘. Reason: Categorical categories must be unique
```

In order achieve the desired behavior it is necessary to pass `allow_merge=True` to `renameUELs`:

```
In [1]: a.renameUELs({"WI": "WISCONSIN"}, allow_merge=True)
In [2]: a.records
Out[2]:
      uni_0     uni_1  value
0  WISCONSIN      iowa   10.0
1  WISCONSIN  illinois   12.0
In [3]: a.getUELs()
Out[3]: ['WISCONSIN', 'iowa', 'illinois']
```

reorderUELs Examples

`reorderUELs` is a method of all GAMS symbol classes. This method allows the user to reorder UELs of a specific symbol dimension – `reorderUELs` will not all any new UELs to be create nor can they be removed. For example:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
j = gt.Set(m, "j", i, records=["j1", "j2", "j3"])
a = gt.Parameter(m, "a", [i, j], records=[(f"i{i}", f"j{i}", i) for i in range(1,4)])
In [1]: i.getUELs()
Out[1]: ['i1', 'i2', 'i3']
In [2]: m.getUELs()
Out[2]: ['i1', 'i2', 'i3', 'j1', 'j2', 'j3']
```

But perhaps we want to reorder the UELs `i1`, `i2`, `i3` to `i3`, `i2`, `i1`.

```
In [1]: i.reorderUELs(['i3', 'i2', 'i1'])
In [2]: i.getUELs()
Out[2]: ['i3', 'i2', 'i1']
In [3]: i.records
Out[3]:
  uni   element_text
0    i1
1    i2
2    i3
```

Note

> This example does not change the indexing scheme of the Pandas DataFrame at all, it only changes the underlying integer numbering scheme for the categories. We can see this by looking at the Pandas `codes`:

```
In [1]: i.records["uni"].cat.codes
Out[1]:
0    2
1    1
2    0
dtype: int8
```

setUELs Examples

`reorderUELs` is a method of all GAMS symbol classes. This method allows the user to create new UELs, rename UELs, and reorder UELs all in one method. For example:

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
```

A user could accomplish a UEL reorder operation with `setUELs`:

```
In [1]: i.setUELs(["i3", "i2", "i1"])
In [2]: i.getUELs()
Out[2]: ['i3', 'i2', 'i1']
In [3]: i.records
Out[3]:
  uni   element_text
0    i1
1    i2
2    i3
```

A user could accomplish a UEL reorder + add UELs operation with `setUELs`:

```
In [1]: i.setUELs(["i3", "i2", "i1", "j1", "j2"])
In [2]: i.getUELs()
Out[2]: ['i3', 'i2', 'i1', 'j1', 'j2']
In [3]: i.records
Out[3]:
  uni   element_text
0    i1
1    i2
2    i3
In [4]: i.records["uni"].cat.codes
Out[4]:
0    2
1    1
2    0
dtype: int8
```

A user could accomplish a UEL reorder + add + rename with `setUELs`:

```
In [1]: i.setUELs(["j3", "j2", "j1", "ham", "cheese"], rename=True)
In [2]: i.getUELs()
Out[2]: ['j3', 'j2', 'j1', 'ham', 'cheese']
In [3]: i.records
Out[3]:
  uni   element_text
0    j3
1    j2
2    j1
In [4]: i.records["uni"].cat.codes
Out[4]:
0    0
1    1
2    2
dtype: int8
```

Note

> This example does not change the indexing scheme of the Pandas DataFrame at all, but the `rename=True` flag means that the records will get updated just as if a `renameUELs` call had been made.

If a user wanted to set new UELs on top of this data, without renaming, they would need to be careful to include the current UELs in the UELs being set. It is possible to loose these labels if they are not included (which will prevent the data from being written to GDX/GMD).

```
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2", "i3"])
i.setUELs(["j1", "i2", "j3", "ham", "cheese"])
In [1]: i.getUELs()
Out[1]: ['j1', 'i2', 'j3', 'ham', 'cheese']
In [2]: i.records
Out[2]:
  uni   element_text
0   NaN
1    i2
2   NaN
```

String Manipulation on UELs

It is easy to perform common string manipulations on UELs at the dimension, symbol and container levels with a series of convenience functions: `lowerUELs`, `upperUELs`, `lstripUELs`, `rstripUELs`, `stripUELs`, `capitalizeUELs`, `casefoldUELs`, `titleUELs`, `ljustUELs`, `rjustUELs`. These methods are wrappers around Python's built in string methods and are designed to efficiently perform bulk UEL transformations on your GAMS data.

The following example shows operations on the entire container:

```
m = gt.Container()
i = gt.Set(m, "i", ["*", "*"], records=[(f"i{i}", f"j{i}") for i in range(3)])
k = gt.Set(m, "k", records=[(f"aaa{i}") for i in range(3)])
In [1]: m.getUELs()
Out[1]: ['i0', 'i1', 'i2', 'j0', 'j1', 'j2', 'aaa0', 'aaa1', 'aaa2']
In [2]: m.upperUELs()
Out[2]: <GAMS Transfer Container (0x7f8110719e10)>
In [3]: m.getUELs()
Out[3]: ['I0', 'I1', 'I2', 'J0', 'J1', 'J2', 'AAA0', 'AAA1', 'AAA2']
In [4]: m.lowerUELs("i")
Out[4]: <GAMS Transfer Container (0x7f8110719e10)>
In [5]: m.getUELs()
Out[5]: ['i0', 'i1', 'i2', 'j0', 'j1', 'j2', 'AAA0', 'AAA1', 'AAA2']
In [6]: m.upperUELs().rjustUELs(4, "_")
Out[6]: <GAMS Transfer Container (0x7f8110719e10)>
In [7]: m.getUELs()
Out[7]: ['__I0', '__I1', '__I2', '__J0', '__J1', '__J2', 'AAA0', 'AAA1', 'AAA2']
```

Note

> The `ljustUELs` and `rjustUELs` methods require the user to specify the final string length and the `fill_character` used to pad the string to achieve the final length.

Similar operations can be performed at the dimension and symbol levels as can be seen in the following examples:

```
In [1]: i.upperUELs(0)
Out[1]: <Set 'i' (0x7f8121661930)>
In [2]: i.getUELs()
Out[2]: ['I0', 'I1', 'I2', 'j0', 'j1', 'j2']
In [3]: i.casefoldUELs()
Out[3]: <Set 'i' (0x7f8121661930)>
In [4]: i.getUELs()
Out[4]: ['i0', 'i1', 'i2', 'j0', 'j1', 'j2']
```

Note

> Symbol dimension is indexed from zero (per Python convention)

Reordering Symbols

The order of the Container file requires the symbols to be sorted such that, for example, a Set used as domain of another symbol appears before that symbol. The Container will try to establish a valid ordering when writing the data. This type of situation could be encountered if the user is adding and removing many symbols (and perhaps rewriting symbols with the same name) – users should attempt to only add symbols to a `Container` once, and care must be taken when creating symbol names. The method `reorderSymbols` attempts to fix symbol ordering problems. The following example shows how this can occur:

Example Symbol reordering

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i" + str(i) for i in range(5)])
j = gt.Set(m, "j", i, records=["i" + str(i) for i in range(3)])
In [1]: m.data
Out[1]: {'i': <Set `i` (0x7f7e98907e50)>, 'j': <Set `j` (0x7f7e987fb580)>}
# now we remove the set i and recreate the data
m.removeSymbols("i")
i = gt.Set(m, "i", records=["i" + str(i) for i in range(5)])
```

The symbols are now out of order in `.data` and must be reordered:

```
In [1]: m.data
Out[1]: {'j': <Set `j` (0x7f7e987fb580)>, 'i': <Set `i` (0x7f7e9885a140)>}
# calling reorderSymbols() will order the dictionary properly, but the domain reference in j is now broken
m.reorderSymbols()
# fix the domain reference in the set j
j.domain = i
In [1]: m.isValid()
Out[1]: True
```

Rename Symbols

It is possible to rename a symbol even after it has been added to a `Container`. There are two methods that can be used to achieve the desired outcome:

- using the container method `renameSymbol`
- directly changing the `name` symbol property

We create a `Container` with two sets:

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego"])
j = gt.Set(m, "j", records=["new-york", "chicago", "topeka"])
```

Example #1 - Change the name of a symbol with the container method

```
In [1]: m.renameSymbol("i","h")
In [2]: m.data
Out[2]: {'h': <Set `h` (0x7f7e988582e0)>, 'j': <Set `j` (0x7f7e801240d0)>}
```

Example #2 - Change the name of a symbol with the .name attribute

```
In [1]: i.name = "h"
In [2]: m.data
Out[2]: {'h': <Set `h` (0x7f7e98907520)>, 'j': <Set `j` (0x7f7ea84bb0d0)>}
```

Note

> Note that the renamed symbols maintain the original symbol order, this will prevent unnecessary reordering operations later in the workflow.

Removing Symbols

Removing symbols from a container is easy when using the `removeSymbols` container method; this method accepts either a `str` or a `list` of `str`.

Attention

> Once a symbol has been removed, it is possible to have hanging references as domain links in other symbols. The user will need to repair these other symbols with the proper domain links in order to avoid validity errors.

GAMS Special Values

The GAMS system contains five special values: `UNDEF` (undefined), `NA` (not available), `EPS` (epsilon), `+INF` (positive infinity), `-INF` (negative infinity). These special values must be mapped to their Python equivalents. `transfer` follows the following convention to generate the `1:1` mapping:

- `+INF` is mapped to `float("inf")`
- `-INF` is mapped to `float("-inf")`
- `EPS` is mapped to `-0.0` (mathematically identical to zero)
- `NA` is mapped to a special `NaN`
- `UNDEF` is mapped to `float("nan")`

`transfer` syntax is designed to quickly get data into a form that is usable in further analyses or visualization; this mapping also highlights the preference for data that is of type `float`, which offers performance benefits within Pandas/NumPy. The user does not need to remember these constants as they are provided within the class `SpecialValues` as `SpecialValues.POSINF`, `SpecialValues.NEGINF`, `SpecialValues.EPS`, `SpecialValues.NA`, and `SpecialValues.UNDEF`. The `SpecialValues` class also contains methods to test for these special values. Some examples are shown below; already, we, begin to introduce some of the `transfer` syntax.

Example (special values in a parameter)

```
import gams.transfer as gt
m = gt.Container()
x = gt.Parameter(
    m,
    "x",
    ["*"],
    records=[
        ("i1", 1),
        ("i2", gt.SpecialValues.POSINF),
        ("i3", gt.SpecialValues.NEGINF),
        ("i4", gt.SpecialValues.EPS),
        ("i5", gt.SpecialValues.NA),
        ("i6", gt.SpecialValues.UNDEF),
    ],
    description="special values",
)
```

The following DataFrame for `x` would look like:

```
In [1]: x.records
Out[1]:
  uni    value
0    i1    1.0
1    i2    inf
2    i3   -inf
3    i4   -0.0
4    i5    NaN
5    i6    NaN
```

The user can now easily test for specific special values in the `value` column of the DataFrame (returns a boolean array):

```
In [1]: gt.SpecialValues.isNA(x.records["value"])
Out[1]: array([False, False, False, False,  True, False])
```

Other data structures can be passed into these methods as long as these structures can be converted into a numpy array with `dtype=float`. It follows that:

```
In [1]: gt.SpecialValues.isEps(gt.SpecialValues.EPS)
Out[1]: True
In [2]: gt.SpecialValues.isPosInf(gt.SpecialValues.POSINF)
Out[2]: True
In [3]: gt.SpecialValues.isNegInf(gt.SpecialValues.NEGINF)
Out[3]: True
```

```
In [4]: gt.SpecialValues.isNA(gt.SpecialValues.NA)
Out[4]: True
In [5]: gt.SpecialValues.isUndef(gt.SpecialValues.UNDEF)
Out[5]: True
In [6]: gt.SpecialValues.isUndef(gt.SpecialValues.NA)
Out[6]: False
In [6]: gt.SpecialValues.isNA(gt.SpecialValues.UNDEF)
Out[6]: False
```

Pandas DataFrames allow data columns to exist with mixed type (`dtype=object`) – `transfer` leverages this convenience feature to enable users to import string representations of `EPS`, `NA`, and `UNDEF`. `transfer` is tolerant of any mixed-case special value string representation. Python offers additional flexibility when representing negative/positive infinity. Any string `x` where `float(x) == float("inf")` evaluates to True can be used to represent positive infinity. Similarly, any string `x` where `float(x) == float("-inf")` evaluates to True can be used to represent negative infinity. Allowed values include `inf`, `+inf`, `INFINITY`, `+INFINITY`, `-inf`, `-INFINITY` and all mixed-case equivalents.

Example (special values defined by strings)

```
import gams.transfer as gt
m = gt.Container()
x = gt.Parameter(
    m,
    "x",
    ["*"],
    records=[
        ("i1", 1),
        ("i2", "+inf"),
        ("i3", "-infinity"),
        ("i4", "eps"),
        ("i5", "na"),
        ("i6", "undef"),
    ],
    description="special values",
)
```

These special strings will be immediately mapped to their `float` equivalents from the `SpecialValues` class in order to ensure that all data entries are float types.

Standard Data Formats

This section is meant to introduce the standard format that `transfer` expects for symbol records. It has already been mentioned that we store data as a Pandas DataFrame, but there is an assumed structure to the column headings and column types that will be important to understand. `transfer` includes convenience functions in order to ease the burden of converting data from a user-centric format to one that is understood by `transfer`. However, advanced users will want to convert their data first and add it directly to the Container to avoid making extra copies of (potentially large) data sets.

Set Records Standard Format

All set records (including singleton sets) are stored as a Pandas DataFrame with `n` number of columns, where `n` is the dimensionality of the symbol + 1. The first `n-1` columns include the domain elements while the last column includes the set element explanatory text. Records are organized such that there is one record per row.

The names of the domain columns are flexible, but `transfer` requires unique column names. Users are encouraged to change the column headings of the underlying dataframe by using the `domain_labels` property. Using this property will ensure that unique column names are generated by adding a `_<dimension>` tag to the end of any user supplied column names. The explanatory text column is called `element_text` and must take the last position in the DataFrame.

All domain columns must be a categorical data type and the `element_text` column must be a `object` type. Pandas allows the categories (basically the unique elements of a column) to be various data types as well, however `transfer` requires that all these are type `str`. All rows in the `element_text` column must be type `str`.

Some examples:

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego"])
j = gt.Set(m, "j", [i, "*"], records=[("seattle", "new-york"), ("san-diego", "st-louis")])
k = gt.Set(m, "k", [i], is_singleton=True, records=["seattle"])
In [1]: i.records
Out[1]:
         uni element_text
0    seattle
1  san-diego
In [2]: j.records
Out[2]:
           i       uni element_text
0    seattle  new-york
1  san-diego  st-louis
In [3]: k.records
Out[3]:
         i element_text
0  seattle
```

Parameter Records Standard Format

All parameter records (including scalars) are stored as a Pandas DataFrame with `n` number of columns, where `n` is the dimensionality of the symbol + 1. The first `n-1` columns include the domain elements while the last column includes the numerical value of the records. Records are organized such that there is one record per row. Scalar parameters have zero dimension, therefore they only have one column and one row.

By default, the names of the domain columns follow a pattern of <`set_name`>; a symbol dimension that is referenced to the universe is labeled `uni`. The domain labels can be customized. Users are encouraged to change the column headings of the underlying dataframe by using the `domain_labels` property. Using this property will ensure that unique column names are generated (if not currently unique) by adding a _<`dimension`> tag to the end of any user supplied column names. The value column is called `value` and must take the last position in the DataFrame.

All domain columns must be a categorical data type and the `value` column must be a `float` type. Pandas allows the categories (basically the unique elements of a column) to be various data types as well, however `transfer` requires that all these are type `str`.

Some examples:

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego"])
a = gt.Parameter(m, "a", ["*"], records=[("seattle", 50), ("san-diego", 100)])
b = gt.Parameter(
    m,
    "b",
    [i, "*"],
    records=[("seattle", "new-york", 32.2), ("san-diego", "st-louis", 123)],
)
c = gt.Parameter(m, "c", records=90)
In [1]: a.records
Out[1]:
       uni    value
0    seattle   50.0
1  san-diego  100.0
In [2]: b.records
Out[2]:
         i       uni    value
0    seattle  new-york   32.2
1  san-diego  st-louis  123.0
In [3]: c.records
Out[3]:
   value
0   90.0
```

Variable/Equation Records Standard Format

Variables and equations share the same standard data format. All records (including scalar variables/equations) are stored as a Pandas DataFrame with `n` number of columns, where `n` is the dimensionality of the symbol + 5. The first `n-5` columns include the domain elements while the last five columns include the numerical values for different attributes of the records. Records are organized such that there is one record per row. Scalar variables/equations have zero dimension, therefore they have five columns and one row.

By default, the names of the domain columns follow a pattern of <`set_name`>; a symbol dimension that is referenced to the universe is labeled `uni`. The domain labels can be customized. Users are encouraged to change the column headings of the underlying dataframe by using the `domain_labels` property. Using this property will ensure that unique column names are generated (if not currently unique) by adding a `_`<`dimension`> tag to the end of any user supplied column names. The attribute columns are called `level`, `marginal`, `lower`, `upper`, and `scale`. These attribute columns must appear in this order. Attributes that are not supplied by the user will be assigned the default GAMS values for that variable/equation type; it is possible to not pass any attributes, `transfer` would then simply assign default values to all attributes.

All domain columns must be a categorical data type and all the attribute columns must be a `float` type. Pandas allows the categories (basically the unique elements of a column) to be various data types as well, however `transfer` requires that all these are type `str`.

Some examples:

```
import gams.transfer as gt
import pandas as pd
m = gt.Container()
i = gt.Set(m, "i", records=["seattle", "san-diego"])
a = gt.Variable(
    m,
    "a",
    "free",
    domain=[i],
    records=pd.DataFrame(
        [("seattle", 50), ("san-diego", 100)], columns=["city", "level"]
    ),
)
In [1]: a.records
Out[1]:
         i    level  marginal  lower  upper  scale
0    seattle   50.0       0.0   -inf    inf    1.0
1  san-diego  100.0       0.0   -inf    inf    1.0
```

GDX Read/Write

Up until now, we have been focused on using `transfer` to create symbols in an empty `Container` using the symbol constructors (or their corresponding container methods). These tools will enable users to ingest data from many different formats and add them to a `Container` – however, it is also possible to read in symbol data directly from GDX files using the `read` container method. In the following sections, we will discuss this method in detail as well as the `write` method, which allows users to write out to new GDX files.

Read GDX

There are two main ways to read in GDX based data.

- Pass the file path directly to the Container constructor (will read all symbols and records)
- Pass the file path directly to the `read` method (default read all symbols, but can read partial files)

The first option here is provided for convenience and will, internally, call the `read` method. This method will read in all symbols as well as their records. This is the easiest and fastest way to get data out of a GDX file and into your Python environment. For the following examples we leverage the GDX output generated from the **`trnsport.gms`** model file.

Example (reading full data w/ Container constructor)

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
In [1]: m.data
Out[1]:
{'i': <Set `i` (0x7f95b8d63e80)>,
 'j': <Set `j` (0x7f95b8d63a60)>,
 'a': <Parameter `a` (0x7f95b8d63ee0)>,
 'b': <Parameter `b` (0x7f95b8d63d00)>,
 'd': <Parameter `d` (0x7f95b8da86a0)>,
 'f': <Parameter `f` (0x7f95b8da8670)>,
 'c': <Parameter `c` (0x7f95b8da83d0)>,
 'x': <Positive Variable `x` (0x7f95b8da83a0)>,
 'z': <Free Variable `z` (0x7f95b8da8400)>,
 'cost': <Eq Equation `cost` (0x7f95b8da82b0)>,
 'supply': <Leq Equation `supply` (0x7f95b8da8280)>,
 'demand': <Geq Equation `demand` (0x7f95b8da8580)>}
 In [1]: m.describeParameters()
 Out[1]:
  name  domain domain_type  dimension  number_records      min     mean      max            where_min            where_max
      sparsity
0    a     [i]     regular          1              2  350.000  475.000  600.000            [seattle]          [san-diego]
      0.0
1    b     [j]     regular          1              3  275.000  300.000  325.000             [topeka]            [new-york]
      0.0
2    c  [i, j]     regular          2              6    0.126    0.176    0.225  [san-diego, topeka]  [seattle, new-york]
      0.0
3    d  [i, j]     regular          2              6    1.400    1.950    2.500  [san-diego, topeka]  [seattle, new-york]
      0.0
4    f      []        none          0              1   90.000   90.000   90.000                 None                 None
      None
```

A user could also read in data with the `read` method as shown in the following example.

Example (reading full data w/ `read` method)

```
import gams.transfer as gt
m = gt.Container()
m.read("trnsport.gdx")
In [1]: m.data
Out[1]:
{'i': <Set `i` (0x7f95b8d63e80)>,
 'j': <Set `j` (0x7f95b8d63a60)>,
 'a': <Parameter `a` (0x7f95b8d63ee0)>,
 'b': <Parameter `b` (0x7f95b8d63d00)>,
 'd': <Parameter `d` (0x7f95b8da86a0)>,
 'f': <Parameter `f` (0x7f95b8da8670)>,
 'c': <Parameter `c` (0x7f95b8da83d0)>,
 'x': <Positive Variable `x` (0x7f95b8da83a0)>,
 'z': <Free Variable `z` (0x7f95b8da8400)>,
 'cost': <Eq Equation `cost` (0x7f95b8da82b0)>,
 'supply': <Leq Equation `supply` (0x7f95b8da8280)>,
 'demand': <Geq Equation `demand` (0x7f95b8da8580)>}
```

It is also possible to read in a partial GDX file with the `read` method, as shown in the following example:

```
m = gt.Container()
m.read("trnsport.gdx", "x")
In [1]: m.data
Out[1]: {'x': <Positive Variable `x` (0x7f9598a38dc0)>}
In [2]: m.data["x"].records
Out[2]:
         i         j    level  marginal  lower  upper  scale
0    seattle  new-york   50.0     0.000    0.0    inf    1.0
1    seattle   chicago  300.0     0.000    0.0    inf    1.0
2    seattle    topeka    0.0     0.036    0.0    inf    1.0
3  san-diego  new-york  275.0     0.000    0.0    inf    1.0
4  san-diego   chicago    0.0     0.009    0.0    inf    1.0
5  san-diego    topeka  275.0     0.000    0.0    inf    1.0
```

This syntax assumes that the user will always want to read in both the metadata as well as the actual data records, but it is possible to skip the reading of the records by passing the argument `records=False`.

```
m = gt.Container()
m.read("trnsport.gdx", "x", records=False)
In [1]: m.data
Out[1]: {'x': <Positive Variable `x` (0x7f9598a3a200)>}
In [2]: m["x"].summary
```

```
Out[2]:
{'name': 'x',
 'description': 'shipment quantities in cases',
 'type': 'positive',
 'domain': ['i', 'j'],
 'domain_type': 'regular',
 'dimension': 2,
 'number_records': 6}
In [3]: type(m["x"].records)
Out[3]: <class 'NoneType'>
```

Attention

> The `read` method attempts to link the domain objects together (in order to have a "regular" `domain_type`) but if domain sets are not part of the read operation there is no choice but to default to a "relaxed" `domain_type`. This can be seen in the last example where we only read in the variable `x` and not the domain sets (`i` and `j`) that the variable is defined over. All the data will be available to the user, but domain checking is no longer possible. The symbol `x` will remain with "relaxed" domain type even if the user were to read in sets `i` and `j` in a second `read` call.

Write GDX

A user can write data to a GDX file by simply passing a file path (as a string). The `write` method will then create the GDX and write all data in the `Container`.

Example

```
m.write("path/to/file.gdx")
```

Example (write a compressed GDX file)

```
m.write("path/to/file.gdx", compress=True)
```

By default, all symbols in the Container will be written, however it is possible to write a subset of the symbols to a GDX file with the `symbols` argument. If a domain set is not included in the `symbols` list then the symbol will automatically be relaxed (but will retain the domain set's name as a string label – it does not get relaxed to $*$). This behavior can be seen in the following example.

```
import gams.transfer as gt
m = gt.Container()
i = gt.Set(m, "i", records=["i1", "i2"])
a = gt.Parameter(
    m,
    "a",
    [i, i],
    records=[("i1", "i1", 10), ("i2", "i2", 12)],
)
m.write("out.gdx", "a")
# create a new container and read in the GDX
m2 = gt.Container("out.gdx")
# look at all the data
In [1]: m2.data
Out[1]: {'a': <Parameter `a` (0x7f9598a61510)>}
# notice that `a` has a relaxed domain type now
In [2]: m2["a"].domain_type
Out[2]: 'relaxed'
# `a` retains the labels from the original domain sets
In [3]: m2["a"].domain
Out[3]: ['i', 'i']
# The original container `m` retains its original state before writing
In [4]: m["a"].domain
Out[4]: [<Set `i` (0x7f9598a39a80)>, <Set `i` (0x7f9598a39a80)>]
```

In line 4 we can see that the auto-relaxation of the domain for `a` is only temporary for writing (in this case, from Container object `m`) and will be restored so as not to disturb the Container state.

Advanced users might want to specify an order to their UEL list (i.e., the universe set); recall that the UEL ordering follows that dictated by the data. As a convenience, it is possible to prepend the UEL list with a user specified order using the `uel_priority` argument.

Example (change the order of the UEL)

```
m = gt.Container()
i = gt.Set(m, "i", records=["a", "b", "c"])
m.write("foo.gdx", uel_priority=["a", "c"])
```

The original UEL order for this GDX file would have been `["a", "b", "c"]`, but this example reorders the UEL with `uel_priority` – the positions of `b` and `c` have been swapped. This can be verified with the `gdxdump` utility (using the `uelTable` argument):

```
gdxdump foo.gdx ueltable=foo

Set foo /
  'a' ,
  'c' ,
  'b' /;
$onEmpty

Set i(*) /
'a',
'c',
'b' /;

$offEmpty
```

GamsDatabase Read/Write

We have discussed how to create symbols in an empty `Container` and we have discussed how to exchange data with GDX files, however it is also possible to read and write data directly in memory by interacting with a GamsDatabase/GMD object – this allows `transfer` to be used to read/write data within an Embedded Python Code environment or in combination with the Python OO API. There are some important differences when compared to data exchange with GDX since we are working with data representations in memory.

Read GamsDatabases

Just as with a GDX, there are two main ways to read in data that is in a GamsDatabase/GMD object.

- Pass the GamsDatabase/GMD object directly to the Container constructor (will read all symbols and records)
- Pass the GamsDatabase/GMD object directly to the `read` method (default read all symbols, but can read partial files)

The first option here is provided for convenience and will, internally, call the `read` method. This method will read in all symbols as well as their records. This is the easiest and fastest way to get data out of a GamsDatabase/GMD object and into your Python environment. While it is possible to generate a custom GamsDatabase/GMD object from scratch (using the `gmdcc` API), most users will be interacting with a GamsDatabase/GMD object that has already been instantiated internally when he/she is using Embedded Python Code or the GamsDatabase class in the Python OO API. Our examples will show how to access the GamsDatabase/GMD object – we leverage the some of the data from the **`trnsport.gms`** model file.

Example (reading full data w/ Container constructor)

```
m = gt.Container(gams.db)
```

Note

Embedded Python Code users will want pass the GamsDatabase object that is part of the GAMS Database object – this will always be referenced as `gams.db` regardless of the model file.

The following example uses embedded Python code to create a new Container, read in all symbols, and display some summary statistics as part of the gams log output.

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

Parameter
   a(i) 'capacity of plant i in cases'
        / seattle    350
          san-diego  600 /

   b(j) 'demand at market j in cases'
        / new-york   325
          chicago    300
          topeka     275 /;

Table d(i,j) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;

$onembeddedCode Python:
import gams.transfer as gt

m = gt.Container(gams.db)
print(m.describeSets())

print(m.describeParameters())

$offEmbeddedCode
```

The gams log output will then look as such (the extra `print` calls are just providing nice spacing for this example):

```

2    d  [i, j]     regular          2               6    1.400    1.950    2.500  [san-diego, topeka]

--- Starting execution - empty program
*** Status: Normal completion

[3 rows x 16 columns]

--- Starting execution - empty program
*** Status: Normal completion
```

A user could also read in a subset of the data located in the GamsDatabase object with the `read` method as shown in the following example. Here we only read in the sets `i` and `j`, as a result the `.describeParameters()` method will return `None`.

Example (reading subset of full data w/ `read` method)

```
Set
   i 'canning plants' / seattle,  san-diego /
   j 'markets'        / new-york, chicago, topeka /;

Parameter
   a(i) 'capacity of plant i in cases'
        / seattle    350
          san-diego  600 /

   b(j) 'demand at market j in cases'
        / new-york   325
          chicago    300
          topeka     275 /;

Table d(i,j) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;

$onembeddedCode Python:
import gams.transfer as gt

m = gt.Container()
m.read(gams.db, symbols=["i","j"])
gams.printLog("")
print(m.describeSets())
print(m.describeParameters())

$offEmbeddedCode
```

```

```

All the typical functionality of the Container exists when working with GamsDatabase/GMD objects. This means that domain linking, matrix conversion, and other more advanced options are available to the user at either compilation time or execution time (depending on the Embedded Code syntax being used, see: Syntax). The next example generates a 1000x1000 matrix and then takes its inverse using the Numpy `linalg` package.

Example (Matrix Generation and Inversion)

```
set i / i1*i1000 /;
alias(i,j);

parameter a(i,j);
a(i,j) = 1 / (ord(i)+ord(j) - 1);
a(i,i) = 1;

embeddedCode Python:
import gams.transfer as gt
import numpy as np
import time

gams.printLog("")
s = time.time()
m = gt.Container(gams.db)
gams.printLog(f"read data: {round(time.time() - s, 3)} sec")

s = time.time()
A = m["a"].toDense()
gams.printLog(f"create matrix A: {round(time.time() - s, 3)} sec")

s = time.time()
invA = np.linalg.inv(A)
gams.printLog(f"generate inv(A): {round(time.time() - s, 3)} sec")

endEmbeddedCode
```

Note

> In this example, the assignment of the `a` parameter is done during execution time so we must use the execution time syntax for embedded code in order to get the numerical records properly.

```
GAMS 43.1.0   Copyright (C) 1987-2023 GAMS Development. All rights reserved
--- Starting compilation
--- test.gms(27) 3 Mb
--- Starting execution: elapsed 0:00:00.003
--- test.gms(9) 36 Mb
--- Initialize embedded library libembpycclib64.dylib
```

```
--- Execute embedded library libembpycclib64.dylib
---
--- read data: 1.1 sec
--- create matrix A: 0.02 sec
--- generate inv(A): 0.031 sec
*** Status: Normal completion
```

We will extend this example in the next section to write the inverse matrix `A` back into a GAMS parameter.

Write to GamsDatabases

A user can write to a GamsDatabase/GMD object with the `.write()` method just as he/she would write a GDX file – however there are some important differences. When a user writes a GDX file the entire GDX file represents a complete data environment (all domains have been resolved, etc.) thus, `transfer` does not need to worry about merge/replace operations. It is possible to merge/replace symbol records when a user is writing data to in-memory data representations with GamsDatabase/GMD. We show a few examples to illustrate this behavior.

Example (Populating a set in GAMS)

```
* note that we need to declare the set i over "*" in order to provide hints about the symbol dimensi
set i(*);

$onembeddedCode Python:
import gams.transfer as gt

m = gt.Container()
i = gt.Set(m, "i", records=["i"+str(i) for i in range(10)])
m.write(gams.db)

$offEmbeddedCode i

embeddedCode Python:
import gams.transfer as gt

m = gt.Container(gams.db)
gams.printLog("")
print(m["i"].records)

endEmbeddedCode
```

Note

> In general, it is possible to use `transfer` to create new symbols in a GamsDatabase and GMD object (and not necessarily merge symbols) but embedded code best practices necessitate the declaration of any GAMS symbols on the GAMS side first, then the records can be filled with `transfer`.

If we break down this example we can see that the set `i` is declared within GAMS (with no records) and then the records for `i` are set by writing a `Container` to the `gams.db` GamsDatabase object (we do this at compile time). The second embedded Python code block runs at execution time and is simply there to read all the records on the set `i` – printing the sets this way adds the output to the `.log` file (we could also use the more common `display i;` operation in GAMS to display the set elements in the LST file).

```
GAMS 43.1.0   Copyright (C) 1987-2023 GAMS Development. All rights reserved
--- Starting compilation
--- test.gms(10) 2 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
--- test.gms(20) 3 Mb
--- Starting execution: elapsed 0:00:01.464
--- test.gms(13) 4 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
---   uni   element_text
0    i0
1    i1
2    i2
3    i3
4    i4
5    i5
6    i6
7    i7
8    i8
9    i9

*** Status: Normal completion
```

Example (Merging set records)

```
set i / i1, i2 /;

$onmulti
$onembeddedCode Python:
import gams.transfer as gt

m = gt.Container()
i = gt.Set(m, "i", records=["i"+str(i) for i in range(10)])
m.write(gams.db, merge_symbols="i")

$offEmbeddedCode i
$offmulti

embeddedCode Python:
import gams.transfer as gt

m = gt.Container(gams.db)
gams.printLog("")
print(m["i"].records)

endEmbeddedCode
```

In this example we need to make use of $onMulti/$offMulti in order to merge new set elements into the the set `i` (the same would be true if we were merging other symbol types) – any symbol that already has records defined (in GAMS) and is being added to with Python (and `transfer`) must be wrapped with $onMulti/$offMulti. As with the previous example, the second embedded Python code block runs at execution time and is simply there to read all the records on the set `i`. Note that the UEL order will be different in this case (`i1` and `i2` come before `i0`).

```
GAMS 43.1.0   Copyright (C) 1987-2023 GAMS Development. All rights reserved
--- Starting compilation
--- test.gms(11) 3 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
--- test.gms(21) 3 Mb
--- Starting execution: elapsed 0:00:01.535
--- test.gms(14) 4 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
---   uni   element_text
0    i1
1    i2
2    i0
3    i3
4    i4
5    i5
6    i6
7    i7
8    i8
9    i9

*** Status: Normal completion
```

Example (Replacing set records)

```
set i / x1, x2 /;

$onmultiR
$onembeddedCode Python:
import gams.transfer as gt

m = gt.Container()
i = gt.Set(m, "i", records=["i"+str(i) for i in range(10)])
m.write(gams.db)

$offEmbeddedCode i
$offmulti

embeddedCode Python:
import gams.transfer as gt

m = gt.Container(gams.db)
gams.printLog("")
print(m["i"].records)

endEmbeddedCode
```

In this example we want to replace the `x1` and `x2` set elements and built up a totally new element list with set elements from the `Container`. Instead of `$onMulti`/`$offMulti` we must use `$onMultiR`/`$offMulti` to ensure that the replacement happens in GAMS; we also need to remove the set `i` from the `merge_symbols` argument.

Attention

If the user seeks to replace all records in a symbol they must use the `$onMultiR` syntax. It is not sufficient to simply remove them from the `merge_symbols` argument in `transfer`. If the user mistakenly uses `$onMulti` the symbols will end up merging without total replacement.

```
GAMS 43.1.0   Copyright (C) 1987-2023 GAMS Development. All rights reserved
--- Starting compilation
--- test.gms(11) 3 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
--- test.gms(21) 3 Mb
--- Starting execution: elapsed 0:00:01.482
--- test.gms(14) 4 Mb
--- Initialize embedded library libembpycclib64.dylib
--- Execute embedded library libembpycclib64.dylib
---    uni   element_text
0     i0
1     i1
2     i2
3     i3
4     i4
5     i5
6     i6
7     i7
8     i8
9     i9

*** Status: Normal completion
```

Example (Merging parameter records)

```
set i;
parameter a(i<) /
i1 1.23
i2 5
/;

$onmulti
$onembeddedCode Python:
import gams.transfer as gt

m = gt.Container()
i = gt.Set(m, "i", records=["i"+str(i) for i in range(10)])
a = gt.Parameter(m, "a", domain=i, records=[("i"+str(i),i) for i in range(10)])
m.write(gams.db, merge_symbols="a")

$offEmbeddedCode i, a
$offmulti

embeddedCode Python:
import gams.transfer as gt

m = gt.Container(gams.db)
gams.printLog("")
print(m["a"].records)
endEmbeddedCode
```

In this example we also need to make use of `$onMulti/$offMulti` in order to merge new set elements into the the set `i`, however the set `i` also needs to contain the elements that are defined in the parameter – here we make use of the < operator that will add the set elements from `a(i)` into the set `i`

Note

It would also be possible to run this example by explicitly defining the `set i /i1, i2/;` before the parameter declaration.

Attention

`transfer` will overwrite all duplicate records when merging. The original values of `a("i1")` and `a("i2")` have been replaced with their new values when writing the Container in this example (see output below).

2  i3    3.0
3  i4    4.0
4  i5    5.0
5  i6    6.0
6  i7    7.0
7  i8    8.0
8  i9    9.0

*** Status: Normal completion
```

Example (Advanced Matrix Generation and Inversion w/ Write Operation)

```
set i / i1*i1000 /;
alias(i,j);

parameter a(i,j);
a(i,j) = 1 / (ord(i)+ord(j) - 1);
a(i,i) = 1;

parameter inv_a(i,j);
parameter ident(i,j);

embeddedCode Python:
import gams.transfer as gt
import numpy as np
```

```
import time

gams.printLog("")
gams.printLog("")

s = time.time()
m = gt.Container(gams.db)
gams.printLog(f"read data: {round(time.time() - s, 3)} sec")

s = time.time()
A = m["a"].toDense()
gams.printLog(f"create matrix A: {round(time.time() - s, 3)} sec")

s = time.time()
invA = np.linalg.inv(A)
gams.printLog(f"calculate inv(A): {round(time.time() - s, 3)} sec")

s = time.time()
m["inv_a"].setRecords(invA)
gams.printLog(f"convert matrix to records for inv(A): {round(time.time() - s, 3)} sec")

s = time.time()
I = np.dot(A,invA)
tol = 1e-9
I[np.where((I<tol) & (I>-tol))] = 0
gams.printLog(f"calculate A*invA + small number cleanup: {round(time.time() - s, 3)} sec")

s = time.time()
m["ident"].setRecords(I)
gams.printLog(f"convert matrix to records for I: {round(time.time() - s, 3)} sec")

s = time.time()
m.write(gams.db, ["inv_a","ident"])
gams.printLog(f"write to GamsDatabase: {round(time.time() - s, 3)} sec")

gams.printLog("")
endEmbeddedCode inv_a, ident

display ident;
```

In this example we extend the example shown in Read GamsDatabases to read data from GAMS, calculate a matrix inversion, do the matrix multiplication, and then write both the `A^-1` and `A*A^-1` (i.e., the identity matrix) back to GAMS for display in the LST file. This data round trip highlights the benefits of using a `transfer` Container (and the linked symbol structure) as the mechanism to move data – converting back and forth from a records format to a matrix format can be cumbersome, but here, `transfer` takes care of all the indexing for the user.

The first few lines of GAMS code generates a 1000x1000 `A` matrix as a parameter (at execution time), we then define two more parameters that we will fill with results of the embedded Python code – specifically we want to fill a parameter with the matrix `A^-1` and we want to verify that another parameter (`ident`) contains the identity matrix (i.e., `I`). Stepping through the code:

1. We start the embedded Python code section (execution time) by importing both `transfer` and Numpy and by reading all the symbols that currently exist in the GamsDatabase. We must read in all this information in order to get the domain set information – `transfer` needs these domain sets in order to generate matricies with the proper size.
2. Generate the matrix `A` by calling `.toDense()` on the symbol object in the Container.

3. Take the inverse of `A` with `np.linalg.inv()`.
4. The Parameter symbol for `inv_a` already exists in the Container, but it does not have any records (i.e., `m["inv_a"].records is None` will evaluate to True). We use `.setRecords()` to convert the `invA` back into a records format.
5. We continue the computations by performing the matrix multiplication using `np.dot()` – we must clean up a lot of small numbers in `I`.
6. The Parameter symbol for `ident` already exists in the Container, but it does not have any records. We use `.setRecords()` to convert `I` back into a records format.
7. Since we are calculating these parameter values at execution time, it is not possible to modify the domain set information (or even merge/replace it). Therefore we only want to write the parameter values to GAMS. We achieve this by writing a subset of the Container symbols out with the `m.write(gams.db, ["inv_a","ident"])` call. This partial write preserves symbol validity in the Container and it does not violate other GAMS requirements.
8. Finally, we can verify that the (albeit large) identity matrix exists in the LST file (or in another GDX file).

Note

It was not possible to just use `np.round` because small negative numbers that round to `-0.0` will be interpreted by `transfer` as the GAMS EPS special value.

The output for this example is shown below:

```

```

Container Read

Containers can read from other `Container` instances. The syntax and behavior is much the same as reading from GDX and GMD sources. It is important to note that a deepcopy of all data is made when reading from these sources. The container object can be passed into the constructor (to be consistent with the shorthand notation) or the object can be passed as a argument to the `.read()` method.

```
import gams.transfer as gt
m = gt.Container("trnsport.gdx")
In [1]: m.data
Out[1]:
```

```
{'i': <Set `i` (0x7fc1d86d8e80)>,
 'j': <Set `j` (0x7fc1d86d8e50)>,
 'a': <Parameter `a` (0x7fc1d86d8df0)>,
 'b': <Parameter `b` (0x7fc1d86d8fa0)>,
 'd': <Parameter `d` (0x7fc1d86d84c0)>,
 'f': <Parameter `f` (0x7fc1d86d9000)>,
 'c': <Parameter `c` (0x7fc1d86d9120)>,
 'x': <Positive Variable `x` (0x7fc1d86d90f0)>,
 'z': <Free Variable `z` (0x7fc1d86d8fd0)>,
 'cost': <Eq Equation `cost` (0x7fc1d86d8cd0)>,
 'supply': <Leq Equation `supply` (0x7fc1d86d8c40)>,
 'demand': <Geq Equation `demand` (0x7fc1d86d8c10)>}
m2 = gt.Container()
m2.read(m)
# equivalent to m2 = gt.Container(m)
In [7]: m2.data
Out[7]:
{'i': <Set `i` (0x7fc1c8153fa0)>,
 'j': <Set `j` (0x7fc1c8153730)>,
 'a': <Parameter `a` (0x7fc1c8153cd0)>,
 'b': <Parameter `b` (0x7fc1d86fc790)>,
 'd': <Parameter `d` (0x7fc1f87dd240)>,
 'f': <Parameter `f` (0x7fc1c8153eb0)>,
 'c': <Parameter `c` (0x7fc1f87ddb40)>,
 'x': <Positive Variable `x` (0x7fc1c81536a0)>,
 'z': <Free Variable `z` (0x7fc1f87ddc60)>,
 'cost': <Eq Equation `cost` (0x7fc1c81539a0)>,
 'supply': <Leq Equation `supply` (0x7fc1f87dcd00)>,
 'demand': <Geq Equation `demand` (0x7fc1d86ff700)>}
```

Combining two containers

In this example we create two containers (which could have been populated from GDX files) and add in all symbol that do not currently exist in the first `Container`

```
import gams.transfer as gt
m1 = gt.Container()
i = gt.Set(m1, "i", records=[f"i{i}" for i in range(10)])
j = gt.Set(m1, "j", records=[f"j{i}" for i in range(10)])
k = gt.Set(m1, "k", records=[f"k{i}" for i in range(10)])
m2 = gt.Container()
a = gt.Set(m2, "a", records=[f"a{i}" for i in range(10)])
b = gt.Set(m2, "b", records=[f"b{i}" for i in range(10)])
k = gt.Set(m2, "k", records=[f"k{i}" for i in range(10)])
# now read in everything from m2 that does not exist in m1 (will read `a` and `b`)
m1.read(m2, [symname for symname, obj in m2 if symname not in m1])
In [1]: m1.data
Out[1]:
{'i': <Set `i` (0x7f9e504231c0)>,
 'j': <Set `j` (0x7f9e3043cc10)>,
 'k': <Set `k` (0x7f9e509bcd00)>,
 'a': <Set `a` (0x7f9e50423760)>,
 'b': <Set `b` (0x7f9e508ed0c0)>}
In [2]: m1.isValid()
Out[2]: True
```

7.5.5 Getting Started

Users have many options to manage their Python installation; in many cases it is advantageous to create a Python "environment" to sandbox an instance of Python (something which can be done with `venv` or `conda`). We recommend that users download a version of `miniconda`. We direct users to the `conda` documentation for installation issues. After the user has installed `miniconda` (or `conda`) we will:

- Verify that `conda` is working
- Create a new scratch Python environment
- Enter the new environment and verify the `python` version
- Install the GAMS API with `pip`

Note

`miniconda` and `conda` are synonymous – both are package + environment managers – however, `conda` comes preloaded with a number of useful data science-related packages. We emphasize `miniconda` because of the smaller install size. The terminal commands we used here apply to both `miniconda` and `conda` versions. The remaining documentation will only use the term `conda`.

Attention

The new API structure cannot be used to simply "update" previous versions – users should build new Python environments from scratch before attempting to install.

7.5.5.1 Verify Conda Installation

To verify that `conda` is accessible from the terminal we simply need to check for the version number. Your version of `conda` may differ. The installation of the GAMS API does not depend on the `conda` version.

7.5.5.2 Create a New Conda Environment

`Conda` can create, manage, and delete Python environments easily – this flexibility allows users to experiment quickly with different tools. If experiments fail, the entire environment can be removed without damaging the rest of the system. In short, each `conda` environment is an isolated sandbox. We will now create a new `conda` environment called `gams` that we will used when installing the GAMS API.

Note

Best practice is to use an environment rather than install into conda's base environment

Note

It is necessary to specify the version of Python to install into the new `conda` environment. The GAMS API currently supports Python 3.8 to 3.12.

We must now "activate" the `conda` environment (i.e., enter the Python sandbox).

Once in the activated environment we should verify the Python version is the one that was specified at creation.

7.5.5.3 Install

The GAMS Python API is distributed through the Python Package Index. The `gamsapi` package comes with several install options (via `pip extras`) that change how dependencies are resolved. `pip` will not install any third-party dependencies if an `extra` label was not provided. For example, to install the `transfer` data tool (and its dependencies to `pandas` and `scipy`).

Note

`xx.y.z` represents your installed GAMS version number (e.g., 46.4.1)

The `extras` that are available for the GAMS Python API are:

extra	Third-party Dependencies to Install
connect	pandas, pyyaml, openpyxl, sqlalchemy, cerberus, pyodbc, psycopg2-binary, pymysql, pymssql
control	urllib3
core	ply
engine	python_dateutil, urllib3
magic	ipython, pandas
tools	pandas
transfer	pandas, scipy
all	installs all third-party dependencies for all sub-modules – a complete install

Attention

Users can chain several `extras` together (separated by commas) in one `pip` install command to install dependencies from several sub-modules at once.

7.5.5.4 macOS Compatibility

The default shell for macOS 10.15+ (Catalina) is `zsh`. Users that wish to install the `gamsapi` will need to modify their install syntax slightly (note the quotations).

Note

`xx.y.z` represents your installed GAMS version number (e.g., 46.4.1)

Apple M1/M2

Apple users that have a M1/M2 (`arm`) chipset must be careful to match build architectures (i.e., `x86` or `arm`) of both the GAMS system and miniconda (Python). Ideally, M1/M2 users will only install native `arm` compatible programs. Apple's Rosetta 2 does allow users to install and run `x86` compiled programs on M1/M2. However, mixed installations (i.e., an `arm` GAMS system but a `x86` miniconda or vice versa) will fail because the `gamsapi` will not be able to properly load the necessary shared libraries.

The `gams audit` tool will return the GAMS build architecture (`x86` or `arm` will be in the returned string):

The build architecture of the Python installation is available with the following command:

Attention

The user must reinstall either a GAMS or Python system if these two returns do not match.

7.5.5.5 Verify the GAMS API

`pip` provides feedback that suggests that the GAMS API was successfully installed, however, it is still wise to verify this. The best way to test is to actually create a short Python script that imports `gams`. The following 1 line will run an `import` operation and, if successful, will output the API version number. The API was not successfully installed if an import error is raised.

Attention

Example problems can be found in the `[PATH TO GAMS]/api/python/examples` folder (organized by sub-module).

7.5.5.6 Uninstall the GAMS API

Removal of the GAMS API is straightforward with `pip`:

7.5.5.7 Remove Conda Environment

Removal of the entire `conda` environment is also straightforward with the following operations:

7.5.5.8 Other Useful Conda Commands

Users are directed to the full `conda` documentation but some useful commands are provided here as a quick reference.

Conda Command	Description
`conda env list`	List all conda environments
`conda list`	List all installed packages in the active environment
`conda deactivate`	Deactivate the current Python environment
`conda remove --name XXX --all`	Remove the `XXX` environment, must be deactivated first
`conda install XXX`	Install package `XXX` with the conda system, not all packages can be installed from `conda` directly

7.5.5.9 Python Virtual Environment (venv)

This documentation assumed users will want to use `conda` to manage their Python environments, but other tools such as `venv` can be used to manage separate Python environments. The details of the `venv` setup, activation, deactivation and removal differ from `conda`, but the `pip` install commands are the same as in `conda`. Interested users are referred to the official `venv` documentation for details on how to create a virtual environment. Users are also directed to additional documentation on: `Installing packages using pip and virtual environments`.

7.5.5.10 Working with Python and multiple GAMS Installations

Some users may want to run multiple versions of GAMS on their system – we recommend that users create separate Python environments in order to compare the behavior between versions of the Python API.

7.5.5.11 A note on using Python site package

Previous API versions could be used by a Python interpreter if the path to the API directory was included in a `sitecustomize.py` script that resided in the `site-packages` directory. This type of installation allows customized packages to be found and used, but not necessarily copied into Python's directory structure. Previous versions of the API benefited from this type of installation, we recommend that users create a separate Python environment and actually install the GAMS API into the environment with `pip`. Users that were using the `sitecustomize.py` installation method might experience issues with `pip` installations if their Python finds an old `sitecustomize.py` file that includes a path to old GAMS API files (`pip` might report that the `requirement is already satisfied`). Users can find out where the `USER_SITE` directory is located by running the following command:

Once this directory has been found, it is necessary to remove all paths (in the `sitecustomize.py` file) that point to previous GAMS API folders and reattempt the `pip` install process.

7.6 Matlab API

The GAMS Matlab API is a Matlab package that contains several sub-packages that enable the control of the GAMS system as well as the movement of data between GAMS and Matlab. The following table gives an overview of all available sub-packages:

Sub-Package	Description
gams.control	Enables full control of the GAMS System
gams.transfer	Data Only API – Allows GAMS data to be maintained outside a GAMS script

Attention

Don't use the data exchange tool GDXMRW anymore and switch to **gams.transfer** instead.

7.6.1 Control

The GAMS Matlab Control API provides a Matlab programming interface to the General Algebraic Model System (GAMS). GAMS Matlab Control API objects allow a convenient way to exchange input data and model results with in-memory representation of data (**Database**), and to create and run GAMS models (**Job**) that can be customized by GAMS options (**Options**). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (**ModelInstance**).

Note

If you only want to exchange data between Matlab and GAMS, use **GAMS Transfer Matlab** as it is very likely to be more efficient than GAMS Matlab Control API in case of exchanging very large data sets.

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. Since the GAMS Matlab Control API is based on the GAMS Java API, the use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute_load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object **Workspace** manages the anchor to the file system.

With the exception of **Workspace** the objects in the gams package cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the **ModelInstance** class).

Note

If you use multiple instances of the **Workspace** in parallel, you should avoid using the same working directory. Otherwise you may end up with conflicting file names.

Currently only `Cplex`, `Gurobi`, and `SoPlex` fully utilize the power of solving **ModelInstances**. Some solvers will not work in a multi-threaded application using **ModelInstances**. For some solvers this is unavoidable because the solver library is not thread safe (e.g. `MINOS`). Moreover, **ModelInstances** are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Matlab Control API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.

To get started, see Getting Started.

7.6.1.1 New Class Names

With GAMS 46 the GAMS Matlab Control API has been restructured and classes have been renamed. The following lists a mapping of old to new class names:

- `GAMS.AbstractRunParameters: gams.control.AbstractRunParameters`
- `GAMS.GAMSCheckpoint: gams.control.Checkpoint`
- `GAMS.GAMSDatabase: gams.control.Database`
- `GAMS.GAMSDatabaseDomainViolation: gams.control.DatabaseDomainViolation`
- `GAMS.GAMSEngineConfiguration: gams.control.engine.Configuration`
- `GAMS.GAMSEngineJob: gams.control.engine.Job`
- `GAMS.GAMSEngineJobBuilder: gams.control.engine.JobBuilder`
- `GAMS.GAMSEngineRunParameters: gams.control.engine.RunParameters`
- `GAMS.GAMSEquation: gams.control.Equation`
- `GAMS.GAMSEquationRecord: gams.control.EquationRecord`
- `GAMS.GAMSGlobals: gams.control.Globals`
- `GAMS.DebugLevel: gams.control.globals.DebugLevel`
- `GAMS.UpdateAction: gams.control.globals.UpdateAction`
- `GAMS.ModelStat: gams.control.globals.ModelStat`
- `GAMS.SolveStat: gams.control.globals.SolveStat`
- `GAMS.SetType: gams.control.globals.SetType`
- `GAMS.VarType: gams.control.globals.VarType`
- `GAMS.EquType: gams.control.globals.EquType`
- `GAMS.ArchType: gams.control.globals.ArchType`
- `GAMS.OSType: gams.control.globals.OSType`
- `GAMS.GAMSJob: gams.control.Job`
- `GAMS.GAMSModelInstance: gams.control.ModelInstance`
- `GAMS.SymbolUpdateType: gams.control.globals.SymbolUpdateType`
- `GAMS.GAMSModelInstanceOpt: gams.control.ModelInstanceOpt`
- `GAMS.GAMSModifier: gams.control.Modifier`
- `GAMS.GAMSOptions: gams.control.Options`
- `GAMS.ZeroResRep: gams.control.options.ZeroResRep`
- `GAMS.TraceOpt: gams.control.options.TraceOpt`
- `GAMS.TFormat: gams.control.options.TFormat`
- `GAMS.SysOut: gams.control.options.SysOut`
- `GAMS.Sys11: gams.control.options.Sys11`
- `GAMS.Sys10: gams.control.options.Sys10`

- GAMS.Suppress: gams.control.options.Suppress
- GAMS.SuffixAlgebraVars: gams.control.options.SuffixAlgebraVars
- GAMS.SuffixDLVars: gams.control.options.SuffixDLVars
- GAMS.StringChk: gams.control.options.StringChk
- GAMS.strictSingleton: gams.control.options.strictSingleton
- GAMS.StepSum: gams.control.options.StepSum
- GAMS.SolveOpt: gams.control.options.SolveOpt
- GAMS.SolveLink: gams.control.options.SolveLink
- GAMS.SolPrint: gams.control.options.SolPrint
- GAMS.ShowOSMemory: gams.control.options.ShowOSMemory
- GAMS.SavePoint: gams.control.options.SavePoint
- GAMS.Replace: gams.control.options.Replace
- GAMS.ReferenceLineNo: gams.control.options.ReferenceLineNo
- GAMS.PyMultInst: gams.control.options.PyMultInst
- GAMS.PutNR: gams.control.options.PutNR
- GAMS.ProcTreeMemMonitor: gams.control.options.ProcTreeMemMonitor
- GAMS.PreviousWork: gams.control.options.PreviousWork
- GAMS.PrefixLoadPath: gams.control.options.PrefixLoadPath
- GAMS.PageContr: gams.control.options.PageContr
- GAMS.On115: gams.control.options.On115
- GAMS.NoNewVarEqu: gams.control.options.NoNewVarEqu
- GAMS.MIIMode: gams.control.options.MIIMode
- GAMS.LstTitleLeftAligned: gams.control.options.LstTitleLeftAligned
- GAMS.LogLine: gams.control.options.LogLine
- GAMS.Listing: gams.control.options.Listing
- GAMS.Keep: gams.control.options.Keep
- GAMS.IntVarUp: gams.control.options.IntVarUp
- GAMS.InteractiveSolver: gams.control.options.InteractiveSolver
- GAMS.ImplicitAssign: gams.control.options.ImplicitAssign
- GAMS.HoldFixedAsync: gams.control.options.HoldFixedAsync
- GAMS.HoldFixed: gams.control.options.HoldFixed
- GAMS.gdxUels: gams.control.options.gdxUels
- GAMS.gdxConvert: gams.control.options.gdxConvert
- GAMS.gdxCompress: gams.control.options.gdxCompress
- GAMS.FreeEmbeddedPython: gams.control.options.FreeEmbeddedPython
- GAMS.ForceWork: gams.control.options.ForceWork

- GAMS.Filtered: gams.control.options.Filtered
- GAMS.FileCase: gams.control.options.FileCase
- GAMS.FDOpt: gams.control.options.FDOpt
- GAMS.ExecMode: gams.control.options.ExecMode
- GAMS.ErrMsg: gams.control.options.ErrMsg
- GAMS.Empty: gams.control.options.Empty
- GAMS.ECImplicitLoad: gams.control.options.ECImplicitLoad
- GAMS.DumpParms: gams.control.options.DumpParms
- GAMS.DumpOpt: gams.control.options.DumpOpt
- GAMS.Digit: gams.control.options.Digit
- GAMS.DFormat: gams.control.options.DFormat
- GAMS.CheckErrorLevel: gams.control.options.CheckErrorLevel
- GAMS.CharSet: gams.control.options.CharSet
- GAMS.LstCase: gams.control.options.LstCase
- GAMS.CaptureModelInstance: gams.control.options.CaptureModelInstance
- GAMS.AsyncSolLst: gams.control.options.AsyncSolLst
- GAMS.AppendOut: gams.control.options.AppendOut
- GAMS.AppendExpand: gams.control.options.AppendExpand
- GAMS.Action: gams.control.options.Action
- GAMS.GAMSParameter: gams.control.Parameter
- GAMS.GAMSParameterRecord: gams.control.ParameterRecord
- GAMS.GAMSRunParameters: gams.control.RunParameters
- GAMS.GAMSSet: gams.control.Set
- GAMS.GAMSSetRecord: gams.control.SetRecord
- GAMS.GAMSSymbol: gams.control.Symbol
- GAMS.GAMSSymbolDomainViolation: gams.control.SymbolDomainViolation
- GAMS.GAMSSymbolRecord: gams.control.SymbolRecord
- GAMS.GAMSVariable: gams.control.Variable
- GAMS.GAMSVariableRecord: gams.control.VariableRecord
- GAMS.GAMSWorkspace: gams.control.Workspace
- GAMS.GAMSWorkspaceInfo: gams.control.WorkspaceInfo

7.6.1.2 Getting Started

The GAMS Matlab Control API is built on top of the GAMS Java Control API and provides convenient access to GAMS from within Matlab (2017b or later) and Octave (5.2 or later).

Install

The Matlab API is located in `api/matlab`. Add this directory to the Matlab path:
```
addpath("[PathToGAMS]/api/matlab")
```

Furthermore, make Matlab aware of the GAMS Java API (see also GAMS Java API below):
```
javaaddpath("[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar")
```

GAMS Java API

Instead of adding the GAMS Java API dynamically as done above, it is also possible to add it statically. For this, locate `javaclasspath.txt` and add the path `[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar`. You can find the location with `cd(prefdir)` in Matlab or `which javaclasspath` in Octave. Finally, restart Matlab or Octave. Adding the GAMS Java API statically is more efficient.

Attention

> Since GAMS 44.1.0, the GAMS Java API requires at least Java SE 11 to compile and run. Matlab usually ships Java SE 8. In that case use `GAMSJavaAPI-8.jar` instead of `GAMSJavaAPI.jar`. However, new or updated functionalities that are released after GAMS 43 are not avaiable in this Java API version. Since Matlab R2023a, Matlab does support Java SE 11 (although it may have to be installed by the user). You can use `jenv system` to use the Java installed on the system instead of Matlab's shipped Java.

Important Classes

This section provides a quick overview of some fundamental classes of the GAMS Control package. Their usage is demonstrated by an extensive set of examples (located in `api/matlab/examples`). All GAMS Matlab Control API classes are contained within the package `gams.control` (with subpackages `gams.control.globals`, `gams.control.engine` and `gams.control.options`). The package provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this package allow convenient exchange of input data and model results (**Database**) and help to create and run GAMS models (**Job**), that can be customized by GAMS options (**Options**). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (**ModelInstance**).

7.7 R API

The R API consists of GAMS Transfer R.

7.7.1 GAMS Transfer R

GAMS Transfer is a package to maintain GAMS data outside a GAMS script in a programming language like Python, Matlab, or R. It allows the user to add GAMS symbols (Sets, Aliases, Parameters, Variables and Equations), to manipulate GAMS symbols, as well as read/write symbols to different data endpoints. GAMS Transfer's main focus is the highly efficient transfer of data between GAMS and the target programming language, while keeping those operations as simple as possible for the user. In order to achieve this, symbol records - the actual and potentially large-scale data sets - are stored in native data structures of the corresponding programming languages. The benefits of this approach are threefold: (1) The user is usually very familiar with these data structures, (2) these data structures come with a large tool box for various data operations, and (3) optimized methods for reading from and writing to GAMS can transfer the data as a bulk - resulting in the high performance of this package.

7.7.1.1 Getting Started

Install

The user must download and install the latest version of GAMS in order to install GAMS Transfer R. GAMS Transfer R can then be installed from either the source package or from the binary package. Installing using binary package is recommended for the new users since it is easier and does not involve compiling the package source.

The binary packages are platform dependent and the instructions for each supported platform are shown below.

Windows
```
install.packages("[PathToGAMS]/apifiles/R/gamstransfer/binary/gamstransfer.zip", type="binary")
```

Linux
```
install.packages("[PathToGAMS]/apifiles/R/gamstransfer/binary/gamstransfer.tar.gz")
```

macOS (same for ARM64 CPUs)
```
install.packages("[PathToGAMS]/apifiles/R/gamstransfer/binary/gamstransfer.tgz", type="binary")
```

GAMS Transfer R depends on packages `R6`, `R.utils`, and `Rcpp`, `collections`.

Installation using the source package can be done with the following command.
```
install.packages("[PathToGAMS]/apifiles/R/gamstransfer/source/gamstransfer_r.tar.gz", dependencies=TRUE)
```

When building from source, GAMS Transfer R also requires the library `zlib`. The user can point to `zlib` by adding the directory containing `zlib` to the environment variable `PATH` or by using `configure.vars` argument of install.packages().

Examples

GDX Read

Reading in all symbols can be accomplished with one line of code (we reference data from the **trnsport.gms** example).
```
library(gamstransfer)
m = Container$new("trnsport.gdx")
```

All symbols are internally stored in the Container data field (dictionary). The users should never have to access or modify the `data` field. The symbols can be accessed via `m[<symbol_name>]` and the records can be accessed via `m[<symbol_name>]$records`. Symbol records are stored in the data frame format.

GDX Write

There are five symbol classes within GAMS Transfer R: Sets, Parameters, Variables, Equations, and Aliases. For purposes of this quick start, we show how to recreate the `distance` data structure from the **trnsport.gms** model (the parameter `d`). This brief example shows how users can achieve "GAMS-like" functionality, but within an R environment. GAMS Transfer R leverages the object oriented programming to simplify the syntax.
```
library(gamstransfer)
m = Container$new()
# create the sets i, j
i = Set$new(m, "i", records = c("seattle", "san-diego"), description = "supply")
j = Set$new(m, "j", records = c("new-york", "chicago", "topeka"), description = "markets")
# add "d" parameter -- domain linked to set objects i and j
d = Parameter$new(m, "d", c(i, j), description = "distance in thousands of miles")
# create some data as a generic data frame
dist = data.frame(
```

```
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),
    to = c("new-york", "chicago", "topeka",
      "new-york", "chicago", "topeka"),
    thousand_miles = c(2.5, 1.7, 1.8, 2.5, 1.8, 1.4)
)
# setRecords will automatically convert the dist data frame into
# a standard data frame format
d$setRecords(dist)
# write the GDX
m$write("out.gdx")
```

This example shows a few fundamental features of GAMS Transfer R:

1. A Container is analogous to a GDX file
2. Symbols will always be linked to a Container (notice that we always pass the Container reference `m` to the symbol constructor)
3. Records can be added to a symbol with the `setRecords()` method, through the `records` constructor argument (internally calls `setRecords()`), or through directly setting the `records` field. GAMS Transfer R will convert many common R data structures into a standard format.
4. Domain linking is possible by passing domain set objects to other symbols.
5. Writing a GDX file can be accomplished in one line with the write() method.

Full Example

It is possible to use GAMS Transfer R to recreate the **trnsport.gms** results in GDX form. As part of this example, we also introduce the write() method (and generate `new.gdx`). We will discuss it in more detail in the following section: Data Exchange with GDX.

```
library(gamstransfer)
# create an empty Container object
m = Container$new()
# add sets
i = Set$new(m, "i", records=c("seattle", "san-diego"), description="supply")
j = Set$new(m, "j", records=c("new-york", "chicago", "topeka"), description="markets")
# add parameters
a = Parameter$new(m, "a", c("*"), description="capacity of plant i in cases")
b = Parameter$new(m, "b", j, description="demand at market j in cases")
d = Parameter$new(m, "d", c(i, j), description="distance in thousands of miles")
f = Parameter$new(
    m, "f", records=90, description="freight in dollars per case per thousand miles"
)
c = Parameter$new(
    m, "c", c(i, j), description="transport cost in thousands of dollars per case"
)
# set parameter records
cap = data.frame(plant = c("seattle", "san-diego"), n_cases = c(350, 600))
a$setRecords(cap)
dem = data.frame(market = c("new-york","chicago", "topeka"), n_cases = c(325, 300, 275))
b$setRecords(dem)
dist = data.frame(
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),
    to = c("new-york", "chicago", "topeka",
      "new-york", "chicago", "topeka"),
    thousand_miles = c(2.5, 1.7, 1.8, 2.5, 1.8, 1.4)
)
d$setRecords(dist)
# c(i,j) = f * d(i,j) / 1000;
cost = d$records
cost$value = f$records$value * cost$value/1000
c$setRecords(cost)
# add variables
q = data.frame(
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),

supplies = data.frame(
  from = c("seattle", "san-diego"),
  level = c(350, 550),
  marginal = c(SpecialValues$EPS, 0),
  lower = c(SpecialValues$NEGINF, SpecialValues$NEGINF),
  upper = c(350, 600)
)
supply$setRecords(supplies)
demands = data.frame(
  from = c("new-york", "chicago", "topeka"),
  level = c(325, 300, 275),
  marginal = c(0.225, 0.153, 0.126),
  lower = c(325, 300, 275)
)
demand$setRecords(demands)
m$write("new.gdx")
```

It can be observed from the above example that a typical work flow for writing using GAMS Transfer R is creating a container, filling it with symbols (Sets, Parameters, Variables, Equations, and Aliases), and write it to a GDX file. To read a GDX file, a Container can simply be initialized with the GDX file name as an argument.

These examples introduced the reader to the GAMS Transfer R syntax. In the remaining sections, we will present details about the core functionality and dig further into the syntax.

7.7.1.2 Manual

Container

Storing, manipulating, and transforming sparse data requires that it lives within an environment. This data can then be linked together to enable various operations. In GAMS Transfer R, we refer to this "environment" as the `Container`, it is the main repository for storing and linking our data. Linking data enables data operations such as implicit set growth, domain checking, and data format transformations (to dense/sparse matrix formats). A Container also enables different read/write operations.

Creating a `Container` is a simple matter of initializing an object. For example:

```
library(gamstransfer)
m = Container$new()
```

This new `Container` object, here called `m`, contains a number of convenient fields and methods that allow the user to interact with the symbols that are in the `Container`. Some of these methods are simply used to filter out different types of symbols, other methods are used to numerically characterize the data within each symbol.

The `Container` constructor arguments are:

Argument	Type	Description	Required	Default
`loadFrom`	`string`, `Container`	Name of the GDX file being read into the `Container`	No	NULL

Container fields

Field	Description	Type
`data`	main `dict` that is used to store all symbol data	`dict` (collections package)
`summary`	output a `list` containing the container information	`list`

Symbols are organized in the `Container` under the `data` field. The users should never have to access the `data` field. Symbols in the container can be accessed via `m[<symbol_name>]`.

Container methods

Method	Description	Arguments/Defaults	Returns
`addAlias`	add an `Alias`	`name` (`string`) `aliasWith` (`Set`,`Alias`)	`Alias` object
`addUniverseAlias`	add a `UniverseAlias`	`name` (`string`)	`UniverseAlias` object
`addEquation`	add an `Equation`	`name` (`string`) `type` (`string`) `domain=NULL` (`string`,`list`) `records=NULL` (`data frame`,`vector`,`NULL`) `domainForwarding=FALSE` (`logical`) `description=""` (`string`)	`Equation` object
`addParameter`	add a `Parameter`	`name` (`string`) `domain=NULL` (`string`,`list`) `records=NULL` (`data frame`,`array`, `matrix`) `domainForwarding=FALSE` (`logical`) `description=""` (`string`)	`Parameter` object
`addSet`	add a `Set`	`name` (`string`) `domain="*"` (`string`,`list`) `isSingleton=FALSE` (`logical`) `records=NULL` (`data frame`,`array`,`matrix`) `domainForwarding=FALSE` (`logical`) `description=""` (`string`)	`Set` object

Method	Description	Arguments/Defaults	Returns
addVariable	add a Variable	name (string) type="free" (string) domain=NULL (string,list) records=NULL (data frame,array,matrix) domainForwarding=FALSE (logical) description="" (string)	Variable object
copy	copies symbols to the destination container. overwrite=TRUE overwrites the symbols with the same name in destination. Symbol domains are relaxed if destination Container does not contain equivalent domain sets	destination (Container), symbols=NULL(character), overwrite=FALSE (logical)	NULL
countDomainViolations	returns a named list containing number of domain violations symbols with non-zero domain violations	symbols=NULL (character) - if NULL, assumes all symbols	list
countDuplicateRecords	returns a named list containing number of duplicate records for symbols with non-zero duplicate records	symbols=NULL (character) - if NULL, assumes all symbols	list
describeAliases	create a summary table with descriptive statistics for Aliases	symbols=NULL (string) - if NULL, assumes all Aliases	data frame
describeEquations	create a summary table with descriptive statistics for Equations	symbols=NULL (string) - if NULL, assumes all equations	data frame
describeParameters	create a summary table with descriptive statistics for Parameters	symbols=NULL (string) - if NULL, assumes all parameters	data frame
describeSets	create a summary table with descriptive statistics for Sets	symbols=NULL (string) - if NULL, assumes all sets	data frame
describeVariables	create a summary table with descriptive statistics for Variables	symbols=NULL (string) - if NULL, assumes all variables	data frame
dropDomainViolations	drops domain violations for symbols in the Container	symbols=NULL (character) - if NULL, assumes all symbols	-
dropDuplicateRecords	drops duplicate records for symbols in the Container	symbols=NULL (character) - if NULL, assumes all symbols, keep= first/last	-

Method	Description	Arguments/Defaults	Returns
equals	Check if two Container objects are equal	other (Container), verbose=FALSE	logical
getAliases	returns a list of object references for Aliases that are isValid	isValid=NULL (logical)	list
getDomainViolations	gets domain violations for symbols in the Container	symbols=NULL (character) - if NULL, assumes all symbols	list of DomainViolation
getEquations	returns a list of object references for Equations that are isValid	isValid=NULL (logical)	list
getParameters	returns a list of object references for Parameters that are isValid	isValid=NULL (logical)	list
getSets	returns a list of object references for Sets that are isValid	isValid=NULL (logical)	list
getSymbolNames	returns the original symbol names for a vector names of any case	names (character)	character
getSymbols	returns a list of object references for symbols	symbols (character) - if NULL assumes all symbols	list
getVariables	returns a list of object references for Variables that are isValid	isValid=NULL (logical)	list
getUELs	returns the UELs used in the Container	symbols=NULL (character), ignoreUnused = FALSE	character vector
hasDomainViolations	returns TRUE if any symbol in the container has domain violations, FALSE otherwise	symbols=NULL (character) - if NULL, assumes all symbols	logical
hasDuplicateRecords	returns TRUE if any symbol in the container has duplicate records, FALSE otherwise	symbols=NULL (character) - if NULL, assumes all symbols	logical
hasSymbols	checks if symbol names for a vector names exists in the container	names (character)	logical
isValid	TRUE if all symbols in the Container are valid	symbols=NULL (character) - if NULL, assumes all symbols, verbose=FALSE (logical) force=FALSE (logical)	logical

Method	Description	Arguments/Defaults	Returns
`listAliases`	list all aliases (`isValid=NULL`), list all valid aliases (`isValid=TRUE`), list all invalid aliases (`isValid=FALSE`) in the container	`isValid=NULL` (`logical`)	`vector`
`listEquations`	list all equations (`isValid=NULL`), list all valid equations (`isValid=TRUE`), list all invalid equations (`isValid=FALSE`) in the container	`isValid=NULL` (`logical`) `types=NULL` (`character` of eqaution types) - if `NULL`, assumes all types	`vector`
`listParameters`	list all parameters (`isValid=NULL`), list all valid parameters (`isValid=TRUE`), list all invalid parameters (`isValid=FALSE`) in the container	`isValid=NULL` (`logical`)	`vector`
`listSets`	list all sets (`isValid=NULL`), list all valid sets (`isValid=TRUE`), list all invalid sets (`isValid=FALSE`) in the container	`isValid=NULL` (`logical`)	`vector`
`listSymbols`	list all symbols (`isValid=NULL`), list all valid symbols (`isValid=TRUE`), list all invalid symbols (`isValid=FALSE`) in the container	`isValid=NULL` (`logical`)	`vector`
`listVariables`	list all variables (`isValid=NULL`), list all valid variables (`isValid=TRUE`), list all invalid variables (`isValid=FALSE`) in the container	`isValid=NULL` (`logical`) `types=NULL` (`character` of variable types) - if `NULL`, assumes all types	`vector`
`read`	main method to read `loadFrom`, can be provided with a list of `symbols` to read in subsets, `records` controls if symbol records are loaded or just metadata	`loadFrom` (`string`, `Container`) `symbols=NULL` (`string`) `records=TRUE` (`logical`)	`NULL`

Method	Description	Arguments/Defaults	Returns
removeSymbols	symbols to remove from the Container, also sets the symbols' container to NULL; removes symbol links from the Container; Aliases are also removed if the parent set is removed	symbols (string) - if NULL assumes all symbols	NULL
removeUELs	removes uels from all symbols the Container	uels=NULL (character), symbols=NULL (character). If Symbols is NULL UELs are removed for all symbols.	NULL
renameSymbol	rename a symbol oldName in the Container	oldName (string), newName (string)	NULL
renameUELs	renames uels in the Container	uels (named character), symbols=NULL (character), allowMerge=FALSE (logical). If allowMerge = TRUE, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility. If Symbols is NULL UELs are renamed for all symbols.	NULL
reorderSymbols	reorder symbols in order to avoid domain violations	-	NULL
write	main bulk write method to a writeTo target	writeTo (string) symbols=NULL (character) - if NULL, assumes all symbols compress=FALSE (logical) uelPriority=NULL (string) mode="mapped" (character "string" or "mapped")	NULL

Symbols

In GAMS Transfer R, a symbol is either a GAMS Set, Parameter, Variable, Equation, Alias. In GAMS Transfer R, a symbol cannot live on its own, but is always part of a Container.

Create a symbol

There are two different ways to create a GAMS set and add it to a Container.

1. Use symbol constructor for Set, Parameter, Variable, Equation, Alias
```
library(gamstransfer)
m = Container$new()
p = Parameter$new(m, "p")
```
2. Use the Container methods addSet, addParameter, addVariable, addEquation, addAlias (which internally calls the symbol constructor)
```
library(gamstransfer)
m = Container$new()
p = m$addParameter("p")
```

Add Symbol Records

Three possibilities exist to assign symbol records:

1. Setting the argument `records` in the symbol constructor/Container method (internally calls `setRecords`)
2. Using the symbol method `setRecords`
3. Setting the field `records` directly

If the data is in a convenient format, a user may want to pass the records directly within the set constructor. This is an optional keyword argument and internally the symbol constructor will simply call the `setRecords` method. The symbol method `setRecords` is a convenience method that transforms the given data into an approved data frame format (see Standard Data Formats). Many native R data types can be easily transformed into data frames, so the `setRecords` method will accept a number of different types for input. The `setRecords` method is called internally on any data structure that is passed through the `records` argument.

The examples of setting records using the above-mentioned methods can be found in the respective documentation for each symbol (Set, Parameter, Variable, Equation, and Alias).

Set

Set Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the Container object that the symbol is being added to	Yes	-
`name`	`string`	Name of symbol	Yes	-

Argument	Type	Description	Required	Default
`domain`	`list`	String, List of domains given either as a string ("∗" for universe set) or as a reference to a Set object	No	"∗"
`isSingleton`	`logical`	Indicates if set is a singleton set (`TRUE`) or not (`FALSE`)	No	FALSE
`records`	string vector, data frame	Symbol records	No	NULL
`domainForwarding`	`logical`	Flag or a vector of flags that forces set elements to be recursively included in corresponding parent sets (i.e., implicit set definition)	No	FALSE
`description`	`string`	Description of symbol	No	""

Set Fields

Field	Description	Type
`description`	description of symbol	`string`
`dimension`	dimension of symbol, setting dimension is a shorthand notation to set `domain` to a list of size n containing "∗"	`integer`
`domain`	list of domains given either as string (∗ for universe set) or as reference to the Set/Alias object	`list`
`domainForwarding`	flag or a vector of flags that forces set elements to be recursively included in corresponding parent sets (i.e., implicit set definition)	`logical`
`domainLabels`	column headings for the `records` data frame	`list` of `string`
`domainNames`	string version of domain names	`list` of `string`
`domainType`	`none`, `relaxed` or `regular` depending on state of domain links	`string`
`isSingleton`	`logical` if symbol is a singleton set	`logical`
`name`	name of symbol	`string`
`numberRecords`	number of symbol records (i.e., returns `nrow(self$records)` if not `NULL`)	`integer`
`records`	the main symbol records	`data frame`
`container`	reference to the Container that the symbol belongs to	`Container`
`summary`	output a `list` of only the metadata	`list`

Set Methods

Method	Description	Arguments/Defaults	Returns
`addUELs`	adds UELs to the symbol	`uels` (character), `dimension=NULL`	`NULL`

Method	Description	Arguments/Defaults	Returns
copy	copies the symbol to the destination container. overwrite=TRUE overwrites the symbol with the same name in destination. Symbol domains are relaxed if destination Container does not contain equivalent domain sets	destination (Container), overwrite=FALSE	NULL
countDomainViolations	returns the number of domain violations for the symbol	-	numeric
countDuplicateRecords	returns the number of duplicate records for the symbol	-	numeric
findDomainViolations	get a view of records data frame that contain any domain violations	-	data.frame
findDuplicateRecords	get a view of records data frame that contain duplicate records. keep = "first" (finds all duplicates while keeping the first instance as unique), keep="last" (finds all duplicates while keeping the last instance as unique), or keep=FALSE (finds all duplicates)	keep= first	data.frame
dropDomainViolations	drops domain violations for the symbol	-	-
dropDuplicateRecords	drops duplicate records for the Symbol	keep= first/last	-
equals	Check if two Symbol objects are equal	other (Symbol), checkUELs=TRUE, checkElementText=TRUE, checkMetaData=TRUE, verbose=FALSE	logical

Method	Description	Arguments/Defaults	Returns
generateRecords	convenience method to set standard data.frame formatted records. Will generate records with the Cartesian product of all domain sets. The density argument can take any value on the interval [0,1]. If density is < 1, then randomly selected records will be removed. density will accept a numeric of length 1 or dimension. This allows users to specify a density per symbol dimension (when vector) or density of the records dataframe. Random number state can be set with seed argument.	density=1.0 (numeric) seed=NULL (integer)	NULL
getDomainViolations	gets domain violations for the symbol	-	list of DomainViolation
getSparsity	get the sparsity of the symbol w.r.t the size of full cartesian product of the domain sets	-	numeric
getUELs	returns the UELs used in the Symbol	dimension = NULL, codes = NULL, ignoreUnused=FALSE	character vector
hasDomainViolations	returns TRUE if the symbol contains domain violations, FALSE otherwise	-	logical
hasDuplicateRecords	returns TRUE if the symbol contains duplicate records, FALSE otherwise	-	logical
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=TRUE, recheck a symbol if force=TRUE	verbose=FALSE force=FALSE	logical
removeUELs	removes UELs from the symbol	uels=NULL (character), dimension=NULL	NULL

Method	Description	Arguments/Defaults	Returns
renameUELs	renames UELs in the symbol	uels(character of same length as current UELs or named character vector), dimension=NULL, allowMerge=FALSE (logical). If allowMerge = TRUE, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	NULL
reorderUELs	reorders UELs in the symbol that appear in the symbol dimensions. If uels is NULL, the UELs are reordered based on symbol records, unused UELs are moved to the end. If dimensions is NULL then reorder UELs in all dimensions of the symbol	uels=NULL(NULL or character of same length as current UELs or named character vector), dimension=NULL (numeric)	NULL
setRecords	main convenience method to set standard data frame formatted records	records (string vector, list, data frame)	NULL
setUELs	sets UELs for the Symbol	uels(character), dimension, rename=FALSE	NULL

Adding Set Records

Three possibilities exist to assign symbol records to a set: We show a few examples of ways to create differently structured sets.

Example #1 - Create a 1D set from a vector

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("seattle", "san-diego"))
# NOTE: the above syntax is equivalent to -
# i = Set$new(m, "i")
# i$setRecords(c("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# m$addSet("i", records= c("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# i = m$addSet("i")
# i$setRecords(c("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# m$addSet("i")
# m["i"]$setRecords(c("seattle", "san-diego"))
> i$records
        uni
1   seattle
2 san-diego
```

Example #2 - Create a 2D set from a list

```
library(gamstransfer)
m = Container$new()
k = Set$new(m, "k", c("*", "*"), records=list("seattle", "san-diego"))
# NOTE: the above syntax is equivalent to -
# k = Set$new(m, "k", c("*", "*"))
# k$setRecords(list("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# m$addSet("k", c("*","*"), records=list("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# k = m$addSet("k", c("*","*"))
# k$setRecords(list("seattle", "san-diego"))
# NOTE: the above syntax is also equivalent to -
# m$addSet("k", c("*", "*"))
# m["k"]$setRecords(list("seattle", "san-diego"))
> k$records
    uni_1     uni_2
1 seattle san-diego
```

Example #3 - Create a 1D set from a data frame slice

```
library(gamstransfer)
m = Container$new()
dist = data.frame(
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),
    to = c("new-york", "chicago", "topeka",
      "new-york", "chicago", "topeka"),
    thousand_miles = c(2.5, 1.7, 1.8, 2.5, 1.8, 1.4)
)
l = Set$new(m, "l", records = unique(dist[["from"]]))
# NOTE: the above syntax is equivalent to -
# l = Set$new(m, "l")
# l$setRecords(unique(dist[["from"]]))
# NOTE: the above syntax is also equivalent to -
# m$addSet("l", records=unique(dist[["from"]]))
# NOTE: the above syntax is also equivalent to -
# l = m$addSet("l")
# l$setRecords(unique(dist[["from"]]))
# NOTE: the above syntax is also equivalent to -
# m$addSet("l")
# m["l"]$setRecords(unique(dist[["from"]]))
> l$records
      uni
1   seattle
2 san-diego
```

Set element text is very handy when labeling specific set elements within a set. A user can add a set element text directly with a set element. Note that it is not required to label all set elements, as can be seen in the following example.

Example #4 - Add set element text

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i",
records = data.frame(city=c("seattle", "san-diego", "washington_dc"),
text=c("home of sub pop records", "", "former gams hq")))
# NOTE: the above syntax is equivalent to -
#
# i = Set$new(m, "i")
# i_recs = data.frame(city=c("seattle", "san-diego", "washington_dc"),
# text=c("home of sub pop records", "", "former gams hq"))
#
# i$setRecords(i_recs)
# NOTE: the above syntax is also equivalent to -
# m$addSet("i", records=i_recs)
# NOTE: the above syntax is also equivalent to -
# i = m$addSet("i")
# i$setRecords(i_recs)
# NOTE: the above syntax is also equivalent to -
# m$addSet("i")
# m["i"]$setRecords(i_recs)
> i$records
          city            element_text
1       seattle home of sub pop records
```

```
2     san-diego
3 washington_dc          former gams hq
```

The primary advantage of the `setRecords` method is that GAMS Transfer R will convert many different (and convenient) data types into the standard data format (a data frame). Users that require higher performance will want to directly pass the Container a reference to a valid data frame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process.
In this section, we walk the user through an example of how to set records directly.

Example #5 - Directly set records (1D set)

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", description = "supply")
# create a standard format data frame
df_i = data.frame(uni_1 = c("seattle", "san-diego"),
element_text = c("", ""))
# need to create categorical column type, referencing elements already in df_i
df_i$uni_1 = factor(df_i$uni_1, ordered = TRUE)
# set the records directly
i$records = df_i
> i$isValid()
[1] TRUE
```

Stepping through this example we take the following steps:

1. Create an empty Container
2. Create a GAMS set `i` in the Container, but do not set the `records`
3. Create a data frame (manually, in this example) taking care to follow the standard format
4. The data frame has the right shape and column labels so we can proceed to set the records.
5. We need to cast the `uni_1` column as a `factor`, so we create a custom ordered category type using `factor`
6. Finally, we set the records directly by passing a reference to `df_i` into the symbol records attribute. The setter function of `records` checks that a data frame is being set, but does not check validity. Thus, as a final step, we call the `$isValid()` method to verify that the symbol is valid.

Note

Users can debug their data frames by running <`symbol_name`>`$isValid(verbose=TRUE)` to get feedback about their data.

Example #6 - Directly set records (1D subset)

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("seattle", "san-diego"), description="supply")
j = Set$new(m, "j", i, description="supply")
# create a standard format data frame
df_j = data.frame(i_1 = c("seattle"), "element_text" = c(""))
# create the categorical column type
df_j$i_1 = factor(df_j$i_1, levels = i$records[, 1], ordered = TRUE)
# set the records
j$records = df_j
> j$isValid()
[1] TRUE
```

This example is more subtle in that we want to create a set `j` that is a subset of `i`. We create the set `i` using the `setRecords` method but then set the records directly for `j`. There are two important details to note: 1) the column labels in `df_j` now reflect the standard format for a symbol with a domain set (as opposed to the universe) and 2) we create the factors by referencing the parent set (`i`) for the `levels` (instead of referencing itself).

Note

One can also use the genereateRecords() method to automatically populate randomly generated symbol records in the standard format.

Parameter

Parameter Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the Container object that the symbol is being added to	Yes	-
`name`	`string`	Name of symbol	Yes	-
`domain`	`list`	List of domains given either as a string ("∗" for universe set) or as a reference to a Set object, an empty domain list will create a scalar parameter	No	NULL
`records`	many	Symbol records	No	NULL
`domainForwarding`	`logical`	Flag or a vector of flags that forces parameter elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	No	FALSE
`description`	`string`	Description of symbol	No	""

Parameter Fields

Field	Description	Type
`container`	reference to the Container that the symbol belongs to	`Container`
`defaultValues`	default values for the symbol	`numeric`
`description`	description of symbol	`character`
`dimension`	dimension of symbol, setting dimension is a shorthand notation to set `domain` to a list of size n containing "∗"	`numeric,integer`
`domain`	list of domains given either as a string (`"*"` for universe set) or as a reference to the Set/Alias object	`list`
`domainForwarding`	Flag or a vector of flags that forces parameter elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	`logical`
`domainLabels`	column headings for the `records` data frame	`list` of `string`
`domainNames`	string version of domain names	`list` of `string`
`domainType`	`none`, `relaxed` or `regular` depending on state of domain links	`string`
`isScalar`	TRUE if `self$dimension = 0`	`logical`
`name`	name of symbol	`string`
`numberRecords`	number of symbol records (i.e., returns `nrow(self$records)` if not `NULL`)	`integer`
`records`	the main symbol records	`data frame`

Field	Description	Type
shape	a vector describing the array dimensions if records were converted with $toDense()	vector
summary	output a list of only the metadata	list

Parameter Methods

Method	Description	Arguments/Defaults	Returns
addUELs	adds UELs to the symbol	uels (character), dimension=NULL	NULL
copy	copies the symbol to the destination container. overwrite=TRUE overwrites the symbol with the same name in destination. Symbol domains are relaxed if destination Container does not contain equivalent domain sets	destination (Container), overwrite=FALSE	NULL
countDomainViolations	returns the number of domain violations for the symbol	-	numeric
countDuplicateRecords	returns the number of duplicate records for the symbol	-	numeric
countEps	total number of SpecialValues$EPS in value column	-	integer
countNA	total number of SpecialValues[["NA"]] in value column	-	integer
countNegInf	total number of SpecialValues$NEGINF in value column	-	integer
countPosInf	total number of SpecialValues$POSINF in value column	-	integer
countUndef	total number of SpecialValues$UNDEF in value column	-	integer
dropDomainViolations	drops domain violations for the symbol	-	-

Method	Description	Arguments/Defaults	Returns
dropDuplicateRecords	drops duplicate records for the Symbol. keep = "first" (drops all duplicates while keeping the first instance as unique), keep="last" (drops all duplicates while keeping the last instance as unique), or keep=FALSE (drops all duplicates)	keep = "first"	-
equals	Check if two Symbol objects are equal	other (Symbol), checkUELs=TRUE, checkMetaData=TRUE, rtol=0 (relative tolernace), atol=0 (absolute tolerance), verbose=FALSE	logical
findDomainViolations	get a view of records data frame that contain any domain violations	-	data.frame
findDuplicateRecords	get a view of records data frame that contain duplicate records. keep = "first" (finds all duplicates while keeping the first instance as unique), keep="last" (finds all duplicates while keeping the last instance as unique), or keep=FALSE (finds all duplicates)	keep= first	data.frame

Method	Description	Arguments/Defaults	Returns
generateRecords	convenience method to set standard data.frame formatted records. Will generate records with the Cartesian product of all domain sets. The density argument can take any value on the interval [0,1]. If density is < 1, then randomly selected records will be removed. density will accept a numeric of length 1 or dimension. This allows users to specify a density per symbol dimension (when vector) or the density of records dataframe. Random numbers can be generated by passing a user-defined function func(size) to func argument (runif() by default). Random number state can be set with seed argument.	density=1.0 (numeric) func=runif() seed=NULL (integer)	NULL
getDomainViolations	gets domain violations for the symbol	-	list of DomainViolation
getMaxValue	get the maximum value in value column	-	numeric
getMaxAbsValue	get the maximum absolute value in value column	-	numeric
getMeanValue	get the mean value in value column	-	numeric
getMinValue	get the minimum value in value column	-	numeric
getSparsity	get the sparsity of the symbol w.r.t the size of full cartesian product of the domain sets	-	numeric
getUELs	returns the UELs used in the Symbol	dimension = NULL, codes = NULL, ignoreUnused=FALSE	character vector
hasDomainViolations	returns TRUE if the symbol contains domain violations, FALSE otherwise	-	logical
hasDuplicateRecords	returns TRUE if the symbol contains duplicate records, FALSE otherwise	-	logical

Method	Description	Arguments/Defaults	Returns
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=TRUE, recheck a symbol if force=TRUE	verbose=FALSE force=FALSE	logical
removeUELs	removes UELs from the symbol	uels=NULL (character), dimension=NULL	NULL
renameUELs	renames UELs in the symbol	uels(character of same length as current UELs or named character vector), dimension=NULL, allowMerge=FALSE (logical). If allowMerge = TRUE, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	NULL
reorderUELs	reorders UELs in the symbol that appear in the symbol dimensions. If uels is NULL, the UELs are reordered based on symbol records, unused UELs are moved to the end. If dimensions is NULL then reorder UELs in all dimensions of the symbol	uels=NULL(NULL or character of same length as current UELs or named character vector), dimension=NULL (numeric)	NULL
setRecords	main convenience method to set standard data frame records	records (many types)	NULL
setUELs	sets UELs for the Symbol	uels(character), dimension, rename=FALSE	NULL
toDense	convert value column of a symbol to a dense matrix or array format	-	array or matrix
whereMax	find the row number in records data frame with a maximum value (return the first instance only)	-	integer
whereMaxAbs	find the row number in records data frame with a maximum absolute value (return the first instance only)	-	integer

Method	Description	Arguments/Defaults	Returns
`whereMin`	find the row number in records data frame with a minimum value (return the first instance only)	-	`integer`

Adding Parameter Records

Three possibilities exist to assign symbol records to a parameter: We show a few examples of ways to create differently structured parameters:

Example #1 - Create a GAMS scalar

```
library(gamstransfer)
m = Container$new()
pi = Parameter$new(m, "pi", records = 3.14159)
# NOTE: the above syntax is equivalent to -
# pi = Parameter$new(m, "pi")
# pi$setRecords(3.14159)
# NOTE: the above syntax is also equivalent to -
# m$addParameter("pi", records=3.14159)
# NOTE: the above syntax is also equivalent to -
# pi = m$addParameter("pi")
# pi$setRecords(3.14159)
# NOTE: the above syntax is also equivalent to -
# m$addParameter("pi")
# m["pi"]$setRecords(3.14159)
> pi$records
    value
1 3.14159
```

Note

GAMS Transfer R will still convert scalar values to a standard format (i.e., a data frame with a single row and column).

Example #2 - Create a 2D parameter (defined over a set) from a

data frame slice

```
library(gamstransfer)
dist = data.frame(
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),
    to = c("new-york", "chicago", "topeka",
      "new-york", "chicago", "topeka"),
    thousand_miles = c(2.5, 1.7, 1.8, 2.5, 1.8, 1.4)
)
m = Container$new()
i = Set$new(m, "i", "*", records = unique(dist$from))
j = Set$new(m, "j", "*", records = unique(dist$to))
a = Parameter$new(m, "a", c(i, j), records = dist)
> a$toDense()
     [,1] [,2] [,3]
[1,]  2.5  1.7  1.8
[2,]  2.5  1.8  1.4
# use a$toDense() to create a new (and identicial) parameter a2
a2 = Parameter$new(m, "a2", c(i, j), records = a$toDense())
> a2$records
          i        j value
1   seattle new-york   2.5
2   seattle  chicago   1.7
3   seattle   topeka   1.8
4 san-diego new-york   2.5
5 san-diego  chicago   1.8
6 san-diego   topeka   1.4
```

Example #3 - Create a 2D parameter from an array using setRecords

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i_", 1:5))
j = Set$new(m, "j", records=paste0("j_", 1:5))
# create the parameter with linked domains (these will control the
# $shape of the symbol)
a = Parameter$new(m, "a", c(i, j))
# here we use the $shape field to easily generate a dense random array
a$setRecords(array(runif(prod(a$shape()), min = 1, max = 10),
dim = a$shape() ))
> a$toDense()
         [,1]     [,2]     [,3]     [,4]     [,5]
[1,] 3.837345 3.632743 9.003275 4.097475 8.608477
[2,] 7.217257 2.465452 3.286330 2.366017 8.822535
[3,] 8.421044 8.546226 5.403918 2.286660 6.319740
[4,] 3.960100 8.538932 2.210829 2.437113 5.324722
[5,] 1.333846 4.508688 7.411279 5.653044 7.248775
```

As with Sets, the primary advantage of the `setRecords` method is that GAMS Transfer will convert many different (and convenient) data types into the standard data format (data frame). Users that require higher performance will want to directly pass the Container a reference to a valid data frame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process. In this section, we walk the user through an example of how to set records directly.

Example #4 - Correctly set records (directly)

```
library(gamstransfer)
df = data.frame(h_1 = paste0("h", 1:8760), m_2 = paste0("m", 1:60),
s_3 = paste0("s", 1:60))
df$value = runif(nrow(df), min = 0, max = 100)
m = Container$new()
hrs = Set$new(m, "h", records = unique(df$h_1))
mins = Set$new(m, "m", records = unique(df$m_2))
secs = Set$new(m, "s", records = unique(df$s_3))
df$h_1 = factor(df$h_1, ordered = TRUE)
df$m_2 = factor(df$m_2, ordered = TRUE)
df$s_3 = factor(df$s_3, ordered = TRUE)
a = Parameter$new(m, "a", c(hrs, mins, secs))
# set records
a$records = df
> a$isValid()
[1] TRUE
```

In this example, we create a large parameter (31,536,000 records and 8880 unique domain elements. We mimic data that is labeled for every second in one year) and assign it to a parameter with `a$records`. GAMS Transfer R requires that all domain columns must be ordered factors. The `records` setter function does very little work other than checking if the object being set is a data frame. This places more responsibility on the user to create a data frame that complies with the standard format. In Example #1, we take care to properly reference the factor from the domain sets, and ensure that the symbol `a` is valid with `a$isValid() = TRUE`.

Users will need to use the `$isValid(verbose=TRUE)` method to debug any structural issues. As an example, we incorrectly generate categorical data types by passing the data frame constructor the generic `factor` argument. This creates factor columns, but they are not ordered and they do not reference the underlying domain set. These errors result in `a` being invalid.

Example #5 - Incorrectly set records (directly)

```
library(gamstransfer)
df = data.frame(h_1 = paste0("h", 1:8760), m_2 = paste0("m", 1:60),
s_3 = paste0("s", 1:60))
df$value = runif(nrow(df), min = 0, max = 100)
m = Container$new()
hrs = Set$new(m, "h", records = unique(df$h_1))
mins = Set$new(m, "m", records = unique(df$m_2))
secs = Set$new(m, "s", records = unique(df$s_3))
df$h_1 = factor(df$h_1)
df$m_2 = factor(df$m_2)
df$s_3 = factor(df$s_3)
a = Parameter$new(m, "a", c(hrs, mins, secs))
# set records
a$records = df
> a$isValid()
[1] FALSE
> a$isValid(verbose=TRUE)
Domain information in column h_1 must be an ORDERED factor
[1] FALSE
```

Note

One can also use the genereateRecords() method to automatically populate randomly generated symbol records in the standard format.

Variable

Variable Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the Container object that the symbol is being added to	Yes	-
`name`	`string`	Name of symbol	Yes	-
`type`	`string`	Type of variable being created [`binary`, `integer`, `positive`, `negative`, `free`, `sos1`, `sos2`, `semicont`, `semiint`]	No	`free`
`domain`	`list`, `vector`	List, vector of domains given either as a string (`"*"` for universe set) or as a reference to a Set object, an empty domain list will create a scalar variable	No	NULL
`records`	many	Symbol records	No	NULL
`domainForwarding`	`logical`	Flag or a vector of flags that forces variable elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	No	FALSE
`description`	`string`	Description of symbol	No	""

Variable Fields

Field	Description	Type
`container`	reference to the Container that the symbol belongs to	`Container`
`defaultValues`	default values for the symbol	`numeric` (named vector)

Field	Description	Type
description	description of symbol	string
dimension	dimension of symbol, setting dimension is a shorthand notation to set domain to a list of size n containing "*"	integer
domain	list of domains given either as string (* for universe set) or as reference to the Set/Alias object	list
domainForwarding	Flag or a vector of flags that forces variable elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	logical
domainLabels	column headings for the records data frame	list of string
domainNames	string version of domain names	list of string
domainType	none, relaxed or regular depending on state of domain links	string
isScalar	TRUE if self$dimension = 0	logical
name	name of symbol	string
numberRecords	number of symbol records (i.e., returns nrow(self$records) if not NULL)	integer
records	the main symbol records	data frame
shape	a vector describing the array dimensions if records were converted with $toDense()	vector
summary	output a list of only the metadata	list
type	string type of variable	list

Variable Methods

Method	Description	Arguments/Defaults	Returns
addUELs	adds UELs to the symbol	uels (character), dimension=NULL	NULL
copy	copies the symbol to the destination container. overwrite=TRUE overwrites the symbol with the same name in destination. Symbol domains are relaxed if destination Container does not contain equivalent domain sets	destination (Container), overwrite=FALSE	NULL
countDomainViolations	returns the number of domain violations for the symbol	-	numeric
countDuplicateRecords	returns the number of duplicate records for the symbol	-	numeric
countEps	total number of SpecialValues$EPS across all columns	columns = "level"	integer
countNA	total number of SpecialValues[["NA"]] across all columns	columns = "level"	integer

Method	Description	Arguments/Defaults	Returns
countNegInf	total number of SpecialValues$NEGINF across all columns	columns = "level"	integer
countPosInf	total number of SpecialValues$POSINF across all columns	columns = "level"	integer
countUndef	total number of SpecialValues$UNDEF across all columns	columns = "level"	integer
dropDomainViolations	drops domain violations for the symbol	-	-
dropDuplicateRecords	drops duplicate records for the Symbol. keep = "first" (drops all duplicates while keeping the first instance as unique), keep="last" (drops all duplicates while keeping the last instance as unique), or keep=FALSE (drops all duplicates)	keep = "first"	-
equals	Check if two Symbol objects are equal	other (Symbol), columns=NULL (character) (if NULL all columns are compared), checkUELs=TRUE, checkMetaData=TRUE, rtol=0 (relative tolernace), atol=0 (absolute tolerance), verbose=FALSE	logical
findDomainViolations	get a view of the records data frame that contain any domain violations	-	data.frame
findDuplicateRecords	get a view of records data frame that contain duplicate records. keep = "first" (finds all duplicates while keeping the first instance as unique), keep="last" (finds all duplicates while keeping the last instance as unique), or keep=FALSE (finds all duplicates)	keep= first	data.frame

Method	Description	Arguments/Defaults	Returns
generateRecords	convenience method to set standard data.frame formatted records. Will generate records with the Cartesian product of all domain sets. The density argument can take any value on the interval [0,1]. If density is < 1, then randomly selected records will be removed. density will accept a numeric of length 1 or dimension. This allows users to specify a density per symbol dimension (when vector) or the density of records dataframe. Random numbers can be generated by passing a user-defined function func(size) to func argument (runif() by default). Random number state can be set with seed argument.	density=1.0 (numeric) func=runif() (named list of functions, function, NULL) seed=NULL (integer)	NULL
getDomainViolations	gets domain violations for the symbol	-	list of DomainViolation
getMaxValue	get the maximum value across all columns	columns = "level"	numeric
getMaxAbsValue	get the maximum absolute value across all columns	columns = "level"	numeric
getMinValue	get the minimum value across all columns	columns = "level"	numeric
getMeanValue	get the mean value across all columns	columns = "level"	numeric
getSparsity	get the sparsity of the symbol w.r.t the size of full cartesian product of the domain sets	-	numeric
getUELs	returns the UELs used in the Symbol	dimension = NULL, codes = NULL, ignoreUnused=FALSE	character vector
hasDomainViolations	returns TRUE if the symbol contains domain violations, FALSE otherwise	-	logical
hasDuplicateRecords	returns TRUE if the symbol contains duplicate records, FALSE otherwise	-	logical

Method	Description	Arguments/Defaults	Returns
`isValid`	checks if the symbol is in a valid format, throw exceptions if `verbose=TRUE`, recheck a symbol if `force=TRUE`	`verbose=FALSE` `force=FALSE`	`logical`
`removeUELs`	removes UELs from the symbol	`uels=NULL` (character), `dimension=NULL`	`NULL`
`renameUELs`	renames UELs in the symbol	`uels`(character of same length as current UELs or named character vector), `dimension=NULL`, `allowMerge=FALSE` (logical). If `allowMerge = TRUE`, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	`NULL`
`reorderUELs`	reorders UELs in the symbol that appear in the symbol `dimensions`. If `uels` is `NULL`, the UELs are reordered based on symbol records, unused UELs are moved to the end. If `dimensions` is `NULL` then reorder UELs in all dimensions of the symbol	`uels=NULL`(`NULL` or character of same length as current UELs or named character vector), `dimension=NULL` (numeric)	`NULL`
`setRecords`	main convenience method to set standard `data frame` records	`records` (many types)	`NULL`
`setUELs`	sets UELs for the Symbol	`uels`(character), `dimension`, `rename=FALSE`	`NULL`
`toDense`	convert symbol to a dense `matrix` or `array` format	column = `level`	`array` or `matrix`
`whereMax`	find the row number in records data frame with a maximum value (return the first instance only)	`column = "level"`	`integer`
`whereMaxAbs`	find the row number in records data frame with a maximum absolute value (return the first instance only)	`column = "level"`	`integer`

Method	Description	Arguments/Defaults	Returns
`whereMin`	find the row number in records data frame with a minimum value (return the first instance only)	`column = "level"`	`integer`

Adding Variable Records

Three possibilities exist to assign symbol records to a variable: We show a few examples of ways to create differently structured variables:

Example #1 - Create a GAMS scalar variable

```
library(gamstransfer)
m = Container$new()
pi = Variable$new(m, "pi", records = data.frame(level = 3.14159))
# NOTE: the above syntax is equivalent to -
# pi = Variable$new(m, "pi", "free")
# pi$setRecords(data.frame(level = 3.14159))
# NOTE: the above syntax is also equivalent to -
# m$addVariable("pi", "free", records=data.frame(level = 3.14159))
> pi$records
    level
1 3.14159
```

Example #2 - Create a 2D positive variable, specifying no numerical data

```
library(gamstransfer)
m = Container$new()
v = Variable$new(m, "v", "positive", c("*", "*"), records =
data.frame(from=c("seattle", "chicago"), to=c("san-diego", c("madison"))))
> v$records
     from        to
1 seattle san-diego
2 chicago   madison
```

Example #3 - Create a 2D variable (defined over a set) from a matrix

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", "*", records = paste0("i", 1:5))
j = Set$new(m, "j", "*", records = paste0("j", 1:5))
# creating records for parameter a
ij = list(i_1 = paste0("i", 1:5), j_2 = paste0("j", 1:5))
df = rev(expand.grid(rev(ij)))
df$value = 1:25
a = Parameter$new(m, "a", c(i, j), records = df)
# create a free variable and set the level and marginal attributes from matricies
v = Variable$new(m, "v", domain = c(i, j), records = list(level = a$toDense(), marginal = a$toDense()))
# if not specified, the toDense() method will convert the level values to a matrix
> v$toDense()
     [,1] [,2] [,3] [,4] [,5]
[1,]    1    2    3    4    5
[2,]    6    7    8    9   10
[3,]   11   12   13   14   15
[4,]   16   17   18   19   20
[5,]   21   22   23   24   25
```

As with Sets, the primary advantage of the `setRecords` method is that GAMS Transfer will convert many different (and convenient) data types into the standard data format (data frame). Users that require higher performance will want to directly pass the Container a reference to a valid data frame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process. In this section, we walk the user through an example of how to set records directly.

Example #4 - Correctly set records (directly)

```
library(gamstransfer)
df = data.frame(h_1 = paste0("h", 1:8760), m_2 = paste0("m", 1:60),
s_3 = paste0("s", 1:60))
df$level = runif(nrow(df), min = 0, max = 100)
df$marginal = 0.0
df$lower = SpecialValues$NEGINF
df$upper = SpecialValues$POSINF
df$scale = 1.0
m = Container$new()
hrs = Set$new(m, "h", records = unique(df$h_1))
mins = Set$new(m, "m", records = unique(df$m_2))
secs = Set$new(m, "s", records = unique(df$s_3))
df$h_1 = factor(df$h_1, ordered = TRUE)
df$m_2 = factor(df$m_2, ordered = TRUE)
df$s_3 = factor(df$s_3, ordered = TRUE)
a = Variable$new(m, "a", domain = c(hrs, mins, secs))
# set records
a$records = df
> a$isValid()
[1] TRUE
```

In this example, we create a large variable (31,536,000 records and 8880 unique domain elements. We mimic data that is labeled for every second in one year) and assign it to a variable with `a$records`. GAMS Transfer R requires that all domain columns must be ordered factors. The `records` setter function does very little work other than checking if the object being set is a data frame. This places more responsibility on the user to create a data frame that complies with the standard format. In Example #1, we take care to properly reference the factor from the domain sets and ensure that the symbol `a` is valid with `a$isValid() = TRUE`.

As with Set and Parameters, users can use the `$isValid(verbose=TRUE)` method to debug any structural issues.

Note

One can also use the genereateRecords() method to automatically populate randomly generated symbol records in the standard format.

Equation

Equation Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the Container object that the symbol is being added to	Yes	-
`name`	`string`	Name of symbol	Yes	-
`type`	`string`	Type of equation being created [`eq` (or `E`/`e`), `geq` (or `G`/`g`), `leq` (or `L`/`l`), `nonbinding` (or `N`/`n`), `external` (or `X`/`x`)]	No	`free`
`domain`	`list`, `vector`	List, vector of domains given either as a string (`"*"` for universe set) or as a reference to a Set object, an empty domain list will create a scalar equation	No	NULL
`records`	many	Symbol records	No	NULL
`domainForwarding`	`logical`	Flag or a vector of flags that forces equation elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	No	FALSE
`description`	`string`	Description of symbol	No	""

Equation Fields

Field	Description	Type
`container`	reference to the Container that the symbol belongs to	`Container`
`defaultValues`	default values for the symbol	`numeric` (named vector)
`description`	description of symbol	`string`
`dimension`	dimension of symbol, setting dimension is a shorthand notation to set `domain` to a list of size n containing "$*$"	`integer`
`domain`	list of domains given either as string ($*$ for universe set) or as reference to the Set/Alias object	`list`
`domainForwarding`	Flag or a vector of flags that forces equation elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	`logical`
`domainLabels`	column headings for the `records` data frame	`list` of `string`
`domainNames`	string version of domain names	`list` of `string`
`domainType`	`none`, `relaxed` or `regular` depending on state of domain links	`string`
`isScalar`	TRUE if `self$dimension = 0`	`logical`
`name`	name of symbol	`string`
`numberRecords`	number of symbol records (i.e., returns `nrow(self$records)` if not `NULL`)	`integer`
`records`	the main symbol records	`data frame`
`shape`	a vector describing the array dimensions if `records` were converted with `$toDense()`	`vector`
`summary`	output a `list` of only the metadata	`list`
`type`	`string` type of equation	`list`

Equation Methods

Method	Description	Arguments/Defaults	Returns
`addUELs`	adds UELs to the symbol	`uels` (character), `dimension=NULL`	`NULL`
`copy`	copies the symbol to the `destination` container. `overwrite=TRUE` overwrites the symbol with the same name in `destination`. Symbol domains are `relaxed` if `destination` Container does not contain equivalent domain sets	`destination` (Container), `overwrite=FALSE`	`NULL`
`countDomainViolations`	returns the number of domain violations for the symbol	-	`numeric`

Method	Description	Arguments/Defaults	Returns
`countDuplicateRecords`	returns the number of duplicate records for the symbol	-	`numeric`
`countEps`	total number of `SpecialValues$EPS` across all `columns`	`columns = "level"`	`integer`
`countNA`	total number of `SpecialValues[["NA"]]` across all `columns`	`columns = "level"`	`integer`
`countNegInf`	total number of `SpecialValues$NEGINF` across all `columns`	`columns = "level"`	`integer`
`countPosInf`	total number of `SpecialValues$POSINF` across all `columns`	`columns = "level"`	`integer`
`countUndef`	total number of `SpecialValues$UNDEF` across all `columns`	`columns = "level"`	`integer`
`dropDomainViolations`	drops domain violations for the symbol	-	-
`dropDuplicateRecords`	drops duplicate records for the Symbol. `keep = "first"` (drops all duplicates while keeping the first instance as unique), `keep="last"` (drops all duplicates while keeping the last instance as unique), or `keep=FALSE` (drops all duplicates)	`keep = "first"`	-
`equals`	Check if two Symbol objects are equal	`other` (`Symbol`), `columns=NULL` (character) (if `NULL` all columns are compared), `checkUELs=TRUE`, `checkMetaData=TRUE`, `rtol=0` (relative tolernace), `atol=0` (absolute tolerance), `verbose=FALSE`	logical
`findDomainViolations`	get a view of records data frame that contain any domain violations	-	`data.frame`

Method	Description	Arguments/Defaults	Returns
`findDuplicateRecords`	get a view of records data frame that contain duplicate records. `keep = "first"` (finds all duplicates while keeping the first instance as unique), `keep="last"` (finds all duplicates while keeping the last instance as unique), or `keep=FALSE` (finds all duplicates)	`keep= first`	`data.frame`
`generateRecords`	convenience method to set standard `data.frame` formatted records. Will generate records with the Cartesian product of all domain sets. The `density` argument can take any value on the interval `[0,1]`. If `density` is < 1, then randomly selected records will be removed. `density` will accept a `numeric` of length 1 or `dimension`. This allows users to specify a density per symbol dimension (when vector) or the density of `records` dataframe. Random numbers can be generated by passing a user-defined function `func(size)` to `func` argument (`runif()` by default). Random number state can be set with `seed` argument.	`density=1.0` (`numeric`) `func=runif()` (named list of functions, function, NULL) `seed=NULL` (`integer`)	`NULL`
`getDomainViolations`	gets domain violations for the symbol	-	list of `DomainViolation`
`getMaxValue`	get the maximum value across all `columns`	`columns = "level"`	`numeric`
`getMaxAbsValue`	get the maximum absolute value across all `columns`	`columns = "level"`	`numeric`
`getMinValue`	get the minimum value iacross all `columns`	`columns = "level"`	`numeric`
`getMeanValue`	get the mean value across all `columns`	`columns = "level"`	`numeric`

Method	Description	Arguments/Defaults	Returns
`getSparsity`	get the sparsity of the symbol w.r.t the size of full cartesian product of the domain sets	-	`numeric`
`getUELs`	returns the UELs used in the Symbol	`dimension = NULL`, `codes = NULL`, `ignoreUnused=FALSE`	`character vector`
`hasDomainViolations`	returns TRUE if the symbol contains domain violations, FALSE otherwise	-	`logical`
`hasDuplicateRecords`	returns TRUE if the symbol contains duplicate records, FALSE otherwise	-	`logical`
`isValid`	checks if the symbol is in a valid format, throw exceptions if `verbose=TRUE`, recheck a symbol if `force=TRUE`	`verbose=FALSE` `force=FALSE`	`logical`
`removeUELs`	removes UELs from the symbol	`uels=NULL` (character), `dimension=NULL`	`NULL`
`renameUELs`	renames UELs in the symbol	`uels`(character of same length as current UELs or named character vector), `dimension=NULL`, `allowMerge=FALSE` (logical). If `allowMerge = TRUE`, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	`NULL`
`reorderUELs`	reorders UELs in the symbol that appear in the symbol `dimensions`. If `uels` is `NULL`, the UELs are reordered based on symbol records, unused UELs are moved to the end. If `dimensions` is `NULL` then reorder UELs in all dimensions of the symbol	`uels=NULL`(`NULL` or character of same length as current UELs or named character vector), `dimension=NULL` (numeric)	`NULL`
`setRecords`	main convenience method to set standard `data frame` records	`records` (many types)	`NULL`
`setUELs`	sets UELs for the Symbol	`uels`(character), `dimension`, `rename=FALSE`	`NULL`
`toDense`	convert symbol to a dense `matrix` or `array` format	`column = "value"`	`array` or `matrix`

Method	Description	Arguments/Defaults	Returns
whereMax	find the row number in records data frame with a maximum value (return the first instance only)	column="level"	integer
whereMaxAbs	find the row number in records data frame with a maximum absolute value (return the first instance only)	column="level"	integer
whereMin	find the row number in records data frame with a minimum value (return the first instance only)	column="level"	integer

Adding Equation Records

Three possibilities exist to assign symbol records to an equation: We show a few examples of ways to create differently structured equations:

Example #1 - Create a GAMS scalar equation

```
library(gamstransfer)
m = Container$new()
pi = Equation$new(m, "pi", type="eq", records = data.frame(level = 3.14159))
# NOTE: the above syntax is equivalent to -
# pi = Equation$new(m, "pi", type="eq")
# pi$setRecords(data.frame(level = 3.14159))
# NOTE: the above syntax is also equivalent to -
# m$addEquation("pi", type="eq", records=data.frame(level = 3.14159))
> pi$records
    level
1 3.14159
```

Example #2 - Create a 2D positive equation, specifying no numerical data

```
library(gamstransfer)
m = Container$new()
e = Equation$new(m, "e", "eq", c("*", "*"), records =
data.frame(from=c("seattle", "chicago"), to=c("san-diego", c("madison"))))
> e$records
     from        to
1 seattle san-diego
2 chicago   madison
```

Example #3 - Create a 2D equation (defined over a set) from a matrix

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", "*", records = paste0("i", 1:5))
j = Set$new(m, "j", "*", records = paste0("j", 1:5))
# creating records for parameter a
ij = list(i_1 = paste0("i", 1:5), j_2 = paste0("j", 1:5))
df = rev(expand.grid(rev(ij)))
df$value = 1:25
a = Parameter$new(m, "a", c(i, j), records = df)
# create a free variable and set the level and marginal attributes from matrices
e = Equation$new(m, "e", "nonbinding", domain = c(i, j), records = list(level = a$toDense(), marginal = a$toDense()))
> e$records
    i  j level marginal
1  i1 j1     1        1
2  i2 j1     6        6
3  i3 j1    11       11
4  i4 j1    16       16
5  i5 j1    21       21
6  i1 j2     2        2
7  i2 j2     7        7
8  i3 j2    12       12
9  i4 j2    17       17
10 i5 j2    22       22
11 i1 j3     3        3
12 i2 j3     8        8
13 i3 j3    13       13
14 i4 j3    18       18
15 i5 j3    23       23
16 i1 j4     4        4
17 i2 j4     9        9
18 i3 j4    14       14
19 i4 j4    19       19
20 i5 j4    24       24
21 i1 j5     5        5
22 i2 j5    10       10
23 i3 j5    15       15
24 i4 j5    20       20
25 i5 j5    25       25
# if not specified, the toDense() method will convert the level values to a matrix
> e$toDense()
     [,1] [,2] [,3] [,4] [,5]
[1,]    1    2    3    4    5
[2,]    6    7    8    9   10
[3,]   11   12   13   14   15
[4,]   16   17   18   19   20
[5,]   21   22   23   24   25
```

As with sets, parameters, and variables the primary advantage of the `setRecords` method is that GAMS Transfer will convert many different (and convenient) data types into the standard data format (data frame). Users that require higher performance will want to directly pass the Container a reference to a valid data frame, thereby skipping some of these computational steps. This places more burden on the user to pass the data in a valid standard form, but it speeds the records setting process. In this section, we walk the user through an example of how to set records directly.

Example #4 - Correctly set records (directly)

```
library(gamstransfer)
df = data.frame(h_1 = paste0("h", 1:8760), m_2 = paste0("m", 1:60),
s_3 = paste0("s", 1:60))
df$level = runif(nrow(df), min = 0, max = 100)
df$marginal = 0.0
df$lower = SpecialValues$NEGINF
df$upper = SpecialValues$POSINF
df$scale = 1.0
m = Container$new()
hrs = Set$new(m, "h", records = unique(df$h_1))
mins = Set$new(m, "m", records = unique(df$m_2))
secs = Set$new(m, "s", records = unique(df$s_3))
df$h_1 = factor(df$h_1, ordered = TRUE)
df$m_2 = factor(df$m_2, ordered = TRUE)
df$s_3 = factor(df$s_3, ordered = TRUE)
a = Equation$new(m, "a", "eq", domain = c(hrs, mins, secs))
# set records
a$records = df
> a$isValid()
[1] TRUE
```

In this example, we create a large equation (31,536,000 records and 8880 unique domain elements. We mimic data that is labeled for every second in one year) and assign it to an equation with `a$records`.

GAMS Transfer R requires that all domain columns must be ordered factors. The `records` setter function does very little work other than checking if the object being set is a data frame. This places more responsibility on the user to create a data frame that complies with the standard format. In Example #1, we take care to properly reference the factor from the domain sets and ensure that the symbol `a` is valid in the end with `a$isValid() = TRUE`.

As with sets, parameters, and variables, users can use the `$isValid(verbose=TRUE)` method to debug any structural issues.

Note

One can also use the genereateRecords() method to automatically populate randomly generated symbol records in the standard format.

Alias

Alias Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the Container object that the symbol is being added to	Yes	-
`name`	`string`	Name of symbol	Yes	-
`aliasWith`	`Set` object	set object to create an alias for	Yes	-

Example - Creating an alias from a set

GAMS Transfer R only stores the reference to the parent set as part of the alias structure. Most properties that are called from an alias object simply point to the properties of the parent set (with the exception of `container`, `name`, and `aliasWith`). It is possible to create an alias from another alias object. In this case, a recursive search will be performed to find the root parent set. This is the set that will ultimately be stored as the `aliasWith` field. We can see this behavior in the following example:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = paste0("i", 1:5))
ip = Alias$new(m, "ip", i)
ipp = Alias$new(m, "ipp", ip)
> ip$aliasWith$name
[1] "i"
> ipp$aliasWith$name
[1] "i"
```

Alias Fields

Field	Description	Type
`aliasWith`	aliased object	`Set`
`description`	description of symbol	`string`
`dimension`	dimension of symbol, setting dimension is a shorthand notation to set `domain` to a list of size n containing "∗"	`integer`

Field	Description	Type
`domainForwarding`	Flag or a vector of flags that forces Alias elements to be recursively included in corresponding parent sets (i.e.,implicit set definition)	`logical`
`domainLabels`	column headings for the `records` data frame	`list` of `string`
`domainNames`	string version of domain names	`list` of `string`
`domainType`	`none`, `relaxed` or `regular` depending on state of domain links	`string`
`isSingleton`	`logical` if symbol is a singleton set	`logical`
`name`	name of symbol	`string`
`numberRecords`	number of symbol records (i.e., returns `nrow(self$records)` if not `NULL`)	`integer`
`records`	the main symbol records	`data frame`
`container`	reference to the Container that the symbol belongs to	`Container`
`summary`	output a `list` of only the metadata	`list`

Alias Methods

Method	Description	Arguments/Defaults	Returns
`addUELs`	adds UELs to the symbol	`uels` (character), `dimension=NULL`	`NULL`
`copy`	copies the `Alias` and the parent `Set` to the `destination` container. `overwrite=TRUE` overwrites the symbol with the same name in `destination`. Symbol domains are `relaxed` if `destination` Container does not contain equivalent domain sets	`destination` (Container), `overwrite=FALSE`	`NULL`
`countDomainViolations`	returns the number of domain violations for the symbol	-	`numeric`
`countDuplicateRecords`	returns the number of duplicate records for the symbol	-	`numeric`
`dropDomainViolations`	drops domain violations for the symbol	-	-
`dropDuplicateRecords`	drops duplicate records for the Symbol. `keep = "first"` (drops all duplicates while keeping the first instance as unique), `keep="last"` (drops all duplicates while keeping the last instance as unique), or `keep=FALSE` (drops all duplicates)	`keep = "first"`	-

Method	Description	Arguments/Defaults	Returns
equals	Check if two Symbol objects are equal	other (Symbol), checkUELs=TRUE, checkElementText=TRUE, checkMetaData=TRUE, verbose=FALSE	logical
findDomainViolations	get a view of records data frame that contain any domain violations	-	data.frame
findDuplicateRecords	get a view of records data frame that contain duplicate records. keep = "first" (finds all duplicates while keeping the first instance as unique), keep="last" (finds all duplicates while keeping the last instance as unique), or keep=FALSE (finds all duplicates)	keep= first	data.frame
generateRecords	convenience method to set standard data.frame formatted records. Will generate records with the Cartesian product of all domain sets. The density argument can take any value on the interval [0,1]. If density is < 1, then randomly selected records will be removed. density will accept a numeric of length 1 or dimension. This allows users to specify a density per symbol dimension (when vector) or the density of records dataframe. Random number state can be set with seed argument.	density=1.0 (numeric) seed=NULL (integer)	NULL
getDomainViolations	gets domain violations for the symbol	-	list of DomainViolation
getSparsity	get the sparsity of the symbol w.r.t the size of full cartesian product of the domain sets	-	numeric
getUELs	returns the UELs used in the Symbol	dimension = NULL, codes = NULL, ignoreUnused=FALSE	character vector

Method	Description	Arguments/Defaults	Returns
`hasDomainViolations`	returns TRUE if the symbol contains domain violations, FALSE otherwise	-	`logical`
`hasDuplicateRecords`	returns TRUE if the symbol contains duplicate records, FALSE otherwise	-	`logical`
`isValid`	checks if the symbol is in a valid format, throw exceptions if `verbose=TRUE`, recheck a symbol if `force=TRUE`	`verbose=FALSE` `force=FALSE`	`logical`
`removeUELs`	removes UELs from the symbol	`uels=NULL` (character), `dimension=NULL`	`NULL`
`renameUELs`	renames UELs in the symbol	`uels`(character of same length as current UELs or named character vector), `dimension=NULL`, `allowMerge=FALSE` (logical). If `allowMerge = TRUE`, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	`NULL`
`reorderUELs`	reorders UELs in the parent set that appear in the parent set `dimensions`. If `uels` is `NULL`, the UELs are reordered based on symbol records, unused UELs are moved to the end. If `dimensions` is `NULL` then reorder UELs in all dimensions of the symbol	`uels=NULL`(`NULL` or character of same length as current UELs or named character vector), `dimension=NULL` (numeric)	`NULL`
`setRecords`	main convenience method to set standard `data frame` formatted records	`records` (string vector, list, data frame)	`NULL`
`setUELs`	sets UELs for the Symbol	`uels`(character), `dimension`, `rename=FALSE`	`NULL`

Adding Alias Records

The linked structure of Aliases offers some unique opportunities to access some of the setter functionality of the parent set. Specifically, GAMS Transfer allows the user to change the `domain`, `description`, `dimension`, and `records` of the underlying parent set as a shorthand notation. We can see this behavior if we look at a modified Example #1 from adding set records.

Example - Creating set records through an alias link

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i")
ip = Alias$new(m, "ip", i)
ip$description = "adding new descriptive set text"
ip$domain = c("*", "*")
ij = list(paste0("i", 1:3), paste0("j", 1:3))
ip_recs = rev(expand.grid(rev(ij)))
colnames(ip_recs) = c("i", "j")
ip$setRecords(ip_recs)
> i$domain
[1] "*" "*"
> i$records
   i  j
1 i1 j1
2 i1 j2
3 i1 j3
4 i2 j1
5 i2 j2
6 i2 j3
7 i3 j1
8 i3 j2
9 i3 j3
```

Note

An alias `$isValid()=TRUE` when the underlying parent set is also valid. If the parent set is removed from the Container the alias will no longer be valid.

One can also use the genereateRecords() method to automatically populate randomly generated symbol records in the standard format.

UniverseAlias

UniverseAlias Constructor

Argument	Type	Description	Required	Default
`container`	`Container`	A reference to the Container object that the symbol is being added to	Yes	-
`name`	`string`	Name of symbol	Yes	-

Example - Creating an alias for the Universe

In GAMS it is possible to create aliases to the universe (i.e., the entire list of UELs) with the syntax:

```
set i / i1, i2 /;
alias(h,*);
set j / j1, j2 /;
```

GAMS Transfer R allows creating aliases to the universe set.

In this small example, `h` would be associated with all four UELs (`i1`, `i2`, `j1` and `j2`) even though set `j` was defined after the alias declaration. GAMS Transfer mimics this behavior with the `UniverseAlias` class. Internally, the `records` attribute will always call the <`Container`>`$getUELs()`. The `UniverseAlias` class is fundamentally different from the `Alias` class because it does not point to a parent set object. It is not possible to perform operations (like `setRecords` or `findDomainViolations`) on the parent set

through a `UniverseAlias` (because there is no parent set object). This means that a `UniverseAlias` can be created by only defining the symbol name. We can see this behavior in the following example:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("i1", "i2"))
h = UniverseAlias$new(m, "h")
j = Set$new(m, "j", records = c("j1","j2"))
> m$listSymbols()
[1] "i" "h" "j"
> m["h"]
GAMS Transfer: R6 object of class UniverseAlias.
    Use h$summary for details
> h$records
 uni
1 i1
2 i2
3 j1
4 j2
```

Note

Unlike other sets, the universe does not hold on to set `element_text`, thus the returned `data frame` for the `UniverseAlias` will only have one column.

UniverseAlias Fields

Field	Description	Type
`aliasWith`	always `"*"`	`string`
`description`	always `Aliased with *`	`string`
`dimension`	always `1`	`integer`
`domainLabels`	always `"uni"`	`character vector`
`domainNames`	always `"*"`	`character vector`
`domainType`	always `none`	`string`
`isSingleton`	always `FALSE`	`logical`
`name`	name of symbol	`string`
`numberRecords`	number of symbol records (i.e., returns `nrow(self$records)` if not `NULL`)	`integer`
`records`	the main symbol records	`data frame`
`container`	reference to the Container that the symbol belongs to	`Container`
`summary`	output a `list` of only the metadata	`list`

UniverseAlias Methods

Method	Description	Arguments/Defaults	Returns
`equals`	Check if two Symbol objects are equal	`other` (`Symbol`), `checkMetaData=TRUE`, `verbose=FALSE`	logical
`copy`	copies the symbol to the `destination` container. `overwrite=TRUE` overwrites the symbol with the same name in `destination`.	`destination` (Container), `overwrite=FALSE`	`NULL`

Method	Description	Arguments/Defaults	Returns
getSparsity	always 0	-	numeric
getUELs	returns the UELs from the Container. Returns only UELs in the data if ignoreUnused=TRUE, otherwise returns all UELs	ignoreUnused=FALSE	character vector
isValid	checks if the symbol is in a valid format, throw exceptions if verbose=TRUE, recheck a symbol if force=TRUE	verbose=FALSE force=FALSE	logical

7.7.1.3 Additional Features

Validating Data

GAMS Transfer R requires that the records for all symbols exist in a standard format (Standard Data Formats) in order for them to be understood by the Container. It is possible that the data could end up in a state that is inconsistent with the standard format (especially if setting symbol attributes directly). GAMS Transfer R includes the $isValid() method in order to determine if a symbol is valid. This method returns a logical. This method does not guarantee that a symbol will be successfully written to GDX. Other data errors (duplicate records, long UEL names, or domain violations) could exist that are not tested in $isValid(). For example, we create two valid sets and then check them with $isValid() to be sure.

It is possible to run $isValid() on both the Container as well as the symbol object. The Container method $isValid() will also return FALSE if there are any invalid symbols in the Container object. In addition, the Container$isValid() method also detects broken Container references in symbols and inconsistent symbol naming between the Container$data field and the symbol objects.

Example (valid data)

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("seattle", "san-diego", "washington_dc"))
j = Set$new(m, "j", i, records = c("san-diego", "washington_dc"))
> i$isValid()
[1] TRUE
> j$isValid()
[1] TRUE
> m$isValid()
[1] TRUE
```

Now we create some data that is invalid due to incorrect column names in the records for set j.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("seattle", "san-diego", "washington_dc"))
j = Set$new(m, "j", i)
j$records = data.frame(cities=c("grayslake", "washington_dc"))
> i$isValid()
[1] TRUE
> j$isValid()
[1] FALSE
> m$isValid()
[1] FALSE
```

In this example, we use records field of the symbol j to set the records. As mentioned in setting the records, when setting records directly, users must adhere to Standard Data Formats. In this example, symbol j does not have the correct number of columns. Moreover, the column headings do not follow the convention (should be "i_1"). The user can get more detailed error reporting if the verbose argument is set to TRUE. For example:

```
> j$isValid(verbose=TRUE)
Symbol 'records' does not have the correct number of columns (<symbol dimension> + 1)
[1] FALSE
```

The $isValid() method checks:

- If the symbol belongs to a Container
- If all domain set symbols exist in the Container
- If all domain set symbols objects are valid
- If all domain sets are one dimensional and not singleton sets
- If records are a data frame (or `NULL`)
- If the records `domainLabels` are unique
- The shape of the records is congruent with the dimensionality of the symbol
- That all data columns are type `numeric`
- To make sure that all domain categories are type `string`

Note

Calling `$isValid()` too often may have a significant impact on the performance.

Comparing GAMS Transfer objects

Equivalence between two symbols or between two containers can be tested using `equals` method. Since the order of records in the `records` data frame is not important from a GDX point of view, `equals` method compares symbol `records` independently from the order in which they are stored in the records data frame. As this requires a merge operation over the domain columns, `equals` is a computationally expensive call.

Attention

We do not recommend using `equals` method inside large loops or when performance is critical. It is, however, very useful for data debugging.

A quick example shows the syntax of `equals`:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i",1:5), description="set i")
j = Set$new(m, "j", records=paste0("i",1:5), description="set j")
> i$equals(j)
[1] FALSE
```

One can debug the reason for inequality using the option `verbose`.

```
> i$equals(j, verbose=TRUE)
Symbol names do not match i != j
[1] FALSE
```

By default, `equals` takes the strictest view of symbol "equality", i.e., everything must be equal. In this case, the symbol names and descriptions differ between the two sets `i` and `j`. We can relax this with a combination of argument flags. Comparing the two symbols again, but ignoring the meta data (i.e., ignoring the symbol name, description and type (if a Variable or Equation)):

```
> i$equals(j, checkMetaData=FALSE)
[1] TRUE
```

The `checkUELs` argument will ensure that the symbol "universe" is the same (in order and content) between two symbols, as illustrated in the following example:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
ip = Set$new(m, "ip", records=c("i1","i3","i2"))
> i$equals(ip, checkMetaData=FALSE)
[1] FALSE
> i$equals(ip, checkMetaData=FALSE, checkUELs=FALSE)
[1] TRUE
```

Numerical comparisons are enabled for `Parameters`, `Variables` and `Equations`. Equality can be flexibly defined through the `equals` method arguments. Again, the strictest view of equality is taken as the default behavior of `equals`.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
a = Parameter$new(m, "a", i, records=data.frame(c("i1","i2","i3"), c(1,2,3)))
ap = Parameter$new(m, "ap", i, records=data.frame(c("i1","i2","i3"), c(1+1e-9,2,3)))
> a$equals(ap, checkMetaData=FALSE)
[1] FALSE
> a$equals(ap, checkMetaData=FALSE, verbose=TRUE)
Symbol records contain numeric differences in the value attribute that are outside the specified tolerances
            rtol=0, atol=0
> a$equals(ap, checkMetaData=FALSE, atol=1e-8)
[1] TRUE
```

In the case of variables and equations, it is possible for the user to confine the numerical comparison to certain attributes (`level`, `marginal`, `lower`, `upper` and `scale`) by specifying the `columns` argument as the following example illustrates:

```
library(gamstransfer)
m = Container$new()
a = Variable$new(m, "a", "free", records=data.frame(level=100))
ap = Variable$new(m, "ap", "free", records=data.frame(level=101))
> a$records
  level
1   100
> ap$records
  level
1   101
> a$equals(ap, checkMetaData=FALSE)
[1] FALSE
> a$equals(ap, checkMetaData=FALSE, columns="level")
[1] FALSE
> a$equals(ap, checkMetaData=FALSE, columns="marginal")
[1] TRUE
```

Similar to symbols, one can compare two `Container` objects using the `equals` method. When comparing `Containers`, the `data` fields are compared and if the same symbol keys exist in the Containers under comparison, symbol `equals` method is used to compare the symbols. Here is a brief example:

```
> library(gamstransfer)
> m = Container$new()
> i = Set$new(m, "i")
> m1 = Container$new()
> i1 = Set$new(m1, "i")
> m$equals(m1)
[1] TRUE
> j = Set$new(m1, "j")
> m$equals(m1)
[1] FALSE
> m$equals(m1, verbose=TRUE)
Error in m$equals(m1, verbose = TRUE) :
  Containers contain different number of symbols.
 self: 1
 other :2
> k = Set$new(m, "k")
> m$equals(m1)
[1] FALSE
> m$equals(m1,verbose=TRUE)
Error in m$equals(m1, verbose = TRUE) :
  Container ‘data‘ field keys do not match. Keys not present in ‘other‘ :k
```

Domain Forwarding

GAMS includes the ability to define sets directly from data using the implicit set notation (see: Implicit Set Definition (or: Domain Defining Symbol Declarations)). This notation has an analogue in GAMS Transfer R called `domainForwarding`.

Note

It is possible to recursively update a subset tree in GAMS Transfer R.

Domain forwarding is available as an argument to all symbol object constructors; the user would simply need to pass `domainForwarding=TRUE` to forward domain across all dimensions or as a logical vector domainForwarding=c(TRUE, FALSE,....) to forward domain across selected dimensions.

In this example, we have raw data that is in the `dist` data frame, and we want to send the domain information into the `i` and `j` sets. We take care to pass the set objects as the domain for parameter `c`.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i")
j = Set$new(m, "j")
dist = data.frame(
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),
    to = c("new-york", "chicago", "topeka",
      "new-york", "chicago", "topeka"),
    thousand_miles = c(2.5, 1.7, 1.8, 2.5, 1.8, 1.4)
)
c = Parameter$new(m, "c", c(i, j), records = dist, domainForwarding = TRUE)
> i$records
        uni
1   seattle
2 san-diego
> j$records
       uni
1 new-york
2  chicago
3   topeka
> c$records
       from       to value
1   seattle new-york   2.5
2   seattle  chicago   1.7
3   seattle   topeka   1.8
4 san-diego new-york   2.5
5 san-diego  chicago   1.8
6 san-diego   topeka   1.4
```

Note

The element order in the sets `i` and `j` mirrors that in the raw data.

We can also selectively use domainForwarding for part of the domain by passing a logical vector to the `domainForwarding` argument as shown in the following example. The domain records are forwarded only to the domain set `i` but not to the domain set `j`.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i")
j = Set$new(m, "j")
dist = data.frame(
    from = c("seattle", "seattle", "seattle",
    "san-diego", "san-diego", "san-diego"),
    to = c("new-york", "chicago", "topeka",
      "new-york", "chicago", "topeka"),
    thousand_miles = c(2.5, 1.7, 1.8, 2.5, 1.8, 1.4)
)
c = Parameter$new(m, "c", c(i, j), records = dist, domainForwarding = c(TRUE, FALSE))
> i$records
        uni
1   seattle
4 san-diego
> j$records
NULL
> c$records
       from       to value
1   seattle new-york   2.5
2   seattle  chicago   1.7
3   seattle   topeka   1.8
4 san-diego new-york   2.5
5 san-diego  chicago   1.8
6 san-diego   topeka   1.4
```

In this example, we show that domain forwarding will also work recursively to update the entire set lineage. The domain forwarding occurs at the creation of every symbol object. The correct order of elements in set `i` is `(z, a, b, c)` because the records from `j` are forwarded first, and then the records from `k` are propagated through (back to `i`).

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i")
```

```
j = Set$new(m, "j", i, records = c("z"), domainForwarding = TRUE)
k = Set$new(m, "k", j, records = c("a", "b", "c"), domainForwarding = TRUE)
> i$records
    uni
1     z
2     a
3     b
4     c
> j$records
    i
1   z
2   a
3   b
4   c
> k$records
    j
1   a
2   b
3   c
```

Describing Data

The methods describeSets, describeParameters, describeVariables, and describeEquations allow the user to get a summary view of key data statistics. The returned data frame aggregates the output for a number of other methods (depending on symbol type). A description of each Container method is provided in the following subsections:

describeSets

Argument	Type	Description	Required	Default
`symbols`	`list`, `string`	A list of sets in the Container to include in the output. describeSets will include aliases if they are explicitly passed by the user.	No	`NULL` (if `NULL` specified, will assume all sets)

Returns: `data frame`

The following table includes a short description of the column headings in the return.

Field / Statistic	Description
`name`	name of the symbol
`isSingleton`	`logical` if the set is a singleton set
`domain`	domain labels for the symbol
`domainType`	`none`, `relaxed` or `regular` depending on the symbol state
`dimension`	dimension
`numberRecords`	number of records in the symbol
`sparsity`	`1 - numberRecs/dense` where `dense` is the size of full cartesian product of the domain sets

Example #1

```
library(gamstransfer)
m = Container$new("trnsport.gdx")
> m$describeSets()
  name isSingleton domain domainType dimension numberRecords sparsity
1    i       FALSE      *       none         1             2       NA
2    j       FALSE      *       none         1             3       NA
```

Example #2 – with aliases

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:10))
j = Set$new(m, "j", records=paste0("j", 1:10))
ip = Alias$new(m, "ip", i)
jp = Alias$new(m, "jp", j)
> m$describeSets()
  name isSingleton domain domainType dimension numberRecords sparsity
1    i       FALSE      *       none         1            10       NA
2    j       FALSE      *       none         1            10       NA
> m$describeSets(append(m$listSets(), m$listAliases()))
  name isSingleton domain domainType dimension numberRecords sparsity
1    i       FALSE      *       none         1            10       NA
3   ip       FALSE      *       none         1            10       NA
2    j       FALSE      *       none         1            10       NA
4   jp       FALSE      *       none         1            10       NA
```

describeParameters

Argument	Type	Description	Required	Default
`symbols`	`list`, `string`	A list of parameters in the Container to include in the output	No	`NULL` (if `NULL` specified, will assume all parameters)

Returns: `data frame`

The following table includes a short description of the column headings in the return.

Field / Statistic	Description
`name`	name of the symbol
`domain`	domain labels for the symbol
`domainType`	`none`, `relaxed` or `regular` depending on the symbol state
`dimension`	dimension
`numberRecords`	number of records in the symbol
`min`	min value in data
`mean`	mean value in data
`max`	max value in data
`whereMin`	row number min value (if multiple, returns only first occurrence)
`sparsity`	`1 - numRecs/dense` where where `dense` is the size of full cartesian product of the domain sets

```
library(gamstransfer)
m = Container$new("trnsport.gdx")
>  name domain domainType dimension numberRecords     min     mean     max
1    a      i    regular         1             2 350.000 475.0000 600.000
2    b      j    regular         1             3 275.000 300.0000 325.000
5    c    i j    regular         2             6   0.126   0.1755   0.225
3    d    i j    regular         2             6   1.400   1.9500   2.500
4    f     NA       none         0             1  90.000  90.0000  90.000
  whereMin whereMax sparsity
1        1        2        0
2        3        1        0
5        6        1        0
3        6        1        0
4        1        1       NA
```

describeVariables

Argument	Type	Description	Required	Default
symbols	list, string	A list of variables in the Container to include in the output	No	NULL (if NULL specified, will assume all variables)

Returns: data frame

The following table includes a short description of the column headings in the return.

Field / Statistic	Description
name	name of the symbol
type	type of variable (i.e., binary,integer,positive,negative,free,sos1,sos2,semicont,semiint)
domain	domain labels for the symbol
domainType	none, relaxed or regular depending on the symbol state
dimension	dimension
numberRecords	number of records in the symbol
sparsity	1 - numRecs/dense, where dense is the size of full cartesian product of the domain sets
minLevel	min value in the level column
meanLevel	mean value in the level column
maxLevel	max value in the level column
whereMaxAbsLevel	max absolute value in the level column

```
library(gamstransfer)
m = Container$new("trnsport.gdx")
> m$describeVariables()
  name     type domain domainType dimension numberRecords sparsity minLevel
1    x positive    i j    regular         2             6        0    0.000
2    z     free     NA       none         0             1       NA  153.675
  meanLevel maxLevel whereMaxAbsLevel
1   150.000  300.000                2
2   153.675  153.675                1
```

describeEquations

Argument	Type	Description	Required	Default
symbols	list, string	A list of equations in the Container to include in the output	No	NULL (if NULL specified, will assume all variables)

Returns: data frame

The following table includes a short description of the column headings in the return.

Field / Statistic	Description
name	name of the symbol
type	type of variable (i.e., binary,integer,positive,negative,free,sos1,sos2,semicont,semiint)
domain	domain labels for the symbol
domainType	none, relaxed or regular depending on the symbol state
dimension	dimension
numberRecords	number of records in the symbol

Field / Statistic	Description
sparsity	1 - numRecs/dense, where dense is the size of full cartesian product of the domain sets
minLevel	min value in the level column
meanLevel	mean value in the level column
maxLevel	max value in the level column
whereMaxAbsLevel	max absolute value in the level column

```
library(gamstransfer)
m = Container$new("trnsport.gdx")
> m$describeEquations()
    name type domain domainType dimension numberRecords sparsity minLevel
1   cost   eq     NA       none         0             1       NA        0
3 demand  geq      j    regular         1             3        0      275
2 supply  leq      i    regular         1             2        0      350
  meanLevel maxLevel whereMaxAbsLevel
1         0        0                1
3       300      325                1
2       450      550                2
```

describeAliases

Argument	Type	Description	Required	Default
symbols	list, string	A list of aliases in the Container to include in the output.	No	NULL (if NULL specified, will assume all aliases)

Returns: data frame

The following table includes a short description of the column headings in the return.

Field / Statistic	Description
name	name of the symbol
aliasWith	name of the parent set
isSingleton	logical if an alias of a singleton set
domain	domain labels for the symbol
domainType	none, relaxed or regular depending on the symbol state
dimension	dimension
numberRecords	number of records in the symbol
sparsity	1 - numberRecs/dense, where dense is the size of full cartesian product of the domain sets

Example #1

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = paste0("i",1:5))
j = Set$new(m, "j", records = paste0("j",1:10))
ip = Alias$new(m, "ip", i)
ipp = Alias$new(m, "ipp", ip)
jp = Alias$new(m, "jp", j)
> m$describeAliases()
  name aliasWith isSingleton domain domainType dimension numberRecords sparsity
1   ip         i       FALSE      *       none         1             5       NA
2  ipp         i       FALSE      *       none         1             5       NA
3   jp         j       FALSE      *       none         1            10       NA
```

Matrix Generation

GAMS Transfer R stores data in a "flat" format, that is, one record entry per data frame row. However, it is often necessary to convert this data format into a matrix/array format. GAMS Transfer R enables users to do this with relative ease using the `toDense` symbol methods This method will return a dense `N`-dimensional array (matrix for 2-Dimensions) with each dimension corresponding to the GAMS symbol dimension; it is possible to output an array up to 20 dimensions (a GAMS limit).

Example (1D data w/o domain linking (i.e., a relaxed domain))

```
library(gamstransfer)
m = Container$new()
a = Parameter$new(m, "a", "i", records = data.frame(uni=c("a","c"), element_text=c(1,3)))
> a$toDense()
[1] 1 3
```

Note that the parameter `a` is not linked to another symbol, so when converting to a matrix, the indexing is referenced to the data structure in `a$records`. Defining a sparse parameter `a` over a set `i` allows us to extract information from the `i` domain and construct a very different dense matrix, as the following example shows:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("a", "b", "c", "d"))
a = Parameter$new(m, "a", i, records = data.frame(c("a","c"), c(1,3)))
> a$toDense()
[1] 1 0 3 0
```

Example (2D data w/ domain linking)

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("a", "b", "c", "d"))
a = Parameter$new(m, "a", c(i, i), records =
data.frame(i=c("a","c"), i=c("a","c"), c(1,3)))
> i$records
    uni
1     a
2     b
3     c
4     d
> a$records
    i i.1 value
1   a   a     1
2   c   c     3
> a$toDense()
     [,1] [,2] [,3] [,4]
[1,]    1    0    0    0
[2,]    0    0    0    0
[3,]    0    0    3    0
[4,]    0    0    0    0
```

Note

If there are unused UELs in the domain symbol, `toDense()` requires that the unused UELs are at the end of UEL list. One can achieve this by calling the `reorderUELs()` method for the domain symbol. Similarly, if the symbol records are in a different order than that of domain symbol UEL, UELs should be reordered to follow the record order. This can also be achived using `reorderUELs()` symbol method.

The Universe Set

A Unique Element (UEL) is an `(i,s)` pair where `i` is an identification number for a string `s`. A list of all UELs is also known as 'the universe' or 'the universe set'. GAMS uses UELs to efficiently store domain entries of a record by storing the UEL ID `i` of a domain entry instead of the actual string `s`. This avoids storing the same string multiple times. The concept of UELs also exists in R and is called a "factor". GAMS Transfer R leverages these types in order to efficiently store strings and enable domain checking within the R environment.

Each domain column in a data frame can be a factor, the effect is that each symbol maintains its own list of UELs per dimension. R lets the user choose if levels in a factor should be regarded as ordered. GAMS Transfer R relies exclusively on `ordered` factors. By using ordered factors, GAMS Transfer R will order the UELs such that elements appear in the order in which they appeared in the data (which is how GAMS defines the UELs). `GAMSTransfer` allows the user to reorder the UELs with the `uelPriority` argument in the `$write()` method.

GAMS Transfer R does not keep track of the UELs separately from other symbols in the Container, it will be created internal to the `$write()` method and is based on the order in which data is added to the container. The user can access the current state of UELs with the `$getUELs()` container method. For example, we set a two dimensional set:

```
library(gamstransfer)
m = Container$new()
j = Set$new(m, "j", c("*", "*"), records = data.frame(i=c("i1","i2"), j=c("j1","j2")))
> j$records
      i     j
1    i1    j1
2    i2    j2
> m$getUELs()
[1] "i1" "i2" "j1" "j2"
```

Customize The Universe Set

GAMS Transfer R allows the users to customize the Universe Set with the help of Symbol UELs methods shown in the following table.

Method	Description	Arguments/Defaults	Returns
`addUELs`	adds UELs to the symbol	`uels` (character), `dimension=NULL`	`NULL`
`getUELs`	returns the UELs used in the Symbol	`dimension = NULL`, `codes = NULL`, `ignoreUnused=FALSE`	`character vector`
`removeUELs`	removes UELs from the symbol	`uels=NULL` (character), `dimension=NULL`	`NULL`
`renameUELs`	renames UELs in the symbol	`uels`(character of same length as current UELs or named character vector), `dimension=NULL`, `allowMerge=FALSE` (logical). If `allowMerge = TRUE`, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	`NULL`
`reorderUELs`	reorders UELs in the symbol that appear in the symbol `dimensions`. If `uels` is `NULL`, the UELs are reordered based on symbol records, unused UELs are moved to the end. If `dimensions` is `NULL`	`uels=NULL`(`NULL` or character of same length as current UELs or named character vector), `dimension=NULL` (numeric)	`NULL`
	then reorder UELs in all dimensions of the symbol		

Method	Description	Arguments/Defaults	Returns
`setUELs`	sets UELs for the Symbol	`uels`(character), `dimension`, `rename=FALSE`	`NULL`

Note

Symbols should be valid in order to use these methods.

when `dimension` argument is optional, the method is applied to all dimensions

Some of these methods are also available as Container methods as shown in the following table. Container methods internally call the corresponding Symbol methods.

Method	Description	Arguments/Defaults	Returns
`getUELs`	returns the UELs used in the Container	`symbols=NULL` (character), `ignoreUnused = FALSE`	`character vector`
`removeUELs`	removes `uels` from all symbols the Container	`uels=NULL` (character)	`NULL`
`renameUELs`	renames `uels` in the Container	`uels` (named character), `allowMerge=FALSE` (logical). If `allowMerge = TRUE`, the underlying integer mapping of a factor is allowed to change to offer additional data flexibility	`NULL`

getUELs Examples

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
j = Set$new(m, "j", records=c("j1","j2","j3"))
a = Parameter$new(m, "a", c(i, j), records=data.frame(paste0("i",1:4), paste0("j",1:4), 1:4))
> i$getUELs()
[1] "i1" "i2" "i3"
> m$getUELs()
[1] "i1" "i2" "i3" "j1" "j2" "j3" "i4" "j4"
> m$getUELs("j")
[1] "j1" "j2" "j3"
```

addUELs Examples

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
j = Set$new(m, "j", records=c("j1","j2","j3"))
a = Parameter$new(m, "a", c(i, j), records=data.frame(paste0("i",1:3), paste0("j",1:3), 1:3))
i$addUELs("ham")
a$addUELs("and", 1)
a$addUELs("cheese", 2)
> i$getUELs()
[1] "i1"  "i2"  "i3"  "ham"
> a$getUELs()
[1] "i1"     "i2"     "i3"     "and"    "j1"     "j2"     "j3"     "cheese"
```

In this example we have added three new (unused) UELs: `ham`, `and`, `cheese`. These three UELs will now appear in the GAMS universe set (accessible with `m$getUELs()`). The addition of unused UELs does not impact the validity of the symbols (i.e., unused UELs will not trigger domain violations).

removeUELs Examples

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
j = Set$new(m, "j", records=c("j1","j2","j3"))
a = Parameter$new(m, "a", c(i, j), records=data.frame(paste0("i",1:3), paste0("j",1:3), 1:3))
i$addUELs("ham")
a$addUELs("and", 1)
a$addUELs("cheese", 2)
# remove symbol UELs explicitly by dimension
i$removeUELs("ham", 1)
a$removeUELs("and", 1)
a$removeUELs(c("and", "cheese"), 2)
# remove symbol UELs for the entire symbol
i$removeUELs("ham")
a$removeUELs(c("and", "cheese"))
# remove ONLY unused UELs from each symbol, independently
i$removeUELs()
a$removeUELs()
# remove ONLY unused UELs from the entire container (all symbols)
m$removeUELs()
> m$getUELs()
[1] "i1" "i2" "i3" "j1" "j2" "j3"
```

If a user removes a UEL that appears in data, that data will be lost perminately. The domain label will be transformed into an NA as seen in this example:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
j = Set$new(m, "j", records=c("j1","j2","j3"))
a = Parameter$new(m, "a", c(i, j), records=data.frame(i=paste0("i",1:3), j=paste0("j",1:3), 1:3))
m$removeUELs("i1")
> i$records
   uni
1 <NA>
2   i2
3   i3
> a$records
     i  j value
1 <NA> j1     1
2   i2 j2     2
3   i3 j3     3
```

Attention

A container cannot be written if there are NA entries in any of the domain columns (in any symbol). An error is thrown if there are missing domain labels.

renameUELs Examples

`renameUELs` is a method of all GAMS `Symbol` classes as well as the `Container` class. This method allows the user to rename UELs in a symbol dimension(s), over several symbols, or over the entire container. This method is handy when attempting to harmonize labeling schemes between data structures that originated from different sources. For example:

```
library(gamstransfer)
m = Container$new()
a = Parameter$new(m, "a", c("*","*"),
records = data.frame(from=c("WI","IL","WI"),
to=c("IL", "IN", "IN"), quantity=c(10, 12.5, 8.7)),
description = "shipment quantities")
b = Parameter$new(m, "b", c("*"),
records = data.frame(state=c("wisconsin","illinois","indiana"),
c(1.2, 1.7, 1.2)), description = "multipliers")
```

results in the following records:

```
> a$records
   from    to value
1    WI    IL  10.0
2    IL    IN  12.5
3    WI    IN   8.7
> b$records
      state value
1 wisconsin   1.2
```

```
2  illinois   1.7
3   indiana   1.2
```

However, two different data sources were used to generate the parameters `a` and `b` – one data source used the uppercase postal abbreviation of the state name and the other source used a lowercase full state name as the uniqe identifier. With the following syntax the user can harmonize to a mixed case postal code labeling scheme (without losing any of the original UEL ordering).

```
m$renameUELs(c("WI"="Wi", "IL"="Il", "IN"="In",
"wisconsin"="Wi", "illinois"="Il","indiana"="In"))
```

This results in the following records and the universe set:

```
> a$records
   from    to value
1    Wi    Il  10.0
2    Il    In  12.5
3    Wi    In   8.7
> b$records
  state value
1    Wi   1.2
2    Il   1.7
> m$getUELs()
[1] "Wi" "Il" "In"
```

reorderUELs Examples

`reorderUELs` is a method of all GAMS symbol classes. This method allows the user to reorder UELs of a specific symbol dimension. `reorderUELs` will not add/remove any UELs. For example:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
> i$getUELs()
[1] "i1" "i2" "i3"
> m$getUELs()
[1] "i1" "i2" "i3" "j1" "j2" "j3"
```

But perhaps we want to reorder the UELs `i1`, `i2`, `i3` to `i3`, `i2`, `i1`.

```
i$reorderUELs(c("i3","i2","i1"))
> i$getUELs()
[1] "i3" "i2" "i1"
> i$records
    uni
1    i1
2    i2
3    i3
```

Note

> This example does not change the indexing scheme of the data frame. It only changes the underlying integer numbering scheme for the factor levels.
> We can see this by looking at the `levels`:

```
> as.integer(i$records$uni)
[1] 3 2 1
```

When `reorderUELs()` is used without the `uels` argument, the UELs are rearranged based on the records order as illustrated in the following example.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
i$setUELs(c("i2","i3","i1"))
> i$getUELs()
[1] "i2" "i3" "i1"
> i$reorderUELs()
> i$getUELs()
[1] "i1" "i2" "i3"
```

Moreover, if there are unused UELs, they are moved to the end as shown below. Here, `i4` is the unused UELs that gets moved to the end after using `reorderUELs`.

```
> i$setUELs(c("i2","i3","i4","i1"))
> i$getUELs()
[1] "i2" "i3" "i4" "i1"
> i$reorderUELs()
> i$getUELs()
[1] "i1" "i2" "i3" "i4"
```

setUELs Examples

> `setUELs` is a method of all GAMS symbol classes. This method allows the user to create new UELs, rename UELs, and reorder UELs all in one method. For example:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
```

A user could accomplish a UEL reorder operation with `setUELs`:

```
> i$setUELs(c("i3","i2","i1"))
> i$getUELs()
[1] "i3" "i2" "i1"
> i$records
    uni
1    i1
2    i2
3    i3
```

A user could accomplish a UEL reorder + add UELs operation with `setUELs`:

```
> i$setUELs(c("i3", "i2", "i1", "j1", "j2"))
> i$getUELs()
[1] "i3" "i2" "i1" "j1" "j2"
> i$records
    uni
1    i1
2    i2
3    i3
> as.integer(i$records$uni)
[1] 3 2 1
```

A user could accomplish a UEL reorder + add + rename with `setUELs`:

```
> i$setUELs(c("j3", "j2", "j1", "ham", "cheese"), rename=TRUE)
> i$setUELs(c("j3", "j2", "j1", "ham", "cheese"), rename=TRUE)
> i$getUELs()
[1] "j3"     "j2"     "j1"     "ham"    "cheese"
> i$records
    uni
1    j1
2    j2
3    j3
> as.integer(i$records$uni)
[1] 3 2 1
```

Note

> This example does not change the indexing scheme of the data frame, but the `rename=TRUE` flag means that the records will get updated as if a `renameUELs` call had been made.

If a user wanted to set new UELs on top of this data, without renaming, they would need to be careful to include the current UELs in the UELs being set. It is possible to lose these labels if they are not included (which will prevent the data from being written to GDX).

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("i1","i2","i3"))
i$setUELs(c("j1", "i2", "j3", "ham", "cheese"))
> i$getUELs()
[1] "j1"     "i2"     "j3"     "ham"    "cheese"
> i$records
  uni_1
1  <NA>
2    i2
3  <NA>
```

Removing Symbols

Removing symbols from a Container is easy when using the `removeSymbols` container method; this method accepts either a `string` or a `list` of `string`.

Reordering Symbols

In order to write the contents of the Container, it is required that the symbols are sorted such that, for example, a Set used as a domain of another symbol appears before that symbol. The Container will try to establish a valid ordering when writing the data. This type of situation could be encountered if the user is adding and removing many symbols (and perhaps rewriting symbols with the same name). Users should attempt to only add symbols to a `Container` once, and care must be taken when naming. The method `reorderSymbols` attempts to fix symbol ordering problems. The following example shows how this can occur:

Example Symbol reordering

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = paste0("i", 1:5))
j = Set$new(m, "j", i, records = paste0("i", 1:3))
> m$listSymbols()
[1] "i" "j"
# now we remove the set i and recreate the data
m$removeSymbols("i")
i = Set$new(m, "i", records = paste0("i", 1:5))
> m$isValid()
[1] TRUE
```

Since the link to `i` is broken, Set `j` is now invalid. The user has to manually set the domain again.

```
# fix the domain reference in the set j
j$domain = i
> m$listSymbols()
[1] "j" "i"
```

Now even though `j` is valid, the symbols are out of order. The order can be fixed as follows.

```
# calling reorderSymbols() will order the list properly,
# but the domain reference in j is now broken
m$reorderSymbols()
> m$listSymbols()
[1] "i" "j"
> m$isValid()
[1] TRUE
```

Domain Violations

Domain violations occur when a symbol uses other Sets as domain(s) – and is thus of domain type regular, see Symbol Domain – and uses a domain entry in its records that is not present in the corresponding referenced domain set. Such a domain violation will lead to a GDX error when writing the data.

For example, the symbol `j` in the following example contains domain violations because `j` is defined over domain set `i` and the records entry "grayslake" is not present in `i`.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records = c("seattle", "san-diego", "washington_dc"))
j = Set$new(m, "j", i)
records = data.frame(cities=c("grayslake", "washington_dc"))
j$setRecords(records)
```

Trying to write this container to a GDX file will fail. To ask for domain violations, call the method `Symbol$getDomainViolations()`. It returns a list of `DomainViolation` objects with respect to each dimension of the symbol. This list can then be used to resolve the domain violations.

```
> dv = j$getDomainViolations()
> dv
[[1]]
GAMS Transfer: DomainViolation with properties:
Symbol: j
dimension:
domain: i
violations: grayslake
```

The GAMS Transfer R feature of domain forwarding offers an automatic expansion of the domain set with the violated entries in order to eliminate domain violations.

Note

Checking for domain violations is not a part of Symbol$isValid() for performance reasons.

The method for automatically resolving the domain violations can be convenient, but it effectively disables domain checking, which is a valuable tool for error detection. We encourage to use domain forwarding as rarely as possible. The same holds for using `relaxed` domain informaiton when `regular` domain information would be possible.

GAMS Special Values

The GAMS system contains five special values: `UNDEF` (undefined), `NA` (not available), `EPS` (epsilon), `+INF` (positive infinity), `-INF` (negative infinity). These special values must be mapped to their R equivalents. GAMS Transfer R follows the following convention to generate the `1:1` mapping:

- `+INF` is mapped to `Inf`
- `-INF` is mapped to `-Inf`
- `EPS` is mapped to `-0.0` (mathematically identical to zero)
- `NA` is mapped to a `NA`
- `UNDEF` is mapped to `NaN`

GAMS Transfer R syntax is designed to quickly get data into a form that is usable in further analyses or visualization. The user does not need to remember these constants as they are provided within the class `SpecialValues` as `SpecialValues$POSINF`, `SpecialValues$NEGINF`, `SpecialValues$EPS`, `SpecialValues[["NA"]]`, and `SpecialValues$UNDEF`. Some examples are shown below.

```
library(gamstransfer)
m = Container$new()
x = Parameter$new(
  m, "x", c("*"),
records = data.frame(uni=paste0("i", 1:6), c(1, SpecialValues[["POSINF"]],
SpecialValues[["NEGINF"]], SpecialValues[["EPS"]], SpecialValues[["NA"]],
SpecialValues[["UNDEF"]])),
description = "special values"
)
```

The following data frame for `x` would look like:

```
> x$records
    uni value
1    i1     1
2    i2   Inf
3    i3  -Inf
4    i4     0
5    i5    NA
6    i6   NaN
```

The user can now easily test for specific special values in the `value` column of the DataFrame (returns a logical vector):

```
> SpecialValues$isNA(x$records$value)
[1] FALSE FALSE FALSE FALSE  TRUE FALSE
> SpecialValues$isNA(x$records$value)
[1] FALSE FALSE FALSE FALSE  TRUE FALSE
> SpecialValues$isEps(SpecialValues$EPS)
[1] TRUE
> SpecialValues$isPosInf(SpecialValues$POSINF)
[1] TRUE
> SpecialValues$isNegInf(SpecialValues$NEGINF)
[1] TRUE
> SpecialValues$isNA(SpecialValues$NEGINF)
SpecialValues$isNA
> SpecialValues$isNA(SpecialValues[["NA"]])
[1] TRUE
> SpecialValues$isUndef(SpecialValues$UNDEF)
[1] TRUE
> SpecialValues$isUndef(SpecialValues[["NA"]])
[1] FALSE
> SpecialValues$isNA(SpecialValues$UNDEF)
[1] FALSE
```

Note

The syntax SpecialValues$NA is not allowed in R. Therefore, to access NA, one has to use `SpecialValues[["NA"]]`. As shown in the example above, double bracket syntax works for other special values too.

Standard Data Formats

This section is meant to introduce the standard format that GAMS Transfer R expects for symbol records. It has already been mentioned that we store data as a data frame, but there is an assumed structure to the column headings and column types that will be important to understand. GAMS Transfer R includes convenience functions in order to ease the burden of converting data from a user-centric format to one that is understood by GAMS Transfer R. However, advanced users will want to convert their data first and add it directly to the Container.

Set Records Standard Format

All set records (including singleton sets) are stored as a data frame with `n` or `n+1` number of columns, where `n` is the dimensionality of the symbol. The first `n` columns include the domain elements while the last column, if present, includes the set element text. Records are organized such that there is one record per row.

The names of the domain columns (domain labels) are unique. If the domain labels are non-unique, they are converted to follow a pattern of <`user_domain_label`>_<`index_position`> by `domainLabels` setter. If the records are passed in a non-data frame format (vector, matrix etc.), domain labels follow a pattern of <`domain_name`>_<`index_position`>. A symbol dimension that is referenced to the universe is labeled `uni`. The explanatory text column is called `element_text` and must take the last position in the data frame.

All domain columns must be `factors` and the `element_text` column must be a `string` type.

Some examples:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("seattle", "san-diego"))
j = Set$new(m, "j", c(i, "*"), records=data.frame(i=c("seattle", "san-diego"), uni=c("new-york", "st-louis")))
k = Set$new(m, "k", i, isSingleton=TRUE, records=c("seattle"))
> i$records
        uni
1   seattle
2 san-diego
> j$records
          i      uni
1   seattle new-york
2 san-diego st-louis
> k$records
        i
1 seattle
```

Parameter Records Standard Format

All parameter records (including scalars) are stored as a data frame with `n` or `n + 1` number of columns, where `n` is the dimensionality of the symbol. The first `n` columns include the domain elements while the last column, if present, includes the numerical value of the records. Records are organized such that there is one record per row. Scalar parameters have zero dimension, therefore they only have one column and one row. In cases where the `value` columns is not present for a parameter, it is assumed that the value is the default parameter value (i.e., 0). Scalar parameters with an empty data frame as records is assumed to contain the default value of 0.

The names of the domain columns (domain labels) are unique. If the domain labels are non-unique, they are converted to follow a pattern of <user_domain_label>_<index_position> by `domainLabels` setter. If the records are passed in a non-data frame format (vector, matrix etc.), domain labels follow a pattern of <domain_name>_<index_position>. A symbol dimension that is referenced to the universe is labeled uni_<index_position>. The value column is called `value` and must take the last position in the data frame.

All domain columns must be `factors` and the `value` column must be a `numeric` type. GAMS Transfer R requires that all the factor levels are of type `string`.

Some examples:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("seattle", "san-diego"))
a = Parameter$new(
  m, "a", "*", records=data.frame(c("seattle", "san-diego"), c(50, 100))
  )
b = Parameter$new(
    m,
    "b",
    c(i, "*"),
    records= data.frame(i=c("seattle", "san-diego"),
    uni=c("new-york", "st-louis"), c(32.2, 123))
)
c = Parameter$new(m, "c", records=90)
> a$records
        uni value
1   seattle    50
2 san-diego   100
> b$records
          i      uni value
1   seattle new-york  32.2
2 san-diego st-louis 123.0
> c$records
  value
1    90
```

Variable/Equation Records Standard Format

Variables and equations share the same standard data format. All records (including scalar variables/equations) are stored as a data frame with `n` to `n` + 5 number of columns, where `n` is the dimensionality of the symbol. The first `n` columns include the domain elements while the remaining columns include the numerical values for different attributes of the records. Records are organized such that there is one record per row. Scalar variables/equations have zero dimension, therefore they have one row. In cases where the records data frame has missing attribute columns, it is assumed that the column contains the default value. Similarly, if the records data frame for a scalar is empty, it is assumed that all the attribute values are at their default. Default values for variables and equations depend on their type.

The names of the domain columns (domain labels) are unique. If the domain labels are non-unique, they are converted to follow a pattern of <user_domain_label>_<index_position> by `domainLabels` setter. If the records are passed in a non-data frame format (vector, matrix etc.), domain labels follow a pattern of <domain_name>_<index_position>. A symbol dimension that is referenced to the universe is labeled uni_<index_position>. The attribute columns are called `level`, `marginal`, `lower`, `upper`, and `scale`. These attribute columns must appear in this order. Attributes that are not supplied by the user will be assigned the default GAMS values for that variable/equation type. It is possible to not pass any attributes, GAMS Transfer R would then simply assign default values to all attributes.

All domain columns must be `factors` and the attribute columns must be a `numeric` type. GAMS Transfer R requires that all the factor levels are of type `string`.

Some examples:

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("seattle", "san-diego"))
a = Variable$new(
    m,
```

```
    "a",
    "free",
    domain= i,
    records=data.frame(
      city = c("seattle", "san-diego"),
      level = c(50, 100)
    )
)
> a$records
       city level
1   seattle    50
2 san-diego   100
```

Generate Records

Container symbol records in standard format can also be generated using the convenience method `generateRecords()`. This method generates records with the cartesian product of domain all sets. If the argument `density` is less than 1, randomly selected records are removed. For symbols that are not scalar, using this method requires that the symbol domain type is "regular" (i.e., <`symbol_name`>`$domainType = "regular"`). A few examples using the method `generateRecords()` for each type of Container symbol are provided below.

Set

Example #1 Create a large (dense) 4D set

Generating the initial `data.frame` could be difficult for `Set` symbols that have a large number of records and a small number of UELs. These higher dimensional symbols will benefit from the generateRecords convenience method.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Set$new(m, "a", c(i, j, k, l))
# generate the records
a$generateRecords()
> a$isValid()
[1] TRUE
> head(a$records)
   i  j  k  l element_text
1 i1 j1 k1 l1
2 i2 j1 k1 l1
3 i3 j1 k1 l1
4 i4 j1 k1 l1
5 i5 j1 k1 l1
6 i6 j1 k1 l1
> tail(a$records)
          i   j   k   l element_text
6249995 i45 j50 k50 l50
6249996 i46 j50 k50 l50
6249997 i47 j50 k50 l50
6249998 i48 j50 k50 l50
6249999 i49 j50 k50 l50
6250000 i50 j50 k50 l50
```

Example #2 Create a large (sparse) 4D set

It is also possible to generate a sparse set (randomly selected rows are removed from the dense dataframe) with the `density` argument to `generateRecords`.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Set$new(m, "a", c(i, j, k, l))
# generate the records
a$generateRecords(density = 0.05)
> a$isValid()
[1] TRUE
> head(a$records)
    i   j   k   l element_text
1 i15  j1  k1  l1
2 i41  j1  k1  l1
3 i37  j2  k1  l1
4 i17  j3  k1  l1
5 i21  j3  k1  l1
6 i37  j3  k1  l1
> tail(a$records)
         i   j   k   l element_text
312495  i6 j48 k50 l50
312496  i9 j49 k50 l50
312497 i14 j49 k50 l50
312498 i41 j49 k50 l50
312499 i44 j49 k50 l50
312500 i35 j50 k50 l50
```

Example #3 Create a large 4D set with 1 sparse dimension

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Set$new(m, "a", c(i, j, k, l))
# generate the records
a$generateRecords(density = c(1, 0.05, 1, 1))
> a$isValid()
[1] TRUE
> head(a$records)
    i   j   k   l element_text
1  i1 j29  k1  l1
2  i2 j29  k1  l1
3  i3 j29  k1  l1
4  i4 j29  k1  l1
5  i5 j29  k1  l1
6  i6 j29  k1  l1
> tail(a$records)
         i   j   k   l element_text
249995 i45 j45 k50 l50
249996 i46 j45 k50 l50
249997 i47 j45 k50 l50
249998 i48 j45 k50 l50
249999 i49 j45 k50 l50
250000 i50 j45 k50 l50
```

Parameter

Example #1 Create a large (dense) 4D Parameter

Generating the initial `data.frame` could be difficult for `Parameter` symbols that have a large number of records and a small number of UELs. These higher dimensional symbols will benefit from the `generateRecords` convenience method.

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
```

```
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Parameter$new(m, "a", c(i, j, k, l))
# generate the records
a$generateRecords()
> a$isValid()
[1] TRUE
> head(a$records)
    i   j   k   l      value
1  i1  j1  k1  l1 0.47998665
2  i2  j1  k1  l1 0.20015289
3  i3  j1  k1  l1 0.57701174
4  i4  j1  k1  l1 0.73032070
5  i5  j1  k1  l1 0.08637669
6  i6  j1  k1  l1 0.45913994
> tail(a$records)
         i   j   k   l      value
6249995 i45 j50 k50 l50 0.91182978
6249996 i46 j50 k50 l50 0.79016549
6249997 i47 j50 k50 l50 0.77912069
6249998 i48 j50 k50 l50 0.63232201
6249999 i49 j50 k50 l50 0.04274219
6250000 i50 j50 k50 l50 0.71523280
```

Note

In Example #1 a large 4D parameter was generated. by default, the value of these records are randomly drawn numbers from the interval `[0,1]` (uniform distribution).

Example #2 - Create a large (sparse) 4D parameter with normally distributed values

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Parameter$new(m, "a", c(i, j, k, l))
# create a custom function to pass to ‘generateRecords‘
value_dist = function(size) {
  return(rnorm(n=size, mean = 10, sd = 2.3))
}
# generate the records
a$generateRecords(density = 0.05, func = value_dist)
> a$isValid()
[1] TRUE
> head(a$records)
    i   j   k   l     value
1 i50  j1  k1  l1 12.499060
2  i6  j2  k1  l1 12.009952
3 i14  j2  k1  l1  9.931126
4 i49  j2  k1  l1 13.073977
5  i7  j3  k1  l1  5.330898
6 i22  j3  k1  l1  7.887725
> tail(a$records)
        i   j   k   l     value
312495 i14 j48 k50 l50 10.213841
312496 i20 j48 k50 l50  4.831503
312497 i26 j48 k50 l50  8.129577
312498 i17 j49 k50 l50 11.570570
312499 i48 j49 k50 l50 11.321228
312500 i35 j50 k50 l50  1.714614
> mean(a$records$value)
[1] 10.00273
> sd(a$records$value)
[1] 2.303193
```

Note

The custom function passed to the argument `func` must expose a `size` argument. It might be tedious to know the exact number of the records that will be generated, especially if a fractional density is specified; therefore, the `generateRecords` method will pass in the correct size automatically.

Example #3 - Create a large 4D parameter with a random number seed

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Parameter$new(m, "a", c(i, j, k, l))
a2 = Parameter$new(m, "a2", c(i, j, k, l))
# generate the records
a$generateRecords(density = 0.05, seed = 123)
a2$generateRecords(density = 0.05)
> a$equals(a2, checkMetaData = FALSE)
[1] FALSE
a2$generateRecords(density = 0.05, seed = 123)
> a$equals(a2, checkMetaData = FALSE)
[1] TRUE
```

Note

The `seed` is an `int` that will set the random number generator state (enables reproducible sequences of random numbers).

Variable and Equation

Generating records for the symbol types `Variable` and `Equation` is similar to that of previously shown examples of parameters and sets. However, since there are more than one attributes to variables and equations, there are a few differences. By default, the random sampling is done is only for the `level` attribute with default values being passed to the other attributes. To randomly generate other attributes, one can use the custom `func` argument. This is shown in the following example.

Example #1 Create a large (sparse) 4D variable and Equation

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
av = Variable$new(m, "av", "free", c(i, j, k, l))
ae = Equation$new(m, "ae", "eq", c(i, j, k, l))
# user can pass the function in-line as follows
av$generateRecords(density=0.05,
func=list(level= function(size) rnorm(n=size, mean=10, sd=2.3),
marginal = function(size) rnorm(n=size, mean=0.5, sd=0.1)))
# functions can also be defined first and then passed
uniform_distr = function(size) return(runif(size))
normal_distr = function(size) return(rnorm(n=size))
ae$generateRecords(density=0.05, func=list(level=uniform_distr, marginal=normal_distr))
> head(av$records)
    i   j   k   l     level  marginal lower upper scale
1 i23  j1  k1  l1 12.244702 0.5587150  -Inf   Inf     1
2 i29  j1  k1  l1  8.265612 0.4242353  -Inf   Inf     1
3  i2  j2  k1  l1 14.164058 0.4166124  -Inf   Inf     1

6 i35  j2  k1  l1 0.08555602 -0.2912885     0     0     1
> tail(ae$records)
          i   j   k   l     level     marginal lower upper scale
312495  i5 j49 k50 l50 0.7844452 -0.569529636     0     0     1
312496 i46 j49 k50 l50 0.2224596 -0.182441937     0     0     1
312497 i11 j50 k50 l50 0.9291730 -0.474982758     0     0     1
312498 i16 j50 k50 l50 0.3347919  0.009303616     0     0     1
312499 i20 j50 k50 l50 0.3590295 -0.533782269     0     0     1
312500 i27 j50 k50 l50 0.7681852 -1.126704380     0     0     1
```

Alias

The method `generateRecords` for an alias simply calls the corresponding method for its referenced set.

Example #1 Create a large (dense) 4D set from an Alias

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=paste0("i", 1:50))
j = Set$new(m, "j", records=paste0("j", 1:50))
k = Set$new(m, "k", records=paste0("k", 1:50))
l = Set$new(m, "l", records=paste0("l", 1:50))
# create and define the symbol ‘a‘ with ‘regular‘ domains
a = Set$new(m, "a", c(i, j, k, l))
# create an Alias ap for the set a
ap = Alias$new(m, "ap", a)
# generate the records
ap$generateRecords()
> ap$isValid()
[1] TRUE
> head(ap$records)
    i   j   k   l element_text
1  i1  j1  k1  l1
2  i2  j1  k1  l1
3  i3  j1  k1  l1
4  i4  j1  k1  l1
5  i5  j1  k1  l1
6  i6  j1  k1  l1
> tail(ap$records)
          i   j   k   l element_text
6249995 i45 j50 k50 l50
6249996 i46 j50 k50 l50
6249997 i47 j50 k50 l50
6249998 i48 j50 k50 l50
6249999 i49 j50 k50 l50
6250000 i50 j50 k50 l50
```

Data Exchange with GDX

Up until now, we have been focused on using GAMS Transfer R to create symbols in an empty Container using the symbol constructors (or their corresponding container methods). These tools will enable users to ingest data from many different formats and add them to a `Container`. However, it is also possible to read in symbol data directly from GDX files using the `read` container method. In the following sections, we will discuss this method in detail as well as the `write` method, which allows users to write out to new GDX files.

Reading from GDX

There are two main ways to read in GDX based data.

- Pass the file path directly to the Container constructor (will read all symbols and records)

- Pass the file path directly to the `read` method (default read all symbols, but can read partial files)

The first option here is provided for convenience and will, internally, call the `read` method. For the following examples, we leverage the GDX output generated from the **trnsport.gms** model file.

Example (reading full data into a Container using the constructor)

```
library(gamstransfer)
m = Container$new("trnsport.gdx")
> m$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m$describeParameters()
  name domain domainType dimension numberRecords     min     mean     max
1    a      i    regular         1             2 350.000 475.0000 600.000
2    b      j    regular         1             3 275.000 300.0000 325.000
5    c    i j    regular         2             6   0.126   0.1755   0.225
3    d    i j    regular         2             6   1.400   1.9500   2.500
4    f     NA       none         0             1  90.000  90.0000  90.000
  whereMin whereMax sparsity
1        1        2        0
2        3        1        0
5        6        1        0
3        6        1        0
4        1        1       NA
```

A user could also read in data with the read method as shown in the following example.

Example (reading full data into a Container with `read` method)

```
library(gamstransfer)
m = Container$new()
m$read("trnsport.gdx")
> m$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
```

It is also possible to read in a partial GDX file with the read method, as shown in the following example:

```
library(gamstransfer)
m = Container$new()
m$read("trnsport.gdx", "x")
> m$listSymbols()
[1] "x"
> m["x"]$records
         i        j level marginal lower upper scale
1   seattle new-york    50    0.000     0   Inf     1
2   seattle  chicago   300    0.000     0   Inf     1
3   seattle   topeka     0    0.036     0   Inf     1
4 san-diego new-york   275    0.000     0   Inf     1
5 san-diego  chicago     0    0.009     0   Inf     1
6 san-diego   topeka   275    0.000     0   Inf     1
```

This syntax assumes that the user will always want to read in both the metadata as well as the actual data records, but it is possible to skip the reading of the records by passing the argument `records=FALSE`.

```
library(gamstransfer)
m = Container$new()
m$read("trnsport.gdx", "x", records = FALSE)
> m$listSymbols()
[1] "x"
> m["x"]$summary
$name
[1] "x"
$description
[1] "shipment quantities in cases"
$type
[1] "positive"
$domain
[1] "i" "j"
$domainType
[1] "relaxed"
$dimension
[1] 2
$numberRecords
[1] 0
> m["x"]$records
NULL
```

Attention

> The `read` method attempts to preserve the symbol domain type from the source but if domain sets are not part of the read operation there is no choice but to default to a "relaxed" `domainType`. This can be seen in the last example where we only read in the variable `x` and not the domain sets (`i` and `j`) that the variable is defined over. All the data will be available to the user, but domain checking is no longer possible. The symbol `x` will remain with "relaxed" domain type even if the user were to read in sets `i` and `j` in a second `read` call.

Writing to GDX

A user can write data to a GDX file by simply passing a file path (as a string). The `write` method will then create the GDX and write all data in the `Container`.

Note

> It is not possible to write the Container when any of its symbols are invalid. If any symbols are invalid an error will be raised and the user will need to inspect the problematic symbols (perhaps using a combination of the `listSymbols(isValid=FALSE)` and `isValid(verbose=TRUE)` methods).

Example

```
m$write("path/to/file.gdx")
```

Example (write a compressed GDX file)

```
m$write("path/to/file.gdx", compress = TRUE)
```

Advanced users might want to specify an order to their UELs (i.e., the universe set); recall that the UEL ordering follows that dictated by the data. As a convenience, it is possible to prepend the list of UELs with a user specified order using the `uelPriority` argument.

Example (change the order of the UEL)

```
library(gamstransfer)
m = Container$new()
i = Set$new(m, "i", records=c("a", "b", "c"))
m$write("foo.gdx", uelPriority=c("a", "c"))
```

The original UEL order for this GDX file would have been `c("a", "b", "c")`, but since this example reorders the UELs with `uelPriority`, the positions of `b` and `c` have been swapped. This can be verified with the gdxdump utility (using the `uelTable` argument):

```
gdxdump foo.gdx ueltable=foo

Set foo /
  'a' ,
  'c' ,
  'b' /;
$onEmpty

Set i(*) /
'a',
'c',
'b' /;

$offEmpty
```

Data Exchange between Containers

GAMS Transfer R allows data exchange between two Containers with the help of read and copy methods.

Data exchange with read

Similar to reading from a GDX file, a Container can read from another Container object. Following examples demonstrate this with the help of the GDX output generated from **trnsport.gms** model file.

Example (reading data from Container)

```
> library(gamstransfer)
> c = Container$new("trnsport.gdx")
> c$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m = Container$new(c)
> m$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m = Container$new()
> m$read(c)
> m$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m = Container$new()
> m$read(c, symbols=c("d","f"))
> m$listSymbols()
[1] "d" "f"
```

Example (reading data when symbol with the same name already exists)

```
> library(gamstransfer)
> c = Container$new()
> i = Set$new(c, "i")
> p = Parameter$new(m, "p")
> m = Container$new()
> i = Set$new(m, "i")
> m$read(c, symbols="i")
Error in private$.containerRead(loadFrom, symbols, records) :
  Attempting to add symbol i, however, one already exists in the Container. Symbol replacement is only possible if the
      symbol is first removed from theContainer with the removeSymbols() method.
```

The container read method does not allow reading from another source (Container, or a GDX file) when a symbol with the same name already exists. The existing symbol must be removed or renamed.

Data exchange with copy

Symbol `copy` method provides an alternative way to exchange data between Containers. Following examples demonstrate this starting from a Container containing data from GDX output generated from **trnsport.gms** model file.

Example (copy symbol from one container to another)

```
> library(gamstransfer)
> c = Container$new("trnsport.gdx")
> c$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m = Container$new()
> c["f"]$copy(m)
> m$listSymbols()
[1] "f"
```

The above example copies symbol `f` from Container `c` to Container `m`. If one copies a symbol with domain that does not exist in the destination Container, domain is relaxed as shown in the following example.

Example (copy symbol to another container without domain symbols)

```
> library(gamstransfer)
> c = Container$new("trnsport.gdx")
> c$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
m = Container$new()
> c["d"]$copy(m)
> m$listSymbols()
[1] "d"
> m["d"]$domain
[1] "i" "j"
> m["d"]$domainType
[1] "relaxed"
```

Example (copy symbol to another container with overwrite)

```
> library(gamstransfer)
> c = Container$new()
> i = Set$new(c, "i", records=c("i1","i2"))
> i$records
   uni
1   i1
2   i2
> m = Container$new()
> i = Set$new(m, "i", records= c("i3","i4"))
> i$records
   uni
1   i3
2   i4
# the following command throws an error
> c["i"]$copy(m)
Error in private$.copy(destination, overwrite) :
  Symbol i already exists in ‘destination‘
> c["i"]$copy(m, overwrite = TRUE)
> m["i"]$records
   uni
1   i1
2   i2
```

Example (bulk copy operation via Container `copy` method)

A bulk operation is also possible via Container `copy` method as shown in the following example.

```
> library(gamstransfer)
> c = Container$new("trnsport.gdx")
> c$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m = Container$new()
> c$copy(m) # copy all symbols
> c$listSymbols()
 [1] "i"      "j"      "a"      "b"      "d"      "f"      "c"      "x"
 [9] "z"      "cost"   "supply" "demand"
> m = Container$new()
> c$copy(m, symbols=c("a","b","d")) # copy a subset of symbols
> m$listSymbols()
[1] "a" "b" "d"
> c$copy(m, symbols="a", overwrite = TRUE) # copy symbols with overwrite
> m$listSymbols()
[1] "a" "b" "d"
```

7.8 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C# API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known `transportation problem`. These examples introduce several API features step by step.

- Getting Started A quick introduction about how to create and configure C# project
- Important Classes of the API Overview of some fundamental classes of the GAMS C# API
- How to use API An extensive set of examples how to use API components

7.8.1 Getting Started

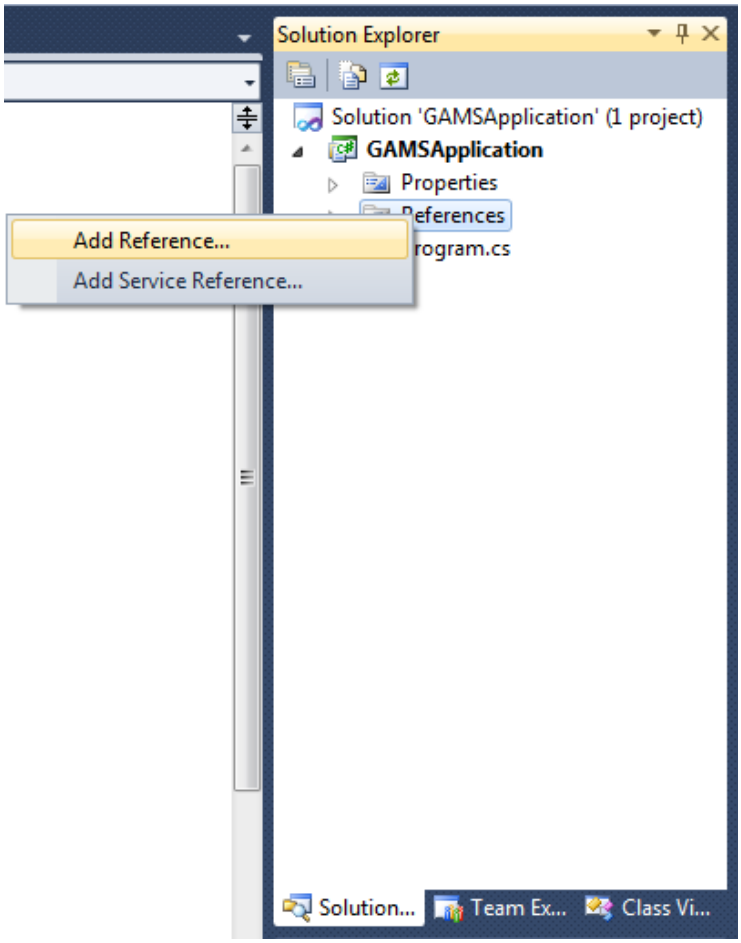
This section takes you through the basic steps of creating and configuring a C# project in Visual Studio 2010 for use with the GAMS C# API. At the end of this section there is also a paragraph about Mono as an alternative to Microsoft Visual Studio.

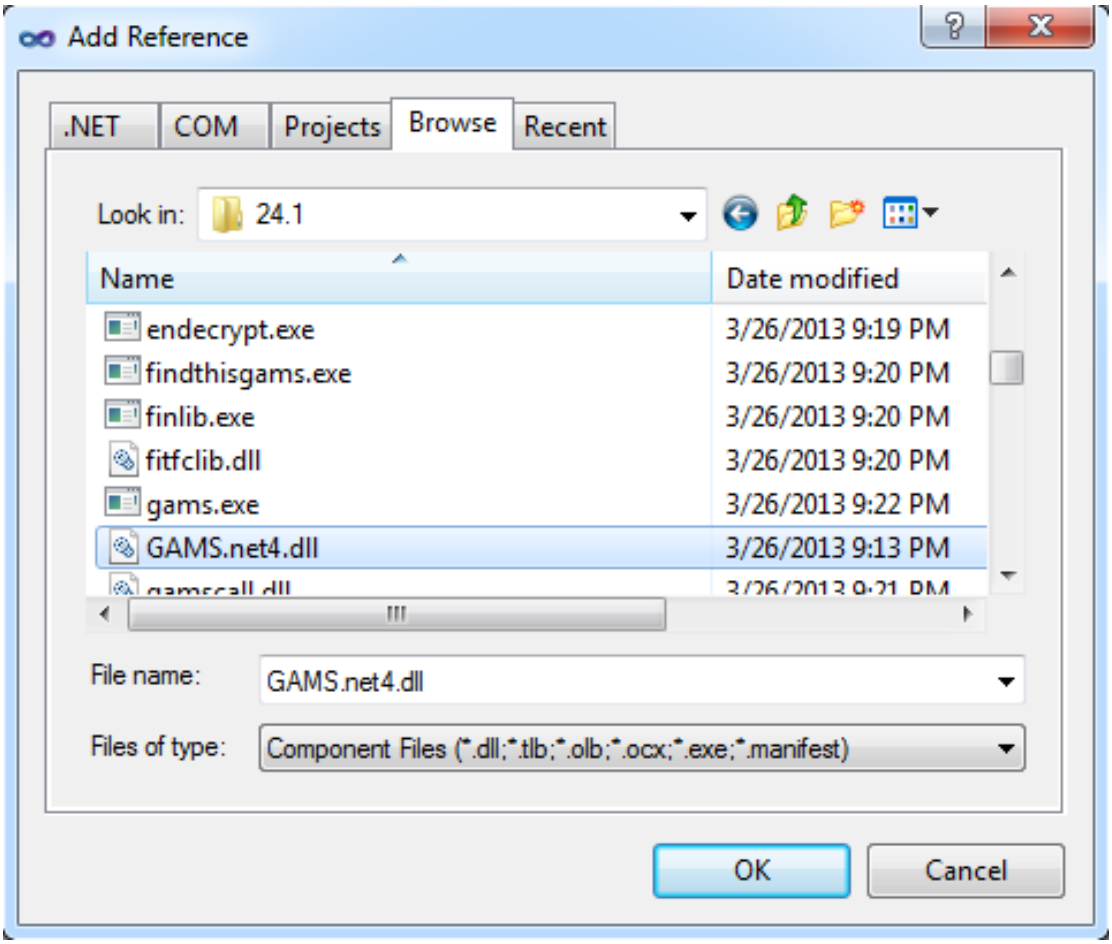
7.8.1.1 Open a new Project

After opening Microsoft Visual Studio you can open the New Project wizard by choosing **File** > **New** > **Project** from the ribbon menu and type a name for your application, e.g. GAMSApplication.

7.8.1.2 Add a Reference to a Project

Once you opened the project add a reference by a right click on **References** inside the solution explorer. Then choose **Add Reference..** and select the **Browse** tab. Next navigate to the location where you installed `GAMS.net4.dll`, typically the GAMS system directory, e.g. `C:\GAMS\win64\`46.4. Then choose **GAMS.net4.dll** and click **OK**.





7.8.1.3 Solving your first Model

This section illustrates how a model from the GAMS model library can be imported and solved.

Open a new project and reference the `GAMS.net4.dll` in your project as explained above. Open `Program.cs` which should be part of your project and replace the content by:

```
using System;
using System.IO;
using System.Collections.Generic;
using System.Text;
using GAMS;
namespace TransportSeq
{
  class Transport0
  {
      static void Main(string[] args)
      {
          GAMSWorkspace ws = new GAMSWorkspace();
          ws.GamsLib("trnsport");
          // create a GAMSJob from file and run it with default settings
          GAMSJob t0 = ws.AddJobFromFile("trnsport.gms");
          t0.Run();
          Console.WriteLine("Ran with Default:");
          foreach (GAMSVariableRecord rec in t0.OutDB.GetVariable("x"))
              Console.WriteLine("x(" + rec.Keys[0] + "," + rec.Keys[1] + "): level=" + rec.Level + " marginal=" +
      rec.Marginal);
          Console.WriteLine("z=" + t0.OutDB.GetVariable("z").LastRecord().Level);
       }
   }
}
```

Then click the highlighted button from figure (a) down below or press **F5** to start debugging. You can also start the program without debugging by pressing **Control + F5** or choosing **Debug > Start Without Debugging** from the ribbon menu as illustrated in figure (b).

Figure (a)

Figure(b)

By following the latter instruction the command line shell remains open and show the produced output.

7.8.1.4 Mono

The GAMS .NET API works also on non-Windows platforms where no Visual Studio is available. It can be used for example with the open source .Net framework Mono (http://www.mono-project.com). Mono offers a IDE that could be used similarly to Visual Studio. If one prefers to compile and execute from a shell, the following code shows how this can be done using the example Transport1 which comes with the GAMS system (this assumes that xbuild and mono are in the PATH):

```
cd <GAMS Dir>/apifiles/CSharp/Transport1
xbuild /t:rebuild /p:Configuration=Release Transport1.csproj
mono bin/Release/Transport1.exe ../../..
```

7.8.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples.

- **GAMS** Namespace
- **GAMSWorkspace** Class
- **GAMSJob** Class
- **GAMSDatabase** Class
- **GAMSOptions** Class
- **GAMSModelInstance** Class

7.8.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C# API. `<GAMS system directory>\apifiles\CSharp` contains a file `TransportSeq.sln` that can be opened in Microsoft Visual Studio. The contained projects deal with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)
- How to import data from GDX (TransportGDX)
- How to run a GAMSJob from file (Transport1)
- How to specify the solver (Transport1)
- How to run a job with a solver option file and capture its log output (Transport1)

- How to use include files (Transport2)
- How to read data from string and export to GDX (Transport3)
- How to run a job using data from GDX (Transport3)
- How to run a job using implicit database communication (Transport3)
- How to define data using C# data structures (Transport4)
- How to prepare a GAMSDatabase from C# data structures (Transport4)
- How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
- How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
- How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
- How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
- How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)
- How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)
- How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
- How to fill a GAMSDatabase by reading from MS Access (Transport9)
- How to fill a GAMSDatabase by reading from MS Excel (Transport10)
- How to create and use a save/restart file (Transport11)

7.8.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing Transport1.exe with C:/GAMS/win64/46.4 we use the 64-bit version of GAMS 46.4 to run `Transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
GAMSWorkspace ws;
if (Environment.GetCommandLineArgs().Length > 1)
  ws = new GAMSWorkspace(systemDirectory: Environment.GetCommandLineArgs()[1]);
else
  ws = new GAMSWorkspace();
...
```

Remember that the bitness of the GAMS system has to match the bitness of your .NET program.

7.8.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented .NET API offers much more than exchanging data between .NET and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in .NET data structures.

```
...
List<string> plants = new List<string>()
{
  "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{
  "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{
  { "Seattle", 350.0 }, { "San-Diego", 600.0 }
```

```
};
Dictionary<string, double> demand = new Dictionary<string, double>()
{
  { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
Dictionary<Tuple<string, string>, double> distance = new Dictionary<Tuple<string, string>, double>()
{
  { new Tuple<string,string> ("Seattle",   "New-York"), 2.5 },
  { new Tuple<string,string> ("Seattle",   "Chicago"),  1.7 },
  { new Tuple<string,string> ("Seattle",   "Topeka"),   1.8 },
  { new Tuple<string,string> ("San-Diego", "New-York"), 2.5 },
  { new Tuple<string,string> ("San-Diego", "Chicago"),  1.8 },
  { new Tuple<string,string> ("San-Diego", "Topeka"),   1.4 }
};
...
```

Different GAMS symbols are represented using different .NET data structures. The data for the GAMS sets is represented using lists of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by dictionaries (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with .NET data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.AddDatabase.

```
...
// prepare a GAMSDatabase with data from the C# data structures
GAMSDatabase db = ws.AddDatabase();
...
```

We start adding GAMS sets using the method `GAMSDatabase.AddSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A foreach-loop iterates through `plants` and adds new records to the recently created GAMSSet instance `i` using `GAMSSet.AddRecord`.

```
...
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.AddSet("i", 1, "canning plants");
foreach (string p in plants)
  i.AddRecord(p);
...
```

GAMSParameter instances can be added by using the method `GAMSDatabase.AddParameter`. It has the same signature as `GAMSDatabase.AddSet`. Anyhow, in this example we use an overload of the method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```
...
// add parameter 'a' with domain 'i'
GAMSParameter a = db.AddParameter("a", "capacity of plant i in cases", i);
foreach (string p in plants)
  a.AddRecord(p).Value = capacity[p];
...
```

As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.Export can be used to create a GDX file.

```
...
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.Export("data.gdx");
...
```

7.8.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.AddDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```
...
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.AddDatabaseFromGDX("data.gdx");
...
```

Reading the data from the GAMSSet `i` into a list can be done as follows:

```
...
// read data from symbols into .NET data structures
List<string> plants2 = new List<string>();
foreach (GAMSSetRecord item in db2.GetSet("i"))
```

```
  plants2.Add(item.Key(0));
...
```

A new list `plants2` is created. `i` is retrieved by calling `GAMSDatabase.GetSet` on `db2`. The returned GAMSSet object can be iterated using a foreach-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameters. Instead of creating a list, we want to have the data in the form of a dictionary. GAMSParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `Dictionary<string, double>`.

```
...
Dictionary<string, double> capacity2 = new Dictionary<string, double>();
foreach (GAMSParameterRecord item in db2.GetParameter("a"))
  capacity2.Add(item.Key(0), item.Value);
...
```

For multi dimensional symbols, we choose the dictionary keys to be tuples instead of string.

```
...
Dictionary<Tuple<string, string>, double> distance2 = new Dictionary<Tuple<string, string>, double>();
foreach (GAMSParameterRecord item in db2.GetParameter("d"))
  distance2.Add(new Tuple<string, string>(item.Key(0), item.Key(1)), item.Value);
...
```

7.8.3.4 How to run a GAMSJob from file (Transport1)

Here we load the model `trnsport` from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the `GAMSWorkspace.AddJobFromFile` Method afterwards. Apparently this method also works with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob `t1` is defined from that file and run by the `GAMSJob.Run` method.

The following lines create the solution output and illustrate the usage of the `GAMSJob.OutDB` property to get access to the `GAMSDatabase` created by the `Run` method. To retrieve the content of variable `x` we use the `GAMSVariableRecord` class and the `GAMSDatabase.GetVariable` method.

```
...
ws.GamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.AddJobFromFile("trnsport.gms");
t1.Run();
Console.WriteLine("Ran with Default:");
foreach (GAMSVariableRecord rec in t1.OutDB.GetVariable("x"))
  Console.WriteLine("x(" + rec.Keys[0] + "," + rec.Keys[1] + "): level=" + rec.Level + " marginal=" + rec.Marginal);
...
```

7.8.3.5 How to specify the solver (Transport1)

The solver can be specified via the GAMSOptions class and the `GAMSWorkspace.AddOptions` method. The `GAMSOptions.AllModelTypes` property sets `xpress` as default solver for all model types which the solver can handle.

```
...
// run the job again with another solver
using (GAMSOptions opt = ws.AddOptions())
{
   opt.AllModelTypes = "xpress";
   t1.Run(opt);
}
...
```

7.8.3.6 How to run a job with a solver option file and capture its log output (Transport1)

At first we use the StreamWriter to create the file `xpress.opt` which will be used as solver option file and is stored in the current working directory. Then we write `algorithm=barrier` to this file and specify the barrier algorithm as algorithm before we close the solver option file. We choose xpress as solver just like in the preceding example and set the `GAMSOptions.OptFile` Property to 1 to tell the solver to look for a solver option file. In addition, we specify the argument `output` in order to write the log of the GAMSJob into the file `transport1_xpress.log`.

```
...
using (StreamWriter optFile = new StreamWriter(Path.Combine(ws.WorkingDirectory, "xpress.opt")))
using (TextWriter logFile = new StreamWriter(Path.Combine(ws.WorkingDirectory, "transport1_xpress.log")))
using (GAMSOptions opt = ws.AddOptions())
{
   optFile.WriteLine("algorithm=barrier");
   optFile.Close();
   opt.AllModelTypes = "xpress";
   opt.OptFile = 1;
   t1.Run(opt, output: logFile);
}
...
```

Instead of writing the log output to a file, it can be written into any `TextWriter`. In order to write the log directly to `Console.Out`, we can use the following code:

```
...
   t1.Run(opt, output: Console.Out);
...
```

7.8.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings `GetDataText` and `GetModelText` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
...
using (StreamWriter writer = new StreamWriter(ws.WorkingDirectory + Path.DirectorySeparatorChar + "tdata.gms"))
{
   writer.Write(GetDataText());
}
...
```

Afterwards we create a `GAMSJob` using the `GAMSWorkspace.AddJobFromString` method. The `GAMSOptions.Defines` field is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line.

```
...
using (GAMSOptions opt = ws.AddOptions())
{
  GAMSJob t2 = ws.AddJobFromString(GetModelText());
   opt.Defines.Add("incname", "tdata");
   t2.Run(opt);
   ...
}
...
```

Note that the string GetModelText contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

7.8.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string `GetDataText` as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding `GAMSJob` a `GAMSDatabase` is created that is available via the `GAMSJob.OutDb` property. We can use the `GAMSDatabase.Export` method to write the content of this database to a gdx file `tdata.gdx`.

```
...
GAMSJob t3 = ws.AddJobFromString(GetDataText());
t3.Run();
t3.OutDB.Export(ws.WorkingDirectory + Path.DirectorySeparatorChar + "tdata.gdx");
...
```

7.8.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in `Transport2` - How to use include files (Transport2).

```
...
t3 = ws.AddJobFromString(GetModelText());
using (GAMSOptions opt = ws.AddOptions())
{
   opt.Defines.Add("gdxincname", "tdata");
   opt.AllModelTypes = "xpress";
   t3.Run(opt);
   ...
}
...
```

Note that there are some changes in `GetModelText` due to the usage of a GDX file instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

7.8.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `OutDB` can be read in directly just like a gdx file. Note that the database needs to be passed to the `GAMSJob.Run` method as additional argument.

```
...
using (GAMSOptions opt = ws.AddOptions())
{
   GAMSJob t3a = ws.AddJobFromString(GetDataText());
   GAMSJob t3b = ws.AddJobFromString(GetModelText());
   t3a.Run();
   opt.Defines.Add("gdxincname", t3a.OutDB.Name);
   opt.AllModelTypes = "xpress";
   t3b.Run(opt, t3a.OutDB);
   ...
}
...
```

7.8.3.11 How to define data using C# data structures (Transport4)

We use the `List<T>` class, the `Dictionary<TKey, TValue>` class and the `Tuple<T1, T2>` class to define C# data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
...
List<string> plants = new List<string>()
{
  "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{
  "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{
   { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
Dictionary<string, double> demand = new Dictionary<string, double>()
{
   { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
Dictionary<Tuple<string,string>, double> distance = new Dictionary<Tuple<string,string>, double>()
{
   { new Tuple<string,string> ("Seattle",   "New-York"), 2.5 },
   { new Tuple<string,string> ("Seattle",   "Chicago"),  1.7 },
   { new Tuple<string,string> ("Seattle",   "Topeka"),   1.8 },
   { new Tuple<string,string> ("San-Diego", "New-York"), 2.5 },
   { new Tuple<string,string> ("San-Diego", "Chicago"),  1.8 },
   { new Tuple<string,string> ("San-Diego", "Topeka"),   1.4 }
};
...
```

7.8.3.12 How to prepare a GAMSDatabase from C# data structures (Transport4)

At first we create an empty GAMSDatabase `db` using the `GAMSWorkspace.AddDatabase` method. Afterwards we prepare the database. To add a set to the database we use the `GAMSSet` class and the `GAMSDatabase.AddSet` method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C# data structure and add them by using the `GAMSSet.AddRecord` method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The `GAMSJob` can be run like explained in the preceding example about implicit database communication.

```
...
GAMSDatabase db = ws.AddDatabase();
GAMSSet i = db.AddSet("i", 1, "canning plants");
foreach (string p in plants)
   i.AddRecord(p);
...
GAMSParameter a = db.AddParameter("a", 1, "capacity of plant i in cases");
foreach (string p in plants)
   a.AddRecord(p).Value = capacity[p];
...
GAMSParameter d = db.AddParameter("d", 2, "distance in thousands of miles");
foreach(Tuple<string,string> t in distance.Keys)
   d.AddRecord(t.Item1,t.Item2).Value = distance[t];
GAMSParameter f = db.AddParameter("f", 0, "freight in dollars per case per thousand miles");
f.AddRecord().Value = 90;
// run a job using data from the created GAMSDatabase
GAMSJob t4 = ws.AddJobFromString(GetModelText());
using (GAMSOptions opt = ws.AddOptions())
{
   opt.Defines.Add("gdxincname", db.Name);
   opt.AllModelTypes = "xpress";
   t4.Run(opt, db);
   ...
}
...
```

7.8.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS Checkpoint, the second one uses the `GAMSWorkspace.AddJobFromString` method to create a `GAMSJob` containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the `GAMSJob.Run` method. Furthermore, it passes an additional checkpoint argument to the Run method. That means the GAMSCheckpoint `cp` captures the state of the `GAMSJob`.

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
...
ws.AddJobFromString(GetModelText()).Run(cp);
...
```

This creates the same checkpoint as for example the following code snippet:

```
GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob t5a = ws.AddJobFromString(GetModelText());
t5a.Run(cp);
```

7.8.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `GetModelText()` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
Scalar bmult  demand multiplier /1/;
...
demand(j) ..   sum(i, x(i,j))  =g=  bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
...
```

We create a list with eight different values for this demand multiplier.

```
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

For each entry of that list we create a GAMSJob `t5` using the `GAMSWorkspace.AddJobFromString` method. Besides the string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a `GAMSJob` combined from the checkpoint plus the content provided by the string.

We run the `GAMSJob` and echo some interesting data from the `OutDB` using the `GAMSDatabase.GetParameter` and `GAMSDatabase.GetVariable` methods, the `GAMSParameter.FindRecord` and `GAMSVariable.FindRecord` methods plus the `GAMSParameterRecord.Value` property and the `GAMSVariableRecord.Level` property.

```
...
foreach (double b in bmultlist)
{
  GAMSJob t5 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat;
      ss=transport.solvestat;", cp);
  t5.Run();
  Console.WriteLine("Scenario bmult=" + b + ":");
  Console.WriteLine("  Modelstatus: " + t5.OutDB.GetParameter("ms").FindRecord().Value);
  Console.WriteLine("  Solvestatus: " + t5.OutDB.GetParameter("ss").FindRecord().Value);
  Console.WriteLine("  Obj: " + t5.OutDB.GetVariable("z").FindRecord().Level);
}
...
```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

7.8.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from `Transport5` in parallel. We initialize the GAMSCheckpoint `cp` and introduce a demand multiplier as we did before :

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object ioMutex that will be used to avoid mixed up output from the parallel jobs. For each element `b` from the list of demand multipliers we call a delegate of the function RunScenario. Note that these calls are parallel!

```
...
// run multiple parallel jobs using the created GAMSCheckpoint
Object ioMutex = new Object();
System.Threading.Tasks.Parallel.ForEach(bmultlist, delegate(double b) { RunScenario(ws, cp, ioMutex, b); });
...
```

In function RunScenario a `GAMSJob` is created and run just like in the preceding example of `Transport5`. The output section is also the same except for the fact that it is marked as critical section by the `lock` keyword. That means the delegates of `RunScenario` are running in parallel but the output block of different delegates cannot be executed in parallel since it is 'locked' by the same object `ioMutex` for all delegates.

```
...
static void RunScenario(GAMSWorkspace ws, GAMSCheckpoint cp, object ioMutex, double b)
{
  GAMSJob t6 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat;
      ss=transport.solvestat;", cp);
  t6.Run();
  // we need to make the ouput a critical section to avoid messed up report information
  lock (ioMutex)
  {
      Console.WriteLine("Scenario bmult=" + b + ":");
      Console.WriteLine("  Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
      Console.WriteLine("  Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
      Console.WriteLine("  Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
   }
}
```

```
...
```

While the output in `Transport5` is strictly ordered subject to the order of the elements of `bmultlist`, in `Transport6` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lock` keyword.

If you want a further impression of the impact of the `lock` keyword, just rerun `Transport6` but comment out the `lock` as follows and compare the output.

```
...
   //lock (ioMutex)
   //{
      Console.WriteLine("Scenario bmult=" + b + ":");
      Console.WriteLine("  Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
      Console.WriteLine("  Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
      Console.WriteLine("  Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
   //}
...
```

7.8.3.16 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In `Transport7` the usage of **GAMS::GAMSModelInstance** is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the GAMSModelInstance `mi` using the `GAMSCheckpoint.AddModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob t7 = ws.AddJobFromString(GetModelText());
t7.Run(cp);
GAMSModelInstance mi = cp.AddModelInstance();
...
```

7.8.3.17 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A `GAMSModelInstance` uses a `SyncDB` to maintain the data. We define `bmult` as `GAMSParameter` using the `GAMSDatabase.AddParameter` method and specify `gurobi` as solver. Afterwards the `GAMSModelInstance` is instantiated with arguments opt and GAMSModifier `bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of ModelInstance mi stay unchanged. We use the `GAMSParameter.AddRecord` method to assign a value to `bmult` that can be varied afterwards using the `GAMSParameter.FirstRecord` method to reproduce our well-known example with different demand multipliers.

```
...
GAMSParameter bmult = mi.SyncDB.AddParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.AddOptions();
opt.AllModelTypes = "gurobi";
mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
bmult.AddRecord().Value = 1.0;
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
foreach (double b in bmultlist)
{
   bmult.FirstRecord().Value = b;
   mi.Solve();
   Console.WriteLine("Scenario bmult=" + b + ":");
   Console.WriteLine("  Modelstatus: " + mi.ModelStatus);
   Console.WriteLine("  Solvestatus: " + mi.SolveStatus);
   Console.WriteLine("  Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
}
...
```

7.8.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a `GAMSModelInstance` just like in the next to last example. We define `x` as `GAMSVariable` and its upper bound as GAMSParameter xup. At the following instantiate method `GAMSModifier` has three arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the `GAMSParameter` that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
mi = cp.AddModelInstance();
GAMSVariable x = mi.SyncDB.AddVariable("x", 2, VarType.Positive, "");
GAMSParameter xup = mi.SyncDB.AddParameter("xup", 2, "upper bound on x");
mi.Instantiate("transport use lp min z", modifiers: new GAMSModifier(x,UpdateAction.Upper,xup));
foreach (GAMSSetRecord i in t7.OutDB.GetSet("i"))
  foreach (GAMSSetRecord j in t7.OutDB.GetSet("j"))
  {
       xup.Clear();
       xup.AddRecord(i.Keys[0],j.Keys[0]).Value = 0;
       mi.Solve();
       Console.WriteLine("Scenario link blocked: " + i.Keys[0]  + " - " + j.Keys[0]);
       Console.WriteLine("  Modelstatus: " + mi.ModelStatus);
       Console.WriteLine("  Solvestatus: " + mi.SolveStatus);
       Console.WriteLine("  Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
   }
...
```

7.8.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint `cp` from a `GAMSJob`. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out-principle. The objects `queueMutex` and `ioMutex` are used later to avoid messed up output. Then we call two delegates of the function ScenSolve in parallel that get the same queue as argument.

```
...
GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
Queue<double> bmultQueue = new Queue<double>(new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 });
Object queueMutex = new Object();
Object ioMutex = new Object();
Parallel.For(0, 2, delegate(int i) { ScenSolve(ws, cp, bmultQueue, queueMutex, ioMutex); });
...
```

In function `ScenSolve` we create and instantiate a `GAMSModelInstance` as in the preceding examples and make `bmult` modifiable. The two delegates of the function extract the elements of the queue using `bmultQueue.Dequeue`. Note that we chose `cplex` as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```
private static void ScenSolve(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<double> bmultQueue, Object queueMutex, Object
      ioMutex, int i)
{
  GAMSModelInstance mi = cp.AddModelInstance();
  GAMSParameter bmult = mi.SyncDB.AddParameter("bmult", 0, "demand multiplier");
  GAMSOptions opt = ws.AddOptions();
  opt.AllModelTypes = "cplex";
  mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
  bmult.AddRecord().Value = 1.0;
  while (true)
  {
      double b;
      // dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
      lock (queueMutex)
      {
          if(0 == bmultQueue.Count)
              return;
          b = bmultQueue.Dequeue();
       }
      bmult.FirstRecord().Value = b;
      mi.Solve();
      // we need to make the output a critical section to avoid messed up report informations
```

```
      lock (ioMutex)
      {
          Console.WriteLine("Scenario bmult=" + b + ":");
          Console.WriteLine("  Modelstatus: " + mi.ModelStatus);
          Console.WriteLine("  Solvestatus: " + mi.SolveStatus);
          Console.WriteLine("  Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
       }
   }
}
```

7.8.3.20 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a `GAMSDatabase`. We call a function `ReadFromAccess` that finally returns a `GAMSDatabase` as shown below.

```
...
GAMSDatabase db = ReadFromAccess(ws);
...
```

The data we are going to read can be found in <`GAMS system directory`>\`apifiles\Data\transport.accdb`. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty `GAMSDatabase`. Afterwards we connect to the MS Access database by first specifying the provider and then defining the aforementioned file as data source. The `OleDbConnection` represents an open connection to a data source. The following lines initialize the connection and use a try and a catch block for potential exceptions, i.e. errors that occur during application execution. To finally read in GAMS sets and parameters we call the functions `ReadSet` and `ReadParameter`. We will use several classes of the `System.Data.OleDb` namespace that are documented here. Furthermore, we recommend the OLE DB Tutorial.

```
static GAMSDatabase ReadFromAccess(GAMSWorkspace ws)
{
  GAMSDatabase db = ws.AddDatabase();
  // connect to database
  string strAccessConn = @"Provider=Microsoft.ACE.OLEDB.12.0;Data Source=..\..\..\..\Data\transport.accdb";
  OleDbConnection connection = null;
  try
  {
      connection = new OleDbConnection(strAccessConn);
  }
  catch (Exception ex)
  {
      Console.WriteLine("Error: Failed to create a database connection. \n{0}", ex.Message);
      Environment.Exit(1);
   }
   // read GAMS sets
   ReadSet(connection, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
   ReadSet(connection, db, "SELECT Market FROM Market", "j", 1, "markets");
   // read GAMS parameters
   ReadParameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
   ReadParameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
   ReadParameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
   return db;
}
```

The function `ReadSet` incorporates a try and a catch block. In the try block we prepare the reading from the MS Access file. Then we add a set symbol to the `GAMSDatabase` that is filled with the data from the MS Access file afterwards. The function `ReadParameter` works quite similar.

```
static void ReadSet(OleDbConnection connect, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string
      setExp = "")
{
  try
  {
      OleDbCommand cmd = new OleDbCommand(strAccessSelect, connect);
      connect.Open();
      OleDbDataReader reader = cmd.ExecuteReader();
      if (reader.FieldCount != setDim)
      {
          Console.WriteLine("Number of fields in select statement does not match setDim");
          Environment.Exit(1);
      }
      GAMSSet i = db.AddSet(setName, setDim, setExp);
      string[] keys = new string[setDim];
      while (reader.Read())
      {
          for (int idx = 0; idx < setDim; idx++)
               keys[idx] = reader.GetString(idx);
          i.AddRecord(keys);
```

```
        }
    }
    catch (Exception ex)
    {
        Console.WriteLine("Error: Failed to retrieve the required data from the DataBase.\n{0}", ex.Message);
        Environment.Exit(1);
    }
    finally
    {
        connect.Close();
    }
}
```

Once we read in all the data we can create a `GAMSJob` from the `GAMSDatabase` and run it as usual.

7.8.3.21 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from <`GAMS system directory`>\`apifiles\Data\transport.xlsx`. The model is given as string without data like in in many examples before. At first we have to add

```
using Excel = Microsoft.Office.Interop.Excel;
```

to the preamble to be able to use the `Microsoft.Office.Interop.Excel` namespace. Then we define `excelApp` as Excel application using the implicit variable type var, use the aforementioned file as workbook wb and define the Excel range that can represent a cell, a row, a column, a selection of cells containing one or more contiguous blocks of cells, or a 3-D range.

```
...
var excelApp = new Excel.Application();
Excel.Workbook wb = excelApp.Workbooks.Open(Directory.GetCurrentDirectory() + @"\..\..\..\..\Data\transport.xlsx");
Excel.Range range;
...
```

The following lines address the different worksheets and read in the contained data. Afterwards we make an errorcheck to ensure that the number of plants and markets is the same in all worksheets.

```
...
Excel.Worksheet capacity = (Excel.Worksheet)wb.Worksheets.get_Item("capacity");
range = capacity.UsedRange;
Array capacityData = (Array)range.Cells.Value;
int iCount = capacity.UsedRange.Columns.Count;
Excel.Worksheet demand = (Excel.Worksheet)wb.Worksheets.get_Item("demand");
range = demand.UsedRange;
Array demandData = (Array)range.Cells.Value;
int jCount = range.Columns.Count;
Excel.Worksheet distance = (Excel.Worksheet)wb.Worksheets.get_Item("distance");
range = distance.UsedRange;
Array distanceData = (Array)range.Cells.Value;
// number of markets/plants have to be the same in all spreadsheets
Debug.Assert((range.Columns.Count - 1) == jCount && (range.Rows.Count - 1) == iCount,
             "Size of the spreadsheets doesn't match");
wb.Close();
...
```

If you have problems to see through the steps above, adding the following output section right after `wb.Close()` might be helpful to understand where which data is stored.

```
...
for (int ii = 1; ii <= iCount; ii++)
{
  Console.WriteLine("capacityData(1, " + ii + ") = " + capacityData.GetValue(1, ii));
  Console.WriteLine("capacityData(2, " + ii + ") = " + capacityData.GetValue(2, ii));
}
for (int jj = 1; jj <= jCount; jj++)
{
  Console.WriteLine("demandData(1, " + jj + ") = " + demandData.GetValue(1, jj));
  Console.WriteLine("demandData(2, " + jj + ") = " + demandData.GetValue(2, jj));
}
for (int ii = 1; ii <= iCount; ii++)
{
  for (int jj = 1; jj <= jCount; jj++)
      Console.WriteLine("distanceData("+ (ii+1) + "," + (jj+1) +") = " + distanceData.GetValue(ii+1, jj+1));
}
...
```

Now we can create the `GAMSWorkspace` as usual and afterwards create a `GAMSDatabase` and fill it with the workbook data as follows:

```
...
GAMSDatabase db = ws.AddDatabase();
GAMSSet Set1 = db.AddSet("i", 1, "Plants");
GAMSSet j = db.AddSet("j", 1, "Markets");
GAMSParameter capacityParam = db.AddParameter("a", 1, "Capacity");
GAMSParameter demandParam = db.AddParameter("b", 1, "Demand");
GAMSParameter distanceParam = db.AddParameter("d", 2, "Distance");
for (int ic = 1; ic <= iCount; ic++)
{
   Set1.AddRecord((string)capacityData.GetValue(1, ic));
   capacityParam.AddRecord((string)capacityData.GetValue(1, ic)).Value = (double)capacityData.GetValue(2, ic);
}
for (int jc = 1; jc <= jCount; jc++)
{
   j.AddRecord((string)demandData.GetValue(1, jc));
   demandParam.AddRecord((string)demandData.GetValue(1, jc)).Value = (double)demandData.GetValue(2, jc);
   for (int ic = 1; ic <= iCount; ic++)
   {
       distanceParam.AddRecord((string)distanceData.GetValue(ic + 1, 1), (string)distanceData.GetValue(1, jc + 1)).Value =
      (double)distanceData.GetValue(ic + 1, jc + 1);
   }
}
...
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we finally set up the database and can run our `GAMSJob` as usual.

```
...
using (GAMSOptions opt = ws.AddOptions())
{
   GAMSJob t10 = ws.AddJobFromString(GetModelText());
   opt.Defines.Add("gdxincname", db.Name);
   opt.AllModelTypes = "xpress";
   t10.Run(opt, db);
   foreach (GAMSVariableRecord rec in t10.OutDB.GetVariable("x"))
      Console.WriteLine("x(" + rec.Keys[0] + "," + rec.Keys[1] + "): level=" + rec.Level + " marginal=" + rec.Marginal);
}
...
```

7.8.3.22 How to create and use a save/restart file (Transport11)

In `Transport11` we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a `GAMSCheckpoint`.

In the main function we start with the creation of a folder called tmp that internally is denoted as `wDir`. Then we call the function `CreateSaveRestart`.

```
...
string wDir = Path.Combine(".", "tmp");
CreateSaveRestart(Path.Combine(wDir, "tbase"));
...
```

In function `CreateSaveRestart` we choose the path of the file given as argument as working directory, so it should be `wDir`. Then we create a `GAMSJob` from a string. Note that the string given via `GetBaseModelText()` contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a `GAMSOption` to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the `GAMSJob` and stored in the file given as argument to the function. This becomes possible because the `AddCheckpoint` method accepts identifiers as well as file names as argument.

```
static void CreateSaveRestart(string cpFileName)
{
  GAMSWorkspace ws;
  if (Environment.GetCommandLineArgs().Length > 1)
       ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName), systemDirectory:
      Environment.GetCommandLineArgs()[1]);
  else
       ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName));
  GAMSJob j1 = ws.AddJobFromString(GetBaseModelText());
  GAMSOptions opt = ws.AddOptions();
  opt.Action = GAMSOptions.EAction.CompileOnly;
  GAMSCheckpoint cp = ws.AddCheckpoint(Path.GetFileName(cpFileName));
  j1.Run(opt, cp);
  opt.Dispose();
}
```

So what you should keep in mind before we return to further explanations of the main function is, that now the file tbase in folder `tmp` which is denoted as `wDir` contains a checkpoint. Now in the main function we define some data using C# data structures as we already did in `Transport4` before we create the `GAMSWorkspace` with working directory `wDir`.

```
...
GAMSWorkspace ws;
if (Environment.GetCommandLineArgs().Length > 1)
   ws = new GAMSWorkspace(workingDirectory: wDir, systemDirectory: Environment.GetCommandLineArgs()[1]);
else
   ws = new GAMSWorkspace(workingDirectory: wDir);
...
```

Afterwards we set up the `GAMSDatabase` like we already did in `Transport4`. Once this is done we run a `GAMSJob` using this data plus the checkpoint stored in file tbase.

```
...
GAMSCheckpoint cpBase = ws.AddCheckpoint("tbase");
using (GAMSOptions opt = ws.AddOptions())
{
   GAMSJob t4 = ws.AddJobFromString(GetModelText(), cpBase);
   opt.Defines.Add("gdxincname", db.Name);
   opt.AllModelTypes = "xpress";
   t4.Run(opt, db);
   foreach (GAMSVariableRecord rec in t4.OutDB.GetVariable("x"))
      Console.WriteLine("x(" + rec.Keys[0] + "," + rec.Keys[1] + "): level=" + rec.Level + " marginal=" + rec.Marginal);
}
...
```

Note that the string from which we create job `t4` is different to the one used to prepare the checkpoint stored in tbase and is only responsible for reading in the data from the `GAMSDatabase` correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

7.9 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C++ API. It allows the user to start working immediately with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step. The GAMS distribution comes with a pre compiled binary version of the GAMS C++ API on Windows, macOS and Linux. Furthermore, the C++ API itself and the provided examples are published under MIT license and are hosted at the GAMS GitHub organization. Therefore it is possible to compile the library manually (e.g. if a certain compiler is required) The GAMS C++ API is implemented and compatible with C++17.

- Getting Started A quick introduction about how to create and configure a C++ project using Qt Creator
- Important Classes of the API Overview of some fundamental classes of the GAMS C++ API
- How to use API An extensive set of examples how to use API components

7.9.1 Getting Started

This section guides you through the basic steps of compiling and running a program from scratch using either Qt Creator, Microsoft Visual Studio or Xcode. If you want to have a look at the API itself you can directly start with the How to use API section instead. While this tutorial uses Qt Creator, Microsoft Visual Studio and Xcode, other IDE's can be used as well.

Note

When using the pre compiled binary distribution of the GAMS C++ API as done in this section, one needs to use a compiler that is compatible with the one that was used during compilation of the library. Depending on the platform, different versions of the pre build binaries can be found under <GAMS system directory>/apifiles/C++/lib. In GAMS versions before 25.0 the binaries can be found under <GAMS system directory>. The distributed libraries use the following compilers:

- Windows: MSVC2017 and MSVC2019
- MacOS (x86_64): GCC and Clang
- MacOS (ARM64): Clang
- Linux: GCC

Note that the compiler needs at least full C++17 support in order to be able to use the GAMS C++ API.

7.9.1.1 Getting Started using Qt Creator

After opening Qt Creator click on **File** > **New File or Project**. Choose **Non-Qt Project** > **Plain C++ Application** and click on **Choose...**. On the next page fill in the name and the location of the new project and click **Next**. As a build system we recommend using CMake, which should be the default for recent Qt Creator versions. Afterwards, select the kits you want to use for the project and click again on **Next**. If you use the precompiled library on Windows, you need to use MSVC2017 or MSVC2019. Confirm the creation of the new project by clicking on **Finish**.

As soon as the project is created open the file CMakeLists.txt located in the root folder of your project. Add the following lines to the file:

```
set(GAMS_INSTALLATION "C:/GAMS/41")
set(VSVERSION "vs2019" CACHE STRING "Visual Studio version")
include_directories("${GAMS_INSTALLATION}/apifiles/C/api"
                    "${GAMS_INSTALLATION}/apifiles/C++/api")
if (WIN32)
    target_link_libraries(${PROJECT_NAME} "${GAMS_INSTALLATION}/apifiles/C++/lib/${VSVERSION}/gamscpp.lib")
else()
    target_link_libraries(${PROJECT_NAME} "${GAMS_INSTALLATION}/apifiles/C++/lib/libgamscpp.so")
endif()
```

Note

Depending on your operating system and the location of your GAMS system you might need to adjust the path to GAMS and Visual Studio version. Furthermore, all pre build binaries are always located at <GAMS system directory>\apifiles\C++\lib, if GAMS 25.0 (or higher) is used. This location may contain additional sub directories, like <GAMS system directory>\apifiles\C++\lib\vs2019. In case a previous version of GAMS is used the binaries are located at <GAMS system directory>.

Save the changes, right click on the project and choose Run CMake.

The last step of creating a first small example is to write code that makes use of the GAMS C++ API. Open the file main.cpp and replace the content of the file with the following lines of code:

```
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[])
{
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" <<
      rec.marginal() << endl;
}
```

Make sure that MSVC2019 64bit is chosen as kit using the Release mode.

Click on the play button below to run (and compile) the small example. If everything works, you should see the output of the example displaying results of the solved transportation problem.

7.9.1.2 Getting Started using Visual Studio 2019

After opening Visual Studio click on **File** > **New** > **Project ...**.

Choose **Console App** and fill in the name and the location of the project and click on **Ok**.

As soon as the project is loaded, open the **Configuration Manager**:

Change the **Active solution configuration** to **Release** and the **Active solution platform** to **x64**.

The next step is to configure the project to find the GAMS C++ API. Rigth click on the project and choose **Properties** from the context menue. Go to **Configuration Properties** > **C/C++** > **General** and add <`GAMS system directory`>\`apifiles\C++\api` to **Additional Include Directories**.

Select **Configuration Properties** > **C/C++** > **Precompiled Headers** on the left. On the right open the dropdown of **Precompiled Header** and select `Not Using Precompiled Headers`.

Go to **Configuration Properties** > **Linker** > **General** and add the apifiles path to the matching version of your Visual Studio (e.g. <`GAMS system directory`>\`apifiles\C++\lib\vs2017`) to **Additional Library Directories**:

Note

Please mind that the pre build binaries for older GAMS versions (before GAMS 25.0) are located at <`GAMS system directory`>.

Choose **Input** and add `gamscpp.lib;` to **Additional Dependencies**. Make sure that all previous entries including `%(AdditionalDependencies)` are present as well.

The last required configuration step is to add a post-build event that copies required files next to the generated executable. Click on **Build Events** > **Post-Build Event** and add the following code to **Command Line**. It is helpful to select <**Edit...**> from the dropdown box as there are two command lines. Note that you might need to adjust the used path depending on the location of your GAMS installation:

```
xcopy /Y "C:\gams\36\apifiles\C++\lib\vs2017\gamscpp.dll" "$(OutDir)"
```

Open the file `GAMSApplication.cpp` and replace its content by the following code:

```
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[])
{
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" <<
      rec.marginal() << endl;
}
```

Click on **Debug** > **Start Without Debugging** in order to compile and run the example. If everything works, you should see the output of the example displaying results of the solved transportation problem.

7.9.1.3 Getting Started using Xcode

After starting Xcode select "Create a new Xcode project" in the welcome screen.

As a platform pick macOS and "Command Line Tool" as Application type.

Give your application a name, an organization identifier and select "C++" as language.

On the next screen pick a location for your new project.

In your project settings go to the "Build Phases" tab add the following entry for "Compile Sources":

- `/Library/Frameworks/GAMS.framework/Versions/Current/Resources/apifiles/C++/api`

Then, under "Link Binary With Libraries" add libgamscpp.dylib. On the system for x86_64, this library is shipped in two versions, a GCC and a Clang version:

- The GCC library can be found in the `/Library/Frameworks/GAMS.framework/Versions/Current/Resources/apif` directory.
- The Clang version is only supported from macOS 10.15 onwards and can be found at `/Library/Frameworks/GAMS.framework/Versions/Current/Resources/apifiles/C++/api/Clang`.

On the system for ARM64, only the Clang version is available and can be found at `/Library/Frameworks/GAMS.framework/`

Open the file `main.cpp` and replace its content by the following code:

```
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[])
{
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" <<
      rec.marginal() << endl;
}
```

7.9.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the gams namespace. Their usage is demonstrated by an extensive set of examples.

- **gams** Namespace
- **gams::GAMSWorkspace** Class
- **gams::GAMSJob** Class
- **gams::GAMSDatabase** Class
- **gams::GAMSOptions** Class
- **gams::GAMSModelInstance** Class
- **gams::GAMSSymbol** Class

7.9.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C++ API. <GAMS system directory>\apifiles\C++ contains several Visual Studio solutions for different versions of Visual Studio (e.g. examples-vs2017.sln, examples-vs2019.sln). The code snippets that are explained in this tutorial are taken from these examples. Furthermore there is a CMakeLists.txt file that can be used for building the examples using CMake.

Note

When using CMake on macOS the Clang library is used by default. There is an option to switch to the GCC library: Add -D USE-GCC="ON" to your CMake command.

The well-known transportation problem is discussed step by step and each example introduces new elements of the GAMS C++ API.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)

7.9.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing Transport1.exe with C:/GAMS/46 we use the 64-bit version of GAMS 46.4 to run `Transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
    wsInfo.setSystemDirectory(argv[1]);
GAMSWorkspace ws(wsInfo);
...
```

Remember that the bitness of the GAMS system has to match the bitness of your C++ program.

7.9.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented C++ API offers much more than exchanging data between C++ and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in C++ data structures.

```
...
vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
map<string, double> demand = {
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
    { make_tuple("Seattle", "New-York"), 2.5 },
    { make_tuple("Seattle", "Chicago"), 1.7 },
    { make_tuple("Seattle", "Topeka"), 1.8 },
    { make_tuple("San-Diego", "New-York"), 2.5 },
    { make_tuple("San-Diego", "Chicago"), 1.8 },
    { make_tuple("San-Diego", "Topeka"), 1.4 }
};
...
```

Different GAMS symbols are represented using different C++ data structures. The data for the GAMS sets is represented using vectors of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by maps (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with C++ data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.

```
...
// create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();
...
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created GAMSSet instance `i` using `GAMSSet.addRecord`.

```
...
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
...
```

GAMSParameter instances can be added by using the method `GAMSDatabase.addParameter`. It has the same signature as `GAMSDatabase.addSet`. Anyhow, in this example we use an overload of the method

which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```
...
// add parameter 'a' with domain 'i'
GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
...
```

As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.doExport can be used to create a GDX file.

```
...
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.doExport("data.gdx");
...
```

7.9.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```
...
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.addDatabaseFromGDX("data.gdx");
...
```

Reading the data from the GAMSSet `i` into a vector can be done as follows:

```
...
// read data from symbols into C++ data structures
vector<string> iNew;
for(GAMSSetRecord rec : db2.getSet("i"))
    iNew.push_back(rec.key(0));
...
```

A new vector `iNew` is created. `i` is retrieved by calling `GAMSDatabase.getSet` on `db2`. The returned GAMSSet object can be iterated using a for-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameters. Instead of creating a vector, we want to have the data in the form of a map. GAMSParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `map<string, double>`.

```
...
map<string, double> aNew;
for(GAMSParameterRecord rec : db2.getParameter("a"))
    aNew[rec.key(0)] = rec.value();
...
```

For multi dimensional symbols, we choose the map keys to be tuples instead of string. We access the individual keys by index and generate a tuple using `make_tuple`.

```
...
map<tuple<string, string>, double> dNew;
for(GAMSParameterRecord rec : db2.getParameter("d"))
    dNew[make_tuple(rec.key(0), rec.key(1))] = rec.value();
...
```

Scalars can be read into a variable of type double by accessing the value of the first and only record.

```
...
double fNew = db2.getParameter("f").firstRecord().value();
...
```

7.9.3.4 How to run a GAMSJob from file (Transport1)

At first we create a `GAMSWorkspace`. Afterwards we load the model `trnsport` from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the `GAMSWorkspace.AddJobFromFile` Method afterwards. Apparently this method also works with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob `t1` is defined from that file and run by the `GAMSJob.run` method. The following lines create the solution output and illustrate the usage of the `GAMSJob.outDB` method to get access to the `GAMSDatabase` created by the `run` method. To retrieve the content of variable `x` we use the `GAMSVariableRecord` class and the `GAMSDatabase.getVariable` method.

```
...
GAMSWorkspace ws;
ws.gamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
// Default run
t1.run();
cout << "Ran with Defaults:" << endl;
for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
    cout << "x(" << rec.key(0) << "," << rec.key(1) << "):" << " level=" << rec.level() << " marginal=" << rec.marginal()
      << endl;
...
```

7.9.3.5 How to specify the solver (Transport1)

The solver can be specified via the GAMSOptions class and the `GAMSWorkspace.addOptions` method. The `GAMSOptions.setAllModelTypes` method sets `xpress` as default solver for all model types which the solver can handle.

```
...
// Run the job again with another solver
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("xpress");
t1.run(opt);
...
```

7.9.3.6 How to run a job with a solver option file (Transport1)

At first create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. We choose xpress as solver just like in the preceding example and call `GAMSOptions.setOptFile` in order to tell the solver to look for a solver option file.

```
...
// Run the job with a solver option file
ofstream xpressopt(ws.workingDirectory() + cPathSep + "xpress.opt");
xpressopt << "algorithm=barrier" << endl;
xpressopt.close();
opt.setAllModelTypes("xpress");
opt.setOptFile(1);
t1.run(opt);
...
```

7.9.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings provided by the methods `getDataText` and `getModelText` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
...
ofstream tdata(ws.workingDirectory() + cPathSep + "tdata.gms");
tdata << getDataText();
tdata.close();
...
```

Afterwards we create a GAMSJob using the GAMSWorkspace.addJobFromString method. The GAMSOptions.setDefine method is used like the 'double dash' GAMS parameters, i.e. it corresponds to --incname=tdata on the command line.

```
...
GAMSOptions opt = ws.addOptions();
GAMSJob t2 = ws.addJobFromString(getModelText());
opt.setDefine("incname", "tdata");
t2.run(opt);
...
```

Note that the string provided by getModelText contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

7.9.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string provided by getDataText as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding GAMSJob a GAMSDatabase is created that is available via the GAMSJob.outDb method. We can use the GAMSDatabase.doExport method to write the content of this database to a gdx file tdata.gdx.

```
...
// data from a string with GAMS syntax with explicit export to GDX file
GAMSJob t3 = ws.addJobFromString(getDataText());
t3.run();
t3.outDB().doExport(ws.workingDirectory() + cPathSep + "tdata.gdx");
...
```

7.9.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in Transport2 - How to use include files (Transport2).

```
...
t3 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", "tdata");
opt.setAllModelTypes("xpress");
t3.run(opt);
...
```

Note that there are some changes in getModelText due to the usage of a GDX file instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

7.9.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs t3a and t3b where the first one contains only the data and the second one contains only the model without data. After running t3a the corresponding outDB can be read in directly just like a gdx file. Note that the database needs to be passed to the GAMSJob.run method as additional argument.

```
...
GAMSJob t3a = ws.addJobFromString(getDataText());
GAMSJob t3b = ws.addJobFromString(getModelText());
t3a.run();
opt.setDefine("gdxincname", t3a.outDB().name());
t3b.run(opt, t3a.outDB());
...
```

7.9.3.11 How to define data using C++ data structures (Transport4)

We use the `vector<T>` and `map<Key, Value>` to define C++ data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
...
vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
map<string, double> demand = {
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
    { make_tuple("Seattle", "New-York"), 2.5 },
    { make_tuple("Seattle", "Chicago"), 1.7 },
    { make_tuple("Seattle", "Topeka"), 1.8 },
    { make_tuple("San-Diego", "New-York"), 2.5 },
    { make_tuple("San-Diego", "Chicago"), 1.8 },
    { make_tuple("San-Diego", "Topeka"), 1.4 }
};
...
```

7.9.3.12 How to prepare a GAMSDatabase from C++ data structures (Transport4)

At first we create an empty GAMSDatabase `db` using the `GAMSWorkspace.addDatabase` method. Afterwards we prepare the database. To add a set to the database we use the `GAMSSet` class and the `GAMSDatabase.addSet` method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C++ data structure and add them by using the `GAMSSet.addRecord` method. We do pretty much the same thing for the parameters.

Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that the scalars can be treated as parameter with dimension 0.

The `GAMSJob` can be run like explained in the preceding example about implicit database communication.

```
...
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
...
GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
...
GAMSParameter d = db.addParameter("d", "distance in thousands of miles", i, j);
for (auto t : distance)
    d.addRecord(get<0>(t.first), get<1>(t.first)).setValue(t.second);
GAMSParameter f = db.addParameter("f", "freight in dollars per case per thousand miles");
f.addRecord().setValue(90);
// run a job using data from the created GAMSDatabase
GAMSJob t4 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t4.run(opt, db);
...
```

7.9.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS checkpoint, the second one uses the `GAMSWorkspace.addJobFromString` method to create a `GAMSJob` containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the `GAMSJob.run` method. Furthermore, it passes an additional checkpoint argument to the `run` method. That means the GAMSCheckpoint `cp` captures the state of the `GAMSJob`.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
...
ws.addJobFromString(getModelText()).run(cp);
...
```

7.9.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `getModelText()` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
Scalar bmult  demand multiplier /1/;
...
demand(j) ..   sum(i, x(i,j))  =g=  bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
...
```

We create a `vector` with eight different values for this demand multiplier.

```
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

For each entry of the vector we create a GAMSJob `t5` using the `GAMSWorkspace.addJobFromString` method. Besides the string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a `GAMSJob` combined from the checkpoint plus the content provided by the string.

We run the `GAMSJob` and echo some interesting data from the `outDB` using the `GAMSDatabase.getParameter` and `GAMSDatabase.getVariable` methods, the `GAMSParameter.findRecord` and `GAMSVariable.findRecord` methods plus the `GAMSParameterRecord.value` and the `GAMSVariableRecord.level` methods.

```
...
for (double b : bmultlist)
{
    GAMSJob t5 = ws.addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
      ss=transport.solvestat;", cp);
    t5.run();
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << "  Modelstatus: " << t5.outDB().getParameter("ms").findRecord().value() << endl;
    cout << "  Solvestatus: " << t5.outDB().getParameter("ss").findRecord().value() << endl;
    cout << "  Obj: " << t5.outDB().getVariable("z").findRecord().level() << endl;
}
...
```

Note

> Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

7.9.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs we already know from `Transport5` in parallel. We create a GAMSCheckpoint `cp` and initialize it by running a `GAMSJob`. Furthermore we introduce a demand multiplier as we did before.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromString(getModelText()).run(cp);
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object `ioMutex` that will be used to avoid mixed up output from the parallel jobs. For each element `b` from the vector of demand multipliers we create a thread executing the `runScenario` method.

```
...
// run multiple parallel jobs using the created GAMSCheckpoint
mutex ioMutex;
vector<thread> v;
for(double b : bmultlist)
    v.emplace_back([&ws, cp, &ioMutex, b]{runScenario(&ws, cp,&ioMutex,b);});
for (auto& t : v)
    t.join();
...
```

In function `runScenario` a `GAMSJob` is created and run just like in the preceding example of `Transport5`. The output section is also the same except for the fact that it is locked by using a `lock_guard` on the `ioMutex`. That means the threads of `runScenario` are running in parallel but the output block of different threads cannot be executed in parallel since it is locked using the same `ioMutex`.

```
...
void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
      ss=transport.solvestat;", cp);
    t6.run();
    // we need to make the ouput a critical section to avoid messed up report information
    lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << "  Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << "  Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << "  Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
...
```

While the output in `Transport5` is strictly ordered subject to the order of the elements of `bmultlist`, in `Transport6` the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lock_guard` mechanism.

If you want a further impression of the impact of the `lock_guard`, just rerun `Transport6` but comment out the `lock_guard` as follows and compare the output.

```
...
void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
      ss=transport.solvestat;", cp);
    t6.run();
    // we need to make the ouput a critical section to avoid messed up report information
    // lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << "  Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << "  Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << "  Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
...
```

7.9.3.16 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In `Transport7` the usage of **gams::GAMSModelInstance** is demonstrated.

At first we create a checkpoint `cp` as in the preceding examples. Then we create the GAMSModelInstance `mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
GAMSJob t7 = ws.addJobFromString(getModelText());
t7.run(cp);
GAMSModelInstance mi = cp.addModelInstance();
...
```

7.9.3.17 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A `GAMSModelInstance` uses a `syncDB` to maintain the data. We define `bmult` as `GAMSParameter` using the `GAMSDatabase.addParameter` method and specify `cplex` as solver. Afterwards the `GAMSModelInstance` is instantiated with three arguments: the solve statement, the `GAMSOptions` object `opt` and `bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of GAMSModelInstance `mi` stay unchanged.

We use the `GAMSParameter.addRecord` method to assign a value to `bmult` that can be varied afterwards using the `GAMSParameter.firstRecord` method to reproduce our well-known example with different demand multipliers.

```
...
```

```
GAMSModelInstance mi = cp.addModelInstance();
GAMSParameter bmult = mi.syncDb().addParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("cplex");
// instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
bmult.addRecord().setValue(1.0);
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
for (double b : bmultlist) {
    bmult.firstRecord().setValue(b);
    mi.solve();
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << "  Modelstatus: " << mi.modelStatusAsString() << endl;
    cout << "  Solvestatus: " << mi.solveStatusAsString() << endl;
    cout << "  Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
}
...
```

7.9.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a `GAMSModelInstance` and define `x` as `GAMSVariable` and its upper bound as `GAMSParameter` `xup`. At the following instantiate method `GAMSModifier` has three arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the `GAMSParameter` that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
mi = cp.addModelInstance();
GAMSVariable x = mi.syncDb().addVariable("x", 2, GAMSEnum::VarType::Positive, "");
GAMSParameter xup = mi.syncDb().addParameter("xup", 2, "upper bound on x");
// instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare upper bound of X mutable
mi.instantiate("transport use lp min z", GAMSModifier (x, GAMSEnum::SymbolUpdateAction::Upper, xup));
for (GAMSSetRecord i : t7.outDB().getSet("i")) {
    for (GAMSSetRecord j : t7.outDB().getSet("j")) {
        xup.clear();
        xup.addRecord(i.key(0), j.key(0)).setValue(0);
        mi.solve();
        cout << "Scenario link blocked=" << i.key(0) << "-" << j.key(0) << endl;
        cout << "  Modelstatus: " << mi.modelStatusAsString() << endl;
        cout << "  Solvestatus: " << mi.solveStatusAsString() << endl;
        cout << "  Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
    }
}
...
```

7.9.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint `cp` from a `GAMSJob`. Then we define a vector that represents the different values of the demand multiplier. While `ioMutex` is used to avoid messed up output, `vectorMutex` synchronizes the access to the `vector`. Then we start multiple thread executing the method `scenSolve`. The number of parallel executed threads is specified by `nrThreads`. All trheads share the same `vector` that provides the different values for `bmult`.

```
...
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromString(getModelText()).run(cp);
vector<double> bmultVector = { 1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6 };
int nrThreads = 2;
std::mutex vectorMutex;
std::mutex ioMutex;
vector<thread> v;
for (int i = 0; i < nrThreads; i++)
    v.emplace_back([&ws, &cp, &bmultVector, &vectorMutex, &ioMutex] {scenSolve(&ws, &cp, &bmultVector, &vectorMutex,
      &ioMutex);});
for (auto& t : v)
    t.join();
...
```

In scenSolve we create and instantiate a GAMSModelInstance as in the preceding examples and make bmult modifiable. As long as bmultVector is not empty, an elements is taken and removed from the vector. The value is used for the scalar bmult. Note that we chose cplex as solver because it is thread safe (gurobi would also be possible). Once the vector is empty the loop terminates.

```
void Transport8::scenSolve(GAMSWorkspace* ws, GAMSCheckpoint* cp, vector<double>* bmultVector, std::mutex* vectorMutex,
      std::mutex* ioMutex)
{
    unique_lock<mutex> vectorLock(*vectorMutex);
    GAMSModelInstance mi = cp->addModelInstance();
    vectorLock.unlock();
    GAMSParameter bmult = mi.syncDb().addParameter("bmult", "demand multiplier");
    GAMSOptions opt = ws->addOptions();
    opt.setAllModelTypes("cplex");
    // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
    bmult.addRecord().setValue(1.0);
    while (true)
    {
        double b;
        // dynamically get a bmult value from the vector instead of passing it to the different threads at creation time
        vectorLock.lock();
        if (bmultVector->empty())
            return;
        b = bmultVector->back();
        bmultVector->pop_back();
        vectorLock.unlock();
        bmult.firstRecord().setValue(b);
        mi.solve();
        // we need to make the output a critical section to avoid messed up report informations
        unique_lock<mutex> ioLock(*ioMutex);
        cout << "Scenario bmult=" << b << ":" << endl;
        cout << "  Modelstatus: " << mi.modelStatus() << endl;
        cout << "  Solvestatus: " << mi.solveStatus() << endl;
        cout << "  Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
        ioLock.unlock();
    }
}
```

7.9.3.20 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a GAMSDatabase. It can only be run on Windows since it makes use of the Microsoft Access Driver. Furthermore the example makes use of the Qt SQL module. Note that you need to have Microsoft Access installed and that its bitness needs to match the bitness of your GAMS version. In the example we call a function readFromAccess that finally returns a GAMSDatabase as shown below.

```
...
GAMSDatabase db = readFromAccess(ws);
...
```

The data we are going to read can be found in <GAMS system directory>\apifiles\Data\transport.accdb. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty GAMSDatabase. Afterwards we create a QSqlDatabase, specify the connection string and open the connection to the database. If opening the connection was successful, data is read from the database into the GAMSDatabase using the methods readSet and readParameter.

```
GAMSDatabase readFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    QSqlDatabase sqlDb = QSqlDatabase::addDatabase("QODBC", "readConnection");
    QString strAccessConn = ("Driver={Microsoft Access Driver (*.mdb, *.accdb)};DSN='';DBQ=" + ws.systemDirectory() \
                            + cPathSep + "apifiles" + cPathSep + "Data" + cPathSep + "transport.accdb").c_str();
    sqlDb.setDatabaseName(strAccessConn);
    if(sqlDb.open())
    {
        // read GAMS sets
        readSet(sqlDb, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
        readSet(sqlDb, db, "SELECT Market FROM Market", "j", 1, "markets");
        // read GAMS parameters
        readParameter(sqlDb, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
        readParameter(sqlDb, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
        readParameter(sqlDb, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
        sqlDb.close();
    }
    else
    {
        cout << "Error: Failed to create a database connection. " << sqlDb.lastError().text().toStdString() << endl;
        exit(1);
```

```
    }
    return db;
}
```

The function readSet creates a QSqlQuery that reads data from a table of the Access database. A GAMSSet is created and populated with the data.

```
void readSet(QSqlDatabase sqlDb, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string setExp = "")
{
    QSqlQuery query(sqlDb);
    if (!query.exec(strAccessSelect.c_str()))
    {
        cout << "Error executing query on set '" << setName << "'" << endl;
        cout << query.lastError().text().toStdString() << endl;
        exit(1);
    }
    if (query.size() && (query.record().count() != setDim))
    {
        cout << "Number of fields in select statement does not match setDim" << endl;
        exit(1);
    }
    GAMSSet i = db.addSet(setName, setDim, setExp);
    vector<string> keys = vector<string>(setDim);
    while (query.next())
    {
        for (int idx = 0; idx < setDim; idx++)
            keys[idx] = query.value(idx).toString().toStdString();
        i.addRecord(keys);
    }
}
```

Once we read in all the data we can create a GAMSJob from the GAMSDatabase and run it as usual. Finally the results are written to transport.accdb.

7.9.3.21 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from <GAMS system directory>\apifiles\Data\transport.xlsx. It can only be run on Windows. Note that you need to have Microsoft Excel installed and that its bitness needs to match the bitness of your GAMS version. The model is given as string without data like in in many examples before. At first we have to add

```
#include <QAxObject>
#include <Windows.h>
```

to be able to use the QAxObject class, which serves as a wrapper for COM objects. Furthermore we include Windows.h to access the functions CoInitialize and CoUninitialize. In the main function we open the aforementioned file to get access to its content. Note that we need to call CoInitialize(0) first in order to initialize ActiveX. We create an instance of the class QAxObject and use the querySubObject method multiple times to get to the sheets of the workbook.

```
...
QAxObject* excel = new QAxObject( "Excel.Application", 0 );
QAxObject* workbooks = excel->querySubObject( "Workbooks" );
QAxObject* workbook = workbooks->querySubObject( "Open(const QString&)", fileName );
QAxObject* sheets = workbook->querySubObject( "Worksheets" );
...
```

The method sheetToParameter is used in order to transfer data from the workbook into GAMSParameter instances. In order to determine from which sheet the actual data needs to be read, the method takes the QAxObject instance referring to the sheets and the actual sheet name. A new GAMSParameter is added to the GAMSDatabase object db using set1 and set2 as domains. The next step is to determine the number of columns and the number of rows used. The for loop reads the actual data, adds the records to the new GAMSParameter and sets their values.

```
...
GAMSParameter sheetToParameter(QAxObject* sheets, string sheetName, GAMSDatabase db, string paramName, string paramText,
      GAMSSet set1, GAMSSet set2)
{
    QAxObject* sheet = sheets->querySubObject( "Item( string )", sheetName.c_str() );
    vector<GAMSDomain> sets {set1, set2};
    GAMSParameter param = db.addParameter(paramName, paramText, sets);
    QAxObject* usedrange = sheet->querySubObject( "UsedRange");
    QAxObject * columns = usedrange->querySubObject("Columns");
    int intCols = columns->property("Count").toInt();
    QAxObject * rows = usedrange->querySubObject("Rows");
    int intRows = rows->property("Count").toInt();
```

```
    for (int j = 2; j <= intCols; j++) {
        string namej = sheet->querySubObject("Cells( int, int )", 1, j)->dynamicCall("Value()").toString().toStdString();
        for (int i = 2; i <= intRows; ++i) {
            string namei = sheet->querySubObject("Cells( int, int )", i,
      1)->dynamicCall("Value()").toString().toStdString();
            GAMSParameterRecord rec = param.addRecord(namei, namej);
            double value = sheet->querySubObject("Cells( int, int )", i, j)->dynamicCall("Value()").toDouble();
            rec.setValue(value);
        }
    }
    return param;
}
...
```

After all required data was read from the workbook, we need to close it and quit the `Excel` application.

```
...
workbook->dynamicCall("Close()");
excel->dynamicCall("Quit()");
...
```

Now we can create und run the `GAMSJob` using the created `GAMSDatabase` as usual.

```
...
GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(getModelText());
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t10.run(opt, db);
for (GAMSVariableRecord record : t10.outDB().getVariable("x"))
    cout << "x(" << record.key(0) << "," << record.key(1) << "): level=" << record.level() <<
            " marginal=" << record.marginal() << endl;
...
```

Finally we need to call 'CoUninitialize' in order to close the `COM` library.

```
...
::CoUninitialize();
...
```

7.9.3.22 How to create and use a save/restart file (Transport11)

In `Transport11` we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a `GAMSCheckpoint`. We start by creating the save/restart file by calling `createSaveRestart`.

```
...
std::string cpName = "tbase";
createSaveRestart(argc, argv, cpName);
...
```

In function `createSaveRestart` we choose the `checkpointName` as relative path to the current directory in order to create a `GAMSWorkspace`. Then we create a `GAMSJob` from a string. Note that the string given via `getBaseModelText()` contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a `GAMSOption` to only compile the job without executing it. Then we create a checkpoint `cp` that is initialized by the following run of the `GAMSJob` and stored in the file given as argument to the function. This becomes possible because the `addCheckpoint` method accepts identifiers as well as file names as argument.

```
void createSaveRestart(int argc, char* argv[], const string &checkpointName)
{
    GAMSWorkspaceInfo wsInfo;
    if (argc > 1)
        wsInfo.setSystemDirectory(argv[1]);
    wsInfo.setWorkingDirectory("." +(cPathSep+ checkpointName));
    GAMSWorkspace ws(wsInfo);
    GAMSJob j1 = ws.addJobFromString(getBaseModelText());
    GAMSOptions opt = ws.addOptions();
    opt.setAction(GAMSOptions::EAction::CompileOnly);
    auto checkpoint = ws.workingDirectory() + cPathSep + checkpointName;
    GAMSCheckpoint cp = ws.addCheckpoint(checkpoint);
    j1.run(opt, cp);
}
```

So what you should keep in mind before we return to further explanations of the main function is, that now the file tbase in folder `tbase` contains a checkpoint. Now in the main function we define some data using C++ data structures as we already did in `Transport4` before we create another `GAMSWorkspace`.

```
...
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
    wsInfo.setSystemDirectory(argv[1]);
wsInfo.setWorkingDirectory("." +(cPathSep+ cpName));
GAMSWorkspace ws(wsInfo);
...
```

Afterwards we set up the `GAMSDatabase` like we already did in `Transport4`. Once this is done we run a `GAMSJob` using this data plus the checkpoint stored in file tbase.

```
...
GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");
GAMSOptions opt = ws.addOptions();
GAMSJob t4 = ws.addJobFromString(getModelText(), cpBase);
opt.setDefine("gdxincname", db.name());
opt.setAllModelTypes("xpress");
t4.run(opt, db);
for (auto record : t4.outDB().getVariable("x"))
    cout << "x(" << record.key(0) << "," << record.key(1) << "): level=" << record.level() <<
            " marginal=" << record.marginal() << endl;
...
```

Note that the string from which we create job `t4` is different to the one used to prepare the checkpoint stored in tbase and is only responsible for reading in the data from the `GAMSDatabase` correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

7.9.4 How to use the pre configured example projects

Depending on the operating system, the GAMS C++ API comes with example project configurations for CMake and Visual Studio. They provide an easy way of building and running the distributed GAMS C++ examples and are located in <`GAMS system directory`>\`apifiles`\`C++`.

7.9.4.1 CMake

Windows:

Create build directory

```
cd <GAMS system directory>\apifiles\C++
mkdir build && cd build
```

Run CMake and build project

```
cmake -G "Visual Studio 16 2019" -DCMAKE_BUILD_TYPE=Release -DVSVERSION:STRING=vs2019 ..
msbuild.exe examples.sln /p:Configuration=Release
```

Note

For other Visual Studio versions, the generator-name (-G) needs to be adjusted (see cmake documentation).

All generated executables can now be found in the CMake build directory. The exact path depends on the project name and the config setting. Assuming the solution was build with `-config Release`, a `transport1.exe` executable is located in <`GAMS system directory`>\`apifiles`\`C++`\`build`\`transport1`\`Release`. Therefore you can use the following commands to execute the transport1 example:In order to execute an example (e.g. transport1) run the following commands:

```
cd transport1\Release
set PATH=%PATH%;<GAMS system directory>\apifiles\C++\lib\vs2019
transport1.exe
```

Linux:

Create build directory

```
cd <GAMS system directory>/apifiles/C++
mkdir build && cd build
```

Run CMake and build project

```
cmake ..
make
```

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

```
cd transport1
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<GAMS system directory>/apifiles/C++/lib
./transport1
```

macOS:

Create build directory

```
cd <GAMS system directory>/apifiles/C++
mkdir build && cd build
```

Run CMake and build project.

Note

> By default, Clang is used as a compiler. If GCC was used to build the gamscpp library, then use `-D USE-GCC="ON"` to select the correct gamscpp library from your GAMS folder. Otherwise, the build will fail.

```
cmake ..
make
```

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

```
cd transport1
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:<GAMS system directory>/apifiles/C++/lib
./transport1
```

7.9.4.2 Microsoft Visual Studio

The Visual Studio solutions are available for Windows only. Open the solution file that matches the version of your Visual Studio installation (e.g. <GAMS system directory>\apifiles\C++\examples-vs2017.sln).

As soon as the solution is loaded, click on **Build** > **Configuration Manager** and adjust the `Active solution configuration` and the `Active solution platform`. The solution configuration needs to be set to `Release` for using the distributed binaries of the GAMS C++ API. Note that the platform needs to match the version of your GAMS installation.

The examples `Transport9` and `Transport10` require a Qt installation. If you do not have one, you need to disable these projects. Right click on a project in the Solution Explorer and choose **Unload Project** from the context menu.

Click on **Build** > **Build Solution** in order to compile and link the examples.

Note

In some cases the build might return with `xcopy` errors. Just build the project again. Make sure that you don't do a rebuild.

In order to run an example, click on **Debug** > **Start Without Debugging**. This will execute the current StartUp project. Changing the StartUp project can be achieved by right clicking on a project in the Solution Explorer and choosing **Set as StartUp Project**.

7.10 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Java API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known **transportation problem**. These examples introduce several API features step by step.

- Getting started A quick introduction about how to compile and run a program from command line or an IDE
- Important Classes of the API Overview of some fundamental classes of the GAMS Java API
- How to use API An extensive set of examples describing how to use API components

7.10.1 Getting started

Since GAMS 44.1.0, a Java program that uses GAMS Java API requires at least Java SE 11 to compile and run. For a Java program that still requires Java SE 8 to compile and run, it is possible to use a separate version of GAMS Java API that targets Java SE 8, but the new or updated functionalities that are released after GAMS 43 are not avaiable in this Java API version.

For all platforms, assume GAMS system has been installed at `[PathToGAMS]` directory, called GAMS directory. The directory `[PathToGAMS]` denotes the path setting according to your GAMS installation on targeted platforms. For instance

- on Windows-based platforms with GAMS distribution 46.4 installed, `[PathToGAMS]` denotes `C:\GAMS\win64\46.4`

- on Unix-based platforms with GAMS distribution 46.4 installed, `[PathToGAMS]` denotes `/usr/gams/gams46.4_linux_x64_64_sfx`

All GAMS Java API classes are contained within one single jar file `GAMSJavaAPI.jar` (or `GAMSJavaAPI-8.jar` for Java SE 8) with a namespace `com.gams.api`. The jar files are distributed with the current GAMS distribution and located at

- on Windows-based platforms:

  `[PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar`

- on Unix-based platforms:

  `[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar`

Note

Since GAMS 44.1.0, GAMS Java API has an additional dependency on JSON.simple, a simple Java library for JSON processing, read and write JSON data. Compiling and running a program that uses `GAMSJavaAPI.jar` requires `json-simple-1.1.1.jar` to be in the same directory as `GAMSJavaAPI.jar` (This is not the case for `GAMSJavaAPI-8.jar`). Missing `json-simple-1.1.1.jar` from the same directory might raise runtime exception when using related functionality in the GAMS Java API.

There are two different approaches of how to use the GAMS Java API. Either the Java source files can be edited with any common editor and compiled from command line or a Java IDE can be used. The following sections give a quick introduction about the different possibilities.

7.10.1.1 Compiling a Program

To compile a Java program, one usually provides the following information to Java compiler:

- the directory(ies) containing all required Java class files
- the directory to place the generated class files
- the name of the Java source file

A Java program that uses GAMS Java API requires class files that are contained in `GAMSJavaAPI.jar` for compilation (or in `GAMSJavaAPI-8.jar` for Java SE 8).

Compiling a Program from Command Line

To compile a Java program that uses GAMS Java API, for instance `HelloAPI.java`, at the command line:

```
javac -cp [CLASSPATH] -d [TARGETDIR] HelloAPI.java
```

where

```
[CLASSPATH]  is 'GAMSJavaAPI.jar' (or 'GAMSJavaAPI-8.jar' for Java SE 8) with its location,
             as it contains class files that are used by 'HelloAPI.java'.
             On Windows-based platform, [CLASSPATH] denotes
                 [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar
             On Unix-based platforms, [CLASSPATH] denotes
                 [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR]  is the directory to place the generated classe file.
```

Note

- it is possible to add [CLASSPATH] to your CLASSPATH environment variable of the operating system as an alternative to specifying -cp [CLASSPATH].
- -d [TARGETDIR] is optional. In case -d [TARGETDIR] is omited and the compilation is successful, the class file will be generated and located under the current directory.
- GAMSJavaAPI.jar has an additional dependency on json-simple-1.1.1.jar (not the case for GAMSJavaAPI-8.jar). Though it is not necessary to add json-simple-1.1.1.jar to [CLASSPATH] as it already been added into the GAMSJavaAPI.jar's Classpath. It is important, however, for json-simple-1.1.1.jar to be in the same directory as GAMSJavaAPI.jar.

To compile other programs, change the arguments accordingly. See also How to compile and run examples from the GAMS

Compiling a Program from Java IDE

In case of compiling a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), the location of the jar file GAMSJavaAPI.jar (or GAMSJavaAPI-8.jar for Java SE 8) shall be added into the Java build path of the IDE's project properties.

For an Eclipse user, see How to import an Eclipse Java Project from the GAMS system directory.

7.10.1.2 Running a Program

To run a Java program, one usually provide the following information to Java Virtual Machine:

- the directory(ies) containing all required Java classes
- the directory(ies) containing all required shared libraries
- the name of an entry point class (in most case containing main method)

A Java program that uses GAMS Java API requires a number of shared libraries for establishing a connection with GAMS software components during run time. These shared libraries are platform dependent and they are located at [PathToGAMS]/apifiles/Java/api directory.

Running a Program from Command Line

To run a Java program that uses GAMS Java API, for instance HelloAPI.class containing in [TARGETDIR] directory, at the command line type:

```
java -cp [CLASSPATH]  HelloAPI
```

where

```
[CLASSPATH]  is the list of two paths, a path of 'GAMSJavaAPI.jar' (or 'GAMSJavaAPI-8.jar' for Java S
             and a path of targeted directory containing 'HelloAPI.class', separated by path separato
             on the targeted platform.
             On Windows-based platform, [CLASSESPATHS] denotes
                 [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;[TARGETDIR]
             On Unix-based platform, [CLASSESPATHS] denotes
                 [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar:[TARGETDIR]

HelloAPI     is the name of an entry point class containing main method
```

Please note that it is possible to add [CLASSPATH] to your CLASSPATH environment variable of the operating system as an alternative to specify -cp [CLASSPATH].

Attention

> Most operations performed by GAMS Java API such as gdx or options operations require shared libraries (located in the folder `[PathToGAMS]/apifiles/Java/api` by default) when running a program. It is recommended to specify the path to shared libraries when running a program. In case no `java.library.path` has been specified when running a program, the Java API will determine the path of the shared libraries from the java class path containing `GAMSJavaAPI.jar`.

It is possible to specify the path to shared libraries by passing the following argument to Java Virtual Machine:

```
-Djava.library.path=[LIBRARYPATH]
```

where `[LIBRARYPATH]` describes the list of paths containing all required shared libraries (as previously mentioned, it is `[PathToGAMS]/apifiles/Java/api` by default). In such case, the Java API will give priority to the java library path when loading all required JNI libraries during run time. The java API will raise an exception when either the java virtual machine fails to load the required libraries from the specified java library path or there is a version conflict of shared libraries during run time.

To run other programs, change the arguments accordingly. See also How to compile and run examples from the GAMS syst

Running a Program from Java IDE

In case of running a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), it is possible to set the nessary arguments via the properties of the IDE project.

For an Eclipse user, see How to import an Eclipse Java Project from the GAMS system directory.

7.10.1.3 Setting Up Your Environment

Since 24.3, the GAMS system directory can be specified within the program during run time. Therefore the setting up of execution environment before running a program is no longer required (see also Release Notes 24.3).

Nevertheless, it is still possible to preconfigure the GAMS system directory before running a program and use the default workspace setting within a program. In the default setting, GAMS system directory is not specified by a user within the program. The directory will be searched during run time from environment variable in the following order (depends on the target platform):

- On Windows-based platform: first from `PATH` environment variable. If not found, from the platform windows registry `gams.location`,
- On macOS-based platform: first from `PATH` environment variable. If not found, from `DYLD_LIBRARY_PATH`,
- On other Unix-based platfrom: from `PATH` environment variable. If not found, from `LD_LIBRARY_PATH`.

The following examples illustrate how to add `[PathToGAMS]` into the environment variable `PATH` on different platforms:

- On Windows 2000, XP, Vista, or Windows 7 desktop:

```
> right-click on 'My Computer'
> choose 'Properties' (alternatively, click on 'System' icon in the control panel)
> click on 'Advanced' tab (or 'Advance system settings')
> click on 'Environment Variables'
> edit 'PATH' by adding [PathToGAMS] to the variable using a semi-colon as a separator.
```

- On Window-based platform via command line terminal:

```
set PATH=[PathToGAMS];%PATH%
```

- On Unix-based platform via command line terminal using Bourne shell and its derivatives:

```
export PATH=[PathToGAMS]:${PATH}
```

- On Unix-based platform via command line terminal using C Shell:

```
setenv PATH [PathToGAMS]:${PATH}
```

7.10.1.4 How to compile and run examples from the GAMS system directory

GAMS provides several examples to demonstrate how to use GAMS Java API. These examples are located in the `[PathToGAMS]/apifiles/Java` directory containing various examples based on the different optimization problems. The following explanations guide you through the compilation and execution process of one example based on the well-known **transportation problem**, assuming that Java Runtime System is already installed on your machine.

For instance, `Transport1.java` under the directory `[PathToGAMS]/apifiles/Java/transport` demonstrates how to retrieve GAMS transport model from GAMS Model Library, execute the model with various GAMS options, and extract results after execution.

To compile `Transport1.java` at the command line under the directory `[PathToGAMS]/apifiles/Java/transport`:

```
javac -cp [CLASSPATH] -d [TARGETDIR] Transport1.java
```

where

```
[CLASSPATH]  is a location of 'GAMSJavaAPI.jar' (or 'GAMSJavaAPI-8.jar' for Java SE 8),
             as it contains classes files that are used by 'Transport1.java'.
             On Windows-based platform, [CLASSPATH] denotes
                [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;
             On Unix-based platforms, [CLASSESPATHS] denotes
                [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR]  is the destination directory to place the generated classed file.
```

As `Transport1.java` is declared under package `com.gams.examples.transport`, the output class file will be located in `[TARGETDIR]` under the directory structure corresponding to package information. This means the compiled output file `Transport1.class` is located under:

- `[TARGETDIR]\com\gams\examples\transport` on Windows-based platform, or
- `[TARGETDIR]/com/gams/examples/transport` on Unix-based platforms.

To run `Transport1.class` from the command line:

```
java -cp [CLASSPATH] com.gams.examples.transport.Transport1
```

where

```
[CLASSPATH]  is the list of two paths, 'GAMSJavaAPI.jar' (or 'GAMSJavaAPI-8.jar'
             for Java SE 8) with its path and a directory containing 'Transport1.class'
             and (in this case [TARGETDIR] from the compliation step), separated by
             path separator on the targeted platform.
             On Windows-based platform, [CLASSESPATHS] denotes
                [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;[TARGEDIR]
             On Unix-based platforms, [CLASSESPATHS] denotes
                [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar:[TARGEDIR]
```

Please note that the path `[TARGETDIR]` can be either absolute or relative path representing the directory that contains `Transport1.class`.

To compile and run other examples under the directory `[PathToGAMS]/apifiles/Java`, adjust the arguments accordingly.

See How to use API for detailed explanations on the series of **transportation problem** examples located in the folder `[PathToGAMS]/apifiles/Java/transport`.

7.10.1.5 How to import an Eclipse Java Project from the GAMS system directory

Since GAMS version 24.2 there is an prepared Java project that can be imported into Eclipse. The project is located in folder `[PathToGAMS]/apifiles/Java/Eclipse` and contains the examples based on the **transportation problem**. The following explanations guide you through the import and preparation process, assuming that the Eclipse Java IDE is already installed on your machine.

To import the project located in folder `[PathToGAMS]/apifiles/Java/Eclipse` into the workspace:

1. open the Eclipse IDE with the chosen workspace location, click on **File** menu and choose **Import**.
2. In the **Import** window, choose **General** > **Existing Projects into Workspace** then click **Next**.
3. In the next page of **Import** window, click **Browse..** and select the folder with the prepared project (`[PathToGAMS]/apifiles/Java/Eclipse`) as root directory.

   We recommend to check for option **Copy projects into workspace**. Click **Finish** to finish the **Import** window.
4. Now the project is imported, and appears in the **Package Explorer** window on the left hand side of of the IDE (shown below with its elements expanded).
5. As every example in the project requires GAMS Java API classes files to compile (all classes are packaged in `GAMSJavaAPI.jar` located in the folder `[PathToGAMS]/apifiles/Java/api`), you need to tell eclipse where to find `GAMSJavaAPI.jar`. To do this, either click on the project then choose **Project** > **Properties** or right click on the project name and choose **Properties** .
6. The **Properties** window of the proejct appears. Click **Java Build Path** on the left of the window, choose **Libraries** tab, choose **Add External JARs...**.

   select `GAMSJavaAPI.jar` located in the folder `[PathToGAMS]/apifiles/Java/api` to be opened.

   and click **OK** to finish addding `[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar` to **Java Build Path**.

7. Now all the java files should be successfully compiled without errors except for `Transport10` (unsuccessful compilation is denoted with red x mark in front of the file name). This is because `Transport10` requires an additional `jexcelapi` JAR file `jxl.jar` from jexcelapi. It can be downloaded and unzipped the downloaded archive into a local directory e.g. `C:\tools`. Then the jar file `C:\tools\jexcelapi\jxl.jar` can be added to the the Java Build Path of the project in a similar way as explained in 6.

8. To run a transport example, for example `Transport1`, you need to create a `Run Configuration`.

   To do this, either click **Run** menu and choose **Run Configurations...**

   or open the drop down menu next to the run button and click on **Run Configurations...**.

   Then create a new run configuration by either press the **New** button in the left hand side of the window or right click at **Java Application** in the left hand side of the window and choose **New**.

9. The run configuration for `Transport1` appears.

   For each run configuration it is possible to configure the execution of a program, such as the arguments of the virtual machine, class paths, environment variables and so on.

   For instance, to specify the `java.library.path` for `Transport1` run configuration, choose **Arguments** tab in the run configuration and specify `-Djava.library.path=[PathToGAMS]/apifiles/Java/api` as one of the **VM arguments**. Then Click **Apply** and **Run**.

Note that the run configuration described in 8. and 9. is needed to be set for every single example. Once this is done you should be able to use the run configuration to repeat the execution of all the transport examples.

For a more detailed explanations on each transport examples see How to use API.

7.10.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples. All GAMS Java API classes are contained within one single jar file `GAMSJavaAPI.jar` (or `GAMSJavaAPI-8.jar` for Java SE 8) with a namespace `com.gams.api`. It provides objects to interact with the General Algebraic Modeling System (`GAMS`). Objects in this namespace allow convenient exchange of input data and model results (**GAMSDatabase**) and help to create and run GAMS models (**GAMSJob**), that can be customized by GAMS options (**GAMSOptions**). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (**GAMSModelInstance**).

Other classes are **GAMSWorkspace**, **GAMSOptions**, **GAMSSymbol**, and **GAMSException**.

7.10.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the Java API. `[PathToGAMS]/apifiles/Java/transport` contains multiple examples dealing with the well-known **transportation problem**. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)

- How to import data from GDX (TransportGDX)
- How to run a GAMSJob from file (Transport1)
- How to retrieve a solution from an output database (Transport1)
- How to specify the solver using GAMSOptions (Transport1)
- How to run a job with a solver option file and capture its log output (Transport1)
- How to use include files (Transport2)
- How to set a non-default working directory (Transport3)
- How to read data from string and export to GDX (Transport3)
- How to run a job using data from GDX (Transport3)
- How to run a job using implicit database communication (Transport3)
- How to define data using Java data structures (Transport4)
- How to prepare a GAMSDatabase from Java data structures (Transport4)
- How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
- How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
- How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
- How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
- How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)
- How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)
- How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
- How to fill a GAMSDatabase by reading from MS Access (Transport9)
- How to fill a GAMSDatabase by reading from MS Excel (Transport10)
- How to create and use a save/restart file (Transport11)

7.10.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `Transport1` with C:/GAMS/win64/46.4 we use the 64-bit version of GAMS 46.4 to run `Transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
  GAMSWorkspaceInfo  wsInfo  = new GAMSWorkspaceInfo();
  if (args.length > 0)
     wsInfo.setSystemDirectory( args[0] );
  GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
...
```

Remember that the bitness of the GAMS system has to match the bitness of your Java Runtime Environment.

7.10.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented Java API offers much more than exchanging data between Java and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in Java data structures.

```
...
  List<String> plants = Arrays.asList("Seattle", "San-Diego");
  List<String> markets = Arrays.asList("New-York", "Chicago", "Topeka");
  Map<String, Double> capacity = new HashMap<String, Double>();
  {
    capacity.put("Seattle", Double.valueOf(350.0));
    capacity.put("San-Diego", Double.valueOf(600.0));
  }
  Map<String, Double> demand = new HashMap<String, Double>();
  {
    demand.put("New-York", Double.valueOf(325.0));
    demand.put("Chicago", Double.valueOf(300.0));
    demand.put("Topeka", Double.valueOf(275.0));
  }
  Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
  {
    distance.put( new Vector<String>( Arrays.asList(new String[]{"Seattle", "New-York"}) ), Double.valueOf(2.5));
    distance.put( new Vector<String>( Arrays.asList(new String[]{"Seattle", "Chicago"}) ),  Double.valueOf(1.7));
    distance.put( new Vector<String>( Arrays.asList(new String[]{"Seattle", "Topeka"}) ),  Double.valueOf(1.8));
    distance.put( new Vector<String>( Arrays.asList(new String[]{"San-Diego", "New-York"}) ), Double.valueOf(2.5));
    distance.put( new Vector<String>( Arrays.asList(new String[]{"San-Diego", "Chicago"}) ),  Double.valueOf(1.8));
    distance.put( new Vector<String>( Arrays.asList(new String[]{"San-Diego", "Topeka"}) ),   Double.valueOf(1.4));
  }
...
```

Different type of GAMS symbols are represented using different Java data structures. The data for the GAMS sets is represented using List of Strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by Map (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses Vectors for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Java data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.

```
...
  // create new GAMSDatabase instance
  GAMSDatabase db = ws.addDatabase();
...
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created GAMSSet instance `i` using `GAMSSet.addRecord`.

```
...
  GAMSSet i = db.addSet("i", 1, "canning plants");
  for(String p : plants)
      i.addRecord(p);
...
```

GAMSParameter instances can be added by using the method `GAMSDatabase.addParameter`. In this example we use the overloaded method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```
...
  GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
  for (String p : plants)
      a.addRecord(p).setValue( capacity.get(p) );
...
```

As soon as all data is prepared in the GAMSDatabase, the method `GAMSDatabase.export` can be used to create a GDX file.

```
...
  db.export("data.gdx");
...
```

7.10.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```
...
  GAMSDatabase gdxdb = ws.addDatabaseFromGDX("data.gdx");
...
```

Reading the data from the GAMSSet `i` into a List of Strings can be done as follows:

```
...
  List<String> gdxPlants = new ArrayList<String>();
  for(GAMSSetRecord rec : gdxdb.getSet("i"))
      gdxPlants.add(rec.getKey(0));
...
```

A new List `gdxPlants` is created. `i` is retrieved by calling `GAMSDatabase.getSet` on `gdxdb`. The returned GAMSSet object can be iterated using a for-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameter. Instead of creating a List, we want to have the data in the form of a Map. GAMSParameterRecord can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter `a` into a `Map<String, Double>`.

```
...
  Map<String, Double> gdxCapacity = new HashMap<String, Double>();
  for(GAMSParameterRecord rec : gdxdb.getParameter("a"))
     gdxCapacity.put(rec.getKey(0), rec.getValue());
...
```

For a key of multi dimensional symbol, we choose Vector of String instead of String.

```
...
  Map<Vector<String>, Double> gdxDistance = new HashMap<Vector<String>, Double>();
  for(GAMSParameterRecord rec : gdxdb.getParameter("d"))
      gdxDistance.put( new Vector<String>( Arrays.asList(new String[]{rec.getKey(0), rec.getKey(1)}) ), rec.getValue());
...
```

Scalar can be read into a variable of type double by accessing the value of the first and only record.

```
...
  double gdxFreight = gdxdb.getParameter("f").getFirstRecord().getValue();
...
```

7.10.3.4 How to run a GAMSJob from file (Transport1)

At first we create our workspace using **GAMSWorkspace** `ws = new GAMSWorkspace();`. Afterward we can create a **GAMSJob** `t1` using the **addJobFromGamsLib** method and run it.

Apparently you can create a **GAMSJob** with any other gms file you might have created on your own as long as it is located in the current working directory. Then the **GAMSJob** `t1` can be defined using the **GAMSJob.addJobFromFile** method.

```
...
  // create GAMSWorkspace "ws" with default working directory
  // (the directory named with current date and time under System.getProperty("java.io.tmpdir"))
  GAMSWorkspace ws = new GAMSWorkspace();
  // create GAMSJob "t1" from "trnsport" model in GAMS Model Libraries
  GAMSJob t1 = ws.addJobFromGamsLib("trnsport");
  // run GAMSJob "t1"
  t1.run();
...
```

See also **Transport1.java**.

7.10.3.5 How to retrieve a solution from an output database (Transport1)

The following lines create the solution output and illustrate the usage of the **GAMSJob.OutDB** property to get access to the **GAMSDatabase** created by the **run** method. To retrieve the content of variable `x` we use the **getVariable** method and the **GAMSVariableRecord** class.

```
...
  // retrieve GAMSVariable "x" from GAMSJob's output databases
  System.out.println("Ran with Default:");
  GAMSVariable x = t1.OutDB().getVariable("x");
  for (GAMSVariableRecord rec : x)
  {
      System.out.print("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "):");
      System.out.print(", level = " + rec.getLevel());
      System.out.println(", marginal = " + rec.getMarginal());
  }
...
```

See also **Transport1.java**.

7.10.3.6 How to specify the solver using GAMSOptions (Transport1)

The solver can be specified via the **GAMSOptions** class and the **GAMSWorkspace.addOptions** method. The `GAMSOptions.setAllModelTypes` property sets `xpress` as default solver for all model types which the solver can handle. Then we run our **GAMSJob** `t1` with the new **GAMSOptions**.

```
...
  // create GAMSOptions "opt1"
  GAMSOptions opt1 = ws.addOptions();
  // set all model types of "opt1" for "xpress"
  opt1.setAllModelTypes("xpress");
  // run GAMSJob "t1" with GAMSOptions "opt1"
  t1.run(opt1);
...
```

See also **Transport1.java**.

7.10.3.7 How to run a job with a solver option file and capture its log output (Transport1)

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterward we use a **GAMSOptions** just like in the preceding example and `GAMSOptions.setOptFile` property to 1 to tell the solver to look for a solver option file. We specify the argument `output` in order to stream the log of the GAMSJob into the file `transport1_xpress.log`. When the `output` argument is omitted then the log will be written to standard output.

```
...
  // write file "xpress.opt" under GAMSWorkspace's working directory
  try {
      BufferedWriter optFile = new BufferedWriter(new FileWriter(
                                    ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "xpress.opt"
                               ));
      optFile.write("algorithm=barrier");
      optFile.close();
  } catch(IOException e) {
      e.printStackTrace();
      System.exit(-1);
  }
  // create GAMSOptions "opt2"
  GAMSOptions opt2 = ws.addOptions();
  // set all model types of "opt2" for "xpress"
  opt2.setAllModelTypes( "xpress" );
  // for "opt2", use "xpress.opt" as solver's option file
  opt2.setOptFile(1);
  try {
      // run GAMSJob "t2" with GAMSOptions "opt2" and capture log into "transport1_xpress.log".
      PrintStream output = new PrintStream(new File(ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR
      +"transport1_xpress.log"));
      t1.run(opt2, output);
  } catch (FileNotFoundException e) {
      // run GAMSJob "t2" with GAMSOptions "opt2" and log is written to standard output
      t1.run(opt2);
  }
...
```

See also **Transport1.java**.

7.10.3.8 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings data and model are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
...
  try {
      BufferedWriter file = new BufferedWriter(new FileWriter(
                                ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gms"
                            ));
      file.write(data);
      file.close();
  } catch(IOException e) {
      e.printStackTrace();
      System.exit(-1);
  }
...
```

Afterwards we create a **GAMSJob** using the **GAMSWorkspace.addJobFromString** method. `GAMSOptions.defines` is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where incname is used as name for the include file in the `model` string.

```
...
  // create GAMSJob "t2" from the "model"
  GAMSJob t2 = ws.addJobFromString(model);
  // create GAMSOption "opt" and define "incname" as "tdata"
  GAMSOptions opt = ws.addOptions();
  opt.defines("incname", "tdata");
  // run GAMSJob "t2" with GAMSOptions "opt"
  t2.run(opt);
...
```

The string model contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

See also **Transport2.java**.

7.10.3.9 How to set a non-default working directory (Transport3)

At first we create a new directory. Once this is done we can use this directory when creating the **GAMSWorkspace** and make it the working directory.

```
...
  // create a directory
  File workingDirectory = new File(System.getProperty("user.dir"), "Transport3");
  workingDirectory.mkdir();
  // create a workspace
  GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
  wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
  GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
...
```

See also **Transport3.java**.

7.10.3.10 How to read data from string and export to GDX (Transport3)

We read the data from the string data. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding **GAMSJob** a **GAMSDatabase** is created that is available via the **GAMSJob.OutDB** property. We can use the **GAMSDatabase.export** method to write the content of this database to a gdx file `tdata.gdx`.

```
...
  // Create and run a job from a data file, then explicitly export to a GDX file
  GAMSJob t3 = ws.addJobFromString(data);
  t3.run();
  t3.OutDB().export( ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gdx" );
...
```

See also **Transport3.java**.

7.10.3.11 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in `Transport2` - How to use include files (Transport2)

```
.
...
  // run a job using an instance of GAMSOptions that defines the data include file
  t3 = ws.addJobFromString(model);
  GAMSOptions opt = ws.addOptions();
  opt.defines("gdxincname", "tdata");
  t3.run(opt);
...
```

Note that there are some minor changes in model due to the usage of a gdx instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

See also **Transport3.java**.

7.10.3.12 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two **GAMSJob**s `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding **OutDB** can be read in directly just like a gdx file. Note that the database needs to be passed to the **GAMSJob.run** method as additional argument.

```
...
  GAMSVariable x = t3.OutDB().getVariable("x");
  for (GAMSVariableRecord rec : x)
      System.out.println("x(" + rec.getKeys()[0] + ", " +rec.getKeys()[1] + "): level=" + rec.getLevel() + " marginal=" +
      rec.getMarginal());
  System.out.println();
  // similar to the previous run but without exporting database into a file
  GAMSJob t3a = ws.addJobFromString(data);
  GAMSJob t3b = ws.addJobFromString(model);
  opt = ws.addOptions();
  t3a.run();
  opt.defines("gdxincname", t3a.OutDB().getName());
  t3b.run(opt, t3a.OutDB());
...
```

See also **Transport3.java**.

7.10.3.13 How to define data using Java data structures (Transport4)

We use the `List<E>` class and the `Map<Key,Value>`to define Java data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
...
  // prepare input data
  List<String> plants = Arrays.asList("Seattle", "San-Diego");
  List<String> markets = Arrays.asList("New-York", "Chicago","Topeka");
  Map<String, Double> capacity = new HashMap<String, Double>();
  {
     capacity.put("Seattle", Double.valueOf(350.0));
     capacity.put("San-Diego", Double.valueOf(600.0));
  }
  Map<String, Double> demand = new HashMap<String, Double>();
  {
     demand.put("New-York", Double.valueOf(325.0));
     demand.put("Chicago", Double.valueOf(300.0));
     demand.put("Topeka", Double.valueOf(275.0));
  }
  Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
  {
     distance.put( new Vector<String>( Arrays.asList(new String[]{"Seattle", "New-York"}) ), Double.valueOf(2.5));
     distance.put( new Vector<String>( Arrays.asList(new String[]{"Seattle", "Chicago"}) ), Double.valueOf(1.7));
     distance.put( new Vector<String>( Arrays.asList(new String[]{"Seattle", "Topeka"}) ), Double.valueOf(1.8));
     distance.put( new Vector<String>( Arrays.asList(new String[]{"San-Diego", "New-York"}) ), Double.valueOf(2.5));
     distance.put( new Vector<String>( Arrays.asList(new String[]{"San-Diego", "Chicago"}) ), Double.valueOf(1.8));
     distance.put( new Vector<String>( Arrays.asList(new String[]{"San-Diego", "Topeka"}) ), Double.valueOf(1.4));
  }
...
```

See also **Transport4.java**.

7.10.3.14 How to prepare a GAMSDatabase from Java data structures (Transport4)

At first we create an empty **GAMSDatabase** `db` using the **GAMSWorkspace.addDatabase** method. Afterwards we prepare the database. To add a set to the database we use the **GAMSSet** class and the **GAMSDatabase.addSet** method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Java data structure and add them by using the **GAMSSet.addRecord** method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The **GAMSJob** can be run like explained in the preceding example about implicit database communication.

```
...
  // add a database and add input data into the database
  GAMSDatabase db = ws.addDatabase();
  GAMSSet i = db.addSet("i", 1, "canning plants");
  for(String p : plants)
      i.addRecord(p);
  GAMSSet j = db.addSet("j", 1, "markets");
  for(String m : markets)
      j.addRecord(m);
  GAMSParameter a = db.addParameter("a", 1, "capacity of plant i in cases");
  for (String p : plants)
      a.addRecord(p).setValue( capacity.get(p) );
  GAMSParameter b = db.addParameter("b", 1, "demand at market j in cases");
  for(String m : markets)
      b.addRecord(m).setValue( demand.get(m) );
  GAMSParameter d = db.addParameter("d", 2, "distance in thousands of miles");
  for(Vector<String> vd : distance.keySet())
      d.addRecord(vd).setValue( distance.get(vd).doubleValue() );
  GAMSParameter f = db.addParameter("f", 0, "freight in dollars per case per thousand miles");
  f.addRecord().setValue( 90 );
  // create and run a job from the model and read gdx include file from the database
  GAMSJob t4 = ws.addJobFromString(model);
  GAMSOptions opt = ws.addOptions();
  opt.defines("gdxincname", db.getName());
  t4.run(opt, db);
...
```

See also **Transport4.java**.

7.10.3.15 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following lines of code conduct several operations. While the first line simply creates a **GAMSCheckpoint**, the second one uses the **GAMSWorkspace.addJobFromString** method to create a **GAMSJob** containing the model text and data but no solve statement. Afterwards the run method gets the **GAMSCheckpoint** as argument. That means the **GAMSCheckpoint** `cp` captures the state of the **GAMSJob**.

```
...
  GAMSCheckpoint cp = ws.addCheckpoint();
  GAMSJob t5 = ws.addJobFromString(model);
  t5.run(cp);
...
```

See also **Transport5.java**.

7.10.3.16 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `model` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
```

```
Scalar ms 'model status', ss 'solve status';
...
```

In **Transport5** we create a list with eight different values for this demand multiplier.

```
...
  double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

For each entry of that list we create a **GAMSJob** `t5` using the **GAMSWorkspace.addJobFromString** method. Besides another string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint cp as additional argument. This results in a **GAMSJob** combined from the checkpoint plus the content provided by the string. We run the **GAMSJob** and echo some interesting data from the **OutDB** using the **GAMSDatabase.getParameter** and **GAMSDatabase.getVariable** methods, the **GAMSParameter.findRecord** and **GAMSVariable.findRecord** methods plus the **GAMSParameterRecord.getValue** property and the **GAMSVariableRecord.getLevel** method.

```
...
// create a new GAMSJob that is initialized from the GAMSCheckpoint
for(double b : bmultlist)
{
   t5 = ws.addJobFromString(
         "bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;",
         cp
        );
   t5.run();

   System.out.println("Scenario bmult=" + b + ":");
   System.out.println(
         " Modelstatus: " + GAMSGlobals.ModelStat.lookup(
                              (int) t5.OutDB().getParameter("ms").findRecord().getValue()
                            )
    );
   System.out.println(
         " Solvestatus: " + GAMSGlobals.SolveStat.lookup(
                              (int)t5.OutDB().getParameter("ss").findRecord().getValue()
                            )
   );
   System.out.println(" Obj: " + t5.OutDB().getVariable("z").findRecord().getLevel());
}
...
```

Note

> Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

See also **Transport5.java**.

7.10.3.17 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from **Transport5** in parallel. We initialize the **GAMSCheckpoint** cp and introduce a demand multiplier as we did before :

```
...
  GAMSJob t6 = ws.addJobFromString(model);
  t6.run(cp);
  double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object `lockObject` that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of `bmultlist` and cause a thread to begin execution.

```
...
  // run multiple parallel jobs using the created checkpoint
  Object lockObject = new Object();
  Scenario[] scenarios = new Scenario[bmultlist.length];
  for (int i=0; i<bmultlist.length; i++)
  {
     scenarios[i] = new Scenario(ws, cp, lockObject, bmultlist[i]);
     scenarios[i].start();
```

```
  }
...
```

In class `Scenario` a **GAMSJob** `t6` is created and run just like in the preceding example of **Transport5**. The output section is also the same except for the fact that it is 'locked' by the object `lockObject` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```
...
static class Scenario extends Thread
{
   GAMSWorkspace workspace;
   GAMSCheckpoint checkpoint;
   Object lockObject;
   double bmult;
   public Scenario(GAMSWorkspace ws, GAMSCheckpoint cp, Object lockObj, double b)
   {
      workspace = ws;
      checkpoint = cp;
      lockObject = lockObj;
      bmult = b;
   }
   public void run()
   {
      GAMSJob t6 = workspace.addJobFromString(
                     "bmult=" + bmult +"; solve transport min z use lp; ms=transport.modelstat;ss=transport.solvestat;",
                     checkpoint
                  );
      t6.run();
      // we need to make the output a critical section to avoid messed up report information
      synchronized (lockObject)
      {
          System.out.println("Scenario bmult=" + bmult + ":");
          System.out.println(
                " Modelstatus: " + GAMSGlobals.ModelStat.lookup(
                                      (int) t6.OutDB().getParameter("ms").findRecord().getValue()
                                    )
          );
          System.out.println(
              " Solvestatus: " + GAMSGlobals.SolveStat.lookup(
                                      (int)t6.OutDB().getParameter("ss").findRecord().getValue()
                                   )
          );
          System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
       }
    }
}
...
```

While the output in **Transport5** is strictly ordered subject to the order of the elements of `bmultlist` in **Transport6** the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lockObject`.

If you want a further impression of the impact of the `lockObject`, just rerun **Transport6** but comment out the lock as follows and compare the output.

```
...
      // synchronized (lockObject)
      // {
          System.out.println("Scenario bmult=" + bmult + ":");
          System.out.println(
              " Modelstatus: " + GAMSGlobals.ModelStat.lookup(
                                      (int) t6.OutDB().getParameter("ms").findRecord().getValue()
                                   )
          );
          System.out.println(
              " Solvestatus: " + GAMSGlobals.SolveStat.lookup(
                                    (int)t6.OutDB().getParameter("ss").findRecord().getValue()
                                   )
          );
          System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
       // }
...
```

See also **Transport6.java**.

7.10.3.18 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In **Transport7** the usage of **com::gams::api::GAMSModelInstance** is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the **GAMSModelInstance** `mi` using the **GAMSCheckpoint.addModelInstance** method. Note that the **GAMSJob** again contains no solve statement and the demand multiplier is already included with default value 1.

```
...
  GAMSCheckpoint cp = ws.addCheckpoint();
  // initialize a checkpoint by running a job
  GAMSJob t7 = ws.addJobFromString(model);
  t7.run(cp);
  GAMSModelInstance mi = cp.addModelInstance();
  ...
```

See also **Transport7.java**.

7.10.3.19 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A **GAMSModelInstance** uses a `SyncDB` to maintain the data. We define `bmult` as **GAMSParameter** using the **GAMSParameter** method and specify gurobi as solver. Afterwards the **GAMSModelInstance** is instantiated with 3 arguments, the solve statement, **GAMSOptions** `opt` and **GAMSModifier** `bmult`. The **GAMSModifier** means that `bmult` is modifiable while all other parameters, variables and equations of ModelInstance `mi` stay unchanged. We use the **GAMSParameter.addRecord** method and the **setValue** function to assign a value to `bmult`. That value can be varied afterwards using the **GAMSParameter.getFirstRecord** method to reproduce our well-known example with different demand multipliers.

```
...
  GAMSParameter bmult = mi.SyncDB().addParameter("bmult", 0,"demand multiplier");
  GAMSOptions opt = ws.addOptions();
  opt.setAllModelTypes("gurobi");
  // instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable
  mi.instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
  bmult.addRecord().setValue( 1.0 );
  double[] bmultlist = new double[] { 0.6, 0.7 , 0.8, 0.9, 1.0,1.1, 1.2, 1.3 };
  for (double b : bmultlist)
  {
     bmult.getFirstRecord().setValue( b );
     mi.solve();
     System.out.println("Scenario bmult=" + b + ":");
     System.out.println(" Modelstatus: " + mi.getModelStatus());
     System.out.println(" Solvestatus: " + mi.getSolveStatus());
     System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
  }
...
```

See also **Transport7.java**.

7.10.3.20 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a **GAMSModelInstance** just like in the next to last example. We define `x` as **GAMSVariable** and its upper bound as **GAMSParameter** `xup`. At the following **instantiate** method **GAMSModifier** has 3 arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the **GAMSParameter** that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
  mi = cp.addModelInstance();
  GAMSVariable x = mi.SyncDB().addVariable("x", 2, GAMSGlobals.VarType.POSITIVE, "");
  GAMSParameter xup = mi.SyncDB().addParameter("xup", 2, "upper bound on x");
  // instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable
  mi.instantiate("transport use lp min z", new GAMSModifier(x, GAMSGlobals.UpdateAction.UPPER, xup));
  for (GAMSSetRecord i : t7.OutDB().getSet("i"))
  {
     for (GAMSSetRecord j : t7.OutDB().getSet("j"))
     {
```

```
        xup.clear();
        String[] keys = { i.getKeys()[0], j.getKeys()[0] };
        xup.addRecord(keys).setValue(0);
        mi.solve();
        System.out.println("Scenario link blocked: " + i.getKeys()[0] + " - " + j.getKeys()[0]);
        System.out.println(" Modelstatus: " + mi.getModelStatus());
        System.out.println(" Solvestatus: " + mi.getSolveStatus());
        System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
      }
  }
...
```

See also **Transport7.java**.

7.10.3.21 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a **GAMSCheckpoint** `cp` from a **GAMSJob**. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out principle The object `IOLockObject` is used later to avoid messed up output. Then we call `Scenarios` multiple times in parallel. The number of parallel calls is specified by `numberOfWorkers`.

```
...
  GAMSJob t8 = ws.addJobFromString(model);
  t8.run(cp);
  Queue<Double> bmultQueue = new LinkedList<Double>(
                    Arrays.asList( Double.valueOf(0.6), Double.valueOf(0.7),
                    Double.valueOf(0.8), Double.valueOf(0.9),
                    Double.valueOf(1.0), Double.valueOf(1.1),
                    Double.valueOf(1.2), Double.valueOf(1.3) )
  );
  // solve multiple model instances in parallel
  Object IOLockObject = new Object();
  int numberOfWorkers = 2;
  Scenarios[] scenarios = new Scenarios[numberOfWorkers];
  for (int i=0; i<numberOfWorkers; i++)
  {
     scenarios[i] = new Scenarios( ws, cp, bmultQueue, IOLockObject, i );
     scenarios[i].start();
  }
...
```

In class `Scenarios` we create and instantiate a **GAMSModelInstance** as in the preceding examples and make parameter `bmult` modifiable. Note that we chose `cplex` as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```
...
static class Scenarios extends Thread
{
   GAMSWorkspace workspace;
   GAMSCheckpoint checkpoint;
   Object IOLockObject;
   Queue<Double> bmultQueue;
   int workerNumber;
   public Scenarios(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<Double> que, Object IOLockObj, int i)
   {
        workspace = ws;
        checkpoint = cp;
        IOLockObject = IOLockObj;
        bmultQueue = que;
        workerNumber = i;
   }
   public void run()
   {
       GAMSModelInstance mi = checkpoint.addModelInstance();
       {
          GAMSParameter bmult = mi.SyncDB().addParameter("bmult", 0, "demand multiplier");
          GAMSOptions opt = workspace.addOptions();
          opt.setAllModelTypes("cplex");
          // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
          mi.instantiate("transport use lp min z", opt, new
          GAMSModifier(bmult));
          bmult.addRecord().setValue( 1.0 );
          while (true)
              double b = 0.0;
              // dynamically get a bmult value from the queue instead of passing it to the different threads at creation
      time
              synchronized (bmultQueue)
                  if (bmultQueue.isEmpty())
                      break;
```

```
                else
                    b = bmultQueue.remove();
            }
            bmult.getFirstRecord().setValue(b);
            mi.solve();
            // we need to make the output a critical section to avoid messed up report informations
            synchronized (IOLockObject)
            {
               System.out.println("#"+workerNumber+":Scenario bmult=" + b + ":");
               System.out.println(" Modelstatus: " + mi.getModelStatus());
               System.out.println(" Solvestatus: " + mi.getSolveStatus());
               System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
            }
         }
      }
   }
}
...
```

See also **Transport8.java**.

7.10.3.22 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a **GAMSDatabase** (on Windows platform only). There are a few prerequisites required to run **Transport9** successfully.

- Install a Microsoft access driver on your machine (if none is available) as the driver must be loaded at runtime to connect to a data source file.
- To access the data source file go to Control `Panel\System` and `Security\Administrative Tools\Data Sources` (ODBC) and set up a data source name (DSN) as "transportdsn", leave out user ID and password, and select `[PathToGAMS]/apfiles/Data/tansport.accdb` as the data source file.
- Note that an architecture mismatch between the Driver and Application might cause problems.

We call a function `readDataFromAccess` that finally returns a **GAMSDatabase** as shown below.

```
...
  GAMSDatabase db = readDataFromAccess(ws);
...
```

The function `readDataFromAccess` begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database by specifying the aforementioned data source name (DSN). To finally read in GAMS sets and parameters we call the functions `readSet` and `readParameter`.

```
static GAMSDatabase readDataFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    try {
         // loading the jdbc odbc driver
         Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
         // creating connection to database
         Connection c = DriverManager.getConnection("jdbc:odbc:transportdsn","","");
         // read GAMS sets
         readSet(c, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
         readSet(c, db, "SELECT Market FROM Market", "j", 1, "markets");
         // read GAMS parameters
         readParameter(c, db, "SELECT Plant, Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
         readParameter(c, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
         readParameter(c, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
         c.close();
    } catch (ClassNotFoundException e) {
         System.err.println("Error: Failed to find a driver for the database.");
         e.printStackTrace();
         System.exit(-1);
    } catch (SQLException e) {
         System.err.println("Error: Failed to retrieve data from the database.");
         e.printStackTrace();
         System.exit(-1);
    }
    return db;
}
```

The function `readSet` adds a set to the **GAMSDatabase** that is filled with the data from the MS Access file afterwards. The function `readParameter` works quite similar.

```
static void readSet(Connection c, GAMSDatabase db, String queryString, String setName, int setDimension, String
      setExplanatoryText) throws SQLException
{
    Statement st = c.createStatement();
    ResultSet rs = st.executeQuery(queryString);
    ResultSetMetaData rsmd = rs.getMetaData();
    if (rsmd.getColumnCount() != setDimension)
    {
        System.err.println("Error: Number of fields in select statement does not match setDimemsion.");
        c.close();
        System.exit(-1);
    }
    GAMSSet set = db.addSet(setName, setDimension, setExplanatoryText);
    String[] keys = new String[setDimension];
    while (rs.next())
    {
        for (int idx=0; idx < setDimension; idx++)
            keys[idx] = rs.getString(idx+1);
        set.addRecord( keys );
    }
    st.close();
}
```

Once we read in all the data we can create a **GAMSJob** from the **GAMSDatabase** and run it as usual.

See also **Transport9.java**.

7.10.3.23 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from `[PathToGAMS]\apifiles\Data\transport`

At first we have to add an additional jar file to the `[CLASSESPATH]` since we use the Java Excel API which can be donwnloaded from jexcelapi. We unzipped the Java Excel API folder in `C:\tools`. To compile and run on a Windows platform from the command line go to `C:\GAMS\win64\24.1\apifiles\Java\transport` and use:

```
javac -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar;. t
```

and

```
java -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar;. c
```

If you are using an IDE like Eclipse add `C:\tools\jexcelapi\jxl.jar` to the class path as explained in the Compiling a Program from Java IDE and Running a Program from Java IDE section.

The model is given as string without data like in many examples before and the Excel file `transport.xlsx` is located at `[gamsdir]\apifiles\Data`.

At first we define the input string and create the corresponding input file.

```
...
  String input = gamsdir + "apifiles" +
  GAMSGlobals.FILE_SEPARATOR + "Data" + GAMSGlobals.FILE_SEPARATOR + "transport.xlsx";
  File inputFile = new File(input);
...
```

The following lines address the different worksheets and read in the contained data.

```
...
  int iCount = 0;
  int jCount = 0;
  String[][] capacityData = null;
  String[][] demandData = null;
  String[][] distanceData = null;
  Workbook w;
```

```
  try {
      w = Workbook.getWorkbook(inputFile);
      Sheet capacity = w.getSheet("capacity");
      capacityData = new String[capacity.getRows()][capacity.getColumns()];
      iCount = capacity.getColumns();
      for (int j = 0; j < capacity.getColumns(); j++)
         for (int i = 0; i < capacity.getRows(); i++)
            capacityData[i][j] = capacity.getCell(j, i).getContents();
      Sheet demand = w.getSheet("demand");
      demandData = new String[demand.getRows()][demand.getColumns()];
      jCount = demand.getColumns();
      for (int j = 0; j < demand.getColumns(); j++)
         for (int i = 0; i < demand.getRows(); i++)
          demandData[i][j] = demand.getCell(j, i).getContents();
      Sheet distance = w.getSheet("distance");
      distanceData = new String[distance.getRows()][distance.getColumns()];
      for (int j = 0; j < distance.getColumns(); j++)
         for (int i = 0; i < distance.getRows(); i++)
           distanceData[i][j] = distance.getCell(j, i).getContents();
      w.close();
  } catch (IOException e) {
     e.printStackTrace();
  } catch (BiffException e) {
     e.printStackTrace();
  }
...
```

Now we can create the **GAMSWorkspace** as usual and afterwards create a **GAMSDatabase** and fill it with the workbook data as follows:

```
...
  GAMSDatabase db = ws.addDatabase();
  GAMSSet i = db.addSet("i", 1, "Plants");
  GAMSSet j = db.addSet("j", 1, "Markets");
  GAMSParameter capacityParam = db.addParameter("a", 1, "Capacity");
  GAMSParameter demandParam = db.addParameter("b", 1, "Demand");
  GAMSParameter distanceParam = db.addParameter("d", 2, "Distance");
  for (int ic = 0; ic < iCount; ic++)
  {
    i.addRecord( capacityData[0][ic] );
    capacityParam.addRecord( capacityData[0][ic] ).setValue( Double.valueOf(capacityData[1][ic]).doubleValue() );
  }
  for (int jc = 0; jc < jCount; jc++)
  {
     j.addRecord( demandData[0][jc] );
     demandParam.addRecord( demandData[0][jc] ).setValue( Double.valueOf(demandData[1][jc]).doubleValue() );
     String[] data = null;
     for (int ic = 0; ic < iCount; ic++)
     {
        data =  new String[] { distanceData[ic+1][0], distanceData[0][jc+1] };
        distanceParam.addRecord( data ).setValue( Double.valueOf(distanceData[ic+1][jc+1]) );
     }
  }
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our **GAMSJob** as usual.

```
...
  GAMSOptions opt = ws.addOptions();
  GAMSJob t10 = ws.addJobFromString(model);
  opt.defines("gdxincname", db.getName());
  opt.setAllModelTypes("xpress");
  t10.run(opt, db);
  for (GAMSVariableRecord rec : t10.OutDB().getVariable("x"))
     System.out.println("x(" + rec.getKeys()[0] + "," + rec.getKeys()[1] + "): level=" + rec.getLevel() + " marginal=" +
      rec.getMarginal());
...
```

See also **Transport10.java**.

7.10.3.24 How to create and use a save/restart file (Transport11)

In **Transport11** we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a **GAMSCheckpoint**. From the main function we call the function `CreateSaveRestart` giving it the current working directory and the desired file name as arguments.

```
...
  CreateSaveRestart( workingDirectory, "tbase" );
...
```

In function `CreateSaveRestart` create a workspace with the given working directory. Then we create a **GAMSJob** from a string. Note that the string given via `baseModel` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a **GAMSOptions** to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the **GAMSJob** and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the **addCheckpoint** method accepts identifiers as well as file names as argument.

```
static void CreateSaveRestart(File workingDirectory, String cpFileName)
{
   GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
   wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
   GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
   GAMSJob j1 = ws.addJobFromString(baseModel);
   GAMSOptions opt = ws.addOptions();
   opt.setAction( GAMSOptions.EAction.CompileOnly );
   GAMSCheckpoint cp = ws.addCheckpoint(cpFileName);
   j1.run(opt, cp);
   opt.dispose();
}
```

So what you should keep in mind before we return to further explanations of the main function is, that the file tbase is now in the current working directory and contains a checkpoint. Now in the main function we define some data using Java data structures as we already did in **Transport4** before we create the **GAMSWorkspace** and a **GAMSDatabase**.

```
...
  GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
  wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
  GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
  GAMSDatabase db = ws.addDatabase();
...
```

Afterwards we set up the **GAMSDatabase** like we already did in **Transport4**. Once this is done we run a **GAMSJob** using this data plus the checkpoint stored in file tbase.

```
...
  GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");
  GAMSOptions opt = ws.addOptions();
  GAMSJob t11 = ws.addJobFromString(model, cpBase);
  opt.defines("gdxincname", db.getName());
  opt.setAllModelTypes("xpress");
  t11.run(opt, db);
...
```

Note that the string from which we create job `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the **GAMSDatabase** correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

See also **Transport11.java**.

7.11 Control

GAMS `control` is a sub-module of the Python API that allows for full control over the GAMS system (data, model instances, and solving). It can be used in conjunction with other Python API sub-modules (`numpy` and `transfer`) to boost performance when pushing/pulling data to/from a GAMS model. The `gams.control` package provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this package allow convenient exchange of input data and model results (`GamsDatabase`), help to create and run GAMS models (`GamsJob`), that can be customized by GAMS options (`GamsOptions`). Furthermore, it introduces a way to solve a sequence of closely related model instances in the most efficient way (`GamsModelInstance`).

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute_load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base class GamsWorkspace manages the anchor to the file system. If external file communication is not an issue in a particular Python application, temporary directories and files will be managed by objects in the namespace.

With the exception of GamsWorkspace the objects in the `gams.control` package cannot be accessed across different threads unless the instance is locked. The classes themself are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GamsModelInstance class).

Note

If you use multiple instances of the GamsWorkspace in parallel, you should avoid using the same working directory. Otherwise you may end up with conflicting file names.

The GAMS `control` Python API lacks support for the following GAMS components: Acronyms, support for GAMS compilation/execution errors (GamsJob.run just throws an exception), structured access to listing file, and proper support for solver options.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GamsModelInstances. Some solvers will not even work in a multi-threaded application using GamsModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GamsModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

7.11.1 Recommended Import

GAMS `control` is available with the following import statement once the API has been installed:

Other sub-modules must be imported with separate import statements.

7.11.1.1 Specifying a GAMS System Directory

There are several ways to specify which system directory should be used. On all platforms, the system directory can be specified in the GamsWorkspace constructor. If no system directory is specified by the user, The API tries to find one automatically:

- Windows: Try to find a system directory in the Windows registry.
- Linux: Try to find a system directory in the `PATH` first. If none was found, search `LD_LIBRARY_PATH`.
- OS X: Try to find a system directory in the `PATH` first. If none was found, search `DYLD_LIBRARY_PATH`.

The environment variable `PATH` can be set as follows on Linux and macOS:

```
export PATH=<Path/To/GAMS>:$PATH
```

Note

On Linux and macOS it is recommended to specify the `PATH` only instead of `(DY)LD_LIBRARY_PATH` since this might cause problems loading the correct version of certain modules (e.g. gdx).

7.11.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS `control` API. Their usage is demonstrated by an extensive set of examples in the How to use the API section.

- **gams::control::workspace::GamsWorkspace** Class
- **gams::control::execution::GamsJob** Class
- **gams::control::database::GamsDatabase** Class
- **gams::control::options::GamsOptions** Class
- **gams::control::execution::GamsModelInstance** Class

7.11.3 How to use the API

The GAMS distribution provides several examples that illustrate the usage of the API. `[GAMSDIR]\api\python\examples\c` contains multiple examples dealing with the well-known `transportation problem`. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to import packages/modules from the GAMS control API (transport1.py)
- How to choose the GAMS system (transport1.py)
- How to export data to GDX (transport_gdx.py)
- How to import data from GDX (transport_gdx.py)
- How to run a GamsJob from file (transport1.py)
- How to retrieve a solution from an output database (transport1.py)
- How to specify the solver using GamsOptions (transport1.py)
- How to run a job with a solver option file and capture its log output (transport1.py)
- How to use include files (transport2.py)
- How to read data from string and export to GDX (transport3.py)
- How to run a job using data from GDX (transport3.py)
- How to run a job using implicit database communication (transport3.py)
- How to define data using Python data structures (transport4.py)
- How to prepare a GamsDatabase from Python data structures (transport4.py)
- How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)
- How to initialize a GamsJob from a GamsCheckpoint (transport5.py)
- How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)
- How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)
- How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)
- How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)
- How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)
- How to fill a GamsDatabase by reading from MS Access (transport9.py)
- How to fill a GamsDatabase by reading from MS Excel (transport10.py)
- How to create and use a save/restart file (transport11.py)

7.11.3.1 How to import packages/modules from the GAMS control API (transport1.py)

Before we can start using the GAMS `control` API, it needs to be installed by following the instructions from the Getting Started section. Afterwards we can use the API by importing the `GamsWorkspace` class like this:

```
from gams import GamsWorkspace
```

Conventional Python packages/modules can by imported like that:

```
import os
import sys
```

7.11.3.2 How to choose the GAMS system (transport1.py)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. If we type `python transport1.py` C:/GAMS/42 we use `GAMS 42` to run `transport1.py` even if our default GAMS system might be a different one. This is managed by the following code:

```
...
sys_dir = sys.argv[1] if len(sys.argv) > 1 else None
ws = GamsWorkspace(system_directory=sys_dir)
...
```

7.11.3.3 How to export data to GDX (transport_gdx.py)

Although the GAMS `control` Python API offers much more than exchanging data between Python and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GamsDatabase. We assume that the data to be exported is available in Python data structures.

```
...
    plants = ["Seattle", "San-Diego"]
    markets = ["New-York", "Chicago", "Topeka"]
    capacity = {"Seattle": 350.0, "San-Diego": 600.0}
    demand = {"New-York": 325.0, "Chicago": 300.0, "Topeka": 275.0}
    distance = {
        ("Seattle", "New-York"): 2.5,
        ("Seattle", "Chicago"): 1.7,
        ("Seattle", "Topeka"): 1.8,
        ("San-Diego", "New-York"): 2.5,
        ("San-Diego", "Chicago"): 1.8,
        ("San-Diego", "Topeka"): 1.4,
    }
...
```

Different GAMS symbols are represented using different Python data structures. The data for the GAMS sets is represented using Python lists of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by Python dictionaries (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses Python tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with standard Python data structures.

A new GamsDatabase instance can be created using GamsWorkspace.add_database.

```
...
    # create new GamsDatabase instance
    db = ws.add_database()
...
```

We start adding GAMS sets using the method GamsDatabase.add_set which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created GamsSet instance `i` using GamsSet.add_record.

```
...
    # add 1-dimensional set 'i' with explanatory text 'canning plants' to the GamsDatabase
    i = db.add_set("i", 1, "canning plants")
    for p in plants:
        i.add_record(p)
...
```

GamsParameter instances can be added by using the method GamsDatabase.add_parameter. It has the same signature as GamsDatabase.add_set. Anyhow, in this example we use GamsDatabase.add_parameter_dc instead which takes a list of GamsSet instances instead of the dimension for creating a parameter with domain information.

```
...
    # add parameter 'a' with domain 'i'
    a = db.add_parameter_dc("a", [i], "capacity of plant i in cases")
    for p in plants:
        a.add_record(p).value = capacity[p]
...
```

As soon as all data is prepared in the GamsDatabase, the method GamsDatabase.export can be used to create a GDX file.

```
...
    # export the GamsDatabase to a GDX file with name 'data.gdx' located in the 'working_directory' of the GamsWorkspace
    db.export("data.gdx")
...
```

7.11.3.4 How to import data from GDX (transport_gdx.py)

Data can be imported from a GDX file using GamsWorkspace.add_database_from_gdx. The method takes a path to a GDX file and creates a GamsDatabase instance.

```
...
    # add a new GamsDatabase and initialize it from the GDX file just created
    db2 = ws.add_database_from_gdx("data.gdx")
...
```

Reading the data from the GamsSet `i` into a list can be done as follows:

```
...
    # read data from symbols into Python data structures
    i = [rec.keys[0] for rec in db2["i"]]
...
```

A Python list is created using list comprehensions. `i` is retrieved by querying the GamsDatabase `db2`. The returned GamsSet object can be iterated using a for-loop to access the records of the set. Each record is of type GamsSetRecord and can be asked for its keys.

You can do the same for GamsParameters. Instead of creating a Python list, we want to have the data in the form of a Python dictionary. GamsParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a Python dictionary using dict comprehensions.

```
...
    a = {rec.keys[0]: rec.value for rec in db2["a"]}
...
```

For multi dimensional symbols, we choose the Python dictionary keys to be tuples instead of string. We access the keys as usual, but do not address a specific key. Instead, we take the whole list of keys and turn it into a tuple.

```
...
    d = {tuple(rec.keys): rec.value for rec in db2["d"]}
...
```

Scalars can be read into a Python identifier by accessing the value of the first and only record.

```
...
    f = db2["f"].first_record().value
...
```

7.11.3.5 How to run a GamsJob from file (transport1.py)

At first we create our workspace using `ws = GamsWorkspace()`. Afterwards we load the `trnsport` model from the GAMS model library which puts the corresponding gms file in our working directory. Note that you can create a GamsJob with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GamsJob `job` can be defined using the add_job_from_file method and afterwards we run the job.

```
...
    ws.gamslib("trnsport")
    job = ws.add_job_from_file("trnsport.gms")
    job.run()
...
```

7.11.3.6 How to retrieve a solution from an output database (transport1.py)

The following lines create the solution output and illustrate the usage of the GamsJob.out_db property to get access to the GamsDatabase created by the run method. To retrieve the content of variable `x` we use squared brackets that internally call the get_symbol method.

```
...
    for rec in job.out_db["x"]:
        print(
            f"x({rec.key(0)},{rec.key(1)}): level={rec.level} marginal={rec.marginal}"
        )
...
```

Note that instead of using the squared brackets we could also use

```
...
    for rec in job.out_db.get_symbol("x"):
...
```

7.11.3.7 How to specify the solver using GamsOptions (transport1.py)

The solver can be specified via the GamsOptions class and the GamsWorkspace.add_options method. The GamsOptions.all_model_types property sets xpress as default solver for all model types that can be handled by the solver. Then we run our GamsJob `job` with the new GamsOption.

```
...
    opt = ws.add_options()
    opt.all_model_types = "xpress"
    job.run(opt)
...
```

7.11.3.8 How to run a job with a solver option file and capture its log output (transport1.py)

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterwards we use a GamsOption just like in the preceding example and set GamsOption.optfile property to 1 to tell the solver to look for a solver option file. In addition, we specify the argument `output` in order to write the log of the GamsJob into the file `transport1_xpress.log`.

```
...
    with open(os.path.join(ws.working_directory, "xpress.opt"), "w") as file:
        file.write("algorithm=barrier")
    opt.optfile = 1
    with open("transport1_xpress.log", "w") as log:
        job.run(opt, output=log)
...
```

Instead of writing the log output to a file, any object that provides the functions `write` and `flush` can be used. In order to write the log directly to `stdout`, we can use the following code:

```
...
    job.run(opt, output=sys.stdout)
...
```

7.11.3.9 How to use include files (transport2.py)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings accessed via `GAMS_DATA` and `GAMS_MODEL` are using GAMS syntax. At first we write an include file `tdata.gms` that contains the data but not the model text and save it in our current working directory.

```
...
    with open(os.path.join(ws.working_directory, "tdata.gms"), "w") as file:
        file.write(GAMS_DATA)
...
```

Afterwards we create a GamsJob using the GamsWorkspace.add_job_from_string method. GamsOptions.defines is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where `incname` is used as name for the include file in `GAMS_MODEL` as shown below.

```
...
    job = ws.add_job_from_string(GAMS_MODEL)
    opt = ws.add_options()
    opt.defines["incname"] = "tdata"
    job.run(opt)
...
```

The string `GAMS_MODEL` contains the following lines to read in the data.

```
...
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
...
```

7.11.3.10 How to read data from string and export to GDX (transport3.py)

We read the data from the string `GAMS_DATA`. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding GamsJob a GamsDatabase is created that is available via the GamsJob.out_db property. We can use the GamsDatabase.export method to write the content of this database to a GDX file `tdata.gdx` in the current working directory.

```
...
    job = ws.add_job_from_string(GAMS_DATA)
    job.run()
    job.out_db.export(os.path.join(ws.working_directory, "tdata.gdx"))
...
```

7.11.3.11 How to run a job using data from GDX (transport3.py)

This works quite similar to the usage of an include file explained in How to use include files (transport2.py).

```
...
    job = ws.add_job_from_string(GAMS_MODEL)
    opt = ws.add_options()
    opt.defines["gdxincname"] = "tdata"
    opt.all_model_types = "xpress"
    job.run(opt)
...
```

Note that there are some minor changes in `GAMS_MODEL` compared to preceding examples due to the usage of a GDX instead of an include file.

```
...
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxIn %gdxincname%
$load i j a b d f
$gdxIn
...
```

7.11.3.12 How to run a job using implicit database communication (transport3.py)

This example does basically the same as the two preceding examples together. We create two GamsJobs `job_data` and `job_model` where the first one contains only the data and the second one contains only the model without data. After running `job_data` the corresponding `out_db` can be read in directly just like a GDX file. Note that the database needs to be passed to the GamsJob.run method as additional argument.

```
...
    job_data = ws.add_job_from_string(GAMS_DATA)
    job_model = ws.add_job_from_string(GAMS_MODEL)
    job_data.run()
    opt.defines["gdxincname"] = job_data.out_db.name
    job_model.run(opt, databases=job_data.out_db)
...
```

7.11.3.13 How to define data using Python data structures (transport4.py)

We use Python lists to define the sets and Python dictionaries for the parameter definition.

```
...
    plants = ["Seattle", "San-Diego"]
    markets = ["New-York", "Chicago", "Topeka"]
    capacity = {"Seattle": 350.0, "San-Diego": 600.0}
    demand = {"New-York": 325.0, "Chicago": 300.0, "Topeka": 275.0}
    distance = {
        ("Seattle", "New-York"): 2.5,
        ("Seattle", "Chicago"): 1.7,
        ("Seattle", "Topeka"): 1.8,
        ("San-Diego", "New-York"): 2.5,
        ("San-Diego", "Chicago"): 1.8,
        ("San-Diego", "Topeka"): 1.4,
    }
...
```

7.11.3.14 How to prepare a GamsDatabase from Python data structures (transport4.py)

At first we create an empty GamsDatabase db using the GamsWorkspace.add_database method. Afterwards we prepare the database. To add a set to the database we use the GamsSet class and the GamsDatabase.add_set method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Python data structure and add them by using the GamsSet.add_record method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The GamsJob can be run like explained in the preceding example How to run a job using implicit database communication

```
...
    db = ws.add_database()
    i = db.add_set("i", 1, "canning plants")
    for p in plants:
        i.add_record(p)
    j = db.add_set("j", 1, "markets")
    for m in markets:
        j.add_record(m)
    a = db.add_parameter_dc("a", [i], "capacity of plant i in cases")
    for p in plants:
        a.add_record(p).value = capacity[p]
    b = db.add_parameter_dc("b", [j], "demand at market j in cases")
    for m in markets:
        b.add_record(m).value = demand[m]
    d = db.add_parameter_dc("d", [i, j], "distance in thousands of miles")
    for k, v in distance.items():
        d.add_record(k).value = v
    f = db.add_parameter("f", 0, "freight in dollars per case per thousand miles")
    f.add_record().value = 90
    job = ws.add_job_from_string(GAMS_MODEL)
    opt = ws.add_options()
    opt.defines["gdxincname"] = db.name
    opt.all_model_types = "xpress"
    job.run(opt, databases=db)
...
```

7.11.3.15 How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)

The following lines of code conduct several operations. While the first line simply creates a GamsCheckpoint, the second one uses the GamsWorkspace.add_job_from_string method to create a GamsJob containing the model text and data but no solve statement. Afterwards the run method gets the GamsCheckpoint as argument. That means the GamsCheckpoint `cp` captures the state of the GamsJob.

```
...
    cp = ws.add_checkpoint()
    job = ws.add_job_from_string(GAMS_MODEL)
    job.run(checkpoint=cp)
...
```

7.11.3.16 How to initialize a GamsJob from a GamsCheckpoint (transport5.py)

Note that the string `GAMS_MODEL` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
...
   bmult 'demand multiplier' / 1 /;
...
   demand(j) 'satisfy demand at market j';
...
Scalar ms 'model status', ss 'solve status';
...
```

In transport5.py we create a list with eight different values for this demand multiplier.

```
...
    bmult = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]
...
```

For each entry of that list we create a GamsJob using the GamsWorkspace.add_job_from_string method. Besides another string which resets the demand multiplier `bmult`, specifies the solve statement and assigns

values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a GamsJob combined from the checkpoint plus the content provided by the string.

We run the GamsJob and print some interesting data from the out_db.

```
...
    for b in bmult:
        job = ws.add_job_from_string(
            f"bmult={b}; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;",
            cp,
        )
        job.run()
        print(f"Scenario bmult={b}:")
        print(f"  Modelstatus: {job.out_db['ms'].find_record().value}")
        print(f"  Solvestatus: {job.out_db['ss'].find_record().value}")
        print(f"  Obj: {job.out_db['z'].find_record().level}")
...
```

NOTE: Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

7.11.3.17 How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)

With the exception of GamsWorkspace the objects in the `gams.control` package cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the `GamsModelInstance` class).

Note

> If you use multiple instances of the `GamsWorkspace` in parallel, you should avoid using the same working directory. Otherwise you may end up with conflicting file names.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GamsModelInstances. Some solvers will not even work in a multi-threaded application using GamsModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GamsModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This example illustrates how to run the jobs known from transport5.py in parallel. We initialize the GamsCheckpoint `cp` and introduce a demand multiplier as we did before:

```
...
    cp = ws.add_checkpoint()
    job = ws.add_job_from_string(GAMS_MODEL)
    job.run(checkpoint=cp)
    bmult = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]
...
```

Furthermore, we introduce a lock object `io_lock` that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of `bmultlist` and cause a thread to begin execution.

```
...
    io_lock = Lock()
    threads = {}
    for b in bmult:
        threads[b] = Thread(target=run_scenario, args=(ws, cp, io_lock, b))
        threads[b].start()
    for b in bmult:
        threads[b].join()
...
```

In function `run_scenario` a GamsJob is created and run just like in the preceding example of transport5.py. The output section is also the same except for the fact that it is 'locked' by the object `io_lock` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```
...
def run_scenario(workspace, checkpoint, io_lock, b):
```

```
    job = workspace.add_job_from_string(
        f"bmult={b}; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;",
        checkpoint,
    )
    job.run()
    # we need to make the ouput a critical section to avoid messed up report informations
    io_lock.acquire()
    print(f"Scenario bmult={b}:")
    print(f"  Modelstatus: {job.out_db['ms'].first_record().value}")
    print(f"  Solvestatus: {job.out_db['ss'].first_record().value}")
    print(f"  Obj: {job.out_db['z'].first_record().level}")
    io_lock.release()
...
```

While the output in transport5.py is strictly ordered subject to the order of the elements of `bmult` in transport6.py the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `io_lock` object.

7.11.3.18 How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)

In transport7.py the usage of GamsModelInstance is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Note that the GamsJob `job` again contains no solve statement and the demand multiplier is already included with default value 1. We create the GamsModelInstance `mi` using the GamsCheckpoint.add_modelinstance method.

```
...
    cp = ws.add_checkpoint()
    job = ws.add_job_from_string(GAMS_MODEL)
    job.run(checkpoint=cp)
    mi = cp.add_modelinstance()
...
```

7.11.3.19 How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)

A GamsModelInstance uses a sync_db to maintain the data. We define `bmult` as GamsParameter using the GamsDatabase.add_parameter method and specify gurobi as solver. Afterwards the GamsModelInstance is instantiated with 3 arguments, the solve statement, GamsModifier `bmult` and GamsOptions `opt`. The GamsModifier means that `bmult` is modifiable while all other parameters, variables and equations of GamsModelInstance `mi` stay unchanged. We use the GamsParameter.add_record method to assign a value to `bmult`. That value can be varied afterwards using the GamsParameter.first_record method to reproduce our well-known example with different demand multipliers.

```
...
    bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
    opt = ws.add_options()
    opt.all_model_types = "cplex"
    mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
    bmult.add_record().value = 1.0
    bmult_list = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]
    for b in bmult_list:
        bmult.first_record().value = b
        mi.solve()
        print(f"Scenario bmult={b}:")
        print(f"  Modelstatus: {mi.model_status}")
        print(f"  Solvestatus: {mi.solver_status}")
        print(f"  Obj: {mi.sync_db['z'].first_record().level}")
...
```

7.11.3.20 How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)

We create a GamsModelInstance using the GamsCheckpoint.add_modelinstance method. Afterwards we define `x` as GamsVariable and a GamsParameter `xup` that will be used as upper bound for `x`. At the following instantiate method GamsModifier has 3 arguments. The first one says that `x` is modifieable, the

second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GamsParameter that holds the new value, in this case `xup`.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
...
    mi = cp.add_modelinstance()
    x = mi.sync_db.add_variable("x", 2, VarType.Positive)
    xup = mi.sync_db.add_parameter("xup", 2, "upper bound on x")
    # instantiate the GamsModelInstance and pass a model definition and GamsModifier to declare upper bound of x mutable
    mi.instantiate("transport use lp min z", GamsModifier(x, UpdateAction.Upper, xup))
    mi.solve()
    for i in job.out_db["i"]:
        for j in job.out_db["j"]:
            xup.clear()
            xup.add_record((i.key(0), j.key(0))).value = 0
            mi.solve()
            print(f"Scenario link blocked: {i.key(0)} - {j.key(0)}")
            print(f"  Modelstatus: {mi.model_status}")
            print(f"  Solvestatus: {mi.solver_status}")
            print(f"  Obj: {mi.sync_db['z'].find_record().level}")
...
```

7.11.3.21 How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)

We initialize a GamsCheckpoint `cp` from a GamsJob. Then we define a list that represents the different values of the demand multiplier. That list will be used like a queue where we extract the last element first. The objects `list_lock` and `io_lock` are used later to avoid multiple reading of one demand multiplier and messed up output. Then we call function `scen_solve` multiple times in parallel. The number of parallel calls is specified by `nr_workers`.

```
...
    cp = ws.add_checkpoint()
    job = ws.add_job_from_string(GAMS_MODEL)
    job.run(checkpoint=cp)
    bmult_list = [1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6]
    list_lock = Lock()
    io_lock = Lock()
    # start 2 threads
    nr_workers = 2
    threads = {}
    for i in range(nr_workers):
        threads[i] = Thread(
            target=scen_solve, args=(cp, bmult_list, list_lock, io_lock)
        )
        threads[i].start()
    for i in range(nr_workers):
        threads[i].join()
```

In function `scen_solve` we create and instantiate a GamsModelInstance as in the preceding examples and make parameter `bmult` modifiable. Note that we choose `cplex` as solver because it is thread safe (gurobi would also be possible).

We have two critical sections that are locked by the objects `list_lock` and `io_lock`. Note that the pop method removes and returns the last element from the list and deletes it. Once the list is empty the loop terminates.

```
...
def scen_solve(checkpoint, bmult_list, list_lock, io_lock):
    list_lock.acquire()
    mi = checkpoint.add_modelinstance()
    list_lock.release()
    bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
    opt = ws.add_options()
    opt.all_model_types = "cplex"
    # instantiate the GamsModelInstance and pass a model definition and GamsModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
    bmult.add_record().value = 1.0
    while True:
        # dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
        list_lock.acquire()
        if not bmult_list:
            list_lock.release()
            return
```

```
        b = bmult_list.pop()
        list_lock.release()
        bmult.first_record().value = b
        mi.solve()
        # we need to make the ouput a critical section to avoid messed up report informations
        io_lock.acquire()
        print(f"Scenario bmult={b}:")
        print(f"  Modelstatus: {mi.model_status}")
        print(f"  Solvestatus: {mi.solver_status}")
        print(f"  Obj: {mi.sync_db['z'].first_record().level}")
        io_lock.release()
...
```

7.11.3.22 How to fill a GamsDatabase by reading from MS Access (transport9.py)

This example illustrates how to import data from Microsoft Access to a GamsDatabase. There are a few prerequisites required to run transport9.py successfully.

- We import `pyodbc`.
- Note that an architecture mismatch might cause problems. The bitness of your MS Access, Python, pyodbc and GAMS should be identical (64 bit).

We call a function `read_data_from_access` that finally returns a GamsDatabase as shown below.

```
...
    db = read_from_access(ws)
...
```

The function `read_from_access` begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database `transport.accdb` which can be found in `[GAMSDIR]\apifiles\Data`. To finally read in GAMS sets and parameters we call the functions `read_set` and `read_parameter` that are explained down below.

```
...
def read_from_access(ws):
    db = ws.add_database()
    # connect to database
    str_access_conn = r"DRIVER={Microsoft Access Driver (*.mdb, *.accdb)};DBQ=..\..\..\..\apifiles\Data\transport.accdb"
    try:
        connection = pyodbc.connect(str_access_conn)
    except Exception as e:
        raise Exception(f"Error: Failed to create a database connection.\n{e}")
    # read GAMS sets
    read_set(connection, db, "SELECT Plant FROM plant", "i", 1, "canning plants")
    read_set(connection, db, "SELECT Market FROM Market", "j", 1, "markets")
    # read GAMS parameters
    read_parameter(
        connection,
        db,
        "SELECT Plant,Capacity FROM Plant",
        "a",
        1,
        "capacity of plant i in cases",
    )
    read_parameter(
        connection,
        db,
        "SELECT Market,Demand FROM Market",
        "b",
        1,
        "demand at market j in cases",
    )
    read_parameter(
        connection,
        db,
        "SELECT Plant,Market,Distance FROM Distance",
        "d",
        2,
        "distance in thousands of miles",
    )
    connection.close()
    return db
...
```

The function `read_set` adds a set to the GamsDatabase that is filled with the data from the MS Access file afterwards. The function `read_parameter` works quite similar.

```
...
def read_set(connection, db, query_string, set_name, set_dim, set_exp=""):
    try:
        cursor = connection.cursor()
        cursor.execute(query_string)
        data = cursor.fetchall()
        if len(data[0]) != set_dim:
            raise Exception(
                "Number of fields in select statement does not match setDim"
            )
        i = db.add_set(set_name, set_dim, set_exp)
        for row in data:
            keys = []
            for key in row:
                keys.append(str(key))
            i.add_record(keys)
    except Exception as ex:
        raise Exception(
            "Error: Failed to retrieve the required data from the database.\n{0}".format(
                ex
            )
        )
    finally:
        cursor.close()
...
```

Once we read in all the data we can create a GamsJob from the GamsDatabase and run it as usual.

7.11.3.23 How to fill a GamsDatabase by reading from MS Excel (transport10.py)

This example illustrates how to read data from Excel, or to be more specific, from `[GAMSDIR]\apifiles\Data\transport.xl`

At first you have to download the `openpyxl` package:

```
pip install openpyxl
```

Now you should be able to run transport10.py.

In transport10.py the model is given as string without data like in many examples before and the Excel file `transport.xlsx` is located at `[GAMSDIR]\apifiles\Data`. At first we define the workbook to read from and the different sheet names. To ensure to have the same number of markets and plants in all spreadsheets, we conduct a little test that checks for the number of rows and columns. Our workspace is only created if this test yields no errors.

```
...
    wb = load_workbook(
        os.path.join(*[os.pardir] * 4, "apifiles", "Data", "transport.xlsx")
    )
    capacity = wb["capacity"]
    demand = wb["demand"]
    distance = wb["distance"]
    # number of markets/plants have to be the same in all spreadsheets
    if (
        distance.max_column - 1 != demand.max_column
        or distance.max_row - 1 != capacity.max_row
    ):
        raise Exception("Size of the spreadsheets doesn't match")
...
```

Now we can create a GamsDatabase and read in the data contained in the different worksheets. We iterate over the columns and read in the set names and the corresponding parameter values.

```
...
    db = ws.add_database()
    i = db.add_set("i", 1, "Plants")
    j = db.add_set("j", 1, "Markets")
    capacity_param = db.add_parameter_dc("a", [i], "Capacity")
    demand_param = db.add_parameter_dc("b", [j], "Demand")
    distance_param = db.add_parameter_dc("d", [i, j], "Distance")
    for c in capacity.iter_cols():
        key = c[0].value
        i.add_record(key)
        capacity_param.add_record(key).value = c[1].value
    for c in demand.iter_cols():
        key = c[0].value
        j.add_record(key)
        demand_param.add_record(key).value = c[1].value
```

```
    for c in range(2, distance.max_column + 1):
        for r in range(2, distance.max_row + 1):
            keys = (
                distance.cell(row=r, column=1).value,
                distance.cell(row=1, column=c).value,
            )
            v = distance.cell(row=r, column=c).value
            distance_param.add_record(keys).value = v
...
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our GamsJob as usual.

```
...
    job = ws.add_job_from_string(GAMS_MODEL)
    opt = ws.add_options()
    opt.defines["gdxincname"] = db.name
    opt.all_model_types = "xpress"
    job.run(opt, databases=db)
    for rec in job.out_db["x"]:
        print(
            f"x({rec.key(0)},{rec.key(1)}): level={rec.level} marginal={rec.marginal}"
        )
...
```

7.11.3.24 How to create and use a save/restart file (transport11.py)

In transport11.py we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GamsCheckpoint.

We create a directory `tmp` with internal identifier `w_dir` in the directory we are currently in. This file will be used as working directory later. From the main function we call the function `create_save_restart` giving it directory `tmp` and the desired name for the save/restart file (`tbase`) as arguments.

```
...
    working_dir = os.path.join(os.curdir, "tmp")
    create_save_restart(sys_dir, os.path.join(working_dir, "tbase"))
...
```

In function `create_save_restart` we create a workspace with the given working directory (`w_dir` refers to `tmp`). Then we create a GamsJob from a string. Note that the string given via `get_base_model_text` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a GamsOption to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the GamsJob and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the add_checkpoint method accepts identifiers as well as file names as argument.

```
...
def create_save_restart(sys_dir, cp_file_name):
    ws = GamsWorkspace(os.path.dirname(cp_file_name), sys_dir)
    job_1 = ws.add_job_from_string(GAMS_BASE_MODEL)
    opt = ws.add_options()
    opt.action = Action.CompileOnly
    cp = ws.add_checkpoint(os.path.basename(cp_file_name))
    job_1.run(opt, cp)
...
```

So what you should keep in mind before we return to further explanations of the main function is, that the file `tbase` is now in the current working directory and contains a checkpoint that will work exactly like a restart file.

In the main function we define some data using Python data structures as we already did in [transport4.py] (How to define data using Python data structures (transport4.py)) before we create the GamsWorkspace and a GamsDatabase.

```
...
    sys_dir = sys.argv[1] if len(sys.argv) > 1 else None
    working_dir = os.path.join(os.curdir, "tmp")
    ws = GamsWorkspace(working_dir, sys_dir)
    db = ws.add_database()
...
```

Afterwards we set up the GamsDatabase like we already did in [transport4.py] (How to prepare a GamsDatabase from Pyth
Once this is done we run a GamsJob using this data plus the checkpoint stored in file `tbase`.

```
...
    cp_base = ws.add_checkpoint("tbase")
    job = ws.add_job_from_string(GAMS_MODEL, cp_base)
    opt = ws.add_options()
    opt.defines["gdxincname"] = db.name
    opt.all_model_types = "xpress"
    job.run(opt, databases=db)
...
```

Note that the string from which we create `job` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the GamsDatabase correctly. The entire model definition is delivered by the checkpoint `cp_base` which is equal to the one we saved in `tbase`.

7.12 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Matlab Control API. It allows the user to start immediately working with the API by providing a set of examples based on the well-known **transportation problem**. Those examples are also part of the GAMS system directory, see `[PathToGAMS]/api/matlab/examples/control`. These examples introduce several API features step by step.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- Choose the GAMS system
- Export data to GDX
- Import data from GDX
- Run a Job from file
- Retrieve a solution from an output database
- Specify solver using Options
- Run Job with solver option file and capture log
- Use include files
- Set non-default working directory
- Read data from string and export to GDX
- Run Job using data from GDX
- Run Job using implicit database communication
- Define data using Matlab data structures
- Prepare Database from Matlab data structures
- Initialize Checkpoint by running Job
- Initialize Job from Checkpoint
- Create ModelInstance from Checkpoint
- Modify parameter of ModelInstance using Modifier
- Modify variable of ModelInstance using Modifier
- Create and use save/restart file

7.12.1 Choose the GAMS system

Example: `transport1`

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `transport1` with C:/GAMS/46 we use GAMS 46.4 to run `transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```
wsInfo = gams.control.WorkspaceInfo();
if nargin > 0
  wsInfo.systemDirectory = varargin{1};
end
ws = gams.control.Workspace(wsInfo);
```

Note

The API can detect GAMS automatically from the `PATH` environment variable. Please note that this is not the `MATLABPATH`. You can inspect the `PATH` with `getenv("PATH")`.

In Matlab you can import the GAMS Control package by `import gams.control.*`. Then, you don't need to call the GAMS classes with the preceding `gams.control.`.

7.12.2 Export data to GDX

Example: `transport_gdx`

Although the Matlab Control API offers much more than exchanging data between Matlab and GDX, a common use case is the export and import of GDX files. The central class for this purpose is **Database**. We assume that the data to be exported is available in Matlab data structures.

```
plants = {'Seattle', 'San-Diego'};
markets = {'New-York', 'Chicago', 'Topeka'};
capacity = containers.Map();
capacity('Seattle') = 350;
capacity('San-Diego') = 600;
demand = containers.Map();
demand('New-York') = 325;
demand('Chicago') = 300;
demand('Topeka') = 275;
distance = containers.Map();
distance('Seattle.New-York') = 2.5;
distance('Seattle.Chicago') = 1.7;
distance('Seattle.Topeka') = 1.8;
distance('San-Diego.New-York') = 2.5;
distance('San-Diego.Chicago') = 1.8;
distance('San-Diego.Topeka') = 1.4;
```

Different type of GAMS symbols are represented using different Matlab data structures. The data for the GAMS sets is represented using a cell of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by a `containers.Map` (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses a dot notation for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Matlab data structures.

A new **Database** instance can be created using **Workspace.addDatabase**.

```
db = ws.addDatabase();
```

We start adding GAMS sets using the method **Database.addSet** which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created **Set** instance `i` using **Set.addRecord**.

```
i = db.addSet('i', 1, 'canning plants');
for p = plants
    i.addRecord(p{1});
end
```

Parameter instances can be added by using the method **Database.addParameter**. In this example we use the overloaded method which takes a list of **Set** instances instead of the dimension for creating a parameter with domain information.

```
a = db.addParameter('a', 'capacity of plant i in cases', i);
for p = plants
    rec = a.addRecord(p{1});
    rec.value = capacity(p{1});
end
```

As soon as all data is prepared in the **Database**, the method **Database.export** can be used to create a GDX file.

```
db.export('data.gdx');
```

7.12.3 Import data from GDX

Example: `transport_gdx`

Data can be imported from a GDX file using **Workspace.addDatabaseFromGDX**. The method takes a path to a GDX file and creates a **Database** instance.

```
gdxdb = ws.addDatabaseFromGDX('data.gdx');
```

Reading the data from the **Set** `i` into a cell of strings can be done as follows:

```
gdxPlantsRecords = gdxdb.getSet('i').records;
gdxPlants = cell(size(gdxPlantsRecords));
for i = 1:numel(gdxPlants)
  gdxPlants{i} = gdxPlantsRecords{i}.key(1);
end
```

`i` is retrieved by calling **Database.getSet** on `gdxdb`. The returned **Set** object has an attribute **records** with an cell array of **SetRecords**. Each record can be asked for its keys.

You can do the same for **Parameter**. Instead of creating a cell, we want to have the data in the form of a `containers.Map`. **ParameterRecord** can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter `a` into a map.

```
gdxCapacity = containers.Map();
for rec = gdxdb.getParameter('a').records
  gdxCapacity(rec{1}.key(1)) = rec{1}.value;
end
```

For a key of multi dimensional symbol, we choose a dot based concatenation of keys.

```
gdxDistance = containers.Map();
for rec = gdxdb.getParameter('d').records
  gdxCapacity([rec{1}.key(1), '.', rec{1}.key(2)]) = rec{1}.value;
end
```

Scalar can be read into a variable of type double by accessing the value of the first and only record.

```
gdxFreight = gdxdb.getParameter('f').record.value;
```

7.12.4 Run a Job from file

Example: `transport1`

At first we create our workspace using **Workspace** `ws = gams.control.Workspace();`. Afterwards, we can create a **Job** `t1` using the **Workspace.addJobFromGamsLib** method and run it.

Apparently you can create a **Job** with any other gms file you might have created on your own as long as it is located in the current working directory. Then the **Job** `t1` can be defined using the **Workspace.addJobFromFile** method.

```
% create Workspace "ws" with default working directory
ws = gams.control.Workspace();
% create Job "t1" from "trnsport" model in GAMS Model Libraries
t1 = ws.addJobFromGamsLib('trnsport');
% run Job "t1"
t1.run();
```

7.12.5 Retrieve a solution from an output database

Example: `transport1`

The following lines create the solution output and illustrate the usage of the **Job.outDB** property to get access to the **Database** created by the **Job.run** method. To retrieve the content of variable `x` we use the **Database.getVariable** method and the **VariableRecord** class.

```
% retrieve Variable "x" from Job's output databases
fprintf('Ran with Default:\n');
for x = t1.outDB.getVariable('x').records
    fprintf('x(%s,%s): level=%g marginal=%g\n', x{1}.keys{:}, x{1}.level, x{1}.marginal);
end
```

7.12.6 Specify solver using Options

Example: `transport1`

The solver can be specified via the **Options** class and the **Workspace.addOptions** method. The **Options.setAllModelTypes** property sets `xpress` as default solver for all model types which the solver can handle. Then we run our **Job** `t1` with the new **Options**.

```
% create Options 'opt1'
opt1 = ws.addOptions();
% set all model types of 'opt1' for 'xpress'
opt1.setAllModelTypes('xpress');
% run Job 't1' with Options 'opt1'
t1.run(opt1);
```

7.12.7 Run Job with solver option file and capture log

Example: `transport1`

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterward we use **Options** just like in the preceding example and **Options.optFile** property to 1 to tell the solver to look for a solver option file. We specify the argument `output` in order to stream the log of the **Job** into the file `transport1_xpress.log`. When the `output` argument is omitted then the log will be written to standard output.

```
% write file 'xpress.opt' under Workspace's working directory
fid = fopen(fullfile(ws.workingDirectory, 'xpress.opt'), 'w');
fprintf(fid, 'algorithm=barrier');
fclose(fid);
% create Options 'opt2'
opt2 = ws.addOptions();
% set all model types of 'opt2' for 'xpress'
opt2.setAllModelTypes('xpress');
% for 'opt2', use 'xpress.opt' as solver's option file
opt2.optFile = 1;
% run Job 't2' with Options 'opt2' and capture log into 'transport1_xpress.log'.
output = gams.control.PrintStream(fullfile(ws.workingDirectory, 'transport1_xpress.log'));
t1.run(opt2, output);
```

7.12.8 Use include files

Example: `transport2`

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings `data` and `model` are using GAMS syntax.

At first we write an include file `tdata.gms` that contains the data but not the model text:

```
% write 'data' into file 'tdata.gms' under Workspace's working directory
fid = fopen(fullfile(ws.workingDirectory, 'tdata.gms'), 'w');
fprintf(fid, data);
fclose(fid);
```

Afterwards we create a **Job** using the **Workspace.addJobFromString** method. **Options.defines** is used like the the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where incname is used as name for the include file in the `model` string.

```
% create Job 't2' from the 'model' string variable
t2 = ws.addJobFromString(model);
% create Options 'opt' and define 'incname' as 'tdata'
opt = ws.addOptions();
opt.defines('incname', 'tdata');
% run Job 't2' with Options 'opt'
t2.run(opt);
```

The string model contains the following lines to read in the data.

```
$if not set incname $abort 'no include file name for data file provided'
$include %incname%
```

7.12.9 Set non-default working directory

Example: `transport3`

At first we create a new directory. Once this is done we can use this directory when creating the **Workspace** and make it the working directory.

```
% create a directory
workingDirectory = fullfile(pwd, 'transport3');
mkdir(workingDirectory);
% create a workspace
wsInfo = gams.control.WorkspaceInfo();
wsInfo.workingDirectory = workingDirectory;
ws = gams.control.Workspace(wsInfo);
```

7.12.10 Read data from string and export to GDX

Example: `transport3`

We read the data from the string data. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding **Job** a **Database** is created that is available via the **Job.outDB** property. We can use the **Database.export** method to write the content of this database to a gdx file `tdata.gdx`.

```
% create and run a job from a data file, then explicitly export to a GDX file
t3 = ws.addJobFromString(data);
t3.run();
t3.outDB.export(fullfile(ws.workingDirectory, 'tdata.gdx'));
```

7.12.11 Run Job using data from GDX

Example: `transport3`

This works quite similar to the usage of an include file explained in `transport2` - Use include files .

```
% run a job using an instance of Options that defines the data include file
t3 = ws.addJobFromString(model);
opt = ws.addOptions();
opt.defines('gdxincname', 'tdata');
t3.run(opt);
```

Note that there are some minor changes in the model due to the usage of a gdx instead of an include file.

```
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
```

7.12.12 Run Job using implicit database communication

Example: `transport3`

This example does basically the same as the two preceding examples together. We create two **Jobs** `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding **Job.outDB** can be read in directly just like a gdx file. Note that the database needs to be passed to the **Job.run** method as additional argument.

```
t3a = ws.addJobFromString(data);
t3b = ws.addJobFromString(model);
opt = ws.addOptions();
t3a.run();
opt.defines('gdxincname', t3a.outDB.name);
t3b.run(opt, t3a.outDB);
```

7.12.13 Define data using Matlab data structures

Example: `transport4`

We use cell arrays and `containers.Map` to define Matlab data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```
plants = {'Seattle', 'San-Diego'};
markets = {'New-York', 'Chicago', 'Topeka'};
capacity = containers.Map();
capacity('Seattle') = 350;
capacity('San-Diego') = 600;
demand = containers.Map();
demand('New-York') = 325;
demand('Chicago') = 300;
demand('Topeka') = 275;
distance = containers.Map();
distance('Seattle.New-York') = 2.5;
distance('Seattle.Chicago') = 1.7;
distance('Seattle.Topeka') = 1.8;
distance('San-Diego.New-York') = 2.5;
distance('San-Diego.Chicago') = 1.8;
distance('San-Diego.Topeka') = 1.4;
```

7.12.14 Prepare Database from Matlab data structures

Example: `transport4`

At first we create an empty **Database** `db` using the **Workspace.addDatabase** method. Afterwards we prepare the database. To add a set to the database we use the **Set** class and the **Database.addSet** method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Matlab data structure and add them by using the **Set.addRecord** method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The **Job** can be run like explained in the preceding example about implicit database communication.

```
db = ws.addDatabase();
i = db.addSet('i', 1, 'canning plants');
for p = plants
  i.addRecord(p{1});
end
j = db.addSet('j', 1, 'markets');
for m = markets
  j.addRecord(m{1});
end
a = db.addParameter('a', 'capacity of plant i in cases', i);
for p = plants
  rec = a.addRecord(p{1});
  rec.value = capacity(p{1});
```

```
end
b = db.addParameter('b', 'demand at market j in cases', j);
for m = markets
  rec = b.addRecord(m{1});
  rec.value = demand(m{1});
end
d = db.addParameter('d', 'distance in thousands of miles', i, j);
for p = plants
  for m = markets
    rec = d.addRecord(p{1}, m{1});
    rec.value = distance([p{1}, '.', m{1}]);
  end
end
f = db.addParameter('f', 'freight in dollars per case per thousand miles');
rec = f.addRecord();
rec.value = 90;
% create and run a job from the model and read gdx include file from the database
t4 = ws.addJobFromString(model);
opt = ws.addOptions();
opt.defines('gdxincname', db.name);
t4.run(opt, db);
```

7.12.15 Initialize Checkpoint by running Job

Example: `transport5`

The following lines of code conduct several operations. While the first line simply creates a **Checkpoint**, the second one uses the **Workspace.addJobFromString** method to create a **Job** containing the model text and data but no solve statement. Afterwards the run method gets the **Checkpoint** as argument. That means the **Checkpoint** `cp` captures the state of the **Job**.

```
cp = ws.addCheckpoint();
t5 = ws.addJobFromString(model);
t5.run(cp);
```

7.12.16 Initialize Job from Checkpoint

Example: `transport5`

Note that the string returned from function `model` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
```

In `transport5` we create a list with eight different values for this demand multiplier.

```
bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3];
```

For each entry of that list we create a **Job** `t5` using the **Workspace.addJobFromString** method. Besides another string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint cp as additional argument. This results in a **Job** combined from the checkpoint plus the content provided by the string. We run the **Job** and echo some interesting data from the **Job.outDB** using the **Database.getParameter** and **Database.getVariable** methods and the **Symbol.record** attribute plus the **ParameterRecord.value** and the **VariableRecord.level** properties.

```
for i = 1:numel(bmultlist)
  job = sprintf('bmult=%f; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;', bmultlist(i));
  t5 = ws.addJobFromString(job, cp);
  t5.run();
  fprintf('Scenario bmult=%f:\n', bmultlist(i));
  fprintf('  Modelstatus: %s\n', gams.control.globals.ModelStat(t5.outDB.getParameter('ms').record.value).select);
  fprintf('  Solvestatus: %s\n', gams.control.globals.SolveStat(t5.outDB.getParameter('ss').record.value).select);
  fprintf('  Obj: %f\n', t5.outDB.getVariable('z').record.level);
end
```

Note

> Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

7.12.17 Create ModelInstance from Checkpoint

Example: transport7

In transport7 the usage of **matlab::gams::control::ModelInstance** is demonstrated.

At first **Checkpoint** cp is created as in the preceding examples. Then we create the **ModelInstance** mi using the **Checkpoint.addModelInstance** method. Note that the **Job** again contains no solve statement and the demand multiplier is already included with default value 1.

```
cp = ws.addCheckpoint();
% initialize a checkpoint by running a job
t7 = ws.addJobFromString(model);
t7.run(cp);
% create a ModelInstance and solve it multiple times with different scalar bmult
mi = cp.addModelInstance();
```

7.12.18 Modify parameter of ModelInstance using Modifier

Example: transport7

A **ModelInstance** uses a **matlab::gams::control::ModelInstance::syncDB** ModelInstance.syncDB to maintain the data. We define bmult as **Parameter** using the **Parameter** method and specify cplex as solver. Afterwards the **ModelInstance** is instantiated with 3 arguments, the solve statement, **Options** opt and **Modifier** bmult. The **Modifier** means that bmult is modifiable while all other parameters, variables and equations of **ModelInstance** mi stay unchanged. We use the **Parameter.addRecord** method and the **ParameterRecord.value** property to assign a value to bmult. That value can be varied afterwards using the **Symbol.record** property to reproduce our well-known example with different demand multipliers.

```
bmult = mi.syncDB.addParameter('bmult', 'demand multiplier');
opt = ws.addOptions();
opt.setAllModelTypes('cplex');
% instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable
mi.instantiate('transport use lp min z', opt, gams.control.Modifier(bmult));
rec = bmult.addRecord();
rec.value = 1.0;
bmultlist = [0.6, 0.7 , 0.8, 0.9, 1.0, 1.1, 1.2, 1.3];
for i = 1:numel(bmultlist)
  rec.value = bmultlist(i);
  mi.solve();
  fprintf('Scenario bmult=%f:\n', bmultlist(i));
  fprintf('  Modelstatus: %s\n', mi.modelStatus);
  fprintf('  Solvestatus: %s\n', mi.solveStatus);
  fprintf('  Obj: %f\n', mi.syncDB.getVariable('z').record.level);
end
```

7.12.19 Modify variable of ModelInstance using Modifier

Example: transport7

We create a **ModelInstance** just like in the next to last example. We define x as **Variable** and its upper bound as **Parameter** xup. At the following **ModelInstance.instantiate** method **Modifier** has 3 arguments. The first one says that x is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the **Parameter** that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```
mi = cp.addModelInstance();
x = mi.syncDB.addVariable('x', 2, gams.control.globals.VarType.POSITIVE, '');
xup = mi.syncDB.addParameter('xup', 2, 'upper bound on x');
% instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable
mi.instantiate('transport use lp min z', gams.control.Modifier(x, gams.control.globals.UpdateAction.UPPER, xup));
for i = t7.outDB.getSet('i').records
```

```
  for j = t7.outDB.getSet('j').records
    xup.clear();
    keys = {i{1}.key(1), j{1}.key(1)};
    rec = xup.addRecord(keys);
    rec.value = 0;
    mi.solve();
    fprintf('Scenario link blocked: %s - %s\n', keys{:});
    fprintf('  Modelstatus: %s\n', mi.modelStatus);
    fprintf('  Solvestatus: %s\n', mi.solveStatus);
    fprintf('  Obj: %f\n', mi.syncDB.getVariable('z').record.level);
  end
end
```

7.12.20 Create and use save/restart file

Example: `transport11`

In `transport11` we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a **Checkpoint**. From the main function we call the function `create_save_restart` giving it the current workspace settings and the desired file name as arguments.

```
create_save_restart(ws.workingDirectory, ws.systemDirectory, ws.debugLevel, 'tbase');
```

In function `create_save_restart` we create a workspace with the given workspace settings. Then we create a **Job** from a string. Note that the string given via `basemodel` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a **Options** to only compile the job but do not execute it. Then we create a **Checkpoint** `cp` that is initialized by the following run of the **Job** and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the **Workspace.addCheckpoint** method accepts identifiers as well as file names as argument.

```
ws = gams.control.Workspace(workdir, systemdir, debuglevel);
j1 = ws.addJobFromString(basemodel);
opt = ws.addOptions();
opt.action = gams.control.options.Action.CompileOnly;
cp = ws.addCheckpoint('tbase');
j1.run(opt, cp);
opt.dispose();
j1.outDB.dispose();
```

So what you should keep in mind before we return to further explanations of the main function is, that the file tbase is now in the current working directory and contains a checkpoint. Now in the main function we define some data using Matlab data structures as we already did in `transport4` before we create the **Workspace** and a **Database**.

```
ws = gams.control.Workspace(wsInfo);
db = ws.addDatabase();
```

Afterwards we set up the **Database** like we already did in `transport4`. Once this is done we run a **Job** using this data plus the checkpoint stored in file tbase.

```
cpBase = ws.addCheckpoint('tbase');
opt = ws.addOptions();
t11 = ws.addJobFromString(model, cpBase);
opt.defines('gdxincname', db.name);
opt.setAllModelTypes('xpress');
t11.run(opt, db);
```

Note that the string from which we create **Job** `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the **Database** correctly. The entire model definition is delivered by the **Checkpoint** `cpBase` which is equal to the one we saved in `tbase`.

7.13 Release Notes

7.13.1 44.1.0 (July 2023)

- Added method `runEngine` to `GAMSJob` class to run jobs on GAMS Engine.

- since GAMS 44.1.0
  - all classes in `GAMSJavaAPI.jar` require Java SE 11 or later to run. `GAMSJavaAPI.jar` has additional dependency on `json-simple-1.1.1.jar`. `GAMSJavaAPI.jar` and `json-simple-1.1.1.jar` are required to be in the same directory to run.
  - all classes that work with Java SE 8 are in `GAMSJavaAPI-8.jar` but without updated functionalities that are released after GAMS 43. Only corrective maintenance support will be provided for this version in the future.
  - all jar files are located under the `[Path/To/GAMS]/apifiles/Java/api/` directory.

7.13.2 43.1.0 (April 2023)

- **GAMSModelInstance** of this version is no longer compatible with GAMS 33 or older.

7.13.3 39.1.0 (April 2022)

- Added `GAMSSet.getSetType` returning property to distinguish between `multi` and `singleton` sets.
- Added `GAMSDatabase.addSet` allowing to set type of Set.
- Fixed defined enumerated value for options **FDOpt** and **DumpOpt**.

7.13.4 35.1.0 (April 2021)

- Fixed `GAMSOptions.setOutput` parameter being ignored in `GAMSJob.run()`.

7.13.5 32.1.0 (July 2020)

- On windows platform, change of window registry configuration used for finding the installed GAMS directory from: `[HKEY_CURRENT_USER|HKEY_CLASSES_ROOT]\gams.location` to: `[HKEY_CURRENT_USER|HKEY_LOCAL_MACHINE]\Software\Classes\gams.location`, effective only when the installed GAMS directory is not found from "PATH" environment variable.

7.13.6 29.1.0 (November 2019)

- Increase the minimum version requirement of the Java Runtime Environment to Java SE 8.
- The remove operation **GAMSDatabaseIterator.remove** is no longer supported. The method now throws an instance of `java.lang.UnsupportedOperationException` and performs no other actions. (To remove all records of the current iterating symbol, use the method **GAMSSymbol.clear** instead.)
- Fixed the behavior of the remove operation **GAMSSymbolIterator.remove**. The method now removes all records of the last GAMSSymbol element returned by an instance of **GAMSSymbolIterator** and can be called only once per call to **GAMSSymbolIterator.next**. The behavior of an iterator is unspecified if the underlying collection is modified while the iteration is in progress in any way other than by calling the method.

7.13.7 28.2.0 (August 2019)

- Added new method **GAMSSymbolRecord.dispose** for on-demand release of external resources hold by non-java library.

7.13.8 28.1.0 (August 2019)

- Announced a plan to increase the minimum version requirement of the Java Runtime Environment to Java SE 8 with the next major release.

7.13.9 25.1.1 (May 2018)

- Changed the naming scheme of a temporary working directory to be created from `yyyyMMdd_HHmmss` to the prefixed `gams_` (defined by `GAMSGlobals.workingDirectoryPrefix`), in case no working directory has been specified.
- Fixed the behavior when GAMSDatabase is added with the name that already exists, now GAMSException will be raised. (see **GAMSWorkspace.addDatabase(String databaseName)** and **GAMSWorkspace.addDatabaseFromGDX(String gdxFileName, String databaseName)**)
- Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available. As calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommened to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See **GAMSDatabase.dispose**, **GAMSModelInstance.dispose**, and GAMSOptions.dispose.
- All Java native interfaces to Expert-Level APIs are now included in the distributed `GAMSJavaAPI.jar`, located under the `[Path/To/GAMS]/apifiles/Java/api/` directory.

7.13.10 25.0.1 (January 2018)

- The minimum version requirement of Java Runtime Environment for using with GAMS Java API is now Java SE 7.
- New `TransportGDX` example to demonstrate how to import and export GDX files.
- Removed `GAMSSymbol.compact`, deprecated since 24.8.1 (December 2016).
- Changed equivalence behavior of `GAMSSymbol` and `GAMSSymbolRecord` objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
  - Two symbols are equivalent if and only if they have the same internal reference.
  - Two symbol records are equivalent if and only if they have the same internal reference.

  The behavior of operator `==` remains unchanged. The following exmaple illustrates the new equivalence behavior:

```
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
GAMSVariable x3 = x1;
assertTrue(x1.equals(x2));   // true,  previously false
assertFalse(x1 == x2);       // false, previously false
assertTrue(x1.equals(x3));   // true,  previously true
assertTrue(x1 == x3);        // true,  previously true
```

7.13.11 24.8.1 (December 2016)

- Deprecated `GAMSSymbol.compact` and the method will be removed in the next major release
- an exception or an error thrown by GAMSWorkspace.finalize and GAMSSymbolIterator.finalize now must be caught or declared to be thrown. Note that an explicit call on one of these two methods is not recommended unless it is necessary to do so.

7.13.12 24.7.4 (September 2016)

- **GAMSModelInstance.instantiate**: Skip creation of GDX file, which was unreachable from within the API anyway

7.13.13 24.7.1 (March 2016)

- Fixed a bug with the property GAMSOptions.defines : When too many entries were added, all of them were ignored.

7.13.14 24.5.1 (August 2015)

- New examples
  - **Clad** at `[Path/To/GAMS]/apifiles/Java/clad/Clad.java`
  - **SpecialValues** at `[Path/To/GAMS]/apifiles/Java/specialvalues/SpecialValues.java`
- New functions **GAMSWorkspace.addJobFromApiLib** and **GAMSWorkspace.addJobFromNoaLib** that can be used to retrieve models from **GAMS API Library** and **Nonlinear Optimization Applications Library**.

7.13.15 24.4.2 (March 2015)

- New property **GAMSSymbol.getDomainsAsStrings**: get domains of symbol, each element is a string
  Note: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.
- Disable unwanted debug output from Couenne when running with **GAMSModelInstance**
- Change naming scheme of gdx oputput scratch file to sequence number.

7.13.16 24.4.1 (December 2014)

- Modify the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of **GAMSSymbol** in a **GAMSDatabase**, the Aliases will be excluded.
  - If we iterate over all **GAMSSymbol** in a **GAMSDatabase**, Aliases will be skipped.
  - If we ask explicitly for an Alias in a **GAMSDatabase** (**GAMSDatabase.getSet**("a") with a being an Alias) we will get a reference to the **GAMSSet** referenced by the Alias, not the Alias itself.
  - Note:
    - Aliases can appear in a **GAMSDatabase** only, if it was initialized by a GDX file containing an Alias.
    - The new example **Alias** at `[Path/To/GAMS]/apifiles/Java/alias/Alias.java` demonstrates this new behavior.

7.13.17 24.3.3 (September 2014)

Fixed

- a location of listing file when creating a job from (full-path) file without giving a job name

7.13.18 24.3.2 (August 2014)

- Make more GAMS options available through the **GAMSOptions** class:
  - GAMSOptions.EAppendExpand (**enum**, `getter`, and `setter`): Expand file append option
  - GAMSOptions.EAppendOut (**enum**, `getter`, and `setter`): Output file append option
  - GAMSOptions.EDumpOpt (**enum**, `getter`, and `setter`): Writes preprocessed input to the file input.dmp
  - GAMSOptions.EDumpParms (**enum**, `getter`, and `setter`): GAMS parameter logging
  - GAMSOptions.EErrMsg (**enum**, `getter`, and `setter`): Placing of compilation error messages
  - GAMSOptions.EAppendExpand (`getter`, and `setter`): Expanded (include) input file name
  - GAMSOptions.FErr (`getter`, and `setter`): Alternative error message file
  - GAMSOptions.JobTrace (`getter`, and sette): Job trace string to be written to the trace file at the end of a Gams job
  - GAMSOptions.LimCol (`getter`, and `setter`): Maximum number of columns listed in one variable block
  - GAMSOptions.LimRow (`getter`, and `setter`): Maximum number of rows listed in one equation block
  - GAMSOptions.ELogLine (enum, `getter`, and `setter`): Amount of line tracing to the log file
  - GAMSOptions.EOn115 (**enum**, `getter`, and `setter`): Generate errors for unknown unique element in an equation
  - GAMSOptions.Output (`getter`, and `setter`): Output file
  - GAMSOptions.EPageContr (**enum**, `getter`, and `setter`): Output file page control option
  - GAMSOptions.PageSize (`getter`, and `setter`): Output file page size (`=0` no paging)
  - GAMSOptions.PageWidth (`getter`, and `setter`): Output file page width
  - GAMSOptions.Reference (`getter`, and `setter`): Symbol reference file
  - GAMSOptions.ScriptExit (`getter`, and `setter`): Program or script to be executed at the end of a GAMS run
  - GAMSOptions.ESuppress (enum, `getter`, and `setter`): Compiler listing option
  - GAMSOptions.Symbol (`getter`, and `setter`): Symbol table file
  - GAMSOptions.TraceLevel (`getter`, and `setter`): Solvestat threshold used in conjunction with `a=GT`

7.13.19 24.3.1 (July 2014)

New

- **Transport14** example at `[Path/To/GAMS]/apifiles/Java/transport/Transport14.java`.
- **GAMSSymbolRecord.getKey** method: to retrieve key of **GAMSWorkspace** on specified position index.

Changed

- no longer necessary to set up environment variable before running a program
  - possible to specify the GAMS system directory during run time using **GAMSWorkspaceInfo.setSystemDirectory(String directory)** and **GAMSWorkspace(GAMSWorkspaceInfo info)**
- no longer necessary to specify `-Djava.library.path` when running a program
  - if `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`
  - otherwise the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.
- when exporting a database to GDX: a symbol with real domains from now on will be registered
- in **GAMSJob.run** : always creates output database `OutDB` even if **GAMSExecutionException** has been raised.
- in **GAMSSymbol.copySymbol** when copy into the Universe symbol (**GAMSDatabase.getSet**("∗")) of a **GAMSDatabase** : merge operation will be performed.
- in **GAMSWorkspace** default constructor: API will apply the default setting, that is, finding GAMS system directory from environment variable in the following order (depends on the target platform):
  - Windows: first from `PATH` environment variable. If not found, from the platform windows registry `gams.location`,
  - macOS: first from `PATH` environment variable. If not found, from `DYLD_LIBRARY_PATH`,
  - Unix: from `PATH` environment variable. If not found, from `LD_LIBRARY_PATH`.
- in non-default **GAMSWorkspace** constructor:
  - user can specify a GAMS system directory during run time, API will not search for a GAMS system directory from an environment variable.
  - in case the specified system directory is null or user speicify other workspace attributes but a system directory, API will apply the default setting (see changed in **GAMSWorkspace** default constructor above).

Fixed

- API memory leak issue in **GAMSDatabaseIterator**.
- a bug when reading an option file on Unix platform with non-standard locale

Removed

- all deprecated classes and methods since 24.1.

7.13.20 24.2.3 (May 2014)

Fixed

- API memory leak issue in **GAMSDatabase**.
- a bug in **GAMSDatabase.getDatabaseDomainViolations**.

7.13.21 24.2.2 (March 2014)

Changed

- null string is treated as an invalid key for all record operations of **GAMSSymbol**.

Fixed

- a bug when creating **GAMSDatabase** from source database.
- a bug when initializing a variable type in **GAMSVariable**.
- a bug in **GAMSSymbol**: methods **getVarType** and **getEquType**.
- a bug in **GAMSWorkspaceInfo** : method **getSystemDirectory**.
- exit codes in **GAMSGlobals.ExitCodeMessage**. Improved
- **GAMSModelInstance.instantiate**: make sure that the method does not solve the model, but only prepares everything required for the following **GAMSModelInstance.solve**.

7.13.22 24.2.1 (December 2013)

New

- tutorial: (`GAMS_java_Tutorial.pdf`) under <`Path/To/GAMS`>`/docs/API`. From the GAMSIDE this document can be accessed at Help -> Docs -> API.
- method in **GAMSGlobals.SpecialValues** : **setValue**, to set a GAMS special value
- method in **GAMSOptions**: export, to write an option into a parameter file
- methods in **GAMSWorkspace** : **addOptions** to create a **GAMSOptions** object from either another object or an option file
- methods in **GAMSWorkspace**: **getAPIVersion**, **getAPIMajorReleaseNumber**, **getAPIMinorReleaseNumber**, and **getAPIGoldReleaseNumber**, to retrieve API version number

Changed

- default value of **GAMSGlobals.SpecialValues**: **NAN**, **PLUS_INF**, **MINUS_INF**, and **EPS**
- deprecated `GAMSGlobals.ModelStat.NONOPTIMAL_INTERMED`, replaced by **GAMSGlobals.ModelStat.FEASIBLE**
- deprecated `GAMSOptions.PoolFree4`, replaced by **GAMSOptions.EIntVarUp**
- deprecated the type of `GAMSOptions.NoNewVarEqu`, replaced by enum **GAMSOptions.ENoNewVarEqu**

Fixed

- a bug when running a job with an input directory `IDir` added into **GAMSOptions** object.

7.13.23 24.1.3 (July 2013)

Improve data iterator

- New classes:
  - **GAMSDatabaseIterator** implements `java.util.Iterator`
  - **GAMSSymbolIterator** implements `java.util.Iterator`
- Deprecated Interface:
  - `GAMSSymbolIterable`, replaced by **GAMSDatabaseIterator** and **GAMSSymbolIterator**
- Changes in **GAMSDatabase** :
  - **GAMSDatabase** implements **GAMSDatabaseIterator** instead of `GAMSSymbolIterable`
  - deprecated the implemented methods of `GAMSSymbolIterable`: next(), hasnext(), and remove()
- Changes in **GAMSSymbol**:
  - **GAMSSymbol** implements **GAMSSymbolIterator** instead of `GAMSSymbolIterable`
  - deprecated the implemented methods of `GAMSSymbolIterable`: next(), hasnext(), and remove()
- New methods in **GAMSSymbolRecord**:
  - **moveNext**: to iterate to the next record using the current data iterator criterion
  - **movePrevious** : to iterate to the previous record using the current data iterator criterion

Update example:

- **Transport12** at `[Path/To/GAMS]/apifiles/Java/transport/Transport12.java`

7.13.24 24.1.1 (May 2013)

Changes in **GAMSDatabase**:

- deprecates the `compact` method, as it has no effect anymore.

Changes in **GAMSGlobals**:

- the default value of working directory has been changed from `System.getProperty("user.dir")` to `System.getProperty("java.io.tmpdir")`.

Changes in **GAMSModelInstance** :

- deprecates the instantiate(GAMSOptions options), instantiate(GAMSModifier[]), and instantiate(GAMSOptions, GAMSModifier[]) methods and replaced by **instantiate**(String, GAMSModifier ...) and **instantiate**(String, GAMSOptions, GAMSModifier ...) methods

Changes in **GAMSWorkspace** and **GAMSWorkspaceInfo**:

- deprecates boolean `debug` flag and replaced by a debug level flag (type of a new class **GAMSGlobals.DebugLevel**).
- allows an override of debug level flag from an environment variable `GAMSOOAPIDEBUG`

New methods in **GAMSDatabase**:

- **GAMSDatabase.addEquation**, **addParameter**, **addSet**, and **addVariable**: to add symbols with domain information.
- **checkDomains**: to check whether or not all records of all symbols are within the specified domain of the symbols.
- **getDatabaseDomainViolations**: to retrieve a domain violation information as a list of **GAMSDatabaseDomainViolation** objects.
- **isAutoDomainCheckingSuppressed** and **suppressAutoDomainChecking**: to control whether domain checking will be called when exporting a database.

New class **GAMSDatabaseDomainViolation**:

- contains domain violation information of all symbols (if any) in the database.
- returns call from a new method **GAMSDatabase.getDatabaseDomainViolations**.

New enumeration class **GAMSGlobals.DebugLevel**:

- defines values of different GAMS Debug Levels.

New methods in **GAMSModelInstance**:

- **copyModelInstance**: to copy a **GAMSModelInstance** object.
- **interrupt** : to send an interrupt signal to a running **GAMSModelInstance** object.

New enumerated value of **GAMSModelInstance.SymbolUpdateType**:

- **GAMSModelInstance.SymbolUpdateType.INHERIT**: to specify **GAMSModelInstance.SymbolUpdateType** separately for each **GAMSModifier**.

New methods in **GAMSModifier**:

- `constructor`: to specify **SymbolUpdateType** for each **GAMSModifier** object.
- **getUpdateType**: to retrieve **SymbolUpdateType** property of the object.

New methods in **GAMSSymbol**:

- **checkDomains**: to check whether or not all records of the symbol are within the specified domain.
- **getDomains**: to retrieve a list of domains of the symbol, each element is either a **GAMSSet** (real domain) or a `String` (relaxed domain).

- **getSymbolDomainViolations**: to retrieve a domain violation information as a list of **GAMSSymbolDomainViolation** objects.
- **mergeRecord**: to add a new symbol record in case the record does not exist.

New class **GAMSSymbolDomainViolation**:

- contains domain violation information of the symbol (if any).
- returns call from a new method **GAMSSymbol.getSymbolDomainViolations**.

New methods in **GAMSWorkspace**

- **getGAMSVersion**: to retrieve information about GAMS Version.
- **getGoldReleaseNumber**: to retrieve GAMS GOLD Release Number.
- **getMajorReleaseNumber**: to retrieve GAMS Major Release Number.
- **getMinorReleaseNumber**: to retrieve GAMS Minor Release Number.

Fixed a bug when iterating through the records of a **GAMSSymbol**

Changes of location of examples:

- **Bender Examples**: from `[Path/To/GAMS]/apifiles/Java/Benders*.java` to `[Path/To/GAMS]/apifiles/Java/`
- **Cutstock**: from `[Path/To/GAMS]/apifiles/Java/Custock.java` to `[Path/To/GAMS]/apifiles/Java/cutstock/`
- **ConsoleInterrupt**: from `[Path/To/GAMS]/apifiles/Java/ConsoleInterrupt.java` to `[Path/To/GAMS]/apifiles/Java/interrupt/ConsoleInterrupt.java`
- **Transport Examples**: from `[Path/To/GAMS]/apifiles/Java/Transport*.java` to `[Path/To/GAMS]/apifiles/Java/transport/Transport*.java`
- **Warehouse**: from `[Path/To/GAMS]/apifiles/Java/Warehouse.java` to `[Path/To/GAMS]/apifiles/Java/wareh`

New examples :

- **SimpleCutstock** at `[Path/To/GAMS]/apifiles/Java/cutstock/SimpleCutstock.java`
- **DomainCheck** at `[Path/To/GAMS]/apifiles/Java/domain/DomainCheck.java`
- **Transport13** at `` `[Path/To/GAMS]/apifiles/Java/transport/Transport13.java ``
- **Tsp** at `[Path/To/GAMS]/apifiles/Java/tsp/Tsp.java`

7.13.25 24.0.2 (February 2013)

New method in **GAMSSymbol**

- added new method **copySymbol**.

7.13.26 24.0.1 (December 2012)

This release contains a beta version of the object-oriented Java API that can be used to control GAMS from a Java program. It allows the seamless integration of GAMS into Java by providing appropriate classes for the interaction with GAMS. GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (**GAMSDatabase**), and to create and run GAMS models (**GAMSJob**) that can be customized by GAMS options (**GAMSOptions**). Furthermore, they introduce a way to solve a sequence of closely related model instances in the more efficient way (**GAMSModelInstance**).

- A Java program that uses object-oriented Java API requires at least Java SE 5 to compile and run.
- All classes are distributed within one single jar file `GAMSJavaAPI.jar` with a namespace `com.gams.api`, located under the `[Path/To/GAMS]/apifiles/Java/api/` directory.
- Java program examples are distributed with namespace `com.gams.examples`, located under `[Path/To/GAMS]/apifiles/Java/` directory.
- Installation and detailed documents can be found in `[Path/To/GAMS]/apifiles/readme.txt` and `[Path/To/GAMS]/docs/API/GAMS_java.pdf`.
- Javadoc for `GAMSJavaAPI.jar` can be found under `[Path/To/GAMS]/apifiles/java/api/javadoc` directory.

7.14 GAMS Environment Object Options

Option	Description	Default
AlgFileType	File type of scratch files	1
Cheat	optCheat solver default Range: [-∞, ∞]	0
CurSolver	Solver id of the last gevcallsolver	0
CutOff	CutOff solver default Range: [-∞, ∞]	0
DomLim	Domain violation limit solver default	0
FDDelta	Step size for finite differences Range: [1e-9, 1]	1e-5
FDOpt	Options for finite differences Range: [0, 14]	0
GamsVersion	GAMS CMEX Version	999
GenSolver	Indicator for generic solver executable	0
HeapLimit	Maximum Heap size allowed	1e20
IDEFlag	IDE Flag 0 unknown environment 1 runs under GAMS IDE	0
Integer1	Range: [-∞, ∞]	0
Integer2	Range: [-∞, ∞]	0
Integer3	Range: [-∞, ∞]	0

Option	Description	Default
Integer4	Range: [-∞, ∞]	0
Integer5	Range: [-∞, ∞]	0
IterLim	Iteration limit solver default	2000000000
Keep	Keep scratch directory Range: [0, 1]	0
License1	License line 1	
License2	License line 2	
License3	License line 3	
License4	License line 4	
License5	License line 5	
LogOption	Log option 0 no log output 1 log output to screen (console) 2 log output to logfile 3 log output to standard output 4 log output to logfile and standard output	1
NameCtrFile	Control file name	
NameCurDir	Current directory	
NameExtFFile	External Function file name	
NameGamsDate	GAMS Date	
NameGamsTime	GAMS Time	
NameInstr	Instruction file name	
NameLogFile	Log file name	
NameMatrix	Matrix file name	
NameParams	Parameter file name	
NameScenFile	Scenario file name	
NameScrDir	Scratch directory	
NameScrExt	Scratch extension	dat
NameStaFile	Status file name	
NameSysDir	System directory	
NameWrkDir	Working directory	
NodeLim	Node limit solver default	0
OptCA	optAbsolute Optimality criterion solver default	0
OptCR	optRelative Optimality criterion solver default	0.1
PageSize	Output file page size	78
PageWidth	Output file page width	123

Option	Description	Default
Real1	Range: [-∞, ∞]	0
Real2	Range: [-∞, ∞]	0
Real3	Range: [-∞, ∞]	0
Real4	Range: [-∞, ∞]	0
Real5	Range: [-∞, ∞]	0
Reform	Reform option	100
ResLim	Resource (CPU) solver default limit	1000
SysOut	Solver Status file reporting option Range: [0, 1]	0
ThreadsRaw	Range: [-∞, ∞]	1
TryInt	TryInt solver default	0
UseCheat	UseCheat solver default	0
UseCutOff	UseCutOff solver default	0
WorkFactor	Work space multiplier for some solvers	1
WorkSpace	Work space for some solvers	0

7.15 GAMS Modeling Object Design

This document gives a brief introduction to GAMS' new model-solver API, including a description of its design goals and philosophy. This document is not intended to be used as a user's manual but rather to give a picture of what the new API can do and a description of some of the conceptual underpinnings for the new API.

Further material: Presentation at ICS 2011

7.15.1 Introduction

Historically, there have been a number of different GAMS solver interface libraries, i.e. libraries that enabled a solver to get all required information from a GAMS model, compute the solution, and return the solution, status information, and other information (e.g. solver log messages, nonlinear function evaluation error messages, node counts, time used) to GAMS. Each library was unique in some way, e.g. in the computer language or subset of GAMS model types it supported. Each library had its own advantages and disadvantages, but all of them were feature-poor and supported a limited scheme of operation: GAMS/Base would write *scratch files* containing the model to be solved, the GAMS solver link executable would use one of the solver interface libraries to read the model from scratch file and write a solution file, and GAMS/Base would read this solution file. While this scheme worked for many years it was inconvenient for the library user, difficult to maintain, slow, and a barrier to further development.

To address these issues and others, GAMS developed a new model-solver interface library, called GMO (GAMS Model Object), and a companion library called GEV (GAMS Environment Object). The two libraries are distinct and help to separate the purely model-specific tasks and information handled by

GMO from the computing and solver environment that the model will be solved in, handled by GEV. The two libraries are typically used together and we will sometimes refer to them as simply GMO. For legacy reasons the new libraries support the old file-based scheme to communicate a model through scratch files.

In what follows, we first describe the basic structure, organization, and usage of GMO (Basic organization). Client applications can be split into two types: those defining or updating the model (Modeler Access to GMO) and those passing the model to a solver (Solver Access to GMO). We next describe some ways to update a model in Updating a GMO instance.

7.15.2 Basic organization

In this section we outline the basic organization of GMO. GMO is implemented as a shared library that interfaces to different languages via language-specific header files and interface code. The header files and code are included in source form with the GAMS distribution. Since the interface code employs dynamic loading, each GMO session begins with a call to initialize the required shared library (i.e. load it and all its symbols) and return an empty model object.

The next step is to load a model into the model object. This is typically done with a single wrapper call, as in the case of loading a model from model scratch files prior to solving in one of the GAMS solver links. It is also possible build up a model from scratch with a sequence of calls to provide the model column-wise or row-wise. If the model is built up column-wise or row-wise, additional information (e.g. about nonlinearities) may be passed to the object after the basic structure is built up. Once the model is complete, a finalization routine is called. This routine prepares the model object for efficient access by the user. Typically the model does not change after this point. There are exceptions to this (see Updating a GMO instance), but they usually involve small modifications to the existing model (like adding alternative bounds) or the addition of constraints and variables that require the *re-finalization* of the model.

When a model is fully loaded, the GMO client can start accessing the model. Typically the GMO client doing this will be a solver, but other clients (e.g. the CONVERT *solver*, the Examiner utility, or a model structure browser) exist also. In addition to querying the model, the client can also request that the model be presented or viewed in various different ways. For example, GMO can be requested to use an objective function or an objective variable. Most types of information are available immediately when the model is loaded, but some type of queries (e.g. Hessians, alternative QP forms) are less common and relatively expensive in time and/or space: these require that an initialization routine be called before the information is requested. Once the client has completed its work it reports on the solution found, if any. Typically, the model object is destroyed at this point. Model access by a client, especially solvers, is an important topic that is discussed in Solver Access to GMO.

The variety of data that go into the interface library when a model is defined and that a solver can request during solution is large, but the data can be divided into two types - data defining the model (e.g. number of rows and columns, coefficients, nonlinear functions) and data defining the solver environment (e.g. available and default GAMS solvers, license info, algorithm tolerances and limits). It is sometimes useful to separate these two types of data, so that it is possible to define and work with a model without specifying anything about the environment it exists in. The environment can be specified separately, and multiple models can make use of the same basic environment. To facilitate this, the solver interface is in two parts: the GMO interface deals with model-specific information and the GEV interface with information about the environment. The two environments are linked, since they are typically used together, with one (or multiple) models existing in one environment, but the separation makes it possible to define a model without defining its environment, etc. Since the bulk of the information and the code lies with GMO, we usually speak of the two libraries as one, called GMO, but it is worth remembering that GEV is a separate object.

7.15.3 Solver Access to GMO

One of the primary purposes of GMO is to provide convenient, efficient access to the model. GAMS links to many solvers, each solver link using GMO to access the model in different ways, so there is a wide array of possible methods to access the model in GMO. We describe them in this section.

There are multiple but equivalent views possible for the same model. For example, the model can be formulated with an objective function or with an objective variable. Free rows can be removed or left in, and the rows and/or columns can be permuted. Prior to accessing the model, the solver link can choose what view it would like to use. The view can be changed later, but since this can obviate the data obtained previously, the choice of view is usually made early on and left unchanged. Moreover, a view can be stored and restored in case multiple users access the same model.

All solvers will need to get basic information about a model - simple things like row and column counts, nonzero counts, etc. These are available via simple access routines. Since the model is essentially fixed (assuming the view does not change), basic information is pre-computed when the model takes its final form and is available at essentially no cost. Information about the rows and columns (e.g. variable level values, marginal values, variable priorities, row types) is also available, either for single rows/cols or in an array for all rows/cols at once.

For linear models, the only information left to get is the matrix of coefficients. This is available in a number of different forms e.g. column-wise or row-wise, either as a complete matrix returned with one call or as separate rows or columns returned via many calls. For nonlinear models, there are more variants on this theme: calls to return the function value or the function value and derivatives, calls for constraints and calls for the objective function. You can request that the nonlinear model be treated as its linearization around a certain point. There are also routines to do interval evaluations of functions and gradients. The GMO library prepares the model object to handle all these calls efficiently when the model takes its final form.

Nonlinear models present several additional challenges. When NL functions are evaluated, mathematical errors can occur (e.g. sqrt(-1)). GMO supports different ways to log and handle these errors. Some algorithms will require or want 2nd-order information. Since this can be relatively expensive to compute, the solver must first call an initialization routine specifying what is desired (e.g. only Hessian-vector products, Lagrangian Hessian, single-row Hessians) and potentially a limit on the memory dedicated to computing Hessians. After this initialization, 2nd-order information is available.

Once the solver finishes, the solution (if any) and related status values must be reported back to GMO. There are a number of convenience routines included in GMO for this purpose.

A convenient interface was and is an important design goal for GMO, especially in the area of solver access to the model. Convenience takes many forms: a number of ways to get the same model data in order to support a variety of different solver libraries, self-contained calls with minimal requirements on previous setup for correct behavior,and a modern interface adhering to design principles like information hiding, encapsulation, and an object model. By keeping these goals at the fore when designing GMO we have made accessing the model convenient and efficient, which greatly simplifies the task of building a correctly-functioning solver link.

In addition to providing convenient access to the model, a solver link needs to expose a particular API to be recognized by the GAMS system. This is not directly connected to the GMO API itself but knowledge about the expected solver link library API is required so we include it here.

GAMS calls a solver through the GEV API function `gevCallSolver` which eventually results in a sequence of calls to functions in the solver link library. GAMS loads solver link libraries dynamically at run time. The name of the library is specified in the configuration file together with the three letter audit code, e.g., `cpx` for CPLEX. All functions in the solver link library are prefixed by this audit code (we use `xyz` in this example). The following functions are recognized:

- `void xyzInitialize(void)` (optional): Function called when loading the solver link library.

- `void xyzFinalize(void)` (optional): Function called when unloading the solver link library.
- `int xyzCreate(void** handle, char* msg, int sizeBuf)`: Function to create a solver link *object*. Returns 0 and stores a non-NULL pointer to the object in `handle` on success, otherwise an error message should be stored in `msg`.
- `void xyzFree(void** handle)`: Function to destroy a solver link object.

Depending on the *solver interface type* (again communicated as part of the configuration file) different functions need to be in the API. For solver interface type 1 we have:

- `int xyzReadyAPI(void* handle, void* gmoHandle)`: Function to set up the model instance in the solver space. Returns 0 on success.
- `int xyzCallSolver(void* handle)`: Function to do the actual solve and solution reporting. Returns 0 on success.
- `int xyzModifyProblem(void* handle)` (optional): Function to modify the problem. Returns 0 on success.

For solver interface type 2 we only have a single call:

- `int xyzCallSolver(void* handle, void* gmoHandle)`: Function to setup and solve. Returns 0 on success.

Usually, a *solve* in GAMS triggers the following sequence of function: `xyzCreate`, `xyzReadyAPI`, `xyzCallSolver`, `xyzFree` (interface type 1) or `xyzCreate`, `xyzCallSolver`, `xyzFree` (interface type 2) and the separation of `xyzReadyAPI` and `xyzCallSolver` seems unnecessary.

With Gather-Update-Solve-Scatter (GUSS) and the `GAMSModelInstance` class in various APIs we repeatedly solve a model with the same rim but different data (bounds, rhs, matrix coefficients). In this case the sequence of solves results in a sequence of function calls. Without the presence of `xyzModifyProblem` the following sequences will be called: `xyzCreate`, `xyzReadyAPI`, `xyzCallSolver`, `xyzReadyAPI`, `xyzCallSolver`, `xyzReadyAPI`, `xyzCallSolver`, ..., `xyzFree` (interface type 1) or `xyzCreate`, `xyzCallSolver`, `xyzCallSolver`, `xyzCallSolver`, ..., `xyzFree` (interface type 2). So, again there is little point (but possible) to split the link work in `xyzReadyAPI` and `xyzCallSolver` without the presence of `xyzModifyProblem`. If `xyzModifyProblem` is present (only with flavor 1) the following sequences will be called: `xyzCreate`, `xyzReadyAPI`, `xyzCallSolver`, `xyzModifyProblem`, `xyzCallSolver`, `xyzModifyProblem`, `xyzCallSolver`, ..., `xyzFree`.

7.15.4 Modeler Access to GMO

In normal operation the modeler creates a model in GAMS source form and the GAMS/Base module handles all the details necessary to build up model instances in GMO. However, there are cases (e.g. solving a model many times over with different scenario data) where it is useful to access and modify a GMO instance outside of GAMS/Base. GMO provides routines to support this, specifically routines to update the model (see Updating a GMO instance), solve the model with one of the GAMS solvers available as part of the GAMS environment and GEV, and retrieve the solution.

Access to a GMO instance is usually done using integer indices, `[1..m]` for the rows and `[1..n]` for the columns. However, it is also possible to reference rows and columns using the notation from the original GAMS model, e.g. `x('seattle','topeka')` or `demand('chicago')`. This is more convenient when specifying what data should be updated to define a new scenario. In order to update a model instance in this case, it is useful to have a convenient, efficient way to translate row and column indices from one form to the other. This translation is done by the *model dictionary* interface DCT.

The DCT API provides information about the variables, equations, and sets used to define the GMO model instance. In addition, given a row or column index, it will translate this index into the equation or variable name and the list of set labels that correspond to this index. It will also do the inverse operation, translating an equation/variable name and list of labels into a row or column index. GAMS builds models in a way that makes this translation very efficient.

This organization is also useful when updating models to create new scenarios. Models are organized so that:

- There is one ordered universe of all labels appearing in the variables and equations of a given model. The order for the labeling does not change from symbol to symbol within a model.
- All of the columns in a model corresponding to a given variable are contiguous. (Ditto for rows and equations)
- The columns corresponding to a given variable are sorted by their index labels, using the universal order, with the left-most index varying slowest. (Ditto for rows and equations)
- GDX data is sorted in the same way: sorted by index label order, left-most index varying slowest. This can be very useful, *provided the model and the GDX data use the same label ordering.*

Using the various GAMS component libraries, it is possible to create a model updating interface that is both convenient for the user (by using the symbolic names referenced in the GAMS source) and efficient in updating the model data.

7.15.5 Updating a GMO instance

There are several possible ways to modify a model contained in a GMO instance. By updating, we mean an actual model change, rather than a change in the view that doesn't alter the set of solutions.

In perhaps the simplest case, the user can specify alternate variable bounds, as is useful when implementing a branch and bound code. The original bounds are retained in this case, so that the model can be reverted to the original bounds with a single call.

It is possible to linearize a model around a given point. This requires no information from the point to linearize around and can be undone easily. This is almost a change in view but since the solutions of the original and linearized models may be quite different we can also consider this a model update.

Many algorithms (e.g. outer approximation, Benders decomposition, Danzig-Wolfe decomposition) involve the addition of rows, and columns incident on these rows, to a core model. Such algorithms can be implemented effectively using GMO by taking advantage of GMO facilities to add rows and columns. There will be only a small amount of work required to prepare the GMO instance for use after each round of additional rows and columns. Note that all the changes to the model in this case are *additions*: the existing structure and data are left as is.

Finally, there are facilities in GMO to update variable bounds (as mentioned before), variable types (e.g. to relax single discrete variables), and the right-hand-side of constraints. The user cannot directly modify matrix coefficients. There is a much better way to safely update exogenous data in a model: GAMS can provide a model instance in which GAMS parameters are visible and can be updated. A reevaluation of the expressions in the models provides the updated matrix elements. The underlying concept is also used in Gather-Update-Solve-Scatter (GUSS) and described in more detail in `this paper`. This is a powerful tool to efficiently do e.g. Monte-Carlo simulation without the need for GAMS to regenerate the entire model over and over.

Chapter 8

Appendix

- Glossary - An alphabetical list of GAMS terms.
- Third-Party Codes - A list of third-party codes that are included in the GAMS distribution.
- Bibliography

8.1 Glossary

acronym	A GAMS data type used for storing non-numeric (aka logical or categorical) data. For more details, see section Acronyms.
alias	An alternative name for a set, used to have multiple indices running over a common set. For more information, see section The Alias Statement: Multiple Names for a Set.
algorithm	A sequence of actions to perform in order to solve a problem. GAMS *solvers* contain algorithm implementations, so the two terms are sometimes used interchangeably.
assignment	The statement used to assign values to an identifier. For a detailed introduction, see section The Assignment Statement.
basic	A column is basic if it is in the basis maintained by the solution method for the problem in question (e.g. by the simplex method for LP). A row is basic if the elementary column associated with its slack variable is basic.
binding	An inequality constraint or variable bound is binding when the value of the associated slack is zero, i.e. when it is satisfied as an equality.
bounds	Upper and lower limits on the possible values that a column may assume in a feasible solution. May be infinite, i.e. no limit is imposed.
column	An individual decision variable in the model passed to a solver. Also called a `single variable` in the GAMS listing file. An indexed GAMS variable typically contains many columns.

compilation	The initial phase of GAMS processing, when the program is being checked for syntax and consistency.
compile-time constant	A compile-time constant is a string that will be replaced at compile-time with a fixed value. These constants are usually related to a function, model attribute or option and are used for their mnemonic and descriptive value. See section Compile-Time Constants.
compile-time variable	Special variables that are substituted with their values at compile-time. For further information, see section Compile-Time Variables.
constraint	A relationship between variables that must hold in a feasible solution. A constraint can refer to a single relationship (i.e. a row) or to a collection of rows, such as an equation.
continuous	Used to describe functions (in the usual mathematical way) and variables. Roughly speaking, a function is continuous if its graph has no breaks or jumps in it. A continuous variable may assume any value within its bounds, in contrast to binary or integer variables.
controlling sets	See driving sets.
data types	Each symbol or identifier must be declared as one of the available data types, e.g set, parameter, equation, or `model`. Note that scalars and tables are not separate data types, but convenient input formats for certain parameters. See also section Data Types and Definitions.
decision variable	A decision variable (aka endogenous variable) represents a decision to be made, e.g. the amount to produce or consume or the unit price to charge. Decision variables are the unknowns of a mathematical programming model. In contrast, exogenous variables or parameters are outside of the decision maker's control..
declaration	The introduction of an identifier along with the specification of its data type. A declaration may also include the specification of data or initial values, in which case it also acts as a definition. See also section Classification of GAMS Statements.
default	The value used, or the action taken, if the user provides no information.
definition	A statement specifying the content or data associated with a GAMS identifier, e.g. the equations in a model, the algebra of an equation, the elements of a set, or the initial values of a parameter. Definitions are processed during compilation. See also section Classification of GAMS Statements.
direction	The direction of optimization, i.e. maximization or minimization.
discontinuous	A function is discontinuous if it is not continuous. Sometimes, we call a function discontinuous if its derivatives are not continuous, i.e. it is nonsmooth.
discrete	A discrete variable is any variable that is not continuous. For example, binary and integer variables are discrete. For more details, see section Types of Discrete Variables.

dollar control option	Directives or options used to control input or output details associated with the GAMS compiler. They are introduced in chapter Dollar Control Options.
dollar operator	An operator used to indicate and define conditional expressions in assignment statements and equation definitions. For more information, see section The Dollar Condition.
domain checking	A system of checks that ensures that operations and relationships involving sets and domains are logically consistent. For example, referencing `pop(t,city)` when we have a declaration of `pop(city,t)` is a logical error that domain checking will catch. For more information, see section Domain Checking.
domain of definition	The set of tuples (i.e. label combinations) for which an indexed equation is defined. When a solve statement is executed, a row of the equation is generated for each member of the domain of definition.
domain restriction condition	The narrowing of the domain of definition with a dollar operator. When used in this way, the dollar operator occurs on the left of the symbol `'..'` in an equation definition. For more details, see section Dollar Control over the Domain of Definition.
driving set	The set or list of sets that an indexed operation or domain runs or is defined over. Loops, indexed operations like `sum`, and domains of definition all make use of driving sets.
dynamic set	A set is dynamic if it has been changed with an assignment statement. Dynamic sets cannot be used with lag operations or in domain declarations. For more information, see chapter Dynamic Sets.
echo print	In the output file, the echo print is a listing of the input with added line numbers. Details are given in section The Echo Print of the Input File.
endogenous	Endogenous variables are used in economics, statistics, and other disciplines. In the GAMS context, they are synonymous with variables, i.e. values that change when a solve statement is processed. See also the discussion in section Functions in Equation Definitions.
equation	The GAMS data type used to specify required relationships between activity levels of variables. They are introduced and discussed in detail in chapter Equations.
execution	The second phase of GAMS processing, when GAMS is actually carrying out data transformations or generating a model.
execution statements	Instructions to carry out actions such as data transformations, model solves and report generation. Examples include the assignment statement, the loop statement and the solve statement. For a full list, see section Classification of GAMS Statements.

exogenous	Exogenous variables are used in economics, statistics, and other disciplines. In the GAMS context, they are synonymous with constants, i.e. values that do *not* change when a solve statement is processed. These are most often parameters but any variable or equation field will be treated exogenously when it appears in an equation. See also the discussion in section Functions in Equation Definitions.
explanatory text	See text.
extended arithmetic	In GAMS, the usual computer arithmetic is extended to include special values (e.g. `inf`) and the results of operations and functions that use them. For example, `6 + inf` is `inf` and `min(6, inf)` is `6`. See section Extended Range Arithmetic and Error Handling for details.
external equation	An equation defined in an external module. For example, on Windows systems, external equations are defined by a DLL. See section External Equations for details.
extrinsic function	A function that is imported into a GAMS program from an external function library. Once imported, extrinsic functions can be used in the same way as intrinsic functions like `cos` and `exp`. See section Extrinsic Functions for details.
e-format	A convenient text-based (i.e. unsuperscripted) way to represent numbers in scientific notation in which the exponent of the 10 is prefixed by the letter `e`. For example, one US mile = 1.609344e+03 meters.
feasible	Often used to describe a model (or a subset of constraints within a model) that has at least one feasible solution, but also used to describe a point that satisfies a set of constraints. See also infeasible.
feasible solution	A solution to a model in which all column activity levels are within the bounds and all the constraints are satisfied.
identifier	The name given to a data entity in a GAMS program. Also called a symbol. See section Identifiers for further details.
indexed operation	An operation (e.g. sum or max) that is performed over one or more indices. See also section Indexed Operations.
inequality constraint	A constraint in which the imposed relationship between the columns is not specified with an equality but instead with an inequality (e.g. "greater than or equal to", "less than or equal to"). The GAMS syntax `=G=` and `=L=` is used in equation definitions to specify these relationships.
infeasible	Not feasible. Used to describe either a model that has no feasible solution or an intermediate solution or point that is not feasible (although feasible solutions may exist).
initialization	Associating or assigning *initial values* to an identifier as part of the declaration or definition of the identifier. We typically talk about the initialization of only those identifiers (e.g. sets and parameters) that can be assigned different values later. For identifiers like models and equations, we say they are *defined*, not *initialized*.

intrinsic function	Functions that are provided by and part of GAMS, including mathematical, string, logical, time/calendar, and utility functions. Contrast to extrinsic functions.
label	Sets are built up from labels (aka *elements*). One-dimensional sets are collections of labels, while multi-dimensional sets contain tuples of labels. See section Labels for details.
list	See list format.
list format	GAMS data may be initialized by data in list format, i.e. a list where each tuple of labels in the data is specified in full. Data may also be displayed in list format, in which case each nondefault value is displayed via a fully-specified tuple of labels.
macro	A macro is a fragment of code that has been given a name: whenever the name is used, that name is replaced by the contents of the macro (i.e. the fragment of code). This is useful for defining and automating structured text replacement, e.g. to replace the text `MYOBJ(x)` with `[sqr(x) + exp(x-2)/7]`. See section Macros in GAMS for details.
marginal	Marginal values (aka "dual values", "reduced costs", "shadow prices", or "multipliers") are stored in the `".m"` variable attribute or equation attribute. The GAMS sign convention is this: the marginal value represents the amount and direction of change in the objective value given a *unit increase* in the binding constant (e.g. an active variable bound or right-hand side).
matrix element	See nonzero element.
model generation	An initial step in processing a solve statement, where a model instance is generated (based on the equation definitions and the data referenced by those definitions) for the solver.
model list	The list of equations that are part of the model, as specified in the model statement. For further details, see section The Model Statement.
model status	An integer returned by the solver that gives information about the model (e.g. INFEASIBLE), about the point returned by the solver (e.g. LOCALLY INFEASIBLE), or both (UNBOUNDED NO SOLUTION RETURNED). For an overview of all values, see section Model Status.
nonbasic	A column that is not basic and (in nonlinear problems) not superbasic. Typically, nonbasic columns behave or are treated as if they are fixed at a bound. If the solution is feasible, the value of a nonbasic column will equal a finite bound (or zero if there are no finite bounds).
nonlinear nonzero	In a linear programming problem, the nonzero elements of the constraint matrix are constant. In a nonlinear problem, elements of the Jacobian matrix vary where variables appear nonlinearly. These non-constant Jacobian elements are called nonlinear nonzeros.

nonoptimal	Not optimal. A solution is nonoptimal if other solutions exist with better objective values. A variable is nonoptimal if its marginal (aka reduced cost) has the wrong sign. For example, in a minimization, a variable at lower bound having a negative marginal is nonoptimal. In the simplex method, a variable is nonoptimal if it is nonbasic and would improve the objective if it entered the basis.
nonsmooth	A function is nonsmooth if it is not smooth, i.e. if the function itself or its derivatives are not continuous. For example, the absolute value function is nonsmooth because of the kink at the origin: its derivative is not continuous there.
nonzero element	An element or coefficient of a matrix (e.g. the constraint matrix of an LP or the Jacobian matrix of an NLP) that is not zero. Most mathematical programming problems are *sparse*, i.e. only a small proportion of the elements in the constraint or Jacobian matrix are nonzero.
objective row (or function)	Solver systems often require the specification of a row or (for nonlinear systems) a function whose value will be optimized. A GAMS model, in contrast, is solved by specifying a scalar objective variable to be optimized.
objective value	The current value of the objective row or of the objective variable.
objective variable	The variable to be optimized, as specified in the solve statement.
optimal	A feasible solution in which the objective value is the best possible..
optimality gap	The optimality gap is a metric for the distance (or an upper bound on the distance) between the objective value of the current feasible solution and the optimal objective value.. In GAMS, MIP and global solvers terminate when the optimality gap is sufficiently reduced: see the options optCA and optCR for details.
option	A control that allows users to change or influence the behavior or parameters in many different parts of the system. Options in GAMS may be set in three different ways: with model attributes, command line parameters, and option statements. A full list of all options with detailed descriptions is given in section Detailed Descriptions of All Options.
ordered set	A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the labels in the universe. Only sets that are ordered (and static) can be treated as sequences, i.e. used in lags and leads and with `Ord`-type operations. For more information, see chapter Sets as Sequences: Ordered Sets.
output file	A file, also called the listing file, produced (by default) by the run of a GAMS program. It contains output that describes or logs the run in question. For details see chapter GAMS Output.
parameter	A data type in GAMS used to store (indexed) constant data. For details on parameters, see chapter Data Entry: Parameters, Scalars and Tables.

problem type	A class of models that is characterized or defined by the type of algebra accepted (e.g. linear or nonlinear), the GLOSSARY_variable_type "variable types" allowed (e.g. continuous vs. discrete), and the definition of what it means to solve the model or problem (e.g. optimization vs. MCP). A list of all problem types in GAMS is given in section Classification of Models.
program	A GAMS input file. Typically a program defines a model and solves it, but programs can also work only with data or act as scripts that call other programs.
relational operator	This term may be used in two ways. First, in an equation definition, it describes the type of relationship that the equation specifies. An example is equality, as specified with the symbol `=e=`. For more information, see Table Equation Types. Second, in a logical expression, a relational operator compares two numerical expressions and returns a logical value. For details see section Logical Conditions: Numerical Relational Operators.
right-hand side	The value of the constant term in a constraint.
row	An individual constraint in the model passed to a solver. Also called a `single equation` in the GAMS listing file. An indexed GAMS equation typically contains many rows.
scalar	An un-indexed parameter, or the statement used to declare or define this parameter. See also section Scalars.
set	A collection of elements (aka *labels*) or element tuples. The set statement is used to declare and define a set. Sets are introduced and discussed in detail in chapter Set Definition.
simplex method	An algorithm often used to solve linear programming problems.
singleton set	A special set that has at most one element (zero elements are allowed as well). For more information, see section Singleton Sets.
slack	The amount by which an inequality constraint or variable bound is not binding.
slack variable	A non-negative variable introduced to represent the slack in an inequality constraint and to convert the inequality into an equality.
smooth	A function that is continuous and whose derivatives are all continuous is smooth. Sometime we consider a function smooth if enough of its derivatives are continuous.
solver	An implementation of an algorithm or algorithms for solving models of a given problem type or types. An example is MINOS and QUADMINOS, which is used to solve both linear and nonlinear programming problems.
solver status	An integer returned by the solver that indicates the solver termination condition, i.e. why the solver stopped. For details, see section Solver Status.

statements	Statements (aka units or sentences) are the fundamental building blocks of GAMS programs: each program is a sequence of statements. Statements are used to declare identifiers, define equations, create loops, and solve models. A full list of GAMS statements is given in section Classification of GAMS Statements.
static set	Used in two slightly different ways: a set is static if it *has not* changed (i.e. it is not dynamic) or if it *cannot* change, i.e. it is *immutable*. Usually, sets are either used in ways that make them immutable (e.g. as domains or with lags and leads) or in ways that make them dynamic (i.e. by assigning to them): in such cases, static is synonymous with immutable.
superbasic	Some algorithms for nonlinear programming make use of superbasic variables that are neither basic (i.e. in the basis) nor nonbasic (i.e. temporarily fixed at a bound). These algorithms often search in the space defined by these superbasic variables.
symbol	An identifier.
table	A table statement is often a convenient way to define a parameter having two or more dimensions. For details see section Tables.
text	An optional description associated with an identifier or with an element of a set. For details see section Text.
unique element	A label used to define set membership.
universe	Also called the *universal set*, it is denoted by the symbol '$*$' and contains all the labels that have been declared in the program plus any labels used as if they were declared (e.g. `link('sink',j) = NO;`). If an identifier is declared using the universe, that effectively turns off or limits domain checking for that identifier. For more details, see section The Universal Set: $*$ as Set Identifier.
variable type	Variables are classified or typed based on their default bounds and the values they are allowed to take. This latter classification partitions variables into continuous or discrete. For example, `free` variables have no default bounds and can take any value between their bounds: they are continuous. In contrast, `binary` variables can take only the values zero and one. See section Variable Types for details.
zero default	Some GAMS data (e.g. parameters, lower bounds for positive variables) have a default value of zero. These default zero values are not stored. However, unless other values are provided via initialization or assignment, zero will be used when the data value is taken.

8.2 Third-Party Codes

The following table lists third-party codes that are included in the GAMS distribution.

Software	Version	Description	License
Addict	3.4	Spell Checker	proprietary

Software	Version	Description	License
ALPHAECP	2.11.01	Mixed-Integer Nonlinear Programming Solver	proprietary
ANTIGONE	1.1	Mixed-Integer Nonlinear Programming Solver	proprietary
BARON	24.03.10	Mixed-Integer Nonlinear Programming Solver	proprietary
BLISS	0.77	Compute canonical labelings and automorphism groups of graphs	LGPL 3.0
Boost	1.84	Portable C++ source libraries	Boost 1.0
CBC	2.10.11	Mixed-Integer Linear Optimization Solver	EPL 2.0
Cerberus	1.3.5	Data validation library	ISC
certifi	2023.11.17	Mozilla's bundle of Certificate Authority certificates	MPL 2.0
Cgl	0.60.8	Cut Generators for Mixed-Integer Linear Optimization	EPL 2.0
cJSON	1.7.12	Ultralightweight JSON parser in ANSI C	MIT
Clp	1.17.9	Linear Optimization Solver	EPL 2.0
CoinUtils	2.11.10	Classes and helper functions used by COIN-OR projects	EPL 2.0
CONOPT 3	3.17P	Nonlinear Programming Solver	proprietary
CONOPT 4	4.33	Nonlinear Programming Solver	proprietary
COPT	7.0.6	Mixed-Integer Linear and Quadratic Programming Solver	proprietary
CPLEX	22.1.1.0	Mixed-Integer Linear and Quadratic Programming Solver	proprietary
CppAD (in SCIP)	20180000.0	C++ Automatic Differentiation	EPL 2.0
CppAD (in SHOT)	20210606	C++ Automatic Differentiation	EPL 2.0
cpr	1.10.2	C++ Requests: Curl for People, a spiritual port of Python Requests	MIT
Curl	8.6.0	transferring data with URLs	curl
D6OnHelpFix		Fixes OnHelp events in Delphi 6 and 7	proprietary
DataTables	1.13.4	Advanced Features for HTML Tables	MIT

Software	Version	Description	License
DECISC		Solver for two-stage stochastic LPs with recourse	proprietary
DECISM		Solver for two-stage stochastic LPs with recourse	proprietary
Delphi		Borland Runtime Package	Borland
DIERCKX/FITPACK		Calculation of smoothing splines for various kinds of data and geometries, with automatic knot selection	public domain
Doxygen Awesome	2.1.0	CSS theme for Doxygen HTML-documentation	MIT
Doxygen Output	1.8.13	Doxygen HTML-documentation Style and JavaScript Files	none
Dream		Editor	proprietary
dtoa		Conversion between decimal and binary format of floating point numbers	MIT-like
EC Software Help Suite		Help Viewer	proprietary
Eigen	3.3.90	C++ template library for linear algebra	MPL 2.0
et-xmlfile	1.1.0	Creation of XML files	MIT
f2clib		Runtime library for programs converted with f2c	unnamed
Fast Memory Manager	4.73	A fast replacement memory manager	MPL 1.1
finlib		Models from A. Consiglio, S.S. Nielsen and S.A. Zenios, Practical Financial Optimization: A library of GAMS models, John Wiley, UK, 2009	none
FMT	6.1.2	C++ string formatting library	MIT
freetds	1.3.18	Implementation of Sybase's DB-, CT-, and ODBC libraries	LGPL 2.0
GAMS-Kestrel		Kestrel solver for remote solver execution	MIT
GAMSCHK	1.3	A system for examining the structure and solution properties of GAMS model instances	proprietary
GCC	13.2.0	C++ and Fortran compiler runtime libraries	GPL 3.0 + exception

Software	Version	Description	License
GKLib	METIS-v5.1.1-DistDGL-0.5	Helper Routines and Frameworks used by METIS	Apache 2.0
GNU Awk	3.1.0	Pattern Scanning and Processing Language	GPL 2
GNU diffutils	2.7	Find Differences between Files	GPL 2
GNU fileutils	3.16	File Management Utilities	GPL 2
GNU grep	2.4	Search one or more input files for lines containing a match to a specified pattern	GPL 2
GNU Gzip	1.2.4	Data Compression	GPL 2
GNU Make	3.78.1	Control the generation of executables and other non-source files from source files	GPL 2
GNU sed	3.02	Non-interactive Command-line Text Editor	GPL 2
GNU shellutils	1.9.4 (1.13 for date)	Shell-manipulation Utilities	GPL 2
GNU Tar	1.12	Archiving Utility	GPL 2
GNU textutils	2.0 (2.1 for md5sum)	Shell Utilities for Text File Processing	GPL 2
GNU xargs	4.1	Build and Execute Command Lines from Standard Input	GPL 2
greenlet	3.0.3	Concurrent programming	MIT
Gurobi	11.0.1	Mixed-Integer Linear and Quadratic Programming Solver	proprietary
HiGHS	1.6.0 (c070f1253)	Mixed-Integer Linear Optimization Solver	MIT
HSL MA27	2003-03-19	Sparse Linear Equations System Solver	proprietary
HSL MA57	3.11.0	Sparse Linear Equations System Solver	proprietary
HSL MA86	1.6.0	Sparse Linear Equations System Solver	proprietary
HSL MA97	2.6.0	Sparse Linear Equations System Solver	proprietary
HSL MC19	1989-03-09	Scaling Linear Equation Systems	proprietary
HSL MC68	3.3.3	Elimination Ordering for Sparse Direct Solver	proprietary
HTMLHelpViewer		HTML Help Viewer	proprietary
HTMLLITE	7.7	HTML Viewer	MIT
Icono	1.3.0	Icon Pack in CSS	MIT

Software	Version	Description	License
Intel Compiler	2021.2.0	C/C++ and Fortran compiler runtime libraries	Intel EULA
Ipopt	3.14.14	Nonlinear Optimization Solver	EPL 2.0
Jinja2	3.1.3	Templating engine	BSD-3-Clause
JQuery	3.5.1	JavaScript Utilities Library	MIT
Json.NET	13.0.2	High-performance JSON framework for .NET	MIT
JSON.simple	1.1.1	A simple Java library for JSON process, read and write JSON data	Apache 2.0
Knitro	14.0.0	Mixed-Integer and Continuous Nonlinear Programming Solver	proprietary
krb5	1.20.1	Network authentication	MIT
libiconv	1.16	Conversion of character encodings	LGPL 2.1
LibYAML	0.2.2	A C library for parsing and emitting YAML	MIT
LINDO API	14.0	Stochastic and global MINLP solver	proprietary
Lunr	2.3.6	Search Engine in JavaScript	MIT
madCollection	1.6f	Collection of Delphi utility functions	proprietary
MarkupSafe	2.1.4	Escapes characters for safe use in HTML and XML	BSD-3-Clause
MathJax	3.2.2	JavaScript Display Engine for Mathematics	Apache 2.0
MC++	2.0.1	Toolkit for Bounding Factorable Functions	EPL 1.0
McCarl GAMS User Guide		A GAMS User Guide written by Bruce McCarl	public domain
METIS	5.2.1	Serial Graph Partitioning and Fill-reducing Matrix Ordering	Apache 2.0
MILES		MCP solver	proprietary
MINOS	5.6	Nonlinear Programming Solver	proprietary
MKL	2023.1 (2021.2 on Windows)	Math Functions optimized for Intel CPUs and GPUs	ISSL
MOSEK	10.1.28	Mixed-Integer Conic Programming Solver	proprietary
MPSGE		Mathematical Programming System for General Equilibrium	proprietary

Software	Version	Description	License
MSVC 2019	14.29.30133	Visual C/C++ compiler runtime libraries	MS EULA
MUMPS	5.6.2	Multifrontal massively parallel sparse direct solver	CeCILL-C 1.0
nauty	2.8.8	Graph canonical labeling and automorphism group computation	Apache 2.0
nlohmann::json	v3.11.2	JSON for Modern C++	MIT
noalib		Models from Neculai Andrei, Nonlinear Optimization Applications Using the GAMS Technology, Springer Optimization and Its Applications, Springer, edition 127, 2013	none
numpy	1.26.3	Scientific computing in Python	BSD-3-Clause
ODHeuristics	7.0.7	Primal Heuristics for Mixed-Integer Linear Optimization	proprietary
oneTBB	2021.11.0	Multithreading Library	Apache 2.0
oneTBB (Windows)	2021.2.0	Multithreading library	ISSL
OpenMP (Intel)		Library for high-level parallelism in Fortran and C/C++	BSD-3-Clause
OpenMP (LLVM)	16.0.5	Library for high-level parallelism in Fortran and C/C++	MIT
openpyxl	3.1.2	Read and write Excel 2010 xlsx/xlsm files	MIT
OpenSSL	3.0.12	Toolkit for General-Purpose Cryptography and Secure Communication	Apache 2.0
Osi	0.108.10	Abstract base class to a generic linear programming (LP) solver	EPL 2.0
pandas	2.1.4	Data analysis and manipulation in Python	BSD-3-Clause
PaPILO	2.1.4.0 (ee0677c4)	Parallel Presolve for Integer and Linear Optimization	LGPL 3.0
PATH	5.0.07	MCP solver	proprietary
PDQSort		Pattern-defeating quicksort	zlib
ply	3.11	lex and yacc implementation in Python	BSD-3-Clause
Prism	1.29.0	JavaScript Syntax Highlighter	MIT

Software	Version	Description	License
psoptlib		Models from Alireza Soroudi, Power system optimization modeling in GAMS, Springer, 2017	none
psycopg2-binary	2.9.9	PostgreSQL adapter	LGPL 3.0
pthreads-win32	2.9.1	POSIX threads library for Microsoft Windows	LGPL 2.1
PyExcelerate	0.10.0	Excel XLSX writing	BSD-2-Clause
pymssql	2.2.10 (2.2.8 on macOS on ARM64)	DB-API interface to Microsoft SQL Server	LGPL 2.1
PyMySQL	1.1.0	MySQL Driver	MIT
pyodbc	5.0.1	Access to ODBC databases	MIT
Python	3.12.1	Scripting language	PSF
python-dateutil	2.8.2	Extensions to the standard Python datetime module	Apache 2.0
pytz	2023.3.post1	World timezone definitions	MIT
pywin32	306	Python for Window Extensions	BSD-3-Clause
PyYAML	6.0.1	YAML parser and emitter	MIT
Qt	6.5.1	Toolkit for creating cross-platform graphical user interfaces and applications	LGPL 3.0
quadMINOS	5.6	Quad-Precision Nonlinear Programming Solver	proprietary
Rave Reports	5.1.4	Components for database reporting	proprietary
sassy	1.1	Preprocessor for symmetry detection	MIT
SBB		Mixed-Integer Nonlinear Programming Solver	proprietary
SCENRED	05/08/2002	Scenario tree reduction tool for Stochastic Programming	proprietary
SCENRED 2	12/12/2008	Scenario tree construction and reduction tool for Stochastic Programming	proprietary
SCIP	8.1.0 (0dff9f8a3e)	Constraint Integer Programming Framework	Apache 2.0
scipy	1.11.4	Fundamental algorithms for scientific computing	BSD-3-Clause
SendMail		Send e-mails	proprietary

Software	Version	Description	License
SHOT	1.1.0 (424b5e48)	Mixed-Integer Nonlinear Programming Solver	EPL 2.0
six	1.16.0	Python 2 and 3 compatibility utilities	MIT
SKA	2c46874	Hashtables	Boost 1.0
SNOPT	7.7.7	Nonlinear Programming Solver	proprietary
SNOPT (in ANTIGONE)	5.3-5	Nonlinear Programming Solver	proprietary
SoPlex	6.0.4 (5a9b664d)	Linear Programming Solver	Apache 2.0
SPDLog	1.8.2	C++ Logging Library	MIT
SQLAlchemy	1.4.51	Database Abstraction Library	MIT
sqlalchemy-access	1.1.4	MS Access for SQLAlchemy	MIT
sqlite	3.8.5	SQL database engine	public domain
TeeTree	2.0	Diagram and FlowChart Controls	proprietary
TFileDrag		Support dropping files from explorer onto a Delphi form	proprietary
TFolderDialog		Wrap Shell32 dialog 'Browse For Folder' into a Delphi component	LGPL 2.0
TinyCThread	1.2	C11 Threads API implementation	zlib
TinyExpr	4dfb202c	Tiny recursive descent parser and evaluation engine	zlib
TinyXML	2.6.2	XML parser	zlib
TinyXML2	7.1.0	C++ XML parser	zlib
TOneInstance	1.02	Prevent application to be started more than once	freeware
TStringAlignGrid	2.0	Text alignment in Delphi forms	freeware
TurboPower Orpheus	4.05	UI toolkit for Borland Delphi	MPL 1.1
TurboPower ShellShock	1.02	Customize applications	MPL 1.1
TurboPower SysTools	4.02	Library of utility routines & classes for Borland Delphi	MPL 1.1
tzdata	2023.4	Compiled IANA time zone database	Apache 2.0
unixodbc	2.3.11	ODBC for Unix platforms	LGPL 2.1

Software	Version	Description	License
UnZip	6.0-28 (6.00 on Windows)	Decompression tool	Info-ZIP
urllib3	2.1.0	HTTP library	MIT
Virtual Treeview	4.8.6	Treeview control	MPL 1.1
XLSReadWriteII	5.20.30	Excel Reader and Writer	proprietary
XlsxWriter	3.1.9	Creation of Excel XLSX files	BSD-2-Clause
Xpress	41.01.03	Mixed-Integer Linear and Nonlinear Programming Solver	proprietary
yaml-cpp	0.7.0	A YAML parser and emitter in C++	MIT
Zip	3.0-13 (3.1c02 BETA on Windows)	Compression tool	Info-ZIP
zlib	1.3.1	Compression Library	zlib
zstr	1.0.5	C++ Zlib Wrapper	MIT
