MatrixTol	The input matrix coefficient tolerance Range: [0, 1e-07]	1e-10
NodeLimit	Limit of nodes for MIP Range: {-1, ..., ∞}	GAMS nodlim
RelGap	The relative gap for MIP Range: [0, ∞]	GAMS optcr
SolTimeLimit	Time limit that is only effictive after a primal feasible solution has been found Range: [0, 1e+20]	1e+20
TimeLimit	Time limit of the optimization Range: [0, 1e+20]	GAMS reslim

5.10.2.2 Presolving and Scaling

Option	Description	Default
Dualize	Whether to dualize a problem before solving it -1: Choose automatically. 0: No dualizing. 1: Dualizing the problem.	-1

Option	Description	Default
Presolve	Level of presolving performed before solving a problem -1: Choose automatically. 0: No presolving. 1: Fast presolving. 2: Normal presolving. 3: Aggressive presolving.	-1
Scaling	Whether to perform scaling before solving a problem -1: Choose automatically. 0: No scaling. 1: Apply scaling.	-1

5.10.2.3 LP solving

Option	Description	Default
BarHomogeneous	Whether to use homogeneous self-dual form in barrier -1: Choose automatically. 0: No. 1: Yes.	-1
BarOrder	Ordering method for barrier -1: Choose automatically. 0: Approximate Minimum Degree (AMD). 1: Nested Dissection (ND).	-1
BarStart	Starting Point method for barrier -1: Choose automatically. 0: Simple. 1: Mehrotra. 2: Modified Mehrotra.	-1
Crossover	Whether to run crossover after barrier -1: Choose automatically. Only run crossover when the LP solution is not primal-dual feasible. 0: No. 1: Yes.	1
DualPerturb	Whether to allow the objective function perturbation -1: Choose automatically. 0: No perturbation. 1: Allow objective function perturbation.	-1
DualPrice	Specifies the dual simplex pricing algorithm -1: Choose automatically. 0: Using Devex pricing algorithm. 1: Using dual steepest-edge pricing algorithm .	-1
LpMethod	Specifies the LP method -1: Dual Simplex for LP. Automatic choice between Dual Simplex and Barrier for MIP. 1: Dual simplex. 2: Barrier. 3: Crossover. 4: Concurrent (Use simplex and barrier simultaneously). 5: Choose automatically.	-1
ReqFarkasRay	Whether to return a Farkas or Ray when an LP is infeasible or unbounded Range: boolean	1

5.10.2.4 MIP solving

Option	Description	Default
ConflictAnalysis	Whether to perform conflict analysis -1: Automatic. 0: No. 1: Yes.	-1
CutLevel	Level of cutting planes generation -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
DivingHeurLevel	Level of diving heuristics -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
FAPHeurLevel	Level of fix-and-propagate heuristics -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
HeurLevel	Level of heuristics -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
MipStartMode	Specifies MIP start mode -1: Automatic. 0: Disable MIP starts. 1: Only use full and feasible MIP starts. 2: Try to complete partial feasible MIP starts by solving subMIPs.	-1, if GAMS tryint = 0, otherwise 2
MipStartNodeLimit	Limit of nodes for MIP start sub-MIP (to complete partial MIP starts) (-1: unlimited) Range: {-1, ..., ∞}	-1
NodeCutRounds	Maximum cut rounds in a local node Range: {-1, ..., ∞}	-1
RootCutLevel	Level of root cutting planes generation -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
RootCutRounds	Maximum cut rounds in the root (-1: unlimited) Range: {-1, ..., ∞}	-1

Option	Description	Default
RoundingHeurLevel	Level of rounding heuristics -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
StrongBranching	Level of strong branching -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
SubMipHeurLevel	Level of sub-MIP heuristics -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1
TreeCutLevel	Level of tree cutting planes generation -1: Automatic. 0: Off. 1: Fast. 2: Normal. 3: Aggressive.	-1

5.10.2.5 Multithreading

Option	Description	Default
BarThreads	Number of threads to use in the barrier solver Range: {-1, ..., 128}	-1
CrossoverThreads	Number of threads to use in the crossover Range: {-1, ..., 128}	-1
MipTasks	Number of parallel tasks in MIP solving (-1: automatic) Range: {-1, ..., 256}	-1
SimplexThreads	Number of threads to use in the simplex solver Range: {-1, ..., 128}	-1
Threads	Number of threads to use (-1: automatic, 0: 1 thread) GAMS threads = 0 sets the default for COPT threads to -1, i.e., let COPT choose the number of processors to use. Range: {-1, ..., 128}	GAMS threads

5.10.2.6 Infeasibility Analysis

Option	Description	Default
.feaspref	preference to include variable bound or equation side into feasibility relaxation The higher the value, the more likely it will be that associated variable bounds or equation sides are relaxed when computing a feasible relaxation. If zero, then the associated variable bounds or equation sides are not to considered for relaxation. Range: [0, ∞)	1.0 for equations, 0.0 for variables
FeasRelax	whether to compute a feasible relaxation instead of solving the problem Range: boolean Synonyms: feasopt	0
FeasRelaxMode	Specifies the feasibility relaxation mode 0: Minimize sum of violations. 1: Optimize original objective function under minimal sum of violations. 2: Minimize number of violations. 3: Optimize original objective function under minimal number of violations. 4: Minimize sum of squared violations. 5: Optimize original objective function under minimal sum of squared violations. Synonyms: feasoptmode	0
iis	whether to compute an Irreducible Inconsistent Subsystem (IIS) if the problem is infeasible 0: no 1: compute IIS after solve if infeasible 2: compute IIS without solving original problem	0
IISMethod	Specifies the IIS method -1: Automatic. 0: Find smaller IIS. 1: Find IIS quickly.	-1

5.10.2.7 Parameter Tuning

Option	Description	Default
TuneMeasure	Method to aggregate multiple permutation solves into a single measure for tuner -1: Choose automatically. 0: Average value. 1: Maximum value.	-1
TuneMethod	Tuning method -1: Choose automatically. 0: Greedy search strategy. 1: Broader search strategy.	-1
TuneMode	Specifies tuning mode for tuner -1: Choose automatically. 0: Solving time. 1: Relative optimality gap. 2: Primal bound (objective function value of incumbent). 3: Dual bound (bound on optimal value).	-1

Option	Description	Default
TuneOutputLevel	Output level for tuner 0: No tuning log. 1: Summary of the improved parameters only. 2: Summary of each tuning attempt. 3: Detailed log of each tuning attempt.	2
TuneParams	COPT parameter file with options to be tuned For each parameter, multiple values can be specified. Range: string	
TunePermutes	Number of permuted solves for each parameter set by tuner (0: auto) Range: {0, ..., ∞}	0
TuneTargetRelGap	Target relative gap for tuning Range: [0, ∞]	0.0001
TuneTargetTime	Target elapsed time for tuning Range: [0, ∞]	0.01
TuneTimeLimit	Time limit of tuning (0: auto) Range: [0, 1e+20]	0
Tuning	If set, enables tuning tool. The option value should be the prefix for names of tuned option files that are written. Range: string	

5.10.2.8 GAMS/COPT link

Option	Description	Default
readparams	read COPT parameter file Range: string	
solnpool	Solution pool file name The name of a solutions index gdx file for writing alternate solutions found by COPT. The GDX file specified by this option will contain a set called index that contains the names of GDX files with the individual solutions. Range: string	
solnpoolmerge	Solution pool file name for merged solutions Range: string	
solvefinal	whether to solve the LP obtained from fixing discrete variables and variables in SOS after a MIP solve If marginals are not accessed after a MIP solve, it is advised to disable this option. Range: boolean	1
solvetrace	name of file for writing solving progress information during solve Range: string	
solvetracenodefreq	frequency in number of nodes for writing to solve trace file The node frequency does not work when COPT is run with multiple threads. Range: {0, ..., ∞}	100
solvetracetimefreq	frequency in seconds for writing to solve trace file Range: (0, ∞)	5
writebas	name of file to which to write advanced starting basis in basis format Range: string	
writebin	name of file to which to write problem in COPT binary format Range: string	
writelp	name of file to which to write problem in LP file format Range: string	

Option	Description	Default
writemps	name of file to which to write problem in MPS file format Range: string	
writemst	name of file to which to write MIP starting point Range: string	

5.11 CPLEX

5.11.1 Introduction

GAMS/Cplex is a GAMS solver that allows users to combine the high level modeling capabilities of GAMS with the power of Cplex optimizers. Cplex optimizers are designed to solve large, difficult problems quickly and with minimal user intervention. Access is provided (subject to proper licensing) to Cplex solution algorithms for linear, quadratically constrained and mixed integer programming problems. While numerous solving options are available, GAMS/Cplex automatically calculates and sets most options at the best values for specific problems.

All Cplex options available through GAMS/Cplex are summarized at the end of this document.

5.11.2 How to Run a Model with Cplex

The following statement can be used inside your GAMS program to specify using Cplex

```
Option LP = Cplex;     { or QCP, MIP, MIQCP, RMIP or RMIQCP }
```

The above statement should appear before the Solve statement. If Cplex was specified as the default solver during GAMS installation, the above statement is not necessary.

Attention

The free bare-bone link mode (previously GAMS/OSICPLEX) that allowed to solve LP and MIP when the user had a separate CPLEX license has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@gams.com to arrange for a GAMS/CPLEX Solver Link license.

5.11.3 Overview of Cplex

5.11.3.1 Linear Programming

Cplex solves LP problems using several alternative algorithms. The majority of LP problems solve best using Cplex's state of the art dual simplex algorithm. Certain types of problems benefit from using the primal simplex algorithm, the network optimizer, the barrier algorithm, or the sifting algorithm. The concurrent option will allow solving with different algorithms in parallel. The solution is returned by the first to finish.

Solving linear programming problems is memory intensive. Even though Cplex manages memory very efficiently, insufficient physical memory is one of the most common problems when running large LPs. When memory is limited, Cplex will automatically make adjustments which may negatively impact performance. If you are working with large models, study the section entitled Physical Memory Limitations carefully.

Cplex is designed to solve the majority of LP problems using default option settings. These settings usually provide the best overall problem optimization speed and reliability. However, there are occasionally reasons for changing option settings to improve performance, avoid numerical difficulties, control optimization run duration, or control output options.

Some problems solve faster with the primal simplex algorithm rather than the default dual simplex algorithm. Very few problems exhibit poor numerical performance in both the primal and the dual. Therefore, consider trying primal simplex if numerical problems occur while using dual simplex.

Cplex has a very efficient algorithm for network models. Network constraints have the following property:

- each non-zero coefficient is either a +1 or a -1
- each column appearing in these constraints has > exactly 2 nonzero entries, one with a +1 > coefficient and one with a -1 coefficient

Cplex can also automatically extract networks that do not adhere to the above conventions as long as they can be transformed to have those properties.

The barrier algorithm is an alternative to the simplex method for solving linear programs. It employs a primal-dual logarithmic barrier algorithm which generates a sequence of strictly positive primal and dual solutions. Specifying the barrier algorithm may be advantageous for large, sparse problems.

Cplex provides a sifting algorithm which can be effective on problems with many more variables than equations. Sifting solves a sequence of LP subproblems where the results from one subproblem are used to select columns from the original model for inclusion in the next subproblem.

GAMS/Cplex also provides access to the Cplex Conflict Refiner previously known as IIS (Irreducibly Inconsistent Set). The conflict refinder takes an infeasible program and produces an set of conflicting constraints. Such a set consists of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Cplex reports the conflict in terms of GAMS equation and variable names and includes the conflict report as part of the normal solution listing.

5.11.3.2 Quadratically Constrained Programming

Cplex can solve models with quadratic constraints. These are formulated in GAMS as models of type QCP. QCP models are solved with the Cplex Barrier method.

QP models are a special case that can be reformulated to have a quadratic objective function and only linear constraints. Those are automatically reformulated from GAMS QCP models. When such problems are convex, Cplex normally solves them efficiently in polynomial time. Nonconvex QPs, however, are known to be quite hard. Cplex applies various approaches to those problems, such approaches as barrier algorithms or branch and bound algorithms. Notably, in the branch and bound approach, there is no theoretical guarantee about the complexity of such a problem. Consequently, solution of such a problem (that is, a nonconvex QP) can take many orders of magnitude longer than the solution of a convex QP of comparable dimensions. Therefore, the default is to reject such model. The parameter OptimalityTarget allows to change this behavior.

For QCP models Cplex returns a primal and in most cases also dual values.

5.11.3.3 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with integer variables, Cplex uses a branch and cut algorithm which solves a series of LP, subproblems. Because a single mixed integer problem generates many subproblems,even small mixed integer problems can be very compute intensive and require significant amounts of physical memory.

GAMS and GAMS/Cplex support Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

Cplex can also solve problems of GAMS model type MIQCP. As in the continuous case, if the base model is a QP the Simplex methods can be used and duals will be available at the solution. If the base model is a QCP, only the Barrier method can be used for the nodes and only primal values will be available at the solution.

5.11.3.4 Feasible Relaxation

The Conflict Refiner identifies the causes of infeasibility by means of inconsistent set of constraints. However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Cplex is known as FeasOpt (for Feasible Optimization) and turned on by parameter FeasOpt in a CPLEX option file. More details can be found in the section entitled Using the Feasibility Relaxation.

5.11.3.5 Solution Pool: Generating and Keeping Multiple Solutions

This section introduces the *solution pool* for storing multiple solutions to a mixed integer programming problem (MIP and MIQCP). The chapter also explains techniques for generating and managing those solutions.

The solution pool stores multiple solutions to a mixed integer programming (MIP and MIQCP) model. With this feature, you can direct the algorithm to generate multiple solutions in addition to the optimal solution. For example, some constraints may be difficult to formulate efficiently as linear expressions, or the objective may be difficult to quantify exactly. In such cases, obtaining multiple solutions will help you choose one which best fits all your criteria,including the criteria that could not be expressed easily in a conventional MIP or MIQCP model. For example,

- You can collect solutions within a given percentage of the optimal solution. To do so, apply the solution pool gap parameters SolnPoolAGap and SolnPoolGap.
- You can collect a set of diverse solutions. To do so, use the solution pool replacement parameter SolnPoolReplace to set the solution pool replacement strategy to 2. In order to control the diversity of solutions even more finely, apply a *diversity filter*.
- In an advanced application of this feature, you can collect solutions with specific properties. To do so, see the use of the *incumbent filter*.
- You can collect all solutions or all optimal solutions to model. To do so, set the solution pool intensity parameter SolnPoolIntensity to its highest value.

Please note, that the value for *best possible* can exceed the optimal solution value if CPLEX has already solved the model to optimality but continues to search for additional solutions.

Filling the Solution Pool

There are two ways to fill the solution pool associated with a model: You can *accumulate* successive incumbents or generate alternative solutions by *populating* the solution pool. The method is selected with the parameter SolnPoolPop:

- The regular optimization procedure automatically adds incumbents to the solution pool as they are discovered (SolnPoolPop = 1).
- Cplex also provides a procedure specifically to generate multiple solutions. You can invoke this procedure by setting option SolnPoolPop = 2. You can also invoke this procedure many times in a row in order to explore the solution space differently. In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory. This is done by specifying a GAMS program (option SolnPoolPopRepeat) that inspects the solutions. In case this GAMS program terminates normally, i.e. no execution or compilation error, the exploration for alternative solutions proceeds.

The option SolnPoolReplace designates the strategy for replacing a solution in the solution pool when the solution pool has reached its capacity. The value 0 replaces solutions according to a first-in, first-out policy. The value 1 keeps the solutions with the best objective values. The value 2 replaces solutions in order to build a set of diverse solutions.

If the solutions you obtain are too similar to each other, try setting SolnPoolReplace to 2.

The replacement strategy applies only to the subset of solutions created in the current call of populate. Solutions already in the pool are not affected by the replacement strategy. They will not be replaced, even if they satisfy the criterion of the replacement strategy. So with every repeated call of the populate procedure the solution pool will be extended by the newly found solution. After the GAMS program specified in SolnPoolPopRepeat determined to continue the search for alternative solutions, the file specified by option SolnPoolPopDel option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

Enumerating All Solutions

With the solution pool, you can collect all solutions to a model. To do so, set the solution pool intensity parameter SolnPoolIntensity to its highest value, 4 and set SolnPoolPop = 2.

You can also enumerate all solutions that are valid for a specific criterion. For example, if you want to enumerate all alternative optimal solutions, do the following:

- Set the pool absolute gap parameter SolnPoolAGap = 0.0 (for models with potential numerical issues, better use a small non-zero like 1e-6).
- Set the pool intensity parameter SolnPoolIntensity = 4.
- Set the populate limit parameter PopulateLim to a value sufficiently large for your model; for example, 2100000000.
- Set the pool population parameter SolnPoolPop = 2.

Beware, however, that, even for small models, the number of possible solutions is likely to be huge. Consequently, enumerating all of them will take time and consume a large quantity of memory.

There may be an infinite number of possible values for a continuous variable, and it is not practical to enumerate all of them on a finite-precision computer. Therefore, populate gives only one solution for each set of binary and integer variables, even though there may exist several solutions that have the same values for all binary and integer variables but different values for continuous variables.

Likewise, for the same reason, the populate procedure does not generate all possible solutions for unbounded models. As soon as the proof of unboundedness is obtained, the populate procedure stops.

Cplex uses numerical methods of finite-precision arithmetic. Consequently, the feasibility of a solution depends on the value given to tolerances. Two parameters define the tolerances that assess the feasibility of a solution:

- the integrality tolerance EpInt
- the feasibility tolerance EpRHS

A solution may be considered feasible for one pair of values for these two parameters, and infeasible for a different pair. This phenomenon is especially noticeable in models with numeric difficulties, for example, in models with BigM coefficients.

Since the definition of a feasible solution is subject to tolerances, the total number of solutions to a model may vary, depending on the approach used to enumerate solutions, and on precisely which tolerances are used. In most models, this tolerance issue is not problematic. But, in the presence of numeric difficulties, Cplex may create solutions that are slightly infeasible or integer infeasible, and therefore create more solutions than expected.

Filtering the Solution Pool

Filtering allows you to control properties of the solutions generated and stored in the solution pool. Cplex provides two predefined ways to filter solutions.

If you want to filter solutions based on their difference as compared to a reference solution, use a *diversity filter*. This filter is practical for most purposes. However, if you require finer control of which solutions to keep and which to eliminate, use the *incumbent filter*.

Diversity Filter

A diversity filter allows you to generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables using dot option DivFlt and lower and upper bounds DivFltLo and DivFltUp. In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution. If you need more than one diversity filter, for example, to generate solutions that share the characteristics of several different solutions, additional filters can be specified through a Cplex Filter File using parameter ReadFLT. Details can be found in the example model `solnpool` in the GAMS model library.

Incumbent Filter

If you need to enforce more complex constraints on solutions (e.g. if you need to enforce nonlinear constraints), you can use the incumbent filtering. The incumbent checking routine is part of the GAMS BCH Facility. It will accept or reject incumbents independent of a solution pool. During the populate or regular optimize procedure, the incumbent checking routine specified by the parameter UserIncbCall is called each time a new solution is found, even if the new solution does not improve the objective value of the incumbent. The incumbent filter allows your application to accept or reject the new solution based on your own criteria. If the GAMS program specified by UserIncbCall terminates normally, the solution is rejected. If this program returns with a compilation or execution error, the incumbent is accepted.

Accessing the Solution Pool

The solutions are stored in GAMS Data eXchange (GDX) file and can be loaded by your GAMS program. Details can be found in the model `solnpool` in the GAMS model library and in . If you instruct Cplex to generate thousands of solution this becomes inefficient. The option SolnPoolMerge triggers the creation of a single GDX file containing all solutions.

The GAMS/Cplex link produces, if properly instructed, a GAMS Data eXchange(GDX) file with name specified in SolnPool that contains a set `Index` with elements `file1`, `file2`, ... The associated text of these elements contain the file names of the individual GDX solution file. The name is constructed using the prefix `soln` (which can be specified differently by option SolnPoolPrefix), the name of the model and a sequence number. For example `soln_loc_p1.gdx`. GAMS/Cplex will overwrite existing GDX files without warning. The set `Index` allows us to conveniently walk through the different solutions in the solution pool. A complete model can be found in the model `solnpool` in the GAMS model library.

```
...
solve mymodel min z using mip;

set soln           possible solutions in the solution pool /file1*file1000/
    solnpool(soln) actual solutions;
file fsol;

execute_load 'solnpool.gdx', solnpool=Index;
loop(solnpool(soln),
  put_utility fsol 'gdxin' / solnpool.te(soln):0:0;
  execute_loadpoint;
  display z.l;
);
```

If you instruct Cplex to generate thousands of solution this method becomes inefficient. The option SolnPoolMerge triggers the creation of a single GDX file containing all solutions. Details on usage of this option can be found in the model `solmpool` in the GAMS model library.

5.11.3.6 Benders Algorithm

CPLEX implements Benders algorithm.

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX makes use of annotations that you supply for your model. This approach can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach can offer significant performance improvements.

The parameter, BendersStrategy, specifies to CPLEX how you want to apply Benders algorithm as a strategy to solve your model. By default, if you did not annotate your model to specify a decomposition, CPLEX executes conventional branch and bound. If you annotated your model, CPLEX attempts to refine your decomposition and applies Benders algorithm. With this parameter, you can direct CPLEX to decompose your model and to apply its implementation of Benders algorithm in one of these alternative ways:

- 1: CPLEX attempts to decompose your model strictly according to your annotations.
- 2: CPLEX decomposes your model by using your annotations as hints and refining the decomposition where it can. CPLEX initially decomposes your model according to your annotation and then attempts to refine that decomposition by further decomposing the specified subproblems. This approach can be useful if you annotate certain variables to go into master, and all others to go into a single subproblem, which CPLEX can then decompose further for you.
- 3: CPLEX automatically decomposes your model, ignoring any annotations you may have supplied. CPLEX puts all integer variables into the master, puts all continuous variables into a subproblem and decomposes that subproblem, if possible.

If you want to specify a decomposition to CPLEX, you need to annotate your model and specify a Benders partition of your variable space. These Benders partition can be conveniently specified with the dot option BendersPartition or through the .stage variable suffix.

These Benders partition values specify to CPLEX whether certain variables belong to the master or to one of the subproblems assigned to workers (where the subproblems are numbered from 1 (one) to N, the number of subproblems). If you annotate a given variable with the value 0 (zero), CPLEX assigns that variable to the master. If you annotate a given variable with the value i, where i is greater than or equal to 1 (one), CPLEX assigns that variable to subproblem i. If a variable is not specified, the default will be to go into the master problem. Note that with `variable.BendersPartition 1` you can assign all variables to the subproblem and then selectively assign the master variables with `varname.BendersPartition 0`.

If you want to communicate the Benders partition values via the .stage variable suffix, the partition numbers are off by one compared to the partition number via the dot option. So the master variables have stage 1, and the subproblems start with stage 2. If you want to leave a variable unassigned you can either make the stage 0 or fractional (e.g. 1.5). Discrete variables are automatically put into the master problem and don't need to be set. In addition to specifying the Benders partition values via the .stage variable suffix the link option BendersPartitionInStage needs to be set to 1.

CPLEX produces an error if the annotated decomposition does not yield disjoint subproblems. For example, if your annotations specify that two (or more) variables belong in different subproblems, yet your model specifies that these variables participate in the same constraint, then these variables are linked. Consequently, the subproblems where these variables appear according to your annotations are not disjoint with respect to the partition.

5.11.3.7 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker's shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Cplex provides tools that simplify the task: Cplex allows you to blend multiple objectives, to treat them *hierarchically*, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or *lexicographic* approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective,

you only consider solutions that would not degrade the objective values of higher-priority objectives. Cplex allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Cplex will only solve multi-objective models with strictly linear objectives. Moreover, for continous models, Cplex will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```
equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defobj..            obj =e= numShifts - 1/100*sumPreferences;
defNumShifts..      numShifts =e= ...;
defSumPreferences.. sumPreferences =e= ...;

model workforce /all/;
solve workforce minimizing obj using mip;
```

With the default setting Cplex will solve the blended objective. Using the parameter MultObj Cplex will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (`defObj`). In the example, the `numShifts` objective with coefficient 1 has higher priority than the `sumPreferences` objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here `numShifts` will be minimized (same direction as on the `solve` statement) while `sumPreferences` will be maximized. GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won't allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: ObjNRelTol and ObjNAbsTol. Their meaning differs for continuous and discrete models:

- Discrete models: By setting one of the two tolerances for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for `numShifts` is 100, and if we set ObjNAbsTol for this objective to 20, then the second optimization step maximizing `sumPreferences` would find the best solution for the second objective from among all solutions with objective 120 or better for `numShifts`. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).
- Continuous Models: ObjNAbsTol does not include a hard constraint for previous objective functions in susequent solves. Instead, ObjNAbsTol defines a threshold for the reduced costs above which nonbasic variables in the associated LP solve will be fixed at the bound at which they reside. The option ObjNRelTol has no effect here. In order to apply the above discrete strategy for continuous models, set MultObjTolMip to `1`.

5.11.4 GAMS Options

The following GAMS options are used by GAMS/Cplex:

- **Option BRatio = x;**

Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Cplex not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed.

- **Option IterLim = n;**

  Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS.

  Cplex handles the iteration limit for MIP problems differently than some other GAMS solvers. The iteration limit is applied per node instead of as a total over all nodes. For MIP problems, controlling the length of the solution run by limiting the execution time (ResLim) is preferable.

  Simlarly, when using the sifting algorithm, the iteration limit is applied per sifting iteration (ie per LP). The number of sifting iterations (LPs) can be limited by setting Cplex parameter SiftItLim. It is the number of sifting iterations that is reported back to GAMS as iterations used.

- **Option ResLim = x;**

  Sets the time limit in seconds. In case resLim assumes its default value (1e+10) Cplex will use its own default (1e+75). The algorithm will terminate and pass on the current solution to GAMS.

- **Option SysOut = On;**

  Will echo Cplex messages to the GAMS listing file. This option may be useful in case of a solver failure.

- ***ModelName*.Cheat = x;**

  Cheat value: each new integer solution must be at least x better than the previous one. Can speed up the search, but you may miss the optimal solution. The cheat parameter is specified in absolute terms (like the OptCA option). The Cplex option ObjDif overrides the GAMS cheat parameter.

- ***ModelName*.Cutoff = x;**

  Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm.

- ***ModelName*.NodLim = x;**

  Maximum number of nodes to process for a MIP problem.

- **Option OptCA = x;**

  Absolute optimality criterion for a MIP problem. The OptCA option asks Cplex to stop when

  $$|BP - BF| < \text{OptCA}$$

  where BF is the objective function value of the current best integer solution while BP is the best possible integer solution.

  Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

- ***ModelName*.OptCR = x;**

  Relative optimality criterion for a MIP problem. Notice that Cplex uses a different definition than GAMS normally uses. The OptCR option asks Cplex to stop when

  $$(|BP - BF|)/(1.0e - 10 + |BF|) < \text{OptCR}$$

  where BF is the objective function value of the current best integer solution while BP is the best possible integer solution. The GAMS definition is:

$$(|BP - BF|)/(|BP|) < \text{OptCR}$$

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

- ***ModelName*.OptFile= 1;**

  Instructs Cplex to read the option file. The name of the option file is `cplex.opt`.

- ***ModelName*.PriorOpt= 1;**

  Instructs Cplex to use priority branching information passed by GAMS through the `variable.prior` parameters.

- ***ModelName*.TryInt= x;**

  Causes GAMS/Cplex to make use of current variable values when solving a MIP problem. If a variable value is within x of a bound, it will be moved to the bound and the preferred branching direction for that variable will be set toward the bound. The preferred branching direction will only be effective when priorities are used. Priorities and tryint are sometimes not very effective and often outperformed by GAMS/CPLEX default settings. Supporting GAMS/CPLEX with knowledge about a known solution can be passed on by different means, please read more about this in section entitled Starting from a MIP Solution.

GAMS/Cplex also sets many model attributes that can by used in your GAMS program by accessing *ModelName.suffix*. A list of model attributes available after the solve can be found here Model Attributes Mainly Used After Solve.

Cplex has the concept of deterministic time i.e. a measure of time that respects the same solution path to arrive at the same values in the solution while it yields the same level of performance for repeated solving of the same model with the same parameter settings, on the same computing platform. The length of a deterministic time tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high. GAMS/Cplex reports the deterministic time ticks spend inside Cplex in the model attribute `ETAlg`. Normally `ETAlg` is reporting the seconds.

5.11.5 Summary of CPLEX Options

The various Cplex options are listed here by category, with a few words about each to indicate its function. The options are listed again, in alphabetical order and with detailed descriptions, in the last section of this document.

5.11.5.1 Preprocessing and General Options

Option	Description	Default
advind	advanced basis use	`determined by GAMS Bratio`
aggfill	aggregator fill parameter	`10`
aggind	aggregator on/off	`-1`
bndrng	do lower / upper bound ranging	
calcqcpduals	calculate the dual values of a quadratically constrained problem	`1`

Option	Description	Default
clocktype	clock type for computation time	2
coeredind	coefficient reduction on/off	-1
cpumask	switch and mask to bind threads to processors (Linux only)	auto
datacheck	controls data consistency checking and modeling assistance	0
depind	dependency checker on/off	-1
dettilim	deterministic time limit	1.0e+75
feasopt	computes a minimum-cost relaxation to make an infeasible model feasible	0
feasoptmode	mode of FeasOpt	0
.feaspref	feasibility preference	1
fixoptfile	name of option file which is read just before solving the fixed problem	
folding	LP folding will be attempted during the preprocessing phase	-1
freegamsmodel	preserves memory by dumping the GAMS model instance representation temporarily to disk	0
iafile	secondary option file to be read in interactive mode triggered by iatriggerfile	
iatriggerfile	file that triggers the reading of a secondary option file in interactive mode	
iatriggertime	time interval in seconds the link looks for the trigger file in interactive mode	60
indicoptstrict	abort in case of an error in indicator constraint in solver option file	1
interactive	allow interactive option setting after a Control-C	0
lpmethod	algorithm to be used for LP problems	0
memoryemphasis	reduces use of memory	0
multobj	controls the hierarchical optimization of multiple objectives	0
multobjdisplay	level of display during multiobjective optimization	1
multobjmethod	method used for multi-objective solves	0
multobjoptfiles	List of option files used for individual solves within multi-objective optimization	
multobjtolmip	enables hard constraints for hierarchical optimization objectives based on degradation tolerances	1
names	load GAMS names into Cplex	1
numericalemphasis	emphasizes precision in numerically unstable or difficult problems	0
objnabstol	allowable absolute degradation for objective	

Option	Description	Default
objnreltol	allowable relative degradation for objective	
objrng	do objective ranging	no objective ranging is done
optimalitytarget	type of optimality that Cplex targets	0
parallelmode	parallel optimization mode	1
predual	give dual problem to the optimizer	0
preind	turn presolver on/off	1
prepass	number of presolve applications to perform	-1
prereform	set presolve reformulations	3
printoptions	list values of all options to GAMS listing file	0
qextractalg	quadratic extraction algorithm in GAMS interface	0
qpmethod	algorithm to be used for QP problems	0
qtolin	linearization of the quadratic terms in the objective function of a QP or MIQP model	-1
randomseed	sets the random seed differently for diversity of solutions	changes with each Cplex release
readparams	read Cplex parameter file	
reduce	primal and dual reduction type	3
relaxpreind	presolve for initial relaxation on/off	-1
rerun	rerun problem if presolve infeasible or unbounded	nono
rhsrng	do right-hand-side ranging	no right-hand-side ranging is done
rngrestart	write GAMS readable ranging information file	ranging information is printed to the listing file
scaind	matrix scaling on/off	0
solutiontype	type of solution (basic or non basic) for an LP or QP	0
threads	global default thread count	GAMS Threads
tilim	overrides the GAMS ResLim option	GAMS ResLim
tuning	invokes parameter tuning tool	
tuningdettilim	tuning deterministic time limit per model or suite	1.0e+75
tuningdisplay	level of information reported by the tuning tool	1
tuningmeasure	measure for evaluating progress for a suite of models	1
tuningrepeat	number of times tuning is to be repeated on perturbed versions	1
tuningtilim	tuning time limit per model or suite	0.2*GAMS ResLim

Option	Description	Default
warninglimit	determines how many times warnings of a specific type (datacheck=2) will be displayed	10
workdir	directory for working files	current or project directory
workmem	memory available for working storage	2048.0

5.11.5.2 Simplex Algorithmic Options

Option	Description	Default
conflictalg	algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model	0
conflictdisplay	decides how much information CPLEX reports when the conflict refiner is working	1
craind	crash strategy (used to obtain starting basis)	1
dpriind	dual simplex pricing	0
dynamicrows	switch for dynamic management of rows	-1
epper	perturbation constant	1.0e-06
iis	run the conflict refiner also known as IIS finder if the problem is infeasible	0
netfind	attempt network extraction	2
netppriind	network simplex pricing	0
perind	force initial perturbation	0
perlim	number of stalled iterations before perturbation	0
ppriind	primal simplex pricing	0
pricelim	pricing candidate list	0, in which case it is determined automatically
reinv	refactorization frequency	0, in which case it is determined automatically
sifting	switch for sifting from simplex optimization	1

5.11.5.3 Simplex Limit Options

Option	Description	Default
itlim	iteration limit	GAMS IterLim
netitlim	iteration limit for network simplex	large
objllim	objective function lower limit	-1.0e+75
objulim	objective function upper limit	1.0e+75
singlim	limit on singularity repairs	10

5.11.5.4 Simplex Tolerance Options

Option	Description	Default
epmrk	Markowitz pivot tolerance	0.01
epopt	optimality tolerance	1.0e-06
eprhs	feasibility tolerance	1.0e-06
ltol	basis identification primal tolerance	0
mtol	basis identification dual tolerance	0
netepopt	optimality tolerance for the network simplex method	1.0e-06
neteprhs	feasibility tolerance for the network simplex method	1.0e-06

5.11.5.5 Barrier Specific Options

Option	Description	Default
baralg	algorithm selection	0
barcolnz	dense column handling	0
barcrossalg	barrier crossover method	0
barepcomp	convergence tolerance	1.0e-08
bargrowth	unbounded face detection	1.0e+12
baritlim	iteration limit	large
barmaxcor	maximum correction limit	-1
barobjrng	maximum objective function	1.0e+20
barorder	row ordering algorithm selection	0
barqcpepcomp	convergence tolerance for the barrier optimizer for QCPs	1.0e-07
barstartalg	barrier starting point algorithm	1

5.11.5.6 Sifting Specific Options

Option	Description	Default
siftalg	sifting subproblem algorithm	0
siftitlim	limit on sifting iterations	large

5.11.5.7 MIP Algorithmic Options

Option	Description	Default
bbinterval	best bound interval	7

Option	Description	Default
.benderspartition	Benders partition	0
benderspartitioninstage	Benders partition through stage variable suffix	0
bendersstrategy	Benders decomposition algorithm as a strategy	0
bndstrenind	bound strengthening	-1
bqpcuts	boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality	0
brdir	set branching direction	0
bttol	backtracking limit	1.0
cardls	decides how often to apply the cardinality local search heuristic (CLSH)	-1
cliques	clique cut generation	0
covers	cover cut generation	0
cutlo	lower cutoff for tree search	-1.0e+75
cuts	default cut generation	0
cutsfactor	cut limit	-1.0
cutup	upper cutoff for tree search	1.0e+75
disjcuts	disjunctive cuts generation	0
divetype	MIP dive strategy	0
eachcutlim	sets a limit for each type of cut	2100000000
flowcovers	flow cover cut generation	0
flowpaths	flow path cut generation	0
fpheur	feasibility pump heuristic	0
fraccuts	Gomory fractional cut generation	0
gubcovers	GUB cover cut generation	0
heurfreq	heuristic frequency	0
heuristiceffort	the effort that CPLEX spends on heuristics during a MIP solve	1.0
implbd	implied bound cut generation	0
.lazy	Lazy constraints activation	0
lazyconstraints	Indicator to use lazy constraints	0
lbheur	local branching heuristic	0
liftprojcuts	lift-and-project cuts	0
localimplied	generation of locally valid implied bound cuts	0
lowerobjstop	in a minimization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value lower than or equal to the specified value	-1e75
mcfcuts	multi-commodity flow cut generation	0

Option	Description	Default
mipemphasis	MIP solution tactics	0
mipkappastats	MIP kappa computation	0
mipordind	priority list on/off	GAMS PriorOpt
mipordtype	priority order generation	0
mipsearch	search strategy for mixed integer programs	0
mipstart	use mip starting values	0
mipstopexpr	stopping expression for branch and bound	
miqcpstrat	MIQCP relaxation choice	0
mircuts	mixed integer rounding cut generation	0
multimipstart	use multiple mipstarts provided via gdx files	
nodecuts	decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree	0
nodefileind	node storage file indicator	1
nodesel	node selection strategy	1
preslvnd	node presolve selector	0
probe	perform probing before solving a MIP	0
qpmakepsdind	adjust MIQP formulation to make the quadratic matrix positive-semi-definite	1
relaxfixedinfeas	accept small infeasibilties in the solve of the fixed problem	0
repeatpresolve	reapply presolve at root after preprocessing	-1
rinsheur	relaxation induced neighborhood search frequency	0
rltcuts	Reformulation Linearization Technique (RLT) cuts	0
solvefinal	switch to solve the problem with fixed discrete variables	1
sos1reform	automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)	0
sos2reform	automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)	0
startalg	MIP starting algorithm	0
strongcandlim	size of the candidates list for strong branching	10
strongitlim	limit on iterations per branch for strong branching	0
subalg	algorithm for subproblems	0
submipnodelim	limit on number of nodes in an RINS subMIP	500
submipscale	scale the problem matrix when CPLEX solves a subMIP during MIP optimization	0
submipstartalg	starting algorithm for a subMIP of a MIP	0
submipsubalg	algorithm for subproblems of a subMIP of a MIP	0

Option	Description	Default
symmetry	symmetry breaking cuts	-1
upperobjstop	in a maximization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value greater than or equal to the specified value	1e75
.usercut	User cut activation	0
usercutpool	Indicator to use user cuts	0
varsel	variable selection strategy at each node	0
workeralgorithm	set method for optimizing benders subproblems	0
zerohalfcuts	zero-half cuts	0

5.11.5.8 MIP Limit Options

Option	Description	Default
aggcutlim	aggregation limit for cut generation	3
auxrootthreads	number of threads for auxiliary tasks at the root node	0
cutpass	maximum number of cutting plane passes	0
fraccand	candidate limit for generating Gomory fractional cuts	200
fracpass	maximum number of passes for generating Gomory fractional cuts	0
intsollim	maximum number of integer solutions	large
nodelim	maximum number of nodes to solve	GAMS NodLim
polishafterdettime	deterministic time before starting to polish a feasible solution	1.0e+75
polishafterepagap	absolute MIP gap before starting to polish a feasible solution	0.0
polishafterepgap	relative MIP gap before starting to polish a solution	0.0
polishafterintsol	MIP integer solutions to find before starting to polish a feasible solution	2147483647
polishafternode	nodes to process before starting to polish a feasible solution	2147483647
polishaftertime	time before starting to polish a feasible solution	1.0e+75
probedettime	deterministic time spent probing	1.0e+75
probetime	time spent probing	1.0e+75
repairtries	try to repair infeasible MIP start	0
trelim	maximum space in memory for tree	1.0e+75

5.11.5.9 MIP Solution Pool Options

Option	Description	Default
.divflt	solution pool range filter coefficients	0

Option	Description	Default
divfltlo	lower bound on diversity	mindouble
divfltup	upper bound on diversity	maxdouble
populatelim	limit of solutions generated for the solution pool by populate method	20
readflt	reads Cplex solution pool filter file	
solnpool	solution pool file name	
solnpoolagap	absolute tolerance for the solutions in the solution pool	1.0e+75
solnpoolcapacity	limits of solutions kept in the solution pool	2100000000
solnpoolgap	relative tolerance for the solutions in the solution pool	1.0e+75
solnpoolintensity	solution pool intensity for ability to produce multiple solutions	0
solnpoolmerge	solution pool file name for merged solutions	
solnpoolnumsym	maximum number of variable symbols when writing merged solutions	10
solnpoolpop	methods to populate the solution pool	1
solnpoolpopdel	file with solution numbers to delete from the solution pool	
solnpoolpoprepeat	method to decide if populating the solution should be repeated	
solnpoolprefix	file name prefix for GDX solution files	soln
solnpoolreplace	strategy for replacing a solution in the solution pool	0

5.11.5.10 MIP Tolerance Options

Option	Description	Default
bendersfeascuttol	Tolerance for whether a feasibility cut has been violated in Benders decomposition	1.0e-06
bendersoptcuttol	Tolerance for optimality cuts in Benders decomposition	1.0e-06
epagap	absolute stopping tolerance	GAMS OptCA
epgap	relative stopping tolerance	GAMS OptCR
epint	integrality tolerance	1.0e-05
eplin	degree of tolerance used in linearization	0.001
objdif	overrides GAMS Cheat parameter	0.0
relobjdif	relative cheat parameter	0.0

5.11.5.11 Output Options

Option	Description	Default
bardisplay	progress display level	1

Option	Description	Default
clonelog	enable clone logs	0
exactkappa	report exact condition number in quality report	0
mipdisplay	progress display level	4
mipinterval	progress display interval	0
miptrace	filename of MIP trace file	
mpslongnum	MPS file format precision of numeric output	1
netdisplay	network display level	2
quality	write solution quality statistics	0
siftdisplay	sifting display level	1
simdisplay	simplex display level	1
writeannotation	produce a Cplex annotation file	
writebas	produce a Cplex basis file	
writeflt	produce a Cplex solution pool filter file	
writelp	produce a Cplex LP file	
writemps	produce a Cplex MPS file	
writemst	produce a Cplex mst file	
writeord	produce a Cplex ord file	
writeparam	produce a Cplex parameter file with all active options	
writepre	produce a Cplex LP/MPS/SAV file of the presolved problem	
writeprob	produce a Cplex problem file and inferrs the type from the extension	
writesav	produce a Cplex binary problem file	

5.11.5.12 BCH Facility Options

Option	Description	Default
usercallparmfile	Command-line parameter include file used in GAMS command-line calls triggered by BCH	
usercutcall	the GAMS command line to call the cut generator	
usercutfirst	calls the cut generator for the first n nodes	10
usercutfreq	determines the frequency of the cut generator model calls	10
usercutinterval	determines the interval when to apply the multiplier for the frequency of the cut generator model calls	100
usercutmult	determines the multiplier for the frequency of the cut generator model calls	2
usercutnewint	calls the cut generator if the solver found a new integer feasible solution	1
usergdxin	the name of the GDX file read back into Cplex	bchin.gdx

Option	Description	Default
usergdxname	the name of the GDX file exported from the solver with the solution at the node	bchout.gdx
usergdxnameinc	the name of the GDX file exported from the solver with the incumbent solution	bchout_i.gdx
usergdxprefix	prefixes usergdxin, usergdxname, and usergdxnameinc	
usergdxsol	the name of the GDX file exported by Cplex to store the solution of extra columns	bchsol.gdx
userheurcall	the GAMS command line to call the heuristic	
userheurfirst	calls the heuristic for the first n nodes	10
userheurfreq	determines the frequency of the heuristic model calls	10
userheurinterval	determines the interval when to apply the multiplier for the frequency of the heuristic model calls	100
userheurmult	determines the multiplier for the frequency of the heuristic model calls	2
userheurnewint	calls the heuristic if the solver found a new integer feasible solution	1
userheurobjfirst	Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement	0
userincbcall	the GAMS command line to call the incumbent checking program	
userincbicall	the GAMS command line to call the incumbent reporting program	
userjobid	postfixes lf, o on call adds –userjobid to the call. Postfixes gdxname, gdxnameinc and gdxin	
userkeep	calls gamskeep instead of gams	0
userlazyconcall	the GAMS command line to call the lazy constraint generator	

5.11.5.13 The GAMS/Cplex Options File

The GAMS/Cplex options file consists of one option or comment per line. An asterisk (∗) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file `cplex.opt`.

```
scaind 1
simdisplay 2
```

It will cause Cplex to use a more aggressive scaling method than the default. The iteration log will have an entry for each iteration instead of an entry for each refactorization.

5.11.6 Special Notes

5.11.6.1 Physical Memory Limitations

For the sake of computational speed, Cplex should use only available physical memory rather than virtual or paged memory. When Cplex recognizes that a limited amount of memory is available it automatically makes algorithmic adjustments to compensate. These adjustments almost always reduce optimization

speed. Learning to recognize when these automatic adjustments occur can help to determine when additional memory should be added to the computer.

On virtual memory systems, if memory paging to disk is observed, a considerable performance penalty is incurred. Increasing available memory will speed the solution process dramatically. Also consider option MemoryEmphasis to conserve memory where possible.

When solving LPs, the Simplex algorithm (lpmethod 1 or 2) usually consumes less memory than the Barrier algorithm (lpmethod 2). During the Simplex algorithm, Cplex performs an operation called refactorization at a frequency determined by the ReInv option setting. The longer Cplex works between refactorizations, the greater the amount of memory required to complete each iteration. Therefore, one means for conserving memory is to increase the refactorization frequency. Since refactorization is an expensive operation, increasing the refactorization frequency by reducing the ReInv option setting generally will slow performance. Cplex will automatically increase the refactorization frequency if it encounters low memory availability. This can be seen by watching the iteration log. The default log reports problem status at every refactorization. If the number of iterations between iteration log entries is decreasing, Cplex is increasing the refactorization frequency. Since Cplex might increase the frequency to once per iteration, the impact on performance can be dramatic. Providing additional memory should be beneficial.

GAMS/Cplex also provides the option FreeGAMSModel to free some memory allocated by the GAMS link and making it available to Cplex. This only works when the GAMS parameter `solveLink` is set 0 which should be always done when memory is tight because GAMS completely vacates memory.

The Threads options also has a significant impact on memory consumption. The concurrent solvers keep multiple copies of the problem in memory which double or even triples the amount of memory consumed. If memory tight, set the Threads parameter to 1.

Not loading GAMS names into CPLEX can also help in saving some memory. This can be done by setting the model attribute dictFile or by using CPLEX option names.

5.11.6.2 Using Special Ordered Sets

For some models a special structure can be exploited. GAMS allows you to declare SOS1 and SOS2 variables (Special Ordered Sets of type 1 and 2).

In Cplex the definition for SOS1 variables is:

- A set of variables for which at most one variable may be non-zero.

The definition for SOS2 variables is:

- A set of variables for which at most two variables may be non-zero. If two variables are non-zero, they must be adjacent in the set.

5.11.6.3 Using Semi-Continuous and Semi-Integer Variables

GAMS allows the declaration of semi-continuous and semi-integer variables. These variable types are directly supported by GAMS/Cplex. For example:

```
SemiCont Variable x;
x.lo = 3.2;
x.up = 8.7;

SemiInt Variable y;
y.lo = 5;
y.up = 10;
```

Variable x will be allowed to take on a value of 0.0 or any value between 3.2 and 8.7. Variable y will be allowed to take on a value of 0 or any integral value between 5 and 10.

5.11.6.4 Running Out of Memory for MIP Problems

The most common difficulty when solving MIP problems is running out of memory. This problem arises when the branch and bound tree becomes so large that insufficient memory is available to solve an LP subproblem. As memory gets tight, you may observe frequent warning messages while Cplex attempts to navigate through various operations within limited memory. If a solution is not found shortly the solution process will be terminated with an unrecoverable integer failure message.

The tree information saved in memory can be substantial. Cplex saves a basis for every unexplored node. When utilizing the best bound method of node selection, the list of such nodes can become very long for large or difficult problems. How large the unexplored node list can become is entirely dependent on the actual amount of physical memory available and the actual size of the problem. Certainly increasing the amount of memory available extends the problem solving capability. Unfortunately, once a problem has failed because of insufficient memory, you can neither project how much further the process needed to go nor how much memory would be required to ultimately solve it.

Memory requirements can be limited by using the WorkMem, option with the NodeFileInd option. Setting NodeFileInd to 2 or 3 will cause Cplex to store portions of the branch and bound tree on disk whenever it grows to larger than the size specified by option WorkMem. That size should be set to something less than the amount of physical memory available.

Another approach is to modify the solution process to utilize less memory.

- Set option NodeSel to use a best estimate strategy or, more drastically a depth-first-search. Depth first search rarely generates a large unexplored node list since Cplex will be diving deep into the branch and bound tree rather than jumping around within it.
- Set option VarSel to use strong branching. Strong branching spends extra computation time at each node to choose a better branching variable. As a result it generates a smaller tree. It is often faster overall, as well.
- On some problems, a large number of cuts will be generated without a correspondingly large benefit in solution speed. Cut generation can be turned off using option Cuts.
- Use the Simplex algorithm instead of the Barrier algorithm using options StartAlg and SubAlg.
- Use option solvefinal to avoid solving the final LP.

See also Physical Memory Limitations.

5.11.6.5 Failing to Prove Integer Optimality

One frustrating aspect of the branch and bound technique for solving MIP problems is that the solution process can continue long after the best solution has been found. Remember that the branch and bound tree may be as large as 2^n nodes, where n equals the number of binary variables. A problem containing only 30 binary variables could produce a tree having over one billion nodes! If no other stopping criteria have been set, the process might continue ad infinitum until the search is complete or your computer's memory is exhausted.

In general you should set at least one limit on the optimization process before beginning an optimization. Setting limits ensures that an exhaustive tree search will terminate in reasonable time. Once terminated, you can rerun the problem using some different option settings.

5.11.6.6 Starting from a MIP Solution

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution. When you provide such a starting solution, you may invoke relaxation induced neighborhood search (RINS heuristic) or solution polishing to improve the given solution. This first integer solution may include continuous and discrete variables of various types, such as semi-continuous variables or special ordered sets.

If you specify values for all discrete variables, GAMS/CPLEX will check the validity of the values as an integer-feasible solution; if you specify values for only a portion of the discrete variables, GAMS/CPLEX will attempt to fill in the missing values in a way that leads to an integer-feasible solution. If the specified values do not lead directly to an integer-feasible solution, GAMS/CPLEX will apply a quick heuristic to try to repair the MIP Start. The number of times that GAMS/CPLEX applies the heuristic is controlled by the repair tries parameter (RepairTries). If this process succeeds, the solution will be treated as an integer solution of the current problem.

A MIP start will only be used by GAMS/CPLEX if the MipStart parameter is set to 1. The starting values must be set via the `.L` variable attribute in the GAMS model before the solve statement.

5.11.6.7 Using the Feasibility Relaxation

The feasibility relaxation is enabled by the FeasOpt parameter in a CPLEX solver option file.

With the FeasOpt option CPLEX accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the dot option FeasPref. A negative or zero preference means that the associated bound or constraint is not to be modified. The weighted penalty function is constructed from these preferences. The larger the preference, the more likely it will be that a given bound or constraint will be relaxed. However, it is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a CPLEX solver option file. The syntax is:

(variable or equation) `.feaspref` *(value)*

For example, suppose we have a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the `cplex.opt` file can be specified by:

```
feasopt 1
v.feaspref            1
v.feaspref('i1',*)    2
v.feaspref('i1','j2') 0

e.feaspref(*,'j1')    0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxation on. Furthermore, we specify that all variables `v(i,j)` have preference of 1, except variables over set element `i1`, which have a preference of 2. The variable over set element `i1` and `j2` has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter FeasOptMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasOptMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations). Please check description of parameters FeasOpt and FeasOptMode for details. Also check example models `feasopt*` in the GAMS Model library.

5.11.6.8 Sensitivity Analysis

Sensitivity analysis (post-optimality analysis) in linear programming allows one to find out more about an optimal solution for a problem. In particular, objective ranging and right-hand-side ranging give information about how much an objective coefficient or a right-hand-side value can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or a right-hand-side.

Although not so much used for practical large scale problems and not available for mixed-integer or nonlinear models, ranging information can still be of use in some circumstances. This section describes how to produce ranging information with GAMS/CPLEX.

To obtain objective ranging information for a particular variable, the name of the GAMS variable should be specified with the ObjRng option. For example, to obtain ranging information for a variable `prod`, add the line

```
objrng prod
```

to a CPLEX options file. The ObjRng option can be repeated to specify ranging for more than one variable. To specify ranging for all variables, use the keyword `all`, i.e.,

```
objrng all
```

Similarly, to obtain right-hand-side ranging information for a particular equation, the name of the equation should be specified with the RhsRng option. Also this option can be repeated to obtain right-hand-side ranging information for several equations. To specify ranging for all equations use the keyword `all`.

As an example, consider solving the model [**TRNSPORT**] from the GAMS model library with CPLEX and options file

```
objrng all
rhsrng all
```

This gives the following table in the listing file:

```
EQUATION NAME                              LOWER      CURRENT        UPPER
-------------                              -----      -------        -----
cost                                        -INF            0         +INF
supply(seattle)                              300          350          625
supply(san-diego)                            550          600         +INF
demand(new-york)                              50          325          375
demand(chicago)                               25          300          350
demand(topeka)                                 0          275          325

VARIABLE NAME                              LOWER      CURRENT        UPPER
-------------                              -----      -------        -----
x(seattle, new-york)                       0.216        0.225        0.225
x(seattle, chicago)                            0        0.153        0.162
x(seattle, topeka)                         0.126        0.162         +INF
x(san-diego, new-york)                     0.225        0.225        0.234
x(san-diego, chicago)                      0.153        0.162         +INF
x(san-diego, topeka)                           0        0.126        0.162
z                                           -INF            1         +INF
```

If obtaining ranging information in a listing file is not sufficient, option RngRestart can be used to specify a file to which to write ranging information in GAMS syntax. For example, using an options file containing

```
rhsrng supply
rhsrng demand
rngrestart ranges.inc
```

will result in a file named `ranges.inc` being written with the following content:

```
* Include file with ranging information
* The set RNGLIM /LO,UP/ is assumed to be
* declared.

PARAMETER  supplyRNG(i,RNGLIM) /
seattle.LO                  300
seattle.UP                  625
san-diego.LO                550
san-diego.UP               +INF
/;
PARAMETER  demandRNG(j,RNGLIM) /
new-york.LO                  50
new-york.UP                 375
chicago.LO                   25
chicago.UP                  350
topeka.LO                     0
topeka.UP                   325
/;
```

For each equation specified, the ranging information is stored in a newly declared corresponding GAMS parameter. The name of the parameter is based on the name of the equation, but with `RNG` appended. The user is responsible for ensuring that the new name does not exceed the maximum symbol name length of GAMS identifiers. Further, the domain list of the new parameter is the same as the domain list for the corresponding equation with an additional dimension added to the end. The user is responsible for ensuring that the new parameter does not exceed the maximum number of index positions.

5.11.7 GAMS/Cplex Log File

Cplex reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the primal simplex algorithm, the iteration log starts with the iteration number followed by the scaled infeasibility value. Once feasibility has been attained, the objective function value is listed instead. At the default value for option simdisplay there is a log line for each refactorization. The screen log has the following appearance:

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =    0.01 sec.
Using conservative initial basis.

Iteration log . . .
Iteration:     1    Scaled infeas =        193998.067174
Iteration:    29    Objective     =         -3484.286415
Switched to devex.
Iteration:    98    Objective     =         -1852.931117
Iteration:   166    Objective     =          -349.706562

Optimal solution found.

Objective :         901.161538
```

The iteration log for the dual simplex algorithm is similar, but the dual infeasibility and dual objective are reported instead of the corresponding primal values:

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =    0.01 sec.

Iteration log . . .
Iteration:     1   Scaled dual infeas =             3.890823
Iteration:    53   Dual objective     =          4844.392441
Iteration:   114   Dual objective     =          1794.360714
Iteration:   176   Dual objective     =          1120.183325
Iteration:   238   Dual objective     =           915.143030
Removing shift (1).

Optimal solution found.

Objective :         901.161538
```

The log for the network algorithm adds statistics about the extracted network and a log of the network iterations. The optimization is finished by one of the simplex algorithms and an iteration log for that is produced as well.

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =    0.01 sec.
Extracted network with 25 nodes and 116 arcs.
Extraction time =   -0.00 sec.
Iteration log . . .
Iteration:     0   Infeasibility     =          1232.378800 (-1.32326e+12)

Network - Optimal:  Objective =    1.5716820779e+03
Network time =    0.01 sec.  Iterations = 26 (24)

Iteration log . . .
Iteration:     1    Scaled infeas =        212696.154729
Iteration:    62    Scaled infeas =         10020.401232
Iteration:   142    Scaled infeas =          4985.200129
Switched to devex.
Iteration:   217    Objective     =         -3883.782587
Iteration:   291    Objective     =         -1423.126582

Optimal solution found.

Objective :         901.161538
```

The log for the barrier algorithm adds various algorithm specific statistics about the problem before starting the iteration log. The iteration log includes columns for primal and dual objective values and infeasibility values. A special log follows for the crossover to a basic solution.

```
Tried aggregator 1 time.
LP Presolve eliminated 2 rows and 39 columns.
Aggregator did 30 substitutions.
Reduced LP has 243 rows, 335 columns, and 3912 nonzeros.
Presolve time =    0.02 sec.
Number of nonzeros in lower triangle of A*A' = 6545
Using Approximate Minimum Degree ordering
Total time for automatic ordering = 0.01 sec.
Summary statistics for Cholesky factor:

  Rows in Factor            = 243
  Integer space required    = 578
  Total non-zeros in factor = 8491
  Total FP ops to factor    = 410889

```

For MIP problems, during the branch and bound search, Cplex reports the node number, the number of nodes left, the value of the Objective function, the number of integer variables that have fractional values, the current best integer solution, the best relaxed solution at a node and an iteration count. The last column show the current optimality gap as a percentage. CPLEX logs an asterisk (∗) in the left-most column for any node where it finds an integer-feasible solution or new incumbent. The + denotes an incumbent generated by the heuristic.

```

5.11.8 Detailed Descriptions of CPLEX Options

These options should be entered in the options file after setting the GAMS ModelName.OptFile parameter to 1. The name of the options file is `cplex.opt`. The options file is case insensitive and the keywords should be given in full.

advind *(integer)*: advanced basis use ↩

Use an Advanced Basis. GAMS/Cplex will automatically use an advanced basis from a previous solve statement. The GAMS `BRatio` option can be used to specify when not to use an advanced basis. The Cplex option `AdvInd` can be used to ignore a basis passed on by GAMS (it overrides *BRatio*).

Default: `determined by GAMS Bratio`

value	meaning
0	Do not use advanced basis
1	Use advanced basis if available
2	Crash an advanced basis if available (use basis with presolve)

aggcutlim *(integer)*: aggregation limit for cut generation ↩

Limits the number of constraints that can be aggregated for generating flow cover and mixed integer rounding cuts. For most purposes, the default will be satisfactory.

Default: `3`

aggfill *(integer)*: aggregator fill parameter ↩

Aggregator fill limit. If the net result of a single substitution is more non-zeros than the setting of the `AggFill` parameter, the substitution will not be made.

Default: `10`

aggind *(integer)*: aggregator on/off ↩

This option, when set to a nonzero value, will cause the Cplex aggregator to use substitution where possible to reduce the number of rows and columns in the problem. If set to a positive value, the aggregator will be applied the specified number of times, or until no more reductions are possible. At the default value of -1, the aggregator is applied once for linear programs and an unlimited number of times for mixed integer problems.

Default: `-1`

value	meaning
`-1`	Once for LP, unlimited for MIP
`0`	Do not use
`>0`	Aggregator will be applied the specified number of times

auxrootthreads *(integer)*: number of threads for auxiliary tasks at the root node ↩

Partitions the number of threads for CPLEX to use for auxiliary tasks while it solves the root node of a problem. On a system that offers N processors or N global threads, if you set this parameter to n, where $N>n>0$ then CPLEX uses at most n threads for auxiliary tasks and at most N-n threads to solve the root node. See also the parameter Threads.

You cannot set n, the value of this parameter, to a value greater than or equal to N, the number of processors or global threads offered on your system. In other words, when you set this parameter to a value other than its default, that value must be strictly less than the number of processors or global threads on your system. Independent of the auxiliary root threads parameter, CPLEX will never use more threads than those defined by the global default thread count parameter. CPLEX also makes sure that there is at least one thread available for the main root tasks. For example, if you set the global threads parameter to 3 and the auxiliary root threads parameter to 4, CPLEX still uses only two threads for auxiliary root tasks in order to keep one thread available for the main root tasks. At its default value, 0 (zero), CPLEX automatically chooses the number of threads to use for the primary root tasks and for auxiliary tasks. The number of threads that CPLEX uses to solve the root node depends on several factors: 1) the number of processors available on your system; 2) the number of threads available to your application on your system (for example, as a result of limited resources or competition with other applications); 3) the value of the global default thread count parameter Threads.

Default: `0`

value	meaning
`-1`	Off: do not use additional threads for auxiliary tasks
`0`	Automatic: let CPLEX choose the number of threads to use
`N>n>0`	Use n threads for auxiliary root tasks

baralg *(integer)*: algorithm selection ↩

Selects which barrier algorithm to use. The default setting of 0 uses the infeasibility-estimate start algorithm for LPs and MIP subproblems and the standard barrier algorithm, option 3, for other cases. The standard barrier algorithm is almost always fastest. The alternative algorithms, options 1 and 2, may eliminate numerical difficulties related to infeasibility, but will generally be slower.

Default: `0`

value	meaning
0	Same as 1 for LPs and MIP subproblems, 3 otherwise
1	Infeasibility-estimate start
2	Infeasibility-constant start
3	standard barrier algorithm

barcolnz *(integer)*: dense column handling ↩

Determines whether or not columns are considered dense for special barrier algorithm handling. At the default setting of 0, this parameter is determined dynamically. Values above 0 specify the number of entries in columns to be considered as dense.

Default: 0

barcrossalg *(integer)*: barrier crossover method ↩

Selects which crossover method is used at the end of a barrier optimization. To turn off crossover set SolutionType to 2.

Default: 0

value	meaning
0	Automatic
1	Primal crossover
2	Dual crossover

bardisplay *(integer)*: progress display level ↩

Determines the level of progress information to be displayed while the barrier method is running.

Default: 1

value	meaning
0	No progress information
1	Display normal information
2	Display diagnostic information

barepcomp *(real)*: convergence tolerance ↩

Determines the tolerance on complementarity for convergence of the barrier algorithm. The algorithm will terminate with an optimal solution if the relative complementarity is smaller than this value.

Default: 1.0e-08

bargrowth *(real)*: unbounded face detection ↩

Used by the barrier algorithm to detect unbounded optimal faces. At higher values, the barrier algorithm will be less likely to conclude that the problem has an unbounded optimal face, but more likely to have numerical difficulties if the problem does have an unbounded face.

Default: 1.0e+12

baritlim *(integer)*: iteration limit ↩

Determines the maximum number of iterations for the barrier algorithm. When set to 0, no Barrier iterations occur, but problem *setup* occurs and information about the setup is displayed (such as Cholesky factorization information). When left at the default value, there is no explicit limit on the number of iterations.

Default: `large`

barmaxcor *(integer)*: maximum correction limit ↩

Specifies the maximum number of centering corrections that should be done on each iteration. Larger values may improve the numerical performance of the barrier algorithm at the expense of computation time. The default of -1 means the number is automatically determined.

Default: `-1`

barobjrng *(real)*: maximum objective function ↩

Determines the maximum absolute value of the objective function. The barrier algorithm looks at this limit to detect unbounded problems.

Default: `1.0e+20`

barorder *(integer)*: row ordering algorithm selection ↩

Determines the ordering algorithm to be used by the barrier method. By default, Cplex attempts to choose the most effective of the available alternatives. Higher numbers tend to favor better orderings at the expense of longer ordering run times. The automatic option includes additional processing and may yield results that differ from the explicit choice.

Default: `0`

value	meaning
0	Automatic
1	Approximate Minimum Degree (AMD)
2	Approximate Minimum Fill (AMF)
3	Nested Dissection (ND)

barqcpepcomp *(real)*: convergence tolerance for the barrier optimizer for QCPs ↩

Range: [`1.0e-12`, `1.0e+75`]

Default: `1.0e-07`

barstartalg *(integer)*: barrier starting point algorithm ↩

This option sets the algorithm to be used to compute the initial starting point for the barrier solver. The default starting point is satisfactory for most problems. Since the default starting point is tuned for primal problems, using the other starting points may be worthwhile in conjunction with the PreDual parameter.

Default: `1`

value	meaning
1	default primal, dual is 0
2	default primal, estimate dual
3	primal average, dual is 0
4	primal average, estimate dual

bbinterval *(integer)*: best bound interval ↩

Set interval for selecting a best bound node when doing a best estimate search. Active only when NodeSel is 2 (best estimate). Decreasing this interval may be useful when best estimate is finding good solutions but making little progress in moving the bound. Increasing this interval may help when the best estimate node selection is not finding any good integer solutions. Setting the interval to 1 is equivalent to setting NodeSel to 1.

Default: `7`

bendersfeascuttol *(real)*: Tolerance for whether a feasibility cut has been violated in Benders decomposition ↩

Default: `1.0e-06`

bendersoptcuttol *(real)*: Tolerance for optimality cuts in Benders decomposition ↩

Default: `1.0e-06`

.benderspartition *(integer)*: Benders partition ↩

Default: `0`

benderspartitioninstage *(boolean)*: Benders partition through stage variable suffix ↩

Default: `0`

bendersstrategy *(integer)*: Benders decomposition algorithm as a strategy ↩

Given a formulation of a problem, CPLEX can decompose the model into a single master and (possibly multiple) subproblems. To do so, CPLEX can make use of annotations that you supply for your model. The strategy can be applied to mixed-integer linear programs (MILP). For certain types of problems, this approach offers significant performance improvements as subproblems can be solved in parallel.

For mixed integer programs (MIP), under certain conditions, CPLEX can apply Benders algorithm to improve the search to find more feasible solutions more quickly.

Default: `0`

value	meaning
-1	Off Execute conventional branch and bound; ignore any Benders annotations. That is, do not use Benders algorithm even if a Benders partition of the current model is present

value	meaning
0	Automatic If annotations specifying a Benders partition of the current model are available, CPLEX attempts to decompose the model. CPLEX uses the master as given by the annotations, and attempts to partition the subproblems further, if possible, before applying Benders algorithm to solve the model. If the user supplied annotations, but the annotations supplied do not lead to a complete decomposition into master and disjoint subproblems (that is, if the annotations are wrong in that sense), CPLEX produces an error.
1	Apply user annotations CPLEX applies Benders algorithm to a decomposition based on annotations supplied by the user. If no annotations to decompose the model are available, this setting produces an error. If the user supplies annotations, but the supplied annotations do not lead to a complete partition of the original model into disjoint master and subproblems, then this setting produces an error.
2	Apply user annotations with automatic support for subproblems CPLEX accepts the master as given and attempts to decompose the remaining elements into disjoint subproblems to assign to workers. It then solves the Benders decomposition of the model. If no annotations to decompose the model are available, this setting produces an error. If the user supplies annotations, but the supplied annotations do not lead to a complete partition of the original model into disjoint master and subproblems, then this setting produces an error.
3	Apply automatic decomposition CPLEX ignores any annotation supplied with the model; CPLEX applies presolve; CPLEX then automatically generates a Benders partition, putting integer variables in master and continuous linear variables into disjoint subproblems. CPLEX then solves the Benders decomposition of the model. If the problem is a strictly linear program (LP), that is, there are no integer-constrained variables to put into master, then CPLEX reports an error. If the problem is a mixed integer linear program (MILP) where all variables are integer-constrained, (that is, there are no continuous linear variables to decompose into disjoint subproblems) then CPLEX reports an error.

bndrng *(string)*: do lower / upper bound ranging ↩

Calculate sensitivity ranges for the specified GAMS lower and upper bounds. Unlike most options, `BNDRng` can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS lower and upper bound named. Specifying `all` will cause range information to be produced for all lower and upper bounds. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

bndstrenind *(integer)*: bound strengthening ↩

Use bound strengthening when solving mixed integer problems. Bound strengthening tightens the bounds on variables, perhaps to the point where the variable can be fixed and thus removed from consideration during the branch and bound algorithm. This reduction is usually beneficial, but occasionally, due to its iterative nature, takes a long time.

Default: `-1`

value	meaning
-1	Determine automatically
0	Don't use bound strengthening
1	Use bound strengthening

bqpcuts *(integer)*: boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality ↩

Default: `0`

value	meaning
`-1`	Do not generate BQP cuts
`0`	Determined automatically
`1`	Generate BQP cuts moderately
`2`	Generate BQP cuts aggressively
`3`	Generate BQP cuts very aggressively

brdir *(integer)*: set branching direction ↩

Used to decide which branch (up or down) should be taken first at each node.

Default: `0`

value	meaning
`-1`	Down branch selected first
`0`	Algorithm decides
`1`	Up branch selected first

bttol *(real)*: backtracking limit ↩

This option controls how often backtracking is done during the branching process. At each node, Cplex compares the objective function value or estimated integer objective value to these values at parent nodes; the value of the `bttol` parameter dictates how much relative degradation is tolerated before backtracking. Lower values tend to increase the amount of backtracking, making the search more of a pure best-bound search. Higher values tend to decrease the amount of backtracking, making the search more of a depth-first search. This parameter is used only once a first integer solution is found or when a cutoff has been specified.

Range: [`0.0`, `1.0`]

Default: `1.0`

calcqcpduals *(integer)*: calculate the dual values of a quadratically constrained problem ↩

Default: `1`

value	meaning
`0`	Do not calculate dual values
`1`	Calculate dual values as long as it does not interfere with presolve reductions
`2`	Calculate dual values and disable any presolve reductions that would interfere

cardls *(integer)*: decides how often to apply the cardinality local search heuristic (CLSH) ↩

Default: `-1`

value	meaning
`-1`	Do not apply CLSH

value	meaning
0	Automatic
1	Apply the CLSH only at the root node
2	Apply the CLSH at the nodes of the branch and bound tree

cliques *(integer)*: clique cut generation ↩

Determines whether or not clique cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate clique cuts
0	Determined automatically
1	Generate clique cuts moderately
2	Generate clique cuts aggressively
3	Generate clique cuts very aggressively

clocktype *(integer)*: clock type for computation time ↩

Decides how computation times are measured for both reporting performance and terminating optimization when a time limit has been set. Small variations in measured time on identical runs may be expected on any computer system with any setting of this parameter.

Default: 2

value	meaning
0	Automatic
1	CPU time
2	Wall clock time

clonelog *(integer)*: enable clone logs ↩

The clone logs contain information normally recorded in the ordinary log file but inconvenient to send through the normal log channel in case of parallel execution. The information likely to be of most interest to you are special messages, such as error messages, that result from calls to the LP optimizers called for the subproblems. The clone log files are named cloneK.log, where K is the index of the clone, ranging from 0 (zero) to the number of threads minus one. Since the clones are created at each call to a parallel optimizer and discarded when it exits, the clone logs are opened at each call and closed at each exit. The clone log files are not removed when the clones themselves are discarded.

Default: 0

value	meaning
-1	Clone log files off
0	Automatic
1	Clone log files on

coeredind *(integer)*: coefficient reduction on/off ↩

Coefficient reduction is a technique used when presolving mixed integer programs. The benefit is to improve the objective value of the initial (and subsequent) linear programming relaxations by reducing the number of non-integral vertexes. However, the linear programs generated at each node may become more difficult to solve.

Default: `-1`

value	meaning
`-1`	Automatic
`0`	Do not use coefficient reduction
`1`	Reduce only to integral coefficients
`2`	Reduce all potential coefficients
`3`	Reduce aggressively with tilting

conflictalg *(integer)*: algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model ↩

Default: `0`

conflictdisplay *(integer)*: decides how much information CPLEX reports when the conflict refiner is working ↩

Default: `1`

value	meaning
`0`	No output
`1`	Summary display
`2`	Detailed display

covers *(integer)*: cover cut generation ↩

Determines whether or not cover cuts should be generated during optimization.

Default: `0`

value	meaning
`-1`	Do not generate cover cuts
`0`	Determined automatically
`1`	Generate cover cuts moderately
`2`	Generate cover cuts aggressively
`3`	Generate cover cuts very aggressively

cpumask *(string)*: switch and mask to bind threads to processors (Linux only) ↩

The value of this parameter serves as a switch to turn on (or to turn off) CPLEX binding of multiple threads to multiple processors on platforms where this feature is available. Hexadecimal values of this parameter serve as a mask to specify to CPLEX which processors (or cores) to use in binding multiple threads to multiple processors. CPU binding is also sometimes known as *processor affinity*. CPU binding reduces the variability of CPLEX runs. On some occasions, running the same CPLEX on the same (non trivial) models would produce a big variation in runtime, e.g. 1000 seconds versus 900 seconds on a 12 core machine. These differences happen

while CPLEX still gets exactly the same results and executes the exact same path, thanks to its completely deterministic algorithms. Running the same tests with CPU binding enabled reduced this variability in running time significantly.

If not set to `off` or `auto` CPLEX treats the value of this parameter as a string that resembles a hexadecimal number without the usual 0x prefix. A valid string consists of these elements: a) any digit from 0 (zero) through 9 (inclusive), b) any lower case character in the range a through f (inclusive), and c) any upper case character in the range A through F (inclusive). CPLEX rejects a string containing any other digits or characters than those.

When the value of this parameter is a valid string, each bit of this string corresponds to a central processing unit (CPU), that is, to a processor or core. The lowest order bit of the string corresponds to the first logical CPU, and the highest order corresponds to the last logical CPU. For example, `00000001` designates processor #0, `00000003` designates processors #0 and #1, `FFFFFFFF` designates all processors #0 through #31. CPLEX uses the ith CPU if and only if the ith bit of this string is set to 1 (one). Tip: For GNU/Linux users, this parameter behaves like the `taskset` command (except that this parameter lacks the prefix 0x).

If this CPU mask parameter is set to a valid string that designates a hexadecimal number, but global Threads count is set to 0 (zero), then CPLEX still starts as many threads as the number of cores on the machine, but only the cores enabled in the mask will be used.

For example, if a user sets this CPU mask parameter to the hexadecimal value "f" on a 16-core machine, and the user sets the global Threads count to 0 (zero), the result is 16 threads. These 16 threads will be bound to the first four cores in a round-robin way: treads 1,5,9,13 to core 1, threads 2,6,10,14 to core 2 and so on. This situation is probably not what the user intended. Therefore, if you set this CPU mask parameter, then you should also set global threads count; indeed, you should set the threads parameter to the number of active cores designated by the mask.

For example, on a 16 core machine, consider the difference between the value "off" and the value *ffff*. If the value of this parameter is "off" CPLEX does no binding. If the value of this parameter is *ffff*, CPLEX binds threads to cores.

Default: `auto`

value	meaning
`auto`	CPLEX decides whether to bind threads to cores (or processors)
`off`	CPLEX performs no binding
`hex`	CPLEX binds the threads in round-robin fashion to the cores specified by the mask

craind *(integer)*: crash strategy (used to obtain starting basis) ↩

The crash option biases the way Cplex orders variables relative to the objective function when selecting an initial basis.

Default: `1`

value	meaning
`-1`	Primal: alternate ways of using objective coefficients. Dual: aggressive starting basis
`0`	Primal: ignore objective coefficients during crash. Dual: aggressive starting basis
`1`	Primal: alternate ways of using objective coefficients. Dual: default starting basis

cutlo *(real)*: lower cutoff for tree search ↩

Sets the lower cutoff tolerance. When the problem is a maximization problem, CPLEX cuts off or discards solutions that are less than the specified cutoff value. If the model has no solution with an objective value greater than or equal to the cutoff value, then CPLEX declares the model infeasible. In other words, setting the lower cutoff value c for a maximization problem is similar to adding this constraint to the objective function of the model: `obj>=c`.

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: `-1.0e+75`

cutpass *(integer)*: maximum number of cutting plane passes ↩

Sets the upper limit on the number of passes that will be performed when generating cutting planes on a mixed integer model.

Default: `0`

value	meaning
`-1`	None
`0`	Automatically determined
`>0`	Maximum passes to perform

cuts *(string)*: default cut generation ↩

Allows generation setting of all optional cuts at once. This is done by changing the meaning of the default value (0: automatic) for the various Cplex cut generation options. The options affected are `Cliques`, `Covers`, `DisjCuts`, `FlowCovers`, `FlowPaths`, `FracCuts`, `GUBCovers`, `ImplBd`, `LiftProjCuts`, `MCFCuts`, `MIRCuts`, and `Symmetry`.

Default: `0`

value	meaning
`-1`	Do not generate cuts
`0`	Determined automatically
`1`	Generate cuts moderately
`2`	Generate cuts aggressively
`3`	Generate cuts very aggressively
`4`	Generate cuts highly aggressively
`5`	Generate cuts extremely aggressively

cutsfactor *(real)*: cut limit ↩

This option limits the number of cuts that can be added. For values between zero and one inclusive (that is, in the range [0.0, 1.0], CPLEX generates no cuts.

For values strictly greater than 1.0 (one), CPLEX limits the number of rows in the model with cuts added.

The limit on this total is the product of *CutsFactor* times the original number of rows. If CPLEX has presolved the model, the *original number of rows* is the number of rows in the presolved model. (This behavior with respect to a presolved model is unchanged.)

CPLEX regards negative values of this parameter as equivalent to the default value -1.0. That is, a negative value specifies no particular limit on the number of cuts. CPLEX computes and dynamically adjusts such a limit automatically

Default: `-1.0`

cutup *(real)*: upper cutoff for tree search ↩

Sets the upper cutoff tolerance. When the problem is a minimization problem, CPLEX cuts off or discards any solutions that are greater than the specified upper cutoff value. If the model has no solution with an objective value less than or equal to the cutoff value, CPLEX declares the model infeasible. In other words, setting an upper cutoff value c for a minimization problem is similar to adding this constraint to the objective function of the model: `obj<=c`.

This option overrides the GAMS Cutoff setting.

This parameter is not effective with FeasOpt. FeasOpt cannot analyze an infeasibility introduced by this parameter. If you want to analyze such a condition, add an explicit objective constraint to your model instead.

Default: `1.0e+75`

datacheck *(integer)*: controls data consistency checking and modeling assistance ↩

When the value of this parameter is set to level 2, CPLEX turns on both data consistency checking and modeling assistance. At this level, CPLEX issues warnings at the start of the optimization about disproportionate values (too large, too small) in coefficients, bounds, and righthand sides (RHS).

Default: `0`

value	meaning
0	Data checking off
1	Data checking on
2	Data checking and model assistance on

depind *(integer)*: dependency checker on/off ↩

This option determines if and when the dependency checker will be used.

Default: `-1`

value	meaning
-1	Automatic
0	Turn off dependency checking
1	Turn on only at the beginning of preprocessing
2	Turn on only at the end of preprocessing
3	Turn on at the beginning and at the end of preprocessing

dettilim *(real)*: deterministic time limit ↩

Sets a time limit expressed in ticks, a unit to measure work done deterministically.

The length of a deterministic tick may vary by platform. Nevertheless, ticks are normally consistent measures for a given platform (combination of hardware and software) carrying the same load. In other words, the correspondence of ticks to clock time depends on the hardware, software, and the current load of the machine. For the same platform and same load, the ratio of ticks per second stays roughly constant, independent of the model solved. However, for very short optimization runs, the variation of this ratio is typically high.

Default: `1.0e+75`

disjcuts *(integer)*: disjunctive cuts generation ↩

Determines whether or not to generate disjunctive cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: `0`

value	meaning
`-1`	Do not generate disjunctive cuts
`0`	Determined automatically
`1`	Generate disjunctive cuts moderately
`2`	Generate disjunctive cuts aggressively
`3`	Generate disjunctive cuts very aggressively

divetype *(integer)*: MIP dive strategy ↩

The MIP traversal strategy occasionally performs probing dives, where it looks ahead at both children nodes before deciding which node to choose. The default (automatic) setting chooses when to perform a probing dive, and the other two settings direct Cplex when to perform probing dives: never or always.

Default: `0`

value	meaning
`0`	Automatic
`1`	Traditional dive
`2`	Probing dive
`3`	Guided dive

.divflt *(real)*: solution pool range filter coefficients ↩

A diversity filter for a solution pool (see option SolnPool) allows you generate solutions that are similar to (or different from) a set of reference values that you specify for a set of binary variables. In particular, you can use a diversity filter to generate more solutions that are similar to an existing solution or to an existing partial solution.

A diversity filter drives the search for multiple solutions toward new solutions that satisfy a measure of diversity specified in the filter. This diversity measure applies only to binary variables. Potential new solutions are compared to a reference set. This reference set is specified with this dot option. If no reference set is specified, the difference measure will be computed relative to the other solutions in the pool. The diversity measure is computed by summing the pair-wise absolute differences from solution and the reference values.

Default: `0`

divfltlo *(real)*: lower bound on diversity ↩

Please check option DivFlt for general information on a diversity filter.

If you specify a lower bound on the diversity using `DivFltLo`, Cplex will look for solutions that are different from the reference values. In other words, you can say, Give me solutions that differ by at least this amount in this set of variables.

Default: `mindouble`

divfltup *(real)*: upper bound on diversity ↩

Please check option DivFlt for general information on a diversity filter.

If you specify an upper bound on diversity `DivFltUp`, Cplex will look for solutions similar to the reference values. In other words, you can say, Give me solutions that are close to this one, within this set of variables.

Default: `maxdouble`

dpriind *(integer)*: dual simplex pricing ↩

Pricing strategy for dual simplex method. Consider using dual steepest-edge pricing. Dual steepest-edge is particularly efficient and does not carry as much computational burden as the primal steepest-edge pricing.

Default: `0`

value	meaning
0	Determined automatically
1	Standard dual pricing
2	Steepest-edge pricing
3	Steepest-edge pricing in slack space
4	Steepest-edge pricing, unit initial norms
5	Devex pricing

dynamicrows *(integer)*: switch for dynamic management of rows ↩

This parameter specifies how CPLEX should manage rows in the current model during dual simplex optimization. More specifically, this parameter controls the use of the kernel simplex method (KSM) for the dual simplex algorithm. That is, CPLEX dynamically adjusts the dimensions of the basis matrix during execution of the dual simplex algorithm, according to the settings of this parameter.

When the value of this parameter is -1, its default value, this parameter specifies that the user wants CPLEX to manage rows dynamically, adjusting the dimensions of the basis matrix during dual simplex optimization. When it is set to 0, this parameter specifies that CPLEX must keep all rows. When it is set to 1, this parameter specifies that CPLEX can keep or discard rows according to its internal calculations.

Default: `-1`

value	meaning
-1	Automatic
0	Keep all rows
1	Manage rows

eachcutlim *(integer)*: sets a limit for each type of cut ↩

This parameter allows you to set a uniform limit on the number of cuts of each type that Cplex generates. By default, the limit is a large integer; that is, there is no effective limit by default.

Tighter limits on the number of cuts of each type may benefit certain models. For example, a limit on each type of cut will prevent any one type of cut from being created in such large number that the limit on the total number of all types of cuts is reached before other types of cuts have an opportunity to be created. A setting of 0 means no cuts.

This parameter does not influence the number of Gomory cuts. For means to control the number of Gomory cuts, see also the fractional cut parameters: FracCand, FracCuts, and FracPass.

Default: `2100000000`

epagap *(real)*: absolute stopping tolerance ↩

Synonym: optca

Absolute tolerance on the gap between the best integer objective and the objective of the best node remaining. When the value falls below the value of the `epagap` setting, the optimization is stopped. This option overrides GAMS OptCA which provides its initial value.

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

Default: `GAMS OptCA`

epgap *(real)*: relative stopping tolerance ↩

Synonym: optcr

Relative tolerance on the gap between the best integer objective and the objective of the best node remaining. When the value falls below the value of the `epgap` setting, the mixed integer optimization is stopped. Note the difference in the Cplex definition of the relative tolerance with the GAMS definition. This option overrides GAMS OptCR which provides its initial value.

Note: This option also influences the SubMIPs (e.g., used for the RINS heuristic) and can thus influence the solution path.

Range: [`0.0`, `1.0`]

Default: `GAMS OptCR`

epint *(real)*: integrality tolerance ↩

Integrality Tolerance. This specifies the amount by which an integer variable can be different than an integer and still be considered feasible.

Range: [`0.0`, `0.5`]

Default: `1.0e-05`

eplin *(real)*: degree of tolerance used in linearization ↩

Default: `0.001`

epmrk *(real)*: Markowitz pivot tolerance ↩

The Markowitz tolerance influences pivot selection during basis factorization. Increasing the Markowitz threshold may improve the numerical properties of the solution.

Range: [`1.0e-04`, `1.0`]

Default: `0.01`

epopt *(real)*: optimality tolerance ↩

The optimality tolerance influences the reduced-cost tolerance for optimality. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: [`1.0e-09`, `0.1`]

Default: `1.0e-06`

epper *(real)*: perturbation constant ↩

Perturbation setting. Highly degenerate problems tend to stall optimization progress. Cplex automatically perturbs the variable bounds when this occurs. Perturbation expands the bounds on every variable by a small amount thereby creating a different but closely related problem. Generally, the solution to the less constrained problem is easier to solve. Once the solution to the perturbed problem has advanced as far as it can go, Cplex removes the perturbation by resetting the bounds to their original values.

If the problem is perturbed more than once, the perturbation constant is probably too large. Reduce the `epper` option to a level where only one perturbation is required. Any value greater than or equal to 1.0e-8 is valid.

Default: `1.0e-06`

eprhs *(real)*: feasibility tolerance ↩

Feasibility tolerance. This specifies the degree to which a problem's basic variables may violate their bounds. This tolerance influences the selection of an optimal basis and can be reset to a higher value when a problem is having difficulty maintaining feasibility during optimization. You may also wish to lower this tolerance after finding an optimal solution if there is any doubt that the solution is truly optimal. If the feasibility tolerance is set too low, Cplex may falsely conclude that a problem is infeasible.

Range: [`1.0e-09`, `0.1`]

Default: `1.0e-06`

exactkappa *(boolean)*: report exact condition number in quality report ↩

Default: `0`

feasopt *(boolean)*: computes a minimum-cost relaxation to make an infeasible model feasible ↩

With `Feasopt` turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option FeasOptMode.

Feasible relaxations are available for all problem types with the exception of quadratically constraint problems.

Default: `0`

value	meaning
0	Turns Feasible Relaxation off
1	Turns Feasible Relaxation on

feasoptmode *(integer)*: mode of FeasOpt ↩

The parameter `FeasOptMode` allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter `FeasOptMode` indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations).

Default: `0`

value	meaning
0	Minimize sum of relaxations Minimize the sum of all required relaxations in first phase only
1	Minimize sum of relaxations and optimize Minimize the sum of all required relaxations in first phase and execute second phase to find optimum among minimal relaxations
2	Minimize number of relaxations Minimize the number of constraints and bounds requiring relaxation in first phase only
3	Minimize number of relaxations and optimize Minimize the number of constraints and bounds requiring relaxation in first phase and execute second phase to find optimum among minimal relaxations
4	Minimize sum of squares of relaxations Minimize the sum of squares of required relaxations in first phase only
5	Minimize sum of squares of relaxations and optimize Minimize the sum of squares of required relaxations in first phase and execute second phase to find optimum among minimal relaxations

.feaspref *(real)*: feasibility preference ↩

You can express the costs associated with relaxing a bound or right hand side value during a FeasOpt run through the `.feaspref` option. The input value denotes the users willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: `1`

fixoptfile *(string)*: name of option file which is read just before solving the fixed problem ↩

flowcovers *(integer)*: flow cover cut generation ↩

Determines whether or not flow cover cuts should be generated during optimization.

Default: `0`

value	meaning
-1	Do not generate flow cover cuts
0	Determined automatically
1	Generate flow cover cuts moderately
2	Generate flow cover cuts aggressively

flowpaths *(integer)*: flow path cut generation ↩

Determines whether or not flow path cuts should be generated during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: 0

value	meaning
-1	Do not generate flow path cuts
0	Determined automatically
1	Generate flow path cuts moderately
2	Generate flow path cuts aggressively

folding *(integer)*: LP folding will be attempted during the preprocessing phase ↩

Default: -1

value	meaning
-1	Automatic
0	Turn off folder
1	Moderate level of folding
2	Aggressive level of folding
3	Very aggressive level of folding
4	Highly aggressive level of folding
5	Extremely aggressive level of folding

fpheur *(integer)*: feasibility pump heuristic ↩

Controls the use of the feasibility pump heuristic for mixed integer programming (MIP) models.

Default: 0

value	meaning
-1	Turns Feasible Pump heuristic off
0	Automatic
1	Apply the feasibility pump heuristic with an emphasis on finding a feasible solution
2	Apply the feasibility pump heuristic with an emphasis on finding a feasible solution with a good objective value

fraccand *(integer)*: candidate limit for generating Gomory fractional cuts ↩

Limits the number of candidate variables for generating Gomory fractional cuts.

Default: 200

fraccuts *(integer)*: Gomory fractional cut generation ↩

Determines whether or not Gomory fractional cuts should be generated during optimization.

Default: `0`

value	meaning
`-1`	Do not generate Gomory fractional cuts
`0`	Determined automatically
`1`	Generate Gomory fractional cuts moderately
`2`	Generate Gomory fractional cuts aggressively

fracpass *(integer)*: maximum number of passes for generating Gomory fractional cuts ↩

Sets the upper limit on the number of passes that will be performed when generating Gomory fractional cuts on a mixed integer model. Ignored if parameter FracCuts is set to a nonzero value.

Default: `0`

value	meaning
`0`	0 Automatically determined
`>0`	Maximum passes to perform

freegamsmodel *(boolean)*: preserves memory by dumping the GAMS model instance representation temporarily to disk ↩

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with `SolveLink=0` and only for models without quadratic constraints.

Default: `0`

gubcovers *(integer)*: GUB cover cut generation ↩

Determines whether or not GUB (Generalized Upper Bound) cover cuts should be generated during optimization. The default of 0 indicates that the attempt to generate GUB cuts should continue only if it seems to be helping.

Default: `0`

value	meaning
`-1`	Do not generate GUB cover cuts
`0`	Determined automatically
`1`	Generate GUB cover cuts moderately
`2`	Generate GUB cover cuts aggressively

heurfreq *(integer)*: heuristic frequency ↩

This option specifies how often to apply the node heuristic. Setting to a positive number applies the heuristic at the requested node interval. A value of 100, for example, means that heuristics are invoked every hundredth node in the tree.

Default: `0`

value	meaning
-1	Do not use the node heuristic
0	Determined automatically
>0	Call heuristic at the requested node interval

heuristiceffort *(real)*: the effort that CPLEX spends on heuristics during a MIP solve ↩

The value is used to increase (if *>1*) or decrease (if *<1*) the effort that CPLEX spends on heuristics during a MIP solve. If set to 0, no heuristic will run.

Default: 1.0

iafile *(string)*: secondary option file to be read in interactive mode triggered by iatriggerfile ↩

If in interactive mode and this option is set, options will be read from the file specified by this option instead of direct user input (as described in interactive). This option file read can be triggered by interrupting Cplex with a Control-C or using the option iatriggerfile. If defined, GAMS/CPLEX looks for this file (content irrelevant) all iatriggertime seconds and if found, reads the option file iafile. The iatriggerfile is removed afterwards so it does not trigger twice.

iatriggerfile *(string)*: file that triggers the reading of a secondary option file in interactive mode ↩

See iafile.

iatriggertime *(real)*: time interval in seconds the link looks for the trigger file in interactive mode ↩

See iafile.

Default: 60

iis *(integer)*: run the conflict refiner also known as IIS finder if the problem is infeasible ↩

Find an set of conflicting constraints or IIS (Irreducably Inconsistent Set) and write an conflict report to the GAMS solution listing if the model is found to be infeasible.

Default: 0

value	meaning
0	No conflict analysis
1	Conflict analysis after solve if infeasible
2	Conflict analysis without previous solve

implbd *(integer)*: implied bound cut generation ↩

Determines whether or not implied bound cuts should be generated during optimization.

Default: 0

value	meaning
-1	Do not generate implied bound cuts
0	Determined automatically
1	Generate implied bound cuts moderately
2	Generate implied bound cuts aggressively

indicoptstrict *(boolean)*: abort in case of an error in indicator constraint in solver option file ↩

If enabled and a variable or equation specified in an indicator constraint is not present in the model, model generation will abort with an error message. Otherwise, if this option is disabled, erroneous indicator constraints are ignored and a warning is printed.

Default: `1`

interactive *(boolean)*: allow interactive option setting after a Control-C ↩

When set to yes, options can be set interactively after interrupting Cplex with a Control-C. Options are entered just as if they were being entered in the `cplex.opt` file. Control is returned to Cplex by entering `continue`. The optimization can be aborted by entering `abort`. This option can only be used when running from the command line. Moreover, the GAMS option `InteractiveSolver` needs to be set to 1.

Default: `0`

intsollim *(integer)*: maximum number of integer solutions ↩

This option limits the MIP optimization to finding only this number of mixed integer solutions before stopping.

Default: `large`

itlim *(integer)*: iteration limit ↩

Synonym: iterlim

The iteration limit option sets the maximum number of iterations before the algorithm terminates, without reaching optimality. This Cplex option overrides the GAMS IterLim option. Any non-negative integer value is valid.

Default: `GAMS IterLim`

.lazy *(boolean)*: Lazy constraints activation ↩

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraint, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Lazy constraints are only active if option LazyConstraints is enabled and are specified through the option `.lazy`. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `0`

lazyconstraints *(boolean)*: Indicator to use lazy constraints ↩

Default: `0`

lbheur *(boolean)*: local branching heuristic ↩

This parameter lets you control whether Cplex applies a local branching heuristic to try to improve new incumbents found during a MIP search. By default, this parameter is off. If you turn it on, Cplex will invoke a local branching heuristic only when it finds a new incumbent. If Cplex finds multiple incumbents at a single node, the local branching heuristic will be applied only to the last one found.

Default: `0`

value	meaning
0	Off
1	Apply local branching heuristic to new incumbent

liftprojcuts *(integer)*: lift-and-project cuts ↩

Default: 0

value	meaning
-1	Do not generate lift-and-project cuts
0	Determined automatically
1	Generate lift-and-project cuts moderately
2	Generate lift-and-project cuts aggressively
3	Generate lift-and-project cuts very aggressively

localimplied *(integer)*: generation of locally valid implied bound cuts ↩

Default: 0

value	meaning
-1	Do not generate locally valid implied bound cuts
0	Determined automatically
1	Generate locally valid implied bound cuts moderately
2	Generate locally valid implied bound cuts aggressively
3	Generate locally valid implied bound cuts very aggressively

lowerobjstop *(real)*: in a minimization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value lower than or equal to the specified value ↩

Default: -1e75

lpmethod *(integer)*: algorithm to be used for LP problems ↩

Specifies which LP algorithm to use. If left at the default value (0 for automatic), and a primal-feasible basis is available, primal simplex will be used. If no primal-feasible basis is available, and Threads is equal to 1, dual simplex will be used. If Threads is greater than 1 and no primal-feasible basis is available, the concurrent option will be used.

Sifting may be useful for problems with many more variables than equations.

The concurrent option runs multiple methods in parallel. The first thread uses dual simplex. The second thread uses barrier. The next thread uses primal simplex. Remaining threads are used by the barrier run. If the aspect ratio (number of columns versus number of rows) is large, and if more than 10 threads are available, then concurrent optimization also invokes sifting on the LP. The solution is returned by first method to finish.

Default: 0

value	meaning
0	Automatic
1	Primal Simplex

value	meaning
2	Dual Simplex
3	Network Simplex
4	Barrier
5	Sifting
6	Concurrent

ltol *(real)*: basis identification primal tolerance ↩

Default: 0

mcfcuts *(integer)*: multi-commodity flow cut generation ↩

Specifies whether Cplex should generate multi-commodity flow (MCF) cuts in a problem where Cplex detects the characteristics of a multi-commodity flow network with arc capacities. By default, Cplex decides whether or not to generate such cuts. To turn off generation of such cuts, set this parameter to -1. Cplex is able to recognize the structure of a network as represented in many real-world models. When it recognizes such a network structure, Cplex is able to generate cutting planes that usually help solve such problems. In this case, the cuts that Cplex generates state that the capacities installed on arcs pointing into a component of the network must be at least as large as the total flow demand of the component that cannot be satisfied by flow sources within the component.

Default: 0

value	meaning
-1	Do not generate MCF cuts
0	Determined automatically
1	Generate MCF cuts moderately
2	Generate MCF cuts aggressively

memoryemphasis *(boolean)*: reduces use of memory ↩

This parameter lets you indicate to Cplex that it should conserve memory where possible. When you set this parameter to its non default value, Cplex will choose tactics, such as data compression or disk storage, for some of the data computed by the barrier and MIP optimizers. Of course, conserving memory may impact performance in some models. Also, while solution information will be available after optimization, certain computations that require a basis that has been factored (for example, for the computation of the condition number Kappa) may be unavailable.

Default: 0

value	meaning
0	Do not conserve memory
1	Conserve memory where possible

mipdisplay *(integer)*: progress display level ↩

The amount of information displayed during MIP solution increases with increasing values of this option.

Default: 4

value	meaning
0	No display
1	Display integer feasible solutions
2	Displays nodes under mipinterval control
3	Same as 2 but adds information on cuts
4	Same as 3 but adds LP display for the root node
5	Same as 3 but adds LP display for all nodes

mipemphasis *(integer)*: MIP solution tactics ↩

This option controls the tactics for solving a mixed integer programming problem.

Default: 0

value	meaning
0	Balance optimality and feasibility
1	Emphasize feasibility over optimality
2	Emphasize optimality over feasibility
3	Emphasize moving the best bound
4	Emphasize hidden feasible solutions
5	Find high quality feasible solutions as early as possible

mipinterval *(integer)*: progress display interval ↩

Controls the frequency of node logging when the parameter MIPDisplay is set higher than 1 (one). Frequency must be an integer; it may be 0 (zero), positive, or negative. By default, CPLEX displays new information in the node log during a MIP solve at relatively high frequency during the early stages of solving a MIP model, and adds lines to the log at progressively longer intervals as solving continues. In other words, CPLEX logs information frequently in the beginning and progressively less often as it works. When the value is a positive integer n, CPLEX displays new incumbents, plus it displays a new line in the log every n nodes. When the value is a negative integer n, CPLEX displays new incumbents, and the negative value determines how much processing CPLEX does before it displays a new line in the node log. A negative value close to zero means that CPLEX displays new lines in the log frequently. A negative value far from zero means that CPLEX displays new lines in the log less frequently. In other words, a negative value of this parameter contracts or dilates the interval at which CPLEX displays information in the node log.

Default: 0

mipkappastats *(integer)*: MIP kappa computation ↩

MIP kappa summarizes the distribution of the condition number of the optimal bases CPLEX encountered during the solution of a MIP model. That summary may let you know more about the numerical difficulties of your MIP model. Because MIP kappa (as a statistical distribution) requires CPLEX to compute the condition number of the optimal bases of the subproblems during branch-and-cut search, you can compute the MIP kappa only when CPLEX solves the subproblem with its simplex optimizer. In other words, in order to obtain results with this parameter, you can not use the sifting optimizer nor the barrier without crossover to solve the subproblems. See the parameters StartAlg and SubAlg.

Computing the kappa of a subproblem has a cost. In fact, computing MIP kappa for the basis matrices can be computationally expensive and thus generally slows down the solution of a

problem. Therefore, the setting 0 (automatic) tells CPLEX generally not to compute MIP kappa, but in cases where the parameter NumericalEmphasis is turned on, CPLEX computes MIP kappa for a sample of subproblems. The value 1 (sample) leads to a negligible performance degradation on average, but can slow down the branch-and-cut exploration by as much as 10% on certain models. The value 2 (full) leads to a 2% performance degradation on average, but can significantly slow the branch-and-cut exploration on certain models. In practice, the value 1 (sample) is a good trade-off between performance and accuracy of statistics. If you need very accurate statistics, then use value 2 (full).

In case CPLEX is instructed to compute a MIP kappa distribution, the parameter Quality is automatically turned on.

Default: `0`

value	meaning
`-1`	No MIP kappa statistics; default
`0`	Automatic: let CPLEX decide
`1`	Compute MIP kappa for a sample of subproblems
`2`	Compute MIP kappa for all subproblems

mipordind *(boolean)*: priority list on/off ↩

Synonym: prioropt

Use priorities. Priorities should be assigned based on your knowledge of the problem. Variables with higher priorities will be branched upon before variables of lower priorities. This direction of the tree search can often dramatically reduce the number of nodes searched. For example, consider a problem with a binary variable representing a yes/no decision to build a factory, and other binary variables representing equipment selections within that factory. You would naturally want to explore whether or not the factory should be built before considering what specific equipment to purchased within the factory. By assigning a higher priority to the build/no build decision variable, you can force this logic into the tree search and eliminate wasted computation time exploring uninteresting portions of the tree. When set at 0 (default), the `MIPOrdInd` option instructs Cplex not to use priorities for branching. When set to 1, priority orders are utilized.

Note: Priorities are assigned to discrete variables using the .prior suffix in the GAMS model. Lower .prior values mean higher priority. The `.prioropt` model suffix has to be used to signal GAMS to export the priorities to the solver.

Default: `GAMS PriorOpt`

value	meaning
`0`	Do not use priorities for branching
`1`	Priority orders are utilized

mipordtype *(integer)*: priority order generation ↩

This option is used to select the type of generic priority order to generate when no priority order is present.

Default: `0`

value	meaning
0	None
1	decreasing cost magnitude
2	increasing bound range
3	increasing cost per coefficient count

mipsearch *(integer)*: search strategy for mixed integer programs ↩

Sets the search strategy for a mixed integer program. By default, Cplex chooses whether to apply dynamic search or conventional branch and cut based on characteristics of the model.

Default: 0

value	meaning
0	Automatic
1	Apply traditional branch and cut strategy
2	Apply dynamic search

mipstart *(integer)*: use mip starting values ↩

This option controls the use of advanced starting values for mixed integer programs. A setting of 2 indicates that the values should be checked to see if they provide an integer feasible solution before starting optimization. For `mipstart` equals 1, 2, 3 or 4 fractional values are rounded to the nearest integer value if the integrality violation is larger than CPLEX's integer tolerance and smaller or equal to tryint. A partial MIP start is applied for `mipstart` equals 1, 3 or 4. Here, for discrete variables only integer values (after possible rounding) are added to the advanced starting values.

Default: 0

value	meaning
0	do not use the values
1	set discrete variable values and use auto mipstart level
2	set all variable values and use check feasibility mipstart level
3	set discrete variable values and use solve fixed mipstart level
4	set discrete variable values and use solve sub-MIP mipstart level
5	set discrete variable values and use solve repair-MIP mipstart level
6	set discrete variable values and use no checks at all. Warning: CPLEX may accept infeasible points as solutions!

mipstopexpr *(string)*: stopping expression for branch and bound ↩

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: etalg, resusd, nodusd, objest, objval. Supported opertators are: +, -, ∗, /, ^, %, !=, ==, <, <=, >, >=, !, &&, ||, (,), abs, ceil, exp, floor, log, log10, pow, sqrt. Example:

```
nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1
```

If multiple stop expressions are given in an option file, the algorithm stops if any of them is true (|| concatenation).

miptrace *(string)*: filename of MIP trace file ↩

For a description of this feature, see chapter Solve trace.

Note: In contrast to other solvers, GAMS/CPLEX doesn't append the MIP trace file after a certain time or node count, but when CPLEX reports global progress. In order to indicate this, the MIP trace file will show `X` instead of `N` or `T`.

miqcpstrat *(integer)*: MIQCP relaxation choice ↩

This option controls how MIQCPs are solved. For some models, the setting 2 may be more effective than 1. You may need to experiment with this parameter to determine the best setting for your model.

Default: `0`

value	meaning
`0`	Automatic
`1`	QCP relaxation Cplex will solve a QCP relaxation of the model at each node.
`2`	LP relaxation Cplex will solve a LP relaxation of the model at each node.

mircuts *(integer)*: mixed integer rounding cut generation ↩

Determines whether or not to generate mixed integer rounding (MIR) cuts during optimization. At the default of 0, generation is continued only if it seems to be helping.

Default: `0`

value	meaning
`-1`	Do not generate MIR cuts
`0`	Determined automatically
`1`	Generate MIR cuts moderately
`2`	Generate MIR cuts aggressively

mpslongnum *(boolean)*: MPS file format precision of numeric output ↩

Determines the precision of numeric output in the MPS file formats. When this parameter is set to its default value 1 (one), numbers are written to MPS files in full-precision; that is, up to 15 significant digits may be written. The setting 0 (zero) writes files that correspond to the standard MPS format, where at most 12 characters can be used to represent a value. This limit may result in loss of precision.

Default: `1`

value	meaning
`0`	Use limited MPS precision
`1`	Use full-precision

mtol *(real)*: basis identification dual tolerance ↩

Default: `0`

multimipstart *(string)*: use multiple mipstarts provided via gdx files ↩

Specifies (multiple) GDX files with values for the variables. Each file is treated as one intial guess for the MIP start. These MIP starts are added in addition to the initial guess provided by the level attribute. A MIP start GDX file can be created, for example, by using the command line option savepoint.

multobj *(boolean)*: controls the hierarchical optimization of multiple objectives ↩

Default: `0`

multobjdisplay *(integer)*: level of display during multiobjective optimization ↩

Default: `1`

value	meaning
0	No display
1	Summary display after each subproblem
2	Summary display after each subproblem, as well as subproblem logs

multobjmethod *(integer)*: method used for multi-objective solves ↩

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the LPMethod parameter. This parameter determines the algorithm used to solve for subsequent objectives.

Default: `0`

multobjoptfiles *(string)*: List of option files used for individual solves within multi-objective optimization ↩

The options given by the option files in multobjoptfiles are applied on top of the default GAMS/CPLEX options. This includes options set by the user via the standard option file.

If the list of option files in multobjoptfiles is less than the number of objective functions, the default GAMS/CPLEX options (incl. user options as before) are used to solve the remaining instances. Additional option files (i.e. more than objective functions) are ignored.

Applied options can be verified by setting multobjdisplay to 2.

multobjtolmip *(boolean)*: enables hard constraints for hierarchical optimization objectives based on degradation tolerances ↩

CPLEX supports two different strategies to handle the degradation tolerances objnabstol and objnreltol depending on the problem type (continuous or discrete), see objnabstol. This setting enables the discrete strategy for continous models. Note that objnreltol has no effect for discrete models. Enabling this option can lead to higher solution times.

Default: `1`

names *(boolean)*: load GAMS names into Cplex ↩

This option causes GAMS names for the variables and equations to be loaded into Cplex. These names will then be used for error messages, log entries, and so forth. Setting names to no may help if memory is very tight.

Default: `1`

netdisplay *(integer)*: network display level ↩

This option controls the log for network iterations.

Default: `2`

value	meaning
0	No network log.
1	Displays true objective values
2	Displays penalized objective values

netepopt *(real)*: optimality tolerance for the network simplex method ↩

This optimality tolerance influences the reduced-cost tolerance for optimality when using the network simplex method. This option setting governs how closely Cplex must approach the theoretically optimal solution.

Range: [1.0e-11, 0.1]

Default: 1.0e-06

neteprhs *(real)*: feasibility tolerance for the network simplex method ↩

This feasibility tolerance determines the degree to which the network simplex algorithm will allow a flow value to violate its bounds.

Range: [1.0e-11, 0.1]

Default: 1.0e-06

netfind *(integer)*: attempt network extraction ↩

Specifies the level of network extraction to be done.

Default: 2

value	meaning
1	Extract pure network only
2	Try reflection scaling
3	Try general scaling

netitlim *(integer)*: iteration limit for network simplex ↩

Iteration limit for the network simplex method.

Default: large

netppriind *(integer)*: network simplex pricing ↩

Network simplex pricing algorithm. The default of 0 (currently equivalent to 3) shows best performance for most problems.

Default: 0

value	meaning
0	Automatic
1	Partial pricing
2	Multiple partial pricing
3	Multiple partial pricing with sorting

nodecuts *(integer)*: decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree ↩

Default: `0`

nodefileind *(integer)*: node storage file indicator ↩

Specifies how node files are handled during MIP processing. Used when parameter WorkMem has been exceeded by the size of the branch and cut tree. If set to 0 when the tree memory limit is reached, optimization is terminated. Otherwise a group of nodes is removed from the in-memory set as needed. By default, Cplex transfers nodes to node files when the in-memory set is larger than 128 MBytes, and it keeps the resulting node *files* in compressed form in memory. At settings 2 and 3, the node files are transferred to disk. They are stored under a directory specified by parameter WorkDir and Cplex actively manages which nodes remain in memory for processing.

Default: `1`

value	meaning
`0`	No node files
`1`	Node files in memory and compressed
`2`	Node files on disk
`3`	Node files on disk and compressed

nodelim *(integer)*: maximum number of nodes to solve ↩

Synonym: nodlim

The maximum number of nodes solved before the algorithm terminates, without reaching optimality. This option overrides the GAMS NodLim model suffix. When this parameter is set to 0 (this is only possible through an option file), Cplex completes processing at the root; that is, it creates cuts and applies heuristics at the root. When this parameter is set to 1 (one), it allows branching from the root; that is, nodes are created but not solved.

Default: `GAMS NodLim`

nodesel *(integer)*: node selection strategy ↩

This option is used to set the rule for selecting the next node to process when backtracking.

Default: `1`

value	meaning
`0`	Depth-first search This chooses the most recently created node.
`1`	Best-bound search This chooses the unprocessed node with the best objective function for the associated LP relaxation.
`2`	Best-estimate search This chooses the node with the best estimate of the integer objective value that would be obtained once all integer infeasibilities are removed.
`3`	Alternate best-estimate search

numericalemphasis *(boolean)*: emphasizes precision in numerically unstable or difficult problems ↩

This parameter lets you indicate to Cplex that it should emphasize precision in numerically difficult or unstable problems, with consequent performance trade-offs in time and memory.

Default: `0`

value	meaning
`0`	Off
`1`	Exercise extreme caution in computation

objdif *(real)*: overrides GAMS Cheat parameter ↩

Synonym: cheat

A means for automatically updating the cutoff to more restrictive values. Normally the most recently found integer feasible solution objective value is used as the cutoff for subsequent nodes. When this option is set to a positive value, the value will be subtracted from (added to) the newly found integer objective value when minimizing (maximizing). This forces the MIP optimization to ignore integer solutions that are not at least this amount better than the one found so far. The option can be adjusted to improve problem solving efficiency by limiting the number of nodes; however, setting this option at a value other than zero (the default) can cause some integer solutions, including the true integer optimum, to be missed. Negative values for this option will result in some integer solutions that are worse than or the same as those previously generated, but will not necessarily result in the generation of all possible integer solutions. This option overrides the GAMS Cheat parameter.

Default: `0.0`

objllim *(real)*: objective function lower limit ↩

Setting a lower objective function limit will cause Cplex to halt the optimization process once the minimum objective function value limit has been exceeded.

Default: `-1.0e+75`

objnabstol *(string)*: allowable absolute degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is `ObjNAbsTol ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. For MIPs (or if MultObjTolMip is enabled), if it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most `ObjNAbsTol`. For LPs, `ObjNAbsTol` defines a threshold for reduced costs above which nonbasic variables in the associated LP solve will be fixed at the bound at which they reside.

objnreltol *(string)*: allowable relative degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is `ObjNRelTol ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. For MIPs (or if MultObjTolMip is enabled), if it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most `ObjNRelTol`$*|z|$. This option has no effect for continuous models.

objrng *(string)*: do objective ranging ↩

Calculate sensitivity ranges for the specified GAMS variables. Unlike most options, `ObjRng` can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS variable named. Specifying `all` will cause range information to be produced for all variables. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

Default: `no objective ranging is done`

objulim *(real)*: objective function upper limit ↩

Setting an upper objective function limit will cause Cplex to halt the optimization process once the maximum objective function value limit has been exceeded.

Default: `1.0e+75`

optimalitytarget *(integer)*: type of optimality that Cplex targets ↩

This parameter specifies the type of solution that CPLEX attempts to compute with respect to the optimality of that solution when CPLEX solves a continuous (QP) or mixed integer (MIQP) quadratic model. In other words, the variables of the model can be continuous or mixed integer and continuous; the objective function includes a quadratic term, and perhaps the objective function is not positive semi-definite (non PSD). This parameter does not apply to quadratically constrained mixed integer problems (MIQCP); that is, this parameter does not apply to mixed integer problems that include a quadratic term among the constraints.

Default: `0`

value	meaning
`0`	Automatic CPLEX first attempts to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX will return with an error (Q is not PSD).
`1`	Search for a globally optimal solution to a convex model CPLEX searches for a globally optimal solution to a convex model. In problems of type QP or MIQP, this setting interacts with linearization switch QToLin for QP, MIQP
`2`	Search for a solution that satisfies first-order optimality conditions no optimality guarantee CPLEX first attempt to compute a provably optimal solution. If CPLEX cannot compute a provably optimal solution because the objective function is not convex, CPLEX searches for a solution that satisfies first-order optimality conditions but is not necessarily globally optimal.
`3`	Search for a globally optimal solution regardless of convexity If the problem type is QP, CPLEX first changes the problem type to MIQP. CPLEX then solves the problem (whether originally QP or MIQP) to global optimality. In problems of type QP or MIQP, this setting interacts with with linearization switch QToLin for QP, MIQP. With this setting information about dual values is not available for the solution.

parallelmode *(integer)*: parallel optimization mode ↩

Sets the parallel optimization mode. Possible modes are automatic, deterministic, and opportunistic.

In this context, deterministic means that multiple runs with the same model at the same parameter settings on the same platform will reproduce the same solution path and results. In contrast, opportunistic implies that even slight differences in timing among threads or in the order in which tasks are executed in different threads may produce a different solution path and consequently different timings or different solution vectors during optimization executed in parallel threads. When running with multiple threads, the opportunistic setting entails less synchronization between threads and consequently may provide better performance.

In deterministic mode, Cplex applies as much parallelism as possible while still achieving deterministic results. That is, when you run the same model twice on the same platform with the same parameter settings, you will see the same solution and optimization run.

More opportunities to exploit parallelism are available if you do not require determinism. In other words, Cplex can find more opportunities for parallelism if you do not require an invariant, repeatable solution path and precisely the same solution vector. To use all available parallelism, you need to select the opportunistic parallel mode. In this mode, Cplex will utilize all opportunities for parallelism in order to achieve best performance.

However, in opportunistic mode, the actual optimization may differ from run to run, including the solution time itself and the path traveled in the search.

Parallel MIP optimization can be opportunistic or deterministic.

Parallel barrier optimization is only deterministic.

A GAMS/Cplex run will use deterministic mode unless explicitly specified.

If `ParallelMode` is explicitly set to 0 (automatic) the settings of this parallel mode parameter interact with settings of the Threads parameter. Let the result number of threads available to Cplex be n (note that negative values for the threads parameter are possible to exclude work on some cores).

Here is is list of possible value:

Default: `1`

value	meaning
`-1`	Enable opportunistic parallel search mode
`0`	Automatic
`1`	Enable deterministic parallel search mode

perind *(boolean)*: force initial perturbation ↩

Perturbation Indicator. If a problem automatically perturbs early in the solution process, consider starting the solution process with a perturbation by setting `PerInd` to 1. Manually perturbing the problem will save the time of first allowing the optimization to stall before activating the perturbation mechanism, but is useful only rarely, for extremely degenerate problems.

Default: `0`

value	meaning
`0`	not automatically perturbed
`1`	automatically perturbed

perlim *(integer)*: number of stalled iterations before perturbation ↩

Perturbation limit. The number of stalled iterations before perturbation is invoked. The default value of 0 means the number is determined automatically.

Default: `0`

polishafterdettime *(real)*: deterministic time before starting to polish a feasible solution ↩

Default: `1.0e+75`

polishafterepagap *(real)*: absolute MIP gap before starting to polish a feasible solution ↩

Solution polishing can yield better solutions in situations where good solutions are otherwise hard to find. More time-intensive than other heuristics, solution polishing is actually a variety of branch-and-cut that works after an initial solution is available. In fact, it requires a solution to be available for polishing, either a solution produced by branch-and-cut, or a MIP start supplied by a user. Because of the high cost entailed by solution polishing, it is not called throughout branch-and-cut like other heuristics. Instead, solution polishing works in a second phase after a first phase of conventional branch-and-cut. As an additional step after branch-and-cut, solution polishing can improve the best known solution. As a kind of branch-and-cut algorithm itself, solution polishing focuses solely on finding better solutions. Consequently, it may not prove optimality, even if the optimal solution has indeed been found. Like the RINS heuristic, solution polishing explores neighborhoods of previously found solutions by solving subMIPs.

Sets an absolute MIP gap (that is, the difference between the best integer objective and the objective of the best node remaining) after which CPLEX stops branch-and-cut and begins polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: `0.0`

polishafterepgap *(real)*: relative MIP gap before starting to polish a solution ↩

Sets a relative MIP gap after which CPLEX will stop branch-and-cut and begin polishing a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: `0.0`

polishafterintsol *(integer)*: MIP integer solutions to find before starting to polish a feasible solution ↩

Sets the number of integer solutions to find before CPLEX stops branch-and-cut and begins to polish a feasible solution. The default value is such that CPLEX does not invoke solution polishing by default.

Default: `2147483647`

polishafternode *(integer)*: nodes to process before starting to polish a feasible solution ↩

Sets the number of nodes processed in branch-and-cut before CPLEX starts solution polishing, if a feasible solution is available.

Default: `2147483647`

polishaftertime *(real)*: time before starting to polish a feasible solution ↩

Tells CPLEX how much time in seconds to spend during mixed integer optimization before CPLEX starts polishing a feasible solution. The default value is such that CPLEX does not start solution polishing by default.

Default: `1.0e+75`

populatelim *(integer)*: limit of solutions generated for the solution pool by populate method ↩

Limits the number of solutions generated for the solution pool during each call to the populate procedure. Populate stops when it has generated *PopulateLim* solutions. A solution is counted if it is valid for all filters (see DivFlt and consistent with the relative and absolute pool gap parameters (see SolnPoolGap and SolnPoolAGap), and has not been rejected by the incumbent checking routine (see UserIncbCall), whether or not it improves the objective of the model. This parameter does not apply to MIP optimization generally; it applies only to the populate procedure.

If you are looking for a parameter to control the number of solutions stored in the solution pool, consider the parameter SolnPoolCapacity instead.

Populate will stop before it reaches the limit set by this parameter if it reaches another limit, such as a time or node limit set by the user.

Default: `20`

ppriind *(integer)*: primal simplex pricing ↩

Pricing algorithm. Likely to show the biggest impact on performance. Look at overall solution time and the number of Phase I and total iterations as a guide in selecting alternate pricing algorithms. If you are using the dual Simplex method use DPriInd to select a pricing algorithm. If the number of iterations required to solve your problem is approximately the same as the number of rows in your problem, then you are doing well. Iteration counts more than three times greater than the number of rows suggest that improvements might be possible.

Default: `0`

value	meaning
`-1`	Reduced-cost pricing This is less compute intensive and may be preferred if the problem is small or easy. This option may also be advantageous for dense problems (say 20 to 30 nonzeros per column).
`0`	Hybrid reduced-cost and Devex pricing
`1`	Devex pricing This may be useful for more difficult problems which take many iterations to complete Phase I. Each iteration may consume more time, but the reduced number of total iterations may lead to an overall reduction in time. Tenfold iteration count reductions leading to threefold speed improvements have been observed. Do not use devex pricing if the problem has many columns and relatively few rows. The number of calculations required per iteration will usually be disadvantageous.
`2`	Steepest edge pricing If devex pricing helps, this option may be beneficial. Steepest-edge pricing is computationally expensive, but may produce the best results on exceptionally difficult problems.
`3`	Steepest edge pricing with slack initial norms This reduces the computationally intensive nature of steepest edge pricing.
`4`	Full pricing

predual *(integer)*: give dual problem to the optimizer ↩

Solve the dual. Some linear programs with many more rows than columns may be solved faster by explicitly solving the dual. The `PreDual` option will cause Cplex to solve the dual while returning the solution in the context of the original problem. This option is ignored if presolve is turned off.

Default: `0`

value	meaning
`-1`	do not give dual to optimizer
`0`	automatic
`1`	give dual to optimizer

preind *(boolean)*: turn presolver on/off ↩

Perform Presolve. This helps most problems by simplifying, reducing and eliminating redundancies. However, if there are no redundancies or opportunities for simplification in the model, if may be faster to turn presolve off to avoid this step. On rare occasions, the presolved model, although smaller, may be more difficult than the original problem. In this case turning the presolve off leads to better performance. Specifying 0 turns the aggregator off as well.

Default: `1`

prepass *(integer)*: number of presolve applications to perform ↩

Number of MIP presolve applications to perform. By default, Cplex determines this automatically. Specifying 0 turns off the presolve but not the aggregator. Set PreInd to 0 to turn both off.

Default: `-1`

value	meaning
`-1`	Determined automatically
`0`	No presolve
`>0`	Number of MIP presolve applications to perform

prereform *(integer)*: set presolve reformulations ↩

Default: `3`

preslvnd *(integer)*: node presolve selector ↩

Indicates whether node presolve should be performed at the nodes of a mixed integer programming solution. Node presolve can significantly reduce solution time for some models. The default setting is generally effective.

Default: `0`

value	meaning
`-1`	No node presolve
`0`	Automatic
`1`	Force node presolve
`2`	Perform probing on integer-infeasible variables
`3`	Perform aggressive node probing

pricelim *(integer)*: pricing candidate list ↩

Size for the pricing candidate list. Cplex dynamically determines a good value based on problem dimensions. Only very rarely will setting this option manually improve performance. Any non-negative integer values are valid.

Default: `0, in which case it is determined automatically`

printoptions *(boolean)*: list values of all options to GAMS listing file ↩

Write the values of all options to the GAMS listing file. Valid values are no or yes.

Default: `0`

probe *(integer)*: perform probing before solving a MIP ↩

Determines the amount of probing performed on a MIP. Probing can be both very powerful and very time consuming. Setting the value to 1 can result in dramatic reductions or dramatic increases in solution time depending on the particular model.

Default: `0`

value	meaning
`-1`	No probing
`0`	Automatic
`1`	Limited probing
`2`	More probing
`3`	Full probing

probedettime *(real)*: deterministic time spent probing ↩

Default: `1.0e+75`

probetime *(real)*: time spent probing ↩

Limits the amount of time in seconds spent probing.

Default: `1.0e+75`

qextractalg *(integer)*: quadratic extraction algorithm in GAMS interface ↩

Default: `0`

value	meaning
`0`	Automatic
`1`	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
`2`	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.
`3`	Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.

qpmakepsdind *(boolean)*: adjust MIQP formulation to make the quadratic matrix positive-semi-definite

↩

Determines whether Cplex will attempt to adjust a MIQP formulation, in which all the variables appearing in the quadratic term are binary. When this feature is active, adjustments will be made to the elements of a quadratic matrix that is not nominally positive semi-definite (*PSD*, as required by Cplex for all QP formulations), to make it PSD, and will also attempt to tighten an already PSD matrix for better numerical behavior. The default setting of 1 means `yes` but you can turn it off if necessary; most models should benefit from the default setting.

Default: `1`

value	meaning
`0`	Off
`1`	On

qpmethod *(integer)*: algorithm to be used for QP problems ↩

Specifies which QP algorithm to use.

At the default of 0 (automatic), barrier is used for QP problems and dual simplex for the root relaxation of MIQP problems.

Default: `0`

value	meaning
`0`	Automatic
`1`	Primal Simplex
`2`	Dual Simplex
`3`	Network Simplex
`4`	Barrier
`5`	Sifting
`6`	Concurrent dual, barrier, and primal

qtolin *(integer)*: linearization of the quadratic terms in the objective function of a QP or MIQP model ↩

This parameter switches on or off linearization of the quadratic terms in the objective function of a quadratic program or of a mixed integer quadratic program.

In a convex mixed integer quadratic program, this parameter controls whether Cplex linearizes the product of binary variables in the objective function during presolve. In a nonconvex quadratic program or mixed integer quadratic program solved to global optimality according to OptimalityTarget, this parameter controls how Cplex linearizes the product of bounded variables in the objective function during presolve.

This parameter interacts with the existing parameter OptimalityTarget: When the solution target type is set to 1 (that is, Cplex searches for a globally optimal solution to a convex model), then in a convex MIQP, this parameter tells Cplex to replace the product of a binary variable and a bounded linear variable by a linearly constrained variable. When the solution target type is set to 3, then in a nonconvex QP or nonconvex MIQP, this parameter controls the initial relaxation.

Default: `-1`

value	meaning
-1	Automatic
0	Off, Cplex does not linearize quadratic terms in the objective
1	On, Cplex linearizes quadratic terms in the objective

quality *(boolean)*: write solution quality statistics ↩

Write solution quality statistics to the listing and log file. If set to yes, the statistics appear after the Solve Summary and before the Solution Listing and contain information about infeasibility levels, solution value magnitued, and the condition number (kappa):

```
Solution Quality Statistics:
                                  unscaled                scaled
                                max         sum         max         sum
primal infeasibility        0.000e+00   0.000e+00   0.000e+00   0.000e+00
dual infeasibility          0.000e+00   0.000e+00   0.000e+00   0.000e+00
primal residual             0.000e+00   0.000e+00   0.000e+00   0.000e+00
dual residual               0.000e+00   0.000e+00   0.000e+00   0.000e+00
primal solution vector      3.000e+02   9.000e+02   3.000e+02   9.000e+02
dual solution vector        1.000e+00   1.504e+00   1.000e+00   1.504e+00
slacks                      5.000e+01   5.000e+01   5.000e+01   5.000e+01
reduced costs               3.600e-02   4.500e-02   3.600e-02   4.500e-02

Condition number of the scaled basis matrix =    9.000e+00
```

Default: 0

randomseed *(integer)*: sets the random seed differently for diversity of solutions ↩

Default: changes with each Cplex release

readflt *(string)*: reads Cplex solution pool filter file ↩

The GAMS/Cplex solution pool options cover the basic use of diversity and range filters for producing multiple solutions. If you need multiple filters, weights on diversity filters or other advanced uses of solution pool filters, you could produce a Cplex filter file with your favorite editor or the GAMS Put Facility and read this into GAMS/Cplex using this option.

readparams *(string)*: read Cplex parameter file ↩

reduce *(integer)*: primal and dual reduction type ↩

Determines whether primal reductions, dual reductions, or both, are performed during preprocessing. It is occasionally advisable to do only one or the other when diagnosing infeasible or unbounded models.

Default: 3

value	meaning
0	No primal or dual reductions
1	Only primal reductions
2	Only dual reductions
3	Both primal and dual reductions

reinv *(integer)*: refactorization frequency ↩

Refactorization Frequency. This option determines the number of iterations between refactorizations of the basis matrix. The default should be optimal for most problems. Cplex's performance is relatively insensitive to changes in refactorization frequency. Only for extremely large, difficult problems should reducing the number of iterations between refactorizations be considered. Any non-negative integer value is valid.

Default: `0, in which case it is determined automatically`

relaxfixedinfeas *(boolean)*: accept small infeasibilties in the solve of the fixed problem ↩

Sometimes the solution of the fixed problem of a MIP does not solve to optimality due to small (dual) infeasibilities. The default behavior of the GAMS/Cplex link is to return the primal solution values only. If the option is set to 1, the small infeasibilities are ignored and a full solution including the dual values are reported back to GAMS.

Default: `0`

value	meaning
0	Off
1	On

relaxpreind *(integer)*: presolve for initial relaxation on/off ↩

This option will cause the Cplex presolve to be invoked for the initial relaxation of a mixed integer program (according to the other presolve option settings). Sometimes, additional reductions can be made beyond any MIP presolve reductions that may already have been done.

Default: `-1`

value	meaning
-1	Automatic
0	do not presolve initial relaxation
1	use presolve on initial relaxation

relobjdif *(real)*: relative cheat parameter ↩

The relative version of the ObjDif option. Ignored if ObjDif is non-zero.

Default: `0.0`

repairtries *(integer)*: try to repair infeasible MIP start ↩

This parameter lets you indicate to Cplex whether and how many times it should try to repair an infeasible MIP start that you supplied. The parameter has no effect if the MIP start you supplied is feasible. It has no effect if no MIP start was supplied.

Default: `0`

value	meaning
-1	None: do not try to repair
0	Automatic
>0	Maximum tries to perform

repeatpresolve *(integer)*: reapply presolve at root after preprocessing ↩

This integer parameter tells Cplex whether to re-apply presolve, with or without cuts, to a MIP model after processing at the root is otherwise complete.

Default: `-1`

value	meaning
`-1`	Automatic
`0`	Turn off represolve
`1`	Represolve without cuts
`2`	Represolve with cuts
`3`	Represolve with cuts and allow new root cuts

rerun *(string)*: rerun problem if presolve infeasible or unbounded ↩

The Cplex presolve can sometimes diagnose a problem as being infeasible or unbounded. When this happens, GAMS/Cplex can, in order to get better diagnostic information, rerun the problem with presolve turned off. The GAMS solution listing will then mark variables and equations as infeasible or unbounded according to the final solution returned by the simplex algorithm. The IIS option can be used to get even more diagnostic information. The rerun option controls this behavior. Valid values are `auto`, `yes`, `no` and `nono`. The value of auto is equivalent to no if names are successfully loaded into Cplex and option IIS is set to no. In that case the Cplex messages from presolve help identify the cause of infeasibility or unboundedness in terms of GAMS variable and equation names. If names are not successfully loaded, rerun defaults to yes. Loading of GAMS names into Cplex is controlled by option Names. The value of `nono` only affects MIP models for which Cplex finds a feasible solution in the branch-and-bound tree but the fixed problem turns out to be infeasible. In this case the value `nono` also disables the rerun without presolve, while the value of no still tries this run. Feasible integer solution but an infeasible fixed problem happens in few cases and mostly with badly scaled models. If you experience this try more aggressive scaling (ScaInd) or tightening the integer feasibility tolerance EPInt. If the fixed model is infeasible only the primal solution is returned to GAMS. You can recognize this inside GAMS by checking the marginal of the objective defining constraint which is always nonzero.

Default: `nono`

value	meaning
`auto`	Automatic
`yes`	Rerun infeasible models with presolve turned off
`no`	Do not rerun infeasible models
`nono`	Do not rerun infeasible fixed MIP models

rhsrng *(string)*: do right-hand-side ranging ↩

Calculate sensitivity ranges for the specified GAMS equations. Unlike most options, `RHSRng` can be repeated multiple times in the options file. Sensitivity range information will be produced for each GAMS equation named. Specifying `all` will cause range information to be produced for all equations. Range information will be printed to the beginning of the solution listing in the GAMS listing file unless option RngRestart is specified.

Default: `no right-hand-side ranging is done`

rinsheur *(integer)*: relaxation induced neighborhood search frequency ↩

Cplex implements a heuristic known a Relaxation Induced Neighborhood Search (RINS) for MIP and MIQCP problems. RINS explores a neighborhood of the current incumbent to try to find a new, improved incumbent. It formulates the neighborhood exploration as a MIP, a subproblem known as the subMIP, and truncates the subMIP solution by limiting the number of nodes explored in the search tree.

Parameter `RINSHeur` controls how often RINS is invoked. A value of 100, for example, means that RINS is invoked every hundredth node in the tree.

Default: `0`

value	meaning
`-1`	Disable RINS
`0`	Automatic
`>0`	Call RINS at the requested node interval

rltcuts *(integer)*: Reformulation Linearization Technique (RLT) cuts ↩

This parameter controls the addition of cuts based on the Reformulation Linearization Technique (RLT) for nonconvex quadratic programs (QP) or mixed integer quadratic programs (MIQP) solved to global optimality. That is, the OptimalityTarget parameter must be set to 3. The `RLTCuts` option is not controlled by the option Cuts.

Default: `0`

value	meaning
`-1`	Do not generate RLT cuts
`0`	Determined automatically
`1`	Generate RLT cuts moderately
`2`	Generate RLT cuts aggressively
`3`	Generate RLT cuts very aggressively

rngrestart *(string)*: write GAMS readable ranging information file ↩

Write ranging information, in GAMS readable format, to the file named. If the file extension is GDX, the ranging information is exported as GDX file. Options ObjRng and RHSRng are used to specify which GAMS variables or equations are included.

Default: `ranging information is printed to the listing file`

scaind *(integer)*: matrix scaling on/off ↩

This option influences the scaling of the problem matrix.

Default: `0`

value	meaning
`-1`	No scaling
`0`	Standard scaling An equilibration scaling method is implemented which is generally very effective.
`1`	Modified, more aggressive scaling method This method can produce improvements on some problems. This scaling should be used if the problem is observed to have difficulty staying feasible during the solution process.

siftalg *(integer)*: sifting subproblem algorithm ↩

Sets the algorithm to be used for solving sifting subproblems.

Default: `0`

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network simplex
4	Barrier

siftdisplay *(integer)*: sifting display level ↩

Determines the amount of sifting progress information to be displayed.

Default: `1`

value	meaning
0	No display
1	Display major iterations
2	Display LP subproblem information

sifting *(boolean)*: switch for sifting from simplex optimization ↩

Default: `1`

siftitlim *(integer)*: limit on sifting iterations ↩

Sets the maximum number of sifting iterations that may be performed if convergence to optimality has not been reached.

Default: `large`

simdisplay *(integer)*: simplex display level ↩

This option controls what Cplex reports (normally to the screen) during optimization. The amount of information displayed increases as the setting value increases.

Default: `1`

value	meaning
0	No iteration messages are issued until the optimal solution is reported
1	An iteration log message will be issued after each refactorization Each entry will contain the iteration count and scaled infeasibility or objective value.
2	An iteration log message will be issued after each iteration The variables, slacks and artificials entering and leaving the basis will also be reported.

singlim *(integer)*: limit on singularity repairs ↩

The singularity limit setting restricts the number of times Cplex will attempt to repair the basis when singularities are encountered. Once the limit is exceeded, Cplex replaces the current basis with the best factorizable basis that has been found. Any non-negative integer value is valid.

Default: `10`

solnpool *(string)*: solution pool file name ↩

The solution pool enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file name contains the information about the different solutions generated by Cplex. Inside your GAMS program you can process the GDX file and read the different solution point files. Please check the GAMS/Cplex solver guide document and the example model `solnpool.gms` from the GAMS model library.

solnpoolagap *(real)*: absolute tolerance for the solutions in the solution pool ↩

Sets an absolute tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the objective of the incumbent solution according to this measure are not kept in the solution pool.

Values of the solution pool absolute gap and the solution pool relative gap SolnPoolGap may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and also within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool absolute gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: `1.0e+75`

solnpoolcapacity *(integer)*: limits of solutions kept in the solution pool ↩

Limits the number of solutions kept in the solution pool. At most, `SolnPoolCapacity` solutions will be stored in the pool. Superfluous solutions are managed according to the replacement strategy set by the solution pool replacement parameter SolnPoolReplace.

The optimization (whether by MIP optimization or the populate procedure) will not stop if more than `SolnPoolCapacity` are generated. Instead, stopping criteria are regular node and time limits and PopulateLim, SolnPoolGap and SolnPoolAGap.

Default: `2100000000`

solnpoolgap *(real)*: relative tolerance for the solutions in the solution pool ↩

Sets a relative tolerance on the objective bound for the solutions in the solution pool. Solutions that are worse (either greater in the case of a minimization, or less in the case of a maximization) than the incumbent solution by this measure are not kept in the solution pool.

Values of the solution pool absolute gap SolnPoolAGap and the solution pool relative gap may differ: For example, you may specify that solutions must be within 15 units by means of the solution pool absolute gap and within 1% of the incumbent by means of the solution pool relative gap. A solution is accepted in the pool only if it is valid for both the relative and the absolute gaps.

The solution pool relative gap parameter can also be used as a stopping criterion for the populate procedure: if populate cannot enumerate any more solutions that satisfy this objective quality, then it will stop. In the presence of both an absolute and a relative solution pool gap parameter, populate will stop when the smaller of the two is reached.

Default: `1.0e+75`

solnpoolintensity *(integer)*: solution pool intensity for ability to produce multiple solutions ↩

Controls the trade-off between the number of solutions generated for the solution pool and the amount of time or memory consumed. This parameter applies both to MIP optimization and to the populate procedure.

Values from 1 to 4 invoke increasing effort to find larger numbers of solutions. Higher values are more expensive in terms of time and memory but are likely to yield more solutions.

Default: `0`

value	meaning
`0`	Automatic Its default value, 0 , lets Cplex choose which intensity to apply.
`1`	Mild: generate few solutions quickly For value 1, the performance of MIP optimization is not affected. There is no slowdown and no additional consumption of memory due to this setting. However, populate will quickly generate only a small number of solutions. Generating more than a few solutions with this setting will be slow. When you are looking for a larger number of solutions, use a higher value of this parameter.
`2`	Moderate: generate a larger number of solutions For value 2, some information is stored in the branch and cut tree so that it is easier to generate a larger number of solutions. This storage has an impact on memory used but does not lead to a slowdown in the performance of MIP optimization. With this value, calling populate is likely to yield a number of solutions large enough for most purposes. This value is a good choice for most models.
`3`	Aggressive: generate many solutions and expect performance penalty For value 3, the algorithm is more aggressive in computing and storing information in order to generate a large number of solutions. Compared to values 1 and 2, this value will generate a larger number of solutions, but it will slow MIP optimization and increase memory consumption. Use this value only if setting this parameter to 2 does not generate enough solutions.
`4`	Very aggressive: enumerate all practical solutions For value 4, the algorithm generates all solutions to your model. Even for small models, the number of possible solutions is likely to be huge; thus enumerating all of them will take time and consume a large quantity of memory.

solnpoolmerge *(string)*: solution pool file name for merged solutions ↩

Similar to `solnpool` this option enables you to generate and store multiple solutions to a MIP problem. The option expects a GDX filename. This GDX file contains all variables with an additional first index (determined through SolnPoolPrefix) as parameters (Cplex only reports the primal solution). Inside your GAMS program you can process the GDX file and read all solutions in one read operation. Please check the GAMS/Cplex solver guide document for further solution pool options and the example model `solmpool.gms` from the GAMS model library.

solnpoolnumsym *(integer)*: maximum number of variable symbols when writing merged solutions ↩

Default: `10`

solnpoolpop *(integer)*: methods to populate the solution pool ↩

Regular MIP optimization automatically adds incumbents to the solution pool as they are discovered. Cplex also provides a procedure known as *populate* specifically to generate multiple solutions. You can invoke this procedure either as an alternative to the usual MIP optimizer or as a successor to the MIP optimizer. You can also invoke this procedure many times in a row in order to explore the solution space differently (see option SolnPoolPopRepeat). In particular, you may invoke this procedure multiple times to find additional solutions, especially if the first solutions found are not satisfactory.

Default: `1`

value	meaning
1	Just collect the incumbents found during regular optimization
2	Calls the populate procedure

solnpoolpopdel *(string)*: file with solution numbers to delete from the solution pool ↩

After the GAMS program specified in SolnPoolPopRepeat determined to continue the search for alternative solutions, the file specified by this option is read in. The solution numbers present in this file will be delete from the solution pool before the populate routine is called again. The file is automatically deleted by the GAMS/Cplex link after processing.

solnpoolpoprepeat *(string)*: method to decide if populating the solution should be repeated ↩

After the termination of the populate procedure (see option SolnPoolPop). The GAMS program specified in this option will be called which can examine the solutions in the solution pool and can decide to run the populate procedure again. If the GAMS program terminates normally (not compilation or execution time error) the search for new alternative solutions will be repeated.

solnpoolprefix *(string)*: file name prefix for GDX solution files ↩

Default: `soln`

solnpoolreplace *(integer)*: strategy for replacing a solution in the solution pool ↩

Default: `0`

value	meaning
0	Replace the first solution (oldest) by the most recent solution; first in, first out
1	Replace the solution which has the worst objective
2	Replace solutions in order to build a set of diverse solutions

solutiontype *(integer)*: type of solution (basic or non basic) for an LP or QP ↩

Specifies the type of solution (basic or non basic) that CPLEX attempts to compute for a linear program (LP) or for a quadratic program (QP). In this context, basic means having to do with the basis, and non basic applies to the variables and constraints not participating in the basis.

By default (that is, when the value of this parameter is 0 (zero) automatic), CPLEX seeks a basic solution (that is, a solution with a basis) for all linear programs (LP) and for all quadratic programs (QP).

When the value of this parameter is 1 (one), CPLEX seeks a basic solution, that is, a solution that includes a basis with a basic status for variables and constraints. In other words, CPLEX behaves the same way for the values 0 (zero) and 1 (one) of this parameter.

When the value of this parameter is 2, CPLEX seeks a pair of primal-dual solution vectors. This setting does not prevent CPLEX from producing status information, but in seeking a pair of primal-dual solution vectors, CPLEX possibly may not produce basic status information; that is, it is possible that CPLEX does not produce status information about which variables and constraints participate in the basis at this setting.

Do not use the deprecated value -1 (minus one) of the parameter barrier `crossover` algorithm to turn off crossover of the barrier algorithm but use this parameter to indicate that a primal-dual pair is sufficient.

Default: `0`

value	meaning
0	Automatic
1	Basic solution
2	primal-dual pair

solvefinal *(boolean)*: switch to solve the problem with fixed discrete variables ↩

Sometimes the solution process after the branch-and-cut that solves the problem with fixed discrete variables takes a long time and the user is interested in the primal values of the solution only. In these cases, `solvefinal` can be used to turn this final solve off. Without the final solve no proper marginal values are available and only NAs are returned to GAMS.

Default: `1`

value	meaning
0	Do not solve the fixed problem
1	Solve the fixed problem and return duals

sos1reform *(integer)*: automatic logarithmic reformulation of special ordered sets of type 1 (SOS1) ↩

Default: `0`

sos2reform *(integer)*: automatic logarithmic reformulation of special ordered sets of type 2 (SOS2) ↩

Default: `0`

startalg *(integer)*: MIP starting algorithm ↩

Selects the algorithm to use for the initial relaxation of a MIP.

Default: `0`

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network simplex
4	Barrier
5	Sifting
6	Concurrent

strongcandlim *(integer)*: size of the candidates list for strong branching ↩

Limit on the length of the candidate list for strong branching (VarSel = 3).

Default: `10`

strongitlim *(integer)*: limit on iterations per branch for strong branching ↩

Limit on the number of iterations per branch in strong branching (VarSel = 3). The default value of 0 causes the limit to be chosen automatically which is normally satisfactory. Try reducing this value if the time per node seems excessive. Try increasing this value if the time per node is reasonable but Cplex is making little progress.

Default: `0`

subalg *(integer)*: algorithm for subproblems ↩

Strategy for solving linear sub-problems at each node.

Default: `0`

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network optimizer followed by dual simplex
4	Barrier with crossover
5	Sifting

submipnodelim *(integer)*: limit on number of nodes in an RINS subMIP ↩

Controls the number of nodes explored in an RINS subMIP. See option RINSHeur.

Default: `500`

submipscale *(integer)*: scale the problem matrix when CPLEX solves a subMIP during MIP optimization ↩

Default: `0`

value	meaning
-1	No scaling
0	Standard scaling
1	Modified, more aggressive scaling method

submipstartalg *(integer)*: starting algorithm for a subMIP of a MIP ↩

Default: `0`

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex

value	meaning
3	Network simplex
4	Barrier
5	Sifting

submipsubalg *(integer)*: algorithm for subproblems of a subMIP of a MIP ↩

Default: 0

value	meaning
0	Automatic
1	Primal simplex
2	Dual simplex
3	Network optimizer followed by dual simplex
4	Barrier with crossover
5	Sifting

symmetry *(integer)*: symmetry breaking cuts ↩

Determines whether symmetry breaking cuts may be added, during the preprocessing phase, to a MIP model.

Default: -1

value	meaning
-1	Automatic
0	Turn off symmetry breaking
1	Moderate level of symmetry breaking
2	Aggressive level of symmetry breaking
3	Very aggressive level of symmetry breaking
4	Highly aggressive level of symmetry breaking
5	Extremely aggressive level of symmetry breaking

threads *(integer)*: global default thread count ↩

Synonym: gthreads

Default number of parallel threads allowed for any solution method. Negative values are interpreted as the number of cores to leave free so setting threads to -1 leaves one core free for other tasks. Cplex does not understand negative values for the `threads` parameter. GAMS/Cplex will translate this into a positive number by applying the following formula: max(1,number of cores-|threads|). Setting threads to 0 lets Cplex use at most 32 threads or the number of cores of the machine, whichever is smaller.

Default: `GAMS Threads`

tilim *(real)*: overrides the GAMS ResLim option ↩

Synonym: reslim

The time limit setting determines the amount of time in seconds that Cplex will continue to solve a problem. This Cplex option overrides the GAMS ResLim option. Any non-negative value is valid.

Default: `GAMS ResLim`

trelim *(real)*: maximum space in memory for tree ↩

Sets an absolute upper limit on the size (in megabytes) of the branch and cut tree. If this limit is exceeded, Cplex terminates optimization.

Default: `1.0e+75`

tuning *(string)*: invokes parameter tuning tool ↩

Invokes the Cplex parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Cplex option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in LP, MPS or SAV format. Cplex will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Cplex option file name without considering the problem provided by GAMS. Due to technical reasons a single option input line is limited by 256 characters. If the list of model files exceeds this length you can provide a second, third, ... line starting again with keyword `tuning` and a list of model instance files.

The result of such a tuning run is the updated GAMS/Cplex option file with a tuned set of parameters. The solver and model status returned to GAMS will be `NORMAL COMPLETION` and `NO SOLUTION`. More details on Cplex tuning can be found on `IBM's web page`. Tuning is incompatible with the BCH facility and other advanced features of GAMS/Cplex.

tuningdettilim *(real)*: tuning deterministic time limit per model or suite ↩

Default: `1.0e+75`

tuningdisplay *(integer)*: level of information reported by the tuning tool ↩

Specifies the level of information reported by the tuning tool as it works.

Default: `1`

value	meaning
0	Turn off display
1	Display standard minimal reporting
2	Display standard report plus parameter settings being tried
3	Display exhaustive report and log

tuningmeasure *(integer)*: measure for evaluating progress for a suite of models ↩

Controls the measure for evaluating progress when a suite of models is being tuned. Choices are mean average and minmax of time to compare different parameter sets over a suite of models

Default: `1`

value	meaning
1	mean average
2	minmax

tuningrepeat *(integer)*: number of times tuning is to be repeated on perturbed versions ↩

Specifies the number of times tuning is to be repeated on perturbed versions of a given problem. The problem is perturbed automatically by Cplex permuting its rows and columns. This repetition is helpful when only one problem is being tuned, as repeated perturbation and re-tuning may lead to more robust tuning results. This parameter applies to only one problem in a tuning session.

Default: `1`

tuningtilim *(real)*: tuning time limit per model or suite ↩

Sets a time limit per model and per test set (that is, suite of models).

As an example, suppose that you want to spend an overall amount of time tuning the parameter settings for a given model, say, 2000 seconds. Also suppose that you want Cplex to make multiple attempts within that overall time limit to tune the parameter settings for your model. Suppose further that you want to set a time limit on each of those attempts, say, 200 seconds per attempt. In this case you need to specify an overall time limit of 2000 using GAMS option `reslim` or Cplex option TiLim and `tuningtilim` to 200.

Default: `0.2*GAMS ResLim`

upperobjstop *(real)*: in a maximization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value greater than or equal to the specified value ↩

Default: `1e75`

usercallparmfile *(string)*: Command-line parameter include file used in GAMS command-line calls triggered by BCH ↩

.usercut *(boolean)*: User cut activation ↩

Determines whether a linear constraint is treated as a user cut. At the beginning of the MIP solution process, any constraint whose usercut attribute is set to 1 (the default value is 0) is removed from the model and placed in the user cut pool. User cuts may be used by CPLEX at any time to improve the solution process. There is no guarantee that they are actually used.

The user cut pool is only active if option usercutpool is enabled and are specified through the option `.usercut`. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `0`

usercutcall *(string)*: the GAMS command line to call the cut generator ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

usercutfirst *(integer)*: calls the cut generator for the first n nodes ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `10`

usercutfreq *(integer)*: determines the frequency of the cut generator model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `10`

usercutinterval *(integer)*: determines the interval when to apply the multiplier for the frequency of the cut generator model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `100`

usercutmult *(integer)*: determines the multiplier for the frequency of the cut generator model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `2`

usercutnewint *(boolean)*: calls the cut generator if the solver found a new integer feasible solution ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `1`

usercutpool *(boolean)*: Indicator to use user cuts ↩

Default: `0`

usergdxin *(string)*: the name of the GDX file read back into Cplex ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `bchin.gdx`

usergdxname *(string)*: the name of the GDX file exported from the solver with the solution at the node ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `bchout.gdx`

usergdxnameinc *(string)*: the name of the GDX file exported from the solver with the incumbent solution ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `bchout_i.gdx`

usergdxprefix *(string)*: prefixes usergdxin, usergdxname, and usergdxnameinc ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

usergdxsol *(string)*: the name of the GDX file exported by Cplex to store the solution of extra columns ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `bchsol.gdx`

userheurcall *(string)*: the GAMS command line to call the heuristic ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst *(integer)*: calls the heuristic for the first n nodes ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

userheurfreq *(integer)*: determines the frequency of the heuristic model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 10

userheurinterval *(integer)*: determines the interval when to apply the multiplier for the frequency of the heuristic model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 100

userheurmult *(integer)*: determines the multiplier for the frequency of the heuristic model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 2

userheurnewint *(boolean)*: calls the heuristic if the solver found a new integer feasible solution ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 1

userheurobjfirst *(integer)*: Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 0

userincbcall *(string)*: the GAMS command line to call the incumbent checking program ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userincbicall *(string)*: the GAMS command line to call the incumbent reporting program ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userjobid *(string)*: postfixes lf, o on call adds –userjobid to the call. Postfixes gdxname, gdxnameinc and gdxin ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userkeep *(boolean)*: calls gamskeep instead of gams ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: 0

userlazyconcall *(string)*: the GAMS command line to call the lazy constraint generator ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Note: There is no guarantee that CPLEX will use all of the added violated lazy constraints provided due to technical and/or efficiency reasons. It may thus happen that a later candidate solution violates previously provided lazy constraints. In this case consider passing the constraint again.

varsel *(integer)*: variable selection strategy at each node ↩

This option is used to set the rule for selecting the branching variable at the node which has been selected for branching. The default value of 0 allows Cplex to select the best rule based on the problem and its progress.

Default: 0

value	meaning
-1	Branch on variable with minimum infeasibility This rule may lead more quickly to a first integer feasible solution, but will usually be slower overall to reach the optimal integer solution.
0	Branch variable automatically selected
1	Branch on variable with maximum infeasibility This rule forces larger changes earlier in the tree, which tends to produce faster overall times to reach the optimal integer solution.
2	Branch based on pseudo costs Generally, the pseudo-cost setting is more effective when the problem contains complex trade-offs and the dual values have an economic interpretation.
3	Strong Branching This setting causes variable selection based on partially solving a number of subproblems with tentative branches to see which branch is most promising. This is often effective on large, difficult problems.
4	Branch based on pseudo reduced costs

warninglimit *(integer)*: determines how many times warnings of a specific type (datacheck=2) will be displayed ↩

By default, when modeling assistance is turned on via the data consistency checking parameter, CPLEX will display 10 warnings for a given modeling issue and then omit the rest. This parameter controls this limit and allows the user to display all of the warnings if desired. In order to see all warnings change the value to its negative.

Default: `10`

workdir *(string)*: directory for working files ↩

The name of an existing directory into which Cplex may store temporary working files. Used for MIP node files and by out-of-core Barrier.

Default: `current or project directory`

workeralgorithm *(integer)*: set method for optimizing benders subproblems ↩

Default: `0`

value	meaning
0	Automatic
1	Primal Simplex
2	Dual Simplex
3	Network Simplex
4	Barrier
5	Sifting

workmem *(real)*: memory available for working storage ↩

Upper limit on the amount of memory, in megabytes, that Cplex is permitted to use for working files. See parameter WorkDir.

Default: `2048.0`

writeannotation *(string)*: produce a Cplex annotation file ↩

writebas *(string)*: produce a Cplex basis file ↩

Write a basis file.

writeflt *(string)*: produce a Cplex solution pool filter file ↩

Write the diversity filter to a Cplex FLT file.

writelp *(string)*: produce a Cplex LP file ↩

Write a file in Cplex LP format.

writemps *(string)*: produce a Cplex MPS file ↩

Write an MPS problem file.

writemst *(string)*: produce a Cplex mst file ↩

Write a Cplex MST (containing the MIP start) file.

writeord *(string)*: produce a Cplex ord file ↩

Write a Cplex ORD (containing priority and branch direction information) file.

writeparam *(string)*: produce a Cplex parameter file with all active options ↩

Write a Cplex parameter (containing all modified Cplex options) file.

writepre *(string)*: produce a Cplex LP/MPS/SAV file of the presolved problem ↩

Synonym: writepremps

Write a Cplex LP, MPS, or SAV file of the presolved problem. The file extension determines the problem format. For example, `WritePre presolved.lp` creates a file `presolved.lp` in Cplex LP format.

writeprob *(string)*: produce a Cplex problem file and inferrs the type from the extension ↩

Write a problem file in a format inferred from the extension. Possible formats are

- `SAV`: Binary matrix and basis file
- `MPS`: MPS format
- `LP`: CPLEX LP format with names modified to conform to LP format
- `REW`: MPS format, with all names changed to generic names
- `RLP`: LP format, with all names changed to generic names
- `ALP`: LP format, with generic name of each variable, type of each variable, bound of each variable If the file name ends with `.bz2` or `.gz`, a compressed file is written.

writesav *(string)*: produce a Cplex binary problem file ↩

Write a binary problem file.

zerohalfcuts *(integer)*: zero-half cuts ↩

Decides whether or not to generate zero-half cuts for the problem. The value 0, the default, specifies that the attempt to generate zero-half cuts should continue only if it seems to be helping. If the dual bound of your model does not make sufficient progress, consider setting this parameter to 2 to generate zero-half cuts more aggressively.

Default: `0`

value	meaning
-1	Off
0	Automatic
1	Generate zero-half cuts moderately
2	Generate zero-half cuts aggressively

5.11.9 Setting up a GAMS/Cplex-Link license

The GAMS/Cplex-Link license requires that you have a valid license agreement with IBM for use of the current version of the Cplex library.

To add the Cplex-Link to your GAMS license, please write to sales@gams.com to confirm that you have such a license agreement and that your use of the GAMS solver will comply with the terms of that license agreement. Please reference your GAMS License ID, DCxxxx.

5.12 Deterministic Equivalent (DE)

Author

Martha Loewe

5.12.1 Introduction

DE is a solver for stochastic programs modeled with GAMS Extended Mathematical Programming for Stochastic Programming (EMP SP). DE can solve multi-stage LP, MIP, QCP, NLP and MINLP stochastic programming models. For details about EMP SP and the syntax to modify an existing GAMS model to be an stochastic programming model in GAMS EMP SP see Stochastic Programming. A list of DE solver options is given at the end of this document.

Stochastic programs are mathematical programs that include data that is not known with certainty, but is approximated by probability distributions. The simplest form of a stochastic program is the two-stage stochastic linear program with recourse. In mathematical terms it is defined as follows.

Let $x \in \mathbb{R}^n$ and $y \in \mathbb{R}^m$ be two variables and let the set of all realizations of the unknown data be given by Ω, $\Omega = \{\omega_1, \ldots, \omega_S\} \subseteq \mathbb{R}^r$, where r is the number of the random variables representing the uncertain parameters. Then the stochastic program is given by

$$\begin{array}{lllllllll} & \text{Min}_x & z = & c^T x & + & \mathbb{E}[Q(x,\omega)] & & & \\ & \text{s.t.} & & Ax & & & = & b, & x \geq 0, \\ \text{where} \quad Q(x,\omega) = & \text{Min}_y & & & & q_\omega^T y(\omega) & & & \\ & \text{s.t.} & & T_\omega x & + & W_\omega y(\omega) & = & h_\omega, & y(\omega) \geq 0, \quad \forall \omega \in \Omega. \end{array} \tag{5.1}$$

The first two lines define the first-stage problem and the last two lines define the second-stage problem. In the first stage, x is the decison variable, c^T represents the cost coefficients of the objective function and $\mathbb{E}[Q(x,\omega)]$ denotes the expected value of the optimal solution of the second stage problem. In addition, A denotes the coefficients and b the right-hand side of the first stage constraints. In the second stage, y is the decision variable, T represents the transition matrix, W the recourse matrix (cost of recourse) and h

the right-hand side of the second stage constraints. Note that all parameters and the decision variable of the second stage are dependent on ω. The objective variable z is also a random variable, since it is a function of ω. As a random variable cannot be optimized, DE automatically optimizes the *expected value* of the objective variable z. DE is also able to optimize other risk measures, as will be discussed later.

In the first stage, a decision has to be made before the realization of the uncertain data is clear. The optimal solution of the first stage is fixed and only then the values that the uncertain parameters take will become known. Given the fixed solution of the first stage and the new data, in the second stage recourse action can be taken and the optimal solution determined. Each possible realization of the uncertain data is represented by an $\omega_s \in \Omega$ and is called a *scenario*. The objective is to find a feasible solution x that minimizes the total cost, namely the sum of the first-stage costs and the expected second-stage costs.

One of the most common methods to solve a two-stage stochastic LP is to build and solve the *deterministic equivalent*. Assume that the uncertain parameters follow a (finite) discrete distribution and that each scenario ω_s occurs with probability $P(\omega_s) = p_s$ for all $s = 1, \ldots, S$ and $\sum_s p_s = 1$. So $\mathbb{E}[Q(x, \omega)] = \sum_s p_s q^T y_s$, where y_s denotes the optimal second-stage decision for the scenario ω_s. Then the deterministic equivalent can be expressed as follows:

$$
\begin{array}{llllllllll}
c^T x & + & p_1 q^T y_1 & + & p_2 q^T y_2 & + & \ldots & + & p_S q^T y_S & \\
\text{s.t.} & & & & & & & & & \\
Ax & & & & & & & & = & b \\
T_1 x & + & W_1 y_1 & & & & & & = & h_1 \\
T_2 x & & & + & W_2 y_2 & & & & = & h_2 \\
\vdots & & & + & & & \ddots & & & \vdots \\
T_S x & & & & & & & + \; W_S y_S & = & h_S \\
x \in \mathbb{R}^n & & y_1 \in \mathbb{R}^m & & y_2 \in \mathbb{R}^m & & & & y_S \in \mathbb{R}^m &
\end{array}
\tag{5.2}
$$

Note that for stochastic linear programs the deterministic equivalent is just a very large linear program.

The solver DE automatically generates the deterministic equivalent of a stochastic program and then hands it over for solution to a solver, termed the *subsolver*. The subsolver is the default solver for the type of model to be solved. The user may choose another subsolver with the option subsolver.

If modelers want to use DE, they may either add the option

```
option emp = de;
```

before the `solve` statement in the model or they may choose the solver DE on the command line, e.g.

```
gams mymodel.gms emp=de
```

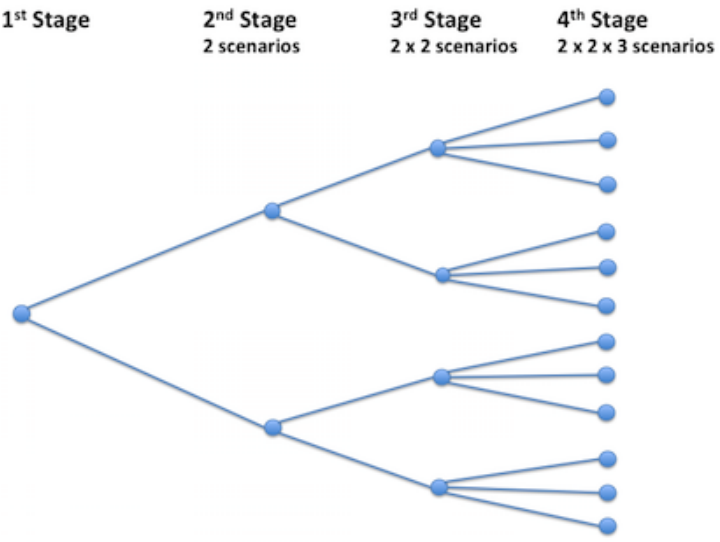
5.12.2 Random Variables

Random variables and their distributions and stages determine the number of scenarios in the model and thus the number of equations that are generated for the deterministic equivalent. If there are two or more random variables in one stage they may be jointly distributed or not.

Assume that there is a two-stage stochastic model $\mathcal{M}_2$ that has two random variables a and b in the second stage. The random variables both follow a discrete distribution, the uncertain data for a is given by Ω_a and the uncertain data for b is given by Ω_b. If the random variables are *not* jointly distributed, then $|\Omega_a| \times |\Omega_b|$ scenarios are generated. If the random variables are jointly distributed, then we need to have $|\Omega_a| = |\Omega_b|$ and the number of scenarios is $|\Omega_a|$.

In addition to two-stage stochastic models, DE can also solve multi-stage stochastic models. Let $\mathcal{M}_4$ be a stochastic model with four stages. In each of the stages after the first stage new data is revealed that was unknown in the previous stages. Assume that in each stage there is just one random variable. Let Ω_{I} denote the uncertain data in the second stage and Ω_{II} and Ω_{III} represent the uncertain data of the third and fourth stage respectively. Let $|\Omega_{\mathrm{I}}| = n_1$, $|\Omega_{\mathrm{II}}| = n_2$ and $|\Omega_{\mathrm{III}}| = n_3$. DE builds the deterministic equivalent of this model by recursively generating a scenario tree. In the second stage the number of scenarios is n_1, in the third stage there are $n_1 \times n_2$ scenarios and in the fourth stage there are $n_1 \times n_2 \times n_3$ scenarios. Note that the number of scenarios in the model equals the number of scenarios in the last stage. However, the number of equations generated for the deterministic equivalent is the sum of the scenarios in each stage, so in this example it is $n_1 + n_1 \times n_2 + n_1 \times n_2 \times n_3 = n_1 \times (1 + n_2 \times (1 + n_3))$.

The following figure illustrates the scenario tree of a stochastic model with four stages.



Note that the structure of the scenario tree is limited: each node in a stage has exactly the same number of arcs.

If there is more than one random variable per stage, then the number of scenarios increases accordingly. Note that there is no absolute limit to the number of stages and random variables, but the model can become very large very quickly as the number of stages and random variables increases. Note further that the random variables are stagewise independent. The realization of the random variables in one stage does not influence the realization of the random variables in a later stage.

5.12.3 Sampling Procedures

DE can solve only stochastic programs with random variables that follow discrete probability distributions. If the random data follows a continuous probability distribution the set Ω has an infinite number of elements. Sampling is a process that generates a finite approximation Ω_N to Ω. The size of Ω_N is N and each element of Ω_N has the same probability $p = \frac{1}{N}$. Thus continuous probability distributions are approximated by discrete distributions. EMP SP provides the keyword `sample` to facilitate sampling. An example follows.

```
randvar d normal 45 10
sample d 100
```

These two lines are a portion of the `emp.info` file. In the first line `d` is defined as a random variable that follows a Normal distribution with mean 45 and standard deviation 10. In the second line it is specified that the continuous distribution is approximated by a sample of size 100. Note that the user determines the sample size N. Note further that the use of the keyword `sample` is mandatory for random variables with continuous distributions. Otherwise the following error message will appear:

```
*** Only random variables with sampled continuous distributions supported.
```

Observe that behind the scenes the sampling is performed by the LINDO system. So the modeler needs a LINDO licence for sample sizes larger than 10 (smaller sample sizes are included in the demo version). The LINDO system offers three variance reduction algorithms: the Antithetic algorithm, the Latin Square algorithm and the Monte Carlo algorithm. They may be enabled using either the option svr_ls_antithetic or svr_ls_latinsquare or svr_ls_montecarlo respectively.

Alternatively, the modeler may chose to generate a sample of the distribution first and then enter the sample as a discrete distribution in the `emp.info` file. There are two stochastic libraries that can be used for this procedure: the GAMS Stochastic Library and the LINDO Sampling Library. An example and details about the procedure using the LINDO library are given in section Sampling in the EMP manual.

5.12.4 The Expected Value Problem

Consider the special case where the sample size is 1 and the "sampled" value equals the expected value of the random variable. This entails that the random variable is replaced by its expected value. The resulting model is deterministic and is called the Expecetd Value Program. DE facilitates solving the Expected Value Problem through the option solveEVProb. If this option is specified in the option file (see example below) the Expected Value Problem is solved after the original stochastic model and the solution is reported. In addition, DE offers the option to choose a separate subsolver for the Expecetd Value Problem, the option evsubsolver.

In the following example the stochastic model is solved with the subsolver Conopt and the Expected Value Problem is solved with the subsolver Minos.

```
$onecho > de.opt
subsolver conopt
solveEVProb
evsubsolver minos
$offecho
mymodel.optfile=1;
solve mymodel min obj using emp scenario dict;
```

Note that the option solveEVProb is not defined for models with chance constraints and models featuring VaR and CVaR. These model types are discussed in the next section.

5.12.5 What types of models can DE handle?

As mentioned earlier, DE can solve two-stage and multi-stage stochastic linear, quadratic and nonlinear models and the mixed-integer versions of all these models. There are two further classes of stochastic models that DE is equipped to solve: stochastic programs with chance constraints and stochastic programs with other risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR). CVaR is also called Expected Shortfall.

In stochastic programs with chance constraints the goal is to make an optimal decision prior to the realization of random data while allowing the constraints to be violated with a certain probability. Mathematically, a stochastic linear program with chance constraints can be expressed as follows:

$$\begin{array}{ll} \text{Min}_x & c^T x \\ \text{s.t.} & P(Ax \leq b) \geq p \\ & x \geq 0, \end{array} \tag{5.3}$$

where $x \in \mathbb{R}^n$ is the decision variable and c^T denotes the coefficients of the objective function, $A \in \mathbb{R}^{m \times n}$ is a random matrix and represents the coefficients and $b \in \mathbb{R}^m$ is a random vector and denotes the right-hand side of the constraints. The distinctive feature of stochastic programs with chance constraints is that the constraints (or some of them) may be violated with probability $\epsilon = 1 - p$, where $0 < p \leq 1$.

DE offers three reformulation options to solve stochastic programs with chance constraints: a reformulation using a mixed-integer program with big M notation, a convex hull reformulation and the use of indicator variables and indicator constraints. Note that the default is the MIP reformulation (the default value of M is set to 10000 and can be customized). With the option ccreform the reformulation method can be determined by the user.

For details on single and joint chance constraints and examples how to use the option `ccreform`, see the section Chance Constraints with EMP in the EMP manual. Note that random variables in programs with chance constraints may follow discrete or continuous probability distributions. Note further that there are no stages in stochastic programs with chance constraints.

As mentioned earlier, DE automatically optimizes the expected value of the objective function variable. DE also supports other risk measures, such as VaR and CVaR. In mathematical terms, DE is able to solve the following:

$$\text{Min}_x \quad \mathcal{R}(z), \tag{5.4}$$

where z represents the objective function variable and $\mathcal{R}$ denotes a risk measure such as the Expected Value, VaR and CVaR or a combination of risk measures (e.g. the weighted sum of Expected Value and CVaR). In addition, the modeler can also choose to trade off risk measures. For more details about risk measures see section Risk Measures with EMP in the EMP manual.

5.12.6 Reformulation Techniques

In this section some details are given about the reformulations that DE is performing behind the scenes.

5.12.6.1 Simple two-stage stochastic model

As mentioned previously, DE converts a stochastic model into its deterministic equivalent. Using the model `nbsimple.gms` from the GAMS EMP model library as an example, we show how exactly the deterministic equivalent is built. Note that this model is also discussed in detail in the section A Simple Example: The News Vendor Problem of the EMP manual.

The model is given by the following equations:

$$\text{Max}_x \quad z(x) = -cx + \mathbb{E}[Q(x, \omega)], \quad x \geq 0, \tag{5.5}$$

where

$$\begin{array}{rlrl} Q(x,\omega) = \text{Max}_{s,i,l} & & vs(\omega) - hi(\omega) - pl(\omega) & \\ \text{s.t.} & x - s(\omega) - i(\omega) & & = 0 \\ & s(\omega) & + l(\omega) & = d(\omega) \\ & s(\omega),\, i(\omega),\, l(\omega) & \geq 0 & \forall \omega \in \Omega. \end{array}$$

Here c, v, h and p are some given parameters, the first-stage decision variable is x, the second-stage decision variables are s, i and l and the uncertain data is represented by the random variable $d(\omega)$. We assume that the annotations specify that d follows a Normal distribution and the sample size to approximate this continuous distribution is 4 (where all scenarios are equally likely, so $p(s) = 0.25$).

First, DE draws 4 values from the Normal distribution specified in the annotations. These 4 values are the basis for the 4 scenarios that are generated. For each scenario, a separate equation for the two second-stage constraints is built (that are 8 equations). In the process, for each of the three decison variables of the second stage 4 variables are generated since the second-stage decison variables may take different values for each scenario. Next, an equation for the profit for each scenario is generated (4 equations) and finally, the equation to compute the average profit is built. So there are a total of 13 equations. They are given here:

$$\begin{array}{lcl} x - s_1 - i_1 & = & 0 \\ x - s_2 - i_2 & = & 0 \\ x - s_3 - i_3 & = & 0 \\ x - s_4 - i_4 & = & 0 \\ s_1 + l_1 & = & d_1 \\ s_2 + l_2 & = & d_2 \\ s_3 + l_3 & = & d_3 \\ s_4 + l_4 & = & d_4 \\ z_1 & = & -cx + vs_1 - hi_1 - pl_1 \\ z_2 & = & -cx + vs_2 - hi_2 - pl_2 \\ z_3 & = & -cx + vs_3 - hi_3 - pl_3 \\ z_4 & = & -cx + vs_4 - hi_4 - pl_4 \\ z & = & 0.25z_1 + 0.25z_2 + 0.25z_3 + 0.25z_4 \end{array} \tag{5.6}$$

Note that there is only one realization of the first-stage decision variable x while for the second-stage decision variables there as many realizations as there are scenarios.

5.12.6.2 A multi-stage stochastic model

DE recursively builds a scenario tree to generate the deterministic equivalent of multi-stage models. We take the model `inventory` from the EMP manual to demonstrate how this is done. The 4-stage model is given by the following equations:

$$\begin{array}{ll} \text{Max}_{y_1,i_1} & z = -\alpha y_1 - \gamma i_1 + \mathbb{E}[Q((y_1,i_1),\omega_{\text{I}}) + \mathbb{E}[Q((y_1,i_1),\omega_{\text{II}}) + \mathbb{E}[Q((y_1,i_1),\omega_{\text{III}})]]] \\ \text{s.t.} & i_1 = y_1 \\ & y_1, i_1 \geq 0, \end{array}$$

where

$$\begin{array}{rlll} Q((y_1,i_1),\omega_\zeta) = & \text{Max}_{s_t,y_t,i_t} & \beta s_t(\omega_\zeta) - \alpha y_t(\omega_\zeta) - \delta i_t(\omega_\zeta) & \\ & \text{s.t.} & i_{t-1} + y_t = s_t + i_t & \\ & & s_t \leq i_{t-1} & \\ & & s_t \leq d_t(\omega_\zeta) & \\ & & i_t \leq \kappa & \\ & & s_t, y_t, i_t \geq 0 \quad \text{for} \quad t = 2,3,4. & \end{array}$$

Here y_1 and i_1 are the first-stage decision variables and y_t, i_t and s_t are the decison variables of the later stages; α, β, γ, δ and κ denote fixed parameters. The uncertain data is represented by the random variable $d_t(\omega_\zeta)$, where $\omega_\zeta \in \Omega_\zeta$ and $\zeta = \mathrm{I}, \mathrm{II}, \mathrm{III}$. Note that s_t, y_t and i_t depend on the realization of d_t. Now assume that d_t follows a continuous distribution and the sample size to approximate this distribution is just 3 for stages 2 to 4. Note that in multi-stage models the sample size may vary for each stage. Note further that for all practical purposes this sample size is too small, it was chosen here for reasons of clarity of exposition. As usual, the distribution(s) and sample size(s) are specified in the annotations. Observe that the last constraint ($i_t \leq \kappa$) is implemented as a bound on the variable i_t, not as an equation. So, in addition to the objective equations, there is one equation in the first stage and three equations in each of the later stages.

This model is reformulated in the following way. First, an equation for the first stage constraint is generated. Secondly, three realizations of d_2 are chosen through a sampling procedure, so there are three scenarios at stage 2. For each of these three realizations of the random variable the equations for the second stage are generated (9 equations). Thirdly, three realizations of d_3 are sampled for stage 3. Each of these three realizations may follow one of the three scenarios of the second stage, so there are nine scenarios in stage 3 and hence $9 \times 3 = 27$ equations are generated for stage 3. The procedure is repeated in stage 4 where there are 27 scenarios and $27 \times 3 = 81$ equations. Next, the value of the objective variable for each scenario is computed by generating 27 equations for z_s and finally, an equation to compute z is built, where $z = \sum_s p(s) z_s$.

5.12.6.3 Chance Constraints

Models with chance constraints are reformulated as mixed integer problems by default. This reformulation is discussed in detail in the section Chance Constraints with EMP in the EMP manual. Reformulations using a convex hull or indicator variables and indicator constraints are also possible. The reformulation method may be determined by the user with the option ccreform.

5.12.6.4 Computing VaR

Models involving VaR are reformulated using mixed integer programs with big M notation. By the example model `portfolio.gms` we demonstrate how this is done. This model is discussed in the section Value at Risk (VaR) in the EMP manual. The model is given by the following equations:

$$\begin{array}{lll} \text{Max} & \underline{VaR}_\theta[R] & \\ \text{s.t} & R = \sum_j w_j v_j(\omega) & \forall \omega \in \Omega \\ & \sum_j w_j = 1 & \\ & w_j \geq 0, & \end{array} \tag{5.7}$$

where $\underline{VaR}_\theta$ is the VaR at the lower θth percentile, the variable R is the return (and is a function of the random variable $v_j(\omega)$), w_j the weight associated with each asset j and $v_j(\omega)$ is the (random variable) return of each asset j. The weights can also be interpreted as proportions of the amount to be invested, their sum must be 1. Note that w_j is the decision variable in this problem.

Let $y(s)$ be a binary variable that acts as an indicator variable. For each scenario, it equals 1 if the return $R \geq \underline{VaR}_\theta[R]$ and it is 0 otherwise. Then the model is reformulated to the following MIP:

$$\begin{array}{lll} \text{Max} & \underline{VaR}_\theta[R] & \\ \text{s.t} & r(s) = \sum_j w_j v_j(s) & \forall s = 1, \ldots, S \\ & r(s) \geq \underline{VaR}_\theta[R] - M(1 - y(s)) & \forall s = 1, \ldots, S \\ & cc = 1 - \sum_s p(s) y(s) & \\ & \sum_j w_j = 1 & \\ & 0 \leq cc \leq \theta & \\ & w_j \geq 0. & \end{array} \tag{5.8}$$

Here $r(s)$ denotes the return per scenario and cc is a variable that represents the probability of violations (a violation occurs if in a scenario the return is smaller than $\underline{VaR}_\theta[R]$). As usual, $p(s)$ is the probability that a scenario occurs and M is the big M. The first three constraints together with the bounds on cc ensure that the probability of violations is smaller than or equal to θ.

Note that the default value for big M for models with VaR is 1000 (and it is different from the default value for big M for chance constraints). It may be customized with the option varbigm.

5.12.6.5 Computing CVaR

Models with CVaR are reformulated by converting the annotations into new variables and equations. Using the model `portfolio.gms` as an example we demonstrate how this is done. This model features in the GAMS EMP library and is also discussed in the section Conditional Value at Risk (CVaR) in the EMP manual. The model is given by:

$$\begin{array}{lll} \text{Max} & \underline{CVaR}_\theta[R] & \\ \text{s.t} & R = \sum_j w_j v_j(\omega) & \forall \omega \in \Omega \\ & \sum_j w_j = 1 & \\ & w_j \geq 0, & \end{array} \tag{5.9}$$

where $\underline{CVaR}_\theta$ is the CVaR at the left tail of the distribution at the confidence level θ and all other variables are as defined above. Note that again, w_j is the decision variable in this problem.

DE reformulates this model by introducing three new variables and three associated equations. Let $r(s)$ denote the return per scenario, t the target return to be achieved with probability approximately $1-\theta$ and $d(s)$, $d(s) \geq 0$, the lower deviation from t per scenario. The equations follow.

$$\begin{aligned} r(s) &= \sum_j w_j v_j(s) \\ d(s) &\geq t - r(s) \\ \underline{CVaR}_\theta[R] &= t - \frac{1}{\theta} \sum p(s) d(s) \end{aligned} \tag{5.10}$$

Thus the model is reformulated to an LP and may be solved by an appropriate solver. It is easy to see that t equals $\underline{VaR}_\theta[R]$.

5.12.7 Logfile

The logfile gives much information about the solver progress. The following is the DE log output from running the **nbdiscjoint** model from the GAMS EMP Model Library:

First, the model in scalar form is generated. It has 5 equations, so the model statistics report 5 rows. Further, it has 6 positive variables, one free variable and 2 random variables, so there are 9 columns. A matrix form representation of the model with the variables as columns and the equations as rows has 19 non-zero entries. Next, DE generates the deterministic equivalent. The statistics for the deterministic equivalent indicate that there are 26 rows, 50 columns and 116 non-zero entries. The stochastic model has 6 scenarios, so for each second-stage equation there are 6 equations in the deterministic equivalent (i.e. a total of 24 equations). In addition, there is one first-stage equation and one equation to compute the expected value of the objective variable, which brings the sum total to 26 equations or rows. Similarly, for each second-stage variable in the stochastic model there are 6 variables in the determininistic equivalent (i.e a total of 48 variables). In addition, there is the first-stage decision variable and a variable for the expected value of the objective adding up to a total of 50 variables or columns.

Note that the model type is identified as an LP and thus the default LP solver is invoked. In this case the subsolver is Cplex and most of the remainder of the logfile is output from the subsolver. At the end the mapping specified in the dictionary is performed.

The logfile of solving stochastic models with VaR or CVaR is similar. It reports that the model type is being determined, the deterministic equivalent built and then handed over to the appropriate subsolver to be solved. However, when solving stochastic programs with chance constraints there is much more happening behind the scenes. DE automatically hands over the model to the subsolver JAMS. By default, JAMS reformulates the model and generates a scalar version of it. The scalar version of the reformulated model is then handed back to the GAMS system to be solved by an appropriate subsolver. The logfile reports the progress of the subsolver until the model is solved. Then the solution from the GAMS subsolver is handed to JAMS and a list of disjunsctions and their activity level is reported. (The equations in the scalar version of the reformulated model that may be left unsatisfied are called *disjunctions*. *Active* disjunctions refer to equations that are satisfied and *not active* disjunctions refer to equations that are not satisfied.)

Parts of the DE logfile from running the **simplechance** model from the GAMS EMP Model Library are given below. These parts of the logfile demonstrate the solution process for stochastic models with chance constraints that was just described.

5.12.8 Summary of DE Options

5.12.8.1 General Options

Option	Description	Default
correlationtype	Sample correlation type	0

Option	Description	Default
empinfofile	Path and name of file containing additional EMP-SP information as randvar, jrandvar, stage etc.	
subsolver	Subsolver to run	
subsolveropt	Optfile value to pass to the subsolver	1
svr_ls_antithetic	Sample variance reduction map to Lindo Antithetic algorithm	
svr_ls_latinsquare	Sample variance reduction map to Lindo Latin Square algorithm	
svr_ls_montecarlo	Sample variance reduction map to Lindo Montecarlo algorithm	

5.12.8.2 Options for chance constraint models

Option	Description	Default
ccreform	Reformulation option passed to JAMS	bigM
jamsopt	JAMS option file	

5.12.8.3 Options for recourse models

Option	Description	Default
evsubsolver	Subsolver to run on expected value problem	
evsubsolveropt	Optfile value to pass to the subsolver for expected value problem	1
maxnodes	Tree size limit	100000
solveEVProb	Solve and report the expected value solution	0
varbigm	Big M for Value at Risk reformulation	1000.0

5.12.9 Detailed Descriptions of DE Options

ccreform *(string)*: Reformulation option passed to JAMS ↩

This option determines how to formulate the indicator contraints of the chance constraints in the deterministic equivalent. The model is passed to JAMS for the actual reformulation and solution with a subsolver. The possible reformulation options are `bigM [big eps threshold]`, `chull [big eps]`, and `indic`. The `indic` setting only works with solver that under stand the indicator syntax in a GAMS option file.

Default: `bigM`

correlationtype *(integer)*: Sample correlation type ↩

Default: `0`

value	meaning
0	Pearson
1	Kendall
2	Spearman

empinfofile *(string)*: Path and name of file containing additional EMP-SP information as randvar, jrandvar, stage etc. ↩

evsubsolver *(string)*: Subsolver to run on expected value problem ↩

evsubsolveropt *(integer)*: Optfile value to pass to the subsolver for expected value problem ↩

Range: {1, ..., 999}

Default: 1

jamsopt *(string)*: JAMS option file ↩

maxnodes *(integer)*: Tree size limit ↩

Range: {1000, ..., ∞}

Default: 100000

solveEVProb *(no value)*: Solve and report the expected value solution ↩

Default: 0

subsolver *(string)*: Subsolver to run ↩

subsolveropt *(integer)*: Optfile value to pass to the subsolver ↩

Range: {1, ..., 999}

Default: 1

svr_ls_antithetic *(string)*: Sample variance reduction map to Lindo Antithetic algorithm ↩

svr_ls_latinsquare *(string)*: Sample variance reduction map to Lindo Latin Square algorithm ↩

svr_ls_montecarlo *(string)*: Sample variance reduction map to Lindo Montecarlo algorithm ↩

varbigm *(real)*: Big M for Value at Risk reformulation ↩

Default: 1000.0

5.13 DECIS

Author

Gerd Infanger; Vienna University of Technology; Stanford University [1]

5.13.1 DECIS

5.13.1.1 Introduction

DECIS is a system for solving large-scale stochastic programs, i.e. programs that include parameters (coefficients and right-hand sides) that are not known with certainty, but are assumed to be known by their probability distribution. It employs Benders decomposition and advanced Monte Carlo sampling techniques. DECIS includes a variety of solution strategies, such as solving the universe problem, the expected value problem, Monte Carlo sampling within the Benders decomposition algorithm, and Monte Carlo pre-sampling. When using Monte Carlo sampling the user has the option of employing crude Monte Carlo without variance reduction techniques, or using as variance reduction techniques importance sampling or control variates, based on either an additive or a multiplicative approximation function. Pre-sampling is limited to using crude Monte Carlo only.

For solving linear and nonlinear programs (master and subproblems arising from the decomposition) DECIS interfaces with MINOS or CPLEX. MINOS, see Murtagh and Saunders (1983) [142] , is a state-of-the-art solver for large-scale linear and nonlinear programs, and CPLEX is one of the fastest linear programming solvers available.

For details about the DECIS system consult the `DECIS User's Guide` see Infanger (1997) [100] . It includes a comprehensive mathematical description of the methods used by DECIS. In this Guide we concentrate on how to use DECIS directly from GAMS, and especially on how to model stochastic programs using the GAMS/DECIS interface. First, however, in section What DECIS Can Do we give a brief description of what DECIS can do and what solution strategies it uses. This description has been adapted from the DECIS User's Guide. In section GAMS/DECIS we discuss in detail how to set up a stochastic problem using GAMS/DECIS and give a description of the parameter setting and outputs obtained. In Appendix A - GAMS/DECIS Illustrative Examples we show the GAMS/DECIS formulation of two illustrative examples (APL1P and APL1PC) discussed in the DECIS User's Guide. A list of DECIS error messages are represented in Appendix B - Error Messages.

5.13.1.2 What DECIS Can Do

DECIS solves two-stage stochastic linear programs with recourse:

$$\begin{array}{lrrcll} \min & z = cx + Ef^{\omega}y^{\omega} & & & & \\ s/t & Ax & & = & b & \\ & -B^{\omega}x + & D^{\omega}y^{\omega} & = & d^{\omega} & \\ & x, & y^{\omega} & \geq & 0, & \omega \in \Omega. \end{array}$$

where x denotes the first-stage, y^ω the second-stage decision variables, c represents the first-stage and f^ω the second-stage objective coefficients, A, b represent the coefficients and right hand sides of the first-stage constraints, and B^ω, D^ω, d^ω represent the parameters of the second-stage constraints, where the transition matrix B^ω couples the two stages. In the literature D^ω is often referred to as the technology matrix or recourse matrix. The first stage parameters are known with certainty. The second stage parameters are random parameters that assume outcomes labeled ω with probability $p(\omega)$, where Ω denotes the set of all possible outcome labels.

At the time the first-stage decision x has to be made, the second-stage parameters are only known by their probability distribution of possible outcomes. Later, after x has already been determined, an actual outcome of the second-stage parameters will become known, and the second-stage decision y^ω is made based on knowledge of the actual outcome ω. The objective is to find a feasible decision x that minimizes the total expected costs, the sum of first-stage costs and expected second-stage costs.

For discrete distributions of the random parameters, the stochastic linear program can be represented by the corresponding *equivalent deterministic linear program*:

$$\begin{array}{rrrrrrrrrrrrr}
\min\ z & = & cx & + & p^1fy^1 & + & p^2fy^2 & + & \cdots & + & p^Wfy^W & & \\
s/t & & Ax & & & & & & & & & = & b \\
 & & -B^1x & + & Dy^1 & & & & & & & = & d^1 \\
 & & -B^2x & & & + & Dy^2 & & & & & = & d^2 \\
 & & \vdots & & & & & & \ddots & & & & \vdots \\
 & & -B^Wx & & & & & & & + & Dy^W & = & d^W \\
 & & x, & & y^1, & & y^2, & & \ldots, & & y^W & \geq & 0,
\end{array}$$

which contains all possible outcomes $\omega \in \Omega$. Note that for practical problems W is very large, e.g., a typical number could be 10^{20}, and the resulting equivalent deterministic linear problem is too large to be solved directly.

In order to see the two-stage nature of the underlying decision making process the folowing representation is also often used:

$$\begin{array}{rrrr}
\min\ cx & + & E\ z^\omega(x) & \\
Ax & & & = b \\
x & & & \geq 0
\end{array}$$

where

$$\begin{array}{rrrl}
z^\omega(x) = \min\ f^\omega y^\omega & & & \\
D^\omega y^\omega & = & d^\omega + B^\omega x & \\
y^\omega & \geq & 0,\ \omega \in \Omega = \{1, 2, \ldots, W\}. &
\end{array}$$

DECIS employs different strategies to solve two-stage stochastic linear programs. It computes an exact optimal solution to the problem or approximates the true optimal solution very closely and gives a confidence interval within which the true optimal objective lies with, say, 95% confidence.

5.13.1.3 Representing Uncertainty

It is favorable to represent the uncertain second-stage parameters in a structure. Using $V = (V_1, \ldots, V_h)$ an h-dimensional independent random vector parameter that assumes outcomes $v^\omega = (v_1, \ldots, v_h)^\omega$ with probability $p^\omega = p(v^\omega)$, we represent the uncertain second-stage parameters of the problem as functions of the independent random parameter V:

$$f^\omega = f(v^\omega), \quad B^\omega = B(v^\omega), \quad D^\omega = D(v^\omega), \quad d^\omega = d(v^\omega).$$

Each component V_i has outcomes $v_i^{\omega_i}$, $\omega_i \in \Omega_i$, where ω_i labels a possible outcome of component i, and Ω_i represents the set of all possible outcomes of component i. An outcome of the random vector

$$v^\omega = (v_1^{\omega_1}, \ldots, v_h^{\omega_h})$$

consists of h independent component outcomes. The set

$$\Omega = \Omega_1 \times \Omega_2 \times \ldots \times \Omega_h$$

represents the crossing of sets Ω_i. Assuming each set Ω_i contains W_i possible outcomes, $|\Omega_i| = W_i$, the set Ω contains $W = \prod W_i$ elements, where $|\Omega| = W$ represents the number of all possible outcomes of the random vector V. Based on independence, the joint probability is the product

$$p^\omega = p_1^{\omega_1} p_2^{\omega_2} \cdots p_h^{\omega_h}.$$

Let η denote the vector of all second-stage random parameters, e.g., $\eta = \text{vec}(f, B, D, d)$. The outcomes of η may be represented by the following general linear dependency model:

$$\eta^\omega = \text{vec}(f^\omega, B^\omega, d^\omega, d^\omega) = Hv^\omega, \omega \in \Omega$$

where H is a matrix of suitable dimensions. DECIS can solve problems with such general linear dependency models.

5.13.1.4 Solving the Universe Problem

We refer to the universe problem if we consider all possible outcomes $\omega \in \Omega$ and solve the corresponding problem exactly. This is not always possible, because there may be too many possible realizations $\omega \in \Omega$. For solving the problem DECIS employs Benders decomposition, splitting the problem into a master problem, corresponding to the first-stage decision, and into subproblems, one for each $\omega \in \Omega$, corresponding to the second-stage decision. The details of the algorithm and techniques used for solving the universe problem are discussed in The DECIS User's Manual.

Solving the universe problem is referred to as strategy 4. Use this strategy only if the number of universe scenarios is reasonably small. There is a maximum number of universe scenarios DECIS can handle, which depends on your particular resources.

5.13.1.5 Solving the Expected Value Problem

The expected value problem results from replacing the stochastic parameters by their expectation. It is a linear program that can also easily be solved by employing a solver directly. Solving the expected value problem may be useful by itself (for example as a benchmark to compare the solution obtained from solving the stochastic problem), and it also may yield a good starting solution for solving the stochastic problem. DECIS solves the expected value problem using Benders decomposition. The details of generating the expected value problem and the algorithm used for solving it are discussed in the DECIS User's Manual. To solve the expected value problem choose strategy 1.

5.13.1.6 Using Monte Carlo Sampling

As noted above, for many practical problems it is impossible to obtain the universe solution, because the number of possible realizations $|\Omega|$ is way too large. The power of DECIS lies in its ability to compute excellent approximate solutions by employing Monte Carlo sampling techniques. Instead of computing the expected cost and the coefficients and the right-hand sides of the Benders cuts exactly (as it is done when solving the universe problem), DECIS, when using Monte Carlo sampling, estimates the quantities in each iteration using an independent sample drawn from the distribution of the random parameters. In addition to using crude Monte Carlo, DECIS uses importance sampling or control variates as variance reduction techniques.

The details of the algorithm and the different techniques used are described in the DECIS User's Manual. You can choose crude Monte Carlo, referred to as strategy 6, Monte Carlo importance sampling, referred to as strategy 2, or control variates, referred to as strategy 10. Both Monte Carlo importance sampling and control variates have been shown for many problems to give a better approximation compared to employing crude Monte Carlo sampling.

When using Monte Carlo sampling DECIS computes a close approximation to the true solution of the problem, and estimates a close approximation of the true optimal objective value. It also computes a confidence interval within which the true optimal objective of the problem lies, say with 95% confidence. The confidence interval is based on rigorous statistical theory. An outline of how the confidence interval is computed is given in the DECIS User's Manual. The size of the confidence interval depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for the estimation. You can expect the confidence interval to be very small, especially when you employ importance sampling or control variates as a variance reduction technique.

When employing Monte Carlo sampling techniques you have to choose a sample size (set in the parameter file). Clearly, the larger the sample size the better will be the approximate solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Setting the sample size too small may lead to bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

5.13.1.7 Monte Carlo Pre-sampling

We refer to pre-sampling when we first take a random sample from the distribution of the random parameters and then generate the approximate stochastic problem defined by the sample. The obtained approximate problem is then solved exactly using decomposition. This is in contrast to the way we used Monte Carlo sampling in the previous section, where we used Monte Carlo sampling in each iteration of the decomposition.

The details of the techniques used for pre-sampling are discussed in the DECIS User's Manual. DECIS computes the exact solution of the sampled problem using decomposition. This solution is an approximate solution of the original stochastic problem. Besides this approximate solution, DECIS computes an estimate of the expected cost corresponding to this approximate solution and a confidence interval within which the true optimal objective of the original stochastic problem lies with, say, 95% confidence. The

confidence interval is based on statistical theory, while its size depends on the variance of the second-stage cost of the stochastic problem and on the sample size used for generating the approximate problem. In conjunction with pre-sampling no variance reduction techniques are currently implemented.

Using Monte Carlo pre-sampling you have to choose a sample size. Clearly, the larger the sample size you choose, the better will be the solution DECIS computes, and the smaller will be the confidence interval for the true optimal objective value. The default value for the sample size is 100. Again, setting the sample size too small may lead to a bias in the estimation of the confidence interval, therefore the sample size should be at least 30.

To use Monte Carlo pre-sampling choose strategy 8.

5.13.1.8 Regularized Decomposition

When solving practical problems, the number of Benders iterations can be quite large. In order to control the decomposition, with the hope to reduce the iteration count and the solution time, DECIS makes use of regularization. When employing regularization, an additional quadratic term is added to the objective of the master problem, representing the square of the distance between the best solution found so far (the incumbent solution) and the variable x. Using this term, DECIS controls the distance between solutions in successive decomposition iterations.

To enable regularization you have to set the corresponding parameter. You also have to choose the value of the constant rho in the regularization term. The default is regularization disabled. Details of how DECIS carries out regularization are represented in the DECIS User's Manual.

Regularization is only implemented when using MINOS as the optimizer for solving subproblems. Regularization has proven to be helpful for problems that need a large number of Benders iteration when solved without regularization. Problems that need only a small number of Benders iterations without regularization are not expected to improve much with regularization, and may need even more iterations with regularization than without.

5.13.2 GAMS/DECIS

GAMS stands for General Algebraic Modeling Language, and is one of the most widely used modeling languages. Using DECIS directly from GAMS spares you from worrying about all the details of the input formats. It makes the problem formulation much easier but still gives you almost all the flexibility of using DECIS directly.

The link from GAMS to DECIS has been designed in such a way that almost no extensions to the GAMS modeling language were necessary for carrying out the formulation and solution of stochastic programs. In a future release of GAMS, however, additions to the language are planned that will allow you to model stochastic programs in an even more elegant way.

5.13.2.1 Setting up a Stochastic Program Using GAMS/DECIS

The interface from GAMS to DECIS supports the formulation and solution of stochastic *linear* programs. DECIS solves them using two-stage decomposition. The GAMS/DECIS interface resembles closely the structure of the SMPS (stochastic mathematical programming interface) discussed in the DECIS User's Manual. The specification of a stochastic problem using GAMS/DECIS uses the following components:

- the deterministic (core) model,
- the specification of the decision stages,
- the specification of the random parameters, and
- setting DECIS as the optimizer to be used.

5.13.2.2 Starting with the Deterministic Model

The core model is a deterministic linear program where all random parameters are replaced by their mean or by a particular realization. One could also see it as a GAMS model without any randomness. It could be a deterministic model that you have, that you intend to expand to a stochastic one. Using DECIS with GAMS allows you to easily extend a deterministic linear programming model to a stochastic one. For example, the following GAMS model represents a deterministic version of the electric power expansion planning illustrative example discussed in Infanger (1994).

```
*   APL1P test model
*   Dr. Gerd Infanger, November 1997
*   Deterministic Program

set g generators / g1, g2/;
set dl demand levels /h, m, l/;

parameter alpha(g) availability / g1  0.68,  g2  0.64 /;
parameter ccmin(g) min capacity / g1  1000,  g2  1000 /;
parameter ccmax(g) max capacity / g1 10000,  g2 10000 /;
parameter c(g) investment       / g1   4.0,  g2   2.5 /;

table f(g,dl) operating cost
             h    m    l
   g1        4.3  2.0  0.5
   g2        8.7  4.0  1.0;

parameter d(dl) demand                   / h  1040, m  1040, l  1040 /;
parameter us(dl) cost of unserved demand / h    10, m    10, l    10 /;

free variable tcost            total cost;
positive variable x(g)         capacity of generators;
positive variable y(g, dl)     operating level;
positive variable s(dl)        unserved demand;

equations
cost        total cost
cmin(g)     minimum capacity
cmax(g)     maximum capacity
omax(g)     maximum operating level
demand(dl)  satisfy demand;

cost .. tcost =e=     sum(g, c(g)*x(g))
                    + sum(g, sum(dl, f(g,dl)*y(g,dl)))
                    + sum(dl,us(dl)*s(dl));

cmin(g) ..    x(g) =g= ccmin(g);
cmax(g) ..    x(g) =l= ccmax(g);
omax(g) ..    sum(dl, y(g,dl)) =l= alpha(g)*x(g);
demand(dl) .. sum(g, y(g,dl)) + s(dl) =g= d(dl);

model apl1p /all/;

option lp=minos;
solve apl1p using lp minimizing tcost;

scalar ccost capital cost;
scalar ocost operating cost;
```

```
ccost = sum(g, c(g) * x.l(g));
ocost = tcost.l -  ccost;
display x.l, tcost.l, ccost, ocost, y.l, s.l;
```

5.13.2.3 Setting the Decision Stages

Next in order to extend a deterministic model to a stochastic one you must specify the decision stages. DECIS solves stochastic programs by two-stage decomposition. Accordingly, you must specify which variables belong to the first stage and which to the second stage, as well as which constraints are first-stage constraints and which are second-stage constraints. First stage constraints involve only first-stage variables, while second-stage constraints involve both first- and second-stage variables. You must specify the stage of a variable or a constraint by setting the stage suffix ".STAGE" to either one or two depending on if it is a first or second stage variable or constraint. For example, expanding the illustrative model above by

```
* setting decision stages
x.stage(g)       = 1;
y.stage(g, dl)   = 2;
s.stage(dl)      = 2;
cmin.stage(g)    = 1;
cmax.stage(g)    = 1;
omax.stage(g)    = 2;
demand.stage(dl) = 2;
```

would make x(g) first-stage variables, y(g, dl) and s(dl) second-stage variables, cmin(g) and cmax(g) first-stage constraints, and omax(g) and demand(g) second-stage constraints. The objective is treated separately, you don't need to set the stage suffix for the objective variable and objective equation.

Note that the use of the `.stage` variable and equation suffix causes the GAMS scaling facility (i.e. the `.scale` suffix) to be unavailable. Stochastic models have to be scaled manually.

5.13.2.4 Specifying the Stochastic Model

DECIS supports any linear dependency model, i.e., the outcomes of an uncertain parameter in the linear program are a linear function of a number of independent random parameter outcomes. DECIS considers only discrete distributions: you must approximate any continuous distributions by discrete ones. The number of possible realizations of the discrete random parameters determines the accuracy of the approximation. A special case of a linear dependency model arises when you have only independent random parameters in your model. In this case the independent random parameters are mapped one to one into the random parameters of the stochastic program. We will present the independent case first and then expand to the case with linear dependency. According to setting up a linear dependency model we present the formulation in GAMS by first defining independent random parameters and then defining the distributions of the uncertain parameters in your model.

Specifying Independent Random Parameters

There are of course many different ways you can set up independent random parameters in GAMS. In the following we show one possible way that is generic and thus can be adapted for different models. The set-up uses the set stoch for labeling outcome named "out" and probability named "pro" of each independent random parameter. In the following we show how to define an independent random parameter, say, v1. The formulation uses the set omega1 as driving set, where the set contains one element for each possible realization the random parameter can assume. For example, the set omega1 has four

elements according to a discrete distribution of four possible outcomes. The distribution of the random parameter is defined as the parameter v1, a two-dimensional array of outcomes "out" and corresponding probability "pro" for each of the possible realizations of the set omega1, "o11", "o12", "o13", and "o14". For example, the random parameter v1 has outcomes of $-1.0, -0.9, -0.5, -0.1$ with probabilities $0.2, 0.3, 0.4, 0.1$, respectively. Instead of using assignment statements for inputting the different realizations and corresponding probabilities you could also use the table statement. Always make sure that the sum of the probabilities of each independent random parameter adds to one.

```
* defining independent stochastic parameters
set stoch /out, pro /;
set omega1 / o11, o12, o13, o14 /;

table v1(stoch, omega1)
      o11   o12   o13   o14
out  -1.0  -0.9  -0.5  -0.1
pro   0.2   0.3   0.4   0.1
;
```

Random parameter v1 is the first out of five independent random parameters of the illustrative model APL1P, where the first two represent the independent availabilities of the generators g1 and g2 and the latter three represent the independent demands of the demand levels h, m, and l. We also represent the definitions of the remaining four independent random parameters. Note that random parameters v3, v4, and v5 are identically distributed.

```
set omega2 / o21, o22, o23, o24, o25 /;
table v2(stoch, omega2)
      o21   o22   o23   o24   o25
out  -1.0  -0.9  -0.7  -0.1  -0.0
pro   0.1   0.2   0.5   0.1   0.1
;

set omega3 / o31, o32, o33, o34 /;
table v3(stoch, omega1)
      o11   o12   o13   o14
out   900  1000  1100  1200
pro  0.15  0.45  0.25  0.15
;

set omega4 / o41, o42, o43, o44 /;
table v4(stoch,omega1)
      o11   o12   o13   o14
out   900  1000  1100  1200
pro  0.15  0.45  0.25  0.15
;

set omega5 / o51, o52, o53, o54 /;
table v5(stoch,omega1)
      o11   o12   o13   o14
out   900  1000  1100  1200
pro  0.15  0.45  0.25  0.15
;
```

Defining the Distributions of the Uncertain Parameters in the Model

Having defined the independent stochastic parameters (you may copy the setup above and adapt it for your model), we next define the stochastic parameters in the GAMS model. The stochastic parameters of the model are defined by writing a file, the GAMS stochastic file, using the put facility of GAMS. The GAMS stochastic file resembles closely the stochastic file of the SMPS input format. The main difference is that we use the row, column, bounds, and right hand side names of the GAMS model and that we can write it in free format.

Independent Stochastic Parameters

First we describe the case where all stochastic parameters in the model are independent, see below the representation of the stochastic parameters for the illustrative example APL1P, which has five independent stochastic parameters.

First define the GAMS stochastic file "MODEL.STG" (only the exact name in uppercase letters is supported) and set up GAMS to write to it. This is done by the first two statements. You may want to consult the GAMS manual for how to use put for writing files. The next statement "INDEP DISCRETE" indicates that a section of independent stochastic parameters follows. We then write all possible outcomes and corresponding probabilities for each stochastic parameter by using loop statements. Of course one could also write each line separately, but the loops work nicely. Writing a "∗" between the definitions of the independent stochastic parameters is merely for optical reasons and can be omitted.

```
* defining distributions (writing file MODEL.STG)
file stg /MODEL.STG/;
put stg;

put "INDEP DISCRETE" /;
loop(omega1,
put "x g1  omax g1   ", v1("out", omega1), " period2 ", v1("pro", omega1) /;
);
put "*" /;
loop(omega2,
put "x g2  omax g2   ", v2("out", omega2), " period2 ", v2("pro", omega2) /;
);
put "*" /;
loop(omega3,
put "RHS  demand h   ", v3("out", omega3), " period2 ", v3("pro", omega3) /;
);
put "*" /;
loop(omega4,
put "RHS  demand m   ", v4("out", omega4), " period2 ", v4("pro", omega4) /;
)
put "*" /;
loop(omega5,
put "RHS  demand l   ", v5("out", omega5), " period2 ", v5("pro", omega5) /;
);
putclose stg;
```

In the example APL1P the first stochastic parameter is the availability of generator g1. In the model the parameter appears as the coefficient of variable x(g1) in equation omax(g1). The definition using the put statement first gives the stochastic parameter as the intersection of variable x(g1) with equation omax(g1), but without having to type the braces, thus *x g1 omax g1*, then the outcome *v1("out", omega1)* and the probability *v1("pro", omega1)* separated by *"period2"*. The different elements of the statement must be separated by blanks. Since the outcomes and probabilities of the first stochastic parameters are

driven by the set omega1 we loop over all elements of the set omega1. We continue and define all possible outcomes for each of the five independent stochastic parameters.

In the example of independent stochastic parameters, the specification of the distribution of the stochasic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:

```
INDEP DISCRETE
x g1  omax g1          -1.00 period2         0.20
x g1  omax g1          -0.90 period2         0.30
x g1  omax g1          -0.50 period2         0.40
x g1  omax g1          -0.10 period2         0.10
*
x g2  omax g2          -1.00 period2         0.10
x g2  omax g2          -0.90 period2         0.20
x g2  omax g2          -0.70 period2         0.50
x g2  omax g2          -0.10 period2         0.10
x g2  omax g2           0.00 period2         0.10
*
RHS  demand h         900.00 period2         0.15
RHS  demand h        1000.00 period2         0.45
RHS  demand h        1100.00 period2         0.25
RHS  demand h        1200.00 period2         0.15
*
RHS  demand m         900.00 period2         0.15
RHS  demand m        1000.00 period2         0.45
RHS  demand m        1100.00 period2         0.25
RHS  demand m        1200.00 period2         0.15
*
RHS  demand l         900.00 period2         0.15
RHS  demand l        1000.00 period2         0.45
RHS  demand l        1100.00 period2         0.25
RHS  demand l        1200.00 period2         0.15
```

For defining stochastic parameters in the right-hand side of the model use the keyword *RHS* as the column name, and the equation name of the equation which right-hand side is uncertain, see for example the specification of the uncertain demands *RHS demand h*, *RHS demand m*, and *RHS demand l*. For defining uncertain bound parameters you would use the keywords *UP*, *LO*, or *FX*, the string *bnd*, and the variable name of the variable whose upper, lower, or fixed bound is uncertain.

Note all the keywords for the definitions are in capital letters, i.e., "INDEP DISCRETE", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that in GAMS equations, variables may appear in the right-hand side, e.g. `"EQ.. X+1 =L= 2*Y"`. When the coefficient 2 is a random variable, we need to be aware that GAMS will generate the following LP row `X - 2*Y =L= -1`. Suppose the probability distribution of this random variable is given by:

```
set s scenario /pessimistic, average, optimistic/;
parameter outcome(s) / pessimistic 1.5
                       average     2.0
                       optimistic  2.3 /;
parameter prob(s)    / pessimistic 0.2
                       average     0.6
                       optimistic  0.2 /;
```

then the correct way of generating the entries in the stochastic file would be:

```
loop(s,
   put  "Y EQ ",(-outcome(s))," PERIOD2 ",prob(s)/;
);
```

Note the negation of the outcome parameter. Also note that expressions in a PUT statement have to be surrounded by parentheses. GAMS reports in the *row listing* section of the listing file how equations are generated. You are encouraged to inspect the row listing to discover or confirm how coefficients appear in a generated LP row.

Dependent Stochastic Parameters

Next we describe the case of general linear dependency of the stochastic parameters in the model, see below the representation of the stochastic parameters for the illustrative example APL1PCA, which has three dependent stochastic demands driven by two independent stochastic random parameters. First we give the definition of the two independent stochastic parameters, which in the example happen to have two outcomes each.

```
* defining independent stochastic parameters
set stoch /out, pro/;

set omega1 / o11, o12 /;
table v1(stoch,omega1)
       o11  o12
out    2.1  1.0
pro    0.5  0.5 ;

set omega2 / o21, o22 /;
table v2(stoch, omega2)
       o21  o22
out    2.0  1.0
pro    0.2  0.8 ;
```

We next define the parameters of the transition matrix from the independent stochastic parameters to the dependent stochastic parameters of the model. We do this by defining two parameter vectors, where the vector $hm1$ gives the coefficients of the independent random parameter $v1$ in each of the three demand levels and the vector $hm2$ gives the coefficients of the independent random parameter $v2$ in each of the three demand levels.

```
parameter hm1(dl) / h  300., m  400., l  200. /;
parameter hm2(dl) / h  100., m  150., l  300. /;
```

Again first define the GAMS stochastic file "MODEL.STG" and set GAMS to write to it. The statement *BLOCKS DISCRETE* indicates that a section of linear dependent stochastic parameters follows.

```
* defining distributions (writing file MODEL.STG)
file stg / MODEL.STG /;
put stg;

put "BLOCKS DISCRETE" /;
scalar h1;
loop(omega1,
put "BL  v1   period2 ", v1("pro", omega1)/;
```

```
loop(dl,
h1 = hm1(dl) * v1("out", omega1);
put "RHS demand ", dl.tl:1, " ", h1/;
);
);
loop(omega2,
put " BL v2   period2 ", v2("pro", omega2) /;
loop(dl,
h1 = hm2(dl) * v2("out", omega2);
put "RHS demand ", dl.tl:1, " ", h1/;
);
);
putclose stg;
```

Dependent stochastic parameters are defined as functions of independent random parameters. The keyword *BL* labels a possible realization of an independent random parameter. The name besides the *BL* keyword is used to distinguish between different outcomes of the same independent random parameter or a different one. While you could use any unique names for the independent random parameters, it appears natural to use the names you have already defined above, e.g., $v1$ and $v2$. For each realization of each independent random parameter define the outcome of every dependent random parameter (as a function of the independent one). If a dependent random parameter in the GAMS model depends on two or more different independent random parameters the contributions of each of the independent parameters are added. We are therefore in the position to model any linear dependency model. (Note that the class of models that can be accommodated here is more general than linear. The functions, with which an independent random variable contributes to the dependent random variables can be any ones in one argument. As a general rule, any stochastic model that can be estimated by linear regression is supported by GAMS/DECIS.)

Define each independent random parameter outcome and the probability associated with it. For example, the statement starting with *BL v1 period2* indicates that an outcome of (independent random parameter) *v1* is being defined. The name *period2* indicates that it is a second-stage random parameter, and *v1("pro", omega1)* gives the probability associated with this outcome. Next list all random parameters dependent on the independent random parameter outcome just defined. Define the dependent stochastic parameter coefficients by the GAMS variable name and equation name, or "RHS" and variable name, together with the value of the parameter associated with this realization. In the example, we have three dependent demands. Using the scalar $h1$ for intermediately storing the results of the calculation, looping over the different demand levels *dl* we calculate *h1 = hm1(dl) * v1("out", omega1)* and define the dependent random parameters as the right-hand sides of equation *demand*(*dl*).

When defining an independent random parameter outcome, if the block name is the same as the previous one (e.g., when *BL v1* appears the second time), a different outcome of the same independent random parameter is being defined, while a different block name (e.g., when *BL v2* appears the first time) indicates that the first outcome of a different independent random parameter is being defined. You must ensure that the probabilities of the different outcomes of each of the independent random parameters add up to one. The loop over all elements of *omega*1 defines all realizations of the independent random parameter $v1$ and the loop over all elements of *omega*2 defines all realizations of the independent random parameter $v2$.

Note that for the first realization of an independent random parameter, you *must* define all dependent parameters and their realizations. The values entered serve as a base case. For any other realization of an independent random parameter you only need to define the dependent parameters that have different coefficients than have been defined in the base case. For those not defined in a particular realization, their values of the base case are automatically added.

In the example of dependent stochastic parameters above, the specification of the distribution of the stochastic parameters using the put facility creates the following file "MODEL.STG", which then is processed by the GAMS/DECIS interface:

```
BLOCKS DISCRETE
BL  v1   period2         0.50
RHS demand h       630.00
RHS demand m       840.00
RHS demand l       420.00
BL  v1   period2         0.50
RHS demand h       300.00
RHS demand m       400.00
RHS demand l       200.00
 BL v2   period2         0.20
RHS demand h       200.00
RHS demand m       300.00
RHS demand l       600.00
 BL v2   period2         0.80
RHS demand h       100.00
RHS demand m       150.00
RHS demand l       300.00
```

Again all the keywords for the definitions are in capital letters, i.e., "BLOCKS DISCRETE", "BL", "RHS", and not represented in the example "UP", "LO", and "FX".

Note that you can only define random parameter coefficients that are nonzero in your GAMS model. When setting up the deterministic core model put a nonzero entry as a placeholder for any coefficient that you wish to specify as a stochastic parameter. Specifying a random parameter at the location of a zero coefficient in the GAMS model causes DECIS to terminate with an error message.

5.13.2.5 Setting DECIS as the Optimizer

After having finished the stochastic definitions you must set DECIS as the optimizer. This is done by issuing the following statements:

```
* setting DECIS as optimizer
* DECISM uses MINOS, DECISC uses CPLEX
option lp=decism;
apl1p.optfile = 1;
```

The statement *option lp = decism* sets DECIS with the MINOS LP engine as the optimizer to be used for solving the stochastic problem. Note that if you do not use DECIS, but instead use any other linear programming optimizer, your GAMS model will still run and optimize the deterministic core model that you have specified. The statement *apl1p.optfile = 1* directs GAMS to process the file `DECIS.OPT`, in which you may define any DECIS parameters.

Setting Parameter Options in the GAMS Model

The options iteration limit and resource limit can be set directly in your GAMS model file. For example, the following statements

```
option iterlim = 1000;
option reslim = 6000;
```

limit the number of decomposition iterations to be less than or equal to 1000, and the elapsed time for running DECIS to be less than or equal to 6000 seconds or 100 minutes.

Setting Parameters in the DECIS Options File

In the DECIS options file you can specify parameters regarding the solution algorithm used and control the output of the DECIS program. There is a record for each parameter you want to specify. Each record consists of the value of the parameter you want to specify and the keyword identifying the parameter, separated by a blank character or a comma. You may specify parameters with the following keywords: istrat, nsamples, nzrows, iwrite, ibug, iscratch, ireg, rho, tolben, and tolw *in any order*. Each keyword can be specified in lower case or upper case text in the format (A10). Since DECIS reads the records in free format you don't have to worry about the format, but some computers require that the text is inputted in quotes. Parameters that are not specified in the parameter file automatically assume their default values. See details of these parameters from Section Description of GAMS/DECIS Options.

Example

In the following example the parameters istrat = 7, nsamples = 200, and nzrows = 200 are specified. All other parameters are set at their default values. DECIS first solves the expected value problem and then the stochastic problem using crude Monte Carlo sampling with a sample size of nsamples = 200. DECIS reserves space for a maximum of nzrows = 50 cuts.

```
7       "ISTRAT"
200     "NSAMPLES"
50      "NZROWS"
```

Setting MINOS Parameters in the MINOS Specification File

When you use MINOS as the optimizer for solving the master and the subproblems, you must specify optimization parameters in the MINOS specification file "MINOS.SPC". Each record of the file corresponds to the specification of one parameter and consists of a keyword and the value of the parameter in free format. Records having a "$*$" as their first character are considered as comment lines and are not further processed. For a detailed description of these parameters, see the MINOS Users' Guide (Murtagh and Saunders (1983) [142] . The following parameters should be specified with some consideration:

- AIJ TOLERANCE — Specifies the nonzero tolerance for constraint matrix elements of the problem. Matrix elements a_{ij} that have a value for which $|a_{ij}|$ is less than "AIJ TOLERANCE" are considered by MINOS as zero and are automatically eliminated from the problem. It is wise to specify "AIJ TOLERANCE 0.0 "
- SCALE — Specifies MINOS to scale the problem ("SCALE YES") or not ("SCALE NO"). It is wise to specify "SCALE NO".
- ROWS — Specifies the number of rows in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ROWS" should be specified as the number of constraints in the core problem or greater.
- COLUMNS — Specifies the number of columns in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "COLUMNS" should be specified as the number of variables in the core problem or greater.
- ELEMENTS — Specifies the number of nonzero matrix coefficients in order for MINOS to reserve the appropriate space in its data structures when reading the problem. "ELEMENTS" should be specified as the number of nonzero matrix coefficients in the core problem or greater.

Example

The following example represents typical specifications for running DECIS with MINOS as the optimizer.

```
BEGIN SPECS
PRINT LEVEL                1
LOG FREQUENCY             10
SUMMARY FREQUENCY         10
MPS FILE                  12
ROWS                   20000
COLUMNS                50000
ELEMENTS              100000
ITERATIONS LIMIT       30000
*
FACTORIZATION FREQUENCY  100
AIJ TOLERANCE            0.0
*
SCALE                     NO
END OF SPECS
```

Setting CPLEX Parameters Using System Environment Variables

When you use CPLEX as the optimizer for solving the master and the subproblems, optimization parameters must be specified through system environment variables. You can specify the parameters "CPLEXLICDIR", "SCALELP", "NOPRESOLVE", "ITERLOG", "OPTIMALITYTOL", "FEASIBILITYTOL", and "DUALSIMPLEX".

- CPLEXLICDIR — Contains the path to the CPLEX license directory. For example, on a Unix system with the CPLEX license directory in /usr/users/cplex/cplexlicdir you issue the command *setenv CPLEXLICDIR /usr/users/cplex/cplexlicdir*.
- SCALELP — Specifies CPLEX to scale the master and subproblems before solving them. If the environment variable is not set no scaling is used. Setting the environment variable, e.g., by issuing the command *setenv SCALELP yes*, scaling is switched on.
- NOPRESOLVE — Allows to switch off CPLEX's presolver. If the environment variable is not set, presolve will be used. Setting the environment variable, e.g., by setting *setenv NOPRESOLVE yes*, no presolve will be used.
- ITERLOG — Specifies the iteration log of the CPLEX iterations to be printed to the file "MODEL.CPX". If you do not set the environment variable no iteration log will be printed. Setting the environment variable, e.g., by setting *setenv ITERLOG yes*, the CPLEX iteration log is printed.
- OPTIMALITYTOL — Specifies the optimality tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting *setenv OPTIMALITYTOL 1.0E-7* sets the CPLEX optimality tolerance to 0.0000001.
- FEASIBILIITYTOL — Specifies the feasibility tolerance for the CPLEX optimizer. If you do not set the environment variable the CPLEX default values are used. For example, setting *setenv FEASIBILITYTOL 1.0E-7* sets the CPLEX optimality tolerance to 0.0000001.
- DUALSIMPLEX — Specifies the dual simplex algorithm of CPLEX to be used. If the environment variable is not set the primal simplex algorithm will be used. This is the default and works beautifully for most problems. If the environment variable is set, e.g., by setting *setenv DUALSIMPLEX yes*, CPLEX uses the dual simplex algorithm for solving both master and subproblems.

5.13.2.6 GAMS/DECIS Output

After successfully having solved a problem, DECIS returns the objective, the optimal primal and optimal dual solution, the status of variables (if basic or not), and the status of equations (if binding or not) to GAMS. In the case of first-stage variables and equations you have all information available in GAMS, as you would with any other solver, but instead of obtaining the optimal values for a deterministic core problem you actually have the optimal values for the stochastic problem. However, for second-stage variables and constraints the e xpected values of the optimal primal and optimal dual solution are reported. This saves space and is useful for the calculation of risk measures. However, the information as to what the optimal primal and dual solutions were in the different scenarios of the stochastic programs is not reported back to GAMS. In a future release of the GAMS/DECIS interface the GAMS language is planned to be extended to handle the scenario second-stage optimal primal and dual values at least for selected variables and equations.

While running, DECIS outputs important information about the progress of the execution to your computer screen. After successfully solving a problem, DECIS also outputs its optimal solution to the solution output file "MODEL.SOL". The debug output file "MODEL.SCR" contains important information about the optimization run, and the optimizer output files "MODEL.MO" (when using DECIS with MINOS) or "MODEL.CPX" (when using DECIS with CPLEX) contain solution output from the optimizer used. In the DECIS User's Guide you find a detailed discussion of how to interpret the screen output, the solution report and the information in the output files.

The Screen Output

The output to the screen allows you to observe the progress of a DECIS run. After the program logo and the copyright statement, you see four columns of output being written to the screen as long as the program proceeds. The first column (from left to right) represents the iteration count, the second column the lower bound (the optimal objective of the master problem), the third column the best upper bound (exact value or estimate of the total expected cost of the best solution found so far), and the fourth column the current upper bound (exact value or estimate of the total expected cost of current solution). After successful completion, DECIS quits with "Normal Exit", otherwise, if an error has been encountered, the programs stops with the message "Error Exit".

Example

When solving the illustrative example APL1P using strategy 5, we obtain the following report on the screen:

```
 T H E   D  E  C  I  S   S Y S T E M

 22          0.2464E+05          0.2464E+05          0.2464E+05

Normal Exit
```

The Solution Output File

The solution output file contains the solution report from the DECIS run. Its name is "MODEL.SOL". The file contains the best objective function value found, the corresponding values of the first-stage variables, the corresponding optimal second-stage cost, and a lower and an upper bound on the optimal objective of the problem. In addition, the number of universe scenarios and the settings for the stopping tolerance are reported. In the case of using a deterministic strategy for solving the problem, exact values are reported. When using Monte Carlo sampling, estimated values, their variances, and the sample size used for the estimation are reported. Instead of exact upper and lower bounds, probabilistic upper and lower bounds, and a 95% confidence interval, within which the true optimal solution lies with 95% confidence, are reported. A detailed description of the solution output file can be found in the DECIS User's Guide.

The Debug Output File

The debug output file contains the standard output of a run of DECIS containing important information about the problem, its parameters, and its solution. It also contains any error messages that may occur during a run of DECIS. In the case that DECIS does not complete a run successfully, the cause of the trouble can usually be located using the information in the debug output file. If the standard output does not give enough information you can set the debug parameter ibug in the parameter input file to a higher value and obtain additional debug output. A detailed description of the debug output file can be found in the DECIS User's Guide.

The Optimizer Output Files

The optimizer output file "MODEL.MO" contains all the output from MINOS when called as a subroutine by DECIS. You can specify what degree of detail should be outputted by setting the appropriate "PRINT LEVEL" in the MINOS specification file. The optimizer output file "MODEL.CPX" reports messages and the iteration log (if switchwd on using the environment variable) from CPLEX when solving master and sub problems.

5.13.3 Description of GAMS/DECIS Options

5.13.3.1 DECIS Solver Options

Option	Description	Default
IBug	Debug output	0

Option	Description	Default
IReg	Indicator for regularized decomposition - MINOS only	0
IScratch	Internal unit number for output and debug	17
IStrat	Defines the solution strategy used	3
IWrite	Subproblem output	0
NSamples	Sample size used for the estimation	100
NZRows	Number of rows reserved for cuts in the master problem	100
Rho	rho parameter of regularization term in the objective function	1000
TolBen	Tolerance for stopping the decomposition algorithm	1e-7
TolW	tolerance when writing debug solution output	1e-9

IBug *(integer)*: Debug output ↩

Default: 0

value	meaning
0	DECIS does not write any debug output
1	Solution of the master problem on each iteration
2	Value 1 plus scenario index and the optimal objective value for each subproblem solved
3	Value 2 plus information regarding importance sampling
4	Value 3 plus optimal dual variables of the cuts
5	Value 4 plus coeffcients and the right-hand side of the cuts
6	Value 5 plus dump of the master problem and the subproblem in MPS format

IReg *(boolean)*: Indicator for regularized decomposition - MINOS only ↩

Default: 0

IScratch *(integer)*: Internal unit number for output and debug ↩

Range: {1, ..., ∞}

Default: 17

IStrat *(integer)*: Defines the solution strategy used ↩

Default: 3

value	meaning
1	Solves the expected value problem
2	Solves the stochastic problem using Monte Carlo importance sampling
3	Refers to istrat = 1 plus istrat = 2
4	Solves the stochastic universe problem
5	Refers to istrat = 1 plus istrat = 4
6	Solves the stochastic problem using crude Monte Carlo sampling
7	Refers to istrat = 1 plus istrat = 6
8	Solves the stochastic problem using Monte Carlo pre-sampling
9	Refers to istrat = 1 plus istrat = 8
10	Solves the stochastic problem using control variates
11	Refers to istrat = 1 plus istrat = 10

IWrite *(integer)*: Subproblem output ↩

Default: 0

value	meaning
0	No optimizer output is written
1	Optimizer output is written to the file

NSamples *(integer)*: Sample size used for the estimation ↩

Range: {30, ..., ∞}

Default: 100

NZRows *(integer)*: Number of rows reserved for cuts in the master problem ↩

Range: {1, ..., ∞}

Default: 100

Rho *(real)*: rho parameter of regularization term in the objective function ↩

Default: 1000

TolBen *(real)*: Tolerance for stopping the decomposition algorithm ↩

Default: 1e-7

TolW *(real)*: tolerance when writing debug solution output ↩

Default: 1e-9

5.13.4 Appendix A - GAMS/DECIS Illustrative Examples

5.13.4.1 Example APL1P

```
*   APL1P test model
*   Dr. Gerd Infanger, November 1997

set g generators /g1, g2/;
set dl demand levels /h, m, l/;

5.13.5 Appendix B - Error Messages

1. ERROR in MODEL.STO: kwd, word1, word2 was not matched in first realization of block
   The specification of the stochastic parameters is incorrect. The stochastic parameter has not been specified in the specification of the first outcome of the block. When specifying the first outcome of a block always include all stochastic parameters corresponding to the block.

2. Option word1 word2 not supported
   You specified an input distribution in the stochastic file that is not supported. Check the DECIS manual for supported distributions.

3. Error in time file
   The time file is not correct. Check the file MODEL.TIM. Check the DECIS manual for the form of the time file.

4. ERROR in MODEL.STO: stochastic RHS for objective, row name2
   The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand side for the objective row (row name2). Check file MODEL.STO.

5. ERROR in MODEL.STO: stochastic RHS in master, row name2
   The specification in the stochastic file is incorrect. You attempted to specify a stochastic right-hand side for the master problem (row name2). Check file MODEL.STO.

6. ERROR in MODEL.STO: col not found, name1
   The specification in the stochastic file is incorrect. The entry in the stochastic file, name1, is not found in the core file. Check file MODEL.STO.

7. ERROR in MODEL.STO: invalid col/row combination, (name1/name2)
   The stochastic file (MODEL.STO) contains an incorrect specification.

8. ERROR in MODEL.STO: no nonzero found (in B or D matrix) for col/row (name1, name2)
   There is no nonzero entry for the combination of name1 (col) and name2(row) in the B-matrix or in the D-matrix. Check the corresponding entry in the stochastic file (MODEL.STO). You may want to include a nonzero coefficient for (col/row) in the core file (MODEL.COR).

9. ERROR in MODEL.STO: col not found, name2
   The column name you specified in the stochastic file (MODEL.STO) does not exist in the core file (MODEL.COR). Check the file MODEL.STO.

10. ERROR in MODEL.STO: stochastic bound in master, col name2
    You specified a stochastic bound on first-stage variable name2. Check file MODEL.STO.

11. ERROR in MODEL.STO: invalid bound type (kwd) for col name2
    The bound type, kwd, you specified is invalid. Check file MODEL.STO.

12. ERROR in MODEL.STO: row not found, name2
    The specification in the stochastic file is incorrect. The row name, name2, does not exist in the core file. Check file MODEL.STO.

13. ERROR: problem infeasible
    The problem solved (master- or subproblem) turned out to be infeasible. If a subproblem is infeasible, you did not specify the problem as having the property of "complete recourse". Complete recourse means that whatever first-stage decision is passed to a subproblem, the subproblem will have a feasible solution. It is the best way to specify a problem, especially if you use a sampling based solution strategy. If DECIS encounters a feasible subproblem, it adds a feasibility cut and continues the execution. If DECIS encounters an infeasible master problem, the problem you specified is infeasible, and DECIS terminates. Check the problem formulation.

14. ERROR: problem unbounded
    The problem solved (master- or subproblem) turned out to be unbounded. Check the problem formulation.

15. ERROR: error code: inform
    The solver returned with an error code from solving the problem (master- or subproblem). Consult the users' manual of the solver (MINOS or CPLEX) for the meaning of the error code, inform. Check the problem formulation.

16. ERROR: while reading SPECS file
    The MINOS specification file (MINOS.SPC) containes an error. Check the specification file. Consult the MINOS user's manual.

17. ERROR: reading mps file, mpsfile
    The core file mpsfile (i.e., MODEL.COR) is incorrect. Consult the DECIS manual for instructions regarding the MPS format.

18. ERROR: row 1 of problem is not a free row
    The first row of the problem is not a free row (i.e., is not the objective row). In order to make the first row a free row, set the row type to be 'N'. Consult the DECIS manual for the MPS specification of the problem.

19. ERROR: name not found = nam1, nam2
    There is an error in the core file (MODEL.COR). The problem cannot be decomposed correctly. Check the core file and check the model formulation.

20. ERROR: matrix not in staircase form
    The constraint matrix of the problem as specified in core file (MODEL.COR) is not in staircase form. The first-stage rows and columns and the second-stage rows and columns are mixed within each other. Check the DECIS manual as to how to specify the core file. Check the core file and change the order of rows and columns.

5.13.6 DECIS License and Warranty

The software, which accompanies this license (the `"Software"`) is the property of Gerd Infanger and is protected by copyright law. While Gerd Infanger continues to own the Software, you will have certain rights to use the Software after your acceptance of this license. Except as may be modified by a license addendum, which accompanies this license, your rights and obligations with respect to the use of this Software are as follows:

- You may
  1. Use one copy of the Software on a single computer,
  2. Make one copy of the Software for archival purposes, or copy the software onto the hard disk of your computer and retain the original for archival purposes,
  3. Use the Software on a network, provided that you have a licensed copy of the Software for each computer that can access the Software over that network, item After a written notice to Gerd Infanger, transfer the Software on a permanent basis to another person or entity, provided that you retain no copies of the Software and the transferee agrees to the terms of this agreement.
- You may not
  1. Copy the documentation, which accompanies the Software,
  2. Sublicense, rent or lease any portion of the Software,
  3. Reverse engineer, de-compile, disassemble, modify, translate, make any attempt to discover the source code of the Software, or create derivative works from the Software.

5.13.6.1 Limited Warranty:

Gerd Infanger warrants that the media on which the Software is distributed will be free from defects for a period of thirty (30) days from the date of delivery of the Software to you. Your sole remedy in the event of a breach of the warranty will be that Gerd Infanger will, at his option, replace any defective media returned to Gerd Infanger within the warranty period or refund the money you paid for the Software. Gerd Infanger does not warrant that the Software will meet your requirements or that operation of the Software will be uninterrupted or that the Software will be error-free.

THE ABOVE WARRANTY IS EXCLUSIVE AND IN LIEU OF ALL OTHER WARRANTIES, WHETHER EXPRESS OR IMPLIED, INCLUDING THE IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.

5.13.6.2 Disclaimer of Damages:

REGARDLESS OF WHETHER ANY REMEDY SET FORTH HEREIN FAILS OF ITS ESSENTIAL PURPOSE, IN NO EVENT WILL GERD INFANGER BE LIABLE TO YOU FOR ANY SPECIAL, CONSEQUENTIAL, INDIRECT OR SIMILAR DAMAGES, INCLUDING ANY LOST PROFITS OR LOST DATA ARISING OUT OF THE USE OR INABILITY TO USE THE SOFTWARE EVEN IF GERD INFANGER HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

IN NO CASE SHALL GERD INFANGER'S LIABILITY EXCEED THE PURCHASE PRICE FOR THE SOFTWARE. The disclaimers and limitations set forth above will apply regardless of whether you accept the Software.

5.13.6.3 General:

This Agreement will be governed by the laws of the State of California. This Agreement may only be modified by a license addendum, which accompanies this license or by a written document, which has been signed by both you and Gerd Infanger. Should you have any questions concerning this Agreement, or if you desire to contact Gerd Infanger for any reason, please write:

Note

5.14 DICOPT

5.14.1 Introduction

`DICOPT` is a program for solving mixed-integer nonlinear programming (MINLP) problems that involve linear binary or integer variables and linear and nonlinear continuous variables. While the modeling and solution of MINLP optimization problems has not yet reached the stage of maturity and reliability achieved by linear, integer, or non-linear programming modeling, these problems still have rich areas of application. For example, they often arise in engineering design, management sciences, and finance. `DICOPT` (DIscrete and Continuous OPTimizer) was originally developed by Jagadisan Viswanathan, Ignacio E. Grossmann, and Aldo Vecchietti at the Engineering Design Research Center (EDRC) at Carnegie Mellon University. Currently, DICOPT is maintained by GAMS. The program is based on the extensions of the outer-approximation algorithm for the equality relaxation strategy. The MINLP algorithm inside `DICOPT` solves a series of NLP and MIP sub-problems. These sub-problems can be solved using any NLP (Nonlinear Programming) or MIP (Mixed-Integer Programming) solver that runs under GAMS. The performance will heavily depend on the choice of the selected subsolvers.

Although the algorithm has provisions to handle non-convexities, it does not necessarily obtain the global optimum.

The `GAMS/DICOPT` system has been designed with two main goals in mind:

- to build on existing modeling concepts, introduce a minimum of extensions to the existing modeling language, and provide upward compatibility to ensure easy transition from existing modeling applications to nonlinear mixed-integer formulations
- to use existing optimizers to solve the `DICOPT` sub-problems. This allows one to match the best algorithms to the problem at hand and guarantees that any new development and enhancements in the NLP and MIP solvers become automatically and immediate available to `DICOPT`.

5.14.2 Requirements

In order to use `DICOPT` you will need to have access to a licensed GAMS BASE system as well as at least one licensed MIP solver and one licensed NLP solver. For difficult models it is advisable to also have access to multiple solvers.

5.14.3 How to Run a Model with GAMS/DICOPT

DICOPT is only able to solve MINLP and MIQCP models. If you did not specify DICOPT as the default solver you can use the following statement in your GAMS model:

```
option minlp = dicopt;
```

This should appear before the solve statement. DICOPT automatically uses the default MIP and NLP solver to solve its sub-problems. One can override this with GAMS statements like:

```
option nlp = conopt;  { or any other nlp solver }
option mip = gurobi;  { or any other mip solver }
```

These options can also be specified on the command line:

```
> gams mymodel minlp=dicopt nlp=conopt mip=gurobi
```

In the Integrated Development Environment (IDE) the command line option can be specified in the edit line in the right upper corner of the main window.

Possible NLP solvers include conopt, ipopt, knitro, minos, and snopt. Possible MIP solvers include cplex, gurobi, and xpress.

With an option file it is even possible to use alternate solvers in different cycles. Section DICOPT Options explains this is in detail.

5.14.4 Overview of DICOPT

DICOPT solves models of the form:

$$\begin{array}{rl} \text{min or max} & f(x,y) \\ \text{subject to} & g(x,y) \sim b \\ & \ell_x \leq x \leq u_x \\ & y \in \lceil \ell_y \rceil, ..., \lfloor u_y \rfloor \end{array} \qquad \text{(MINLP)}$$

where x are the continuous variables and y are the discrete variables. The symbol $\sim$ is used to denote a vector of relational operators $\{\leq, =, \geq\}$. The constraints can be either linear or non-linear. Bounds ℓ and u on the variables are handled directly. $\lceil x \rceil$ indicates the smallest integer, greater than or equal to x. Similarly, $\lfloor x \rfloor$ indicates the largest integer, less than or equal to x. The discrete variables can be either integer variables or binary variables.

5.14.5 The Algorithm

The algorithm in DICOPT is based on three key ideas:

- Outer Approximation
- Equality Relaxation
- Augmented Penalty

Outer Approximation refers to the fact that the surface described by a convex function lies above the tangent hyper-plane at any interior point of the surface. (In 1-dimension, the analogous geometrical result is that the tangent to a convex function at an interior point lies below the curve). In the algorithm outer-approximations are attained by generating linearizations at each iterations and accumulating them in order to provide successively improved linear approximations of nonlinear convex functions that underestimate the objective function and overestimate the feasible region.

Equality Relaxation is based on the following result from non-linear programming. Suppose the MINLP problem is formulated in the form:

$$\begin{array}{rl} \text{minimize or maximize} & f(x) + c^T y \\ \text{subject to} & G(x) + Hy \sim b \\ & \ell \leq x \leq u \\ & y \in \{0,1\} \end{array}$$

i.e. the discrete variables are binary variables and they appear linearly in the model.

Let $y^{(0)}$ be any fixed binary vector and let $x^{(0)}$ be the solution of the corresponding NLP subproblem:

$$\begin{array}{rl} \text{minimize} & c^T y^{(0)} + f(x) \\ \text{subject to} & Ay^{(0)} + h(x) = 0 \\ & By^{(0)} + g(x) \leq 0 \\ & \ell \leq x \leq u \end{array}$$

Further let

$$\begin{array}{rl} T^{(0)} & = \text{diag}(t_{i,i}) \\ t_{i,i} & = \text{sign}(\lambda_i) \end{array}$$

where λ_i is the Lagrange multiplier of the i-th equality constraint.

If f is pseudo-convex, h is quasi-convex, and g is quasi-convex, then x^0 is also the solution of the following NLP:

$$\begin{array}{rl} \text{minimize} & c^T y^{(0)} + f(x) \\ \text{subject to} & T^{(0)}(Ay^{(0)} + h(x)) \leq 0 \\ & By^{(0)} + g(x) \leq 0 \\ & \ell \leq x \leq u \end{array}$$

In colloquial terms, under certain assumptions concerning the convexity of the nonlinear functions, an equality constraint can be `relaxed` to be an inequality constraint. This property is used in the MIP master problem to accumulate linear approximations.

Augmented Penalty refers to the introduction of (non-negative) slack variables on the right hand sides of the just described inequality constraints and the modification of the objective function when assumptions concerning convexity do not hold.

The algorithm underlying `DICOPT` starts by solving the NLP in which the 0-1 conditions on the binary variables are relaxed. If the solution to this problem yields an integer solution the search stops. Otherwise, it continues with an alternating sequence of nonlinear programs (NLP) called subproblems and mixed-integer linear programs (MIP) called master problems. The NLP subproblems are solved for fixed 0-1 variables that are predicted by the MIP master problem at each (major) iteration. For convex problems the master problem also provides a lower bound on the objective function. This lower bound (in the case of minimization) increases monotonically as iterations proceed due to the accumulation of linear approximations. Note that in the case of maximization this bound is an upper bound which can be used as a stopping criterion through a DICOPT option `stop 1` (see section DICOPT Options). Another stopping criterion that tends to work very well for non-convex problems (and even for convex problems) is based on the heuristic: stop as soon as the NLP subproblems start worsening (i.e. the current NLP subproblem has an optimal objective function that is worse than the previous NLP subproblem). This stopping criterion relies on the use of the augmented penalty, and is used in the description of the algorithm below. This is also the default stopping criterion in the implementation of DICOPT. The algorithm can be stated briefly as follows:

1. Solve the NLP relaxation of the MINLP program. If $y^{(0)} = y$ is integer, stop(`integer optimum found`). Else continue with step 2.
2. Find an integer point $y^{(1)}$ with an MIP master problem that features an augmented penalty function to find the minimum over the convex hull determined by the half-spaces at the solution $(x^{(0)}, y^{(0)})$.
3. Fix the binary variables $y = y^{(1)}$ and solve the resulting NLP. Let $(x^{(1)}, y^{(1)})$ be the corresponding solution.
4. Find an integer solution $y^{(2)}$ with a MIP master problem that corresponds to the minimization over the intersection of the convex hulls described by the half-spaces of the KKT points at $y^{(0)}$ and $y^{(1)}$.
5. Repeat steps 3 and 4 until there is an increase in the value of the NLP objective function. (Repeating step 4 means augmenting the set over which the minimization is performed with additional linearizations - i.e. half-spaces - at the new KKT point).

In the MIP problems integer cuts are added to the model to exclude previously determined integer vectors $y^{(1)}, y^{(2)}, ..., y^{(K)}$.

For a detailed description of the theory and references to earlier work, see [193] [110] [52] .

The algorithm has been extended to handle general integer variables and integer variables appearing nonlinearly in the model.

5.14.6 Modeling

5.14.6.1 Relaxed Model

Before solving a model with DICOPT, the user is strongly advised to experiment with the relaxed model where the integer restrictions are ignored. This is the `RMINLP` model. As the DICOPT will start solving the relaxed problem and can use an existing relaxed optimal solution, it is a good idea to solve the `RMINLP` always before attempting to solve the `MINLP` model, i.e., the following fragment is not detrimental with respect to performance:

```
  model m /all/;
  option nlp=conopt;
  option mip=cplex;
  option rminlp=conopt;
  option minlp=dicopt;
*
* solve relaxed model
*
  solve m using rminlp minimizing z;
  abort$(m.modelstat > 2.5) "Relaxed model could not be solved";

*
* solve minlp model
*
  solve m using minlp minimizing z;
```

The second `SOLVE` statement will only be executed if the first `SOLVE` was successful, i.e., if the model status was one (optimal) or two (locally optimal).

In general it is not a good idea to try to solve an MINLP model if the relaxed model cannot be solved reliably. As the RMINLP model is a normal NLP model, some obvious points of attention are:

- Scaling. If a model is poorly scaled an NLP solver may not be able find the optimal or even a feasible solution. Some NLP solvers have automatic scaling algorithms, but often it is better to attack this problem on the modeling level. The GAMS scaling facility can help in this respect.
- Starting point. If a poor starting point is used, the NLP solver may not be able to find a feasible or optimal solution. A starting point can be set by setting level values, e.g. `X.L = 1;`. The GAMS default levels are zero, with is often not a good choice.
- Adding bounds. Add bounds so that all functions can be properly evaluated. If you have a function $\sqrt{x}$ or $\log(x)$ in the model, you may want to add a bound `X.LO=0.001;`. If a function like $\log(f(x))$ is used, you may want to introduce an auxiliary variable and equation $y = f(x)$ with an appropriate bound `Y.LO=0.001;`.

In some cases the relaxed problem is the most difficult model. If more than one NLP solver is available you may want to try them in a sequence:

```
  model m /all/;
  option nlp=conopt;
  option mip=cplex;
  option rminlp=conopt;
  option minlp=dicopt;
*
* solve relaxed model
*
  solve m using rminlp minimizing z;
  if (m.modelstat > 2.5,
     option rminlp=minos;
     solve m using rminlp minimizing z;
  );
  if (m.modelstat > 2.5,
     option rminlp=snopt;
     solve m using rminlp minimizing z;
  );

*
* solve minlp model
*
  solve m using minlp minimizing z;
```

In this fragment we first try to solve the relaxed model using CONOPT. If that fails we try MINOS, and if that solve also fails we try SNOPT.

It is worthwhile to spend some time getting the relaxed model to solve reliably and speedily. In most cases, modeling improvements in the relaxed model, such as scaling, will also benefit the subsequent NLP sub-problems. In general these modeling improvements turn out to be rather solver independent: changes that improve the performance with CONOPT will also help solving the model with MINOS.

5.14.6.2 OPTCR and OPTCA

The DICOPT algorithm assumes that the integer sub-problems are solved to optimality. The GAMS options for OPTCR and OPTCA are therefore ignored: subproblems are solved with both tolerances set to zero. If you want to solve a MIP sub-problem with an optimality tolerance you can use the DICOPT option file to set OPTCR or OPTCA. For more information see section DICOPT Options.

For models with many discrete variables, it may be necessary to introduce an OPTCR or OPTCA option in order to solve the model in acceptable time. For models with a limited number of integer variables the default to solve MIP sub-models to optimality may be acceptable.

5.14.6.3 Integer Formulations

A number of MIP formulations are not very obvious and pose a demand on the modeler's knowledge and experience. A good overview of integer programming modeling is given in [202] .

Many integer formulations use a so-called big- M construct. It is important to choose small values for those big- M numbers. As an example consider the fixed charge problem where $y_i \in \{0,1\}$ indicate if facility i is open or closed, and where x_i is the production at facility i. Then the cost function can be modeled as:

$$\begin{aligned} C_i &= f_i y_i + v_i x_i \\ x_i &\leq M_i y_i \\ & y_i \in \{0,1\} \\ & 0 \leq x_i \leq cap_i \end{aligned}$$

where f_i is the fixed cost and v_i the variables cost of operating a facility i. In this case the chosen M_i should be large enough that x_i is not restricted if $y_i = 1$. On the other hand, it should be as small as possible. This leads to a choice to have M_i equal to the (tight) upperbound of variable x_i (i.e. the capacity cap_i of facility i).

5.14.6.4 Non-smooth Functions

GAMS alerts NLP modelers against the use of non-smooth functions such as min(), max(), smin(), smax() and abs(). In order to use these functions, a non-linear program needs to be declared as a DNLP model instead of a regular NLP model:

```
option dnlp=conopt;
model m /all/;
solve m minimizing z using dnlp;
```

This construct will warn the user that problems may arise due to the use of non-smooth functions.

A possible solution is to use a smooth approximation. For instance, the function $f(x) = |x|$ can be approximated by $g(x) = \sqrt{x^2 + \varepsilon}$ for some $\varepsilon > 0$. This approximation does not contain the point $(0, 0)$. An alternative approximation can be devised that has this property:

$$f(x) \approx \frac{2x}{1 + e^{-x/h}} - x$$

MINLP models do not have such protection against non-smooth functions, but the use of such functions is just as problematic here. It is possible to use discrete variables with MINLP models in order to model if-then-else situations. For instance, in the case of the absolute value we can replace x by $x^+ - x^-$ and $|x|$ by $x^+ + x^-$ by using:

$$\begin{aligned} x &= x^+ - x^- \\ |x| &= x^+ + x^- \\ x^+ &\leq \delta M \\ x^- &\leq (1 - \delta) M \\ x^+, x^- &\geq 0 \\ \delta &\in \{0, 1\} \end{aligned}$$

where δ is a binary variable.

5.14.7 GAMS Options

GAMS options are specified in the GAMS model source, using either the `option` statement or a model suffix.

5.14.7.1 The OPTION Statement

An option statement sets a global parameter. An option statement should appear *before* the `solve` statement, as in:

```
model m /all/;
option iterlim=100;
solve m using minlp minimizing z;
```

Option statements that affect the behavior of `DICOPT` are listed below:

- **option domlim** = n;
  This option sets a limit on the total accumulated number of non-linear function evaluation errors that are allowed while solving the NLP subproblems or inside `DICOPT` itself. An example of a function evaluation error or domain error is taking the square root of a negative number. This situations can be prevented by adding proper bounds. The default is zero, i.e. no function evaluation errors are allowed.

  In case a domain error occurs, the listing file will contain an appropriate message, including the equation that is causing the problem. For instance:

```
**** ERRORS(S) IN EQUATION loss(cc,sw)
     2 instance(s) of - UNDEFINED REAL POWER (RETURNED  0.0E+00)
```

If such errors appear you can increase the DOMLIM limit, but often it is better to prevent the errors from occurring in the first place. In many cases this can be accomplished by adding appropriate bounds. Sometimes extra variables and equations need to be added to accomplish this. For instance, with an expression like $\log(x-y)$, you may want to introduce a variable $z > \varepsilon$ and an equation $z = x - y$, so that the expression can be rewritten as $\log(z)$.

- **option iterlim =** n**;**
  This option sets a limit on the total accumulated (minor) iterations performed in the MIP and NLP subproblems.
- **option minlp =** *dicopt***;**
  This option selects DICOPT to solve MINLP problems.
- **option mip =** s**;**
  This option sets the MIP solver to be used for the MIP master problems. Note that changing from one MIP solver to another can lead to different results, and may cause DICOPT to follow a different path.
- **option nlp =** s**;**
  This option sets the NLP solver to be used for the NLP sub-problems. Note that changing from one NLP solver to another can lead to different results, and may cause DICOPT to follow a different path.
- **option optca =** x**;**
  This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.
- **option optcr =** x**;**
  This option is ignored. MIP master problems are solved to optimality unless specified differently in the DICOPT option file.
- **option reslim =** x**;**
  This option sets a limit on the total accumulated time (in seconds) spent inside DICOPT and the subsolvers.
- **option sysout = on;**
  This option will print extra information to the listing file.

In the list above (and in the following) n indicates an integer number. GAMS will also accept fractional values, which will be rounded. Options marked with an x parameter expect a real number. Options with an s parameter expect a string argument.

5.14.7.2 The Model Suffix

Some options are set by assigning a value to a model suffix, as in:

```
model m /all/;
m.optfile=1;
solve m using minlp minimizing z;
```

Model suffixes that affect the behavior of DICOPT are listed below:

- m**.dictfile = 1;**
  This option tells GAMS to write a dictionary file containing information about GAMS identifiers (equation and variables names). Such information is needed when the DICOPT option nlptracelevel is used, otherwise the option can be ignored.

- ***m*.iterlim = *n*;**
  Sets the total accumulated (minor) iteration limit. This option overrides the global iteration limit set by an option statement, e.g.,

  ```
  model m /all/;
  m.iterlim = 100;
  option iterlim = 1000;
  solve m using minlp minimizing z;
  ```

  will cause DICOPT to use an iteration limit of 100.

- ***m*.optfile = 1;**
  This option instructs DICOPT to read an option file dicopt.opt. This file should be located in the current directory (or the project directory when using the GAMS IDE). The contents of the option file will be echoed to the listing file and to the screen (the log file):

  ```
  --- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
  > maxcycles 10
  --- DICOPT: Starting major iteration 1
  ```

  If the option file does not exist, the algorithm will proceed using its default settings. An appropriate message will be displayed in the listing file and in the log file:

  ```
  --- DICOPT: Reading option file D:\MODELS\SUPPORT\DICOPT.OPT
  --- DICOPT: File does not exist, using defaults...
  --- DICOPT: Starting major iteration 1
  ```

- ***m*.optfile = *n*;**
  If $n > 1$ then the option file that is read is called dicopt.op n (for $n = 2, ..., 9$) or dicopt.o n (for $n = 10, ..., 99$). E.g. m.optfile=2; will cause DICOPT to read dicop.op2.

- ***m*.prioropt = 1;**
  This option turns on the use of priorities on the discrete variables. Priorities influence the branching order chosen by the MIP solver during solution of the MIP master problems. The use of priorities can greatly impact MIP solver performance. The priorities themselves have to be specified using the .prior variables suffix, e.g. x.prior(i,j) = ord(i);. Contrary to intuition, variables with a lower value for their priority are branched on before variables with a higher priority, i.e., the most important variables should get lower priority values.

- ***m*.reslim = *x*;**
  Sets the total accumulated time limit. This option overrides the global time limit set by an option statement.

5.14.8 DICOPT Options

This sections describes the options that can be specified in the DICOPT option file. This file is usually called dicopt.opt. The optfile model suffix must be set to tell DICOPT to read this file:

```
model m /all/;
m.optfile=1;
solve m using minlp minimizing z;
```

The option file is searched for in the current directory, or in the project directory when the IDE is used.

The option file is a standard text file, with a single option on each line. All options are case-insensitive. A line is a comment line if it starts with an asterisk, $*$ in column one. A valid option file can look like:

```
* stop only on infeasible MIP or hitting a limit
stop 0
* use minos to solve first NLP sub problem
* and conopt for all subsequent ones
nlpsolver minos conopt
```

A convenient way to write the option file from within a GAMS model is to use the following construct:

```
$onecho > dicopt.opt
stop 0
nlpsolver minos conopt
$offecho
```

This will make the model self-contained. Notice, however, that this overwrites an existing file `dicopt.opt`.

Available `DICOPT` options are listed below:

5.14.8.1 Algorithmic options

Option	Description	Default
continue	How to proceed in case of NLP errors	2
convex	If enabled, the defaults for a number of other options are set to values appropriate to convex MINLPs	0
dumpsubprob	Whether to dump MIP and NLP subproblems into GAMS files	0
infbnd	Bound to use for unbounded integer variables in integer cuts	10000
infeasder	Use derivatives of infeasible nonlinear subproblems	0
maxcycles	Maximum number of cycles	20
relaxed	How to start DICOPT	1
solvelink	Solvelink for NLP and MIP subsolver	5
stop	Stopping criterion	2
usexinit	Use the user initial point as starting point for all NLP solves	0
weight	Penalty parameter, set above 1e20 to disable penalty relaxation	1000

5.14.8.2 Tolerances

Option	Description	Default
epsmip	Tolerance on test on monotonic improvement of MIP master problem	1.0e-6
epsx	Tolerance for integer values when loading relaxed solution	1.0e-3

5.14.8.3 MIP masterproblem options

Option	Description	Default
mipiterlim	List of iteration limits	
mipoptfile	List of option files for MIP solver	
mipreslim	List of resource limits	
mipsolver	List of MIP solvers	
optca	List of OPTCA values	
optcr	List of OPTCR values	

5.14.8.4 NLP subproblem options

Option	Description	Default
domlim	List of allowed number of domain errors	
nlpiterlim	List of iteration limits	
nlpoptfile	List of option files for NLP solver	
nlpreslim	List of resource limits	
nlpsolver	List of NLP solvers	
nlptracefile	Base name of trace files	`nlptrace`
nlptracelevel	Trace level	0

5.14.8.5 Feasibility Pump

Option	Description	Default
feaspump	Whether to run the Feasibility Pump	0
fp_acttol	Tolerance on when to consider an equation as active	1E-6
fp_cutoffdecr	Additional relative decrement of cutoff value for the original objective function	0.1
fp_dumpsubprob	Whether to dump subproblems (NLPs and MIPs) into GAMS files	0
fp_integercuts	Whether to add integer cuts after an NLP subproblem has been solved to optimality	1
fp_iterlimit	Major Iteration limit	20
fp_mipgap	Optimality tolerance (relative gap) to use for solving MIP projection problem	0.01
fp_projcuts	Whether to add cut derived from projection of MIP solution onto NLP feasible set	1
fp_projzerotol	Tolerance on when to consider optimal value of projection problem as zero, which may trigger the solution of a Sub-NLP	1E-4
fp_sollimit	Stop when a number of (improving) solutions has been bound	maxint
fp_stalllimit	Stop when no improving solution has been bound for a number of FP iterations, -1 to disable	5

Option	Description	Default
fp_subsolverlog	Whether to show the log of subsolvers	0
fp_timelimit	Time limit	maxdouble
fp_transfercuts	Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible)	1

5.14.8.6 Detailed Options Description

continue *(integer)*: How to proceed in case of NLP errors ↩

This option can be used to let DICOPT continue in cases of NLP solver failure. The preferred approach is to fix the model so that NLP subproblems solve without problems. In some cases, however, (partial) failures of an NLP solver in solving the NLP subproblems can be ignored, as DICOPT may recover later on. Adding the option `continue 0` during model debugging enables DICOPT to function in a more specific way.

Default: 2

value	meaning
0	Stop on solver failure Stop on solver failure. DICOPT will terminate when an NLP subproblem can not be solved to optimality. Some NLP solvers terminate with a status other than optimal if not all of the termination criteria are met. For instance, the change in the objective function is negligible (indicating convergence) but the reduced gradients are not within the required tolerance. Such a solution may or may not be close to the (local) optimum. Using `continue 0` will prevent DICOPT from accepting such a solution.
1	Accept non-optimal feasible solutions NLP subproblem failures resulting in a non-optimal but feasible solutions are accepted. Sometimes an NLP solver cannot make further progress towards meeting all optimality conditions, although the current solution is feasible. Such a solution can be accepted by this option.
2	Ignore infeasible solutions NLP subproblem failures resulting in a non-optimal but feasible solution are accepted (as in option `continue 1`). NLP subproblem failures resulting in an infeasible solution are ignored. The corresponding configuration of discrete variables is forbidden to be used again. An integer cut to accomplish this is added to subsequent MIP master problems. Note that the relaxed NLP solution should be feasible. This setting is the default.

convex *(boolean)*: If enabled, the defaults for a number of other options are set to values appropriate to convex MINLPs ↩

If this option is enable, the default option values will be changed such that DICOPT will stop on crossover (stop set to 1), linearizations from infeasible NLP subproblems will be added to the MIP master problem (infeasder set to 1), penalty relaxation is no longer applied to linearizations (weight set to maxdouble), and the feasibility pump is run if there are no semicontinuous or semiinteger variables and no special ordered sets (feaspump set to 1).

Default: 0

domlim *(string)*: List of allowed number of domain errors ↩

domlim i_1 i_2 ... i_n. Sets a limit of the number of function and derivative evaluation errors for a particular cycle. A number of -1 means that the global GAMS option `domlim` is used. The last number i_n sets a domain error limit for all cycles $n, n+1, \ldots$.

Example: `domlim 0 100 0`
The NLP solver in the second cycle is allowed to make up to 100 evaluation errors, while all other cycles must be solved without evaluation errors.

The default is to use the global GAMS `domlim` option.

dumpsubprob *(boolean)*: Whether to dump MIP and NLP subproblems into GAMS files ↩

For subproblems of the feasibility pump, use option fp_dumpsubprob.

Default: `0`

epsmip *(real)*: Tolerance on test on monotonic improvement of MIP master problem ↩

This option can be used to relax the test on MIP objective functions. The objective function values of the MIP master problems should form a monotonic worsening curve. This is not the case if the MIP master problems are not solved to optimality. If the options `OPTCR` or `OPTCA` are set to a nonzero value, this test is bypassed. If the test fails, `DICOPT` will fail with a message:

```
The MIP solution became better after adding integer cuts.  Something
is wrong.  Please check if your model is properly scaled.  Also check
your big M formulations -- the value of M should be relatively small.
This error can also occur if you used a MIP solver option file with
a nonzero OPTCR or OPTCA setting.  In that case you may want to increase
the EPSMIP setting using a DICOPT option file.
```

The value of

$$\frac{\text{PreviousObj} - \text{CurrentObj}}{1 + |\text{PreviousObj}|}$$

is compared against `epsmip`. In case the test fails but you want `DICOPT` to continue anyway, you may want to increase the value of `epsmip`. The current values used in the test (previous and current MIP objective, `epsmip`) are printed along with the above message to provide information about how much you should increase `epsmip` to pass the test. Normally, you should not have to change this value.

Default: `1.0e-6`

epsx *(real)*: Tolerance for integer values when loading relaxed solution ↩

This tolerance is used to distinguish integer variables that are set to an integer value by the user, or integer variables that are fractional. See the option relaxed.

Default: `1.0e-3`

feaspump *(integer)*: Whether to run the Feasibility Pump ↩

Default: `0`

value	meaning
0	Do not run the Feasibility Pump
1	Run the Feasibility Pump if there are no semicontinuous or semiinteger variables and no special ordered sets
2	Always run the Feasibility Pump

fp_acttol *(real)*: Tolerance on when to consider an equation as active ↩

Default: `1E-6`

fp_cutoffdecr *(real)*: Additional relative decrement of cutoff value for the original objective function ↩

Default: `0.1`

fp_dumpsubprob *(boolean)*: Whether to dump subproblems (NLPs and MIPs) into GAMS files ↩

Default: `0`

fp_integercuts *(integer)*: Whether to add integer cuts after an NLP subproblem has been solved to optimality ↩

Default: `1`

value	meaning
0	Do not use integer cuts
1	Use integer cuts only for mixed-binary problems
2	Always use integer cuts

fp_iterlimit *(integer)*: Major Iteration limit ↩

Default: `20`

fp_mipgap *(real)*: Optimality tolerance (relative gap) to use for solving MIP projection problem ↩

Default: `0.01`

fp_projcuts *(boolean)*: Whether to add cut derived from projection of MIP solution onto NLP feasible set ↩

Default: `1`

fp_projzerotol *(real)*: Tolerance on when to consider optimal value of projection problem as zero, which may trigger the solution of a Sub-NLP ↩

Default: `1E-4`

fp_sollimit *(integer)*: Stop when a number of (improving) solutions has been bound ↩

Default: `maxint`

fp_stalllimit *(integer)*: Stop when no improving solution has been bound for a number of FP iterations, -1 to disable ↩

Range: {`-1`, ..., ∞}

Default: `5`

fp_subsolverlog *(boolean)*: Whether to show the log of subsolvers ↩

Default: `0`

fp_timelimit *(real)*: Time limit ↩

Default: `maxdouble`

fp_transfercuts *(boolean)*: Whether to transfer cuts from the Feasibility Pump MIP to the DICOPT MIP (all except from the round in which the FP MIP became infeasible) ↩

Default: `1`

infbnd *(real)*: Bound to use for unbounded integer variables in integer cuts ↩

Value to use for missing bounds on discrete variables when constructing integer cuts.

Default: `10000`

infeasder *(integer)*: Use derivatives of infeasible nonlinear subproblems ↩

This option is to determine whether linearizations of infeasible NLP subproblems are added or not added to the MIP master problem.

Default: `0`

value	meaning
`0`	No linearizations of infeasible NLP subproblems This is the default option in which no linearizations are added in the infeasible NLP subproblems. In this case a simple integer cut is added to remove from consideration the 0-1 vector that gave rise to the infeasible NLP. Since this may slow the convergence, it is recommended to reformulate the MINLP with "elastic" constraints (i.e., adding slacks to infeasible constraints and adding a penalty for them in the objective) to ensure that the NLP subproblems are mathematically feasible.
`1`	Add linearization for infeasible NLP subproblems This will add linearizations derived from the infeasible NLP subproblem to the master problem. This option is recommended to speed up convergence when the MINLP is known to be convex (i.e. its continuous relaxation is convex). The possibility of cutting-off the global optimum is increased if it is used for a nonconvex MINLP.

maxcycles *(integer)*: Maximum number of cycles ↩

The maximum number of cycles or major iterations performed by DICOPT.

Default: `20`

mipiterlim *(string)*: List of iteration limits ↩

mipiterlim i_1 i_2 ... i_n sets an iteration limit on individual MIP master problems. The last number i_n is valid for all subsequent cycles $n, n+1, \ldots$. A number of -1 indicates that there is no (individual) limit on the corresponding MIP master problem. A global iteration limit is maintained through the GAMS option iterlim.

Example: `mipiterlim 10000 -1`
The first MIP master problem cannot use more than 10000 iterations, while subsequent MIP master problems are not individually restricted.

Example: `mipiterlim 10000`
Sets an iteration limit of 10000 on all MIP master problems.

When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict iteration counts on individual solves of MIP master problems. The default for this option is not to restrict iteration counts on individual solves of MIP master problems.

mipoptfile *(string)*: List of option files for MIP solver ↩

mipoptfile s_1 s_2 ... s_n specifies the option file to be used for the MIP master problems. Several option files can be specified, separated by a blank. If a digit `1` is entered the default option file for the MIP solver in question is being used. The digit `0` indicates that no option file is to be used. The last option file is also used for subsequent MIP master problems.

Example: `mipoptfile mip.opt mip2.opt 0`
This option will cause the first MIP master problem solver to read the option file `mip.opt` and the second one to read the option file `mip2.opt`; subsequent MIP master problem solvers will not use any option file.

Example: `mipoptfile 1`
This will cause the MIP solver for all MIP subproblems to read a default option file (e.g. `cplex.opt`, `xpress.opt`, `gurobi.opt` etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

mipreslim *(string)*: List of resource limits ↩

mipreslim x_1 x_2 ... x_n sets a resource (time) limit on individual MIP master problems. The last number x_n is valid for all subsequent cycles $n, n+1, \ldots$. A number -1.0 means that the corresponding MIP master problem is not individually time restricted. A global time limit is maintained through the GAMS option reslim.

Example: `mipreslim -1 10000 -1`
The MIP master problem in cycle 2 cannot use more than 100 seconds, while subsequent MIP master problems are not individually restricted.

Example: `mipreslim 1000`
Sets a time limit on all MIP master problems of 1000 seconds.

When this option is used it is advised to have the option `continue` set to its default of 2. The default for this option is not to restrict individually the time a solver can spent on the MIP master problem.

mipsolver *(string)*: List of MIP solvers ↩

This option specifies with MIP solver to use for the MIP master problems.

Example: `mipsolver cplex xpress`
This instructs `DICOPT` to use Cplex for the first MIP and XPRESS for the second and subsequent MIP problems. The last entry may be used for more than one problem.

The names to be used for the solvers are the same as one uses in the GAMS statement `OPTION MIP=...;`. The default is to use the default MIP solver.
Note that changing from one MIP solver to another can lead to different results, and may cause `DICOPT` to follow a different path.

nlpiterlim *(string)*: List of iteration limits ↩

nlpiterlim i_1 i_2 ... i_n sets an iteration limit on individual NLP subproblems. The last number i_n is valid for all subsequent cycles $n, n+1, \ldots$. A number of -1 indicates that there is no (individual) limit on the corresponding NLP subproblem. A global iteration limit is maintained through the GAMS option reslim.

Example: `nlpiterlim 1000 -1`
The first (relaxed) NLP subproblem cannot use more than 1000 iterations, while subsequent NLP subproblems are not individually restricted.

Example: `nlpiterlim 1000`
Sets an iteration limit of 1000 on all NLP subproblems.

When this option is used it is advised to have the option continue set to its default of 2. This default does not restrict the amount of iterations an NLP solver can spend on an NLP subproblem, other than the global iteration limit.

nlpoptfile *(string)*: List of option files for NLP solver ↩

nlpoptfile s_1 s_2 ... s_n specifies the option file to be used for the NLP subproblems. Several option files can be specified, separated by a blank. If a digit `1` is entered, the default option file for the NLP solver in question is being used. The digit `0` indicates that no option file is to be used. The last option file is also used for subsequent NLP subproblems.

Example: `nlpoptfile nlp.opt nlp2.opt 0`
This option will cause the first NLP subproblem solver to read the option file `nlp.opt` and the second one to read the option file `nlp2.opt`; subsequent NLP subproblem solvers will not use any option file.

Example: `nlpoptfile 1`
This will cause the NLP solver for all NLP subproblems to read a default option file (e.g. `conopt.opt`, `minos.opt`, `snopt.opt` etc.).

Option files are located in the current directory (or the project directory when using the IDE). The default is not to use an option file.

nlpreslim *(string)*: List of resource limits ↩

nlpreslim x_1 x_2 ... x_n sets a resource (time) limit on individual NLP subproblems. The last number x_n is valid for all subsequent cycles $n, n+1, \ldots$. A number -1.0 means that the corresponding NLP subproblem is not individually time restricted. A global time limit is maintained through the GAMS option reslim.

Example: `nlpreslim 100 -1`
The first (relaxed) NLP subproblem can not use more than 100 seconds, while subsequent NLP subproblems are not individually restricted.

Example: `nlpreslim 1000`
Sets a time limit of 1000 seconds on all NLP subproblems.

When this option is used it is advised to have the option `continue` set to its default of 2. This default does not restrict the time an NLP solver can spend on an NLP subproblem (other than the global resource limit).

nlpsolver *(string)*: List of NLP solvers ↩

nlpsolver s_1 s_2 ... s_n. This option specifies which NLP solver to use for the NLP subproblems.

Example: `nlpsolver conopt minos snopt`
tells `DICOPT` to use `CONOPT` for the relaxed NLP, MINOS for the second NLP subproblem, and `SNOPT` for the third and subsequent ones. The last entry is used for more than one subproblem: for all subsequent ones `DICOPT` will use the last specified solver.

The names to be used for the solvers are the same as those used in the GAMS statement`OPTION NLP=...;`. The default is to use the default NLP solver. Note that changing from one NLP solver to another can lead to different results, and may cause `DICOPT` to follow a different path.

nlptracefile *(string)*: Base name of trace files ↩

Name of the files written if the option `nlptracelevel` is set. Only the stem is needed: if the name is specified as `nlptracefile nlptrace`, then files of the form `nlptrace.001`, `nlptrace.002`, etc. are written. These files contain the settings of the integer variables so that NLP subproblems can be investigated independently of `DICOPT`.

Default: `nlptrace`

nlptracelevel *(integer)*: Trace level ↩

This sets the level for NLP tracing, which writes a file for each NLP sub-problem, so that NLP sub-problems can be investigated outside the `DICOPT` environment. See also the option DICOPTnlptracefile "nlptracefile".

By including a trace file in your original problem and changing it into an MINLP problem, the subproblem will be solved directly by an NLP solver. This option only works if the names in the model (names of variables and equations) are exported by GAMS. This can be accomplished by using the `m.dictfile` model suffix, as in `m.dictfile=1;`. In general it is more convenient to use the `CONVERT` solver to generate isolated NLP models (see section Model Debugging).

Default: `0`

value	meaning
`0`	No trace info is written No trace files are written. This is the default.
`1`	GAMS file with fixed integer variables A GAMS file for each NLP subproblem is written which fixes the discrete variables.
`2`	Include levels of continuous variables As `nlptracelevel 1`, but in addition level values of the continuous variables are written.
`3`	Include all levels and marginals As `nlptracelevel 2`, but in addition marginal values for the equations and variables are written.

optca *(string)*: List of OPTCA values ↩

optca x_1 x_2 ... x_n. The absolute optimality criterion for the MIP master problems. The GAMS option optca is ignored, as, by default, `DICOPT` wants to solve MIP master problems to optimality. It is possible to stop the MIP solver earlier to allow it to solve a large problem, by specifying a value for `optca` or `optcr` in a `DICOPT` option file. With setting a value for `optca`, the MIP solver is instructed to stop as soon as the gap between the best possible integer solution and the best found integer solution is less than x, i.e. stop as soon as

$$|\text{BestFound} - \text{BestPossible}| \leq x$$

It is possible to specify a different `optca` value for each cycle. The last number x_n is valid for all subsequent cycles $n, n+1, \ldots$.

Example: `optca 10`
Stop the search in all MIP problems as soon as the absolute gap is less than 10.

Example: `optca 0 10 0`
Sets a nonzero `optca` value of 10 for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

optcr *(string)*: List of OPTCR values ↩

optcr x_1 x_2 ... x_n. The relative optimality criterion for the MIP master problems. The GAMS option optcr is ignored, as by default `DICOPT` wants to solve MIP master problems to optimality. To allow it to solve a large problem it is possible to stop the MIP solver earlier by specifying a value for `optca` or `optcr` in a `DICOPT` option file. With setting a value for `optcr`, the MIP solver is instructed to stop as soon as the relative gap between the best possible integer solution and the best found integer solution is less than x, i.e., stop as soon as

$$\frac{|\text{BestFound} - \text{BestPossible}|}{|\text{BestPossible}|} \leq x$$

Note that the relative gap cannot be evaluated if the best possible integer solution is zero. In these cases the absolute optimality criterion `optca` can be used. It is possible to specify a different `optcr` value for each cycle. The last number x_n is valid for all subsequent cycles $n, n+1, \ldots$.

Example: `optcr 0.1`
Stop the search in all the MIP problems as soon as the relative gap is smaller than 10%.

Example: `optcr 0 0.01 0`
Sets a nonzero `optcr` value of 1% for cycle 2, while all other MIP master problems are solved to optimality.

The default is zero.

relaxed *(integer)*: How to start DICOPT ↩

In some cases it may be possible to use a known configuration of the discrete variables. Some users have very difficult problems, where the relaxed problem cannot be solved but where NLP sub-problems with the integer variables fixed are much easier. If a reasonable integer configuration is known in advance in theses cases we can bypass the relaxed NLP and tell `DICOPT` to directly start with this integer configuration. The integer variables need to be specified by the user before the solve statement by assigning values to the levels, as in `Y.L(I) = INITVAL(I);`.

Default: `1`

value	meaning
`0`	Start with all integers fixed to the starting value The first NLP sub-problem will be executed with all integer variables fixed to the values specified by the user. If you don't assign a value to an integer variable,it will retain it's current value, which is zero by default
`1`	Start with relaxed NLP The first NLP problem is the relaxed NLP problem: all integer variables are relaxed between their bounds. This is the default.
`2`	Start with mixture of fixed and relaxed integers The first NLP subproblem will be executed with some variables fixed and some relaxed. The program distinguishes the fixed from the relaxed variables by

solvelink *(integer)*: Solvelink for NLP and MIP subsolver ↩

This option defines the solvelink used for the NLP and MIP subsolver.

Default: `5`

value	meaning
`1`	Call NLP and MIP solver via script
`2`	Call NLP and MIP solver via module
`5`	Call NLP and MIP solver in memory

stop *(integer)*: Stopping criterion ↩

This option defines the stopping criterion to be used. The search is always stopped when the (minor) iteration limit (the `iterlim` option), the resource limit (the `reslim` option), or the major iteration limit (see maxcycles) is hit or when the MIP master problem becomes infeasible.
Note: In general a higher number stops earlier, although in some cases stopping rule 2 may terminate the search earlier than rule 1. Section Modeling shows some experiments with these stopping criteria.

Default: `2`

value	meaning
`0`	Stop on maxcycles Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that `DICOPT` does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general `DICOPT` will often find the optimal solution using one of the more optimistic stopping rules. Do not stop unless an iteration limit, resource limit, or major iteration limit is hit or an infeasible MIP master problem becomes infeasible. This option can be used to verify that DICOPT does not stop too early when using one of the other stopping rules. In general it should not be used on production runs, as in general DICOPT will find often the optimal solution using one of the more optimistic stopping rules.
`1`	Stop on crossover Stop as soon as the bound defined by the objective of the last MIP master problem is worse or close (w.r.t. GAMS option optcr) to the best NLP solution found (a `crossover` occurred). For convex problems this gives a global solution, provided the weights are large enough and optcr is set to 0. This stopping criterion should only be used if it is known or it is very likely that the nonlinear functions are convex. In the case of non-convex problems the bounds of the MIP master problem are not rigorous. Therefore, the global optimum can be cut off with the setting `stop 1`.
`2`	Stop on worsening Stop as soon as the NLP subproblems stop improving. This `worsening` criterion is a heuristic. For non-convex problems in which valid bounds can not be obtained the heuristic often works very well. Even on convex problems, in many cases it terminates the search very early while providing an optimal or a very good integer solution. The criterion is not checked before major iteration three.
`3`	Stop on crossover or worsening Stop as soon as a crossover occurs or when the NLP subproblems start to worsen. (This is a combination of 1 and 2).

usexinit *(boolean)*: Use the user initial point as starting point for all NLP solves ↩

Default: 0

weight *(real)*: Penalty parameter, set above 1e20 to disable penalty relaxation ↩

The value of the penalty coefficients.

Default: 1000

5.14.9 DICOPT Output

DICOPT generates lots of output on the screen. DICOPT itself and also the NLP and MIP solvers that handle the sub-problems write messages to the screen. The most important part is the last part of the screen output.

In this section we will discuss the output DICOPT writes to the screen and the listing file using the model procsel.gms (this model is part of the GAMS model library). A DICOPT log is written and the reason why DICOPT terminated is explanied.

```
--- DICOPT: Checking convergence
--- DICOPT: Search stopped on worsening of NLP subproblems
--- DICOPT: Log File:
 Major Major     Objective    CPU time  Itera- Evaluation Solver
 Step  Iter       Function     (Sec)    tions   Errors
  NLP    1         5.35021      0.05        8      0      conopt
  MIP    1         2.48869      0.28        7      0      cplex
  NLP    2         1.72097<     0.00        3      0      conopt
  MIP    2         2.17864      0.22       10      0      cplex
  NLP    3         1.92310<     0.00        3      0      conopt
  MIP    3         1.42129      0.22       12      0      cplex
  NLP    4         1.41100      0.00        8      0      conopt
--- DICOPT: Terminating...
--- DICOPT: Stopped on NLP worsening

      The search was stopped because the objective function
      of the NLP subproblems started to deteriorate.

--- DICOPT: Best integer solution found: 1.923099
--- Reading solution for model process
*** Status: Normal completion
```

Notice that the integer solutions are provided by the NLP's except for major iteration one (the first NLP is the relaxed NLP). For all NLP's except the relaxed one the binary variables are fixed, according to a pattern determined by the previous MIP which operates on a linearized model. The integer solutions marked with a ' <' are an improvement. We see that the NLP in cycle 4 starts to deteriorate, and DICOPT stops based on its default stopping rule.

Note that if the criterion stop 1 had been used the search would have been terminated at iteration 3. The reason is that the upper bound to the profit predicted by the MIP (1.42129) exceeds the best current NLP solution (1.9231). Since it can be shown that the MINLP involves convex nonlinear functions, 1.9231 is the global optimum and the criterion stop 1 is rigorous.

In case the DICOPT run was not successful, or if one of the subproblems could not be solved, the listing file will contain all the status information provided by the solvers of the subproblems. For each iteration the configuration of the binary variables will also be printed. This extra information can also be requested via the GAMS option:

```
option sysout = on ;
```

5.14.10 Special Notes

This section covers some special topics of interest to users of DICOPT.

5.14.10.1 Stopping Rule

Although the default stopping rule behaves quite well in practice there some cases where it terminates too early. In this section we discuss the use of the stopping criteria.

When we run the example procsel.gms with stopping criterion 0, we see the following DICOPT log:

```
--- DICOPT: Starting major iteration 10
--- DICOPT: Search terminated: infeasible MIP master problem
--- DICOPT: Log File:
 Major Major     Objective    CPU time  Itera- Evaluation Solver
 Step  Iter       Function     (Sec)    tions   Errors
  NLP    1         5.35021      0.06        8      0      conopt
  MIP    1         2.48869      0.16        7      0      cplex
  NLP    2         1.72097<     0.00        3      0      conopt
  MIP    2         2.17864      0.10       10      0      cplex
  NLP    3         1.92310<     0.00        3      0      conopt
  MIP    3         1.42129      0.11       12      0      cplex
  NLP    4         1.41100      0.00        8      0      conopt
  MIP    4         0.00000      0.22       23      0      cplex
  NLP    5         0.00000      0.00        3      0      conopt
  MIP    5        -0.27778      0.16       22      0      cplex
  NLP    6        -0.27778      0.00        3      0      conopt
  MIP    6        -1.00000      0.16       21      0      cplex
  NLP    7        -1.00000      0.00        3      0      conopt
  MIP    7        -1.50000      0.22       16      0      cplex
  NLP    8        -1.50000      0.00        3      0      conopt
  MIP    8        -2.50000      0.11       16      0      cplex
  NLP    9        -2.50000      0.00        3      0      conopt
  MIP    9        *Infeas*      0.11        0      0      cplex
--- DICOPT: Terminating...
--- DICOPT: Stopped on infeasible MIP

      The search was stopped because the last MIP problem
      was infeasible. DICOPT will not be able to find
      a better integer solution.

--- DICOPT: Best integer solution found: 1.923099
--- Restarting execution
--- PROCSEL.GMS(98) 0 Mb
--- Reading solution for model process
*** Status: Normal completion
```

This example shows some behavioral features that are not uncommon for other MINLP models. First, DICOPT often finds the best integer solution in the first few major iterations. Second, in many cases as soon as the NLP's start to give worse integer solution no better integer solution will be found. This observation is the motivation to make stopping option 2, where DICOPT stops as soon as the NLP's start to deteriorate, the default stopping rule. In this example DICOPT would have stopped in major iteration 4 (you can verify this in the previous section). In many cases this will give the best integer solution. For this problem, DICOPT has indeed found the global optimum.

Based on experience with other models, we find that the default stopping rule (stop when the NLP becomes worse) performs well in practice. In many cases it finds the global optimum solution for both convex and non-convex problems. In some cases, however, it may provide a sub-optimal solution. In those cases where you want more reassurance that no good integer solutions are missed you can use one of the other stopping rules.

Changing the MIP or NLP solver can change the path that `DICOPT` follows, since the sub-problems may have non-unique solutions. The optimum stopping rule for a particular problem depends on the MIP and NLP solvers used.

The bounds of the MIP master problem are not rigorous in the case of non-convex problems. Therefore, the global optimum can be cut-off with `stop 1`. However, this option is the best stopping criterion for convex problems.

5.14.10.2 Solving the NLP Problems

Using a combination of NLP solvers has been found effective in cases where the relaxed NLP and/or the other NLP sub-problems are very difficult. For example, `MINOS` has many more difficulties to establish if a model is infeasible, so one would like to use `CONOPT` for NLP subproblems that are either infeasible or barely feasible. The `nlpsolver` option can be used to specify the NLP solver to be used for each iteration.

Infeasible NLP sub-problems can be problematic for `DICOPT` Those subproblems cannot be used to form a new linearization. Effectively only the current integer configuration is excluded from further consideration by adding appropriate integer cuts, but otherwise an infeasible NLP sub-problem provides no useful information to be used by the `DICOPT` algorithm. If your model shows many infeasible NLP sub-problems you can try to use the `infeasder` option. Otherwise a strategy that can help is to introduce explicit slack variables and add them with a penalty to the objective function.

Assume your model is of the form:

$$\begin{array}{ll} \min & f(x,y) \\ & g(x,y) \sim b \\ & \ell \leq x \leq u \\ & y \in \{0,1\} \end{array}$$

where $\sim$ is a vector of relational operators $\{\leq, =, \geq\}$. x are continuous variables and y are the binary variables. If many of the NLP subproblems are infeasible, we can try the following `elastic` formulation:

$$\begin{array}{ll} \min & f(x,y) + M \sum_i (s_i^+ + s_i^-) \\ & y = y^B + s^+ - s^- \\ & g(x,y) \sim b \\ & \ell \leq x \leq u \\ & 0 \leq y \leq 1 \\ & 0 \leq s^+, s^- \leq 1 \\ & y^B \in \{0,1\} \end{array}$$

I.e., the variables y are relaxed to be continuous with bounds $[0,1]$, and binary variables y^B are introduced that are related to the variables y through a set of the slack variables s^+, s^-. The slack variables are added to the objective with a penalty parameter M. The choice of a value for M depends on the size of $f(x,y)$, on the behavior of the model, etc. Typical values are 100 or 1000.

5.14.10.3 Solving the MIP Master Problems

MIP master problems may become expensive to solve when there are many discrete variables. One of the first things to try is to see if a different MIP solver can solve your particular problems more efficiently.

Different formulations can have dramatic impact on the performance of MIP solvers. Therefore it is advised to try out several alternative formulations. The use of priorities can have a big impact on some models. It is possible to specify a nonzero value for `OPTCA` and `OPTCR` in order to prevent the MIP solver from spending an unacceptable long time proving optimality of MIP master problems.

If the MIP master problem is infeasible the `DICOPT` solver will terminate. In this case you may want to try the same reformulation discussed in the previous paragraph.

5.14.10.4 Feasibility Pump

The feasibility pump is similar to the Outer-approximation, but its objective is to completely focus on finding good feasible solutions rather than optimal ones. The main idea of this algorithm is to decompose the original mathematical programming problem in two parts: integer feasibility and constraint feasibility. By solving an MIP subproblem its solution is an integer feasible solution, which may violate the constraints; and by solving a continuous relaxation of the original MINLP (NLP subproblem) the solution is constraint feasible but might not be integral. By minimizing in successive iterations the distance between these two types of solutions it is expected to achieve a solution that is both constraint and integral feasible.

The feasibility pump can be used as a standalone solver for convex MINLP problems. This is achieved by iteratively applying the method, while including a bound to the objective function. This bound is obtained by the best known solution and an epsilon improvement. This will result in the global optimum of a convex MINLP [28]. The drawback of this algorithm is that it may require many iterations, since each time the objective function is restricted to improve only by epsilon.

In DICOPT, the feasibility pump can be applied before the Outer-approximation method by setting option feaspump. In the feasibility pump, large improvements in the objective function are enforced at each iteration (option fp_cutoffdecr). After the method finishes, all the cuts and the best known solution are passed to the Outer-approximation method to prove optimality. More details on the implementation of the feasibility pump in DICOPT can be found in [19].

5.14.10.5 Model Debugging

In this paragraph we discuss a few techniques that can be helpful in debugging your MINLP model.

- Start with solving the model as an `RMINLP` model. Make sure this model solves reliably before solving it as a proper `MINLP` model. If you have access to different NLP solvers, make sure the `RMINLP` model solves smoothly with all NLP solvers. `CONOPT`, especially, can generate useful diagnostics such as Jacobian elements (i.e. matrix elements) that become too large.
- Try different NLP and MIP solvers on the subproblems. Example: use the GAMS statement `OPTION NLP=KNITRO;` to solve all NLP subproblem using the solver `KNITRO`.
- The GAMS option statement `OPTION SYSOUT = ON;` can generate extra solver information that can be helpful for diagnosing problems.
- If many of the NLP subproblems are infeasible, add slacks as described in section Solving the NLP Problems.
- Run `DICOPT` in pedantic mode by using the `DICOPT` option: `CONTINUE 0`. Make sure all NLP subproblems solve to optimality.

- Don't allow any nonlinear function evaluation errors, i.e. keep the DOMLIM limit at zero. See the discussion on DOMLIM in section The OPTION Statement.
- If you have access to another MINLP solver such as AlphaECP, SHOT, or SBB or even global solvers like Antigone or BARON, try to use a different solver on your model. To select another solver (here SBB) use the following GAMS option statement: `OPTION MINLP=SBB;`.
- Individual NLP or MIP subproblems can be extracted from the MINLP by using the CONVERT solver, which will write a model in scalar GAMS notation that can then be solved using any GAMS NLP or MIP solver. E.g., to generate the second NLP subproblem, you can use the following DICOPT option: `NLPSOLVER CONOPT CONVERT`. The model will be written to the file GAMS.GMS. A disadvantage of this technique is that some precision is lost due to the fact that files are being written in plain ASCII. The advantage is that you can visually inspect these files and look for possible problems such as poor scaling.

5.15 EXAMINER

5.15.1 Introduction

This document describes GAMS/Examiner, a tool for examining points and making an unbiased, independent assessment of their merit. In short, it checks if solutions are *really* solutions. As an example, it can take a solution point reported as optimal by a solver and examine it for primal feasibility, dual feasibility, and optimality. Examiner has a number of different modes, allowing it to check the input point from GAMS/Base as well as the solution passed by a solver back to GAMS.

Many of the tests done by Examiner (perhaps all of them!) are already being done by the GAMS solvers, so Examiner is in a sense redundant. However, the ability to make an independent, transparent check of a solver's solution is very useful in solver development, testing, and debugging. It is also useful when comparing the solutions returned by two different solvers. Finally, a tool like the Examiner allows one to examine solutions using different optimality tolerances and optimality criteria in a way that is not possible when working with the solvers directly.

GAMS/Examiner is installed automatically with your GAMS system. Without a full GAMS/Base license, examiner will run in student or demonstration mode (i.e. it will examine small models only).

5.15.2 Usage

Examiner can be used with all supported model types. Since Examiner doesn't really solve any problems, it is not a good choice for a default solver, and when installing GAMS it does not appear as an option in the list of possible solver defaults. However, you can choose Examiner via the command line:

```
gams trnsport LP=examiner;
```

or via a GAMS option statement

```
option LP=examiner;
```

somewhere before the `solve` statement.

Since Examiner is not really a solver, many of the usual GAMS options controlling solvers have no impact on it. However, the `sysout` option is interpreted in the usual way.

The optimality checks done in Examiner are first-order optimality checks done at a given point. A discussion here of these conditions and all they imply would be redundant: any good intro text in optimization will cover them. For linear programming, first-order optimality is all one needs to prove global optimality. For nonlinear programming, these conditions may or may not be necessary or sufficient for optimality; this depends on the convexity of the feasible set and objective and the form of the constraints. For integer programming models, these checks only make sense if we turn the global problem into a local one by adding bounds to the model, essentially fixing each discrete variable to its current value: these bounds are added automatically by Examiner.

Examiner runs in two basic modes of operation: it can examine the input point passed from GAMS/Base to the solver, and it can examine the point passed from the solver back to GAMS. Each mode can be used independent of the other. By default it will operate in the first mode, examining the initial "solution" passed to it by GAMS, but only if GAMS indicates it is passing an advanced basis to the solver (cf. the GAMS User Guide and the `bratio` option). If you wish to use the second `solver-check` mode, you may specify an appropriate subsolver using the `subsolver` option (see section Options). If no `subsolver` is selected, the default solver for the model type being solved is used. In most cases you will want to use an option file to specify exactly what type of examination you wish to perform. The rules for using an option file are described in The Solver Options File.

5.15.2.1 Solution Points: Definition

There are a number of different ways a solution point can be defined. Of course the different definitions will typically result in the same points being produced, but there are cases where this will not be precisely so. Since Examiner is intended to explore and analyze these cases, we must make these definitions precise. The following four points are defined and used in Examiner:

1. The `gamspoint` is the input point provided by GAMS to Examiner. The GAMS input point includes level & marginal values for the rows and columns: Examiner uses these exactly as given.
2. The `initpoint` is determined by the variable levels (primal vars) and equation marginals (dual vars) provided by GAMS to Examiner. These values are used to *compute* the equation levels and variable marginals / reduced costs using the function evaluator in Examiner, rather than using the values passed in by GAMS.
3. The `solupoint` is similar to the `initpoint`: it uses the variable levels (primal vars) and equation marginals (dual vars) to *compute* the equation levels and variable marginals. The variable levels and equation marginals used are those returned by the subsolver.
4. The `solvpoint` is the point returned by the subsolver. The subsolver returns both level and marginal values for the rows and columns: Examiner uses these, exactly as given.

5.15.2.2 Checks Performed

There are a number of checks that can be performed on any of the solution points. By default, Examiner tries to choose the appropriate checks. For example, if a primal simplex solver returns a model status of nonoptimal, the only checks that make sense are feasibility in the primal variables and constraints. However, this automatic choice of appropriate checks is not possible when checking points passed in from GAMS/Base.

1. **Primal variable feasibility**: check that all primal variables are within bounds.

2. **Primal constraint feasibility**: check that all primal constraints are satisfied.
3. **Dual variable feasibility**: check that all dual variables are within bounds.
4. **Dual constraint feasibility**: check that all dual constraints are satisfied.
5. **Primal complementary slackness**: check complementarity between the primal variables and the dual constraints / reduced costs.
6. **Dual complementary slackness**: check complementarity between the dual variables / equation marginals and the equation slacks.
7. **Equilibrium condition complementarity**: check complementarity of the equation/variable pairs in complementarity models (MCP, MPEC).

The checks above are implemented with default tolerances. These tolerances can be changed via an option file (see section Options).

Different ways exist to check the items mentioned above. For example, different norms can be used to measure the error of the residual when checking for primal feasibility. Currently, we have only implemented one way to make these checks.

For optimization models, it is possible to define a merit function that measures how well a given point satisfies conditions 1 through 6 above. Such a function is always nonnegative, and its value represents the error between the given point and a true solution. If such an input point is well-defined (e.g. if only one point is selected for examination) then Examiner will compute the merit function value at this point and return it in the RObj model attribute.

5.15.2.3 Scaling

By default, Examiner makes its checks on the original, unscaled model. In many cases, however, it is important to take scaling into account. Consider the effect of row scaling on the simple constraint $x^2 \leq 9$ where $x = 3.5$. Multiplying this constraint through by large or small constants changes the amount of the constraint violation proportionately, but the distance to feasibility is not changed. Applying row scaling to the original model eliminates this problem.

Most solvers scale a model before solving it, so any feasibility or optimality checks and tolerances are applied to the scaled model. The process of unscaling the model can result in a loss of feasibility or optimality. Even though we do not have access to the scales applied by the solver and cannot precisely construct the same scaled model, we can get a better idea of how the solver performed by looking at a model scaled by Examiner than by looking at the original.

It is also interesting to see what the model scaling looks like, even if we do not apply the scales to do the Examiner checks. If the row scales are in a nice range, say [.1,100], we can have some confidence that the model is well-scaled. In contrast, if the row scales are in the range `[1,1e8]` we may question the precision of the solution provided.

For each row, Examiner computes the true row scale as

$$\max(\|RHS_i\|, \max_j(\|A_{ij}\| \cdot \max(1, \|x_j\|)))$$

In this way variables with a large level value lead to large scale factors. To make the scale factor independent of the variable values, use an option file line of `"AbsXScale 0"`. This replaces the term $\max(1, \|x_j\|)$ above with 1.

Since the user may wish to limit the size of the scale factors applied, the true row scales are projected onto the scale factor bounds to get the applied scale factors. The scale factors are applied when making a scaled check by dividing the rows by the scale factors and multiplying the corresponding Lagrange multipliers by these same factors. When making unscaled checks information about the true scales is still included in the output to give the user a hint about potential scaling issues.

Note that the scaled and unscaled checks are made independently. By default only the unscaled checks are performed. If you turn the scaled checks on via an option file line `"scaled 1"`, this will not turn off the unscaled checks. You will need an option file line of `"unscaled 0"` to turn off unscaled checks.

5.15.3 Options

The following options control the behavior of GAMS/Examiner. Many of these are boolean (i.e. on/off) options. In this case, zero indicates off, nonzero on. For details on how to create and use an option file, see the section on the Solver Option File.

5.15.3.1 General Options

Option	Description	Default
absXScale	Whether to make scale factors dependent on x values. If on, the matrix coefficients are multiplied by max(1,abs(x)) when computing the scale factors. If off, the matrix coefficients are taken as is. See Section Scaling.	1
dumpGamsPoint	Whether to dump the GamsPoint to a basis file in GAMS source format.	0
dumpInitPoint	Whether to dump the InitPoint to a basis file in GAMS source format.	0
dumpSoluPoint	Whether to dump the SoluPoint to a basis file in GAMS source format.	0
dumpSolvPoint	Whether to dump the SolvPoint to a basis file in GAMS source format.	0
examineGamsPoint	Whether to examine the GamsPoint.	0
examineInitPoint	Whether to examine the InitPoint. By default, this option is on if GAMS/Base passes an advanced basis, and off otherwise.	auto
examineSoluPoint	Whether to examine the SoluPoint. By default, this option is on if a subsolver has been selected, and off otherwise.	auto
examineSolvPoint	Whether to examine the SolvPoint. By default, this option is on if a subsolver has been selected, and off otherwise.	auto
fCheckAll	If set, forces all checks on or off.	auto
fCheckATTR	If set, forces the model attributes check on or off.	auto
fCheckDCMP	If set, forces the dual complementary slackness check on or off.	auto
fCheckDCON	If set, forces the dual constraint feasibility check on or off.	auto
fCheckDVAR	If set, forces the dual variable feasibility check on or off.	auto
fCheckPCMP	If set, forces the primal complementary slackness check on or off.	auto
fCheckPCON	If set, forces the primal constraint feasibility check on or off.	auto
fCheckPVAR	If set, forces the primal variable feasibility check on or off.	auto
objvarAutoAdjust	Adjust objective variable to satisfy objective equation	0
perpSys	Controls output during examination of solution points. If on, print out the point in a way that allows for easy visual inspection and verification of the KKT or first order optimality conditions. First, the primal level values and bounds are printed next to the reduced costs. Next, the duals levels and bounds are printed next to the row slacks.	0
returnGamsPoint	Whether to return the GamsPoint as a solution to GAMS/Base.	0
returnInitPoint	Whether to return the InitPoint as a solution to GAMS/Base.	auto

Option	Description	Default
returnSoluPoint	Whether to return the SoluPoint as a solution to GAMS/Base.	auto
returnSolvPoint	Whether to return the SolvPoint as a solution to GAMS/Base.	auto
scaled	Whether to apply checks to a scaled version of the model.	0
scaleLB	Lower bound for applied row scales.	1
scaleUB	Upper bound for applied row scales.	maxdouble
showSlacks	explicitly show the infeasibilities or slacks for failed checks	0
subSolver	Indicates what subsolver to run. By default, the subsolver used is the default subsolver for the model type in question.	auto
subSolverOpt	optfile value to pass to the subsolver	auto
trace	If set, trace information will be computed and appended to this file.	none
unScaled	Whether to apply checks to the original, unscaled version of the model.	1

5.15.3.2 Tolerance Options

Option	Description	Default
dualCSTol	Tolerance on dual complementary slackness, i.e. between the dual variables and the primal constraints.	1e-7
dualFeasTol	Tolerance on dual feasibility, i.e. to check feasibility of the dual variables and the dual constraints.	1e-6
ECTol	Tolerance on equilibrium condition complementarity. Applicable to MCP and MPEC models, where the equilibrium conditions are given by the equation-variable pairs in the model statement.	1e-6
primalCSTol	Tolerance on primal complementary slackness, i.e. between the primal variables and the dual constraints.	1e-7
primalFeasTol	Tolerance on primal feasibility, i.e. to check feasibility of the primal variables and constraints.	1e-6
showTol	relative tolerance for showSlacks - we only want to see explicit slacks that are relatively small	1e-4

5.16 GAMSCHK

Abridged GAMSCHK USER DOCUMENTATION - Version 1.1
A System for Examining the Structure and Solution Properties of GAMS Model Instances

Author

Bruce A. McCarl, Professor, Department of Agricultural Economics, Texas A&M University

Date

April 2013

5.16.1 GAMSCHK USER DOCUMENTATION

This document describes procedures designed to aid users who wish to examine empirical GAMS models for possible flaws. The conceptual basis for many of the routines herein is supplied in McCarl and Spreen, and McCarl et.al.

The function of the specific components of GAMSCHK are to:

- List coefficients for user selected equations and/or variables using the DISPLAYCR procedure.
- List the characteristics of selected groups of variables and/or equations using MATCHIT.
- List the characteristics of equation and variable blocks using BLOCKLIST.
- Examine a GAMS model to see whether any variables and equations contain specification errors using ANALYSIS.
- Generate schematics depicting the characteristics of coefficients by variable and equation blocks using BLOCKPIC.
- Generate a schematic for small GAMS models or portions of larger models depicting the location of coefficients by sign and magnitude using PICTURE.
- Reconstruct the reduced cost of variables and the activity within equations after a model solution using POSTOPT.
- Help resolving problems with unbounded or infeasible models using NONOPT and ADVISORY.

5.16.2 General Notes on Package Usage

GAMSCHK must replace a solver. This is done using a GAMS option statement of the form:

```
OPTION LP= GAMSCHK;
```

or

```
OPTION NLP=GAMSCHK;
```

or

```
OPTION MIP=GAMSCHK;
```

which replaces either the solver of the particular model type with GAMSCHK. In turn, the user will invoke the solver using the statement:

```
SOLVE MODELNAME USING LP MINIMIZING OBJNAME;
```

where MODELNAME is the name used in the GAMS MODEL statement; OBJNAME is the objective variable name for the model; and the type of solver that GAMSCHK has replaced which must also be able to solve this type of problem (LP, NLP, MIP, ...) is identified. The following are examples of GAMS sequences which can be added to the GAMS file:

```
OPTION NLP=GAMSCHK;
SOLVE TRANSPORT USING NLP MINIMIZING Z;
```

or

```
OPTION LP=GAMSCHK;
SOLVE FEED USING LP MINIMIZING COST;
```

or

```
OPTION MIP=GAMSCHK;
SOLVE RESOURCE USING MIP MAXIMIZING PROFIT;
```

5.16.2.1 Selecting a Procedure and Providing Input - the ∗.GCK File

GAMSCHK requires that the user indicate which procedures are to be employed. This is specified through the use of the ∗.GCK file where the ∗ refers to the filename from the GAMS execution instruction. [2] The general form of that file is:

```
FIRST PROCEDURE NAME
  ITEM SELECTION INPUT

SECOND PROCEDURE NAME
  ITEM SELECTION INPUT
```

Spaces and capitalization are ignored in this input. For example, a ∗.GCK file could look like

```
 DISPLAYCR
          variables
              SELL(*,*,FANCY)
              maketable
          Invariables
              transport(plant2,*,fancy)
          Equations
              objT
              notthere
          inequations
              resourceq(plant1)
PICTURE
```

The first procedure name in this case is DISPLAYCR and the following 10 lines indicate the items to be selected. Then, we also request PICTURE. Selection entries are treated using several assumptions. In particular:

1. If the ∗.GCK file is empty then it is assumed that the BLOCKPIC procedure is selected.
2. Spaces maybe freely used in the GCK input file.
3. Upper, lower, or mixed case input is accepted.
4. GAMSCHK recognizes certain words. These words are listed in Appendix A: Reserved Names and cannot be used as variable or equation names.

5.16.2.2 The ∗.GCK file: General Notes on Item Selection

Some of the procedures permit selection of variables, equations or functions. Specifically, the DISPLAYCR, PICTURE, POSTOPT, and MATCHIT procedures accept input identifying the variables and equations to be utilized. Also NONOPT accepts limited input controlling its function. General observations about the selection requests are

1. Variables can be chosen by entering the word VARIABLE or VARIABLES possibly with a modifier, followed by variable selection statements.

[2] Thus, if the GAMS instructions are in the file called MYMODEL, and GAMS is invoked using the DOS command GAMS MYMODEL, then the GCK file would be called MYMODEL.GCK. If GAMS instructions are on the filename with a period in it then the name up to the period will be used, i.e., the GCK file associated with MYMODEL.IT would be MYMODEL.GCK

2. Variables can also be selected using the INEQUATION or INEQUATIONS syntax followed by names of equations. Use of this syntax results in selection of variables with coefficients in the named equations.

3. Equations are selected by entering the keyword, EQUATION or EQUATIONS possibly with a modifier, followed by equation selection statements.

4. Equations can also be selected using the INVARIABLE or INVARIABLES syntax followed by names of variables. Use of this syntax results in selection of equations in which the named variables have coefficients.

5. Certain item selection modifier keywords can be used depending on procedure. The INTERSECT keyword works with procedures DISPLAYCR and POSTOPT. The INEQUATION and INVARIABLE keywords work with procedures DISPLAYCR, PICTURE and POSTOPT. LISTEQUATION and LISTVARIABLE keywords work with the MATCHIT procedure. INSOLUTION, NOTINSOLUTION, BINDING, and NOTBINDING keywords work with POSTOPT. The keywords VERBOSE and IDENTIFY work with NONOPT.

6. If variable or equation names do not follow the keyword, then usually all variables or equations are assumed selected.

When variables or equations are to be selected after an item selection keyword, a number of input conventions apply. These conventions are:

1. If a variable or equation name is entered without any following parentheses, then all cases for that variable or equation are selected.

2. The selection entries identify specific elements from among the sets over which the variables and equations are defined. In specifying these elements one can use various wild card entries as discussed below or an element name. Note GAMS set or subset names cannot be used. Set membership information is not available to the GAMSCHK routines.

3. Wild cards can be used to select items. An "$*$" will select any item. For example, "B$*$" will select anything starting with a B. "A?B" will select anything beginning with A, ending with B with one intervening alpha numeric character.

4. When individual elements are specified, you need not enclose them in quotes (").

5. Quotes must be specified to include set item names with spaces, and special characters. In that case wild cards do not work and all input up to the next quote is simply copied.

6. When the selected item has more dimensions than specified, then all later dimensions are handled as if a wild card were specified. For example, when a variable X is defined with reference to 4 sets in the GAMS instructions, but only 3 parameters are specified in the GAMSCHK input, then the request is handled as if all elements of the 4th are desired.

7. When the selected item has less dimensions in GAMS than in the item selection input, then all additional dimensions are ignored. Thus, when a variable X is defined with reference to 3 sets in GAMS, but 4 parameters are specified in the item selection file, then the 4th specification is ignored.

8. Multiple selection statements can appear on successive lines of the $*$.GCK file. Output is ordered according to the way items are found in the GAMS file which is determined by the ordering of variables, equations, and set elements in the original GAMS input.

9. Error messages will be generated when an entry cannot be matched to a GAMS element.

10. Examples include

Example	Explanation
X(∗,CLEVELAND)	which indicates that X will be selected for any element of the first set where the element in the second set equals CLEVELAND
X(SEATTLE)	when X is two dimensional selects all cases where the first set element is SEATTLE
X(SEATTLE,CHICAGO,Z)	when X is two dimensional selects the case where the first set element equals SEATTLE, and the second element equals CHICAGO. The third is ignored.
X	all X's will be selected
X(S∗, C.O, Z)	when X is three dimensional selects where all X's with first element starting with S, second element beginning with C and ending with O and third element Z will be selected.
∗	all variables or equations will be selected
{empty selection set}	all variables or equations will be selected

5.16.2.3 Procedure Output

In all cases the output generated by the procedure will be written to the ∗.LST file associated with the GAMS call. Thus, if the file is called MODEL with the ∗.GCK file (MODEL.GCK), then all output will be on MODEL.LST.

5.16.2.4 Nonlinear Terms

GAMS models examined with GAMSCHK may involve nonlinear terms. In such cases, GAMSCHK uses the value of the nonlinear term sent forth from GAMS which is an accurate marginal, not total value. GAMS develops this value based on the current level value of the variable. This will either be: a) the starting point selected by GAMS, if the model has not been solved, or b) the current solution value, if the model has been solved. The most accurate portrayals of the coefficients will be generated after the model has been solved through a GAMS SOLVE command before invoking GAMSCHK. Some cases may require a solution and/or the specification of a good starting point before using GAMSCHK. Also, nonlinear terms potentially cause misleading coefficients as those values are local marginal, not global, values determined by the current levels of the variables. Nonlinear terms are marked with ∗∗∗ in the DISPLAYCR, POSTOPT, and NONOPT output.

5.16.2.5 Entering Comments in the ∗.GCK File

The ∗.GCK file has been programmed so that users can enter comments. These comments can take one of two forms. Comments that begin with a hash mark are copied to the output when the program runs. Comments which begin with a question mark are simply overlooked. Thus, one can temporarily comment GAMSCHK selection statements making them inactive by putting in question marks. If multiple procedures are being run or if some sort of output is decided to screen in the computer output then the hash marks can be entered.

5.16.2.6 Controlling Page Width in the ∗.GCK File

When running multiple procedures, in particular the pictures with other procedures, it is often desirable to have some procedures run with wide page widths, but the rest with a narrower page width. The GCK file provides the option to narrow the page width using a PW= command. In particular, what one can do is run GAMS with a large page width, i.e. run GAMS BLOCK pw=200, then insert in the GCK file instructions which narrow that page width for selected procedures. Users should note that the page width can never be made any wider than the default page width when running with GAMS. Information in excess of the page width will be ignored. Thus, if the model is run under the default status which has a page width of 75 characters then GAMSCHK will reduce the page width down to the maximum page width allowed. Consequently, the pw= command can only be used to narrow the page width from the default page width, not increase it.

5.16.2.7 Running Multiple Procedures

GAMSCHK can run multiple procedures during one job. This is done by simply stacking the sequence of the commands in the .GCK file.

5.16.3 Use of the Procedures

The following section describes the procedures available in GAMSCHK and their input requirements.

5.16.3.1 DISPLAYCR

Brief Purpose: DISPLAYCR displays all coefficients from the empirical model for a set of user selected equations and variables. All nonzero coefficients under each selected variable or in each selected equation are displayed with the associated variable or equation name and coefficient value. The selection entries may refer to all terms in equations under variables or only those coefficients at the intersection of the selected variables and equations.

Usage Notes: This option mirrors the GAMS LIMCOL and LIMROW options, but allows the user to select the specific items to be displayed. Partial displays within a variable or equation are also allowed using INTERSECT. Use of VARIABLE and EQUATION keywords followed by selection statements allows one to select variables and equations. Use of the INVARIABLE command allows users to select the equations which are associated with a particular variable. For example, if one is having trouble with a particular variable and wants to look at competition in the equations in which it appears, then selecting the variable under the INVARIABLE command will display the complete contents of all the equations in which the selected variables have coefficients. Similarly, the INEQUATION command will display the complete contents of all variables which fall in a particular equation. Nonlinear terms are marked with ***. When the keyword INTERSECT is found then only the coefficients at the intersection of the specified equations and variables are selected. Use of INTERSECT with the INVARIABLE syntax results in the named variables and the equations in which they fall being selected. Similarly, use of INTERSECT with the INEQUATION syntax results in selection of the named equations and the variables which fall in those equations

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: The keyword DISPLAYCR is entered followed by optional lines of item selection input identifying the variables and equations to be displayed. This file can contain the keywords VARIABLE, INVARIABLE, EQUATION, and INEQUATION, with each followed by a specification of the items to be selected using the procedure input specification conventions that were described above. The keyword INTERSECT can also be used. Several special cases are relevant:

- If none of the above keywords are found after DISPLAYCR and another procedure name does not follow, then the input is assumed to identify variables.
- If input is found but the VARIABLE or INEQUATION keyword cannot be found then no variables are assumed selected.
- If the VARIABLE keyword is entered, but is followed by the end of file or an Appendix A reserved word and INEQUATION does not appear, then all variables are assumed selected.
- If the EQUATION or INVARIABLE keyword cannot be found, then no equations are assumed selected.
- If the EQUATION keyword is entered, but is followed by the end of the file or a reserved word and the INVARIABLE command does not occur, then all equations are assumed selected.

- The keyword INVARIABLE is allowed. It should be followed by variable selection statements. In turn, DISPLAYCR selects all equations which have nonzero entries under the INVARIABLE selections.
- The keyword INEQUATION may be used. It should be followed by equation selection statements. In turn, DISPLAYCR selects all variables which have nonzero entries in the INEQUATION selections.
- The keyword INTERSECT causes only coefficients at the intersection of the specified equations and variables to be displayed. This occurs for all specifications in this run of DISPLAYCR. One should use DISPLAYCR again if some intersecting and some non-intersecting displays are desired.
- When INTERSECT appears along with INVARIABLE, the named variable is selected along with all the equations in which it falls. Similarly, when INTERSECT and INEQUATION appear then all the named equations and the variables appearing in them are selected.

5.16.3.2 MATCHIT

Brief Purpose: MATCHIT retrieves the names and characteristics of selected variables and equations. The characteristics reported tell whether the items are nonlinear as well as reporting scaling characteristics and counts of the coefficients. MATCHIT will summarize the items which match a request or list all the items individually.

Usage Notes: The input to MATCHIT can include the keywords VARIABLE and EQUATION along with those keywords with the prefix LIST attached. When the LIST prefix is not used, the procedure summarizes the characteristics of all items which match the item requests counting the number of matching items, the number of those items which are nonlinear, the total coefficients under or in those items, the number of positive, negative, and nonlinear coefficients that fall under or in those items. This does not list the names of the individual items which match. If the LIST prefix is used (entering LISTVARIABLE or LISTEQUATION) then the individual matching items are printed in the order in which they are encountered. For each matching item the information tells whether it is nonlinear, how many total coefficients it has, the count of positive, negative, and nonlinear coefficients falling under it, and the minimum and maximum absolute values of coefficients under it (excluding the objective function coefficient).

Note that when GAMS internal scaling features are employed then by default scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: This file contains the keyword MATCHIT, followed by optional item selection input data. The optional input identifies the variables and equations to be displayed. This input can contain the keywords VARIABLE or LISTVARIABLE followed by a specification of the variables to be selected using the procedure input specification conventions that were described above. This can be followed by the keyword EQUATION or LISTEQUATION and the specified entries.

Several special cases are relevant:

- If the procedure name is not followed by any selection input, then a count of all variables and equations appears.
- If the input is found, but the input does not begin with VARIABLE, EQUATION, LISTVARIABLE, or LISTEQUATION keywords, then the input is assumed to contain variable names.
- If the VARIABLE keyword is entered, but is not followed by variable selection statements, and LISTVARIABLE does not appear, then all variables are assumed selected.
- If the EQUATION or LISTEQUATION keyword cannot be found, then equations are assumed selected.

- If the EQUATION keyword is entered, but is not followed by equation selection statements or a LISTEQUATION entry, then all equations are assumed selected.
- The keyword LISTVARIABLE is allowed. It should be followed by variable selection statements. In turn, MATCHIT lists all variables which fall under the request.
- The keyword LISTEQUATION may also be used. It should be followed by equation selection statements. In turn, MATCHIT lists all equations which fall under the request.

5.16.3.3 ANALYSIS

Brief Purpose: Analyzes the structure of all variables and equations. Information is given on errors involving obvious model misspecifications causing redundancy, zero variable values, infeasibility, unboundedness, or obvious constraint relaxations in linear programs. The checks are those identified in Tables 1, 2 and 3.

Usage Notes: The analysis tests given in Tables 1 and 2 are utilized to determine if individual variables or equations in the model possess obvious specification errors. One test, for example, considers whether or not in a maximization problem a variable appears which has a positive return in the objective function, but no coefficients in the constraints indicating an obviously unbounded model. Similarly, information is provided on whether certain equations can never be satisfied. For example, tests examine whether an equality equation appears with a negative right hand side and all positives on the left hand side. Also tests see whether the bounds on variables preclude equation satisfaction or make equations redundant (Table 3). In ANALYSIS these tests are applied to each and every variable and equation. The BLOCKPIC and BLOCKLIST routines utilize the tests on a block by block basis. Thus, the messages will be triggered only if every variable or equation in that block has the same problem. Also interactions between variables and equations are not checked so ANALYSIS only finds flaws contained in individual variables/equations.

Input File: The keyword ANALYSIS is all that is accepted.

5.16.3.4 BLOCKLIST

Brief Purpose: The BLOCKLIST procedure displays the number and characteristics of the items in each GAMS variable and equation block.

Usage Notes: The characteristic information gives:

1. The variable sign restriction or equation inequality type.
2. The number of variables or equations in this block;
3. The number of variables or equations with at least one nonlinear term in this block.
4. The number of positive coefficients under the variables or in the equations.
5. The number of negative coefficients under the variables or in the equations.
6. The number of nonlinear coefficients under the variables or in the equations.
7. The largest coefficient in absolute value in this block;
8. The smallest coefficient in absolute value in this block. Analysis tests are also performed as discussed under the ANALYSIS procedure.

Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: No input other than the procedure name is needed.

5.16.3.5 BLOCKPIC

Brief Purpose: Generates model schematics and scaling information. The schematics depict coefficient signs, total and average number of coefficients within each GAMS equation and variable block.

Usage Notes: These schematics are designed to aid users in identifying flaws in coefficient placement and sign. The summary information on problem scaling characteristics is designed to help users in scaling data. The scaling information is usually reported after any GAMS scaling (using the variablename.scale and equationname.scale features) but before solver scaling. (The user can change whether descaling is done - see the options file). Analysis tests are done using the procedures in Tables 1 and 2.

Note that when GAMS internal scaling features are employed the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: The keyword BLOCKPIC is all that is recognized.

5.16.3.6 PICTURE

Brief Purpose: Generates a schematic depicting the location, sign and magnitude of coefficients for selected variables and equations. Users can use this schematic to help identify flaws in coefficient placement, magnitude, or sign. Reports are also generated on the number of individual elements in the pictured portions of each variable and equation.

Usage Notes: This output can be quite large, so PICTURE should only be used for small models or model components. Note that when GAMS internal scaling features are employed, the default option is that the scaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: Optional input instructions may appear after the PICTURE keyword. This input selects the variables and equations to be included. Only coefficients at the intersection of the selected variables and equations are portrayed. The selected item in the .GCK file can contain the keywords VARIABLE, or INVARIABLE followed by a specification of the selected variables using the procedure input specification conventions above. This can be followed by the keywords EQUATION or INEQUATION and the specified entries. Several special cases are also relevant:

- If the VARIABLE or INEQUATION keywords cannot be found, then all variables are assumed selected.
- If the EQUATION or INVARIABLE keywords cannot be found, then all equations are assumed to selected.
- If the none of the VARIABLE, INVARIABLE, EQUATION, or INEQUATION keywords are found, everything is pictured and all other input is ignored.
- When the INVARIABLE keyword is used, then all equations in which those variables have coefficients are selected along with the named variables.
- When the INEQUATION keyword is used, then all variables which have coefficients in the named equations are selected along with the named equations.

5.16.3.7 POSTOPT

Brief Purpose: Does post optimality computations. In that capacity POSTOPT either:

- Reconstructs the reduced cost of variables after a GAMS model solution. Modelers can use this information to discover why certain variables are nonbasic or why certain shadow prices take on particular values, or
- Reconstructs the usage and supply across an equation after a GAMS model solution. Modelers can use this information to discover why certain variables or slacks take on particular values, as well as to find out where items within equations are produced and/or used.

Usage Notes: POSTOPT uses essentially the same input conventions as does DISPLAYCR. Thus, the usage notes in that selection are also relevant here. In addition:

1. POSTOPT requires a solution has been obtained GAMSCHK will automatically cause a solver to be invoked unless suppressed by the options file;
2. Nonlinear terms may not be accurate in the row sums as their marginal value not their total value is used but GAMS will have adjusted the right-hand sides for their presence; and
3. Attention can be restricted to only certain types of variables or equations. Variables that are INSOLUTION (Nonzero or with Zero marginals), NOTINSOLUTION (zero with a nonzero marginal) can be requested, BINDING or NONBINDING equations can be focused on.

Note that when GAMS internal scaling features are employed, the default option is that the unscaled output is displayed. This can be altered using the DESCALE feature of the solver options file.

Input File: An optional input file is read in, indicating the specific variables desired using the conventions explained under DISPLAYCR above. In addition:

- One can enter INSOLUTION to restrict attention to variables which are nonzero or have zero marginals.
- One can enter NOTINSOLUTION to restrict attention to zero variables.
- The above entries restrict alteration in all VARIABLE or INEQUATION selection statements in a POSTOPT run.
- One can enter BINDING to only consider equations with zero slack. Similarly, NONBINDING considers equations with nonzero slack.
- The above equation specifications restrict all sections by all EQUATION or INVARIABLES items in a POSTOPT run.

5.16.3.8 ADVISORY

Brief Purpose: To identify variables which could be unbounded or equations and variable bounds which could cause a model to be infeasible.

Usage Notes: The ADVISORY procedure causes a presolution report on the set of all: a) variables which could be unbounded and/or b) equations and variable bounds which could cause infeasibility. The tests used are summarized in Table 3. This procedure identifies all variables which would need to be bounded as well as all constraints which need artificial variables if one wishes to diagnose problems in a model. The same output is also generated by NONOPT but the ADVISORY version does not require a solution.

Input file: Just the word ADVISORY

5.16.3.9 NONOPT

Brief Purpose: To help diagnose unbounded and infeasible models.

Usage Notes: The NONOPT procedure can be used in either an informative mode or with models which terminate as unbounded or infeasible. NONOPT will look through an optimal model reporting all variables which may be potentially unbounded or infeasible and all equations which may be infeasible using the checks explained under the ADVISORY section. Also in an unbounded model NONOPT can report the names of unbounded or infeasible variables or equations as well as either budgeting or row summing them. NONOPT runs after a solution and causes a solve to occur.

Input File: NONOPT may be followed by optional keywords IDENTIFY or VERBOSE. The IDENTIFY keyword causes GAMSCHK to report potential unbounded variables and/or infeasible equations. VERBOSE causes full budgets and row summing as done by the POSTOPT procedure on infeasible equations, and/or variables as well as unbounded variables and/or equations. Only the last encountered of the VERBOSE or IDENTIFY keywords will be obeyed. The details on these options are as follows:

1. If the IDENTIFY keyword is used, then the rules in Table 3 are applied to the model. Identify also anticipates that large upper bounds and/or artificial variables may be present. In an optimal condition all variable and equation levels that have exponents greater than the user supplied level filter in the options file (or 6 by default) are identified as items which could be involved with an unbounded model. Similarly, all variables or equations with marginals greater in exponent than the user supplied marginal exponent filter will be identified as items potentially involved with an infeasible model.
2. When the VERBOSE keyword is read then all variables and equations which are listed as nonoptimal or infeasible are treated using the budgeting and row summing aspects of POSTOPT.
3. When no keyword is found and the model solution is not optimal then the nonoptimal equations, infeasible equations and/or nonoptimal variables automatically listed.

5.16.4 Options File

GAMSCHK accepts an option file controlling solver choice (when needed); descaling; and size of the nonoptimal filters; the number of variable and column blocks selection entries allowed. The file is called GAMSCHK.OPT

5.16.4.1 Solver Choice Options

GAMSCHK calls for the solution of the problem when the POSTOPT or NONOPT procedures are used. In doing this, GAMSCHK internally selects the default GAMS solver for a problem class. Users may override this choice using the solver options file. Users may also force or suppress the solution process.

There are 16 solver related keywords allowed in the options file. These are as follows:

OPTION	Purpose
LP	Gives name of solver for LP problems
MIP	Gives name of solver for MIP problems
RMIP	Gives name of solver for RMIP problems
NLP	Gives name of solver for NLP problems
MCP	Gives name of solver for MCP problems
MPEC	Gives name of solver for MPEC problems

OPTION	Purpose
RMPEC	Gives name of solver for RMPEC problems
CNS	Gives name of solver for CNS problems
DNLP	Gives name of solver for DNLP problems
MINLP	Gives name of solver for MINLP problems
RMINLP	Gives name of solver for RMINLP problems
SOLVERNAME	Gives name of solver to be used regardless of problem type
NOSOLVE	Suppresses solution of the problem
SOLVE	Forces solution of the problem
DESCALE	Controls treatment of scaling
OPTFILE	Solver options file number

In the first five cases, the option name is followed by the name of one of the licensed solvers. If the options file is empty, then the default solver will be used. If a solver name is given, then that solver will be used provided it matches the name of a solver GAMS recognizes.

5.16.4.2 When Should I Use SOLVE or NOSOLVE

Ordinarily GAMSCHK will cause a solver to be used if either the POSTOPT or the NONOPT options are used. However, users can force solutions under other cases or suppress solutions if desired.

One should only force a solution (using the SOLVE option) when one wishes to use the solution information after GAMSCHK is done either to examine the solution output or do post optimality calculations. Forcing a solution will not cause GAMSCHK to have improved representations of nonlinear terms. That will only occur when a SOLVE statement is executed before the SOLVE statement involving GAMSCHK.

5.16.4.3 Control of Number of Variable and Row Selections Allowed

The GAMSCHK program uses an upper estimate on the number of variable or equation blocks. In rare circumstances users may wish to override this choice. The options for this are:

OPTION	Purpose
VARBLOCK	Maximum number of variable blocks allowed
EQUBLOCK	Maximum number of equation blocks allowed

These options are followed by a number, but should not be routinely used.

5.16.4.4 Scaling

GAMS users may be utilizing internal features which involve scaling through the Modelname.SCALEOPT=1, VariableName.SCALE, and EquationName.SCALE options. GAMSCHK can work with these options to create output which reflects scaled, unscaled or partially unscaled output. In particular, the command DESCALE can be entered with one of three options: NEVER, ALL, or PART. If you enter NEVER, then none of the model output will be descaled. If you enter ALL, then all of the model output will be descaled. The third option is to use PART. In that case the NONOPT and POSTOPT output will be descaled whereas scaled information will be displayed for PICTURE, BLOCKPIC, BLOCKLIST, MATCHIT and DISPLAYCR. The PART option allows investigation of scaling. If you do not enter a DESCALE option then all information will be reported as if the PART option was chosen.

5.16.4.5 NONOPT Filters

The NONOPT model in "IDENTIFY" mode checks through a model solution to identify large marginals and/or large variable values. The limits on these checks are provided by two options:

OPTION	Purpose
LEVELFILT	Numerical value of exponent on "unbounded levels"
MARGFILT	Numerical value of exponent on "infeasible marginals"

These options provide upper bounds on the exponents of the absolute values for the levels and marginals. They are followed by an integer which gives the exponent. Thus, entries like

```
LEVELFILT  7
MARGFILT   7
```

will cause the reporting of all marginals and levels which are greater in absolute value than 10^7.

5.16.4.6 Example Options File

The GAMSCHK option file is called GAMSCHK.OPT. An example of a file could look like the following 6 lines:

```
LP          SOPLEX
MIP         CBC
VARBLOCK    50
SOLVE
DESCALE     PART
LEVELFILT   4
```

5.16.4.7 Solver Options File

One other important aspect regarding the options file involves the use of a problem solver options file when a solver such as SOPLEX, CBC, IPOPT etc. is also being used. As seen above the GAMSCHK.OPT does not recognize option commands such as those which would be submitted to the programming model solvers - SOPLEX for example. In all cases GAMSCHK will cause the default option file for the solver to be used when invoking the solver. Thus if SOPLEX and the options file is invoked is being used, SOPLEX options are controlled by the option file SOPLEX.OPT while GAMSCHK.OPT controls GAMSCHK operation. Users can change the number of the solver options file being used by using the OPTFILE parameter in the options file. OPTFILE 2 would cause use of solver options file .OP2.

5.16.5 Known Bugs

There are a few bugs that can cause GAMSCHK to report improper outputs or results. A list of the known bugs, their symptoms and a remedy is given below.

Symptom	Cause	Remedy
Zero Shadow Prices in POSTOPT	Old GAMS version or no Prior Solve	1) Make sure the model was solved, 2) if it was, do not suppress solve in option file, or 3) update to most recent GAMS version
Descaling Does Not Work	Old Version of GAMS	Update
GAMS Blows up after GAMSCHK Runs	Old GAMS version	Ignore, *.LST file, results are fine, can be fixed by updating to the most recent version of GAMS
POSTOPT has error in budgets equal to twice objective function coefficient for nonlinear maximizations	Old GAMS MINOS version	Switch to a minimization formulation or update GAMS/MINOS
ROWSUM does not fully account for the value of nonlinear terms in POSTOPT	Value of nonlinear terms sent from GAMS are only a marginal value	None planned. GAMSCHK would need reprogramming
Error message about size of VARBLOCK or EQNBLOCK	exceeded maximum number of blocks	Modify option file, enlarging or eliminating parameters
GAMSCHK won't run	Files are not properly installed	Recheck installation. If still doesn't work report to author
Zero shadow prices when using NOSOLVE	Old version of GAMS solvers or Shadow prices suppressed	Try changing GAMSCOMP.TXT lines 2 or 0 to 12 or 10, if that doesn't work update GAMS.

5.16.6 Tables

Table 1: Conditions under which a modeler should be advised of potential difficulty for equations without nonlinear terms.

- `a/` The PS cases indicate, because the variables in this equation follow this pattern, that:
  1. The variables appearing with nonzeros in this equation are forced to equal zero.
  2. This equation can never be satisfied and is obviously infeasible.
  3. This equation is redundant. The nonnegativity conditions are a stronger restriction.
- `b/` In the examples x denotes indexed non-negative variables, y indexed non-positive variables, and z a single unrestricted variable.
- `c/` Here and in the cases below at least one nonzero must occur.
- `d/` These entries give examples of the problem covered by each warning. Namely, in the first case examining only the nonnegative variables suppose all those variables have signs ≥ 0 but the right-hand-side is zero. Thus, we have $X \geq 0$ and $X \leq 0$ which implies $X = 0$. A warning is generated in that case.
- `e/` Only one coefficient is allowed.

Type of constraint	Count of coefficients under a variable of this type with a particular sign						Sign of RHS	Type of PS[a/]	Examples[b]
	Nonnegative		Nonpositive		Unrestricted				
	+	-	+	-	+	-			
≤	≥ 0 [c/]	0	0	≥ 0	0	0	0	Zero Variables - Case 1	$\sum x \leq 0^{d/},\ -\sum y \leq 0,$
	≥ 0	0	0	≥ 0	0	0	-	Infeasible -Case 2	$\sum x \leq -k,\ -\sum y \leq -k,$
	0	≥ 0	≥ 0	0	0	0	+ or 0	Redundant -Case 3	$-\sum x \leq +k,\ \sum y \leq +k,$
=	≥0	0	0	≥0	0	0	0	Zero Variables - Case 1	$\sum x = 0,\ -\sum y = 0,\ \sum$
	0	≥0	≥0	0	0	0	0	Zero Variables - Case 1	$-\sum x = 0,\ \sum y = 0,\ -$
	≥0	0	0	≥0	0	0	-	Infeasible - Case 2	$\sum x - \sum y =$
	0	≥0	≥0	0	0	0	+	Infeasible - Case 2	$-\sum x + \sum y$
	0	0	0	0	≥$0^{e/}$	≥$0^{e/}$	0	Zero Variable - Case 1	$z = 0,\ -z =$
≥	0	≥0	≥0	0	0	0	0	Zero Variables - Case 1	$-\sum x \geq 0,\ \sum y \geq 0,\ -$
	0	≥0	≥0	0	0	0	0 or +	Infeasible -Case 2	$-\sum x \geq k,\ \sum y \geq k,\ -$
	≥0	0	0	≥0	0	0	- or 0	Redundant -Case 3	$\sum x \geq -k,\ -\sum y \geq -k,$

Table 2: Conditions under which a modeler should be warned about variables in a maximization problem.

Type of Variable	Objective function coefficient sign	Number of a_{ij}'s of a sign in ≥ rows +	≥ rows -	= rows +	= rows -	≤ rows +	≤ rows -	PS[a/]	Example
Nonnegative	+	≥0	0	0	0	0	≥0	Unbounded Variable case 1	$max\ x^{b/}$ $x+DQ\geq$ $-x+EQ\geq$
	-	0	≥0	0	0	≥0	0	Zero optimal solution case 2	$max\ -x$ $-x+DQ\geq$ $x+EQ\leq$
	0	≥0	0	0	0	0	≥0	Variable Relaxes constraint case 3	$max\ ox$ $x+DQ\geq$ $-x+DQ\geq$
	0	≥0	0	≥0[c/]	≥0[c/]	0	≥0	Variable Relaxes constraint case 4	$max\ ox$ $x+DQ\geq$ $x+FQ=$ $-x+EQ\geq$
Nonpositive	-	0	≥0	0	0	≥0	0	Unbounded Variable case 1	$max\ -y$ $-y+DQ\geq$ $y+EQ\leq$
	+	≥0	0	0	0	0	≥0	Zero optimal solution case 2	$max\ y^{b/}$ $y+DQ>$ $-y+EQ\geq$
	0	0	≥0	0	0	≥0	0	Variable Relaxes constraint case 3	$max\ ox$ $-y+DQ\geq$ $y+EQ\leq$
	0	≥0	0	≥0[c/]	≥0[c/]	0	≥0	Variable Relaxes constraint case 4	$max\ ox$ $-y+DQ\geq$ $y+FQ=$ $y+EQ\leq$
Unrestricted	+/-	0	0	0	0	0	0	Unbounded Variable case 1	$max\ \pm x$

- **a/** PS cases are: The variables which satisfy this condition are:
  1. Unbounded as they contribute to the objective function while satisfying the constraints.
  2. Obviously zero since they consume constraint resources and have a cost in the objective function.
  3. Warning this variable relaxes all constraints in which it appears
  4. Warning this variable relaxes all the equality constraints in which it appears in one direction
- **b/** Here x(y) has a positive objective term and can be increased without ever violating any constraints so x(y) is unbounded.
- **c/** Only one coefficient can be present in the equality rows

Table 3: Conditions When Model Elements Could be Unbounded or Infeasible.

Conditions for Potential Unbounded Variables – Presence of Bounds

Types of Variables	Sign of Objective in Max Problem	Upper	Lower
$\geq 0^{a/}$	+	None	—$^{b/}$
≤ 0	-	—	None
Unrestricted	+	None	—
Unrestricted	—	—	None

- **a/** If a non negative variable has a positive objective function coefficient without an upper bound, then the variable could be unbounded.
- **b/** Any reasonable value can exist for this item

Conditions for Potential Infeasibility Caused by Bounds on Variables

	Existence of Bounds	
Types of Variables	Lower	Upper
$\geq^{c/} 0$	+	—
≤ 0	—	—
Unrestricted	+	—
Unrestricted	—	—

- **c/** If a nonnegative variable has a positive lower bound then it could cause infeasibility.

Conditions for Potential Infeasibility in Equations

Type of Equations	RHS
$\leq^{d/}$	-
$\geq$	+
$=$	+ or -

- **d/** When a less than or equal equation is present it may not be able to be satisfied if it has a negative RHS.

Table 4: Conditions for Potential Infeasibility or Redundancy in Equations Based on Bounds on Variables.

	TYPE OF CONSTRAINT		PS
	≤b	≥b	
SUM OF THE SMALLEST VALUE[a/]	>b	—	INFEASIBLE
	—	>b	REDUNDANT
SUM OF THE LARGEST VALUE[b/]	—	<b	INFEASIBLE
	<b	—	REDUNDANT

Note:

- **a/** Suppose X_j is bounded with LB_j (lower bound) $\leq X_j \leq UB_j$ (upper bound), and we have the sum evaluated at the lower bounds will be the smallest value which could happen in that sum. If the constraint is $< b$, then if the sum is $> b$, we know that this constraint will never be satisfied. If the constraint is $> b$, and the sum is $> b$, we know that this constraint will not limit any possible X value. Hence, it is redundant.
- **b/** Suppose X_j is bounded as follows, LB_j (lower bound) $\leq X_j \leq UB_j$ (upper bound), and we have the sum evaluated at the upper bounds which is either $> b$ or $< b$, in that sum. If the sum is $< b$, and the constraint holds it $< b$ then we know that this constraint will not limit any possible X value. Hence, it is redundant. If the constraint holds it greater than b, but the sum is $< b$, we know that this constraint will never be satisfied.
- **c/** Thanks to Paul Preckel for bringing these tests to the authors' attention.

5.16.8 Appendix B: GAMSCHK One Page Summary

Invoking GAMSCHK **OPTION LP=GAMSCHK** **Keywords allowed in GCK file**

Keyword	Allowed SubKEYWORDS	Brief Description
DISPLAYCR		Displays coefficients of selected variables and equations
	VARIABLE*	Indicates variable selections follow
	INVARIABLE*	Indicates equations are wanted in which selected variables fall
	EQUATION*	Indicates equation selections follow
	INEQUATION*	Indicates variables are wanted that fall in selected equations
	INTERSECT++	Show coefficients which appear at intersections of selected var/eqn
MATCHIT		List variable and equation names and summarize characteristics
	VARIABLE*	Summarizes all variables matching selection statements
	LISTVARIABLE*	Lists each variable matching a selection statement
	EQUATION*	Summarizes all equations matching a selection statement
	LISTEQUATION*	Lists each equation matching a selection statement
ANALYSIS		Checks for obvious structural defects
BLOCKLIST		Summarizes characteristics of variable and equation blocks
BLOCKPIC		Generates block level schematics
PICTURE		Generates tableau schematics
	VARIABLE*	Indicates variable selections follow
	INVARIABLE*	Indicates equations are wanted in which selected variables fall
	EQUATION*	Indicates equation selections follow
	INEQUATION*	Indicates variables are wanted that fall in selected equations
POSTOPT		Reconstructs reduced cost and equation activity
	VARIABLE*	Indicates variable selections follow
	INVARIABLE*	Indicates variable selections follow
	EQUATION*	Indicates equation selections follow
	INEQUATION*	Indicates variables are wanted that fall in selected equations
	INTERSECT++	Show coefficients which appear at intersections of selected var/eqn
	NOTINSOLUTION++	Only nonzero vars or those with zero reduced cost
	INSOLUTION++	Only zero vars will be selected
	BINDING++	Only eqns with zero slack will be computed
	NONBINDING++	Only eqns with nonzero slack will be computed
ADVISORY		List potential infeasible and unbounded items
NONOPT		Lists potential or actual nonoptimal items
	IDENTIFY	Same as ADVISORY but after solution
	VERBOSE	Does POSTOPT computations on nonoptimals

Other Notes

- Items marked above with an $*$ are followed by item selection statements.
- Items marked with ++ modifiy the types of variables, equations and coefficients selected.
- In item selection an $*$ is a wild card for multiple characters while a . is a wildcard for one character.
- Spaces and capitalization don't matter in any of the input.
- Options file controls scaling, solver choice, nonopt filters and maximum allowed selections.
- Page width is controlled by a PW= keyword but cannot exceed GAMS page width.
- Lines beginning with a ? or a # are treated as comments.

5.16.9 Appendix C: Summary of GAMSCHK Options

Option	Description	Default
CNS	solver for CNS problems	
DESCALE	controls treatment of scaling	part
DNLP	solver for DNLP problems	
EQUBLOCK	maximum number of equation blocks allowed Range: {-∞, ..., ∞}	-5
LEVELFILT	numerical value of exponent on "unbounded levels" Range: {-5, ..., ∞}	6
LP	solver for LP problems	
MARGFILT	numerical value of exponent on "infeasible marginals" Range: {-5, ..., ∞}	6
MCP	solver for MCP problems	
MINLP	solver for MINLP problems	
MIP	solver for MIP problems	
MPEC	solver for MPEC problems	
NLP	solver for NLP problems	
NOSOLVE	suppresses solution of the problem	
OPTFILE	solver options file number	
RMINLP	solver for RMINLP problems	
RMIP	solver for RMIP problems	
RMPEC	solver for RMPEC problems	
SOLVE	forces solution of the problem	
SOLVERNAME	solver for any problems	
VARBLOCK	maximum number of variable blocks allowed Range: {-∞, ..., ∞}	-5

5.17 Gurobi

Gurobi Optimization, [www.gurobi.com] (http://www.gurobi.com)

5.17.1 Introduction

The Gurobi suite of optimization products include state-of-the-art simplex and parallel barrier solvers for linear programming (LP) and quadratic programming (QP), parallel barrier solver for quadratically constrained programming (QCP), as well as parallel mixed-integer linear programming (MILP), mixed-integer quadratic programming (MIQP), mixed-integer quadratically constrained programming (MIQCP) and (mixed-integer) nonlinear programming (NLP) solvers.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

While numerous solving options are available, Gurobi automatically calculates and sets most options at the best values for specific problems. All Gurobi options available through GAMS/Gurobi are summarized at the end of this chapter.

We offer a GAMS/Gurobi-Link license that works in combination with a Gurobi callable library license from Gurobi Optimization Inc.

Attention

> The free bare-bone link mode (previously GAMS/OSIGUROBI) that allowed to solve LP and MIP when the user had a separate GUROBI license has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@gams.com to arrange for a GAMS/Gurobi-Link license.

5.17.2 How to Run a Model with Gurobi

The following statement can be used inside your GAMS program to specify using Gurobi

```
Option LP = Gurobi;  { or MIP or RMIP or QCP or MIQCP or RMIQCP }
```

The above statement should appear before the `solve` statement. If Gurobi was specified as the default solver during GAMS installation, the above statement is not necessary.

5.17.3 Overview of GAMS/Gurobi

5.17.3.1 Linear, Quadratic and Quadratic Constrained Programming

Gurobi can solve LP and convex QP problems using several alternative algorithms, while the only choice for solving convex QCP is the parallel barrier algorithm. The majority of LP problems solve best using Gurobi's state-of-the-art dual simplex algorithm, while most convex QP problems solve best using the parallel barrier algorithm. Certain types of LP problems benefit from using the parallel barrier or the primal simplex algorithms, while for some types of QP, the dual or primal simplex algorithm can be a better choice. If you are solving LP problems on a multi-core system, you should also consider using the concurrent optimizer. It runs different optimization algorithms on different cores, and returns when the first one finishes.

GAMS/Gurobi also provides access to the Gurobi infeasibility finder. The infeasibility finder takes an infeasible linear program and produces an irreducibly inconsistent set of constraints (IIS). An IIS is a set of constraints and variable bounds which is infeasible but becomes feasible if any one member of the set is dropped. GAMS/Gurobi reports the IIS in terms of GAMS equation and variable names and includes the IIS report as part of the normal solution listing. The infeasibility finder is activated by the option IIS. Another option for analyzing infeasible model the FeasOpt option which instructs GAMS/Gurobi to find a minimal feasible relaxation of an infeasible model. See section Feasible Relaxation for details.

GAMS/Gurobi supports sensitivity analysis (post-optimality analysis) for linear programs which allows one to find out more about an optimal solution for a problem. In particular, objective ranging and constraint ranging give information about how much an objective coefficient or a right-hand-side and variable bounds can change without changing the optimal basis. In other words, they give information about how sensitive the optimal basis is to a change in the objective function or the bounds and right-hand side. GAMS/Gurobi reports the sensitivity information as part of the normal solution listing. Sensitivity analysis is activated by the option Sensitivity.

The Gurobi presolve can sometimes diagnose a problem as being infeasible *or* unbounded. When this happens, GAMS/Gurobi can, in order to get better diagnostic information, rerun the problem with presolve turned off. The rerun without presolve is controlled by the option ReRun. In default mode only problems that are small (i.e. demo sized) will be rerun.

Gurobi can either presolve a model or start from an advanced basis or primal/dual solution pair. Often the solve from scratch of a presolved model outperforms a solve from an unpresolved model started from an advanced basis/solution. It is impossible to determine a priori if presolve or starting from a given advanced basis/solution without presolve will be faster. By default, GAMS/Gurobi will automatically use an advanced basis or solution from a previous `solve` statement. The GAMS BRatio option can be used to specify when not to use an advanced basis/solution. The GAMS/Gurobi option UseBasis can be used to ignore or force a basis/solution passed on by GAMS (it overrides BRatio). In case of multiple solves in a row and slow performance of the second and subsequent solves, the user is advised to set the GAMS BRatio option to 1.

5.17.3.2 Mixed-Integer Programming

The methods used to solve pure integer and mixed integer programming problems require dramatically more mathematical computation than those for similarly sized pure linear or quadratic programs. Many relatively small integer programming models take enormous amounts of time to solve.

For problems with discrete variables, Gurobi uses a branch and cut algorithm which solves a series of subproblems, LP subproblems for MILP, QP subproblems for MIQP, and QCP subproblems or LP outer approximation subproblems for MIQCP. Because a single mixed integer problem generates many subproblems, even small mixed integer problems can be very compute intensive and require significant amounts of physical memory. With option nonConvex Gurobi can also solve nonconvex (MI)QP and (MI)QCP problems using a spatial branch-and-bound method.

GAMS/Gurobi supports Special Order Sets of type 1 and type 2 as well as semi-continuous and semi-integer variables.

You can provide a known solution (for example, from a MIP problem previously solved or from your knowledge of the problem) to serve as the first integer solution.

If you specify some or all values for the discrete variables together with GAMS/Gurobi option MipStart, Gurobi will check the validity of the values as an integer-feasible solution. If this process succeeds, the solution will be treated as an integer solution of the current problem.

The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation is deterministic: two separate runs on the same model will produce identical solution paths.

5.17.3.3 Nonlinear Programming

Gurobi can solve (mixed-integer) nonlinear programs to global optimality either directly or by approximating the model by piecewise-linear functions and/or reformulating nonlinear constraints into supported linear and/or quadratic constraints (see also funcnonlinear.)

For Gurobi to accept a nonlinear constraint, it has to be in one of the forms listed below. Furthermore, GAMS/Gurobi can automatically reformulate a nonlinear constraint into the supported form by enabling nlreform.

- **MAX constraint:**

```
eq1.. r =e= max(x1,x2,x3,...,c);
eq2.. r =e= smax(i, x(i));
```

- **MIN constraint:**

```
eq1.. r =e= min(x1,x2,x3,...,c);
eq2.. r =e= smin(i, x(i));
```

- **AND constraint:**

```
eq1.. r =e= b1 and b2 and b3 and ...;
eq2.. r =e= sand(i, b(i));
```

- **OR constraint:**

```
eq1.. r =e= b1 or b2 or b3 or ...;
eq2.. r =e= sor(i, b(i));
```

- **ABS constraint:**

```
eq.. r =e= abs(x);
```

- **EXP constraint:**

```
eq1.. r =e= exp(x);
eq2.. r =e= x**a;
eq3.. r =e= a**x;
```

  Here, `a` $>$ `0` and for `eq3` the lower bound of `x` must be nonnegative.

- **LOG constraint:**

```
eq1.. r =e= log(x);
eq2.. r =e= log2(x);
eq3.. r =e= log10(x);
```

- **SIN / COS / TAN constraint:**

```
eq1.. r =e= sin(x);
eq2.. r =e= cos(x);
eq3.. r =e= tan(x);
```

- **NORM constraint:**

```
eq1_1.. r =e= sum(i, abs(x(i)));
eq1_2.. r =e= abs(x1) + abs(x2) + abs(x3) + abs(x4);

eq2_1.. r =e= edist(x1,x2,x3,...);
eq2_2.. r =e= sqrt(sum(i, sqr(x(i))));
eq2_3.. r =e= sqrt(sqr(x1) + sqr(x2) + sqr(x3) + sqr(x4));

eq3_1.. r =e= smax(i, abs(x(i)));
eq3_2.. r =e= max(abs(x1), abs(x2), abs(x3), abs(x4));
```

  Note that a 2-norm constraint can lead to a non-convex quadratic model which is much harder to solve than a convex quadratic or linear model.

- **POLY constraint:**

```
eq.. r =e= poly(x, a0, a1, a2, ...);
```

- **SIGMOID constraint:**

```
eq1.. r =e= sigmoid(x);
eq2.. r =e= 1 / (1 + exp(-x));
```

Note

If nlreform is disabled, nonlinear constraints must perfectly match one of the above forms. The model is then directly passed to Gurobi without reformulation. If the constraint doesn't match one of the above forms, GAMS/Gurobi will raise a capability error. For example, it is not possible to interchange left-hand-side and right-hand-side of the above constraints. For more flexibility, enable nlreform.

Attention

When reformulating the model using nlreform, the nonlinear constraint is split into multiple smaller constraints. Therefore, the termination tolerances, in particular feasibilitytol, are applied differently. As a result, the solution returned to GAMS may not satisfy the requested tolerances.

5.17.3.4 Feasible Relaxation

The Infeasibility Finder identifies the causes of infeasibility by means of inconsistent set of constraints (IIS). However, you may want to go beyond diagnosis to perform automatic correction of your model and then proceed with delivering a solution. One approach for doing so is to build your model with explicit slack variables and other modeling constructs, so that an infeasible outcome is never a possibility. An automated approach offered in GAMS/Gurobi is known as FeasOpt (for Feasible Optimization) and turned on by parameter FeasOpt in a GAMS/Gurobi option file.

With the FeasOpt option GAMS/Gurobi accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section of the listing file.

By default all equations are candidates for relaxation and weighted equally but none of the variables can be relaxed. This default behavior can be modified by assigning relaxation preferences to variable bounds and constraints. These preferences can be conveniently specified with the `.feaspref` option. The input value denotes the users willingness to relax a constraint or bound. The larger the preference, the more likely it will be that a given bound or constraint will be relaxed. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed. It is not necessary to specify a unique preference for each bound or range. In fact, it is conventional to use only the values 0 (zero) and 1 (one) except when your knowledge of the problem suggests assigning explicit preferences.

Preferences can be specified through a GAMS/Gurobi solver option file using dot options. The syntax is:

(variable or equation)`.feaspref`*(value)*

For example, suppose we have a GAMS declaration:

```
Set i /i1*i5/;
Set j /j2*j4/;
variable v(i,j); equation e(i,j);
```

Then, the relaxation preference in the *gurobi.opt* file can be specified by:

```
feasopt 1
v.feaspref            1
v.feaspref('i1',*)    2
v.feaspref('i1','j2') 0

e.feaspref(*,'j1')    0
e.feaspref('i5','j4') 2
```

First we turn the feasible relaxtion on. Futhermore, we specify that all variables `v(i,j)` have preference of 1, except variables over set element `i1`, which have a preference of 2. The variable over set element `i1` and `j2` has preference 0. Note that preferences are assigned in a procedural fashion so that preferences assigned later overwrite previous preferences. The same syntax applies for assigning preferences to equations as demonstrated above. If you want to assign a preference to all variables or equations in a model, use the keywords `variables` or `equations` instead of the individual variable and equations names (e.g. `variables.feaspref 1`).

The parameter FeasOptMode allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require only as much relaxation as it found necessary in the first phase. Values of the parameter FeasOptMode indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations). Please check description of parameter FeasOptMode for details. Also check example models `feasopt*` in the GAMS Model library.

5.17.3.5 Parameter Tuning Tool

The Gurobi Optimizer provides a wide variety of parameters that allow you to control the operation of the optimization engines. The level of control varies from extremely coarse-grained (e.g., the Method parameter, which allows you to choose the algorithm used to solve continuous models) to very fine-grained (e.g., the MarkowitzTol parameter, which allows you to adjust the precise tolerances used during simplex basis factorization). While these parameters provide a tremendous amount of user control, the immense space of possible options can present a significant challenge when you are searching for parameter settings that improve performance on a particular model. The purpose of the Gurobi tuning tool is to automate this search.

The Gurobi tuning tool performs multiple solves on your model, choosing different parameter settings for each, in a search for settings that improve runtime. The longer you let it run, the more likely it is to find a significant improvement.

A number of tuning-related parameters allow you to control the operation of the tuning tool. The most important is probably TuneTimeLimit, which controls the amount of time spent searching for an improving parameter set. Other parameters include TuneTrials (which attempts to limit the impact of randomness on the result), TuneResults (which limits the number of results that are returned), and TuneOutput (which controls the amount of output produced by the tool).

While parameter settings can have a big performance effect for many models, they aren't going to solve every performance issue. One reason is simply that there are many models for which even the best possible choice of parameter settings won't produce an acceptable result. Some models are simply too large and/or difficult to solve, while others may have numerical issues that can't be fixed with parameter changes.

Another limitation of automated tuning is that performance on a model can experience significant variations due to random effects (particularly for MIP models). This is the nature of search. The Gurobi algorithms often have to choose from among multiple, equally appealing alternatives. Seemingly innocuous changes to the model (such as changing the order of the constraint or variables), or subtle changes to the algorithm (such as modifying the random number seed) can lead to different choices. Often times, breaking a single tie in a different way can lead to an entirely different search. We've seen cases where subtle changes in the search produce 100X performance swings. While the tuning tool tries to limit the impact of these effects, the final result will typically still be heavily influenced by such issues.

The bottom line is that automated performance tuning is meant to give suggestions for parameters that could produce consistent, reliable improvements on your models. It is not meant to be a replacement for efficient modeling or careful performance testing.

5.17.3.6 Compute Server

The Gurobi Compute Server allows you to use one or more servers to offload all of your Gurobi computations.

Gurobi compute servers support queuing and load balancing. You can set a limit on the number of simultaneous jobs each compute server will run. When this limit has been reached, subsequent jobs will be queued. If you have multiple compute servers, the current job load is automatically balanced among the available servers. By default, the Gurobi job queue is serviced in a First-In, First-Out (FIFO) fashion. However, jobs can be given different priorities. Jobs with higher priorities are then selected from the queue before jobs with lower priorities.

Gurobi Compute Server licenses and software are not included in GAMS/Gurobi. Contact Gurobi directly to inquire about the software and license.

5.17.3.7 Distributed Parallel Algorithms

Gurobi Optimizer implements a number of distributed algorithms that allow you to use multiple machines to solve a problem faster. Available distributed algorithms are:

- A **distributed MIP solver**, which allows you to divide the work of solving a single MIP model among multiple machines. A manager machine passes problem data to a set of worker machines in order to coordinate the overall solution process.
- A **distributed concurrent solver**, which allows you to use multiple machines to solve an LP or MIP model. Unlike the distributed MIP solver, the concurrent solver doesn't divide the work associated with solving the problem among the machines. Instead, each machine uses a different strategy to solve the whole problem, with the hope that one strategy will be particularly effective and will finish much earlier than the others. For some problems, this concurrent approach can be more effective than attempting to divide up the work.
- **Distributed parameter tuning**, which automatically searches for parameter settings that improve performance on your optimization model. Tuning solves your model with a variety of parameter settings, measuring the performance obtained by each set, and then uses the results to identify the settings that produce the best overall performance. The distributed version of tuning performs these trials on multiple machines, which makes the overall tuning process run much faster.

These distributed parallel algorithms are designed to be almost entirely transparent to the user. The user simply modifies a few parameters, and the work of distributing the computation to multiple machines is handled behind the scenes by Gurobi.

Specifying the Worker Pool

Once you've set up a set of one or more distributed workers, you should list at least one of their names in the WorkerPool parameter. You can provide either machine names or IP addresses, and they should be comma-separated.

You can provide the worker access password through the WorkerPassword parameter. All servers in the worker pool must have the same access password.

Requesting Distributed Algorithms

Once you've set up the worker pool through the appropriate parameters, the last step to use a distributed algorithm is to set the TuneJobs, ConcurrentJobs, or DistributedMIPJobs parameter. These parameters are used to indicate how many distinct tuning, concurrent, or distributed MIP jobs should be started on the available workers.

If some of the workers in your worker pool are running at capacity when you launch a distributed algorithm, the algorithm won't create queued jobs. Instead, it will launch as many jobs as it can (up to the requested value), and it will run with these jobs.

These distributed algorithms have been designed to be nearly indistinguishable from the single machine versions. Our hope is that, if you know how to use the single machine version, you'll find it straightforward to use the distributed version. The distributed algorithms respect all of the usual parameters. For distributed MIP, you can adjust strategies, adjust tolerances, set limits, etc. For concurrent MIP, you can allow Gurobi to choose the settings for each machine automatically or specify a set of options. For distributed tuning, you can use the usual tuning parameters, including TuneTimeLimit, TuneTrails, and TuneOutput.

There are a few things to be aware of when using distributed algorithms, though. One relates to relative machine performance. Distributed algorithms work best if all of the workers give very similar performance. For example, if one machine in your worker pool were much slower than the others in a distributed tuning run, any parameter sets tested on the slower machine would appear to be less effective than if they were run on a faster machine. Similar considerations apply for distributed MIP and distributed concurrent. We strongly recommend that you use machines with very similar performance. Note that if your machines have similarly performing cores but different numbers of cores, we suggest that you use the Threads parameter to make sure that all machines use the same number of cores.

Logging for distributed MIP is very similar to the standard MIP logging. The main differences are in the progress section. The header for the standard MIP logging looks like this:

```
    Nodes    |    Current Node    |     Objective Bounds      |     Work
 Expl Unexpl |  Obj  Depth IntInf | Incumbent    BestBd   Gap | It/Node Time
```

By contrast, the distributed MIP header looks like this:

```
    Nodes    |    Current Node    |     Objective Bounds      |     Work
 Expl Unexpl |  Obj  Depth IntInf | Incumbent    BestBd   Gap | ParUtil Time
```

Instead of showing iterations per node, the last field in the distributed log shows parallel utilization. Specifically, it shows the fraction of the preceding time period (the time since the previous progress log line) that the workers spent actively processing MIP nodes.

Here is an example of a distributed MIP progress log:

```
    Nodes    |    Utilization     |     Objective Bounds      |     Work
 Expl Unexpl |  Obj  Depth IntInf | Incumbent    BestBd   Gap | ParUtil Time

H    0                            157344.61033          -      -          0s
H    0                            40707.729144          -      -          0s

 2468495 11516     cutoff           11801.1857 11699.9393  0.86%   78%   40s
 2481830     0     cutoff           11801.1857 11801.1857  0.00%   54%   40s
```

One thing you may find in the progress section is that node counts may not increase monotonically. Distributed MIP tries to create a single, unified view of node numbers, but with multiple machines processing nodes independently, possibly at different rates, some inconsistencies are inevitable.

Another difference is the line that indicates that the distributed ramp-up phase is complete. At this point, the distributed strategy transitions from a concurrent approach to a distributed approach. The log line indicates which worker was the winner in the concurrent approach. Distributed MIP continues by dividing the partially explored MIP search tree from this worker among all of the workers.

Another difference in the distributed log is in the summary section. The distributed MIP log includes a breakdown of how runtime was spent:

```
Runtime breakdown:
  Active:  37.85s (93%)
  Sync:     2.43s (6%)
  Comm:     0.34s (1%)
```

This is an aggregated view of the utilization data that is displayed in the progress log lines. In this example, the workers spent 93% of runtime actively working on MIP nodes, 6% waiting to synchronize with other workers, and 1% communicating data between machines.

The installation instructions for the Gurobi Remote Services can be found on Gurobi's web page [www.gurobi.com] (http://www.gurobi.com).

Gurobi Instant Cloud

An alternative to setting up your own pool of machines is to use the Gurobi Instant Cloud. You only need a GAMS/Gurobi link license when you solve your problems in the Gurobi Instant Cloud. The cost for the Gurobi license is paid on a per use basis directly to Gurobi. If you follow through the steps on the Gurobi web site, you eventually get the names of the machines Gurobi has started for you in the cloud. In order to use these machines from GAMS/Gurobi, you need to provide a Gurobi license with access instructions for the Gurobi Instant Cloud (detailed instructions for configuring the client license file).

5.17.3.8 Solution Pool

While the default goal of the Gurobi Optimizer is to find one proven optimal solution to your model, with a possible side-effect of finding other solutions along the way, the solver provides a number of parameters that allow you to change this behavior.

By default, the Gurobi MIP solver will try to find one proven optimal solution to your model. It will typically find multiple sub-optimal solutions along the way, which can be retrieved later. However, these solutions aren't produced in a systematic way. The set of solutions that are found depends on the exact path the solver takes through the MIP search. You could solve a MIP model once, obtaining a set of interesting sub-optimal solutions, and then solve the same problem again with different parameter settings, and find only the optimal solution.

To store (some of the) solutions found along the way, you can enable the Solution Pool feature by setting option solnpool. If you'd like more control over how solutions are found and retained, the Gurobi Optimizer has a number of parameters available for this. The first and simplest is PoolSolutions, which controls the size of the solution pool. Changing this parameter won't affect the number of solutions that are found - it simply determines how many of those are retained.

You can use the PoolSearchMode parameter to control the approach used to find solutions. In its default setting (0), the MIP search simply aims to find one optimal solution. Setting the parameter to 1 causes the MIP search to expend additional effort to find more solutions, but in a non-systematic way. You will get more solutions, but not necessarily the best solutions. Setting the parameter to 2 causes the MIP to do a systematic search for the n best solutions. For both non-default settings, the PoolSolutions parameter sets the target for the number of solutions to find.

If you are only interested in solutions that are within a certain gap of the best solution found, you can set the PoolGap parameter. Solutions that are not within the specified gap are discarded.

Obtaining an OPTIMAL optimization return status when using PoolSearchMode=2 indicates that the MIP solver succeeded in finding the desired number of best solutions, or it proved that the model doesn't have that many distinct feasible solutions. If the solver terminated early (e.g., due to a time limit), you *PoolObjBound* attribute (printed to the log) to evaluate the quality of the solutions that were found. This attribute gives a bound on the objective of any solution that isn't already in the solution pool. The difference between this attribute and ObjBound is that the latter gives a bound on the objective for any solution, and which is often looser than PoolObjBound. The *PoolObjBound* attribute gives a bound on the objective of undiscovered solutions. Further tree exploration won't find better solutions. You can use this bound to get a count of how many of the n best solutions you found: any solutions whose objective values are at least as good as *PoolObjBound* are among the n best.

Solution Pool Example

Let's continue with a few examples of how these parameters would be used. Imagine that you are solving a MIP model with an optimal (minimization) objective of 100. Further imagine that, using default settings, the MIP solver finds four solutions to this model with objectives 100, 110, 120, and 130.

If you set the PoolSolutions parameter to 3 and solve the model again, the MIP solver would discard the worst solution and return with 3 solutions in the solution pool. If you instead set the PoolGap parameter to value 0.2, the MIP solver would discard any solutions whose objective value is worse than 120 (which would also leave 3 solutions in the solution pool).

If you set the PoolSearchMode parameter to 2 and the PoolSolutions parameter to 10, the MIP solver would attempt to find the 10 best solutions to the model. An OPTIMAL return status would indicate that either (i) it found the 10 best solutions, or (ii) it found all feasible solutions to the model, and there were fewer than 10. If you also set the PoolGap parameter to a value of 0.1, the MIP solver would try to find 10 solutions with objective no worse than 110. While this may appear equivalent to asking for 10 solutions and simply ignoring those with objective worse than 110, the solve will typically complete significantly faster with this parameter set, since the solver does not have to expend effort looking for solutions beyond the requested gap.

Solution Pool Subtleties

There are a few subtleties associated with finding multiple solutions that we'll cover now.

Continuous Variables

One subtlety arises when considering multiple solutions for models with continuous variables. Specifically, you may have two solutions that take identical values on the integer variables but where some continuous variables differ. By choosing different points on the line between these two solutions, you actually have an infinite number of choices for feasible solutions to the problem. To avoid this issue, we define two solutions as being equivalent if they take the same values on all integer variables (and on all continuous variables that participate in SOS constraints). A solution will be discarded if it is equivalent to another solution that is already in the pool.

Optimality Gap

The interplay between the optimality gap (MIPGap or MIPGapAbs) and multiple solutions can be a bit subtle. When using the default PoolSearchMode, a non-zero optimality gap indicates that you are willing to allow the MIP solver to declare a solution optimal, even though the model may have other, better solutions. The claim the solver makes upon termination is that no other solution would improve the incumbent objective by more than the optimality gap. Terminating at this point is ultimately a pragmatic choice - we'd probably rather have the true best solution, but the cost of reducing the optimality gap to zero can often be prohibitive.

This pragmatic choice can produce a bit of confusion when finding multiple optimal solutions. Specifically, if you ask for the n best solutions, the optimality gap plays a similar role as it does in the default case, but the implications may be a bit harder to understand. Specifically, a non-zero optimality gap means that you are willing to allow the solver to declare that it has found the n best solutions, even though there may be solutions that are better than those that were returned. The claim in this case is that any solution not among the reported n best would improve on the objective for the worst among the n best by less than the optimality gap.

If you want to avoid this source of potential confusion, you should set the optimality gap to 0 when using `PoolSearchMode=2`.

Logging

If you browse the log from a MIP solve with PoolSearchMode set to a non-default value, you may see the lower bound on the objective exceed the upper bound. This can't happen with the default `PoolSearchMode` - if you are only looking for one optimal solution, the search is done as soon as the lower bound reaches the upper bound. However, if you are looking for the n best solutions, you have to prove that the model has no solution better than the n-th best. The objective for that n-th solution could be much worse than that of the incumbent. In this situation, the log file will include a line of the form:

```
Optimal solution found at node 123 - now completing solution pool...
```

Distributed MIP

One limitation that we should point out related to multiple solutions is that the distributed MIP solver has not been extended to support non-default PoolSearchMode settings. Distributed MIP will typically produce many more feasible solutions than non-distributed MIP, but there's no way to ask it to find the n best solutions.

5.17.3.9 Multiple Objectives

While typical optimization models have a single objective function, real-world optimization problems often have multiple, competing objectives. For example, in a production planning model, you may want to both maximize profits and minimize late orders, or in a workforce scheduling application, you may want to both minimize the number of shifts that are short-staffed while also respecting worker's shift preferences.

The main challenge you face when working with multiple, competing objectives is deciding how to manage the tradeoffs between them. Gurobi provides tools that simplify the task: Gurobi allows you to blend multiple objectives, to treat them *hierarchically*, or to combine the two approaches. In a blended approach, you optimize a weighted combination of the individual objectives. In a hierarchical or *lexicographic* approach, you set a priority for each objective, and optimize in priority order. When optimizing for one objective, you only consider solutions that would not degrade the objective values of higher-priority objectives. Gurobi allows you to enter and manage your objectives, to provide weights for a blended approach, or to set priorities for a hierarchical approach. Gurobi will only solve multi-objective models with strictly linear objectives. Moreover, for continous models, Gurobi will report a primal only solution (not dual information).

Following the workforce application the specifications of the objectives would be done as follows:

```
equations defObj, defNumShifts, defSumPreferences;
variables obj, numShifts, sumPreferences;

defobj..            obj =e= numShifts - 1/100*sumPreferences;
defNumShifts..      numShifts =e= ...;
defSumPreferences.. sumPreferences =e= ...;

model workforce /all/;
solve workforce minimizing obj using mip;
```

With the default setting GUROBI will solve the blended objective. Using the parameter MultObj GUROBI will use a hierarchical approach. A hierarchical or lexicographic approach assigns a priority to each objective, and optimizes for the objectives in decreasing priority order. At each step, it finds the best solution for the current objective, but only from among those that would not degrade the solution quality for higher-priority objectives. The priority is specified by the absolute value of the objective coefficient in the blended objective function (`defObj`). In the example, the `numShifts` objective with coefficient 1 has higher priority than the `sumPreferences` objective with absolute objective coefficient 1/100. The sign of the objective coefficient determines the direction of the particular objective function. So here `numShifts` will be minimized (same direction as on the `solve` statement) while `sumPreferences` will be maximized. GAMS needs to identify the various objective functions, therefore the objective variables can only appear in the blended objective functions and in the particular objective defining equation.

By default, the hierarchical approach won't allow later objectives to degrade earlier objectives. This behavior can be relaxed through a pair of attributes: ObjNRelTol and ObjNAbsTol. By setting one of these for a particular objective, you can indicate that later objectives are allowed to degrade this objective by the specified relative or absolute amount, respectively. In our earlier example, if the optimal value for `numShifts` is 100, and if we set ObjNAbsTol for this objective to 20, then the second optimization step maximizing `sumPreferences` would find the best solution for the second objective from among all solutions with objective 120 or better for `numShifts`. Note that if you modify both tolerances, later optimizations would use the looser of the two values (i.e., the one that allows the larger degradation).

5.17.4 GAMS Options

The following GAMS options are used by GAMS/Gurobi:

Option BRatio = x;

> Determines whether or not to use an advanced basis. A value of 1.0 causes GAMS to instruct Gurobi not to use an advanced basis. A value of 0.0 causes GAMS to construct a basis from whatever information is available. The default value of 0.25 will nearly always cause GAMS to pass along an advanced basis if a solve statement has previously been executed. This GAMS option is overridden by the GAMS/Gurobi option UseBasis

Option IterLim = n;

> Sets the simplex iteration limit. Simplex algorithms will terminate and pass on the current solution to GAMS. For MIP problems, if the number of the cumulative simplex iterations exceeds the limit, Gurobi will terminate. This GAMS option is overridden by the GAMS/Gurobi option IterationLimit

Option NodLim = x;

> Maximum number of nodes to process for a MIP problem. This GAMS option is overridden by the GAMS/Gurobi option NodeLimit.

Option OptCA = x;

Absolute optimality criterion for a MIP problem. The OptCA option asks Gurobi to stop when

$$|BP - BF| < \text{OptCA}$$

where BF is the objective function value of the current best integer solution while BP is the best possible integer solution. This GAMS option is overridden by the GAMS/Gurobi option MipGapAbs.

Option OptCR = x;

Relative optimality criterion for a MIP problem. Notice that Gurobi uses a different definition than GAMS normally uses. The OptCR option asks Gurobi to stop when

$$|BP - BF| < |BF| * \text{OptCR}$$

where BF is the objective function value of the current best integer solution while BP is the best possible integer solution. The GAMS definition is:

$$|BP - BF| < |BP| * \text{OptCR}$$

This GAMS option is overridden by the GAMS/Gurobi option MipGap.

Option ResLim = x;

Sets the time limit in seconds. The algorithm will terminate and pass on the current solution to GAMS. Gurobi measures time in wall time on all platforms. Some other GAMS solvers measure time in CPU time on some Unix systems. In case resLim assumes its default value (1e+10) Gurobi will use its own default (infinity). This GAMS option is overridden by the GAMS/Gurobi option TimeLimit.

Option SysOut = On;

Will echo Gurobi messages to the GAMS listing file. This option may be useful in case of a solver failure.

***ModelName*.Cutoff = x;**

Cutoff value. When the branch and bound search starts, the parts of the tree with an objective worse than x are deleted. This can sometimes speed up the initial phase of the branch and bound algorithm. This GAMS option is overridden by the GAMS/Gurobi option CutOff.

***ModelName*.OptFile = 1;**

Instructs GAMS/Gurobi to read the option file. The name of the option file is `gurobi.opt`.

***ModelName*.PriorOpt = 1;**

Instructs GAMS/Gurobi to use the priority branching information passed by GAMS through variable suffix values *variable*`.prior`.

5.17.5 Summary of GUROBI Options

5.17.5.1 Termination options

Option	Description	Default
bariterlimit	Barrier iteration limit	infinity
bestbdstop	Best objective bound to stop	maxdouble
bestobjstop	Best objective value to stop	mindouble
cutoff	Objective cutoff	maxdouble
iterationlimit	Simplex iteration limit	infinity
memlimit	Memory limit	maxdouble
nodelimit	MIP node limit	maxdouble
softmemlimit	Soft memory limit	maxdouble
solutionlimit	MIP feasible solution limit	maxint
timelimit	Time limit	GAMS reslim
worklimit	Work limit	maxdouble

5.17.5.2 Tolerances options

Option	Description	Default
barconvtol	Barrier convergence tolerance	1e-08
barqcpconvtol	Barrier QCP convergence tolerance	1e-06
feasibilitytol	Primal feasibility tolerance	1e-06
intfeastol	Integer feasibility tolerance	1e-05
markowitztol	Threshold pivoting tolerance	0.0078125
mipgap	Relative MIP optimality gap	GAMS optcr
mipgapabs	Absolute MIP optimality gap	GAMS optca
optimalitytol	Dual feasibility tolerance	1e-06
psdtol	Positive semi-definite tolerance	1e-06

5.17.5.3 Simplex options

Option	Description	Default
lpwarmstart	Warm start usage in simplex	1
networkalg	Network simplex algorithm	-1
normadjust	Simplex pricing norm	-1
perturbvalue	Simplex perturbation magnitude	0.0002
quad	Quad precision computation in simplex	-1
sifting	Sifting within dual simplex	-1

Option	Description	Default
siftmethod	LP method used to solve sifting sub-problems	-1
simplexpricing	Simplex variable pricing strategy	-1

5.17.5.4 Barrier options

Option	Description	Default
barcorrectors	Central correction limit	-1
barhomogeneous	Barrier homogeneous algorithm	-1
barorder	Barrier ordering algorithm	-1
crossover	Barrier crossover strategy	-1
crossoverbasis	Crossover initial basis construction strategy	-1
qcpdual	Compute dual variables for QCP models	1

5.17.5.5 Scaling options

Option	Description	Default
objscale	Objective scaling	0
scaleflag	Model scaling	-1

5.17.5.6 MIP options

Option	Description	Default
branchdir	Branch direction preference	0
concurrentjobs	Enables distributed concurrent solver	0
concurrentmethod	Chooses continuous solvers to run concurrently	-1
concurrentmip	Enables concurrent MIP solver	1
degenmoves	Degenerate simplex moves	-1
distributedmipjobs	Enables the distributed MIP solver	0
dumpbcsol	Dump incumbents to GDX files during branch-and-cut	
fixoptfile	Option file for fixed problem optimization	
heuristics	Turn MIP heuristics up or down	0.05
improvestartgap	Trigger solution improvement	0
improvestartnodes	Trigger solution improvement	maxdouble
improvestarttime	Trigger solution improvement	maxdouble
.lazy	Lazy constraints value	0

Option	Description	Default
lazyconstraints	Indicator to use lazy constraints	0
minrelnodes	Minimum relaxation heuristic control	-1
mipfocus	Set the focus of the MIP solver	0
mipstart	Use mip starting values	0
mipstopexpr	Stop expression for branch and bound	
miqcpmethod	Method used to solve MIQCP models	-1
multimipstart	Use multiple (partial) mipstarts provided via gdx files	
nlpheur	Controls the NLP heuristic for non-convex quadratic models	1
nodefiledir	Directory for MIP node files	.
nodefilestart	Memory threshold for writing MIP tree nodes to disk	maxdouble
nodemethod	Method used to solve MIP node relaxations	-1
nonconvex	Control how to deal with non-convex quadratic programs	-1
norelheurtime	Limits the amount of time (in seconds) spent in the NoRel heuristic	0
norelheurwork	Limits the amount of work performed by the NoRel heuristic	0
obbt	Controls aggressiveness of optimality-based bound tightening	-1
.partition	Variable partition value	0
partitionplace	Controls when the partition heuristic runs	15
.prior	Branching priorities	1
pumppasses	Feasibility pump heuristic control	-1
rins	RINS heuristic	-1
solfiles	Location to store intermediate solution files	
solnpool	Controls export of alternate MIP solutions	
solnpoolmerge	Controls export of alternate MIP solutions for merged GDX solution file	
solnpoolnumsym	Maximum number of variable symbols when writing merged GDX solution file	10
solnpoolprefix	First dimension of variables for merged GDX solution file or file name prefix for GDX solution files	soln
solvefixed	Indicator for solving the fixed problem for a MIP to get a dual solution	1
startnodelimit	Node limit for MIP start sub-MIP	-1
submipnodes	Nodes explored by sub-MIP heuristics	500
symmetry	Symmetry detection	-1
varbranch	Branch variable selection strategy	-1
zeroobjnodes	Zero objective heuristic control	-1

5.17.5.7 Presolve options

Option	Description	Default
aggfill	Allowed fill during presolve aggregation	-1
aggregate	Presolve aggregation control	1
dualreductions	Disables dual reductions in presolve	1
precrush	Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model	0
predeprow	Presolve dependent row reduction	-1
predual	Presolve dualization	-1
premiqcpform	Format of presolved MIQCP model	-1
prepasses	Presolve pass limit	-1
preqlinearize	Presolve Q matrix linearization	-1
Presolve	Presolve level	-1
presos1bigm	Controls largest coefficient in SOS1 reformulation	-1
presos1encoding	Controls SOS1 reformulation	-1
presos2bigm	Controls largest coefficient in SOS2 reformulation	-1
presos2encoding	Controls SOS2 reformulation	-1
presparsify	Presolve sparsify reduction	-1

5.17.5.8 Tuning options

Option	Description	Default
tunecleanup	Enables a tuning cleanup phase	0
tunecriterion	Specify tuning criterion	-1
tunedynamicjobs	Enables distributed tuning using a dynamic set of workers	0
tunejobs	Enables distributed tuning using a static set of workers	0
tunemetric	Metric to aggregate results into a single measure	-1
tuneoutput	Tuning output level	2
tuneresults	Number of improved parameter sets returned	-1
tunetargetmipgap	A target gap to be reached	0
tunetargettime	A target runtime in seconds to be reached	0.005
tunetimelimit	Time limit for tuning	maxdouble
tunetrials	Perform multiple runs on each parameter set to limit the effect of random noise	0

5.17.5.9 Multiple Solutions options

Option	Description	Default
poolgap	Relative gap for solutions in pool	maxdouble
poolgapabs	Absolute gap for solutions in pool	maxdouble
poolsearchmode	Choose the approach used to find additional solutions	0
poolsolutions	Number of solutions to keep in pool	10

5.17.5.10 MIP Cuts options

Option	Description	Default
bqpcuts	BQP cut generation	-1
cliquecuts	Clique cut generation	-1
covercuts	Cover cut generation	-1
cutaggpasses	Constraint aggregation passes performed during cut generation	-1
cutpasses	Root cutting plane pass limit	-1
cuts	Global cut generation control	-1
flowcovercuts	Flow cover cut generation	-1
flowpathcuts	Flow path cut generation	-1
gomorypasses	Root Gomory cut pass limit	-1
gubcovercuts	GUB cover cut generation	-1
impliedcuts	Implied bound cut generation	-1
infproofcuts	Infeasibility proof cut generation	-1
liftprojectcuts	Lift-and-project cut generation	-1
mipsepcuts	MIP separation cut generation	-1
mircuts	MIR cut generation	-1
mixingcuts	Mixing cut generation	-1
modkcuts	Mod-k cut generation	-1
networkcuts	Network cut generation	-1
projimpliedcuts	Projected implied bound cut generation	-1
psdcuts	PSD cut generation	-1
relaxliftcuts	Relax-and-lift cut generation	-1
rltcuts	RLT cut generation	-1
strongcgcuts	Strong-CG cut generation	-1
submipcuts	Sub-MIP cut generation	-1
zerohalfcuts	Zero-half cut generation	-1

5.17.5.11 Distributed algorithms options

Option	Description	Default
workerpassword	Password for distributed worker cluster	
workerpool	Distributed worker cluster	

5.17.5.12 Other options

Option	Description	Default
disconnected	Disconnected component strategy	-1
displayinterval	Frequency at which log lines are printed	5
.dofuncpieceerror	Error allowed for PWL translation of function constraints	1e-3
.dofuncpiecelength	Piece length for PWL translation of function constraints	1e-2
.dofuncpieceratio	Control whether to under- or over-estimate function values in PWL approximation	-1
.dofuncpieces	Sets strategy for PWL function approximation	0
feasopt	Computes a minimum-cost relaxation to make an infeasible model feasible	0
feasoptmode	Mode of FeasOpt	0
.feaspref	feasibility preference	1
feasrelaxbigm	Big-M value for feasibility relaxations	1e+06
freegamsmodel	Preserves memory by dumping the GAMS model instance representation temporarily to disk	0
funcmaxval	Maximum value for x and y variables in function constraints	1e+06
funcnonlinear	Controls whether general function constraints are treated as nonlinear functions or via PWL approximation	1
funcpieceerror	Error allowed for PWL translation of function constraint	0.001
funcpiecelength	Piece length for PWL translation of function constraint	0.01
funcpieceratio	Controls whether to under- or over-estimate function values in PWL approximation	-1
funcpieces	Sets strategy for PWL function approximation	0
iis	Run the Irreducible Inconsistent Subsystem (IIS) finder if the problem is infeasible	0
iismethod	IIS method	-1
integralityfocus	Set the integrality focus	0
kappa	Display approximate condition number estimates for the optimal simplex basis	0
kappaexact	Display exact condition number estimates for the optimal simplex basis	0
method	Algorithm used to solve continuous models	-1
miptrace	Filename of MIP trace file	

Option	Description	Default
miptracenode	Node interval when a trace record is written	100
miptracetime	Time interval when a trace record is written	1
multiobjmethod	Warm-start method to solve for subsequent objectives	-1
multiobjpre	Initial presolve on multi-objective models	-1
multobj	Controls the hierarchical optimization of multiple objectives	0
names	Indicator for loading names	1
nlreform	Reform nonlinear equations to Gurobi general constraints	1
numericfocus	Set the numerical focus	0
objnabstol	Allowable absolute degradation for objective	
objnreltol	Allowable relative degradation for objective	
printoptions	List values of all options to GAMS listing file	0
qextractalg	quadratic extraction algorithm in GAMS interface	0
readparams	Read Gurobi parameter file	
rerun	Resolve without presolve in case of unbounded or infeasible	-1
rngrestart	Write GAMS readable ranging information file	
seed	Modify the random number seed	0
sensitivity	Provide sensitivity information	0
solutiontarget	Specify the solution target for LP	-1
threads	Number of parallel threads to use	GAMS threads
Tuning	Parameter Tuning	
usebasis	Use basis from GAMS	GAMS bratio
varhint	Guide heuristics and branching through variable hints	0
writeparams	Write Gurobi parameter file	
writeprob	Save the problem instance	

5.17.5.13 The GAMS/Gurobi Options File

The GAMS/Gurobi options file consists of one option or comment per line. An asterisk (∗) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by any amount of white space (blanks or tabs).

Following is an example options file *gurobi.opt*.

```
simplexpricing 3
method 0
```

It will cause Gurobi to use quick-start steepest edge pricing and will use the primal simplex algorithm.

5.17.6 GAMS/Gurobi Log File

Gurobi reports its progress by writing to the GAMS log file as the problem solves. Normally the GAMS log file is directed to the computer screen.

The log file shows statistics about the presolve and continues with an iteration log.

For the simplex algorithms, each log line starts with the iteration number, followed by the objective value, the primal and dual infeasibility values, and the elapsed wall clock time. The dual simplex uses a bigM approach for handling infeasibility, so the objective and primal infeasibility values can both be very large during phase I. The frequency at which log lines are printed is controlled by the DisplayInterval option. By default, the simplex algorithms print a log line roughly every five seconds, although log lines can be delayed when solving models with particularly expensive iterations.

The simplex screen log has the following appearance:

```
Presolve removed 977 rows and 1539 columns
Presolve changed 3 inequalities to equalities
Presolve time: 0.078000 sec.
Presolved: 1748 Rows, 5030 Columns, 32973 Nonzeros

Iteration    Objective       Primal Inf.    Dual Inf.      Time
       0    3.8929476e+31   1.200000e+31   1.485042e-04      0s
    5624    1.1486966e+05   0.000000e+00   0.000000e+00      2s

Solved in 5624 iterations and 1.69 seconds
Optimal objective  1.148696610e+05
```

The barrier algorithm log file starts with barrier statistics about dense columns, free variables, nonzeros in AA' and the Cholesky factor matrix, computational operations needed for the factorization, memory estimate and time estimate per iteration. Then it outputs the progress of the barrier algorithm in iterations with the primal and dual objective values, the magnitude of the primal and dual infeasibilites and the magnitude of the complementarity violation. After the barrier algorithm terminates, by default, Gurobi will perform crossover to obtain a valid basic solution. It first prints the information about pushing the dual and primal superbasic variables to the bounds and then the information about the simplex progress until the completion of the optimization.

The barrier screen log has the following appearance:

```
Presolve removed 2394 rows and 3412 columns
Presolve time: 0.09s
Presolved: 3677 Rows, 8818 Columns, 30934 Nonzeros

Ordering time: 0.20s

Barrier statistics:
 Dense cols : 10
 Free vars  : 3
 AA' NZ     : 9.353e+04
 Factor NZ  : 1.139e+06 (roughly 14 MBytes of memory)
 Factor Ops : 7.388e+08 (roughly 2 seconds per iteration)

                 Objective                Residual
Iter       Primal          Dual         Primal    Dual     Compl     Time

```

For MIP problems, the Gurobi solver prints regular status information during the branch and bound search. The first two output columns in each log line show the number of nodes that have been explored so far in the search tree, followed by the number of nodes that remain unexplored. The next three columns provide information on the most recently explored node in the tree. The solver prints the relaxation objective value for this node, followed by its depth in the search tree, followed by the number of integer variables with fractional values in the node relaxation solution. The next three columns provide information on the progress of the global MIP bounds. They show the objective value for the best known integer feasible solution, the best bound on the value of the optimal solution, and the gap between these lower and upper bounds. Finally, the last two columns provide information on the amount of work performed so far. The first column gives the average number of simplex iterations per explored node, and the next column gives the elapsed wall clock time since the optimization began.

At the default value for option DisplayInterval, the MIP solver prints one log line roughly every five seconds. Note, however, that log lines are often delayed in the MIP solver due to particularly expensive nodes or heuristics.

```
Presolve removed 12 rows and 11 columns
Presolve tightened 70 bounds and modified 235 coefficients
Presolve time: 0.02s
Presolved: 114 Rows, 116 Columns, 424 Nonzeros
Objective GCD is 1

```

5.17.7 Detailed Descriptions of GUROBI Options

aggfill *(integer)*: Allowed fill during presolve aggregation ↩

Controls the amount of fill allowed during presolve aggregation. Larger values generally lead to presolved models with fewer rows and columns, but with more constraint matrix non-zeros.

The default value chooses automatically, and usually works well.

Default: `-1`

aggregate *(integer)*: Presolve aggregation control ↩

Default: `1`

barconvtol *(real)*: Barrier convergence tolerance ↩

The barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance.

Default: `1e-08`

barcorrectors *(integer)*: Central correction limit ↩

The default value is chosen automatically, depending on problem characteristics.

Default: `-1`

barhomogeneous *(integer)*: Barrier homogeneous algorithm ↩

Determines whether to use the homogeneous barrier algorithm. At the default setting (-1), it is only used when barrier solves a node relaxation for a MIP model. Setting the parameter to 0 turns it off, and setting it to 1 forces it on. The homogeneous algorithm is useful for recognizing infeasibility or unboundedness. It is a bit slower than the default algorithm.

Default: `-1`

value	meaning
-1	Auto
0	Homogeneous Barrier off
1	Force Homogeneous Barrier on

bariterlimit *(integer)*: Barrier iteration limit ↩

Default: `infinity`

barorder *(integer)*: Barrier ordering algorithm ↩

Default: `-1`

value	meaning
-1	Auto
0	Approximate Minimum Degree ordering
1	Nested Dissection ordering

barqcpconvtol *(real)*: Barrier QCP convergence tolerance ↩

When solving a QCP model, the barrier solver terminates when the relative difference between the primal and dual objective values is less than the specified tolerance. Tightening this tolerance may lead to a more accurate solution, but it may also lead to a failure to converge.

Default: `1e-06`

bestbdstop *(real)*: Best objective bound to stop ↩

Terminates as soon as the engine determines that the best bound on the objective value is at least as good as the specified value.

Default: `maxdouble`

bestobjstop *(real)*: Best objective value to stop ↩

Terminate as soon as the engine finds a feasible solution whose objective value is at least as good as the specified value.

Default: `mindouble`

bqpcuts *(integer)*: BQP cut generation ↩

Default: `-1`

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

branchdir *(integer)*: Branch direction preference ↩

This option allows more control over how the branch-and-cut tree is explored. Specifically, when a node in the MIP search is completed and two child nodes, corresponding to the down branch and the up branch are created, this parameter allows you to determine whether the MIP solver will explore the down branch first, the up branch first, or whether it will choose the next node based on a heuristic determination of which sub-tree appears more promising.

Default: `0`

value	meaning
`-1`	Always explore the down branch first
`0`	Automatic
`1`	Always explore the up branch first

cliquecuts *(integer)*: Clique cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Conservative
`2`	Aggressive

concurrentjobs *(integer)*: Enables distributed concurrent solver ↩

Enables distributed concurrent optimization, which can be used to solve LP or MIP models on multiple machines. A value of n causes the solver to create n independent models, using different parameter settings for each. Each of these models is sent to a distributed worker for processing. Optimization terminates when the first solve completes. Use the WorkerPool parameter to provide a list of available distributed workers.

By default, Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search. By bringing the resources of multiple machines to bear on a single model, this approach can sometimes solve models much faster than a single machine.

Default: `0`

concurrentmethod *(integer)*: Chooses continuous solvers to run concurrently ↩

This parameter is only evaluated when solving an LP with a concurrent solver (Method = 3 or 4). It controls which methods are run concurrently by the concurrent solver.

Default: `-1`

value	meaning
`-1`	Auto
`0`	barrier, dual, primal simplex
`1`	barrier and dual simplex
`2`	barrier and primal simplex
`3`	dual and primal simplex

concurrentmip *(integer)*: Enables concurrent MIP solver ↩

This parameter enables the concurrent MIP solver. When the parameter is set to value n, the MIP solver performs n independent MIP solves in parallel, with different parameter settings for each. Optimization terminates when the first solve completes. Gurobi chooses the parameter settings used for each independent solve automatically. The intent of concurrent MIP solving is to introduce additional diversity into the MIP search. This approach can sometimes solve models much faster than applying all available threads to a single MIP solve, especially on very large parallel machines.

The concurrent MIP solver divides available threads evenly among the independent solves. For example, if you have 6 threads available and you set ConcurrentMIP to 2, the concurrent MIP solver will allocate 3 threads to each independent solve. Note that the number of independent solves launched will not exceed the number of available threads.

The concurrent MIP solver produces a slightly different log from the standard MIP solver. The log only provides periodic summary information. Each concurrent MIP log line shows the objective for the best feasible solution found by any of the independent solves to that point, the best objective bound proved by any of the independent solves, and the relative gap between these two values. Gurobi also includes node counts from one of the independent solves, as well as elapsed times, to give some indication of forward progress.

Default: `1`

covercuts *(integer)*: Cover cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Conservative
`2`	Aggressive

crossover *(integer)*: Barrier crossover strategy ↩

Use value 0 to disable crossover; the solver will return an interior solution. Other options control whether the crossover algorithm tries to push primal or dual variables to bounds first, and then which simplex algorithm is used once variable pushing is complete. Options 1 and 2 push dual variables first, then primal variables. Option 1 finishes with primal, while option 2 finishes with dual. Options 3 and 4 push primal variables first, then dual variables. Option 3 finishes with primal, while option 4 finishes with dual The default value of -1 chooses automatically.

Default: `-1`

crossoverbasis *(integer)*: Crossover initial basis construction strategy ↩

Default: `-1`

value	meaning
`-1`	Auto
`0`	Chooses an initial basis quickly
`1`	Can take much longer, but often produces a more numerically stable start basis

cutaggpasses *(integer)*: Constraint aggregation passes performed during cut generation ↩

A non-negative value indicates the maximum number of constraint aggregation passes performed during cut generation. See the description of the global Cuts parameter for further information.

Default: `-1`

cutoff *(real)*: Objective cutoff ↩

Optimization will terminate if the engine determines that the optimal objective value for the model is worse than the specified cutoff. This option overwrites the GAMS cutoff option.

Default: `maxdouble`

cutpasses *(integer)*: Root cutting plane pass limit ↩

Default: `-1`

cuts *(integer)*: Global cut generation control ↩

The parameters, `Cuts`, CliqueCuts, CoverCuts, FlowCoverCuts, FlowPathCuts, GUBCoverCuts, ImpliedCuts, InfProofCuts, MIPSepCuts, MIRCuts, ModKCuts, NetworkCuts, GomoryPasses, StrongCGCuts, SubMIPCuts, CutAggPasses and ZeroHalfCuts, affect the generation of MIP cutting planes. In all cases except GomoryPasses and CutAggPasses, a value of -1 corresponds to an automatic setting, which allows the solver to determine the appropriate level of aggressiveness in the cut generation. Unless otherwise noted, settings of 0, 1, and 2 correspond to no cut generation, conservative cut generation, or aggressive cut generation, respectively. The `Cuts` parameter provides global cut control, affecting the generation of all cuts. This parameter also has a setting of 3, which corresponds to very aggressive cut generation. The other parameters override the global `Cuts` parameter (so setting `Cuts` to 2 and CliqueCuts to 0 would generate all cut types aggressively, except clique cuts which would not be generated at all. Setting `Cuts` to 0 and GomoryPasses to 10 would not generate any cuts except Gomory cuts for 10 passes).

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Conservative
`2`	Aggressive
`3`	Very aggressive

degenmoves *(integer)*: Degenerate simplex moves ↩

Limits degenerate simplex moves. These moves are performed to improve the integrality of the current relaxation solution. By default, the algorithm chooses the number of moves to perform automatically.

Changing the value of this parameter can help performance in cases where an excessive amount of time is spent after the initial root relaxation has been solved but before the cut generation process or the root heuristics have started.

Default: `-1`

disconnected *(integer)*: Disconnected component strategy ↩

A MIP model can sometimes be made up of multiple, completely independent sub-models. This parameter controls how aggressively we try to exploit this structure. A value of 0 ignores this structure entirely, while larger values try more aggressive approaches. The default value of -1 chooses automatically. This only affects mixed integer programming (MIP) models.

Default: `-1`

value	meaning
-1	Auto
0	Ignores structure entirely
1	Conservative
2	Aggressive

displayinterval *(integer)*: Frequency at which log lines are printed ↩

Default: `5`

distributedmipjobs *(integer)*: Enables the distributed MIP solver ↩

Enables distributed MIP. A value of n causes the MIP solver to divide the work of solving a MIP model among n machines. Use the WorkerPool parameter to provide the list of available machines.

Default: `0`

.dofuncpieceerror *(real)*: Error allowed for PWL translation of function constraints ↩

Default: `1e-3`

.dofuncpiecelength *(real)*: Piece length for PWL translation of function constraints ↩

The default length behavior for piecewise-linear approximation of a function constraint is controlled by funcPieceLength. This dot option `.doFuncPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `1e-2`

.dofuncpieceratio *(real)*: Control whether to under- or over-estimate function values in PWL approximation ↩

The default ratio behavior for piecewise-linear approximation of a function constraint is controlled by funcPieceRatio. This dot option `.doFuncPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `-1`

.dofuncpieces *(integer)*: Sets strategy for PWL function approximation ↩

The default strategy for performing a piecewise-linear approximation of a function constraint is set by funcPieces. This dot option `.doFuncPieces` allows to overwrite the default strategy by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

dofuncpieceerror The default error behavior for piecewise-linear approximation of a function constraint is controlled by funcPieceError. This dot option `.doFuncPieceError` allows to overwrite the default behavior by constraint. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `0`

value	meaning
-2	Bounds the relative error of the approximation; the error bound is provided in the FuncPieceError parameter
-1	Bounds the absolute error of the approximation; the error bound is provided in the FuncPieceError parameter
0	Automatic based on relative error approach
1	Uses a fixed width for each piece; the actual width is provided in the FuncPiece-Length parameter
>=2	Sets the number of pieces; pieces are equal width

dualreductions *(boolean)*: Disables dual reductions in presolve ↩

Default: 1

dumpbcsol *(string)*: Dump incumbents to GDX files during branch-and-cut ↩

The content of this string option is used as a file stem for GDX point files. The file name gets completed by the solution number. So if this option has beed set to `mysol` then GDX files containing the new solution with the names `mysol0.gdx`, `mysol1.gdx`, ... will be created. The number of GDX files created depends on the number of solutions Gurobi finds during branch-and-cut.

feasibilitytol *(real)*: Primal feasibility tolerance ↩

All constrains must be satisfied to a tolerance of `FeasibilityTol`.

Range: [1e-09, 0.01]

Default: 1e-06

feasopt *(boolean)*: Computes a minimum-cost relaxation to make an infeasible model feasible ↩

With `Feasopt` turned on, a minimum-cost relaxation of the right hand side values of constraints or bounds on variables is computed in order to make an infeasible model feasible. It marks the relaxed right hand side values and bounds in the solution listing.

Several options are available for the metric used to determine what constitutes a minimum-cost relaxation which can be set by option FeasOptMode.

Feasible relaxations are available for all problem types.

Default: 0

value	meaning
0	Turns Feasible Relaxation off
1	Turns Feasible Relaxation on

feasoptmode *(integer)*: Mode of FeasOpt ↩

The parameter `FeasOptMode` allows different strategies in finding feasible relaxation in one or two phases. In its first phase, it attempts to minimize its relaxation of the infeasible model. That is, it attempts to find a feasible solution that requires minimal change. In its second phase, it finds an optimal solution (using the original objective) among those that require

only as much relaxation as it found necessary in the first phase. Values of the parameter `FeasOptMode` indicate two aspects: (1) whether to stop in phase one or continue to phase two and (2) how to measure the minimality of the relaxation (as a *sum* of required relaxations; as the *number* of constraints and bounds required to be relaxed; as a *sum of the squares* of required relaxations).

Default: `0`

value	meaning
`0`	Minimize sum of relaxations Minimize the sum of all required relaxations in first phase only
`1`	Minimize sum of relaxations and optimize Minimize the sum of all required relaxations in first phase and execute second phase to find optimum among minimal relaxations
`2`	Minimize number of relaxations Minimize the number of constraints and bounds requiring relaxation in first phase only
`3`	Minimize number of relaxations and optimize Minimize the number of constraints and bounds requiring relaxation in first phase and execute second phase to find optimum among minimal relaxations
`4`	Minimize sum of squares of relaxations Minimize the sum of squares of required relaxations in first phase only
`5`	Minimize sum of squares of relaxations and optimize Minimize the sum of squares of required relaxations in first phase and execute second phase to find optimum among minimal relaxations

.feaspref *(real)*: feasibility preference ↩

You can express the costs associated with relaxing a bound or right hand side value during a FeasOpt run through the `.feaspref` option. The syntax for dot options is explained in the Introduction chapter of the Solver Manual. The input value denotes the users willingness to relax a constraint or bound. More precisely, the reciprocal of the specified value is used to weight the relaxation of that constraint or bound. The user may specify a preference value less than or equal to 0 (zero), which denotes that the corresponding constraint or bound must not be relaxed.

Default: `1`

feasrelaxbigm *(real)*: Big-M value for feasibility relaxations ↩

When relaxing a constraint in a feasibility relaxation, it is sometimes necessary to introduce a big-M value. This parameter determines the default magnitude of that value.

Default: `1e+06`

fixoptfile *(string)*: Option file for fixed problem optimization ↩

flowcovercuts *(integer)*: Flow cover cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

flowpathcuts *(integer)*: Flow path cut generation ↩

See the description of the global Cuts parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

freegamsmodel *(boolean)*: Preserves memory by dumping the GAMS model instance representation temporarily to disk ↩

In order to provide the maximum amount of memory to the solver this option dumps the internal representation of the model instance temporarily to disk and frees memory. This option only works with SolveLink=0 and only for models without quadratic constraints.

Default: 0

funcmaxval *(real)*: Maximum value for x and y variables in function constraints ↩

Very large values in piecewise-linear approximations can cause numerical issues. This parameter limits the bounds on the variables that participate in function constraints. Specifically, if x or y participate in a function constraint, any bound larger than funcMaxVal (in absolute value) will be truncated.

Default: 1e+06

funcnonlinear *(boolean)*: Controls whether general function constraints are treated as nonlinear functions or via PWL approximation ↩

Default: 1

value	meaning
0	Piecewise-linear approximations
1	Nonlinear functions

funcpieceerror *(real)*: Error allowed for PWL translation of function constraint ↩

If the funcPieces parameter is set to value -1 or -2, this parameter provides the maximum allowed error (absolute for -1, relative for -2) in the piecewise-linear approximation.

Default: 0.001

funcpiecelength *(real)*: Piece length for PWL translation of function constraint ↩

If the funcPieces parameter is set to value 1, this parameter gives the length of each piece of the piecewise-linear approximation.

Default: `0.01`

funcpieceratio *(real)*: Controls whether to under- or over-estimate function values in PWL approximation ↩

This option controls whether the piecewise-linear approximation of a function constraint is an underestimate of the function, an overestimate, or somewhere in between. A value of 0 will always underestimate, while a value of 1 will always overestimate. A value in between will interpolate between the underestimate and the overestimate. A special value of -1 chooses points that are on the original function.

Default: `-1`

funcpieces *(integer)*: Sets strategy for PWL function approximation ↩

Default: `0`

value	meaning
`-2`	Bounds the relative error of the approximation; the error bound is provided in the FuncPieceError parameter
`-1`	Bounds the absolute error of the approximation; the error bound is provided in the FuncPieceError parameter
`0`	Automatic PWL approximation
`1`	Uses a fixed width for each piece; the actual width is provided in the FuncPiece-Length parameter
`>=2`	Sets the number of pieces; pieces are equal width

gomorypasses *(integer)*: Root Gomory cut pass limit ↩

A non-negative value indicates the maximum number of Gomory cut passes performed. See the description of the global Cuts parameter for further information.

Default: `-1`

gubcovercuts *(integer)*: GUB cover cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Conservative
`2`	Aggressive

heuristics *(real)*: Turn MIP heuristics up or down ↩

Larger values produce more and better feasible solutions, at a cost of slower progress in the best bound.

Range: [0, 1]

Default: 0.05

iis *(integer)*: Run the Irreducible Inconsistent Subsystem (IIS) finder if the problem is infeasible ↩

Default: 0

value	meaning
0	No conflict analysis
1	Conflict analysis after solve if infeasible
2	Conflict analysis without previous solve

iismethod *(integer)*: IIS method ↩

Chooses the IIS method to use. Method 0 is often faster, while method 1 can produce a smaller IIS. Method 2 ignores the bound constraints. Method 3 will return the IIS for the LP relaxation of a MIP model if the relaxation is infeasible, even though the result may not be minimal when integrality constraints are included. The default value of -1 chooses automatically.

Default: -1

impliedcuts *(integer)*: Implied bound cut generation ↩

See the description of the global Cuts parameter for further information.

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

improvestartgap *(real)*: Trigger solution improvement ↩

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify an optimality gap at which the MIP solver will switch to this strategy. For example, setting this parameter to 0.1 will cause the MIP solver to switch once the relative optimality gap is smaller than 0.1.

Default: 0

improvestartnodes *(real)*: Trigger solution improvement ↩

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify the node count at which the MIP solver switches to a solution improvement strategy. For example, setting this parameter to 10 will cause the MIP solver to switch strategies once the node count is larger than 10.

Default: maxdouble

improvestarttime *(real)*: Trigger solution improvement ↩

The MIP solver can change parameter settings in the middle of the search in order to adopt a strategy that gives up on moving the best bound and instead devotes all of its effort towards finding better feasible solutions. This parameter allows you to specify a time limit when the MIP solver will switch to this strategy. For example, setting this parameter to 10 will cause the MIP solver to switch 10 seconds after starting the optimization.

Default: `maxdouble`

infproofcuts *(integer)*: Infeasibility proof cut generation ↩

Controls infeasibility proof cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: `-1`

integralityfocus *(boolean)*: Set the integrality focus ↩

One unfortunate reality in MIP is that integer variables don't always take exact integral values. While this typically doesn't create significant problems, in some situations the side-effects can be quite undesirable. The best-known example is probably a trickle flow, where a continuous variable that is meant to be zero when an associated binary variable is zero instead takes a non-trivial value. More precisely, given a constraint `y =l= Mb`, where y is a non-negative continuous variable, b is a binary variable, and M is a constant that captures the largest possible value of y, the constraint is intended to enforce the relationship that y must be zero if b is zero. With the default integer feasibility tolerance, the binary variable is allowed to take a value as large as *1e-5* while still being considered as taking value zero. If the M value is large, then the M b upper bound on the y variable can be substantial.

Reducing the value of the intFeasTol parameter can mitigate the effects of such trickle flows, but often at a significant cost, and often with limited success. The *integralityFocus* parameter provides a better alternative. Setting this parameter to 1 requests that the solver work harder to try to avoid solutions that exploit integrality tolerances. More precisely, the solver tries to find solutions that are still (nearly) feasible if all integer variables are rounded to exact integral values. We should say that the solver won't always succeed in finding such solutions, and that this setting introduces a modest performance penalty, but the setting will significantly reduce the frequency and magnitude of such violations.

Default: `0`

value	meaning
`0`	Disable the integrality focus
`1`	Enable the integrality focus

intfeastol *(real)*: Integer feasibility tolerance ↩

An integrality restriction on a variable is considered satisfied when the variable's value is less than `IntFeasTol` from the nearest integer value.

Range: [`1e-09`, `0.1`]

Default: `1e-05`

iterationlimit *(real)*: Simplex iteration limit ↩

Default: `infinity`

kappa *(boolean)*: Display approximate condition number estimates for the optimal simplex basis ↩

Default: `0`

value	meaning
`0`	Do not compute and display approximate condition number
`1`	Compute and display approximate condition number

kappaexact *(boolean)*: Display exact condition number estimates for the optimal simplex basis ↩

Default: `0`

value	meaning
`0`	Do not compute and display exact condition number
`1`	Compute and display exact condition number

.lazy *(integer)*: Lazy constraints value ↩

Determines whether a linear constraint is treated as a lazy constraint. At the beginning of the MIP solution process, any constraint whose Lazy attribute is set to 1, 2, or 3 (the default value is 0) is removed from the model and placed in the lazy constraint pool. Lazy constraints remain inactive until a feasible solution is found, at which point the solution is checked against the lazy constraint pool. If the solution violates any lazy constraint, the solution is discarded and one or more of the violated lazy constraints are pulled into the active model.

Larger values for this attribute cause the constraint to be pulled into the model more aggressively. With a value of 1, the constraint can be used to cut off a feasible solution, but it won't necessarily be pulled in if another lazy constraint also cuts off the solution. With a value of 2, all lazy constraints that are violated by a feasible solution will be pulled into the model. With a value of 3, lazy constraints that cut off the relaxation solution are also pulled in.

Any constraint whose Lazy attribute is set to -1 is treated as a user cut; it is removed from the model and placed in the user cut pool. User cuts may be added to the model at any node in the branch-and-cut search tree to cut off relaxation solutions.

The main difference between user cuts and lazy constraints is that the former are not allowed to cut off integer-feasible solutions. In other words, they are redundant for the MIP model, and the solver is free to decide whether or not to use them to cut off relaxation solutions. The hope is that adding them speeds up the overall solution process. Lazy constraints have no such restrictions. They are essential to the model, and the solver is forced to apply them whenever a solution would otherwise not satisfy them.

Only affects MIP models. Lazy constraints are only active if option LazyConstraints is enabled and are specified through the option `.lazy`. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `0`

lazyconstraints *(boolean)*: Indicator to use lazy constraints ↩

Default: `0`

liftprojectcuts *(integer)*: Lift-and-project cut generation ↩

Controls lift-and-project cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: `-1`

lpwarmstart *(integer)*: Warm start usage in simplex ↩

Controls whether and how Gurobi uses warm start information for an LP optimization. The non default setting of 2 is particularly useful for communicating advanced start information while retaining the performance benefits of presolve.

As a general rule, setting this parameter to 0 ignores any start information and solves the model from scratch. Setting it to 1 (the default) uses the provided warm start information to solve the original, unpresolved problem, regardless of whether presolve is enabled. Setting it to 2 uses the start information to solve the presolved problem, assuming that presolve is enabled. This involves mapping the solution of the original problem into an equivalent (or sometimes nearly equivalent) crushed solution of the presolved problem. If presolve is disabled, then setting 2 still prioritizes start vectors, while setting 1 prioritizes basis statuses. Taken together, the LPWarmStart parameter setting, the LP algorithm specified by Gurobi's Method parameter, and the available advanced start information determine whether Gurobi will use basis statuses only, basis statuses augmented with information from start vectors, or a basis obtained by applying the crossover method to the provided primal and dual start vectors to jump start the optimization.

When Gurobi's Method parameter requests the barrier solver, primal and dual start vectors are prioritized over basis statuses (but only if you provide both). These start vectors are fed to the crossover procedure. This is the same crossover that is used to compute a basic solution from the interior solution produced by the core barrier algorithm, but in this case crossover is started from arbitrary start vectors. If you set the LPWarmStart parameter to 1, crossover will be invoked on the original model using the provided vectors. Any provided basis information will not be used in this case. If you set LPWarmStart to 2, crossover will be invoked on the presolved model using crushed start vectors. If you set the parameter to 2 and provide a basis but no start vectors, the basis will be used to compute the corresponding primal and dual solutions on the original model. Those solutions will then be crushed and used as primal and dual start vectors for the crossover, which will then construct a basis for the presolved model. Note that for all of these settings and start combinations, no barrier algorithm iterations are performed.

The simplex algorithms provide more warm-starting options, with a parameter value of 1, simplex will start from a provided basis, if available. Otherwise, it uses a provided start vector to refine the crash basis it computes.

With a value of 2, simplex will use the crushed start vector on the presolved model to refine the crash basis. This is true regardless of whether the start is derived from start vectors or a starting basis from the original model. The difference is that if you provide an advanced basis, the basis will be used to compute the corresponding primal and dual solutions on the original model from which the primal or dual start on the presolved model will be derived.

Note: Only affects linear programming (LP) models.

Default: `1`

markowitztol *(real)*: Threshold pivoting tolerance ↩

Used to limit numerical error in the simplex algorithm. A larger value may avoid numerical problems in rare situations, but it will also harm performance.

Range: [`0.0001`, `0.999`]

Default: `0.0078125`

memlimit *(real)*: Memory limit ↩

Limits the total amount of memory (in GB, i.e., 10^9 bytes) available to Gurobi. If more is needed, Gurobi will fail with an OUT_OF_MEMORY error.

Default: `maxdouble`

method *(integer)*: Algorithm used to solve continuous models ↩

Synonyms: lpmethod rootmethod

Algorithm used to solve continuous models or the root node of a MIP model. Options are: -1=automatic, 0=primal simplex, 1=dual simplex, 2=barrier, 3=concurrent, 4=deterministic concurrent, 5=deterministic concurrent simplex.

In the current release, the default Automatic (-1) setting will typically choose non-deterministic concurrent (Method=3) for an LP, barrier (Method=2) for a QP or QCP, and dual (Method=1) for the MIP root node. Only the simplex and barrier algorithms are available for continuous QP models. Only primal and dual simplex are available for solving the root of an MIQP model. Only barrier is available for continuous QCP models.

Concurrent optimizers run multiple solvers on multiple threads simultaneously, and choose the one that finishes first. Method=3 and Method=4 will run dual simplex, barrier, and sometimes primal simplex (depending on the number of available threads). Method=5 will run both primal and dual simplex. The deterministic options (Method=4 and Method=5) give the exact same result each time, while Method=3 is often faster but can produce different optimal bases when run multiple times.

The default setting is rarely significantly slower than the best possible setting, so you generally won't see a big gain from changing this parameter. There are classes of models where one particular algorithm is consistently fastest, though, so you may want to experiment with different options when confronted with a particularly difficult model.

Note that if memory is tight on an LP model, you should consider using the dual simplex method (Method=1). The concurrent optimizer, which is typically chosen when using the default setting, consumes a lot more memory than dual simplex alone.

Default: `-1`

value	meaning
`-1`	Automatic
`0`	Primal simplex
`1`	Dual simplex
`2`	Barrier
`3`	Concurrent
`4`	Deterministic concurrent
`5`	Both primal and dual simplex

minrelnodes *(integer)*: Minimum relaxation heuristic control ↩

Number of nodes to explore in the minimum relaxation heuristic. Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

The default value automatically chooses whether to apply the heuristic. It will only rarely choose to do so.

Default: `-1`

mipfocus *(integer)*: Set the focus of the MIP solver ↩

Default: `0`

value	meaning
0	Balance between finding good feasible solutions and proving optimality
1	Focus towards finding feasible solutions
2	Focus towards proving optimality
3	Focus on moving the best objective bound

mipgap *(real)*: Relative MIP optimality gap ↩

The MIP engine will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than `MipGap` times the upper bound.

Range: [0, ∞]

Default: `GAMS optcr`

mipgapabs *(real)*: Absolute MIP optimality gap ↩

The MIP solver will terminate (with an optimal result) when the gap between the lower and upper objective bound is less than `MIPGapAbs`.

Range: [0, ∞]

Default: `GAMS optca`

mipsepcuts *(integer)*: MIP separation cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

mipstart *(boolean)*: Use mip starting values ↩

Default: `0`

value	meaning
0	Do not use the values
1	Use the values

mipstopexpr *(string)*: Stop expression for branch and bound ↩

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: resusd, nodusd, objest, objval. Supported opertators are: +, -, *, /, ^, %, !=, ==, <, <=, >, >=, !, &&, ||, (,), abs, ceil, exp, floor, log, log10, pow, sqrt. Example:
```
nodusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1
```

If multiple stop expressions are given in an option file, the algorithm stops if any of them is true (|| concatenation).

miptrace *(string)*: Filename of MIP trace file ↩

More info is available in chapter Solve trace.

miptracenode *(integer)*: Node interval when a trace record is written ↩

Default: `100`

miptracetime *(real)*: Time interval when a trace record is written ↩

Default: `1`

miqcpmethod *(integer)*: Method used to solve MIQCP models ↩

Controls the method used to solve MIQCP models. Value 1 uses a linearized, outer-approximation approach, while value 0 solves continuous QCP relaxations at each node. The default setting (-1) chooses automatically.

Default: `-1`

value	meaning
-1	Auto
0	Continuous QCP relaxations at each node
1	Linearized, outer-approximation approach

mircuts *(integer)*: MIR cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

mixingcuts *(integer)*: Mixing cut generation ↩

Controls Mixing cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: `-1`

modkcuts *(integer)*: Mod-k cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

multimipstart *(string)*: Use multiple (partial) mipstarts provided via gdx files ↩

Specifies (multiple) GDX files with values for the variables. Each file is treated as one intial guess for the MIP start. These MIP starts are added in addition to the initial guess provided by the level attribute. A MIP start GDX file can be created, for example, by using the command line option savepoint.

This option further allows to add partial MIP starts where some variable level records are not given. GUROBI will then try to construct a full MIP start out of it. In order to not provide a certain variable level record, simply not include that record in the GDX file or set the level value to NA or UNDEF.

This option requires mipstart enabled.

multiobjmethod *(integer)*: Warm-start method to solve for subsequent objectives ↩

When solving a continuous multi-objective model using a hierarchical approach, the model is solved once for each objective. The algorithm used to solve for the highest priority objective is controlled by the Method parameter. This parameter determines the algorithm used to solve for subsequent objectives. As with the Method parameters, values of 0 and 1 use primal and dual simplex, respectively. A value of 2 indicates that warm-start information from previous solves should be discarded, and the model should be solved from scratch (using the algorithm indicated by the Method parameter). The default setting of -1 usually chooses primal simplex.

Default: `-1`

multiobjpre *(integer)*: Initial presolve on multi-objective models ↩

Controls the initial presolve level used for multi-objective models. Value 0 disables the initial presolve, value 1 applies presolve conservatively, and value 2 applies presolve aggressively. The default -1 value usually applies presolve conservatively. Aggressive presolve may increase the chance of the objective values being slightly different than those for other options.

Default: `-1`

multobj *(boolean)*: Controls the hierarchical optimization of multiple objectives ↩

Default: `0`

names *(boolean)*: Indicator for loading names ↩

Default: `1`

value	meaning
0	Do not load GAMS names into Gurobi model
1	Load GAMS names into Gurobi model

networkalg *(integer)*: Network simplex algorithm ↩

Default: `-1`

networkcuts *(integer)*: Network cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Conservative
`2`	Aggressive

nlpheur *(boolean)*: Controls the NLP heuristic for non-convex quadratic models ↩

The NLP heuristic uses a non-linear barrier solver to find feasible solutions to non-convex quadratic models. It can often find solutions much more quickly than the alternative, but in some cases it can consume significant runtime without producing a solution.

Note: Only affects non-convex quadratic models.

Default: `1`

nlreform *(boolean)*: Reform nonlinear equations to Gurobi general constraints ↩

Default: `1`

nodefiledir *(string)*: Directory for MIP node files ↩

Determines the directory into which nodes are written when node memory usage exceeds the specified NodefileStart value.

Default: `.`

nodefilestart *(real)*: Memory threshold for writing MIP tree nodes to disk ↩

Controls the point at which MIP tree nodes are written to disk. Whenever node storage exceeds the specified value (in GBytes), nodes are written to disk.

Default: `maxdouble`

nodelimit *(real)*: MIP node limit ↩

Default: `maxdouble`

nodemethod *(integer)*: Method used to solve MIP node relaxations ↩

Algorithm used for MIP node relaxations. Note that barrier is not an option for MIQP node relaxations.

Default: `-1`

value	meaning
`-1`	Automatic
`0`	Primal simplex
`1`	Dual simplex
`2`	Barrier

nonconvex *(integer)*: Control how to deal with non-convex quadratic programs ↩

Sets the strategy for handling non-convex quadratic objectives or non-convex quadratic constraints. With setting 0, an error is reported if the original user model contains non-convex quadratic constructs (unless Q matrix linearization, as controlled by the PreQLinearize parameter, removes the non-convexity). With setting 1, an error is reported if non-convex quadratic constructs could not be discarded or linearized during presolve. With setting 2, non-convex quadratic problems are solved by translating them into bilinear form and applying spatial branching. The default -1 setting is currently almost equivalent to 2, except that it takes less care to avoid presolve reductions that might transform a convex constraint into one that can no longer be detected to be convex, and thus can sometimes perform more presolve reductions.

Default: `-1`

norelheurtime *(real)*: Limits the amount of time (in seconds) spent in the NoRel heuristic ↩

Limits the amount of time (in seconds) spent in the NoRel heuristic. This heuristic searches for high-quality feasible solutions before solving the root relaxation. It can be quite useful on models where the root relaxation is particularly expensive. Note that this parameter will introduce non-determinism - different runs may take different paths. Use norelheurwork parameter for deterministic results.

Default: `0`

norelheurwork *(real)*: Limits the amount of work performed by the NoRel heuristic ↩

Limits the amount of work spent in the NoRel heuristic. This heuristic searches for high-quality feasible solutions before solving the root relaxation. It can be quite useful on models where the root relaxation is particularly expensive. The work metric used in this parameter is tough to define precisely. A single unit corresponds to roughly a second, but this will depend on the machine, the core count, and in some cases the model. You may need to experiment to find a good setting for your model.

Default: `0`

normadjust *(integer)*: Simplex pricing norm ↩

Chooses from among multiple pricing norm variants. The default value of -1 chooses automatically.

Default: `-1`

numericfocus *(integer)*: Set the numerical focus ↩

The `NumericFocus` parameter controls the degree to which the code attempts to detect and manage numerical issues. The default setting makes an automatic choice, with a slight preference for speed. Settings 1-3 increasingly shift the focus towards being more careful in numerical computations. With higher values, the code will spend more time checking the numerical accuracy of intermediate results, and it will employ more expensive techniques in order to avoid potential numerical issues.

Default: `0`

obbt *(integer)*: Controls aggressiveness of optimality-based bound tightening ↩

Default: `-1`

objnabstol *(string)*: Allowable absolute degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is `ObjNAbsTol ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most `ObjNAbsTol`.

objnreltol *(string)*: Allowable relative degradation for objective ↩

This parameter is used to set the allowable degradation for an objective when doing hierarchical multi-objective optimization (MultObj). The syntax for this parameter is `ObjNRelTol ObjVarName value`.

Hierarchical multi-objective optimization will optimize for the different objectives in the model one at a time, in priority order. If it achieves objective value z when it optimizes for this objective, then subsequent steps are allowed to degrade this value by at most `ObjNRelTol`$*|z|$.

objscale *(real)*: Objective scaling ↩

Divides the model objective by the specified value to avoid numerical errors that may result from very large objective coefficients. The default value of 0 decides on the scaling automatically. A value less than zero uses the maximum coefficient to the specified power as the scaling (so `ObjScale=-0.5` would scale by the square root of the largest objective coefficient).

Range: [`-1`, ∞]

Default: `0`

optimalitytol *(real)*: Dual feasibility tolerance ↩

Reduced costs must all be larger than `OptimalityTol` in the improving direction in order for a model to be declared optimal.

Range: [`1e-09`, `0.01`]

Default: `1e-06`

.partition *(integer)*: Variable partition value ↩

The MIP solver can perform a solution improvement heuristic using user-provided partition information. The provided partition number can be positive, which indicates that the variable should be included when the correspondingly numbered sub-MIP is solved, 0 which indicates that the variable should be included in every sub-MIP, or -1 which indicates that the variable should not be included in any sub-MIP. Variables that are not included in the sub-MIP are fixed to their values in the current incumbent solution.

To give an example, imagine you are solving a model with 400 variables and you set the partition attribute to -1 for variables 0-99, 0 for variables 100-199, 1 for variables 200-299, and 2 for variables 300-399. The heuristic would solve two sub-MIP models: sub-MIP 1 would fix variables 0-99 and 300-399 to their values in the incumbent and solve for the rest, while sub-MIP 2 would fix variables 0-99 and 200-299.

The parameter PartitionPlace controls the use of the heursitic. The parition numbers are specified through the option `.partition`. The syntax for dot options is explained in the Introduction chapter of the Solver Manual.

Default: `0`

partitionplace *(integer)*: Controls when the partition heuristic runs ↩

This option works in combination with the Partition number for variables. Setting this option and providing some partitions enables the partitioning heuristic, which uses large-neighborhood search to try to improve the current incumbent solution.

This parameter determines where that heuristic runs. Options are:

- Before the root relaxation is solved (16)
- At the start of the root cut loop (8)
- At the end of the root cut loop (4)
- At the nodes of the branch-and-cut search (2)
- When the branch-and-cut search terminates (1)

The parameter value is a bit vector, where each bit turns the heuristic on or off at that place. The numerical values next to the options listed above indicate which bit controls the corresponding option. Thus, for example, to enable the heuristic at the beginning and end of the root cut loop (and nowhere else), you would set the 8 bit and the 4 bit to 1, which would correspond to a parameter value of 12.

The recommended value is 15 which indicates that every option except the first one listed above is enabled.

Default: `15`

perturbvalue *(real)*: Simplex perturbation magnitude ↩

Range: [`0`, ∞]

Default: `0.0002`

poolgap *(real)*: Relative gap for solutions in pool ↩

Determines how large a gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (relative) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of `PoolGap=0.2` would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: `maxdouble`

poolgapabs *(real)*: Absolute gap for solutions in pool ↩

Determines how large a (absolute) gap to tolerate in stored solutions. When this parameter is set to a non-default value, solutions whose objective values exceed that of the best known solution by more than the specified (absolute) gap are discarded. For example, if the MIP solver has found a solution at objective 100, then a setting of `PoolGapAbs=20` would discard solutions with objective worse than 120 (assuming a minimization objective).

Default: `maxdouble`

poolsearchmode *(integer)*: Choose the approach used to find additional solutions ↩

With the default setting (`PoolSearchMode=0`), the MIP solver tries to find an optimal solution to the model. It keeps other solutions found along the way, but those are incidental. By setting this parameter to a non-default value, the MIP search will continue after the optimal solution has been found in order to find additional, high-quality solutions. With a setting of 2, it will find the n best solutions, where n is determined by the value of the PoolSolutions parameter. With a setting of 1, it will try to find additional solutions, but with no guarantees about the quality of those solutions. The cost of the solve will increase with increasing values of this parameter.

Once optimization is complete, the *PoolObjBound* attribute (printed to the log) can be used to evaluate the quality of the solutions that were found. For example, a value of `PoolObjBound=100` indicates that there are no other solutions with objective better 100, and thus that any known solutions with objective better than 100 are better than any as-yet undiscovered solutions.

Default: `0`

poolsolutions *(integer)*: Number of solutions to keep in pool ↩

Determines how many MIP solutions are stored. For the default value of PoolSearchMode, these are just the solutions that are found along the way in the process of exploring the MIP search tree. For other values of PoolSearchMode, this parameter sets a target for how many solutions to find, so larger values will impact performance.

Default: `10`

precrush *(boolean)*: Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model ↩

Allows presolve to translate constraints on the original model to equivalent constraints on the presolved model. This parameter is turned on when you use BCH with Gurobi.

Default: `0`

predeprow *(integer)*: Presolve dependent row reduction ↩

Controls the presolve dependent row reduction, which eliminates linearly dependent constraints from the constraint matrix. The default setting (-1) applies the reduction to continuous models but not to MIP models. Setting 0 turns the reduction off for all models. Setting 1 turns it on for all models.

Default: `-1`

predual *(integer)*: Presolve dualization ↩

Depending on the structure of the model, solving the dual can reduce overall solution time. The default setting uses a heuristic to decide. Setting 0 forbids presolve from forming the dual, while setting 1 forces it to take the dual. Setting 2 employs a more expensive heuristic that forms both the presolved primal and dual models (on two threads), and heuristically chooses one of them.

Default: `-1`

premiqcpform *(integer)*: Format of presolved MIQCP model ↩

Option 0 leaves the model in MIQCP form, so the branch-and-cut algorithm will operate on a model with arbitrary quadratic constraints. Option 1 always transforms the model into MISOCP form; quadratic constraints are transformed into second-order cone constraints. Option 2 always transforms the model into disaggregated MISOCP form; quadratic constraints are transformed into rotated cone constraints, where each rotated cone contains two terms and involves only three variables.

Default: `-1`

value	meaning
-1	Auto
0	Always leaves the model in MIQCP form
1	Always transforms the model into MISOCP form
2	Always transforms the model into disaggregated MISOCP form

prepasses *(integer)*: Presolve pass limit ↩

Limits the number of passes performed by presolve. The default setting (-1) chooses the number of passes automatically.

Default: -1

preqlinearize *(integer)*: Presolve Q matrix linearization ↩

Options 1 and 2 attempt to linearize quadratic constraints or a quadratic objective, potentially transforming an MIQP or MIQCP model into an MILP. Option 1 focuses on getting a strong LP relaxation. Option 2 aims for a compact relaxation. Option 0 always leaves Q matrices unmodified. The default setting (-1) chooses automatically.

Default: -1

value	meaning
-1	Auto
0	Linearization off
1	Force Linearization and get strong LP relaxation
2	Force Linearization and get compact relaxation

Presolve *(integer)*: Presolve level ↩

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

presos1bigm *(real)*: Controls largest coefficient in SOS1 reformulation ↩

Controls the automatic reformulation of SOS1 constraints into binary form. SOS1 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS1 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of -1 chooses a threshold automatically. You should set the parameter to 0 to shut off SOS1 reformulation entirely, or a large value to force reformulation.

Range: [-1, 1e+10]

Default: -1

presos1encoding *(integer)*: Controls SOS1 reformulation ↩

Controls the automatic reformulation of SOS1 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several diffent ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS1 constraint using a formulation whose size is linear in the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS1 using a formulation of logarithmic size. They both only apply when all the variables in the SOS1 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS1 is equal to 1. Logarithmic formulations are often advantageous when the SOS1 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS1 constraint automatically.

Note that the reformulation of SOS1 constraints is also influenced by the PreSOS1BigM parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: `-1`

presos2bigm *(real)*: Controls largest coefficient in SOS2 reformulation ↩

Controls the automatic reformulation of SOS2 constraints into binary form. SOS2 constraints are often handled more efficiently using a binary representation. The reformulation often requires big-M values to be introduced as coefficients. This parameter specifies the largest big-M that can be introduced by presolve when performing this reformulation. Larger values increase the chances that an SOS2 constraint will be reformulated, but very large values (e.g., 1e8) can lead to numerical issues.

The default value of 0 disables the reformulation. You can set the parameter to -1 to choose an automatic approach, or a large value to force reformulation.

Range: [`-1`, `1e+10`]

Default: `-1`

presos2encoding *(integer)*: Controls SOS2 reformulation ↩

Controls the automatic reformulation of SOS2 constraints. Such constraints can be handled directly by the MIP branch-and-cut algorithm, but they are often handled more efficiently by reformulating them using binary or integer variables. There are several diffent ways to perform this reformulation; they differ in their size and strength. Smaller reformulations add fewer variables and constraints to the model. Stronger reformulations reduce the number of branch-and-cut nodes required to solve the resulting model.

Options 0 and 1 of this parameter encode an SOS2 constraint using a formulation whose size is linear in the the number of SOS members. Option 0 uses a so-called multiple choice model. It usually produces an LP relaxation that is easier to solve. Option 1 uses an incremental model. It often gives a stronger representation, reducing the amount of branching required to solve harder problems.

Options 2 and 3 of this parameter encode the SOS2 using a formulation of logarithmic size. They both only apply when all the variables in the SOS2 are non-negative. Option 3 additionally requires that the sum of the variables in the SOS2 is equal to 1. Logarithmic formulations are often advantageous when the SOS2 constraint has a large number of members. Option 2 focuses on a formulation whose LP relaxation is easier to solve, while option 3 has better branching behaviour.

The default value of -1 chooses a reformulation for each SOS2 constraint automatically.

Note that the reformulation of SOS2 constraints is also influenced by the PreSOS2BigM parameter. To shut off the reformulation entirely you should set that parameter to 0.

Default: `-1`

presparsify *(integer)*: Presolve sparsify reduction ↩

This reduction can sometimes significantly reduce the number of nonzero values in the presolved model.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Disable the presolve sparsify reduction
`1`	Enable the presolve sparsify reduction for MIPs
`2`	Enable the presolve sparsify reduction for all model types

printoptions *(boolean)*: List values of all options to GAMS listing file ↩

Default: `0`

value	meaning
`0`	Do not list option values to GAMS listing file
`1`	List option values to GAMS listing file

.prior *(real)*: Branching priorities ↩

GAMS allows to specify priorities for discrete variables only. Gurobi can detect that continuous variables are implied discrete variables and can utilize priorities. Such priorities can be specified through a GAMS/Gurobi solver option file. The syntax for dot options is explained in the Introduction chapter of the Solver Manual. The priorities are only passed on to Gurobi if the model attribute `priorOpt` is turned on.

Default: `1`

projimpliedcuts *(integer)*: Projected implied bound cut generation ↩

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Moderate
`2`	Aggressive

psdcuts *(integer)*: PSD cut generation ↩

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Moderate
`2`	Aggressive

psdtol *(real)*: Positive semi-definite tolerance ↩

Positive semi-definite tolerance (for QP/MIQP). Sets a limit on the amount of diagonal perturbation that the optimizer is allowed to automatically perform on the Q matrix in order to correct minor PSD violations. If a larger perturbation is required, the optimizer will terminate stating the problem is not PSD.

Range: [`0`, ∞]

Default: `1e-06`

pumppasses *(integer)*: Feasibility pump heuristic control ↩

Note that this heuristic is only applied at the end of the MIP root.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: `-1`

qcpdual *(boolean)*: Compute dual variables for QCP models ↩

Determines whether dual variable values are computed for QCP models. Computing them can add significant time to the optimization, so you should turn this parameter to 0 if you do not need them.

Default: `1`

value	meaning
`0`	Do not compute dual for QCP problem
`1`	Compute dual for QCP problem

qextractalg *(integer)*: quadratic extraction algorithm in GAMS interface ↩

Default: `0`

value	meaning
`0`	Automatic
`1`	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
`2`	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.

value	meaning
3	Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.

quad *(integer)*: Quad precision computation in simplex ↩

Enables or disables quad precision computation in simplex. The -1 default setting allows the algorithm to decide.

Default: `-1`

readparams *(string)*: Read Gurobi parameter file ↩

relaxliftcuts *(integer)*: Relax-and-lift cut generation ↩

Default: `-1`

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

rerun *(integer)*: Resolve without presolve in case of unbounded or infeasible ↩

In case Gurobi reports *Model was proven to be either infeasible or unbounded*, this option decides about a resolve without presolve which will determine the exact model status. If the option is set to *auto* and the model fits into demo limits, the problems is resolved.

Default: `-1`

value	meaning
-1	No
0	Auto
1	Yes

rins *(integer)*: RINS heuristic ↩

Default value (-1) chooses automatically. A value of 0 shuts off RINS. A positive value n applies RINS at every n-th node of the MIP search tree.

Default: `-1`

rltcuts *(integer)*: RLT cut generation ↩

Default: `-1`

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

rngrestart *(string)*: Write GAMS readable ranging information file ↩

If the extension specified is `gdx`, a GDX file is exported, and a GAMS file otherwise.

scaleflag *(integer)*: Model scaling ↩

Controls model scaling. By default, the rows and columns of the model are scaled in order to improve the numerical properties of the constraint matrix. The scaling is removed before the final solution is returned. Scaling typically reduces solution times, but it may lead to larger constraint violations in the original, unscaled model. Turning off scaling `ScaleFlag=0` can sometimes produce smaller constraint violations. Choosing a more aggressive scaling option `ScaleFlag=2` can sometimes improve performance for particularly numerically difficult models.

Default: `-1`

seed *(integer)*: Modify the random number seed ↩

Modifies the random number seed. This acts as a small perturbation to the solver, and typically leads to different solution paths.

Default: `0`

sensitivity *(boolean)*: Provide sensitivity information ↩

Default: `0`

value	meaning
`0`	Do not provide sensitivity information
`1`	Provide sensitivity information

sifting *(integer)*: Sifting within dual simplex ↩

Enables or disables sifting within dual simplex. Sifting is often useful for LP models where the number of variables is many times larger than the number of constraints. With a *Moderate* setting, sifting will be applied to LP models and to the root node for MIP models. With an *Aggressive* setting, sifting will be also applied to the nodes of a MIP. Note that this parameter has no effect if you aren't using dual simplex. Note also that sifting will be skipped in cases where it is obviously a worse choice, even when sifting has been selected.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Moderate
`2`	Agressive

siftmethod *(integer)*: LP method used to solve sifting sub-problems ↩

Note that this parameter only has an effect when you are using dual simplex and sifting has been selected (either by the automatic method, or through the Sifting parameter).

Default: `-1`

value	meaning
-1	Auto
0	Primal Simplex
1	Dual Simplex
2	Barrier

simplexpricing *(integer)*: Simplex variable pricing strategy ↩

Default: -1

value	meaning
-1	Auto
0	Partial Pricing
1	Steepest Edge
2	Devex
3	Quick-Start Steepest Edge

softmemlimit *(real)*: Soft memory limit ↩

Default: maxdouble

solfiles *(string)*: Location to store intermediate solution files ↩

During the MIP solution process, multiple incumbent solutions are typically found on the path to finding a proven optimal solution. Setting this parameter to a non-empty string causes these solutions to be written to files (in .sol format) as they are found. The MIP solver will append _n.sol to the value of the parameter to form the name of the file that contains solution number n. For example, setting the parameter to value solutions/mymodel will create files mymodel_0.sol, mymodel_1.sol, etc., in directory solutions.

solnpool *(string)*: Controls export of alternate MIP solutions ↩

The GDX file specified by this option will contain a set call index that contains the names of GDX files with the individual solutions. For details see example model **dumpsol** in the GAMS Test Library. The option PoolSolutions, PoolSearchModel, and PoolGap control the search for alternative solutions. Please also refer to the secion Solution Pool.

solnpoolmerge *(string)*: Controls export of alternate MIP solutions for merged GDX solution file ↩

Similar to SolnPool this option stores multiple alternative solutions to a MIP problem, but in a single GDX file. The GDX file specified by this option will contain all variables with an additional first index (determined through SolnPoolPrefix) as parameters. The option PoolSolutions, PoolSearchModel, and PoolGap control the search for alternative solutions. Please also refer to the secion Solution Pool.

solnpoolnumsym *(integer)*: Maximum number of variable symbols when writing merged GDX solution file ↩

Default: 10

solnpoolprefix *(string)*: First dimension of variables for merged GDX solution file or file name prefix for GDX solution files ↩

Default: soln

solutionlimit *(integer)*: MIP feasible solution limit ↩

Default: maxint

solutiontarget *(integer)*: Specify the solution target for LP ↩

Default: -1

value	meaning
-1	Auto
0	primal and dual optimal, and basic
1	primal and dual optimal

solvefixed *(boolean)*: Indicator for solving the fixed problem for a MIP to get a dual solution ↩

Default: 1

value	meaning
0	Do not solve the fixed problem
1	Solve the fixed problem

startnodelimit *(integer)*: Node limit for MIP start sub-MIP ↩

This parameter limits the number of branch-and-bound nodes explored when completing a partial MIP start. The default value of -1 uses the value of the SubMIPNodes parameter. A value of -2 means to only check full MIP starts for feasibility and to ignore partial MIP starts. A value of -3 shuts off MIP start processing entirely. Non-negative values are node limits.

Default: -1

strongcgcuts *(integer)*: Strong-CG cut generation ↩

Controls Strong Chvátal-Gomory (Strong-CG) cut generation. Use 0 to disable these cuts, 1 for moderate cut generation, or 2 for aggressive cut generation. The default -1 value chooses automatically. Overrides the Cuts parameter.

Default: -1

submipcuts *(integer)*: Sub-MIP cut generation ↩

See the description of the global Cuts parameter for further information.

Default: -1

submipnodes *(integer)*: Nodes explored by sub-MIP heuristics ↩

Limits the number of nodes explored by the heuristics, like RINS. Exploring more nodes can produce better solutions, but it generally takes longer.

Default: 500

symmetry *(integer)*: Symmetry detection ↩

Default: -1

value	meaning
-1	Auto
0	Off
1	Conservative
2	Aggressive

threads *(integer)*: Number of parallel threads to use ↩

Default number of parallel threads allowed for any solution method. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

Default: `GAMS threads`

timelimit *(real)*: Time limit ↩

Default: `GAMS reslim`

tunecleanup *(real)*: Enables a tuning cleanup phase ↩

Enables a cleanup phase at the end of tuning. The parameter indicates the percentage of total tuning time to devote to this phase, with a goal of reducing the number of parameter changes required to achieve the best tuning result.

Default: `0`

tunecriterion *(integer)*: Specify tuning criterion ↩

Modifies the tuning criterion for the tuning tool. The primary tuning criterion is always to minimize the runtime required to find a proven optimal solution. However, for MIP models that don't solve to optimality within the specified time limit, a secondary criterion is needed. Set this parameter to 1 to use the optimality gap as the secondary criterion. Choose a value of 2 to use the objective of the best feasible solution found. Choose a value of 3 to use the best objective bound. Choose 0 to ignore the secondary criterion and focus entirely on minimizing the time to find a proven optimal solution. The default value of -1 chooses automatically.

Default: `-1`

tunedynamicjobs *(integer)*: Enables distributed tuning using a dynamic set of workers ↩

Enables distributed parallel tuning, which can significantly increase the performance of the tuning tool. A value of n causes the tuning tool to use a dynamic set of up to n workers in parallel. These workers are used for a limited amount of time and afterwards potentially released so that they are available for other remote jobs. A value of -1 allows the solver to use an unlimited number of workers. Note that this parameter can be combined with TuneJobs to get a static set of workers and a dynamic set of workers for distributed tuning. You can use the WorkerPool parameter to provide a distributed worker cluster.

Note that distributed tuning is most effective when the worker machines have similar performance. Distributed tuning doesn't attempt to normalize performance by server, so it can incorrectly attribute a boost in performance to a parameter change when the associated setting is tried on a worker that is significantly faster than the others.

Default: `0`

tunejobs *(integer)*: Enables distributed tuning using a static set of workers ↩

Enables distributed parallel tuning, which can significantly increase the performance of the tuning tool. A value of n causes the tuning tool to distribute tuning work among n parallel jobs. These jobs are distributed among a set of workers. Use the WorkerPool parameter to provide a list of available workers.

Note that distributed tuning is most effective when the workers have similar performance. Distributed tuning doesn't attempt to normalize performance by worker, so it can incorrectly attribute a boost in performance to a parameter change when the associated setting is tried on a worker that is significantly faster than the others.

Default: `0`

tunemetric *(integer)*: Metric to aggregate results into a single measure ↩

A single tuning run typically produces multiple timing results for each candidate parameter set, either as a result of performing multiple trials, or tuning multiple models, or both. This parameter controls how these results are aggregated into a single measure. The default setting (-1) chooses the aggregation automatically; setting 0 computes the average of all individual results; setting 1 takes the maximum.

Default: `-1`

tuneoutput *(integer)*: Tuning output level ↩

Default: `2`

value	meaning
`0`	No output
`1`	Summary output only when a new best parameter set is found
`2`	Summary output for each parameter set that is tried
`3`	Summary output, plus detailed solver output, for each parameter set tried

tuneresults *(integer)*: Number of improved parameter sets returned ↩

The tuning tool often finds multiple parameter sets that improve over the baseline settings. This parameter controls how many of these sets should be retained when tuning is complete. A non-negative value indicates how many sets should be retained. The default value (-1) retains the efficient frontier of parameter sets. That is, it retains the best set for one changed parameter, the best for two changed parameters, etc. Sets that aren't on the efficient frontier are discarded. If you interested in all the sets, use value -2 for the parameter.

Note that the first set in the results is always the set of parameters which was used for the first solve, the baseline settings. This set serves as the base for any improvement. So if you are interested in the best tuned set of parameters you need to request at least 2 tune results. The first one (with index 0) will be the baseline setting and the second one (with index 1) will be the best set found during tuning.

Default: `-1`

tunetargetmipgap *(real)*: A target gap to be reached ↩

A target gap to be reached. As soon as the tuner has found parameter settings that allow Gurobi to reach the target gap for the given model(s), it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see TuneCleanup parameter).

Default: `0`

tunetargettime *(real)*: A target runtime in seconds to be reached ↩

A target runtime in seconds to be reached. As soon as the tuner has found parameter settings that allow Gurobi to solve the model(s) within the target runtime, it stops trying to improve parameter settings further. Instead, the tuner switches into the cleanup phase (see TuneCleanup parameter).

Default: `0.005`

tunetimelimit *(real)*: Time limit for tuning ↩

Limits total tuning runtime (in seconds). The default setting (-1) chooses a time limit automatically.

Default: `maxdouble`

tunetrials *(integer)*: Perform multiple runs on each parameter set to limit the effect of random noise ↩

Performance on a MIP model can sometimes experience significant variations due to random effects. As a result, the tuning tool may return parameter sets that improve on the baseline only due to randomness. This parameter allows you to perform multiple solves for each parameter set, using different Seed values for each, in order to reduce the influence of randomness on the results. The default value of 0 indicates an automatic choice that depends on model characteristics.

Note: Only affects mixed integer programming (MIP) models

Default: `0`

Tuning *(string)*: Parameter Tuning ↩

Invokes the Gurobi parameter tuning tool. The mandatory value following the keyword specifies a GAMS/Gurobi option file. All options found in this option file will be used but not modified during the tuning. A sequence of file names specifying existing problem files may follow the option file name. The files can be in MPS, REW, LP, RLP, and ILP format created by the WriteProb option. Gurobi will tune the parameters either for the problem provided by GAMS (no additional problem files specified) or for the suite of problems listed after the GAMS/Gurobi option file name without considering the problem provided by GAMS. The result of such a run is the updated GAMS/Gurobi option file with a tuned set of parameters. In case the option TuneResults is larger than 1, GAMS/Gurobi will create a sequence of GAMS/Gurobi option files. The solver and model status returned to GAMS will be `NORMAL COMPLETION` and `NO SOLUTION`. Tuning is incompatible with advanced features like FeasOpt of GAMS/Gurobi.

usebasis *(integer)*: Use basis from GAMS ↩

If `UseBasis` is not specified, GAMS (via option `BRatio`) decides if the starting basis or a primal/dual solution is given to Gurobi. If `UseBasis` is explicitly set in an option file then the basis or a primal/dual solution is passed to Gurobi independent of the GAMS option `BRatio`. Please note, if Gurobi uses a starting basis presolve will be skipped.

Default: `GAMS bratio`

value	meaning
0	No basis
1	Supply basis if basis is full otherwise provide primal dual solution
2	Supply basis iff basis is full
3	Supply primal dual solution

varbranch *(integer)*: Branch variable selection strategy ↩

Default: `-1`

value	meaning
-1	Auto
0	Pseudo Reduced Cost Branching

value	meaning
1	Pseudo Shadow Price Branching
2	Maximum Infeasibility Branching
3	Strong Branching

varhint *(boolean)*: Guide heuristics and branching through variable hints ↩

If you know that a variable is likely to take a particular value in high quality solutions of a MIP model, you can provide this information as a hint. If `VarHint` option is active, GAMS/Gurobi will pass variable levels rounded to the nearest integer as hints to Gurobi if their level is within `TryInt` of an integer. The closer the level is to the rounded integer the higher your level of confidence in this hint. Internally this is recalculated into a Gurobi variable hint priority: $\lceil \frac{1}{\max(10^{-6}, \lvert x.l - [x.l] \rvert)} \rceil$

The Gurobi MIP solver will use these variable hints in a number of different ways. Hints will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree. In general, high quality hints should produce high quality MIP solutions faster. In contrast, low quality hints will lead to some wasted effort, but shouldn't lead to dramatic performance degradations.

Variables hints and MIP starts are similar in concept, but they behave in very different ways. If you specify a MIP start, the Gurobi MIP solver will try to build a single feasible solution from the provided set of variable values. If you know a solution, you should use a MIP start to provide it to the solver. In contrast, variable hints provide guidance to the MIP solver that affects the entire solution process. If you have a general sense of the likely values for variables, you should provide them through variable hints.

Default: `0`

workerpassword *(string)*: Password for distributed worker cluster ↩

When using a distributed algorithm (the distributed concurrent MIP solver or distributed tuning), this parameter allows you to specify the password for the workers listed in the WorkerPool parameter.

workerpool *(string)*: Distributed worker cluster ↩

When using a distributed algorithm (distributed MIP, distributed concurrent, or distributed tuning), this parameter allows you to specify a Remote Services cluster that will provide distributed workers. You should also specify the access password for that cluster, if there is one, in the WorkerPassword parameter.

You can provide a comma-separated list of machines for added robustness. If the first node in the list is unavailable, the client will attempt to contact the second node, etc.

To give an example, if you have a Remote Services cluster that uses port 61000 on a pair of machines named server1 and server2, you could set WorkerPool to `server1:61000` `server1:61000,server2:61000`.

worklimit *(real)*: Work limit ↩

Limits the total work expended (in work units).

In contrast to the TimeLimit, work limits are deterministic. This means that on the same hardware and with the same parameter and attribute settings, a work limit will stop the optimization of a given model at the exact same point every time. One work unit corresponds very roughly to one second on a single thread, but this greatly depends on the hardware on which Gurobi is running and the model that is being solved.

Note that optimization may not stop immediately upon hitting the work limit. It will stop when the optimization is next in a deterministic state, and it will then perform the required additional computations of the attributes associated with the terminated optimization. As a result, the Work attribute may be larger than the specified WorkLimit upon completion, and repeating the optimization with a WorkLimit set to the Work attribute of the stopped optimization may result in additional computations and a larger attribute value.

Default: `maxdouble`

writeparams *(string)*: Write Gurobi parameter file ↩

writeprob *(string)*: Save the problem instance ↩

zerohalfcuts *(integer)*: Zero-half cut generation ↩

See the description of the global Cuts parameter for further information.

Default: `-1`

value	meaning
`-1`	Auto
`0`	Off
`1`	Conservative
`2`	Aggressive

zeroobjnodes *(integer)*: Zero objective heuristic control ↩

Note that this heuristic is only applied at the end of the MIP root, and only when no other root heuristic finds a feasible solution.

This heuristic is quite expensive, and generally produces poor quality solutions. You should generally only use it if other means, including exploration of the tree with default settings, fail to produce a feasible solution.

Default: `-1`

5.17.8 Setting up a GAMS/Gurobi-Link license

The GAMS/Gurobi-Link requires two licenses:

- A GAMS license with components GAMS/GUROBI-Link and GAMS/BASE (to generate models beyond the demo limits)

- A Gurobi license which you need to get directly from Gurobi

An attempt to use the GAMS/Gurobi solver with a GAMS/Gurobi-Link license but without a properly set up Gurobi license will result in a licensing error with a message describing the problem. For example, the following message is sent to the log when attempting to solve a model with dimensions beyond the community limits:

```
--- Executing GUROBI (Solvelink=2): elapsed 0:00:00.047[LST:85]

Gurobi           32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window

Gurobi link license.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
```

Starting with GAMS distribution 24.7, even demo sized models require a license from Gurobi. An attempt to solve a demo sized model without a Gurobi license installed results in:

```
--- Executing GUROBI (Solvelink=2): elapsed 0:00:00.016[LST:208]

Gurobi           32.2.0 rc62c018 Released Aug 26, 2020 WEI x86 64bit/MS Window

*** This solver runs with a demo license. No commercial use.
GAMS/Gurobi demo/community requires a Gurobi license from Gurobi Optimization.
*** Cannot initialize Gurobi environment.
*** Could be a missing or invalid license. (status=10009|10009)
```

To make the GAMS/Gurobi-Link work you do **not** need to download or install the Gurobi software but only your Gurobi license. GAMS will use it's own Gurobi DLL/shared library, so the **Gurobi license has to be valid for the Gurobi version GAMS uses**. You can download your Gurobi license from www.gurobi.com. Log in to your Gurobi account and go to `Download & Licenses` –> `Your Gurobi licenses`.

Now click on the license you want to download and click on `Get License Details`. On the license detail page, copy the `grbgetkey` command on the bottom.

Paste the `grbgetkey` command to a command/terminal prompt. Your GAMS system directory contains the `grbgetkey` program, so to make sure it is found you should open the terminal via GAMS Studio or add your GAMS system directory to the path variable. After running the `grbgetkey` command, you will be asked where you would like to save your Gurobi license.

```
$ ./grbgetkey [...]
info  : grbgetkey version 9.0.3, build v9.0.3rc0
info  : Contacting Gurobi key server...
info  : Key for license ID [...] was successfully retrieved
info  : License expires at the end of the day on 2021-08-31
info  : Saving license key...

In which directory would you like to store the Gurobi license key file?
[hit Enter to store it in /opt/gurobi]: /home/nb/gurobilic

info  : License [...] written to file /home/nb/gurobilic/gurobi.lic
info  : You may have saved the license key to a non-default location
info  : You need to set the environment variable GRB_LICENSE_FILE before you can use this license key
info  : GRB_LICENSE_FILE=/home/nb/gurobilic/gurobi.lic
```

Once you have saved your `gurobi.lic` file, you need to make GAMS/Gurobi aware of that license via environment variable `GRB_LICENSE_FILE`. The `environmentVariables` section in the GAMS configuration file (available as of GAMS version 31.1.0) is a convenient way to set the `GRB_LICENSE_FILE` environment variable. This can either be done by manually opening and editing the `gamsconfig.yaml` file which can be found in one of the standard locations or via the corresponding GAMS Configuration Editor in GAMS Studio. As a result, the configuration file should contain an entry for environment variable `GRB_LICENSE_FILE` that points to the Gurobi license, e.g.

```
[...]
environmentVariables:
  [...]
  - GRB_LICENSE_FILE:
      value: /home/nb/gurobilic/gurobi.lic
[...]
```

As an alternative you could also set `GRB_LICENSE_FILE` via the usual OS-specific ways to set environment variables.

To test whether the license setup has been successful, you can solve a model from the GAMS Model library, e.g. **[INDUS89]**, where you should get the following output.

```
$ gamslib indus89
Copy ASCII : indus89.gms
$ gams indus89 lp gurobi
--- Job indus89 Start 09/01/20 12:41:41 32.2.0 rc62c018 LEX-LEG x86 64bit/Linux
[...]
Gurobi           32.2.0 rc62c018 Released Aug 26, 2020 LEG x86 64bit/Linux

Gurobi link license.
Gurobi library version 9.0.3

       0    7.1618935e+31   2.041808e+32   7.161894e+01      0s
    2990    1.1487366e+05   0.000000e+00   0.000000e+00      0s

Solved in 2990 iterations and 0.32 seconds
Optimal objective  1.148736556e+05

User-callback calls 3040, time in user-callback 0.00 sec
LP status(2): Model was solved to optimality (subject to tolerances).
--- Reading solution for model wsisn
*** Status: Normal completion
--- Job indus89.gms Stop 09/01/20 12:29:49 elapsed 0:00:00.835
```

Note

To install a Gurobi license key as described above, the `grbgetkey` program needs to be able to communicate with the Gurobi website. If it fails to work, the `grbprobe` program which can also be found in your GAMS system directory may be used to retrieve the required hardware information which then needs to be manually submitted to the Gurobi Website (detailed instructions can be found here).

5.18 Gather-Update-Solve-Scatter (GUSS)

5.18.1 Introduction

The purpose of this chapter is to detail an extension of the GAMS modeling system that allows collections of models (parameterized exogenously by a set of samples or indices) to be described, instantiated, and solved efficiently.

As a specific example, we consider the parametric optimization problem $\mathcal{P}(s)$ defined by:

$$\min_{x \in X(s)} f(x;s) \text{ s.t. } g(x;s) \leq 0 \tag{5.11}$$

where $s \in S = \{1, \ldots, K\}$. Note that each scenario s represents a different problem for which the optimization variable is x. The form of the constraint set as given above is simply for concreteness; equality constraints and range and bound constraints are trivial extensions of the above framework. Clearly the problems $\mathcal{P}(s)$ are interlinked. We intend to show how such problems can be easily specified within GAMS, and detail one type of algorithmic extension that can exploit the nature of the linkage. Other extensions of GAMS allow solves to be executed in parallel or by using grid computing resources. Note that in our description we will use the terms indexed, parameterized, and scenario somewhat interchangeably. An extended version of this chapter containing several examples is available as a paper at http://www.gams.com/modlib/adddocs/gusspaper.pdf.

5.18.2 Design Methodology

One of the most important functions of GAMS is to build a model instance from the collection of equations (i.e. an optimization model defined by the GAMS keyword `MODEL`) and corresponding data (consisting of the content of GAMS (sub)sets and parameters). Such a model instance is constructed or generated when the GAMS execution system executes a `SOLVE` statement. The generated model instance is passed to a solver which searches for a solution of this model instance and returns status information, statistics, and a (primal and dual) solution of the model instance. After the solver terminates, GAMS brings the solution back into the GAMS database, i.e. it updates the level (`.L`) and marginal (`.M`) fields of variable and equation symbols used in the model instance. Hence, the `SOLVE` statement can be interpreted as a complex operator against the GAMS database. The model instance generated by a `SOLVE` statement only lives during the execution of this one statement, and hence has no representation within the GAMS language. Moreover, its structure does fit the relational data model of GAMS. A model instance consists of vectors of bounds and right hand sides, a sparse matrix representation of the Jacobian, a representation of the non-linear expressions that allow the efficient calculation of gradient vectors and Hessian matrices, and so on.

This chapter is concerned with solving collections of models that have similar structure but modified data. As an example, consider a linear program of the form:

$$\min c^T x \text{ s.t. } Ax \geq b,\ \ell \leq x \leq u.$$

The data in this problem is (A, b, c, ℓ, u). Omitting some details, the following code could be used within GAMS to solve a collection of such linear programs in which each member of the collection has a different A matrix and lower bound ℓ:

```
Set       i / ... /, j / ... /;
Parameter A(i,j), b(i);
Variable  x(j), z, ...;
Equation  e(i), ...;
e(i).. sum(j, A(i,j)*x(j)) =g= b(i);
...
```

```
model mymodel /all/;

Set s / s1*s10 /
Parameter
    A_s(s,i,j) 'Scenario data'
    xlo_s(s,j) 'Scenario lower bound for variable x'
    xl_s(s,j)  'Scenario solution for x.l'
    em_s(s,i)  'Scenario solution for e.m';
Loop(s,
  A(i,j) = A_s(s,i,j);
  x.lo(j)= xlo_s(s,j);
  solve mymodel min z using lp;
  xl_s(s,j) = x.l(j);
  em_s(s,i) = e.m(i);
);
```

Summarizing, we solve one particular model (`mymodel`) in a loop over `s` with an unchanged model rim (i.e. the same individual variables and equations) but with different model data and different bounds for the variables. The change in model data for a subsequent solve statement does not depend on the previous model solutions in the loop.

The purpose of this new Gather-Update-Solve-Scatter (GUSS) manager is to provide syntax at the GAMS modeling level that makes an instance of a problem that provides limited access to treat that instance as an object, and allows the modeler to update portions of it iteratively. Specifically, we provide syntax that gives a list of data changes to an instance, and allows these changes to be applied sequentially to the instance (which is then solved without returning to GAMS). Thus, we can simulate a limited set of actions to be applied to the model instance object and retrieve portions of the solution of these changed instances back in the modeling environment. Such changes can be done to any model type in GAMS, including nonlinear problems and mixed integer models. However, the only changes we allow are to named parameters appearing in the equations and lower and upper bounds used in the model definition.

Thus, in the above example GUSS allows us to replace lines 15-21 by

```
Set dict / s.   scenario. ''
           A.   param.    A_s
           x.   lower.    xlo_s
           x.   level.    xl_s
           e.   marginal. em_s   /;
solve mymodel min z using lp scenario dict;
```

The three dimensional `set dict` (you can freely choose the name of this symbol) contains mapping information between symbols in the model (in the first position) and symbols that supply required update data or store solution information (in the third position), and the type of update/storing (in the second position). An exception to this rule is the tuple with label `scenario` in the second position. This tuple determines the symbol (in the first position) that is used as the scenario index. This scenario symbol can be a multidimensional set. A tuple in this set represents a single scenario. The remaining tuples in the `set dict` can be grouped into input and output tuples. Input tuples determine the modifications of the model instance prior to solving, while output tuples determine which part of the solution gets saved away. The following keywords can be used in the second position of the set `dict`:

Type	Keywords	Description
Input:	`param`	Supplies scenario data for a parameter used in the model
	`lower`	Supplies scenario lower bounds for a variable
	`upper`	Supplies scenario upper bounds for a variable
	`fixed`	Supplies scenario fixed bounds for a variable
Output:	`level`	Stores the levels of a scenario solution of variable or equation
	`marginal`	Stores the marginals of a scenario solution of variable or equation

Sets in the model cannot be updated. GUSS works as follows: GAMS generates the model instance for the original data. As with regular `SOLVE` statements, all the model data (e.g. parameter `A`) needs to be defined at this time. The model instance with the original data is also called the *base case*. The solution of the base case is reported back to GAMS in the regular way and is accessible via the regular `.L` and `.M` fields after the `SOLVE` statement. After solving the base case, the update data for the first scenario is applied to the model. The tuples with `lower`, `upper`, `fixed` update the bounds of the variables, whereas the tuples with `param` update the parameters in the model.

The scenario index `s` needs to be the first index in the parameters mapped in the `set dict`. The update of the model parameters goes far beyond updating the coefficients of the constraint matrix/objective function or the right hand side of an equation, as one can do with some other systems. GAMS stores all the necessary expressions of the constraints with the model instance, so the change in the constraint matrix coefficient is the result of an expression evaluation. For example, consider a term in the calculation of the cost for shipping a variable amount of goods `x(i,j)` between cities `i` and `j`. The expression for shipping cost is `d(i,j)*f*x(i,j)`, i.e. the distance between the cities times a freight rate `f` times the variable amount of goods. In order to find out the sensitivity of the solution with respect to the freight rate `f`, one can solve the same model with different values for `f`. In a matrix representation of the model one would need to calculate the coefficient of `x(i,j)` which is `d(i,j)*f`, but with GUSS it is sufficient to supply different values for `f` that potentially result in many modified coefficients on the matrix level. GUSS evaluates the shipping cost term and communicates the resulting matrix coefficient to the solver reliably behind the scenes.

After the variable bound and the model parameter updates have been applied and the resulting updates to the model instance data structures (e.g. constraint matrix) has been determined, the modified model instance is passed to the solver. Some solvers (e.g. Cplex, Gurobi, SoPlex, and Xpress) allow modifying a model instance. In these cases GUSS only communicates the changes from the previous model instance to the solver. This reduces the amount of data communicated to the solver and also, in the case of an LP model, allows the solver to restart from an advanced basis and its factorization. In the case of an NLP model, this provides initial values. After the solver determines the solution of a model instance, GUSS stores the part of the solution requested by the output tuples of `dict` to some GAMS parameters and continues with the next scenario. GUSS emphasizes on speed and only works with solver that allow to communicate the model instance through memory, Hence, the following solvers cannot be used as subsolvers of GUSS: ALPHAECP, BARON, CONVERT, DECISC, DECISM, DICOPT, EXAMINER, GAMSCHK, JAMS, KESTREL, LOGMIP, MILES, MPSGE, NLPEC, PATHNLP, SBB.

5.18.3 GUSS Options

The execution of GUSS can be parameterized using some options. Options are not passed through a solver option file but via another tuple in the `dict` set. The keyword in the second position of this tuple is `opt`. A one dimensional parameter is expected in the first position (or the label `&prime;&prime;`). This parameter may contain some of the following labels with values:

Options	Description
`OptfileInit`:	Option file number for the first solve (default from GAMS OptFile setting)
`Optfile`:	Option file number for subsequent solves (default 0)
`LogOption`:	Determines amount of log output: `0` - Moderate log (default) `1` - Minimal log `2` - Detailed log
`NoHotStart`:	Disable hot start capability in solver that supports hot starts (default 0)
`NoMatchLimit`:	Limit of unmatched scenario records (default 0)
`RestartType`::	Determines restart point for the scenarios `0` - Restart from last solution (default) `1` - Restart from solution of base case `2` - Restart from input point

Options	Description
SkipBaseCase:	Switch for solving the base case (0 solves the base case)
ReportLastScen:	Switch for reporting the solution of the last scenario rather than solution of the base case (default 0)
SolveEmpty:	Limit of solved empty scenarios, afterwards empty scenarios will be skipped (default 0)
UpdateType:	Scenario update mechanism: 0 - Set everything to zero and apply changes (default) 1 - Reestablish base case and apply changes 2 - Build on top of last scenario and apply changes

For the example model above the UpdateType setting would mean:

```
UpdateType=0:  loop(s, A(i,j) = A_s(s,i,j))
UpdateType=1:  loop(s, A(i,j) = A_base(i,j);
                       A(i,j) $= A_s(s,i,j))
UpdateType=2:  loop(s, A(i,j) $= A_s(s,i,j))
```

The option SkipBaseCase=1 allows the user to skip the base case. This means only the scenarios are solved and there is no solution reported back to GAMS in the traditional way. The third position in the opt-tuple can contain a parameter for storing the scenario solution attribute information, e.g. model and solve status, or needs to have the label ′′. The labels to store solution status information must be known to GAMS, so one needs to declare a set with such labels. A convenient way to enter these attributes is via System.GUSSModelAttributes:

```
Set ma 'GUSS Model Attributes' / System.GUSSModelAttributes /; display ma;

----      1 SET ma  GUSS Model Attributes

ModelStat,    SolveStat,    NumInfes ,    SumInfes ,    IterUsd
ResUsd   ,    ObjVal   ,    NodUsd   ,    ObjEst   ,    DomUsd
RObj     ,    MaxInfes ,    MeanInfes
```

The following example shows how to use some of the GUSS options and the use of a parameter to store some solution status information:

```
Set h solution headers / System.GUSSModelAttributes /;
Parameter
   o / SkipBaseCase 1, UpdateType 1, Optfile 1 /
   r_s(s,h) Solution status report;
Set dict / s.   scenario. ''
           o.   opt.      r_s
           a.   param.    a_s
           x.   lower.    xlo_s
           x.   level.    xl_s
           e.   marginal. em_s   /;
solve mymodel min z using lp scenario dict;
```

Please note that the domain set of the solution status report attributes (here h) must only contain model attributes known to GUSS. If this domain (unless the domain in $*$) contains a label unknown to GUSS, a compilation error is triggered.

5.18.4 Implementation Details

This section describes some technical details that may provide useful insight in case of unexpected behavior.

Because GUSS changes all model parameters mentioned in the `dict` set to variables, a linear model can produce some non-linear instructions (e.g. `d(i,j)*f*x(i,j)` becomes a non-linear expression since `f` becomes a variable in the model instance given to GUSS). This also explains why some models compile without complaint, but if the model is used in the context of GUSS, the compile time check of the model will fail because a parameter that is turned into a variable can no longer be used in that way. For example, suppose the model contains a constraint `e(i).. sum(j$A(i,j), ...)`. If `A(i,j)` is a parameter in the regular model, the compiler will not complain, but if `A` becomes a parameter that shows up in the first position of a `param` tuple in the `dict` set, the GAMS compiler will turn `A` into a variable and complain that an endogenous variable cannot be used in a `$`-condition.

The sparsity pattern of a model can be greatly affected by GUSS. In a regular model instance GAMS will only generate and pass on non-zero matrix elements of a constraint `e(i).. sum(j, A(i,j)*x(j)) ...`, so the sparsity of `A` determines the sparsity of the generated model instance. GUSS allows to use this constraint with different values for `A` hence GUSS cannot exclude any of the pairs `(i,j)` and generate a dense matrix. The user can enforce some sparsity by explicitly restricting the `(i,j)` pairs: `e(i).. sum(ij(i,j), A(i,j)*x(j)) ...`

Attention

> While GUSS is available for many model types quadratic models require special attention. Linear solvers that have been extended to cover (convex) quadratic models, e.g. Cplex, Gurobi, Mosek, Xpress, do not work properly if the modifying parameter affects the left hand side of linear equations or any modifications of quadratic equations. Bound updates as well as changes of the right hand side of linear constraints are okay (see the example of the quadratic support vector machine below). Unfortunately, detecting if a quadratic model is okay or not for a given solver is at the moment difficult to detect, so use caution with quadratic models in combination with such (linear) solvers.

The actual change of the GAMS language required for the implementation of GUSS is minimal. The only true change is the extension of the `SOLVE` statement with the term `SCENARIO dict`. Existing language elements have been used to store symbol mapping information, options, and model result statistics. Some parts of the GUSS presentation look somewhat unnatural, e.g. since `dict` is a three dimensional `set` the specification the scenario `set` using keyword `scenario` requires a third dummy label `&prime;&prime;`. However, this approach gives maximum flexibility for future extension, allows reliable consistency checks at compile and execution time, and allows the user to delay the commitment for significant and permanent syntax changes of a developing method to handle model instances at a GAMS language level.

5.18.5 Applications

5.18.5.1 Cross Validation in GAMS via GUSS

Cross validation is a statistical/machine learning technique that aims to evaluate the generalizability of a classifier (or other decision) process. It does this by setting aside a portion of the data for testing, and uses the remaining data entries to produce the classifier. The testing data is subsequently used to evaluate how well the classifier works. Cross validation performs this whole process a number of times in order to estimate the true power of the classifier.

Ten-fold cross validation is a special case, where the original data is split into ten pieces, and cross validation is performed using each of these ten pieces as the testing set. Thus, the training process is performed ten times, each of which uses the data obtained by deleting the testing set from the whole dataset. We show below how to carry this out using the Gather-Update-Solve-Scatter (GUSS) facility in GAMS.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available here.

GUSS formulation in GAMS

The following example compares the two formulations for a feature-selection model under cross-validation using data files a_data.inc and b_data.inc . The actual source code for both of these GAMS formulations is available here.

Original GAMS formulation (without the GAMS/DEA interface):

```
$title Ten-fold cross validation example
$eolcom !

$setglobal num_folds 10

set a 'set for category 1'         /1*1505/
    b 'set for category 2'         /1*957/
    o 'observations'               /1*14/
    p 'folds to perform'           /1*%num_folds%/
    f 'maximum features to select' /1*10/

* Read in the data from the data files
parameter a_data(a, o) /
$offlisting
$include "a_data.inc"
$onlisting
/;

parameter b_data(b, o) /
$offlisting
$include "b_data.inc"
$onlisting
/;

set a_test(p,a), b_test(p,b) 'testing sets'
    a_trai(a),   b_trai(b)   'training sets';

* Define problem
scalar w_tol /1/
       features /6/;

positive variables a_err(a), sla(a)
                   b_err(b), slb(b);

variables c,
          weight(o),
          gamma;

binary variable y(o);

equations w_def1(o),
          w_def2(o),
          y_def,
          c_def,
          a_def(a),
          b_def(b);

w_def1(o)..
```

```
        weight(o) =l= w_tol*y(o);

w_def2(o)..
        weight(o) =g= -w_tol*y(o);

y_def..
        sum(o, y(o)) =e= features;

c_def..
        c =e= sum(a, a_err(a)) + sum(b, b_err(b));

a_def(a)..
        -sum(o, a_data(a, o)*weight(o)) + gamma + 1 =l= a_err(a) + sla(a);

b_def(b)..
         sum(o, b_data(b, o)*weight(o)) - gamma + 1 =l= b_err(b) + slb(b);

model train /all/;

$batinclude gentestset.inc "p,a" "p,b"

set headers 'report' / modelstat, solvestat, objval /;
parameter rep(p,headers);

The batinclude file gentestset.inc . gives instructions for generating the testing sets. It produces a_test and b_test that detail which equations are left out on solve p.

The actual model is set up to include all the data points in the equations a_def and b_def. To delete the equations that correspond to the test set, we introduce nonnegative slack variables into all the equations. We then set the upper bounds of the slack variables to zero in equations corresponding to the training set, and to infinity in equations corresponding to the testing set. At the same time we fix the error measures a_err and b_err belonging to the testing set by setting their upper bounds to zero. Thus the testing set equations are always satisfiable by choice of the slack variables alone - essentially they are discarded from

the model as required. An alternative formulation could "include" the data equations that you need in each scenario, but the update from one scenario to the next in the defining data is much larger.

Cross validation formulated using GUSS: This model essentially mimics what the standard model does, but the implementation of the solver loop behind the scenes is much more efficient, and the consquences are that are clear to see if you execute both model runs. The changes are in the last 40 lines of the GAMS code.

bfree(p,b)$b_test(p,b) = inf;

option mip=xpress, optcr=0, optca=0;
solve train using mip minimizing c scenario dict;
display scenrep, gval;
```

Firstly, parameters `aupper`, `bupper`, `afree` and `bfree` are used to set the bounds on the error and slack variables in the testing set equations respectively. The setting of the upper bounds are governed by the syntax shown in the controlling set dict. Furthermore, the output of the classifier (`w,gamma`) for each fold of the cross validation uses the dict set to place results into the parameters `wval` and `gval` respectively. Finally, the GUSS options are used to guarantee that the subsequent solves are instructed to process solver

options (`Optfile 1`) which instruct the solver to use the previous solution to start the branch-and-cut process (`loadmipsol=1`).

The complete data and model files for this example are found in (galaxy zip archive). The data and model for a second instance based on the Wisconsin Diagnostic Breast Cancer Database is downloadable as (wdbc zip archive).

Quadratic Programs

GUSS is not limited to linear programs, but can be used more generally. Simple (indexed) quadratic models can be solved using GUSS. The following example illustrates the use of GUSS for quadratic programs. In this example, a support vector machine is used to determine a linear classifier that separates data into two categories. We use the following model:

$$\begin{array}{ll} \text{Min}_{w,g,z} & (1/2)\|w\|2^2 + Ce^T z \\ \text{subject to} & D(Aw - g) + z \geq 1 \\ & z \geq 0 \end{array} \tag{5.12}$$

Here, A is a matrix containing the training data (patients by features) and D is a diagonal matrix with values $+1$ or -1 (each denoting one of the two classes). C is a parameter weighting the importance of maximizing the margin between the classes $(2/\|w\|_2)$ versus minimizing the misclassification error (z). The solution w and g are used to define a separating hyperplane $\{x|w^T x = g\}$ to classify (unseen) data points.

As given, the standard linear support vector machine is not a slice model per se. It becomes a slice model under cross-validation training, where it is solved multiple times on different pieces of data. In this case, only the data A and D vary between solves, appropriately fitting the definition of a slice model.

The data for this example comes from the Wisconsin Diagnosis Breast Cancer Database, and is available here . The data was converted to the GAMS file wdbc.gms , which defines A and D. The actual source code for the following GAMS formulation is available here.

The GUSS formulation for quadratic svm:

```
$title Ten-fold cross validation example using GUSS
$eolcom !

$setglobal num_folds 10

set p /1*%num_folds%/;  ! folds to perform

! Read in data
$include "wdbc.gms"

set test(p,i);          ! testing set

! Define problem
parameter C /1/;
positive variables z(i);
variables obj, w(k), gamma, slack(i);

equations obj_def, sep_def(i);

obj_def..  obj =e= 1/2*sum(k, sqr(w(k))) + C*sum(i, z(i));
sep_def(i)..
```

```
          D(i)*(sum(k, A(i,k)*w(k)) - gamma) + z(i) + slack(i) =g= 1;

model train /all/;

! Generate testing sets (to be deleted in each problem)
loop(p,
$batinclude gentestset2.inc "p,i"
);

set headers report / modelstat, solvestat, objval /;
parameter
    scenrep(p,headers)
    scopt / SkipBaseCase 1, LogOption 2 /;

set dict / p.    scenario.''
           scopt.opt.     scenrep
           z.    upper.   iupper
           slack.upper.   ifree /;

Parameter iupper(p,i), ifree(p,i);
iupper(p,i)$(not test(p,i)) = inf;
ifree(p,i)$test(p,i)        = inf;

option qcp=conopt, optcr=0, optca=0;
solve train using qcp minimizing obj scenario dict;
display scenrep;
```

Because the problem is quadratic, we must use a quadratic program solver. The variable values for weight and gamma could be saved for later testing using the same method as detailed above for the linear case.

The batinclude file gentestset2.inc is very similar to gentestset.inc from the earlier cross-validation examples. In gentestset2.inc, though, only one set is being dealt with rather than two. The complete source GAMS code for this formulation is available in this zip archive.

5.18.5.2 DEA Modeling in GAMS via GUSS

Data Envelopment Analysis (DEA) models can be solved most efficiently in GAMS using the Gather-Update-Solve-Scatter (GUSS) facility. This is the preferred method since release 23.7 of GAMS and hence the GAMS/DEA solver is no longer available.

A paper with the title "GUSS: Solving Collections of Data Related Models within GAMS" that contains two additional application examples for GUSS is available here.

Introduction

The basic (CCR) DEA model is a collection of models indexed by k and defined by

$$\begin{array}{lll} \max_{u,v} & u^T Y_{*,k} & \text{(objective slice)} \\ \text{subject to} & v^T X_{*,k} = 1 & \text{(slice constraint)} \\ & u^T Y \le v^T X & \text{(core constraint)} \\ & u, v \ge 0 & \text{(core constraint)} \end{array} \tag{5.13}$$

where X, Y are data matrices.

Without using GUSS in GAMS, a model would be defined and solved in a loop over k, requiring the model to be generated multiple times with different instances for each value of k. GUSS is an alternative (and more efficient) way to define the individual programs and pass them to any underlying GAMS solver. In this way, individual programs are not re-generated, but are instead defined as data modifications of each other. This reduces overall model generation time. Further, previous solutions can be used as starting points in later solves to speed up overall processing time.

Some DEA examples compare the two formulations. The actual source code for both of these formulations is available here.

DEA Examples

Original GAMS formulation (without GUSS): In all these models the model setup and data are given at the top of the file and the code of interest is in the last 10 or so lines. In this setting we loop over the set k and change the data in the objective function and the first constraint of the model explicitly before each solve. We only output a minimal summary of the solution.

```
$title Data  Envelopment Analysis - DEA

$ontext
Data Envelopment Analysis (DEA) is a technique for measuring the relative
performance of organizational units where presence of multiple inputs and
outputs makes comparison difficult.

            efficiency = weighted sum of output / weighted sum of input

Find weights that maximize the efficiency for one unit while ensuring
that no other units has an efficiency < 1 using these weights. A primal
and dual formulation is presented.

solve dea using lp max eff scenario dict;
```

```
display scenrep,eff_k;
```

In the GUSS version we indicate the collection of models to be solved using the set `dict`. The first element of `dict` determines the set to be used for the scenario (collection) index, in this case k. The second element of dict then details that in each scenario k, the parameter slice is instantiated using a slice of the parameter data. Essentially, this corresponds to the GAMS statement:

slice(j) = data(k,j)

Note the scenario index k must appear as the first index of the parameter data. The third element of `dict` allows the modeler to collect information from each solve and store it into a GAMS parameter. Essentially, the third element of `dict` corresponds to the GAMS statement:

eff_k(k) = eff.l

that gets executed immediately after the solve of scenario k.

More complex scenario models can also be formulated using GUSS, including multiple equations being updated. This is shown by the dual of the basic DEA model, given by

$$\begin{array}{lcl} \min_{z,\lambda} & z & \text{(objective)} \\ \text{subject to} & X^*\lambda \leq zX_{*,k} & \text{(slice constraint)} \\ & Y^*\lambda \geq Y_{*,k} & \text{(slice constraint)} \\ & \lambda \geq 0 & \text{(core constraint)} \end{array} \tag{5.14}$$

The next example compares the two formulations for this model. The actual source code for both of these formulations is available here.

Original GAMS formulation (without GUSS):

```
$title Data Envelopment Analysis - DEA (traditional)

Extensions of these models to formulations with weighted outputs or variable returns to scale are easy to formulate with the scenario solver within GAMS. This extended model can be downloaded here.

The **DEA model** in the model library is similar to the extended model, but does not make use of GUSS.

5.19 HiGHS

HiGHS is an optimization package for solving continuous and mixed-integer linear programming problems

(LPs and MIPs) using simplex, interior-point, and branch-and-cut algorithms. HiGHS is developed by the Edinburgh Research Group in Optimization.

For more detailed information on the implemented simplex method, we refer to [98].

5.19.1 Usage

The following statement can be used inside your GAMS program to specify using HiGHS

```
Option MIP = HIGHS;     { or LP or RMIP }
```

The above statement should appear before the Solve statement. If HiGHS was specified as the default solver during GAMS installation, the above statement is not necessary.

5.19.1.1 Specification of HiGHS Options

GAMS/HiGHS supports the GAMS parameters reslim, iterlim, nodlim. optca, optcr, cutoff, and threads.

Options can be specified by a HiGHS options file. A HiGHS options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a highs.opt file is:

```
solver = ipm
ipm_optimality_tolerance = 1e-6
run_crossover = false
```

It causes HiGHS to use an interior point solver for an LP solve, increases the optimality tolerance to 10^{-6}, and turns off crossover to a basis solution.

5.19.2 List of HiGHS Options

In the following, we give a detailed list of all HiGHS options.

Option	Description	Default
dual_feasibility_tolerance	Dual feasibility tolerance Range: [1e-10, ∞]	1e-07
infinite_bound	Limit on |constraint bound|: values greater than or equal to this will be treated as infinite Range: [1e+15, ∞]	1e+20
infinite_cost	Limit on |cost coefficient|: values greater than or equal to this will be treated as infinite Range: [1e+15, ∞]	1e+20
ipm_iteration_limit	Iteration limit for IPM solver Range: {0, ..., ∞}	GAMS iterlim

Option	Description	Default
ipm_optimality_tolerance	IPM optimality tolerance Range: [1e-12, ∞]	1e-08
large_matrix_value	Upper limit on |matrix entries|: values greater than or equal to this will be treated as infinite Range: [1, ∞]	1e+15
mip_abs_gap	Tolerance on absolute gap of MIP, |ub-lb|, to determine whether optimality has been reached for a MIP instance Range: [0, ∞]	GAMS optca
mip_detect_symmetry	Whether MIP symmetry should be detected Range: boolean	1
mip_feasibility_tolerance	MIP feasibility tolerance Range: [1e-10, ∞]	1e-06
mip_heuristic_effort	Effort spent for MIP heuristics Range: [0, 1]	0.05
mip_lp_age_limit	Maximal age of dynamic LP rows before they are removed from the LP relaxation in the MIP solver Range: {0, ..., 32767}	10
mip_max_improving_sols	Limit on the number of improving solutions found to stop the MIP solver prematurely Range: {1, ..., ∞}	∞
mip_max_leaves	MIP solver max number of leave nodes Range: {0, ..., ∞}	∞
mip_max_nodes	MIP solver max number of nodes Range: {0, ..., ∞}	GAMS nodlim, if > 0, ∞ otherwise
mip_max_stall_nodes	MIP solver max number of nodes where estimate is above cutoff bound Range: {0, ..., ∞}	∞
mip_min_cliquetable_entries_for_parallelism	Minimal number of entries in the MIP solver cliquetable before neighbourhood queries of the conflict graph use parallel processing Range: {0, ..., ∞}	100000
mip_min_logging_interval	MIP minimum logging interval Range: [0, ∞]	5
mip_pool_age_limit	Maximal age of rows in the MIP solver cutpool before they are deleted Range: {0, ..., 1000}	30
mip_pool_soft_limit	Soft limit on the number of rows in the MIP solver cutpool for dynamic age adjustment Range: {1, ..., ∞}	10000

Option	Description	Default
mip_pscost_minreliable	Minimal number of observations before MIP solver pseudo costs are considered reliable Range: {0, ..., ∞}	8
mip_rel_gap	Tolerance on relative gap, |ub-lb|/|ub|, to determine whether optimality has been reached for a MIP instance Range: [0, ∞]	GAMS optcr
mipstart	Whether to pass initial level values as starting point to MIP solver If the solution is not feasible, HiGHS will solve the LP obtained from fixing all discrete variables to their initial level values. Range: boolean	0
objective_bound	Objective bound for termination of the dual simplex solver Range: real	GAMS cutoff
objective_target	Objective target for termination of the MIP solver Range: real	-∞
output_flag	Enables or disables solver output Range: boolean	0, if GAMS logoption = 0, otherwise 1
parallel	Parallel option: "off", "choose" or "on" Range: string	choose
presolve	Presolve option: "off", "choose" or "on" Range: string	choose
primal_feasibility_tolerance	Primal feasibility tolerance Range: [1e-10, ∞]	1e-07
random_seed	Random seed used in HiGHS Range: {0, ..., ∞}	0
run_crossover	Run IPM crossover: "off", "choose" or "on" Range: string	on
sensitivity	Whether to run sensitivity analysis after solving an LP with a simplex method Range: boolean	0
simplex_dual_edge_weight_strategy	Strategy for simplex dual edge weights: Choose / Dantzig / Devex / Steepest Edge (-1/0/1/2) Range: {-1, ..., 2}	-1
simplex_iteration_limit	Iteration limit for simplex solver when solving LPs, but not subproblems in the MIP solver Range: {0, ..., ∞}	GAMS iterlim
simplex_max_concurrency	Maximum level of concurrency in parallel simplex Range: {1, ..., 8}	8

Option	Description	Default
simplex_primal_edge_weight_strategy	Strategy for simplex primal edge weights: Choose / Dantzig / Devex / Steepest Edge (-1/0/1/2) Range: {-1, ..., 2}	-1
simplex_scale_strategy	Simplex scaling strategy: off / choose / equilibration / forced equilibration / max value 0 / max value 1 (0/1/2/3/4/5) Range: {0, ..., 5}	1
simplex_strategy	Strategy for simplex solver 0 => Choose; 1 => Dual (serial); 2 => Dual (PAMI); 3 => Dual (SIP); 4 => Primal Range: {0, ..., 4}	1
simplex_update_limit	Limit on the number of simplex UPDATE operations Range: {0, ..., ∞}	5000
small_matrix_value	Lower limit on |matrix entries|: values less than or equal to this will be treated as zero Range: [1e-12, ∞]	1e-09
solution_file	Solution file Range: string	<inputname>.sol
solver	LP algorithm to run: "simplex", "choose", or "ipm"; ignored for MIP Range: string	choose
solvetrace	Name of file for writing solving progress information during MIP solve Range: string	
solvetracenodefreq	Frequency in number of nodes for writing to solve trace file Range: {0, ..., ∞}	100
solvetracetimefreq	Frequency in seconds for writing to solve trace file Range: [0, ∞]	5
threads	Number of threads used by HiGHS (0: automatic) Range: {0, ..., ∞}	GAMS threads
time_limit	Time limit (seconds) Range: [0, ∞]	GAMS reslim
write_model_file	Write model file Range: string	<inputname>.lp
write_model_to_file	Write the model to a file Range: boolean	0

Option	Description	Default
write_solution_style	Style of solution file (raw = computer-readable, pretty = human-readable): -1 => HiGHS old raw (deprecated); 0 => HiGHS raw; 1 => HiGHS pretty; 2 => Glpsol raw; 3 => Glpsol pretty; 4 => HiGHS sparse raw Range: {-1, ..., 4}	0
write_solution_to_file	Write the primal and dual solution to a file Range: boolean	0
Options for expert users		
allow_unbounded_or_infeasible	whether to spend extra effort to distinguish unboundedness and infeasibility if necessary Range: boolean	0
allowed_cost_scale_factor	Largest power-of-two factor permitted when scaling the costs Range: {0, ..., 20}	0
allowed_matrix_scale_factor	Largest power-of-two factor permitted when scaling the constraint matrix Range: {0, ..., 30}	20
cost_scale_factor	Scaling factor for costs Range: {-20, ..., 20}	0
dual_simplex_cost_perturbation_multiplier	Dual simplex cost perturbation multiplier: 0 => no perturbation Range: [0, ∞]	1
dual_simplex_pivot_growth_tolerance	Dual simplex pivot growth tolerance Range: [1e-12, ∞]	1e-09
dual_steepest_edge_weight_error_tolerance	Tolerance on dual steepest edge weight errors Range: [0, ∞]	∞
dual_steepest_edge_weight_log_error_threshold	Threshold on dual steepest edge weight errors for Devex switch Range: [1, ∞]	10
factor_pivot_threshold	Matrix factorization pivot threshold Range: [0.0008, 0.5]	0.1
factor_pivot_tolerance	Matrix factorization pivot tolerance Range: [0, 1]	1e-10
highs_analysis_level	Analysis level in HiGHS Range: {0, ..., 63}	0
highs_debug_level	Debugging level in HiGHS Range: {0, ..., 3}	0
icrash	Run iCrash Range: boolean	0
icrash_approx_iter	iCrash approximate minimization iterations Range: {0, ..., 100}	50

Option	Description	Default
icrash_breakpoints	Exact subproblem solution for iCrash Range: boolean	0
icrash_dualize	Dualize strategy for iCrash Range: boolean	0
icrash_exact	Exact subproblem solution for iCrash Range: boolean	0
icrash_iterations	iCrash iterations Range: {0, ..., 200}	30
icrash_starting_weight	iCrash starting weight Range: [1e-10, 1e+50]	0.001
icrash_strategy	Strategy for iCrash Range: string	ICA
ipx_dualize_strategy	Strategy for dualizing before IPX Range: {-1, ..., 3}	2
less_infeasible_DSE_check	Check whether LP is candidate for LiDSE Range: boolean	1
less_infeasible_DSE_choose_row	Use LiDSE if LP has right properties Range: boolean	1
log_dev_level	Output development messages: 0 => none; 1 => info; 2 => verbose Range: {0, ..., 3}	0
lp_presolve_requires_basis_postsolve	Prevents LP presolve steps for which postsolve cannot maintain a basis Range: boolean	1
max_dual_simplex_cleanup_level	Max level of dual simplex cleanup Range: {0, ..., ∞}	1
max_dual_simplex_phase1_cleanup_level	Max level of dual simplex phase 1 cleanup Range: {0, ..., ∞}	2
mip_report_level	MIP solver reporting level Range: {0, ..., 2}	1
no_unnecessary_rebuild_refactor	No unnecessary refactorization on simplex rebuild Range: boolean	1
presolve_pivot_threshold	Matrix factorization pivot threshold for substitutions in presolve Range: [0.0008, 0.5]	0.01
presolve_reduction_limit	Limit on number of presolve reductions -1 => no limit Range: {-1, ..., ∞}	-1
presolve_rule_logging	Log effectiveness of presolve rules for LP Range: boolean	0

Option	Description	Default
presolve_rule_off	Bit mask of presolve rules that are not allowed Range: {0, ..., ∞}	0
presolve_substitution_maxfillin	Maximal fillin allowed for substitutions in presolve Range: {0, ..., ∞}	10
primal_simplex_bound_perturbation_multiplier	Primal simplex bound perturbation multiplier: 0 => no perturbation Range: [0, ∞]	1
rebuild_refactor_solution_error_tolerance	Tolerance on solution error when considering refactorization on simplex rebuild Range: real	1e-08
simplex_crash_strategy	Strategy for simplex crash: off / LTSSF / Bixby (0/1/2) Range: {0, ..., 9}	0
simplex_dualize_strategy	Strategy for dualizing before simplex Range: {-1, ..., 1}	-1
simplex_initial_condition_check	Perform initial basis condition check in simplex Range: boolean	1
simplex_initial_condition_tolerance	Tolerance on initial basis condition in simplex Range: [1, ∞]	1e+14
simplex_min_concurrency	Minimum level of concurrency in parallel simplex Range: {1, ..., 8}	1
simplex_permute_strategy	Strategy for permuting before simplex Range: {-1, ..., 1}	-1
simplex_price_strategy	Strategy for PRICE in simplex Range: {0, ..., 3}	3
simplex_unscaled_solution_strategy	Strategy for solving unscaled LP in simplex Range: {0, ..., 2}	1
start_crossover_tolerance	Tolerance to be satisfied before IPM crossover will start Range: [1e-12, ∞]	1e-08
use_implied_bounds_from_presolve	Use relaxed implied bounds from presolve Range: boolean	0
use_original_HFactor_logic	Use original HFactor logic for sparse vs hyper-sparse TRANs Range: boolean	1

5.20 IPOPT and IPOPTH

COIN-OR IPOPT (**I**nterior **P**oint **Opt**imizer) is an open-source solver for large-scale nonlinear programming (NLP). The code has been written primarily by Andreas Wächter.

IPOPT implements an interior point line search filter method for nonlinear programming models which functions can be nonconvex, but should be twice continuously differentiable. For more information on the algorithm we refer to [144] [196] [195] [197] [194] and the IPOPT documentation. Most of the IPOPT documentation in the section was taken from the IPOPT manual [104] .

5.20.1 Available linear solvers

The performance and robustness of IPOPT on larger models heavily relies on the used solver for sparse symmetric indefinite linear systems.

GAMS/IPOPT includes the sparse solver MUMPS [8] [9] (currently the default), and MKL PARDISO [166] [167]. The latter is not available for systems on ARM64 CPUs. In the commerically licensed GAMS/IPOPTH version, also the Harwell Subroutine Library (HSL) solvers MA27, MA57, HSL_MA86, and HSL_MA97 are available and MA27 is used by default.

MUMPS, MA57, HSL_MA86, and HSL_MA97 use METIS for matrix ordering [103], see also the METIS manual . METIS is copyrighted by the regents of the University of Minnesota.

IPOPT and IPOPTH can exploit parallelization of the linear solvers MKL Pardiso, HSL MA86, and HSL MA97 and the linear algebra routines (see next section).

The linear solver is chosen by the linear_solver option. Benchmarks have shown that MA57 and HSL_MA97 are often able to outperform MA27 on larger instances. Further, PARDISO often allows for performance that is better than MUMPS and similar to the HSL solvers. If IPOPT fails to solve an instance with PARDISO, it's worth to try changing the options pardisomkl_order and pardisomkl_max_iterative_refinement_steps.

It is also possible to use the linear solver PARDISO from the PARDISO Solver Project or the HSL routines with GAMS/IPOPT if a user provides libraries that can be loaded at runtime. PARDISO from the PARDISO Solver Project can provide performance that exceeds the one of PARDISO from Intel MKL. To build the HSL routines, COIN-OR project ThirdParty-HSL may be useful. See also options linear_solver, linear_system_scaling, nlp_scaling_method, pardisolib, and hsllib. Note that it is your responsibility to ensure that you are entitled to download and use these routines!

5.20.2 The linear algebra library

On systems for AMD and Intel CPUs, the IPOPT library distributed by GAMS and most of the linear solvers used by IPOPT use the Intel oneAPI Math Kernel Library (MKL), which provides a fast and parallel implementation of linear algebra routines (BLAS/LAPACK) and the linear solver PARDISO. MKL chooses an internal code path that provides the best possible performance for the used CPU type. As a consequence, results can be different when changing from one CPU to another. By setting an environment variable, the code path to use can be set by the user. See the Intel MKL documentation regarding Conditional Numerical Reproducibility for more details.

Intel MKL has been optimized for use with Intel CPUs. On CPUs from other vendors, MKL may not use an internal code path that could provide a better performance on that CPU. For example, it may not use AVX2 instructions on an AMD CPU that provides AVX2. However, Intel recently started to add optimized code for AMD's Zen CPUs.

To gain more insight into the use of MKL in GAMS/IPOPT, one may set the environment variable MKL_VERBOSE to 1. This will print out information about the MKL library used, functions being called, time spend there, etc.

On the GAMS system for macOS on ARM64 CPUs, the Apple Accelerate framework is used as linear algebra library.

5.20.3 Usage

The following statement can be used inside your GAMS program to specify using IPOPT

```
Option NLP = IPOPT;      { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

The above statement should appear before the Solve statement. If IPOPT was specified as the default solver during GAMS installation, the above statement is not necessary.

To use IPOPTH, the statement should be

```
Option NLP = IPOPTH;     { or LP, RMIP, DNLP, RMINLP, QCP, RMIQCP, CNS }
```

5.20.3.1 Specification of Options

IPOPT has many options that can be adjusted for the algorithm (see Section List of IPOPT Options). Options are all identified by a string name, and their values can be of one of three types: Number (real), Integer, or String. Number options are used for things like tolerances, integer options are used for things like maximum number of iterations, and string options are used for setting algorithm details, like the NLP scaling method. Options can be set by creating a `ipopt.opt` file in the directory you are executing IPOPT.

The `ipopt.opt` file is read line by line and each line should contain the option name, followed by whitespace, and then the value. Comments can be included with the `#` symbol. For example, the following is a valid `ipopt.opt` file:

```
# This is a comment

# Turn off the NLP scaling
nlp_scaling_method none

# Change the initial barrier parameter
mu_init 1e-2

# Set the max number of iterations
max_iter 500
```

GAMS/IPOPT understands currently the following GAMS parameters: reslim (time limit), iterlim (iteration limit), domlim (domain violation limit). Further the option threads can be used to control the number of threads used in the linear algebra routines and the linear solver. Setting `threads=0` currently does not enable multithreaded linear algebra.

5.20.3.2 Warmstarting IPOPT

As an interior point solver, it is difficult to warm start IPOPT. By default, only the level values of the variables are passed as starting point to IPOPT. Setting the IPOPT option warm_start_init_point to `yes` enables that also dual values for variables and constraints are passed to IPOPT.

However, the expected behavior that IPOPT finishes within one iteration if optimal primal and dual values are passed is not reached this way, yet. This is, because IPOPT by default moves any initial value that is close to a bound into the interior. The amount on how much the initial point is moved can be controlled by various `bound_push` and `bound_frac` options. To make IPOPT accept an optimal primal/dual solution within one iteration, it should be sufficient to set the following options:

```
warm_start_init_point       yes
warm_start_bound_push       1e-9
warm_start_bound_frac       1e-9
warm_start_slack_bound_frac 1e-9
warm_start_slack_bound_push 1e-9
warm_start_mult_bound_push  1e-9
```

Further, it can be useful to specify that IPOPT can use a less central path in its first iterations by reducing the value of option mu_init. This option is only used if option mu_strategy is set to "monotone", so the option file entries would be

```
mu_strategy monotone
mu_init     0.0001
```

Finally, IPOPT by default checks whether it should scale the problem. The computed scaling depends on the starting point, which can be undesired when warmstarting. Thus, it may be useful to turn off scaling via option nlp_scaling_method:

```
nlp_scaling_method none
```

If a modified but structually equivalent problem instance is solved, e.g., via GUSS, option warm_start_init_point is automatically set to "yes" for every solve following the first one. If this is not desired, warm_start_init_point should explicitly be set to "no" in an IPOPT options file.

5.20.4 Output

This section describes the standard IPOPT console output. The output is designed to provide a quick summary of each iteration as IPOPT solves the problem.

Before IPOPT starts to solve the problem, it displays the problem statistics (number of nonzero-elements in the matrices, number of variables, etc.). Note that if you have fixed variables (both upper and lower bounds are equal), IPOPT may remove these variables from the problem internally and not include them in the problem statistics.

Following the problem statistics, IPOPT will begin to solve the problem and you will see output resembling the following,

```
iter    objective    inf_pr   inf_du lg(mu)  ||d||  lg(rg) alpha_du alpha_pr  ls
   0  1.6109693e+01 1.12e+01 5.28e-01   0.0 0.00e+00    -  0.00e+00 0.00e+00   0
   1  1.8029749e+01 9.90e-01 6.62e+01   0.1 2.05e+00    -  2.14e-01 1.00e+00f  1
   2  1.8719906e+01 1.25e-02 9.04e+00  -2.2 5.94e-02   2.0 8.04e-01 1.00e+00h  1
```

and the columns of output are defined as

item

The current iteration count. This includes regular iterations and iterations while in restoration phase. If the algorithm is in the restoration phase, the letter `r` will be appended to the iteration number.

objective

The unscaled objective value at the current point. During the restoration phase, this value remains the unscaled objective value for the original problem.

inf_pr

The unscaled constraint violation at the current point. This quantity is the infinity-norm (max) of the (unscaled) constraint violation. During the restoration phase, this value remains the constraint violation of the original problem at the current point. The option inf_pr_output can be used to switch to the printing of a different quantity. During the restoration phase, this value is the primal infeasibility of the original problem at the current point.

inf_du

The scaled dual infeasibility at the current point. This quantity measure the infinity-norm (max) of the internal dual infeasibility (Eq. (4a) in [197]), including inequality constraints reformulated using slack variables and problem scaling. During the restoration phase, this is the value of the dual infeasibility for the restoration phase problem.

lg(mu)

$\log_{10}$ of the value of the barrier parameter μ.

||d||

The infinity norm (max) of the primal step (for the original variables `x` and the internal slack variables `s`). During the restoration phase, this value includes the values of additional variables, `p` and `n` in Eq. (10) of [197] .

lg(rg)

$\log_{10}$ of the value of the regularization term for the Hessian of the Lagrangian in the augmented system (δ_w in Eq. (26) of [197]). A dash (`-`) indicates that no regularization was done.

alpha_du

The stepsize for the dual variables (α_k^z in Eq. (14c) of [197]).

alpha_pr

The stepsize for the primal variables (α_k in Eq. (14a) of [197]). The number is usually followed by a character for additional diagnostic information regarding the step acceptance criterion:

- `f`: f-type iteration in the filter method w/o second order correction
- `F`: f-type iteration in the filter method w/ second order correction
- `h`: h-type iteration in the filter method w/o second order correction
- `H`: h-type iteration in the filter method w/ second order correction
- `k`: penalty value unchanged in merit function method w/o second order correction

- `K`: penalty value unchanged in merit function method w/ second order correction
- `n`: penalty value updated in merit function method w/o second order correction
- `N`: penalty value updated in merit function method w/ second order correction
- `R`: Restoration phase just started
- `w`: in watchdog procedure
- `s`: step accepted in soft restoration phase
- `t`/`T`: tiny step accepted without line search
- `r`: some previous iterate restored

ls

The number of backtracking line search steps (does not include second-order correction steps).

Note that the step acceptance mechanisms in IPOPT consider the barrier objective function (Eq. (3a) in [197]) which is usually different from the value reported in the `objective` column. Similarly, for the purposes of the step acceptance, the constraint violation is measured for the internal problem formulation, which includes slack variables for inequality constraints and potentially scaling of the constraint functions. This value, too, is usually different from the value reported in `inf_pr`. As a consequence, a new iterate might have worse values both for the objective function and the constraint violation as reported in the iteration output, seemingly contradicting globalization procedure.

When the algorithm terminates, IPOPT will output a message to the screen. The following is a list of the possible output messages and a brief description.

Optimal Solution Found.

This message indicates that IPOPT found a (locally) optimal point within the desired tolerances.

Solved To Acceptable Level.

This indicates that the algorithm did not converge to the "desired" tolerances, but that it was able to obtain a point satisfying the "acceptable" tolerance level as specified by `acceptable-`$*$ options. This may happen if the desired tolerances are too small for the current problem.

Feasible point for square problem found.

This message is printed if the problem is "square" (i.e., it has as many equality constraints as free variables) and IPOPT found a point that is feasible w.r.t. constr_viol_tol. It may, however, not be feasible w.r.t. tol.

Converged to a point of local infeasibility. Problem may be infeasible.

The restoration phase converged to a point that is a minimizer for the constraint violation (in the ℓ_1-norm), but is not feasible for the original problem. This indicates that the problem may be infeasible (or at least that the algorithm is stuck at a locally infeasible point). The returned point (the minimizer of the constraint violation) might help you to find which constraint is causing the problem. If you believe that the NLP is feasible, it might help to start the optimization from a different point.

Search Direction is becoming Too Small.

This indicates that IPOPT is calculating very small step sizes and making very little progress. This could happen if the problem has been solved to the best numerical accuracy possible given the current scaling.

Iterates divering; problem might be unbounded.

This message is printed if the max-norm of the iterates becomes larger than the value of the option diverging_iterates_tol. This can happen if the problem is unbounded below and the iterates are diverging.

Stopping optimization at current point as requested by user.

This message is printed if either an interrupt signal was received (e.g., Ctrl+C was pressed) or the domain violation limit is reached.

Maximum Number of Iterations Exceeded.

This indicates that IPOPT has exceeded the maximum number of iterations as specified by the IPOPT option max_iter or the GAMS option iterlim.

Maximum wallclock time exceeded.

This indicates that IPOPT has exceeded the maximum number of wallclock seconds as specified by the IPOPT option max_wall_time or the GAMS option reslim.

Maximum CPU time exceeded.

This indicates that IPOPT has exceeded the maximum number of CPU seconds as specified by the IPOPT option max_cpu_time.

Restoration Failed!

This indicates that the restoration phase failed to find a feasible point that was acceptable to the filter line search for the original problem. This could happen if the problem is highly degenerate, does not satisfy the constraint qualification, or if an external or extrinsic function in GAMS provides incorrect derivative information.

Error in step computation!

This messages is printed if IPOPT is unable to compute a step towards a new iterate and the current iterate is not acceptable for the specified tolerances.

A possible reason is that a search direction could not be computed despite several attempts to modify the iteration matrix. Usually, the value of the regularization parameter then becomes too large.

Another reason is that the feasibility restoration phase could not be activated because the current iterate is not infeasible. Reasons for this again include that the problem is highly degenerate, badly scaled, or does not satisfy the constraint qualification. Before IPOPT 3.14, this resulted in a Restoration_Failed status code with message "Restoration phase is called at almost feasible point...".

Problem has too few degrees of freedom.

This indicates that your problem, as specified, has too few degrees of freedom. This can happen if you have too many equality constraints, or if you fix too many variables (IPOPT removes fixed variables by default, see also the option fixed_variable_treatment).

Not enough memory.

An error occurred while trying to allocate memory. The problem may be too large for your current memory and swap configuration. Sometimes it can help to choose a different linear solver.

INTERNAL ERROR: Unknown SolverReturn value - Notify IPOPT Authors.

An unknown internal error has occurred. Please notify the authors of the GAMS/IPOPT link or IPOPT (refer to support@gams.com).

5.20.4.1 Diagnostic Tags for IPOPT

To print additional diagnostic tags for each iteration of IPOPT, set the options print_info_string to `yes`. With this, a tag will appear at the end of an iteration line with the following diagnostic meaning that are useful to flag difficulties for a particular IPOPT run. The following is a list of possible strings:

- `!`: Tighten resto tolerance if only slightly infeasible, see Sec. 3.3 in [197]
- `A`: Current iteration is acceptable (alternate termination)
- `a`: Perturbation for PD Singularity can't be done, assume singular, see Sec. 3.1 in [197]
- `C`: Second Order Correction taken, see Sec. 2.4 in [197]
- `Dh`: Hessian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- `Dhj`: Hessian/Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- `Dj`: Jacobian degenerate based on multiple iterations, see Sec. 3.1 in [197]
- `dx`: δ_x perturbation too large, see Sec. 3.1 in [197]
- `e`: Cutting back α due to evaluation error (in backtracking line search)
- `F-`: Filter should be reset, but maximal resets exceeded, see Sec. 2.3 in [197]
- `F+`: Resetting filter due to last few rejections of filter, see Sec. 2.3 in [197]
- `L`: Degenerate Jacobian, δ_c already perturbed, see Sec. 3.1 in [197]
- `l`: Degenerate Jacobian, δ_c perturbed, see Sec. 3.1 in [197]
- `M`: Magic step taken for slack variables (in backtracking line search)
- `Nh`: Hessian not yet degenerate, see Sec. 3.1 in [197]
- `Nhj`: Hessian/Jacobian not yet degenerate, see Sec. 3.1 in [197]
- `Nj`: Jacobian not yet degenerate, see Sec. 3.1 in [197]
- `NW`: Warm start initialization failed (in Warm Start Initialization)
- `q`: PD system possibly singular, attempt to improve solution quality, see Sec. 3.1 in [197]
- `R`: Solution of restoration phase, see Sec. 3.3 in [197]
- `S`: PD system possibly singular, accept current solution, see Sec. 3.1 in [197]
- `s`: PD system singular, see Sec. 3.1 in [197]
- `s`: Square Problem. Set multipliers to zero (default initialization routine)
- `Tmax`: Trial θ is larger than $\theta_{\max}$ (filter parameter, Eq. (21) in [197])
- `W`: Watchdog line search procedure successful, see Sec. 3.2 in [197]
- `w`: Watchdog line search procedure unsuccessful, stopped, see Sec. 3.2 in [197]
- `Wb`: Undoing most recent SR1 update, see Sec. 5.4.1 in [23]
- `We`: Skip Limited-Memory Update in restoration phase, see Sec. 5.4.1 in [23]
- `Wp`: Safeguard $B^0 = \sigma I$ for Limited-Memory Update, see Sec. 5.4.1 in [23]
- `Wr`: Resetting Limited-Memory Update, see Sec. 5.4.1 in [23]
- `Ws`: Skip Limited-Memory Update since $s^T y$ is not positive, see Sec. 5.4.1 in [23]
- `WS`: Skip Limited-Memory Update since Δx is too small, see Sec. 5.4.1 in [23]
- `y`: Dual infeasibility, use least square multiplier update (during IPOPT algorithm)
- `z`: Apply correction to bound multiplier if too large (during IPOPT algorithm)

5.20.5 List of IPOPT Options

5.20.5.1 Termination

Option	Description	Default
acceptable_compl_inf_tol	"Acceptance" threshold for the complementarity conditions.	0.01
acceptable_constr_viol_tol	"Acceptance" threshold for the constraint violation.	0.01
acceptable_dual_inf_tol	"Acceptance" threshold for the dual infeasibility.	1e+10
acceptable_iter	Number of "acceptable" iterates before triggering termination.	0
acceptable_obj_change_tol	"Acceptance" stopping criterion based on objective function change.	1e+20
acceptable_tol	"Acceptable" convergence tolerance (relative).	1e-06
compl_inf_tol	Desired threshold for the complementarity conditions.	0.0001
constr_viol_tol	Desired threshold for the constraint and variable bound violation.	1e-06
diverging_iterates_tol	Threshold for maximal value of primal iterates.	1e+20
dual_inf_tol	Desired threshold for the dual infeasibility.	1
max_cpu_time	Maximum number of CPU seconds.	1e+20
max_iter	Maximum number of iterations.	GAMS iterlim
max_wall_time	Maximum number of walltime clock seconds.	GAMS reslim
mu_target	Desired value of complementarity.	0
tol	Desired convergence tolerance (relative).	1e-08
Options for expert users		
s_max	Scaling threshold for the NLP error.	100

5.20.5.2 Output

Option	Description	Default
inf_pr_output	Determines what value is printed in the "inf_pr" output column.	original
print_eval_error	Switch to enable printing information about function evaluation errors into the GAMS listing file.	yes
print_frequency_iter	Determines at which iteration frequency the summarizing iteration output line should be printed.	1
print_frequency_time	Determines at which time frequency the summarizing iteration output line should be printed.	0
print_info_string	Enables printing of additional info string at end of iteration output.	no
print_level	Output verbosity level.	5
print_options_mode	format in which to print options documentation	text
print_timing_statistics	Switch to print timing statistics.	no

Option	Description	Default
report_mininfeas_solution	Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible.	no
Options for expert users		
print_advanced_options	whether to print also advanced options	no

5.20.5.3 NLP

Option	Description	Default
bound_relax_factor	Factor for initial relaxation of the bounds.	1e-10
check_derivatives_for_naninf	Indicates whether it is desired to check for Nan/Inf in derivative matrices	no
fixed_variable_treatment	Determines how fixed variables should be handled.	make_parameter
honor_original_bounds	Indicates whether final points should be projected into original bounds.	no
Options for expert users		
dependency_detection_with_rhs	Indicates if the right hand sides of the constraints should be considered in addition to gradients during dependency detection	no
dependency_detector	Indicates which linear solver should be used to detect linearly dependent equality constraints.	none
kappa_d	Weight for linear damping term (to handle one-sided bounds).	1e-05

5.20.5.4 NLP Scaling

Option	Description	Default
nlp_scaling_max_gradient	Maximum gradient after NLP scaling.	100
nlp_scaling_method	Select the technique used for scaling the NLP.	gradient-based if GAMS scaleopt is not set, otherwise none
nlp_scaling_min_value	Minimum value of gradient-based scaling values.	1e-08
Options for expert users		
nlp_scaling_constr_target_gradient	Target value for constraint function gradient size.	0
nlp_scaling_obj_target_gradient	Target value for objective function gradient size.	0

5.20.5.5 Initialization

Option	Description	Default
bound_frac	Desired minimum relative distance from the initial point to bound.	0.01
bound_mult_init_method	Initialization method for bound multipliers	constant
bound_mult_init_val	Initial value for the bound multipliers.	1

Option	Description	Default
bound_push	Desired minimum absolute distance from the initial point to bound.	0.01
constr_mult_init_max	Maximum allowed least-square guess of constraint multipliers.	1000
least_square_init_duals	Least square initialization of all dual variables	no
least_square_init_primal	Least square initialization of the primal variables	no
slack_bound_frac	Desired minimum relative distance from the initial slack to bound.	0.01
slack_bound_push	Desired minimum absolute distance from the initial slack to bound.	0.01

5.20.5.6 Warm Start

Option	Description	Default
warm_start_bound_frac	same as bound_frac for the regular initializer	0.001
warm_start_bound_push	same as bound_push for the regular initializer	0.001
warm_start_init_point	Warm-start for initial point	yes, if run on modified model instance (e.g., from GUSS), otherwise no
warm_start_mult_bound_push	same as mult_bound_push for the regular initializer	0.001
warm_start_mult_init_max	Maximum initial value for the equality multipliers.	1e+06
warm_start_slack_bound_frac	same as slack_bound_frac for the regular initializer	0.001
warm_start_slack_bound_push	same as slack_bound_push for the regular initializer	0.001
Options for expert users		
warm_start_target_mu		0

5.20.5.7 Miscellaneous

Option	Description	Default
timing_statistics	Indicates whether to measure time spend in components of Ipopt and NLP evaluation	no
Options for expert users		
replace_bounds	Whether all variable bounds should be replaced by inequality constraints	no

5.20.5.8 Barrier Parameter Update

Option	Description	Default
adaptive_mu_globalization	Globalization strategy for the adaptive mu selection mode.	obj-constr-filter
barrier_tol_factor	Factor for mu in barrier stop test.	10

Option	Description	Default
fixed_mu_oracle	Oracle for the barrier parameter when switching to fixed mode.	average_compl
mu_init	Initial value for the barrier parameter.	0.1
mu_linear_decrease_factor	Determines linear decrease rate of barrier parameter.	0.2
mu_max	Maximum value for barrier parameter.	100000
mu_max_fact	Factor for initialization of maximum value for barrier parameter.	1000
mu_min	Minimum value for barrier parameter.	1e-11
mu_oracle	Oracle for a new barrier parameter in the adaptive strategy.	quality-function
mu_strategy	Update strategy for barrier parameter.	adaptive
mu_superlinear_decrease_power	Determines superlinear decrease rate of barrier parameter.	1.5
quality_function_max_section_steps	Maximum number of search steps during direct search procedure determining the optimal centering parameter.	8
Options for expert users		
adaptive_mu_kkt_norm_type	Norm used for the KKT error in the adaptive mu globalization strategies.	2-norm-squared
adaptive_mu_kkterror_red_fact	Sufficient decrease factor for "kkt-error" globalization strategy.	0.9999
adaptive_mu_kkterror_red_iters	Maximum number of iterations requiring sufficient progress.	4
adaptive_mu_monotone_init_factor	Determines the initial value of the barrier parameter when switching to the monotone mode.	0.8
adaptive_mu_restore_previous_iterate	Indicates if the previous accepted iterate should be restored if the monotone mode is entered.	no
filter_margin_fact	Factor determining width of margin for obj-constr-filter adaptive globalization strategy.	1e-05
filter_max_margin	Maximum width of margin in obj-constr-filter adaptive globalization strategy.	1
mu_allow_fast_monotone_decrease	Allow skipping of barrier problem if barrier test is already met.	yes
quality_function_balancing_term	The balancing term included in the quality function for centrality.	none
quality_function_centrality	The penalty term for centrality that is included in quality function.	none
quality_function_norm_type	Norm used for components of the quality function.	2-norm-squared
quality_function_section_qf_tol	Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space).	0
quality_function_section_sigma_tol	Tolerance for the section search procedure determining the optimal centering parameter (in sigma space).	0.01

Option	Description	Default
sigma_max	Maximum value of the centering parameter.	100
sigma_min	Minimum value of the centering parameter.	1e-06
tau_min	Lower bound on fraction-to-the-boundary parameter tau.	0.99

5.20.5.9 Line Search

Option	Description	Default
accept_every_trial_step	Always accept the first trial step.	no
alpha_for_y	Method to determine the step size for constraint multipliers (alpha_y) .	primal
alpha_for_y_tol	Tolerance for switching to full equality multiplier steps.	10
max_soc	Maximum number of second order correction trial steps at each iteration.	4
recalc_y	Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates.	no
recalc_y_feas_tol	Feasibility threshold for recomputation of multipliers.	1e-06
soc_method	Ways to apply second order correction	0
watchdog_shortened_iter_trigger	Number of shortened iterations that trigger the watchdog.	10
watchdog_trial_iter_max	Maximum number of watchdog iterations.	3
Options for expert users		
accept_after_max_steps	Accept a trial point after maximal this number of steps even if it does not satisfy line search conditions.	-1
alpha_min_frac	Safety factor for the minimal step size (before switching to restoration phase).	0.05
alpha_red_factor	Fractional reduction of the trial step size in the backtracking line search.	0.5
constraint_violation_norm_type	Norm to be used for the constraint violation in the line search.	1-norm
corrector_compl_avrg_red_fact	Complementarity tolerance factor for accepting corrector step.	1
corrector_type	The type of corrector steps that should be taken.	none
delta	Multiplier for constraint violation in the switching rule.	1
eta_phi	Relaxation factor in the Armijo condition.	1e-08
filter_reset_trigger	Number of iterations that trigger the filter reset.	5
gamma_phi	Relaxation factor in the filter margin for the barrier function.	1e-08
gamma_theta	Relaxation factor in the filter margin for the constraint violation.	1e-05
kappa_sigma	Factor limiting the deviation of dual variables from primal estimates.	1e+10
kappa_soc	Factor in the sufficient reduction rule for second order correction.	0.99

Option	Description	Default
line_search_method	Globalization method used in backtracking line search	filter
max_filter_resets	Maximal allowed number of filter resets	5
nu_inc	Increment of the penalty parameter.	0.0001
nu_init	Initial value of the penalty parameter.	1e-06
obj_max_inc	Determines the upper bound on the acceptable increase of barrier objective function.	5
rho	Value in penalty parameter update formula.	0.1
s_phi	Exponent for linear barrier function model in the switching rule.	2.3
s_theta	Exponent for current constraint violation in the switching rule.	1.1
skip_corr_if_neg_curv	Whether to skip the corrector step in negative curvature iteration.	yes
skip_corr_in_monotone_mode	Whether to skip the corrector step during monotone barrier parameter mode.	yes
slack_move	Correction size for very small slacks.	1.81899e-12
theta_max_fact	Determines upper bound for constraint violation in the filter.	10000
theta_min_fact	Determines constraint violation threshold in the switching rule.	0.0001
tiny_step_tol	Tolerance for detecting numerically insignificant steps.	2.22045e-15
tiny_step_y_tol	Tolerance for quitting because of numerically insignificant steps.	0.01

5.20.5.10 Linear Solver

Option	Description	Default
hsllib	Name of library containing HSL routines for load at runtime	libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)
linear_scaling_on_demand	Flag indicating that linear scaling is only done if it seems required.	yes
linear_solver	Linear solver used for step computations.	ma27, if IpoptH, otherwise mumps
linear_system_scaling	Method for scaling the linear system.	mc19, if IpoptH, otherwise none
pardisolib	Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime	libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)

5.20.5.11 Step Calculation

Option	Description	Default
fast_step_computation	Indicates if the linear system should be solved quickly.	no
first_hessian_perturbation	Size of first x-s perturbation tried.	0.0001

Option	Description	Default
jacobian_regularization_value	Size of the regularization for rank-deficient constraint Jacobians.	1e-08
max_hessian_perturbation	Maximum value of regularization parameter for handling negative curvature.	1e+20
max_refinement_steps	Maximum number of iterative refinement steps per linear system solve.	10
mehrotra_algorithm	Indicates whether to do Mehrotra's predictor-corrector algorithm.	no
min_hessian_perturbation	Smallest perturbation of the Hessian block.	1e-20
min_refinement_steps	Minimum number of iterative refinement steps per linear system solve.	1
neg_curv_test_reg	Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014).	yes
neg_curv_test_tol	Tolerance for heuristic to ignore wrong inertia.	0
perturb_dec_fact	Decrease factor for x-s perturbation.	0.333333
perturb_inc_fact	Increase factor for x-s perturbation.	8
perturb_inc_fact_first	Increase factor for x-s perturbation for very first perturbation.	100
Options for expert users		
jacobian_regularization_exponent	Exponent for mu in the regularization for rank-deficient constraint Jacobians.	0.25
perturb_always_cd	Active permanent perturbation of constraint linearization.	no
residual_improvement_factor	Minimal required reduction of residual test ratio in iterative refinement.	1
residual_ratio_max	Iterative refinement tolerance	1e-10
residual_ratio_singular	Threshold for declaring linear system singular after failed iterative refinement.	1e-05

5.20.5.12 Restoration Phase

Option	Description	Default
bound_mult_reset_threshold	Threshold for resetting bound multipliers after the restoration phase.	1000
constr_mult_reset_threshold	Threshold for resetting equality and inequality multipliers after restoration phase.	0
evaluate_orig_obj_at_resto_trial	Determines if the original objective function should be evaluated at restoration phase trial points.	yes
expect_infeasible_problem	Enable heuristics to quickly detect an infeasible problem.	no
expect_infeasible_problem_ctol	Threshold for disabling "expect_infeasible_problem" option.	0.001
expect_infeasible_problem_ytol	Multiplier threshold for activating "expect_infeasible_problem" option.	1e+08
required_infeasibility_reduction	Required reduction of infeasibility before leaving restoration phase.	0.9
soft_resto_pderror_reduction_factor	Required reduction in primal-dual error in the soft restoration phase.	0.9999

Option	Description	Default
start_with_resto	Whether to switch to restoration phase in first iteration.	no
Options for expert users		
max_resto_iter	Maximum number of successive iterations in restoration phase.	3000000
max_soft_resto_iters	Maximum number of iterations performed successively in soft restoration phase.	10
resto_failure_feasibility_threshold	Threshold for primal infeasibility to declare failure of restoration phase.	0
resto_penalty_parameter	Penalty parameter in the restoration phase objective function.	1000
resto_proximity_weight	Weighting factor for the proximity term in restoration phase objective.	1

5.20.5.13 Hessian Approximation

Option	Description	Default
hessian_approximation	Indicates what Hessian information is to be used.	exact
limited_memory_init_val	Value for B0 in low-rank update.	1
limited_memory_init_val_max	Upper bound on value for B0 in low-rank update.	1e+08
limited_memory_init_val_min	Lower bound on value for B0 in low-rank update.	1e-08
limited_memory_initialization	Initialization strategy for the limited memory quasi-Newton approximation.	scalar1
limited_memory_max_history	Maximum size of the history for the limited quasi-Newton Hessian approximation.	6
limited_memory_max_skipping	Threshold for successive iterations where update is skipped.	2
limited_memory_special_for_resto	Determines if the quasi-Newton updates should be special during the restoration phase.	no
limited_memory_update_type	Quasi-Newton update formula for the limited memory quasi-Newton approximation.	bfgs
Options for expert users		
hessian_approximation_space	Indicates in which subspace the Hessian information is to be approximated.	nonlinear-variables
limited_memory_aug_solver	Strategy for solving the augmented system for low-rank Hessian.	sherman-morrison

5.20.5.14 MA27 Linear Solver

Option	Description	Default
ma27_la_init_factor	Real workspace memory for MA27.	5
ma27_liw_init_factor	Integer workspace memory for MA27.	5
ma27_meminc_factor	Increment factor for workspace size for MA27.	2

Option	Description	Default
ma27_pivtol	Pivot tolerance for the linear solver MA27.	1e-08
ma27_pivtolmax	Maximum pivot tolerance for the linear solver MA27.	0.0001
ma27_print_level	Debug printing level for the linear solver MA27	0
Options for expert users		
ma27_ignore_singularity	Whether to use MA27's ability to solve a linear system even if the matrix is singular.	no
ma27_skip_inertia_check	Whether to always pretend that inertia is correct.	no

5.20.5.15 MA57 Linear Solver

Option	Description	Default
ma57_automatic_scaling	Controls whether to enable automatic scaling in MA57	no
ma57_block_size	Controls block size used by Level 3 BLAS in MA57BD	16
ma57_node_amalgamation	Node amalgamation parameter	16
ma57_pivot_order	Controls pivot order in MA57	5
ma57_pivtol	Pivot tolerance for the linear solver MA57.	1e-08
ma57_pivtolmax	Maximum pivot tolerance for the linear solver MA57.	0.0001
ma57_pre_alloc	Safety factor for work space memory allocation for the linear solver MA57.	1.05
ma57_print_level	Debug printing level for the linear solver MA57	0
ma57_small_pivot_flag	Handling of small pivots	0

5.20.5.16 MA77 Linear Solver

Option	Description	Default
ma77_buffer_lpage	Number of scalars per MA77 in-core buffer page in the out-of-core solver MA77	4096
ma77_buffer_npage	Number of pages that make up MA77 buffer	1600
ma77_file_size	Target size of each temporary file for MA77, scalars per type	2097152
ma77_maxstore	Maximum storage size for MA77 in-core mode	0
ma77_nemin	Node Amalgamation parameter	8
ma77_order	Controls type of ordering used by MA77	metis
ma77_print_level	Debug printing level for the linear solver MA77	-1
ma77_small	Zero Pivot Threshold	1e-20
ma77_static	Static Pivoting Threshold	0
ma77_u	Pivoting Threshold	1e-08
ma77_umax	Maximum Pivoting Threshold	0.0001

5.20.5.17 MA86 Linear Solver

Option	Description	Default
ma86_nemin	Node Amalgamation parameter	32
ma86_order	Controls type of ordering	auto
ma86_print_level	Debug printing level	-1
ma86_scaling	Controls scaling of matrix	mc64
ma86_small	Zero Pivot Threshold	1e-20
ma86_static	Static Pivoting Threshold	0
ma86_u	Pivoting Threshold	1e-08
ma86_umax	Maximum Pivoting Threshold	0.0001

5.20.5.18 MA97 Linear Solver

Option	Description	Default
ma97_nemin	Node Amalgamation parameter	8
ma97_order	Controls type of ordering	auto
ma97_print_level	Debug printing level	-1
ma97_scaling	Specifies strategy for scaling	dynamic
ma97_small	Zero Pivot Threshold	1e-20
ma97_u	Pivoting Threshold	1e-08
ma97_umax	Maximum Pivoting Threshold	0.0001
Options for expert users		
ma97_scaling1	First scaling.	mc64
ma97_scaling2	Second scaling.	mc64
ma97_scaling3	Third scaling.	mc64
ma97_solve_blas3	Controls if blas2 or blas3 routines are used for solve	no
ma97_switch1	First switch, determine when ma97_scaling1 is enabled.	od_hd_reuse
ma97_switch2	Second switch, determine when ma97_scaling2 is enabled.	never
ma97_switch3	Third switch, determine when ma97_scaling3 is enabled.	never

5.20.5.19 Pardiso (pardiso-project.org) Linear Solver

Option	Description	Default
pardiso_matching_strategy	Matching strategy to be used by Pardiso	complete+2x2
pardiso_max_iterative_refinement_steps	Limit on number of iterative refinement steps.	0

Option	Description	Default
pardiso_msglvl	Pardiso message level	0
pardiso_order	Controls the fill-in reduction ordering algorithm for the input matrix.	metis
Options for expert users		
pardiso_iter_coarse_size	Maximum Size of Coarse Grid Matrix	5000
pardiso_iter_dropping_factor	dropping value for incomplete factor	0.5
pardiso_iter_dropping_schur	dropping value for sparsify schur complement factor	0.1
pardiso_iter_inverse_norm_factor		5e+06
pardiso_iter_max_levels	Maximum Size of Grid Levels	10
pardiso_iter_max_row_fill	max fill for each row	10000000
pardiso_iter_relative_tol	Relative Residual Convergence	1e-06
pardiso_iterative	Switch for iterative solver in Pardiso library	no
pardiso_max_droptol_corrections	Maximal number of decreases of drop tolerance during one solve.	4
pardiso_max_iter	Maximum number of Krylov-Subspace Iteration	500
pardiso_redo_symbolic_fact_only_if_inertia_wrong	Toggle for handling case when elements were perturbed by Pardiso.	no
pardiso_repeated_perturbation_means_singular	Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization.	no
pardiso_skip_inertia_check	Whether to pretend that inertia is correct.	no

5.20.5.20 Pardiso (MKL) Linear Solver

Option	Description	Default
pardisomkl_matching_strategy	Matching strategy to be used by Pardiso	complete+2x2
pardisomkl_max_iterative_refinement_steps	Limit on number of iterative refinement steps.	1
pardisomkl_msglvl	Pardiso message level	0
pardisomkl_order	Controls the fill-in reduction ordering algorithm for the input matrix.	metis
Options for expert users		
pardisomkl_redo_symbolic_fact_only_if_inertia_wrong	Toggle for handling case when elements were perturbed by Pardiso.	no
pardisomkl_repeated_perturbation_means_singular	Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization.	no
pardisomkl_skip_inertia_check	Whether to pretend that inertia is correct.	no

5.20.5.21 Mumps Linear Solver

Option	Description	Default
mumps_mem_percent	Percentage increase in the estimated working space for MUMPS.	1000
mumps_permuting_scaling	Controls permuting and scaling in MUMPS	7
mumps_pivot_order	Controls pivot order in MUMPS	7
mumps_pivtol	Pivot tolerance for the linear solver MUMPS.	1e-06
mumps_pivtolmax	Maximum pivot tolerance for the linear solver MUMPS.	0.1
mumps_print_level	Debug printing level for the linear solver MUMPS	0
mumps_scaling	Controls scaling in MUMPS	77
Options for expert users		
mumps_dep_tol	Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS.	0

5.20.6 Detailed Options Description

accept_after_max_steps *(advanced)*: Accept a trial point after maximal this number of steps even if it does not satisfy line search conditions. ↩

Setting this to -1 disables this option.

Range: {-1, ..., ∞}

Default: -1

accept_every_trial_step: Always accept the first trial step. ↩

Setting this option to "yes" essentially disables the line search and makes the algorithm take aggressive steps, without global convergence guarantees.

Range: yes, no

Default: no

acceptable_compl_inf_tol: "Acceptance" threshold for the complementarity conditions. ↩

Absolute tolerance on the complementarity. "Acceptable" termination requires that the max-norm of the (unscaled) complementarity is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 0.01

acceptable_constr_viol_tol: "Acceptance" threshold for the constraint violation. ↩

Absolute tolerance on the constraint violation. "Acceptable" termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 0.01

acceptable_dual_inf_tol: "Acceptance" threshold for the dual infeasibility. ↩

Absolute tolerance on the dual infeasibility. "Acceptable" termination requires that the (max-norm of the unscaled) dual infeasibility is less than this threshold; see also acceptable_tol.

Range: (0, ∞]

Default: 1e+10

acceptable_iter: Number of "acceptable" iterates before triggering termination. ↩

If the algorithm encounters this many successive "acceptable" iterates (see "acceptable_tol"), it terminates, assuming that the problem has been solved to best possible accuracy given round-off. If it is set to zero, this heuristic is disabled.

Range: {0, ..., ∞}

Default: 0

acceptable_obj_change_tol: "Acceptance" stopping criterion based on objective function change. ↩

If the relative change of the objective function (scaled by Max(1,|f(x)|)) is less than this value, this part of the acceptable tolerance termination is satisfied; see also acceptable_tol. This is useful for the quasi-Newton option, which has trouble to bring down the dual infeasibility.

Range: [0, ∞]

Default: 1e+20

acceptable_tol: "Acceptable" convergence tolerance (relative). ↩

Determines which (scaled) overall optimality error is considered to be "acceptable". There are two levels of termination criteria. If the usual "desired" tolerances (see tol, dual_inf_tol etc) are satisfied at an iteration, the algorithm immediately terminates with a success message. On the other hand, if the algorithm encounters "acceptable_iter" many iterations in a row that are considered "acceptable", it will terminate before the desired convergence tolerance is met. This is useful in cases where the algorithm might not be able to achieve the "desired" level of accuracy.

Range: (0, ∞]

Default: 1e-06

adaptive_mu_globalization: Globalization strategy for the adaptive mu selection mode. ↩

To achieve global convergence of the adaptive version, the algorithm has to switch to the monotone mode (Fiacco-McCormick approach) when convergence does not seem to appear. This option sets the criterion used to decide when to do this switch. (Only used if option "mu_strategy" is chosen as "adaptive".)

value	meaning
kkt-error	nonmonotone decrease of kkt-error
obj-constr-filter	2-dim filter for objective and constraint violation
never-monotone-mode	disables globalization

Default: obj-constr-filter

adaptive_mu_kkt_norm_type *(advanced)*: Norm used for the KKT error in the adaptive mu globalization strategies. ↩

When computing the KKT error for the globalization strategies, the norm to be used is specified with this option. Note, this option is also used in the QualityFunctionMuOracle.

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)
2-norm	use 2-norm

Default: 2-norm-squared

adaptive_mu_kkterror_red_fact *(advanced)*: Sufficient decrease factor for "kkt-error" globalization strategy. ↩

For the "kkt-error" based globalization strategy, the error must decrease by this factor to be deemed sufficient decrease.

Range: (0, 1)

Default: 0.9999

adaptive_mu_kkterror_red_iters *(advanced)*: Maximum number of iterations requiring sufficient progress. ↩

For the "kkt-error" based globalization strategy, sufficient progress must be made for "adaptive_mu_kkterror_red_iters" iterations. If this number of iterations is exceeded, the globalization strategy switches to the monotone mode.

Range: {0, ..., ∞}

Default: 4

adaptive_mu_monotone_init_factor *(advanced)*: Determines the initial value of the barrier parameter when switching to the monotone mode. ↩

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode and fixed_mu_oracle is chosen as "average_compl", the barrier parameter is set to the current average complementarity times the value of "adaptive_mu_monotone_init_factor".

Range: (0, ∞]

Default: 0.8

adaptive_mu_restore_previous_iterate *(advanced)*: Indicates if the previous accepted iterate should be restored if the monotone mode is entered. ↩

When the globalization strategy for the adaptive barrier algorithm switches to the monotone mode, it can either start from the most recent iterate (no), or from the last iterate that was accepted (yes).

Range: yes, no

Default: no

alpha_for_y: Method to determine the step size for constraint multipliers (alpha_y) . ↩

value	meaning
primal	use primal step size
bound-mult	use step size for the bound multipliers (good for LPs)
min	use the min of primal and bound multipliers
max	use the max of primal and bound multipliers
full	take a full step of size one
min-dual-infeas	choose step size minimizing new dual infeasibility
safer-min-dual-infeas	like "min_dual_infeas", but safeguarded by "min" and "max"
primal-and-full	use the primal step size, and full step if delta_x $\leq$ alpha_for_y_tol
dual-and-full	use the dual step size, and full step if delta_x $\leq$ alpha_for_y_tol
acceptor	Call LSAcceptor to get step size for y

Default: primal

alpha_for_y_tol: Tolerance for switching to full equality multiplier steps. ↩

This is only relevant if "alpha_for_y" is chosen "primal-and-full" or "dual-and-full". The step size for the equality constraint multipliers is taken to be one if the max-norm of the primal step is less than this tolerance.

Range: [0, ∞]

Default: 10

alpha_min_frac *(advanced)*: Safety factor for the minimal step size (before switching to restoration phase). ↩

This is gamma_alpha in Eqn. (23) in the implementation paper.

Range: (0, 1)

Default: 0.05

alpha_red_factor *(advanced)*: Fractional reduction of the trial step size in the backtracking line search. ↩

At every step of the backtracking line search, the trial step size is reduced by this factor.

Range: (0, 1)

Default: 0.5

barrier_tol_factor: Factor for mu in barrier stop test. ↩

The convergence tolerance for each barrier problem in the monotone mode is the value of the barrier parameter times "barrier_tol_factor". This option is also used in the adaptive mu strategy during the monotone mode. This is kappa_epsilon in implementation paper.

Range: (0, ∞]

Default: 10

bound_frac: Desired minimum relative distance from the initial point to bound. ↩

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: (0, 0.5]

Default: 0.01

bound_mult_init_method: Initialization method for bound multipliers ↩

This option defines how the iterates for the bound multipliers are initialized. If "constant" is chosen, then all bound multipliers are initialized to the value of "bound_mult_init_val". If "mu-based" is chosen, then each value is initialized to the the value of "mu_init" divided by the corresponding slack variable. This latter option might be useful if the starting point is close to the optimal solution.

value	meaning
constant	set all bound multipliers to the value of bound_mult_init_val
mu-based	initialize to mu_init/x_slack

Default: constant

bound_mult_init_val: Initial value for the bound multipliers. ↩

All dual variables corresponding to bound constraints are initialized to this value.

Range: (0, ∞]

Default: 1

bound_mult_reset_threshold: Threshold for resetting bound multipliers after the restoration phase. ↩

After returning from the restoration phase, the bound multipliers are updated with a Newton step for complementarity. Here, the change in the primal variables during the entire restoration phase is taken to be the corresponding primal Newton step. However, if after the update the largest bound multiplier exceeds the threshold specified by this option, the multipliers are all reset to 1.

Range: [0, ∞]

Default: 1000

bound_push: Desired minimum absolute distance from the initial point to bound. ↩

Determines how much the initial point might have to be modified in order to be sufficiently inside the bounds (together with "bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: (0, ∞]

Default: 0.01

bound_relax_factor: Factor for initial relaxation of the bounds. ↩

Before start of the optimization, the bounds given by the user are relaxed. This option sets the factor for this relaxation. Additional, the constraint violation tolerance constr_viol_tol is used to bound the relaxation by an absolute value. If it is set to zero, then then bounds relaxation is disabled. See Eqn.(35) in implementation paper. Note that the constraint violation reported by Ipopt at the end of the solution process does not include violations of the original (non-relaxed) variable bounds. See also option honor_original_bounds.

Range: [0, ∞]

Default: 1e-10

check_derivatives_for_naninf: Indicates whether it is desired to check for Nan/Inf in derivative matrices ↩

Activating this option will cause an error if an invalid number is detected in the constraint Jacobians or the Lagrangian Hessian. If this is not activated, the test is skipped, and the algorithm might proceed with invalid numbers and fail. If test is activated and an invalid number is detected, the matrix is written to output with print_level corresponding to J_MOREDETAILED (7); so beware of large output!

Range: yes, no

Default: no

compl_inf_tol: Desired threshold for the complementarity conditions. ↩

Absolute tolerance on the complementarity. Successful termination requires that the max-norm of the (unscaled) complementarity is less than this threshold.

Range: (0, ∞]

Default: 0.0001

constr_mult_init_max: Maximum allowed least-square guess of constraint multipliers. ↩

Determines how large the initial least-square guesses of the constraint multipliers are allowed to be (in max-norm). If the guess is larger than this value, it is discarded and all constraint multipliers are set to zero. This options is also used when initializing the restoration phase. By default, "resto.constr_mult_init_max" (the one used in RestoIterateInitializer) is set to zero.

Range: [0, ∞]

Default: 1000

constr_mult_reset_threshold: Threshold for resetting equality and inequality multipliers after restoration phase. ↩

After returning from the restoration phase, the constraint multipliers are recomputed by a least square estimate. This option triggers when those least-square estimates should be ignored.

Range: [0, ∞]

Default: 0

constr_viol_tol: Desired threshold for the constraint and variable bound violation. ↩

Absolute tolerance on the constraint and variable bound violation. Successful termination requires that the max-norm of the (unscaled) constraint violation is less than this threshold. If option bound_relax_factor is not zero 0, then Ipopt relaxes given variable bounds. The value of constr_viol_tol is used to restrict the absolute amount of this bound relaxation.

Range: (0, ∞]

Default: 1e-06

constraint_violation_norm_type *(advanced)*: Norm to be used for the constraint violation in the line search. ↩

Determines which norm should be used when the algorithm computes the constraint violation in the line search.

value	meaning
1-norm	use the 1-norm
2-norm	use the 2-norm
max-norm	use the infinity norm

Default: 1-norm

corrector_compl_avrg_red_fact *(advanced)*: Complementarity tolerance factor for accepting corrector step. ↩

This option determines the factor by which complementarity is allowed to increase for a corrector step to be accepted. Changing this option is experimental.

Range: (0, ∞]

Default: 1

corrector_type *(advanced)*: The type of corrector steps that should be taken. ↩

If "mu_strategy" is "adaptive", this option determines what kind of corrector steps should be tried. Changing this option is experimental.

value	meaning
none	no corrector
affine	corrector step towards mu=0
primal-dual	corrector step towards current mu

Default: none

delta *(advanced)*: Multiplier for constraint violation in the switching rule. ↩

See Eqn. (19) in the implementation paper.

Range: (0, ∞]

Default: 1

dependency_detection_with_rhs *(advanced)*: Indicates if the right hand sides of the constraints should be considered in addition to gradients during dependency detection ↩

Range: yes, no

Default: no

dependency_detector *(advanced)*: Indicates which linear solver should be used to detect linearly dependent equality constraints. ↩

This is experimental and does not work well.

value	meaning
none	don't check; no extra work at beginning
mumps	use MUMPS

Default: none

diverging_iterates_tol: Threshold for maximal value of primal iterates. ↩

If any component of the primal iterates exceeded this value (in absolute terms), the optimization is aborted with the exit message that the iterates seem to be diverging.

Range: (0, ∞]

Default: 1e+20

dual_inf_tol: Desired threshold for the dual infeasibility. ↩

Absolute tolerance on the dual infeasibility. Successful termination requires that the max-norm of the (unscaled) dual infeasibility is less than this threshold.

Range: (0, ∞]

Default: 1

eta_phi *(advanced)*: Relaxation factor in the Armijo condition. ↩

See Eqn. (20) in the implementation paper.

Range: (0, 0.5)

Default: 1e-08

evaluate_orig_obj_at_resto_trial: Determines if the original objective function should be evaluated at restoration phase trial points. ↩

Enabling this option makes the restoration phase algorithm evaluate the objective function of the original problem at every trial point encountered during the restoration phase, even if this value is not required. In this way, it is guaranteed that the original objective function can be evaluated without error at all accepted iterates; otherwise the algorithm might fail at a point where the restoration phase accepts an iterate that is good for the restoration phase problem, but not the original problem. On the other hand, if the evaluation of the original objective is expensive, this might be costly.

Range: yes, no

Default: yes

expect_infeasible_problem: Enable heuristics to quickly detect an infeasible problem. ↩

This options is meant to activate heuristics that may speed up the infeasibility determination if you expect that there is a good chance for the problem to be infeasible. In the filter line search procedure, the restoration phase is called more quickly than usually, and more reduction in the constraint violation is enforced before the restoration phase is left. If the problem is square, this option is enabled automatically.

Range: yes, no

Default: no

expect_infeasible_problem_ctol: Threshold for disabling "expect_infeasible_problem" option. ↩

If the constraint violation becomes smaller than this threshold, the "expect_infeasible_problem" heuristics in the filter line search are disabled. If the problem is square, this options is set to 0.

Range: [0, ∞]

Default: 0.001

expect_infeasible_problem_ytol: Multiplier threshold for activating "expect_infeasible_problem" option. ↩

If the max norm of the constraint multipliers becomes larger than this value and "expect_infeasible_problem" is chosen, then the restoration phase is entered.

Range: (0, ∞]

Default: 1e+08

fast_step_computation: Indicates if the linear system should be solved quickly. ↩

If enabled, the algorithm assumes that the linear system that is solved to obtain the search direction is solved sufficiently well. In that case, no residuals are computed to verify the solution and the computation of the search direction is a little faster.

Range: yes, no

Default: no

filter_margin_fact *(advanced)*: Factor determining width of margin for obj-constr-filter adaptive globalization strategy. ↩

When using the adaptive globalization strategy, "obj-constr-filter", sufficient progress for a filter entry is defined as follows: (new obj) < (filter obj) - filter_margin_fact∗(new constr-viol) OR (new constr-viol) < (filter constr-viol) - filter_margin_fact∗(new constr-viol). For the description of the "kkt-error-filter" option see "filter_max_margin".

Range: (0, 1)

Default: 1e-05

filter_max_margin *(advanced)*: Maximum width of margin in obj-constr-filter adaptive globalization strategy. ↩

Range: (0, ∞]

Default: 1

filter_reset_trigger *(advanced)*: Number of iterations that trigger the filter reset. ↩

If the filter reset heuristic is active and the number of successive iterations in which the last rejected trial step size was rejected because of the filter, the filter is reset.

Range: {1, ..., ∞}

Default: 5

first_hessian_perturbation: Size of first x-s perturbation tried. ↩

The first value tried for the x-s perturbation in the inertia correction scheme. This is delta_0 in the implementation paper.

Range: (0, ∞]

Default: 0.0001

fixed_mu_oracle: Oracle for the barrier parameter when switching to fixed mode. ↩

Determines how the first value of the barrier parameter should be computed when switching to the "monotone mode" in the adaptive strategy. (Only considered if "adaptive" is selected for option "mu_strategy".)

value	meaning
probing	Mehrotra's probing heuristic
loqo	LOQO's centrality rule
quality-function	minimize a quality function
average_compl	base on current average complementarity

Default: average_compl

fixed_variable_treatment: Determines how fixed variables should be handled. ↩

The main difference between those options is that the starting point in the "make_constraint" case still has the fixed variables at their given values, whereas in the case "make_parameter(_nodual)" the functions are always evaluated with the fixed values for those variables. Also, for "relax_bounds", the fixing bound constraints are relaxed (according to" bound_relax_factor"). For all but "make_parameter_nodual", bound multipliers are computed for the fixed variables.

value	meaning
make_parameter	Remove fixed variable from optimization variables
make_parameter_nodual	Remove fixed variable from optimization variables and do not compute bound multipliers for fixed variables
make_constraint	Add equality constraints fixing variables
relax_bounds	Relax fixing bound constraints

Default: make_parameter

gamma_phi *(advanced)*: Relaxation factor in the filter margin for the barrier function. ↩

See Eqn. (18a) in the implementation paper.

Range: (0, 1)

Default: 1e-08

gamma_theta *(advanced)*: Relaxation factor in the filter margin for the constraint violation. ↩

See Eqn. (18b) in the implementation paper.

Range: (0, 1)

Default: 1e-05

hessian_approximation: Indicates what Hessian information is to be used. ↩

This determines which kind of information for the Hessian of the Lagrangian function is used by the algorithm.

value	meaning
exact	Use second derivatives provided by the NLP.
limited-memory	Perform a limited-memory quasi-Newton approximation

Default: exact

hessian_approximation_space *(advanced)*: Indicates in which subspace the Hessian information is to be approximated. ↩

value	meaning
nonlinear-variables	only in space of nonlinear variables.
all-variables	in space of all variables (without slacks)

Default: nonlinear-variables

honor_original_bounds: Indicates whether final points should be projected into original bounds. ↩

Ipopt might relax the bounds during the optimization (see, e.g., option "bound_relax_factor"). This option determines whether the final point should be projected back into the user-provide original bounds after the optimization. Note that violations of constraints and complementarity reported by Ipopt at the end of the solution process are for the non-projected point.

Range: yes, no

Default: no

hsllib: Name of library containing HSL routines for load at runtime ↩

Range: string

Default: libhsl.so (Linux), libhsl.dylib (macOS), libhsl.dll (Windows)

inf_pr_output: Determines what value is printed in the "inf_pr" output column. ↩

Ipopt works with a reformulation of the original problem, where slacks are introduced and the problem might have been scaled. The choice "internal" prints out the constraint violation of this formulation. With "original" the true constraint violation in the original NLP is printed.

value	meaning
internal	max-norm of violation of internal equality constraints
original	maximal constraint violation in original NLP

Default: original

jacobian_regularization_exponent *(advanced)*: Exponent for mu in the regularization for rank-deficient constraint Jacobians. ↩

This is kappa_c in the implementation paper.

Range: [0, ∞]

Default: 0.25

jacobian_regularization_value: Size of the regularization for rank-deficient constraint Jacobians. ↩

This is bar delta_c in the implementation paper.

Range: [0, ∞]

Default: 1e-08

kappa_d *(advanced)*: Weight for linear damping term (to handle one-sided bounds). ↩

See Section 3.7 in implementation paper.

Range: [0, ∞]

Default: 1e-05

kappa_sigma *(advanced)*: Factor limiting the deviation of dual variables from primal estimates. ↩

If the dual variables deviate from their primal estimates, a correction is performed. See Eqn. (16) in the implementation paper. Setting the value to less than 1 disables the correction.

Range: (0, ∞]

Default: 1e+10

kappa_soc *(advanced)*: Factor in the sufficient reduction rule for second order correction. ↩

This option determines how much a second order correction step must reduce the constraint violation so that further correction steps are attempted. See Step A-5.9 of Algorithm A in the implementation paper.

Range: (0, ∞]

Default: 0.99

least_square_init_duals: Least square initialization of all dual variables ↩

If set to yes, Ipopt tries to compute least-square multipliers (considering ALL dual variables). If successful, the bound multipliers are possibly corrected to be at least bound_mult_init_val. This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP. This overwrites option "bound_mult_init_method".

value	meaning
no	use bound_mult_init_val and least-square equality constraint multipliers
yes	overwrite user-provided point with least-square estimates

Default: no

least_square_init_primal: Least square initialization of the primal variables ↩

If set to yes, Ipopt ignores the user provided point and solves a least square problem for the primal variables (x and s) to fit the linearized equality and inequality constraints.This might be useful if the user doesn't know anything about the starting point, or for solving an LP or QP.

value	meaning
no	take user-provided point
yes	overwrite user-provided point with least-square estimates

Default: no

limited_memory_aug_solver *(advanced)*: Strategy for solving the augmented system for low-rank Hessian. ↩

value	meaning
sherman-morrison	use Sherman-Morrison formula
extended	use an extended augmented system

Default: sherman-morrison

limited_memory_init_val: Value for B0 in low-rank update. ↩

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: (0, ∞]

Default: 1

limited_memory_init_val_max: Upper bound on value for B0 in low-rank update. ↩

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: (0, ∞]

Default: 1e+08

limited_memory_init_val_min: Lower bound on value for B0 in low-rank update. ↩

The starting matrix in the low rank update, B0, is chosen to be this multiple of the identity in the first iteration (when no updates have been performed yet), and is constantly chosen as this value, if "limited_memory_initialization" is "constant".

Range: (0, ∞]

Default: 1e-08

limited_memory_initialization: Initialization strategy for the limited memory quasi-Newton approximation. ↩

Determines how the diagonal Matrix B_0 as the first term in the limited memory approximation should be computed.

value	meaning
scalar1	sigma = s^Ty/s^Ts
scalar2	sigma = y^Ty/s^Ty
scalar3	arithmetic average of scalar1 and scalar2
scalar4	geometric average of scalar1 and scalar2
constant	sigma = limited_memory_init_val

Default: scalar1

limited_memory_max_history: Maximum size of the history for the limited quasi-Newton Hessian approximation. ↩

This option determines the number of most recent iterations that are taken into account for the limited-memory quasi-Newton approximation.

Range: {0, ..., ∞}

Default: 6

limited_memory_max_skipping: Threshold for successive iterations where update is skipped. ↩

If the update is skipped more than this number of successive iterations, the quasi-Newton approximation is reset.

Range: {1, ..., ∞}

Default: 2

limited_memory_special_for_resto: Determines if the quasi-Newton updates should be special during the restoration phase. ↩

Until Nov 2010, Ipopt used a special update during the restoration phase, but it turned out that this does not work well. The new default uses the regular update procedure and it improves results. If for some reason you want to get back to the original update, set this option to "yes".

Range: yes, no

Default: no

limited_memory_update_type: Quasi-Newton update formula for the limited memory quasi-Newton approximation. ↩

value	meaning
bfgs	BFGS update (with skipping)
sr1	SR1 (not working well)

Default: bfgs

line_search_method *(advanced)*: Globalization method used in backtracking line search ↩

Only the "filter" choice is officially supported. But sometimes, good results might be obtained with the other choices.

value	meaning
filter	Filter method
cg-penalty	Chen-Goldfarb penalty function
penalty	Standard penalty function

Default: filter

linear_scaling_on_demand: Flag indicating that linear scaling is only done if it seems required. ↩

This option is only important if a linear scaling method (e.g., mc19) is used. If you choose "no", then the scaling factors are computed for every linear system from the start. This can

be quite expensive. Choosing "yes" means that the algorithm will start the scaling method only when the solutions to the linear system seem not good, and then use it until the end.

Range: yes, no

Default: yes

linear_solver: Linear solver used for step computations. ↩

Determines which linear algebra package is to be used for the solution of the augmented linear system (for obtaining the search directions). Note, that MA27, MA57, MA86, and MA97 are included with a commercially supported GAMS/IpoptH license only. To use MA27, MA57, MA86, or MA97 with GAMS/Ipopt, or to use HSL_MA77, a HSL library needs to be provided by the user. To use Pardiso from pardiso-project.org, a Pardiso library needs to be provided by the user. **ATTENTION**: Before Ipopt 3.14 (GAMS 36), value ***pardiso*** specified to use Pardiso from Intel MKL. With GAMS 36, this value has been renamed to ***pardisomkl***. On GAMS systems for ARM64 CPUs, option value `pardisomkl` is not available.

value	meaning
ma27	IpoptH: use the Harwell routine MA27; Ipopt: load the Harwell routine MA27 from user-provided library
ma57	IpoptH: use the Harwell routine MA57; Ipopt: load the Harwell routine MA57 from user-provided library
ma77	load the Harwell routine HSL_MA77 from user-provided library
ma86	IpoptH: use the Harwell routine HSL_MA86; Ipopt: load the Harwell routine HSL_MA86 from user-provided library
ma97	IpoptH: use the Harwell routine HSL_MA97; Ipopt: load the Harwell routine HSL_MA97 from user-provided library
pardiso	load the Pardiso package from pardiso-project.org from user-provided library at runtime
pardisomkl	use the Pardiso package from Intel MKL
mumps	use the Mumps package

Default: ma27, if IpoptH, otherwise mumps

linear_system_scaling: Method for scaling the linear system. ↩

Determines the method used to compute symmetric scaling factors for the augmented system (see also the "linear_scaling_on_demand" option). This scaling is independent of the NLP problem scaling. Note, that MC19 is included with a commercially supported GAMS/IpoptH license only. To use MC19 with GAMS/Ipopt, a HSL library needs to be provided by the user.

value	meaning
none	no scaling will be performed
mc19	IpoptH: use the Harwell routine MC19; Ipopt: load the Harwell routine MC19 from user-provided library
slack-based	use the slack values

Default: mc19, if IpoptH, otherwise none

ma27_ignore_singularity *(advanced)*: Whether to use MA27's ability to solve a linear system even if the matrix is singular. ↩

Setting this option to "yes" means that Ipopt will call MA27 to compute solutions for right hand sides, even if MA27 has detected that the matrix is singular (but is still able to solve the linear system). In some cases this might be better than using Ipopt's heuristic of small perturbation of the lower diagonal of the KKT matrix.

Range: yes, no

Default: no

ma27_la_init_factor: Real workspace memory for MA27. ↩

The initial real workspace memory = la_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]

Default: 5

ma27_liw_init_factor: Integer workspace memory for MA27. ↩

The initial integer workspace memory = liw_init_factor * memory required by unfactored system. Ipopt will increase the workspace size by ma27_meminc_factor if required.

Range: [1, ∞]

Default: 5

ma27_meminc_factor: Increment factor for workspace size for MA27. ↩

If the integer or real workspace is not large enough, Ipopt will increase its size by this factor.

Range: [1, ∞]

Default: 2

ma27_pivtol: Pivot tolerance for the linear solver MA27. ↩

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)

Default: 1e-08

ma27_pivtolmax: Maximum pivot tolerance for the linear solver MA27. ↩

Ipopt may increase pivtol as high as ma27_pivtolmax to get a more accurate solution to the linear system.

Range: (0, 1)

Default: 0.0001

ma27_print_level: Debug printing level for the linear solver MA27 ↩

0: no printing; 1: Error messages only; 2: Error and warning messages; 3: Error and warning messages and terse monitoring; 4: All information.

Range: {0, ..., 4}

Default: 0

ma27_skip_inertia_check *(advanced)*: Whether to always pretend that inertia is correct. ↩

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

ma57_automatic_scaling: Controls whether to enable automatic scaling in MA57 ↩

For higher reliability of the MA57 solver, you may want to set this option to yes. This is ICNTL(15) in MA57.

Range: yes, no

Default: no

ma57_block_size: Controls block size used by Level 3 BLAS in MA57BD ↩

This is ICNTL(11) in MA57.

Range: {1, ..., ∞}

Default: 16

ma57_node_amalgamation: Node amalgamation parameter ↩

This is ICNTL(12) in MA57.

Range: {1, ..., ∞}

Default: 16

ma57_pivot_order: Controls pivot order in MA57 ↩

This is ICNTL(6) in MA57.

Range: {0, ..., 5}

Default: 5

ma57_pivtol: Pivot tolerance for the linear solver MA57. ↩

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: (0, 1)

Default: 1e-08

ma57_pivtolmax: Maximum pivot tolerance for the linear solver MA57. ↩

Ipopt may increase pivtol as high as ma57_pivtolmax to get a more accurate solution to the linear system.

Range: (0, 1)

Default: 0.0001

ma57_pre_alloc: Safety factor for work space memory allocation for the linear solver MA57. ↩

If 1 is chosen, the suggested amount of work space is used. However, choosing a larger number might avoid reallocation if the suggest values do not suffice.

Range: [1, ∞]

Default: 1.05

ma57_print_level: Debug printing level for the linear solver MA57 ↩

0: no printing; 1: Error messages only; 2: Error and warning messages; 3: Error and warning messages and terse monitoring; ≥4: All information.

Range: {0, ..., ∞}

Default: 0

ma57_small_pivot_flag: Handling of small pivots ↩

If set to 1, then when small entries defined by CNTL(2) are detected they are removed and the corresponding pivots placed at the end of the factorization. This can be particularly efficient if the matrix is highly rank deficient. This is ICNTL(16) in MA57.

Range: {0, ..., 1}

Default: 0

ma77_buffer_lpage: Number of scalars per MA77 in-core buffer page in the out-of-core solver MA77 ↩

Must be at most ma77_file_size.

Range: {1, ..., ∞}

Default: 4096

ma77_buffer_npage: Number of pages that make up MA77 buffer ↩

Number of pages of size buffer_lpage that exist in-core for the out-of-core solver MA77.

Range: {1, ..., ∞}

Default: 1600

ma77_file_size: Target size of each temporary file for MA77, scalars per type ↩

MA77 uses many temporary files, this option controls the size of each one. It is measured in the number of entries (int or double), NOT bytes.

Range: {1, ..., ∞}

Default: 2097152

ma77_maxstore: Maximum storage size for MA77 in-core mode ↩

If greater than zero, the maximum size of factors stored in core before out-of-core mode is invoked.

Range: {0, ..., ∞}

Default: 0

ma77_nemin: Node Amalgamation parameter ↩

Two nodes in elimination tree are merged if result has fewer than ma77_nemin variables.

Range: {1, ..., ∞}

Default: 8

ma77_order: Controls type of ordering used by MA77 ↩

value	meaning
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm (if available)

Default: metis

ma77_print_level: Debug printing level for the linear solver MA77 ↩

<0: no printing; 0: Error and warning messages only; 1: Limited diagnostic printing; >1 Additional diagnostic printing.

Range: {-∞, ..., ∞}

Default: -1

ma77_small: Zero Pivot Threshold ↩

Any pivot less than ma77_small is treated as zero.

Range: [0, ∞]

Default: 1e-20

ma77_static: Static Pivoting Threshold ↩

See MA77 documentation. Either ma77_static=0.0 or ma77_static>ma77_small. ma77_static=0.0 disables static pivoting.

Range: [0, ∞]

Default: 0

ma77_u: Pivoting Threshold ↩

See MA77 documentation.

Range: [0, 0.5]

Default: 1e-08

ma77_umax: Maximum Pivoting Threshold ↩

Maximum value to which u will be increased to improve quality.

Range: [0, 0.5]

Default: 0.0001

ma86_nemin: Node Amalgamation parameter ↩

Two nodes in elimination tree are merged if result has fewer than ma86_nemin variables.

Range: {1, ..., ∞}

Default: 32

ma86_order: Controls type of ordering ↩

value	meaning
auto	Try both AMD and MeTiS, pick best
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm (if available)

Default: auto

ma86_print_level: Debug printing level ↩

<0: no printing; 0: Error and warning messages only; 1: Limited diagnostic printing; >1 Additional diagnostic printing.

Range: {-∞, ..., ∞}

Default: -1

ma86_scaling: Controls scaling of matrix ↩

value	meaning
none	Do not scale the linear system matrix
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma86_small: Zero Pivot Threshold ↩

Any pivot less than ma86_small is treated as zero.

Range: [0, ∞]

Default: 1e-20

ma86_static: Static Pivoting Threshold ↩

See MA86 documentation. Either ma86_static=0.0 or ma86_static>ma86_small. ma86_static=0.0 disables static pivoting.

Range: [0, ∞]

Default: 0

ma86_u: Pivoting Threshold ↩

See MA86 documentation.

Range: [0, 0.5]

Default: 1e-08

ma86_umax: Maximum Pivoting Threshold ↩

Maximum value to which u will be increased to improve quality.

Range: [0, 0.5]

Default: 0.0001

ma97_nemin: Node Amalgamation parameter ↩

Two nodes in elimination tree are merged if result has fewer than ma97_nemin variables.

Range: {1, ..., ∞}

Default: 8

ma97_order: Controls type of ordering ↩

value	meaning
auto	Use HSL_MA97 heuristic to guess best of AMD and METIS
best	Try both AMD and MeTiS, pick best
amd	Use the HSL_MC68 approximate minimum degree algorithm
metis	Use the MeTiS nested dissection algorithm
matched-auto	Use the HSL_MC80 matching with heuristic choice of AMD or METIS
matched-metis	Use the HSL_MC80 matching based ordering with METIS
matched-amd	Use the HSL_MC80 matching based ordering with AMD

Default: auto

ma97_print_level: Debug printing level ↩

<0: no printing; 0: Error and warning messages only; 1: Limited diagnostic printing; >1 Additional diagnostic printing.

Range: {-∞, ..., ∞}

Default: -1

ma97_scaling: Specifies strategy for scaling ↩

value	meaning
none	Do not scale the linear system matrix
mc30	Scale all linear system matrices using MC30
mc64	Scale all linear system matrices using MC64
mc77	Scale all linear system matrices using MC77 [1,3,0]
dynamic	Dynamically select scaling according to rules specified by ma97_scalingX and ma97_switchX options.

Default: dynamic

ma97_scaling1 *(advanced)*: First scaling. ↩

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch1. If ma97_switch2 is triggered it is disabled.

value	meaning
none	No scaling
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma97_scaling2 *(advanced)*: Second scaling. ↩

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch2. If ma97_switch3 is triggered it is disabled.

value	meaning
none	No scaling
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma97_scaling3 *(advanced)*: Third scaling. ↩

If ma97_scaling=dynamic, this scaling is used according to the trigger ma97_switch3.

value	meaning
none	No scaling
mc30	Scale linear system matrix using MC30
mc64	Scale linear system matrix using MC64
mc77	Scale linear system matrix using MC77 [1,3,0]

Default: mc64

ma97_small: Zero Pivot Threshold ↩

Any pivot less than ma97_small is treated as zero.

Range: [0, ∞]

Default: 1e-20

ma97_solve_blas3 *(advanced)*: Controls if blas2 or blas3 routines are used for solve ↩

value	meaning
no	Use BLAS2 (faster, some implementations bit incompatible)
yes	Use BLAS3 (slower)

Default: no

ma97_switch1 *(advanced)*: First switch, determine when ma97_scaling1 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling1 is enabled according to this condition. If ma97_switch2 occurs this option is henceforth ignored.

value	meaning
never	Scaling is never enabled.
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr
high_delay	Scaling to be used after more than 0.05∗n delays are present

value	meaning
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05∗n additional delays, otherwise reuse scaling from previous itr
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse

Default: od_hd_reuse

ma97_switch2 *(advanced)*: Second switch, determine when ma97_scaling2 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling2 is enabled according to this condition. If ma97_switch3 occurs this option is henceforth ignored.

value	meaning
never	Scaling is never enabled.
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr
high_delay	Scaling to be used after more than 0.05∗n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05∗n additional delays, otherwise reuse scaling from previous itr
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse

Default: never

ma97_switch3 *(advanced)*: Third switch, determine when ma97_scaling3 is enabled. ↩

If ma97_scaling=dynamic, ma97_scaling3 is enabled according to this condition.

value	meaning
never	Scaling is never enabled.
at_start	Scaling to be used from the very start.
at_start_reuse	Scaling to be used on first iteration, then reused thereafter.
on_demand	Scaling to be used after Ipopt request improved solution (i.e. iterative refinement has failed).
on_demand_reuse	As on_demand, but reuse scaling from previous itr
high_delay	Scaling to be used after more than 0.05∗n delays are present
high_delay_reuse	Scaling to be used only when previous itr created more that 0.05∗n additional delays, otherwise reuse scaling from previous itr
od_hd	Combination of on_demand and high_delay
od_hd_reuse	Combination of on_demand_reuse and high_delay_reuse

Default: never

ma97_u: Pivoting Threshold ↩

See MA97 documentation.

Range: [0, 0.5]

Default: 1e-08

ma97_umax: Maximum Pivoting Threshold ↩

See MA97 documentation.

Range: [0, 0.5]

Default: 0.0001

max_cpu_time: Maximum number of CPU seconds. ↩

A limit on CPU seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: (0, ∞]

Default: 1e+20

max_filter_resets *(advanced)*: Maximal allowed number of filter resets ↩

A positive number enables a heuristic that resets the filter, whenever in more than "filter_reset_trigger" successive iterations the last rejected trial steps size was rejected because of the filter. This option determine the maximal number of resets that are allowed to take place.

Range: {0, ..., ∞}

Default: 5

max_hessian_perturbation: Maximum value of regularization parameter for handling negative curvature. ↩

In order to guarantee that the search directions are indeed proper descent directions, Ipopt requires that the inertia of the (augmented) linear system for the step computation has the correct number of negative and positive eigenvalues. The idea is that this guides the algorithm away from maximizers and makes Ipopt more likely converge to first order optimal points that are minimizers. If the inertia is not correct, a multiple of the identity matrix is added to the Hessian of the Lagrangian in the augmented system. This parameter gives the maximum value of the regularization parameter. If a regularization of that size is not enough, the algorithm skips this iteration and goes to the restoration phase. This is delta_w^max in the implementation paper.

Range: (0, ∞]

Default: 1e+20

max_iter: Maximum number of iterations. ↩

The algorithm terminates with a message if the number of iterations exceeded this number.

Range: {0, ..., ∞}

Default: GAMS iterlim

max_refinement_steps: Maximum number of iterative refinement steps per linear system solve. ↩

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the maximum number of iterative refinement steps.

Range: {0, ..., ∞}

Default: 10

max_resto_iter *(advanced)*: Maximum number of successive iterations in restoration phase. ↩

The algorithm terminates with an error message if the number of iterations successively taken in the restoration phase exceeds this number.

Range: {0, ..., ∞}

Default: 3000000

max_soc: Maximum number of second order correction trial steps at each iteration. ↩

Choosing 0 disables the second order corrections. This is p^{max} of Step A-5.9 of Algorithm A in the implementation paper.

Range: {0, ..., ∞}

Default: 4

max_soft_resto_iters *(advanced)*: Maximum number of iterations performed successively in soft restoration phase. ↩

If the soft restoration phase is performed for more than so many iterations in a row, the regular restoration phase is called.

Range: {0, ..., ∞}

Default: 10

max_wall_time: Maximum number of walltime clock seconds. ↩

A limit on walltime clock seconds that Ipopt can use to solve one problem. If during the convergence check this limit is exceeded, Ipopt will terminate with a corresponding message.

Range: (0, ∞]

Default: GAMS reslim

mehrotra_algorithm: Indicates whether to do Mehrotra's predictor-corrector algorithm. ↩

If enabled, line search is disabled and the (unglobalized) adaptive mu strategy is chosen with the "probing" oracle, and "corrector_type=affine" is used without any safeguards; you should not set any of those options explicitly in addition. Also, unless otherwise specified, the values of "bound_push", "bound_frac", and "bound_mult_init_val" are set more aggressive, and sets "alpha_for_y=bound_mult". The Mehrotra's predictor-corrector algorithm works usually very well for LPs and convex QPs.

Range: yes, no

Default: no

min_hessian_perturbation: Smallest perturbation of the Hessian block. ↩

The size of the perturbation of the Hessian block is never selected smaller than this value, unless no perturbation is necessary. This is delta_w^min in implementation paper.

Range: [0, ∞]

Default: 1e-20

min_refinement_steps: Minimum number of iterative refinement steps per linear system solve. ↩

Iterative refinement (on the full unsymmetric system) is performed for each right hand side. This option determines the minimum number of iterative refinements (i.e. at least "min_refinement_steps" iterative refinement steps are enforced per right hand side.)

Range: {0, ..., ∞}

Default: 1

mu_allow_fast_monotone_decrease *(advanced)*: Allow skipping of barrier problem if barrier test is already met. ↩

value	meaning
no	Take at least one iteration per barrier problem even if the barrier test is already met for the updated barrier parameter
yes	Allow fast decrease of mu if barrier test it met

Default: yes

mu_init: Initial value for the barrier parameter. ↩

This option determines the initial value for the barrier parameter (mu). It is only relevant in the monotone, Fiacco-McCormick version of the algorithm. (i.e., if "mu_strategy" is chosen as "monotone")

Range: (0, ∞]

Default: 0.1

mu_linear_decrease_factor: Determines linear decrease rate of barrier parameter. ↩

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by taking the minimum of mu∗"mu_linear_decrease_factor" and mu^"superlinear_decrease_power". This is kappa_mu in implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: (0, 1)

Default: 0.2

mu_max: Maximum value for barrier parameter. ↩

This option specifies an upper bound on the barrier parameter in the adaptive mu selection mode. If this option is set, it overwrites the effect of mu_max_fact. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: (0, ∞]

Default: 100000

mu_max_fact: Factor for initialization of maximum value for barrier parameter. ↩

This option determines the upper bound on the barrier parameter. This upper bound is computed as the average complementarity at the initial point times the value of this option. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: (0, ∞]

Default: 1000

mu_min: Minimum value for barrier parameter. ↩

This option specifies the lower bound on the barrier parameter in the adaptive mu selection mode. By default, it is set to the minimum of 1e-11 and min("tol","compl_inf_tol")/("barrier_tol_factor"+1), which should be a reasonable value. (Only used if option "mu_strategy" is chosen as "adaptive".)

Range: (0, ∞]

Default: 1e-11

mu_oracle: Oracle for a new barrier parameter in the adaptive strategy. ↩

Determines how a new barrier parameter is computed in each "free-mode" iteration of the adaptive barrier parameter strategy. (Only considered if "adaptive" is selected for option "mu_strategy").

value	meaning
probing	Mehrotra's probing heuristic
loqo	LOQO's centrality rule
quality-function	minimize a quality function

Default: quality-function

mu_strategy: Update strategy for barrier parameter. ↩

Determines which barrier parameter update strategy is to be used.

value	meaning
monotone	use the monotone (Fiacco-McCormick) strategy
adaptive	use the adaptive update strategy

Default: adaptive

mu_superlinear_decrease_power: Determines superlinear decrease rate of barrier parameter. ↩

For the Fiacco-McCormick update procedure the new barrier parameter mu is obtained by taking the minimum of mu∗"mu_linear_decrease_factor" and mu^"superlinear_decrease_power". This is theta_mu in implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: (1, 2)

Default: 1.5

mu_target: Desired value of complementarity. ↩

Usually, the barrier parameter is driven to zero and the termination test for complementarity is measured with respect to zero complementarity. However, in some cases it might be desired to have Ipopt solve barrier problem for strictly positive value of the barrier parameter. In this case, the value of "mu_target" specifies the final value of the barrier parameter, and the termination tests are then defined with respect to the barrier problem for this value of the barrier parameter.

Range: [0, ∞]

Default: 0

mumps_dep_tol *(advanced)*: Threshold to consider a pivot at zero in detection of linearly dependent constraints with MUMPS. ↩

This is CNTL(3) in MUMPS.

Range: real

Default: 0

mumps_mem_percent: Percentage increase in the estimated working space for MUMPS. ↩

When significant extra fill-in is caused by numerical pivoting, larger values of mumps_mem_percent may help use the workspace more efficiently. On the other hand, if memory requirement are too large at the very beginning of the optimization, choosing a much smaller value for this option, such as 5, might reduce memory requirements.

Range: {0, ..., ∞}

Default: 1000

mumps_permuting_scaling: Controls permuting and scaling in MUMPS ↩

This is ICNTL(6) in MUMPS.

Range: {0, ..., 7}

Default: 7

mumps_pivot_order: Controls pivot order in MUMPS ↩

This is ICNTL(7) in MUMPS.

Range: {0, ..., 7}

Default: 7

mumps_pivtol: Pivot tolerance for the linear solver MUMPS. ↩

A smaller number pivots for sparsity, a larger number pivots for stability.

Range: [0, 1]

Default: 1e-06

mumps_pivtolmax: Maximum pivot tolerance for the linear solver MUMPS. ↩

Ipopt may increase pivtol as high as pivtolmax to get a more accurate solution to the linear system.

Range: [0, 1]

Default: 0.1

mumps_print_level: Debug printing level for the linear solver MUMPS ↩

0: no printing; 1: Error messages only; 2: Error, warning, and main statistic messages; 3: Error and warning messages and terse diagnostics; ≥4: All information.

Range: {0, ..., ∞}

Default: 0

mumps_scaling: Controls scaling in MUMPS ↩

This is ICNTL(8) in MUMPS.

Range: {-2, ..., 77}

Default: 77

neg_curv_test_reg: Whether to do the curvature test with the primal regularization (see Zavala and Chiang, 2014). ↩

value	meaning
yes	use primal regularization with the inertia-free curvature test
no	use original IPOPT approach, in which the primal regularization is ignored

Default: yes

neg_curv_test_tol: Tolerance for heuristic to ignore wrong inertia. ↩

If nonzero, incorrect inertia in the augmented system is ignored, and Ipopt tests if the direction is a direction of positive curvature. This tolerance is alpha_n in the paper by Zavala and Chiang (2014) and it determines when the direction is considered to be sufficiently positive. A value in the range of [1e-12, 1e-11] is recommended.

Range: [0, ∞]

Default: 0

nlp_scaling_constr_target_gradient *(advanced)*: Target value for constraint function gradient size. ↩

If a positive number is chosen, the scaling factors for the constraint functions are computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the constraint functions.

Range: [0, ∞]

Default: 0

nlp_scaling_max_gradient: Maximum gradient after NLP scaling. ↩

This is the gradient scaling cut-off. If the maximum gradient is above this value, then gradient based scaling will be performed. Scaling parameters are calculated to scale the maximum gradient back to this value. (This is g_max in Section 3.8 of the implementation paper.) Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: (0, ∞]

Default: 100

nlp_scaling_method: Select the technique used for scaling the NLP. ↩

Selects the technique used for scaling the problem internally before it is solved. For user-scaling, the parameters come from the NLP.

value	meaning
none	no problem scaling will be performed
gradient-based	scale the problem so the maximum gradient at the starting point is nlp_scaling_max_gradient
equilibration-based	scale the problem so that first derivatives are of order 1 at random points (GAMS/Ipopt: requires user-provided library with HSL routine MC19)

Default: gradient-based if GAMS scaleopt is not set, otherwise none

nlp_scaling_min_value: Minimum value of gradient-based scaling values. ↩

This is the lower bound for the scaling factors computed by gradient-based scaling method. If some derivatives of some functions are huge, the scaling factors will otherwise become very small, and the (unscaled) final constraint violation, for example, might then be significant. Note: This option is only used if "nlp_scaling_method" is chosen as "gradient-based".

Range: [0, ∞]

Default: 1e-08

nlp_scaling_obj_target_gradient *(advanced)*: Target value for objective function gradient size. ↩

If a positive number is chosen, the scaling factor for the objective function is computed so that the gradient has the max norm of the given size at the starting point. This overrides nlp_scaling_max_gradient for the objective function.

Range: [0, ∞]

Default: 0

nu_inc *(advanced)*: Increment of the penalty parameter. ↩

Range: (0, ∞]

Default: 0.0001

nu_init *(advanced)*: Initial value of the penalty parameter. ↩

Range: (0, ∞]

Default: 1e-06

obj_max_inc *(advanced)*: Determines the upper bound on the acceptable increase of barrier objective function. ↩

Trial points are rejected if they lead to an increase in the barrier objective function by more than obj_max_inc orders of magnitude.

Range: (1, ∞]

Default: 5

pardiso_iter_coarse_size *(advanced)*: Maximum Size of Coarse Grid Matrix ↩

DPARM(3)

Range: {1, ..., ∞}

Default: 5000

pardiso_iter_dropping_factor *(advanced)*: dropping value for incomplete factor ↩

DPARM(5)

Range: (0, 1)

Default: 0.5

pardiso_iter_dropping_schur *(advanced)*: dropping value for sparsify schur complement factor ↩

DPARM(6)

Range: (0, 1)

Default: 0.1

pardiso_iter_inverse_norm_factor *(advanced)*: ↩

DPARM(8)

Range: (1, ∞]

Default: 5e+06

pardiso_iter_max_levels *(advanced)*: Maximum Size of Grid Levels ↩

DPARM(4)

Range: {1, ..., ∞}

Default: 10

pardiso_iter_max_row_fill *(advanced)*: max fill for each row ↩

DPARM(7)

Range: {1, ..., ∞}

Default: 10000000

pardiso_iter_relative_tol *(advanced)*: Relative Residual Convergence ↩

DPARM(2)

Range: (0, 1)

Default: 1e-06

pardiso_iterative *(advanced)*: Switch for iterative solver in Pardiso library ↩

Range: yes, no

Default: no

pardiso_matching_strategy: Matching strategy to be used by Pardiso ↩

This is IPAR(13) in Pardiso manual.

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

Default: complete+2x2

pardiso_max_droptol_corrections *(advanced)*: Maximal number of decreases of drop tolerance during one solve. ↩

This is relevant only for iterative Pardiso options.

Range: {1, ..., ∞}

Default: 4

pardiso_max_iter *(advanced)*: Maximum number of Krylov-Subspace Iteration ↩

DPARM(1)

Range: {1, ..., ∞}

Default: 500

pardiso_max_iterative_refinement_steps: Limit on number of iterative refinement steps. ↩

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: {-∞, ..., ∞}

Default: 0

pardiso_msglvl: Pardiso message level ↩

This is MSGLVL in the Pardiso manual.

Range: {0, ..., ∞}

Default: 0

pardiso_order: Controls the fill-in reduction ordering algorithm for the input matrix. ↩

value	meaning
amd	minimum degree algorithm
one	
metis	MeTiS nested dissection algorithm
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm
four	
five	

Default: metis

pardiso_redo_symbolic_fact_only_if_inertia_wrong *(advanced)*: Toggle for handling case when elements were perturbed by Pardiso. ↩

value	meaning
no	Always redo symbolic factorization when elements were perturbed

value	meaning
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

Default: no

pardiso_repeated_perturbation_means_singular *(advanced)*: Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization. ↩

Range: yes, no

Default: no

pardiso_skip_inertia_check *(advanced)*: Whether to pretend that inertia is correct. ↩

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

pardisolib: Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime ↩

Range: string

Default: libpardiso.so (Linux), libpardiso.dylib (macOS), libpardiso.dll (Windows)

pardisomkl_matching_strategy: Matching strategy to be used by Pardiso ↩

This is IPAR(13) in Pardiso manual.

value	meaning
complete	Match complete (IPAR(13)=1)
complete+2x2	Match complete+2x2 (IPAR(13)=2)
constraints	Match constraints (IPAR(13)=3)

Default: complete+2x2

pardisomkl_max_iterative_refinement_steps: Limit on number of iterative refinement steps. ↩

The solver does not perform more than the absolute value of this value steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. If negative, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement. The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and this option is set to 0.

Range: {-∞, ..., ∞}

Default: 1

pardisomkl_msglvl: Pardiso message level ↩

This is MSGLVL in the Pardiso manual.

Range: {0, ..., ∞}

Default: 0

pardisomkl_order: Controls the fill-in reduction ordering algorithm for the input matrix. ↩

value	meaning
amd	minimum degree algorithm
one	undocumented
metis	MeTiS nested dissection algorithm
pmetis	parallel (OpenMP) version of MeTiS nested dissection algorithm

Default: metis

pardisomkl_redo_symbolic_fact_only_if_inertia_wrong *(advanced)*: Toggle for handling case when elements were perturbed by Pardiso. ↩

value	meaning
no	Always redo symbolic factorization when elements were perturbed
yes	Only redo symbolic factorization when elements were perturbed if also the inertia was wrong

Default: no

pardisomkl_repeated_perturbation_means_singular *(advanced)*: Whether to assume that matrix is singular if elements were perturbed after recent symbolic factorization. ↩

Range: yes, no

Default: no

pardisomkl_skip_inertia_check *(advanced)*: Whether to pretend that inertia is correct. ↩

Setting this option to "yes" essentially disables inertia check. This option makes the algorithm non-robust and easily fail, but it might give some insight into the necessity of inertia control.

Range: yes, no

Default: no

perturb_always_cd *(advanced)*: Active permanent perturbation of constraint linearization. ↩

Enabling this option leads to using the delta_c and delta_d perturbation for the computation of every search direction. Usually, it is only used when the iteration matrix is singular.

Range: yes, no

Default: no

perturb_dec_fact: Decrease factor for x-s perturbation. ↩

The factor by which the perturbation is decreased when a trial value is deduced from the size of the most recent successful perturbation. This is kappa_w^- in the implementation paper.

Range: (0, 1)

Default: 0.333333

perturb_inc_fact: Increase factor for x-s perturbation. ↩

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of all perturbations except for the first. This is kappa_w^+ in the implementation paper.

Range: (1, ∞]

Default: 8

perturb_inc_fact_first: Increase factor for x-s perturbation for very first perturbation. ↩

The factor by which the perturbation is increased when a trial value was not sufficient - this value is used for the computation of the very first perturbation and allows a different value for the first perturbation than that used for the remaining perturbations. This is bar_kappa_w^+ in the implementation paper.

Range: (1, ∞]

Default: 100

print_advanced_options *(advanced)*: whether to print also advanced options ↩

Range: yes, no

Default: no

print_eval_error: Switch to enable printing information about function evaluation errors into the GAMS listing file. ↩

Range: no, yes

Default: yes

print_frequency_iter: Determines at which iteration frequency the summarizing iteration output line should be printed. ↩

Summarizing iteration output is printed every print_frequency_iter iterations, if at least print_frequency_time seconds have passed since last output.

Range: {1, ..., ∞}

Default: 1

print_frequency_time: Determines at which time frequency the summarizing iteration output line should be printed. ↩

Summarizing iteration output is printed if at least print_frequency_time seconds have passed since last output and the iteration number is a multiple of print_frequency_iter.

Range: [0, ∞]

Default: 0

print_info_string: Enables printing of additional info string at end of iteration output. ↩

This string contains some insider information about the current iteration. For details, look for "Diagnostic Tags" in the Ipopt documentation.

Range: yes, no

Default: no

print_level: Output verbosity level. ↩

Sets the default verbosity level for console output. The larger this value the more detailed is the output.

Range: {0, ..., 12}

Default: 5

print_options_mode: format in which to print options documentation ↩

value	meaning
text	Ordinary text
latex	LaTeX formatted
doxygen	Doxygen (markdown) formatted

Default: text

print_timing_statistics: Switch to print timing statistics. ↩

If selected, the program will print the time spend for selected tasks. This implies timing_statistics=yes.

Range: yes, no

Default: no

quality_function_balancing_term *(advanced)*: The balancing term included in the quality function for centrality. ↩

This determines whether a term is added to the quality function that penalizes situations where the complementarity is much smaller than dual and primal infeasibilities. Only used if option "mu_oracle" is set to "quality-function".

value	meaning
none	no balancing term is added
cubic	Max(0,Max(dual_inf,primal_inf)-compl)^3

Default: none

quality_function_centrality *(advanced)*: The penalty term for centrality that is included in quality function. ↩

This determines whether a term is added to the quality function to penalize deviation from centrality with respect to complementarity. The complementarity measure here is the xi in the Loqo update rule. Only used if option "mu_oracle" is set to "quality-function".

value	meaning
none	no penalty term is added
log	complementarity $*$ the log of the centrality measure
reciprocal	complementarity $*$ the reciprocal of the centrality measure
cubed-reciprocal	complementarity $*$ the reciprocal of the centrality measure cubed

Default: none

quality_function_max_section_steps: Maximum number of search steps during direct search procedure determining the optimal centering parameter. ↩

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: {0, ..., ∞}

Default: 8

quality_function_norm_type *(advanced)*: Norm used for components of the quality function. ↩

Only used if option "mu_oracle" is set to "quality-function".

value	meaning
1-norm	use the 1-norm (abs sum)
2-norm-squared	use the 2-norm squared (sum of squares)
max-norm	use the infinity norm (max)
2-norm	use 2-norm

Default: 2-norm-squared

quality_function_section_qf_tol *(advanced)*: Tolerance for the golden section search procedure determining the optimal centering parameter (in the function value space). ↩

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, 1)

Default: 0

quality_function_section_sigma_tol *(advanced)*: Tolerance for the section search procedure determining the optimal centering parameter (in sigma space). ↩

The golden section search is performed for the quality function based mu oracle. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, 1)

Default: 0.01

recalc_y: Tells the algorithm to recalculate the equality and inequality multipliers as least square estimates. ↩

This asks the algorithm to recompute the multipliers, whenever the current infeasibility is less than recalc_y_feas_tol. Choosing yes might be helpful in the quasi-Newton option. However, each recalculation requires an extra factorization of the linear system. If a limited memory quasi-Newton option is chosen, this is used by default.

value	meaning
no	use the Newton step to update the multipliers
yes	use least-square multiplier estimates

Default: no

recalc_y_feas_tol: Feasibility threshold for recomputation of multipliers. ↩

If recalc_y is chosen and the current infeasibility is less than this value, then the multipliers are recomputed.

Range: (0, ∞]

Default: 1e-06

replace_bounds *(advanced)*: Whether all variable bounds should be replaced by inequality constraints ↩

This option must be set for the inexact algorithm.

Range: yes, no

Default: no

report_mininfeas_solution: Switch to report intermediate solution with minimal constraint violation to GAMS if the final solution is not feasible. ↩

This option allows to obtain the most feasible solution found by Ipopt during the iteration process, if it stops at a (locally) infeasible solution, due to a limit (time, iterations, ...), or with a failure in the restoration phase.

Range: no, yes

Default: no

required_infeasibility_reduction: Required reduction of infeasibility before leaving restoration phase. ↩

The restoration phase algorithm is performed, until a point is found that is acceptable to the filter and the infeasibility has been reduced by at least the fraction given by this option.

Range: [0, 1)

Default: 0.9

residual_improvement_factor *(advanced)*: Minimal required reduction of residual test ratio in iterative refinement. ↩

If the improvement of the residual test ratio made by one iterative refinement step is not better than this factor, iterative refinement is aborted.

Range: (0, ∞]

Default: 1

residual_ratio_max *(advanced)*: Iterative refinement tolerance ↩

Iterative refinement is performed until the residual test ratio is less than this tolerance (or until "max_refinement_steps" refinement steps are performed).

Range: (0, ∞]

Default: 1e-10

residual_ratio_singular *(advanced)*: Threshold for declaring linear system singular after failed iterative refinement. ↩

If the residual test ratio is larger than this value after failed iterative refinement, the algorithm pretends that the linear system is singular.

Range: (0, ∞]

Default: 1e-05

resto_failure_feasibility_threshold *(advanced)*: Threshold for primal infeasibility to declare failure of restoration phase. ↩

If the restoration phase is terminated because of the "acceptable" termination criteria and the primal infeasibility is smaller than this value, the restoration phase is declared to have failed. The default value is actually 1e2∗tol, where tol is the general termination tolerance.

Range: [0, ∞]

Default: 0

resto_penalty_parameter *(advanced)*: Penalty parameter in the restoration phase objective function. ↩

This is the parameter rho in equation (31a) in the Ipopt implementation paper.

Range: (0, ∞]

Default: 1000

resto_proximity_weight *(advanced)*: Weighting factor for the proximity term in restoration phase objective. ↩

This determines how the parameter zeta in equation (29a) in the implementation paper is computed. zeta here is resto_proximity_weight∗sqrt(mu), where mu is the current barrier parameter.

Range: [0, ∞]

Default: 1

rho *(advanced)*: Value in penalty parameter update formula. ↩

Range: (0, 1)

Default: 0.1

s_max *(advanced)*: Scaling threshold for the NLP error. ↩

See paragraph after Eqn. (6) in the implementation paper.

Range: (0, ∞]

Default: 100

s_phi *(advanced)*: Exponent for linear barrier function model in the switching rule. ↩

See Eqn. (19) in the implementation paper.

Range: (1, ∞]

Default: 2.3

s_theta *(advanced)*: Exponent for current constraint violation in the switching rule. ↩

See Eqn. (19) in the implementation paper.

Range: (1, ∞]

Default: 1.1

sigma_max *(advanced)*: Maximum value of the centering parameter. ↩

This is the upper bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: (0, ∞]

Default: 100

sigma_min *(advanced)*: Minimum value of the centering parameter. ↩

This is the lower bound for the centering parameter chosen by the quality function based barrier parameter update. Only used if option "mu_oracle" is set to "quality-function".

Range: [0, ∞]

Default: 1e-06

skip_corr_if_neg_curv *(advanced)*: Whether to skip the corrector step in negative curvature iteration. ↩

The corrector step is not tried if negative curvature has been encountered during the computation of the search direction in the current iteration. This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no

Default: yes

skip_corr_in_monotone_mode *(advanced)*: Whether to skip the corrector step during monotone barrier parameter mode. ↩

The corrector step is not tried if the algorithm is currently in the monotone mode (see also option "barrier_strategy"). This option is only used if "mu_strategy" is "adaptive". Changing this option is experimental.

Range: yes, no

Default: yes

slack_bound_frac: Desired minimum relative distance from the initial slack to bound. ↩

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_push"). (This is kappa_2 in Section 3.6 of implementation paper.)

Range: (0, 0.5]

Default: 0.01

slack_bound_push: Desired minimum absolute distance from the initial slack to bound. ↩

Determines how much the initial slack variables might have to be modified in order to be sufficiently inside the inequality bounds (together with "slack_bound_frac"). (This is kappa_1 in Section 3.6 of implementation paper.)

Range: (0, ∞]

Default: 0.01

slack_move *(advanced)*: Correction size for very small slacks. ↩

Due to numerical issues or the lack of an interior, the slack variables might become very small. If a slack becomes very small compared to machine precision, the corresponding bound is moved slightly. This parameter determines how large the move should be. Its default value is mach_eps^{3/4}. See also end of Section 3.5 in implementation paper - but actual implementation might be somewhat different.

Range: [0, ∞]

Default: 1.81899e-12

soc_method: Ways to apply second order correction ↩

This option determines the way to apply second order correction, 0 is the method described in the implementation paper. 1 is the modified way which adds alpha on the rhs of x and s rows.

Range: {0, ..., 1}

Default: 0

soft_resto_pderror_reduction_factor: Required reduction in primal-dual error in the soft restoration phase. ↩

The soft restoration phase attempts to reduce the primal-dual error with regular steps. If the damped primal-dual step (damped only to satisfy the fraction-to-the-boundary rule) is not decreasing the primal-dual error by at least this factor, then the regular restoration phase is called. Choosing "0" here disables the soft restoration phase.

Range: [0, ∞]

Default: 0.9999

start_with_resto: Whether to switch to restoration phase in first iteration. ↩

Setting this option to "yes" forces the algorithm to switch to the feasibility restoration phase in the first iteration. If the initial point is feasible, the algorithm will abort with a failure.

Range: yes, no

Default: no

tau_min *(advanced)*: Lower bound on fraction-to-the-boundary parameter tau. ↩

This is tau_min in the implementation paper. This option is also used in the adaptive mu strategy during the monotone mode.

Range: (0, 1)

Default: 0.99

theta_max_fact *(advanced)*: Determines upper bound for constraint violation in the filter. ↩

The algorithmic parameter theta_max is determined as theta_max_fact times the maximum of 1 and the constraint violation at initial point. Any point with a constraint violation larger than theta_max is unacceptable to the filter (see Eqn. (21) in the implementation paper).

Range: (0, ∞]

Default: 10000

theta_min_fact *(advanced)*: Determines constraint violation threshold in the switching rule. ↩

The algorithmic parameter theta_min is determined as theta_min_fact times the maximum of 1 and the constraint violation at initial point. The switching rule treats an iteration as an h-type iteration whenever the current constraint violation is larger than theta_min (see paragraph before Eqn. (19) in the implementation paper).

Range: (0, ∞]

Default: 0.0001

timing_statistics: Indicates whether to measure time spend in components of Ipopt and NLP evaluation ↩

The overall algorithm time is unaffected by this option.

Range: yes, no

Default: no

tiny_step_tol *(advanced)*: Tolerance for detecting numerically insignificant steps. ↩

If the search direction in the primal variables (x and s) is, in relative terms for each component, less than this value, the algorithm accepts the full step without line search. If this happens repeatedly, the algorithm will terminate with a corresponding exit message. The default value is 10 times machine precision.

Range: [0, ∞]

Default: 2.22045e-15

tiny_step_y_tol *(advanced)*: Tolerance for quitting because of numerically insignificant steps. ↩

If the search direction in the primal variables (x and s) is, in relative terms for each component, repeatedly less than tiny_step_tol, and the step in the y variables is smaller than this threshold, the algorithm will terminate.

Range: [0, ∞]

Default: 0.01

tol: Desired convergence tolerance (relative). ↩

Determines the convergence tolerance for the algorithm. The algorithm terminates successfully, if the (scaled) NLP error becomes smaller than this value, and if the (absolute) criteria according to "dual_inf_tol", "constr_viol_tol", and "compl_inf_tol" are met. This is epsilon_tol in Eqn. (6) in implementation paper. See also "acceptable_tol" as a second termination criterion. Note, some other algorithmic features also use this quantity to determine thresholds etc.

Range: (0, ∞]

Default: 1e-08

warm_start_bound_frac: same as bound_frac for the regular initializer ↩

Range: (0, 0.5]

Default: 0.001

warm_start_bound_push: same as bound_push for the regular initializer ↩

Range: (0, ∞]

Default: 0.001

warm_start_init_point: Warm-start for initial point ↩

Indicates whether this optimization should use a warm start initialization, where values of primal and dual variables are given (e.g., from a previous optimization of a related problem.)

value	meaning
no	do not use the warm start initialization
yes	use the warm start initialization

Default: yes, if run on modified model instance (e.g., from GUSS), otherwise no

warm_start_mult_bound_push: same as mult_bound_push for the regular initializer ↩

Range: (0, ∞]

Default: 0.001

warm_start_mult_init_max: Maximum initial value for the equality multipliers. ↩

Range: real

Default: 1e+06

warm_start_slack_bound_frac: same as slack_bound_frac for the regular initializer ↩

Range: (0, 0.5]

Default: 0.001

warm_start_slack_bound_push: same as slack_bound_push for the regular initializer ↩

Range: (0, ∞]

Default: 0.001

warm_start_target_mu *(advanced)*: ↩

Experimental!

Range: real

Default: 0

watchdog_shortened_iter_trigger: Number of shortened iterations that trigger the watchdog. ↩

If the number of successive iterations in which the backtracking line search did not accept the first trial point exceeds this number, the watchdog procedure is activated. Choosing "0" here disables the watchdog procedure.

Range: {0, ..., ∞}

Default: 10

watchdog_trial_iter_max: Maximum number of watchdog iterations. ↩

This option determines the number of trial iterations allowed before the watchdog procedure is aborted and the algorithm returns to the stored point.

Range: {1, ..., ∞}

Default: 3

5.21 JAMS and LogMIP

5.21.1 Introduction

EMP (Extended Mathematical Programming) is not a solver but an (experimental) framework for automated mathematical programming reformulations. The idea behind EMP is that new upcoming types of models which currently cannot be solved reliably are reformulated into models of established math programming classes in order to use mature solver technology. At this stage, EMP supports the modeling of Bilevel Programs, Variational Inequalities, Disjunctive Programs, Extended Nonlinear Programs and Embedded Complementarity Systems.

Extended mathematical programs are collections of functions and variables joined together using specific optimization and complementarity primitives. EMP annotates the existing relationships within a model to facilitate higher level structure identification. A specific implementation of this framework is outlined that reformulates the original GAMS model automatically using directives contained in an "empinfo" file into an equivalent model that can be solved using existing GAMS solvers.

The reformulation is done by the solver JAMS which currently is the only solver that is capable of handling EMP models. Examples showing how to use the EMP framework and the solver JAMS are made available through the GAMS EMP Library which is included in the GAMS Distribution. In order to generate a copy of and EMPLIB model, one can use the library facility of the GAMS IDE, or execute the command line directive `emplib <modelname>`, where modelname is the (stem of the) file containing the model.

EMP has been developed jointly by Michael Ferris of UW-Madison, Ignacio Grossmann of Carnegie Mellon University, and GAMS Development Corporation. EMP and JAMS come free of charge with any licensed GAMS system but require a subsolver to solve the generated models.

5.21.2 JAMS: a reformulation tool

EMP models are currently processed by the JAMS solver. The solver JAMS creates a scalar version of the given GAMS model. This scalar version of the model is then solved by an appropriate subsolver. By default, there are no reformulations carried out, so the model generated is simply a GAMS scalar form of the model the actual subsolver will process. The subsolver used is by default the currently specified solver for the given model type.

5.21.2.1 The JAMS Option File

As with any GAMS solver, JAMS has an option file, typically called `jams.opt`. A JAMS option subsolver is available to change the subsolver used for the reformulated model, along with an option to utilize a subsolver option file (subsolveropt).

The actual scalar version of the model can also be seen by the modeler using the option filename. For example, the option file

```
subsolver path
subsolveropt 1
filename mcpmod.gms
```

when applied to an EMP model that is a complementarity problem will create a file called `mcpmod.gms` in the current directory and solve that model using the solver PATH utilizing any options for PATH that are specified in `path.opt`. The scalarized model is not particularly useful to look at since all of the original variables have been renamed into a scalar form. The mapping between original variables and the ones used in the scalar version of the model is given in a dictionary file that can also be seen by the modeler using the dict option. If a user simply wants to generate this scalar model, then the option terminate will not solve the generated model.

After the scalar version of the model is solved, the solution values are mapped back into the original namespace and returned to the modeler as usual in the listing file. The JAMS option margtol allows the modeler to suppress reporting marginals that have (absolute) values smaller than this tolerance.

Obviously, all of the above functionality is not of much value: the key part of JAMS is to interpret additional directives to take the original model and produce a *reformulated* scalar model. This is carried out using an "empinfo" file. The syntax and use of this file is the content of the remaining sections of this document.

The option EMPInfoFile allows the user to specify the path and name of a file containing additional EMP information. The syntax of this file is described by examples elsewhere in this document and in section Empinfo file details . There is a subtlety that should be mentioned when a user writes this file in the default location in the GAMS scratch directory of the current run specified in the gams file using:

```
file empinfo / '%emp.info%' /;
```

wherein certain additional formatting instructions are given. If instead, the file handle is given by:

```
file empinfo / 'empinfo.txt' /;
```

for example, then to produce the same file the following lines must be added to the gams source file:

```
empinfo.pc = 8;
empinfo.pw = 255;
```

The following tables list all available options.

5.21.2.2 Reformulation Options

Option	Description	Default
KeepObj	Keep original objective function and variables in generated MCP model. This option is only valid for reformulations into complementarity systems. If KeepObj is set the generated MCP program will incorporate the original objective function and the Karush-Kuhn-Tucker condition of the original objective variable.	0
MargTol	Only report marginals with an absolute value above the tolerance	1e-6
ObjVarName	Name of objective variable in generated model.	objvar

5.21.2.3 General Options

Option	Description	Default
CompModel	Complementarity model (MCP or VI) to generate for equilibrium problems.	mcp
Dict	Generate a dictionary file that maps original variable and equation names to the ones of the scalar JAMS model.	dict.txt
DisjBinRelax	Relax requirement that disjunction variables are binary.	0
EMPInfoFile	Path and name of file containing additional EMP information as disjunctions, perpendiculars, bilevel characterization etc. By default, the file is expected to exist in the GAMS scratch directory of the current run (gams.scrdir). If this option is used, EMP searches for the file based on the provided relative or absolute path. In case of a given relative path, it is assumed to be relative to the working directory.	
FileName	Filename of generated scalar reformulated GAMS model.	emp.gms
ImplVarModel	Reformulation model to generate for implicit variables. Replication: Shared variables are replicated for each agent Substitution: Shared multipliers are substituted out: assumes implicit function Switching: Switch function-variable matching to avoid replication	switching
NLConsToFunc	Stick nonlinear constraints into functional part when generating a VI model for equilibrium problems	0
SharedEqu	Allow shared equations in equilibrium problems	0
SubSolvePar	User defined GAMS parameters for subsolve	
SubSolver	Subsolver used to solve the reformulated model. The subsolver chosen has to be suitable for the chosen reformulation type. The user can also provide a solver related option file, see SubSolverOpt.	
SubSolverOpt	Optfile value to pass to the subsolver Range: {1, ..., 999}	1
Terminate	Generate the GAMS source code of the reformulated model in a file and terminate without solving the model.	0
UserPFFile	Filename of extra GAMS options when running the reformulated GAMS model.	
ZipDebug	Zip-file name to create if the internal GAMS model fails	none

5.21.3 Forming Optimality Conditions: NLP2MCP

The first nontrivial use of the JAMS solver is to automatically generate the first order conditions of a linear or nonlinear program; essentially we *reformulate* the optimization problem as a mixed complementarity problem (MCP). The "empinfo" file to do this simply contains the following line:

```
modeltype mcp
```

Behind the scenes, JAMS forms the Lagrangian of the nonlinear program and then forms its Karush-Kuhn-Tucker optimality conditions. To be clear, given the original nonlinear program

$$\min_x f(x) \text{ s.t. } g(x) \leq 0,\ h(x) = 0, \tag{NLP}$$

the Lagrangian is:

$$\mathcal{L}(x, \lambda, \mu) = f(x) - \langle \lambda, g(x) \rangle - \langle \mu, h(x) \rangle.$$

The first order conditions are the following MCP:

$$\begin{array}{lcl} 0 = \nabla_x \mathcal{L}(x, \lambda, \mu) & \perp & x \text{ free} \\ 0 \geq -\nabla_\lambda \mathcal{L}(x, \lambda, \mu) & \perp & \lambda \leq 0 \\ 0 = -\nabla_\mu \mathcal{L}(x, \lambda, \mu) & \perp & \mu \text{ free} \end{array}$$

A specific example is:

$$\begin{array}{ll} \min\limits_{x,y,z} & -3x + y \\ \text{s.t.} & x + y \leq 1,\ x + y - z = 2,\ x, y \geq 0 \end{array}$$

which is found in the EMPLIB model **nlp2mcp**:

```
Positive Variables x, y;
Variables f, z;
Equations g, h, defobj;
g..      x + y     =l= 1;
h..      x + y - z =e= 2;
defobj.. f         =e= -3*x + y;
model comp / defobj, g, h /;
file info / '%emp.info%' /;
putclose info / 'modeltype mcp';
solve comp using emp minimizing f;
```

The putclose line writes out the default "empinfo" file whose location is provided in the system string `%emp.info%`. Armed with this additional information, the EMP tool automatically creates the following MCP:

$$\begin{array}{lcl} 0 \leq -3 - \lambda - \mu & \perp & x \geq 0 \\ 0 \leq 1 - \lambda - \mu & \perp & y \geq 0 \\ 0 = \mu & \perp & z \text{ free} \\ 0 \geq x + y - 1 & \perp & \lambda \leq 0 \\ 0 = x + y - z - 2 & \perp & \mu \text{ free.} \end{array}$$

5.21.4 Soft Constraints

In many cases, we wish to relax certain constraints in a model during solution (to help identify feasibility issues for example). As an example, consider the problem

$$\begin{aligned} \min_{x_1,x_2,x_3} \quad & \exp(x_1) \\ \text{s.t.} \quad & \log(x_1) = 1, \\ & x_2^2 \leq 2, \\ & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0, \end{aligned}$$

which can be formulated in GAMS as

```
$title simple example of ENLP
Variables obj, x1, x2, x3;
Equations f0, f1, f2, f3, f4;
f0.. obj       =e= exp(x1);
f1.. log(x1)   =e= 1;
f2.. sqr(x2)   =g= 2;
f3.. x1/x2     =e= log(x3);
f4.. 3*x1 + x2 =l= 5;
x1.lo = 0; x2.lo = 0;
model enlpemp /all/;
x1.l = 1; x2.l = 1; x3.l = 1;
solve enlpemp using nlp min obj;
```

5.21.4.1 Reformulation as a classical NLP

Soft constraints allow us to treat certain equations in the model as "soft" by removing the constraints and adding a penalty term to the objective function. Explicitly, we replace the above problem by:

$$\begin{aligned} \min_{x_1,x_2,x_3} \quad & \exp(x_1) + 5\left\|\log(x_1) - 1\right\|^2 + 2\max(x_2^2 - 2, 0) \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0. \end{aligned}$$

In this problem, we still force $x_1/x_2 = \log(x_3)$, but apply a least squares penalty to $\log(x_1) - 1$ and a smaller one-sided penalization to $x_2^2 - 2$.

The above formulation is nonsmooth due to the "max" term in the objective function; in practice we would replace this by:

$$\begin{aligned} \min_{x_1,x_2,x_3,w} \quad & \exp(x_1) + 5\left(\log(x_1) - 1\right)^2 + 2w \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\ & w \geq x_2^2 - 2, w \geq 0 \end{aligned}$$

and recover a standard form NLP.

The "empinfo" file:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxz 2
```

coupled with replacing the last line with

```
solve enlpemp using emp min obj;
```

achieves this goal. The parameter values provide the penalty coefficients above.

5.21.4.2 Reformulation as an MCP

As an alternative, we can rewrite the problem as an MCP, also dealing explicitly with the nonsmoothness. The "empinfo" file is given by:

```
modeltype NLP
adjustequ
f1 sqr 5
f2 maxz 2
```

and this generates the following MCP:

$$\begin{array}{lcl}
0 = \log(x_1) - 1 + y_1/10 & \perp & y_1 \text{ free}, \\
0 \le x_2^2 - 2 & \perp & y_2 \ge 0, \\
0 = x_1/x_2 - \log(x_3) & \perp & y_3 \text{ free}, \\
0 \ge 3x_1 + x_2 - 5 & \perp & y_4 \le 0, \\
0 \le exp(x_1) - y_1/x_1 - y_3/x_2 - 3y_4 & \perp & x_1 \ge 0, \\
0 \le -2y_2x_2 + x_1y_3/x_2^2 - y_4 & \perp & x_2 \ge 0, \\
0 = y_3/x_3 & \perp & x_3 \text{ free},
\end{array}$$

where y represent the multipliers.

A complete description of the process to derive this MCP will be given later in section Extended Nonlinear Programs .

5.21.5 Bilevel Programs

Mathematical programs with optimization problems in their constraints have a long history in operations research including [15] [29] [71] . New codes are being developed that exploit this structure, at least for simple hierarchies, and attempt to define and implement algorithms for their solution.

The simplest case is that of bilevel programming, where an upper level problem depends on the solution of a lower level optimization. For example:

$$\begin{array}{ll}
\min\limits_{x,y} & f(x,y) \\
\text{s.t.} & g(x,y) \le 0, \\
& y \text{ solves } \min\limits_{y} v(x,y) \text{ s.t.} \quad h(x,y) \ge 0.
\end{array}$$

Often, the upper level is referred to as the "leader", while the lower level is the "follower".

This problem can be reformulated as a Mathematical Program with Complementarity Constraints (MPCC) by replacing the lower level optimization problem by its first order optimality conditions:

$$\begin{array}{ll}
\min\limits_{x,y} & f(x,y) \\
\text{s.t.} & g(x,y) \le 0, \\
& 0 = \nabla_y v(x,y) - \lambda^T \nabla_y h(x,y) \perp x \text{ free} \\
& 0 \le h(x,y) \perp \lambda \ge 0.
\end{array}$$

We find a solution of the MPCC, not of the bilevel program. This approach allows the MPCC to be solved using the NLPEC code, for example. Note that this reformulation is potentially problematic. First order

conditions require theoretical assumptions to be necessary and sufficient for *local optimality*. There may be cases where the lower level problem has multiple local solutions, but the modeler really was interested in the *global* solution. The approach here may not produce this solution, even if a global solver is used within NLPEC.

The following example is Example 5.1.1, page 197 from [15] . Mathematically, the problem is

$$\begin{aligned}
&\min_{x,y} x - 4y \\
&\text{s.t. } y \text{ solves } \min_{y} y \\
&\qquad\qquad \text{s.t. } x + y \geq 3 \\
&\qquad\qquad\qquad 2x - y \geq 0 \\
&\qquad\qquad\qquad -2x - y \geq -12 \\
&\qquad\qquad\qquad -3x + 2y \geq -4
\end{aligned}$$

and the EMPLIB model **bard511** contains the following code:

```
Positive variables x, y;
Variables objout, objin;
equations defout, defin, e1, e2, e3, e4;
defout.. objout  =e= x - 4*y;
defin..  objin   =e= y;
e1..     x +   y =g=   3;
e2..   2*x -   y =g=   0;
e3..  -2*x -   y =g= -12;
e4..  -3*x + 2*y =g=  -4;
model bard / all /;
$echo bilevel x min objin y defin e1 e2 e3 e4 > "%emp.info%"
solve bard using emp minimizing objout;
```

Note that first the functions that form the objectives and constraints of the model are defined and the model is assembled. The `$echo` line writes the "empinfo" file and states that the lower level problem involves the objective `objin` which is to be minimized by choice of variables `y` subject to the constraints specified in (`defin`), `e1`, `e2`, `e3`, and `e4`.

Note that the variables x are declared to be variables of the upper level problem and this example has no upper level constraints g. Having written the problem in this way, the MPCC is generated automatically, and passed on to a solver. In the case where that solver is NLPEC, a further reformulation of the model is carried out to convert the MPCC into an equivalent NLP or a parametric sequence of NLP's.

Further examples of bilevel models in **EMPLIB** are named: `bard`$*$, `ccmg74`, `ccmg153`, `flds`$*$, `jointc1`, `jointc2`, `mirrlees`, `transbp`.

The EMP model type allows multiple lower level problems to be specified within the bilevel format. An example of this is given in EMPLIB as **ccmg71**. The equations and objectives are specified in the normal manner; the only change is the definition of the "empinfo" file, shown below:

```
...
defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 u1 u2 u3 u4 defh1 e1
min h2 v1 v2 v3 v4 defh2 e2
$offecho
```

This corresponds to a bilevel program with two followers, both solving minimization problems. The first follower minimizes the objective function `h1` (defined in `defh1`) over the variables `u1`, `u2`, `u3`, and `u4` subject to the constraint given in `e1`. The second followers problem is defined analogously next. Note that `h1` involves the variables `x1`, `x2`, `x3`, and `x4` that are optimization variables of the leader. The constraint in `e1` could also include these variables, and also the variables `v1`, `v2`, `v3`, or `v4` of the second follower, but all of these would be treated as parameters by the first follower.

The actual model (**ccmg71**) in EMPLIB uses a shortcut notation:

```
...
defh1.. h1 =e= sqr(u1-x1) + sqr(u2-x2) + sqr(u3-x3) + sqr(u4-x4);
```

```
e1.. 3*u1 + u2 + 2*u3 + u4 =e= 6;
...
$onecho > "%emp.info%"
bilevel x1 x2 x3 x4
min h1 * defh1 e1
min h2 * defh2 e2
$offecho
```

In the followers problem, the '$*$' notation indicates that this agent will optimize over all the variables used in `defh1` and `e1` that are not under the control of any other follower or the leader. In this case, this means `u1`, `u2`, `u3`, and `u4`. To avoid confusion, it is recommended that the modeler explicity names all the variables in each followers problem as shown before.

5.21.6 Variational Inequalities

A variational inequality $VI(F, X)$ is to find $x \in X$:

$$\langle F(x), (z - x)\rangle \geq 0, \text{ for all } z \in X.$$

Here X is a closed (frequently assumed convex) set, defined for example as

$$X = \{x \mid x \geq 0, h(x) \geq 0\}.$$

Note that the first-order (minimum principle) conditions of a nonlinear program

$$\min_{z \in X} f(z)$$

are precisely of this form with $F(x) = \nabla f(x)$.

It is well known that such problems can be reformulated as complementarity problems when the set X has the representation $\{x \mid x \geq 0, h(x) \geq 0\}$ by introducing multipliers λ on the constraints $h(x) \geq 0$:

$$\begin{array}{lcl} 0 \leq F(x) - \langle \lambda, \nabla h(x)\rangle & \perp & x \geq 0 \\ 0 \leq h(x) & \perp & \lambda \geq 0. \end{array}$$

If X has a different representation, this construction would be modified appropriately.

A simple two dimensional example may be useful to improve understanding. Let

$$F(x) = \begin{bmatrix} x_1 + 2 \\ x_1 + x_2 - 3 \end{bmatrix}, \; X = \{x \geq 0\}\, x_1 + x_2 \leq 1,$$

so that F is an affine function, but F is not the gradient of any function $f : \mathbf{R}^2 \to \mathbf{R}$. For this particular data, $VI(F, X)$ has a unique solution $x = (0, 1)$.

```
Set J  / 1, 2 /;
Positive Variable x(J)  'vars, perp to f(J)';
Equations F(J), h;
F(J)..  (x('1') + 2)$sameas(J,'1') + (x('1') + x('2') - 3)$sameas(J,'2') =n= 0 ;
h..     x('1') + x('2') =l= 1;
model simpleVI / F, h/;
file fx /"%emp.info%"/;
putclose fx 'vi F x h';
solve simpleVI using emp;
```

Note that the first lines of this file define the F and h using standard GAMS syntax and include the defining equations in the model `simpleVI`. The extension is the annotation "empinfo" file that indicates certain equations are to be treated differently by the EMP tool. The annotation simply says that the model is a VI (`vi`) that pairs `F` with `x` and that the remaining (unpaired) equations form the constraint set X. (Alternative notation allows the keyword `vi` to be replaced by `vifunc`.) Thus, model equations `F` define a function F that is to be part of a variational inequality, while the equations `h` define constraints of X. It is also acceptable in this setting to use the "empinfo" file defined by:

```
putclose fx 'vi F x';
```

In this case, by default, any equations that are given in the model statement but not included as a pair in the `vi` statement are automatically used to form X. An alternative way to write this model without using `sameas` is given in EMPLIB as **affinevi**.

Some subtleties related to VI's are demonstrated in the EMPLIB model **zerofunc**. In this model, the set X is defined using variables y and z, for which z does not appear in the definition of $F \equiv F_y$. In this case, the variable z is then matched with a "0" function. The "empinfo" file can be written in a number of different ways:

```
putclose fx 'vi F_y y';
```

or

```
putclose fx 'vi z F_y y';
```

or

```
putclose fx 'vi z F_y y gCons';
```

or

```
putclose fx 'vi F_z z F_y y gCons';
```

where `F_z` simply defines the zero function. To some extent, our preferred notation is the one listed third: it explicitly includes all the variables and constraints that are present in the model and does not require the modeler to define `F_z` at all.

Further example models in EMPLIB are **simplevi**, **simplevi2**, **simplevi3**, **target**, **traffic**, **traffic2**, and **transvi**.

Note also that the lower level problems of a bilevel program could be VI's instead of optimization problems - these problems are called Mathematical Programs with Equilibrium Constraints (MPEC) in the literature. Note that since MPCC is a special case of MPEC, the GAMS model type MPEC covers both. An example demonstrating this setup is given in EMPLIB as **multmpec**. The actual model to solve is:

$$\begin{aligned}
\min_{u,v,w,z}\ & z \\
\text{s.t.}\ & \exp(z) + w = 2, z \geq 1 \\
& (u,v) \text{ solves VI}([v+w+z-1; u-\log(v)], \{(u,v) \mid u \geq 0, v \geq 0\}) \\
& w \text{ solves VI}(w+z+3, \{w \mid w \text{ free}\})
\end{aligned}$$

Note that the two VI's (due to the definitional sets) correspond respectively to a complementarity problem:

$$\begin{aligned}
0 \leq v+w+z-1 \quad & \perp \quad u \geq 0 \\
0 \leq u-\log(v) \quad & \perp \quad v \geq 0
\end{aligned}$$

and a linear equation:

$$w+z+3=0$$

The actual GAMS code is as follows:

```
Positive Variable u;
Variables v, w, z;
Equations f1, f2, f3, h;
f1.. v + w + z  =n= 1;
f2.. u          =n= log(v);
f3.. w + z      =n= -3;
h..  exp(z) + w =e= 2;
v.lo = 0; v.l = 1; z.lo = 1;
model mpecmod /all/;
$onecho > %emp.info%
bilevel
 vi f1 u
    f2 v
 vi f3 w
$offecho
solve mpecmod using emp min z;
```

The initial level value for `v` (`v.l = 1`) is needed to protect the evaluation of $\log(v)$. The two complementarity problems are specified in the empinfo file (it is not really necessary to split these VI's apart, but it may give information to a solver that can be exploited). It is of course possible to write the MPCC directly in GAMS using the model type MPEC instead of EMP.

5.21.7 Embedded Complementarity Systems

A different type of embedded optimization model that arises frequently in applications is:

$$\begin{array}{lll} \max\limits_{x} & f(x,y) & \\ \text{s.t.} & g(x,y) \leq 0 & (\perp\ p \geq 0) \\ & H(x,y,p) = 0 & (\perp\ y \text{ free}) \end{array}$$

Note the difference here: the optimization problem is over the variable x, and is parameterized by the variable y. The choice of y is fixed by the (auxiliary) complementarity relationships depicted here by H. Note that the H equations are not part of the optimization problem, but are essentially auxiliary constraints to tie down remaining variables in the model.

A specific example is:

$$\begin{array}{lll} \max\limits_{x} & x & \\ \text{s.t.} & x + y \leq 1 & \\ & -3x + y = 0.5 & (\perp\ y \text{ free}) \end{array}$$

which is found in the EMPLIB model **simpequil2**:

```
Variables y;
Positive variables x;
Equations optcons, vicons;
optcons.. x + y =l= 1;
vicons.. -3*x + y =e= 0.5;
model comp / optcons, vicons /;
file info / '%emp.info%' /;
put info / 'equilibrium';
put      / 'max x optcons';
putclose / 'vi vicons y';
solve comp using emp;
```

In order that this model can be processed correctly as an EMP, the modeler provides additional annotations to the model defining equations in an "empinfo" file. Specifically, first it is indicated that the problem is an equilibrium problem involving one or more agent problems. Next, the first agent is defined as an optimizer (over `x`). Finally, the second agent is defined as solving a VI in `y`. Armed with this additional information, the EMP tool automatically creates the following MCP:

$$\begin{array}{lll} 0 \leq -1 + p & \perp & x \geq 0 \\ 0 \leq 1 - x - y & \perp & p \geq 0 \\ 0 = -3x + y - 0.5 & \perp & y \text{ free}, \end{array}$$

(which is formed by the steps we outline below). EMP explicitly enforces the rule that every variable and constraint is under the control of exactly one agent. Thus a constraint or a variable cannot appear in both the max problem and the VI problem.

The above example is slightly simpler than the general form described above in which H is a function of x, y, and p, the multiplier on the constraint of the optimization problem. The problem is that we do not have that variable around in the model code if we only specify the optimization problem there. This occurs for example in the classical PIES Model due to Hogan. In this setting, the problem is described by a linear program

$$\begin{array}{ll} \min_x & c^T x \\ \text{s.t.} & Ax = q(p) \\ & Bx = b \\ & x \geq 0 \end{array}$$

in which the quantity q is a function of p, which is a multiplier on one of the LP constraints. To do this in EMP, we simply add the annotation:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
put myinfo 'equilibrium ';
put 'min obj c o ct ot lt ht defobj dembal cmbal ombal lmbal hmbal ruse';
putclose 'dualvar p dembal';
solve piesemp using emp;
```

where `dembal` is the name of the constraint for which `p` needs to be the multiplier. The full model is found in the EMPLIB model **pies**. Two final points: the `dualvar` directive identifies the variable `p` with the multiplier on the `dembal` constraint, and all variables and constraints must be owned by a single agent. In this case, since there is only one agent (the minimizer), all constraints of the model are explicitly claimed, along with all variables except for `p`. However, next, `p` is identified with the `dembal` constraint, which is owned by the min agent, and hence `p` is also owned by that agent.

There are several shorthands possible here. The first is that the explicit statement of variables can be replaced by the '$*$' form:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
put myinfo 'equilibrium ';
put 'min obj * defobj dembal cmbal ombal lmbal hmbal ruse ';
```

Alternatively, an even shorter version is possible since there is only one agent present in this model, namely:

```
model piesemp / defobj, dembal, cmbal, ombal, lmbal, hmbal, ruse /;
file myinfo /'%emp.info%'/;
putclose myinfo 'dualvar p dembal';
solve piesemp using emp minimizing obj;
```

Note that in this form, all the variables and constraints of the original model are included in the (single) agents problem, and the original variable `p` is identified in the constructed MCP with the multiplier on the `dembal` constraint.

In the general case where the "empinfo" file contains all three lines:

```
min x optcons
vi vicons y
dualvar p optcons
```

namely that the function H that is defined in `vicons` is complementary to the variable `y` (and hence the variable `y` is a parameter to the optimization problem), and furthermore that the dual variable associated with the equation optcons in the optimization problem is one and the same as the variable `p` used to define H, the EMP tool automatically creates the following MCP:

$$\begin{array}{lcl} 0 = \nabla_x \mathcal{L}(x,y,p) & \perp & x \text{ free} \\ 0 \geq -\nabla_p \mathcal{L}(x,y,p) & \perp & p \leq 0 \\ 0 = H(x,y,p) & \perp & y \text{ free,} \end{array}$$

where the Lagrangian is defined as

$$\mathcal{L}(x, y, p) = f(x, y) - \langle p, g(x, y)\rangle.$$

Essentially, this MCP consists of the first order optimality conditions of the optimization problem, coupled with the VI that is the second agents problem. An example that does both of these things together is provided in EMPLIB as **scarfemp-primal**.

Note that since the PIES model has no y variables, this is a special case of the general form in which the second agents (VI) problem is simply not present.

Example models are **ferris43**, **flipper pies**, **scarfemp-dual**, **simpequil**, **transecs**, and **transeql**.

5.21.8 MOPECs

MOPECs (Multiple Optimization Problems with Equilibrium Constraints) are a simple conceptual extension of the aforementioned embedded complementarity system. Instead of having a single optimizing agent and a variational inequality, one instead allows multiple optimizing agents coupled with an equilibrium constraint (the variational inequality).

Perhaps the most popular use of this formulation is where competition is allowed between agents. A standard method to deal with such cases is via the concept of Nash Games. In this setting x^* is a Nash Equilibrium if

$$x_i^* \in \arg\min_{x_i \in X_i} \ell_i(x_i, x_{-i}^*, q), \forall i \in \mathcal{I},$$

where x_{-i} are other players decisions and the quantities q are given exogenously, or via complementarity:

$$0 \leq H(x, q) \quad \perp \quad q \geq 0.$$

This mechanism is extremely popular in economics, and Nash famously won the Nobel Prize for his contributions to this literature.

This format is again an EMP, more general than the example given above in two respects. Firstly, there is more than one optimization problem specified in the embedded complementarity system. Secondly, the parameters in each optimization problem consist of two types. Firstly, there are the variables q that are tied down by the auxiliary complementarity condition and hence are treated as parameters by the ith Nash player. Also there are the variables x_{-i} that are treated as parameters by the ith Nash player, but are treated as variables by a different player j.

While we do not specify the syntax here for these issues, **EMPLIB** provides examples that outline how to carry out this matching within GAMS. Finally, two points of note: first it is clear that the resulting model is a complementarity problem and can be solved using PATH, for example. Secondly, performing the conversion from an embedded complementarity system or a Nash Game automatically is a critical step in making such models practically useful.

We note that there is a large literature on discrete-time finite-state stochastic games: this has become a central tool in analysis of strategic interactions among forward-looking players in dynamic environments. The model of dynamic competition in an oligopolistic industry given in [55] is exactly in the format described above, and has been used extensively in applications such as advertising, collusion, mergers, technology adoption, international trade and finance. Ongoing work aims to use the EMP format to model these problems.

5.21.9 Extended Nonlinear Programs

Optimization models have traditionally been of the form (NLP). Specialized codes have allowed certain problem structures to be exploited algorithmically, for example simple bounds on variables. However, for the most part, assumptions of smoothness of f, g and h are required for many solvers to process these problems effectively. In a series of papers, Rockafellar and colleagues [152] [153] [154] have introduced the notion of extended nonlinear programming, where the (primal) problem has the form:

$$\min_{x \in X} f(x) + \theta(g_1(x), \ldots, g_m(x)). \tag{ENLP}$$

In this setting, X is assumed to be a nonempty polyhedral set, and the functions $f, g_1, \ldots, g_m$ are smooth. The function θ can be thought of as a generalized penalty function that may well be nonsmooth. However, when θ has the form

$$\theta(u) = \sup_{y \in Y} \{\langle y, u \rangle - k(y)\}, \tag{θ conj}$$

a computationally exploitable and theoretically powerful framework can be developed based on conjugate duality. A key point for computation and modeling is that the function θ can be fully described by defining the set Y and the function k. Furthermore, from a modeling perspective, an extended nonlinear program can be specified simply by defining the functions $f, g_1, \ldots, g_m$ in the manner already provided by the modeling system, with the additional issue of simply defining Y and k. Conceptually, this is not much harder than what is carried out already, but leads to significant enhancements to the types of models that are available. Once a modeler determines which constraints are treated via which choice of k and Y, the EMP model interface automatically forms an equivalent variational inequality or complementarity problem. As we show later, there may be alternative formulations that are computationally more appealing; such reformulations can be generated using different options to JAMS.

5.21.9.1 Forms of theta

The EMP model type makes the problem format (ENLP) available to users in GAMS. As special cases, we can model piecewise linear penalties, least squares, and L_1 approximation problems, as well as the notion of soft and hard constraints.

For ease of exposition, we now describe a subset of the types of functions θ that can be generated by particular choices of Y and k. In many cases, the function θ is separable, that is

$$\theta(u) = \sum_{i=1}^{m} \theta_i(u_i),$$

so we can either specify θ_i or θ itself.

Extended nonlinear programs include the classical nonlinear programming form (NLP) as a special case. This follows from the observation that if K is a closed convex cone, and we let ψ_K denote the "indicator function" of K defined by:

$$\psi_K(u) = \begin{cases} 0 & \text{if } u \in K, \\ \infty & \text{else,} \end{cases}$$

then (NLP) can be rewritten as:

$$\min_x f(x) + \psi_K((g(x), h(x)), \qquad K = \mathbf{R}^m_- \times \{0\}^p,$$

where m and p are the dimensions of g and h respectively and $\mathbf{R}^m_- = \{u \in \mathbf{R}^m \mid u \leq 0\}$. An elementary calculation shows that

$$\psi_K(u) = \sup_{v \in K^\circ} \langle u, v \rangle,$$

where $K^\circ = \{u \mid \langle u, v\rangle \leq 0, \forall v \in K\}$ is the polar cone of the given cone K. Thus, when $\theta(u) = \psi_K(u)$ we simply take $k \equiv 0$ and $Y = K^\circ$. In our example, $K^\circ = \mathbf{R}^m_+ \times \mathbf{R}^p$. To some extent, this is just a formalism that allows us to claim the classical case as a specialization; however when we take the cone K to be more general than the polyhedral cone used above, we can generate conic programs for example.

The second example involves a piecewise linear function θ: Formally, for $u \in \mathbf{R}$,

$$\theta(u) = \begin{cases} \rho u & \text{if } u \geq 0, \\ \sigma u & \text{else.} \end{cases}$$

In this case, simple calculations prove that θ has the form (θ conj) for the choices

$$k \equiv 0 \text{ and } Y = [\sigma, \rho].$$

The special case where $\sigma = -\rho$ results in

$$\theta(u) = \rho\,|u|\,.$$

This allows us to model nonsmooth L_1 approximation problems. Another special case results from the choice of $\sigma = -\gamma$, $\rho = 0$, whereby

$$\theta(u) = \gamma \max\{-u, 0\}.$$

This formulation corresponds to a soft penalization on an inequality constraint, namely if $\theta(-g_1(x))$ is used then nothing is added to the objective function if $g_1(x) \leq 0$, but $\gamma g_1(x)$ is added if the constraint $g_1(x) \leq 0$ is violated. Contrast this to the classical setting above, where ∞ is added to the objective if the inequality constraint is violated. It is interesting to see that truncating the set Y, which amounts to bounding the multipliers, results in replacing the classical constraint by a linearized penalty.

The third example involves a more interesting choice of k. If we wish to replace the "absolute value" penalization given above by a quadratic penalization (as in classical least squares analysis), that is

$$\theta(u) = \gamma u^2$$

then a simple calculation shows that we should take

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = \mathbf{R}.$$

By simply specifying this different choice of k and Y we can generate such models easily and quickly within the modeling system. Note, however, that the reformulation we would use in $\theta(u) = \rho\,|u|$ and $\theta(u) = \gamma u^2$ are very different as we shall explain in the simple example below. Furthermore, in many applications it has become popular to penalize violations using a quadratic penalty only within a certain interval, afterwards switching to a linear penalty (chosen to make the penalty function θ continuously differentiable - see [99]). That is:

$$\theta(u) = \begin{cases} \gamma u - \frac{1}{2}\gamma^2 & \text{if } u \geq \gamma \\ \frac{1}{2} u^2 & \text{if } u \in [-\gamma, \gamma] \\ -\gamma u - \frac{1}{2}\gamma^2 & \text{else.} \end{cases}$$

Such functions arise from quadratic k and simple bound sets Y. In particular, the somewhat more general function

$$\theta(u) = \begin{cases} \gamma\beta^2 + \rho(u - \beta) & \text{if } u \geq \beta \\ \gamma u^2 & \text{if } u \in [\alpha, \beta] \\ \gamma\alpha^2 + \sigma(u - \alpha) & \text{else} \end{cases}$$

arises from the choice of

$$k(y) = \frac{1}{4\gamma} y^2 \text{ and } Y = [\sigma, \rho],$$

with $\alpha = \frac{\sigma}{2\gamma}$ and $\beta = \frac{\rho}{2\gamma}$.

The final example that we give is that of L_∞ penalization. This example is different to the examples given above in that θ is not separable. However, straightforward calculation can be used to show

$$\theta(u) = \max_{i=1,\ldots,m} u_i$$

results from the choice of

$$k \equiv 0 \text{ and } Y = \left\{ y \in \mathbf{R}^m \mid y \geq 0, \sum_{i=1}^m y_i = 1 \right\},$$

that is, Y is the unit simplex.

5.21.9.2 Underlying theory

The underlying structure of θ leads to a set of extended optimality conditions and an elegant duality theory. This is based on an extended form of the Lagrangian:

$$\mathcal{L}(x,y) = f(x) + \sum_{i=1}^{m} y_i g_i(x) - k(y)$$
$$x \in X, y \in Y$$

Note that the Lagrangian $\mathcal{L}$ is smooth - all the nonsmoothness is captured in the θ function. The theory is an elegant combination of calculus arguments related to g_i and its derivatives, and variational analysis for features related to θ.

It is shown in [153] that under a standard constraint qualification, the first-order conditions of (ENLP) are precisely in the form of the following variational inequality:

$$\text{VI}\left(\begin{bmatrix} \nabla_x \mathcal{L}(x,y) \\ -\nabla_y \mathcal{L}(x,y) \end{bmatrix}, X \times Y\right). \tag{ENLP VI}$$

When X and Y are simple bound sets, this is simply a complementarity problem.

Note that EMP exploits this result. In particular, if an extended nonlinear program of the form (ENLP) is given to EMP, then the optimality conditions (ENLP VI) are formed as a variational inequality problem and can be processed as outlined above. For a specific example, we cite the fact that if we use the (classical) choice $k \equiv 0$ and $Y = K^\circ$, then the optimality conditions of (ENLP) are precisely the standard complementarity problem given as (ENLP VI). While this is of interest, we believe that other choices of k and Y may be more useful and lead to models that have more practical significance.

Under appropriate convexity assumptions on this Lagrangian, it can be shown that a solution of the VI (ENLP VI) is a saddle point for the Lagrangian on $X \times Y$. Furthermore, in this setting, the saddle point generates solutions to the primal problem (ENLP) and its dual problem:

$$\max_{y \in Y} d(y), \quad \text{where } d(y) = \inf_{x \in X} \mathcal{L}(x,y),$$

with no duality gap.

Unfortunately, the perturbations y in Rockafellar's theory are precisely the negative of those used throughout the GAMS system. Thus, we need to replace y by $-y$ throughout in the above to recover the same multipliers as those GAMS uses.

5.21.9.3 A simple example

As an example, consider the problem

$$\begin{aligned} \min_{x_1,x_2,x_3} \quad & \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2\max(x_2^2 - 2, 0) \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \le 5, x_1 \ge 0, x_2 \ge 0. \end{aligned}$$

In this problem, we would take

$$X = \left\{x \in \mathbf{R}^3 \mid 3x_1 + x_2 \le 5, x_1 \ge 0, x_2 \ge 0\right\}.$$

The function θ essentially treats 3 separable pieces:

$$\begin{aligned} g_1(x) &= \log(x_1) - 1, \\ g_2(x) &= x_2^2 - 2, \\ g_3(x) &= x_1/x_2 - \log(x_3). \end{aligned}$$

A classical problem would force $g_1(x) = 0$, $g_2(x) \leq 0$. and $g_3(x) = 0$, while minimizing $f(x) = \exp(x_1)$. In our problem, we still force $g_3(x) = 0$, but apply a (soft) least squares penalty on $g_1(x)$ and a smaller one-sided penalization on $g_2(x)$. The above formulation is nonsmooth due to the "max" term in the objective function; in practice we could replace this by:

$$\begin{aligned} \min_{x_1,x_2,x_3,w} \quad & \exp(x_1) + 5\|\log(x_1) - 1\|^2 + 2w \\ \text{s.t.} \quad & x_1/x_2 = \log(x_3), \\ & 3x_1 + x_2 \leq 5, x_1 \geq 0, x_2 \geq 0 \\ & w \geq x_2^2 - 2, w \geq 0 \end{aligned}$$

and recover a standard form NLP. If the penalty on $g_1(x)$ would be replaced by a one-norm penalization (instead of least squares), we would have to play a similar game, moving the function $g_1(x)$ into the constraints and adding additional variable(s). To some extent, this seems unnatural - a modeler should be able to interchange the penalization without having to reformulate the problem from scratch. The proposed extended NLP would not be reformulated at all by the modeler, but allows all these "generalized constraints" to be treated in a similar manner within the modeling system. The actual formulation would take:

$$\theta(u) = \theta_1(u_1) + \theta_2(u_2) + \theta_3(u_3)$$

where

$$\begin{aligned} \theta_1(u_1) &= 5u_1^2, \\ \theta_2(u_2) &= 2\max(u_2, 0), \\ \theta_3(u_3) &= \psi_{\{0\}}(u_3). \end{aligned}$$

The discussion above allows us to see that

$$\begin{aligned} Y &= -(\mathbf{R} \times [0, 2] \times \mathbf{R}), \\ k(y) &= \frac{1}{20}y_1^2 + 0 + 0. \end{aligned}$$

The corresponding Lagrangian is the smooth function:

$$\mathcal{L}(x, y) = f(x) - \sum_{i=1}^{3} y_i g_i(x) - k(y).$$

The corresponding VI (ENLP VI) can almost be formulated in GAMS (except that the linear constraint in X cannot be handled currently except by introducing a $\theta_4(x)$). Thus

$$g_4(x) = 3x_1 + x_2 - 5, \ \theta_4(u) = \psi_{\mathbf{R}_-}$$

resulting in the following choices for Y and k:

$$\begin{aligned} Y &= -(\mathbf{R} \times [0, 2] \times \mathbf{R} \times \mathbf{R}_+), \\ k(y) &= \frac{1}{20}y_1^2 + 0 + 0 + 0. \end{aligned}$$

Since X and Y are now simple bound sets, (ENLP VI) is now a complementarity problem and can be solved for example using PATH. A simple "empinfo" file details the choices of Y and k from the implemented library:

```
Adjustequ
e1 sqr 5
e2 MaxZ 2
```

5.21.9.4 Reformulation as a classical NLP

Suppose

$$\theta(u) = \sup_{y \in Y} \{\langle u, y\rangle - \frac{1}{2}\langle y, Qy\rangle\}$$

for a polyhedral set $Y \in \mathbf{R}^m$ and a symmetric positive semidefinite $Q \in \mathbf{R}^{m\times m}$ (possibly $Q = 0$).

Suppose further that

$$X = \{x \mid Rx \leq r \ \}, Y = \left\{y \mid S^T y \leq s\right\},$$
$$Q = DJ^{-1}D^T, \ \ F(x) = (g_1(x), \ldots, g_m(x)),$$

where J is symmetric and positive definite (for instance $J = I$). Then, as outlined by [154] , the optimal solutions $\overline{x}$ of (ENLP) are the $\bar{x}$ components of the optimal solutions $(\bar{x}, \bar{z}, \bar{w})$ to

$$\begin{array}{ll} \min & f(x) + \langle s, z\rangle + \frac{1}{2}\langle w, Jw\rangle \\ \text{s.t.} & Rx \leq r, z \geq 0, F(x) - Sz - Dw = 0. \end{array}$$

The multiplier on the equality constraint in the usual sense is the multiplier associated with $\bar{x}$ in the extended Lagrangian for (ENLP). (Note that a Cholesky factorization may be needed to determine D.)

It may be better to solve this reformulated NLP than to solve the VI (ENLP VI). However, it is important that we can convey all types of nonsmooth optimization problems to a solver as smooth optimization problems, and hence it is important to communicate the appropriate structure to the solver interface. We believe that specifying Y and k is a theoretically sound way to do this.

5.21.10 Disjunctive Programs (LogMIP)

There are many ways that the EMP model type can be used for further extensions to the modeling capabilities of a given system. In particular, the procedures outlined in [190] [73] for disjunctive programming extensions are also implemented within the EMP model type.

The disjunctive programming procedures are also known as the LogMIP 2.0 solver for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications.

LogMIP 2.0 has been developed by Dr. Aldo Vecchietti from INGAR (Santa Fe, Argentina) and Professor Ignacio E. Grossmann from Carnegie Mellon University (Pittsburgh, USA), and supersedes its previous version, LogMIP 1.0 (GAMS releases 22.6 (December 2007) to 23.6 (December 2010)). Changes in version 2.0 are at the level of language, where now the EMP syntax and modeltype is used, and at the level of solvers, where Big-M and convex-hull relaxations are combined. For more information see the website http://www.logmip.ceride.gov.ar/ and the documentation http://www.logmip.ceride.gov.ar/files/pdfs/newUserManual.pdf.

One simple example to highlight the disjunctive programming feature is the notion of an ordering of tasks, namely that either job i completes before job j starts or the converse, i.e., that the jobs cannot overlap. Such a disjunction can be specified using an empinfo file containing lines:

```
disjunction * seq(i,j) else seq(j,i)
```

In such an example, one can implement a Big-M method, employ indicator constraints, or utilize a convex hull reformulation. The convex hull reformulation is the default strategy; to utilize the Big-M formulation, the additional option

```
default bigm 1000
```

would add binary variables and constraints to impose the disjunction using a Big-M value of 1000. Alternatively, the option setting

```
default indic
```

writes out a model and an option file that implements a reformulation using indicator constraints, which can be handled by the solvers CPLEX, SCIP, and XPRESS. The EMPLIB model **sequence** is sequencing model that implements all of these options.

More complicated (nonlinear) examples make the utility of this approach clearer. The design of a multiproduct batch plan with intermediate storage described in [189] and a synthesis problem involving 8 processes from [186] are also included in the EMP model library. As a final example, the gasoline emission model outlined in [72] is precisely in the form that could exploit the features of EMP related to (nonlinear) disjunctive programming.

5.21.11 Empinfo file details

We have explained above many of the standard vectorized ways to write an "empinfo" file. The "empinfo" file has a vectorized format and a more powerful (but more complex) scalar version. We describe some of the features of the scalar version in this section.

An example of the use of the scalar syntax is given below

```
file info / '%emp.info%' /;
put info / 'equilibrium';
loop(h,
  put / 'min' obj(h) /;
  loop(j, put x(h,j)); put /;
  loop(k, put z(h,k));
  put / costdef(h) /;
  loop(i, put nodebal(h,i)); put /;
);
loop(a, put 'vi',flowdef(a),f(a) /);
```

This is an example of a MOPEC in which the optimization agents are indexed by h and each of these agents control variables x_{hj} and z_{hk}. The objective function for each h is defined in `costdef`, the constraints of each minimization problem are defined in `nodebal`, and the equilibrium constraints that link all the optimization problems are a VI defined by variables f_a and functions within `flowdef`. Sometimes it is necessary to use syntax that generates the "tl" fields of sets, but this seems only necessary when abnormal side conditions are needed.

The format of the empinfo file is given below:

```
Disjunction [chull [big eps] | bigM [big eps threshold] | indic]
            [NOT] var|* [NOT] {equ} {ELSEIF [NOT] var|* [NOT] {equ}} [ELSE [NOT] {equ}]

Default [chull [big eps] | bigM [big eps threshold] | indic]

ParallelStep1 {equ|*}

AdjustEqu equ abs|sqr|maxz|... {weight}
```

```
ModelType MCP|NLP|MIP|...

BiLevel {var} {MAX|MIN obj {var|*} {[-] equ}} {VI {var|*} {[-] equ var} {[-] equ}}
              {DualVar {var [-] equ}}

Equilibrium {Implicit {var equ}} {VIsol {equ}}
            {MAX|MIN obj {var|*} {[-] equ}} {VI {var|*} {[-] equ var} {[-] equ}}
            {DualVar {var [-] equ}}

VI {var|*} {[-] equ var} {[-] equ}

DualEqu {[-] equ var}

DualVar {var [-] equ}

-------
[ ] optional      | exclusive      { } can be repeated
```

5.22 KESTREL - Remote Solver Execution on NEOS Servers

5.22.1 Background

The Kestrel client/server is a way of sending your GAMS solve job to be solved via the NEOS Server from within your usual GAMS modeling environment and receiving results that can be processed as with any local solver. Starting with distribution 23.7 the Kestrel solver is part of the GAMS distribution. The solve statement using the GAMS/KESTREL solver invokes a client program that sends your problem to a solver running on one of the NEOS Server's remote computers. The results from the NEOS Server are eventually returned through Kestrel to GAMS, where you can view and manipulate them locally in the usual way. The introduction below covers everything you need to know to start using GAMS/KESTREL. Further information about more advanced features and other uses of Kestrel can be found at the Kestrel page on the NEOS Server. Please also make you familiar with the NEOS optimization service terms of use before submitting jobs via GAMS/KESTREL.

5.22.2 Using GAMS/KESTREL

The Kestrel solver can be used to solve a GAMS model remotely. For example, consider the **trnsport model**. It can be solved locally in GAMS through the following statements,

```
model transport /all/;
solve transport using lp minimizing z;
```

which specify the `trnsport` model and solve it with the default linear programming solver. We can add an option statement to the code to explicitly specify the solver. For example, if we change the linear programming solver to GAMS/MINOS, the code becomes

```
model transport /all/;
option lp=minos;
solve transport using lp minimizing z;
```

To solve the same problem remotely through the NEOS Server, we simply change the linear programming solver to Kestrel. In addition we have to provide an email address. This can be specified either in an option file or by setting the environment variable NEOS_EMAIL. In order to set this permanently, it is recommended to add NEOS_EMAIL to your gamsconfig.yaml file.

Without an option file Kestrel will submit the model instance to the NEOS server and use the default LP solver on NEOS.

```
option lp=kestrel;
solve transport using lp minimizing z;
```

We can support a Kestrel option file and determine the solver on the NEOS server:

```
transport.optfile=1;
option lp=kestrel;
solve transport using lp minimizing z;
$echo email jdoe@jeangreyhigh.edu > kestrel.opt
$echo kestrel_solver minos >> kestrel.opt
```

The statement transport.optfile=1 specifies that an options file, called kestrel.opt, will be used. The options file contains the email address, the remote solver name as well as any options for the remote solver. We instruct the Kestrel solver to use GAMS/MINOS as the remote solver by writing the following kestrel.opt file:

```
email jdoe@jeangreyhigh.edu
kestrel_solver minos
```

If you do not know what solvers are available via GAMS/KESTREL on NEOS, submitting a job with a nonexistent solver set will return a list of enabled solvers. If you want to change the URL of the server, you can specify the option neos_server. The complete format of the parameter is protocol://host:port.

A subsequent run of the code through the GAMS interpreter results in the transport model being solved through the NEOS Server with the GAMS/MINOS solver. Once the job is submitted to the NEOS Server, a job number, password, and Web address are displayed to the screen, which provide information on accessing the job and viewing the intermediate output, for example,

```
--- Executing KESTREL
Job has been submitted to Kestrel
Kestrel/NEOS Job number    : 93478
Kestrel/NEOS Job password  : utiwtxTK
Check the following URL for progress report :
     https://neos-server.org/neos/cgi-bin/nph-neos-solver.cgi?admin=results&jobnumber=93478&pass=utiw
```

To look at the solver's output while it is running, point your browser at the URL given in the Kestrel output as shown above, and click on View Intermediate Results in the web page that appears. This will take you to another page that shows all of the output produced by the solver for your problem so far. To track the solver's progress, simply update this page periodically.

If the NEOS Server or the network becomes unavailable after the submission, a particular job can be retrieved by setting both the kestrel job and kestrel password in the options file.

```
kestrel_solver minos
kestrel_job 93478
kestrel_password utiwtxTK
```

Re-issuing the command gams trnsport with this options file will retrieve the results for the specified job number.

By specifying neos_username and neos_user_password in the option file, you can submit an authenticated job using your NEOS user account. Authenticated jobs will appear in your user account on the NEOS website.

```
neos_username username
neos_user_password password
```

5.23 KNITRO

5.23.1 Introduction

Artelys Knitro is a software package for finding local solutions of both continuous (i.e. smooth) optimization problems, with or without constraints, and discrete optimization problems with integer or binary variables. Even though Knitro has been designed for solving large-scale general problems, it is efficient for solving all of the following classes of optimization problems:

- unconstrained,
- bound constrained,
- equality constrained,
- systems of nonlinear equations,
- least squares problems,
- linear programming problems (LPs),
- quadratic programming problems (QPs),
- general (inequality) constrained problems,
- (convex) mixed integer nonlinear programs (MINLP) of moderate size.

The Knitro package provides the following features:

- Efficient and robust solution of small or large problems,
- Solvers for both continuous and discrete problems,
- Derivative-free, 1st derivative and 2nd derivative options,
- Both interior-point (barrier) and active-set optimizers,
- Both feasible and infeasible versions,
- Both iterative and direct approaches for computing steps,

The problems solved by Knitro have the form

$$\begin{aligned} \text{minimize} \quad & f(x) && (1a)\\ \text{subject to} \quad & c^L \leq c(x) \leq c^U && (1b)\\ & b^L \leq x \leq b^U, && (1c) \end{aligned}$$

where the variables x can be continuous, binary, or integer. This allows many forms of constraints, including bounds on the variables. Knitro requires that the functions $f(x)$ and $c(x)$ be smooth functions.

Knitro implements both state-of-the-art interior-point and active-set methods for solving nonlinear optimization problems. In the interior method (also known as a barrier method), the nonlinear programming problem is replaced by a series of barrier sub-problems controlled by a barrier parameter μ. The algorithm uses trust regions and a merit function to promote convergence. The algorithm performs one or more minimization steps on each barrier problem, then decreases the barrier parameter, and repeats the process until the original problem (1) has been solved to the desired accuracy.

Knitro provides two procedures for computing the steps within the interior point approach. In the version known as `Interior/CG` each step is

computed using a projected conjugate gradient iteration. This approach differs from most interior methods proposed in the literature in that it does not compute each step by solving a linear system involving the KKT (or primal-dual) matrix. Instead, it factors a projection matrix, and uses the conjugate gradient method, to approximately minimize a quadratic model of the barrier problem.

The second procedure for computing the steps, which we call `Interior/Direct`, always attempts to compute a new iterate by solving the primal-dual KKT matrix using direct linear algebra. In the case when this step cannot be guaranteed to be of good quality, or if negative curvature is detected, then the new iterate is computed by the `Interior/CG` procedure.

`Knitro` also implements an active-set sequential linear-quadratic programming (SLQP) algorithm which we call `Active`. This method is similar in nature to a sequential quadratic programming method but uses linear programming sub-problems to estimate the active-set at each iteration. This active-set code may be preferable when a good initial point can be provided, for example, when solving a sequence of related problems.

For problems with discrete variables, Knitro provides two variants of the branch and bound algorithm. The first is a standard implementation, while the second is specialized for convex, mixed-integer nonlinear problems.

We encourage the user to try all algorithmic options to determine which one is more suitable for the application at hand. For guidance on choosing the best algorithm see section Algorithm Options .

For a detailed description of the algorithm implemented in `Interior/CG` see [30] and for the global convergence theory see [31] . The method implemented in `Interior/Direct` is described in [198] . The `Active` algorithm is described in [33] and the global convergence theory for this algorithm is in [34] . An important component of Knitro is the HSL routine `MA27` [92] which is used to solve the linear systems arising at every iteration of the algorithm. In addition, the `Active Set` algorithm in Knitro may make use of the COIN-OR `Clp` linear programming solver module. The version used in `Knitro` may be downloaded from `http://www.artelys.com/tools/clp/`.

5.23.2 Usage

Basic details of solver usage, including how to choose Knitro as the solver and how to use a solver-specific option file, are part of Chapter Solver Usage.

As an NLP solver, Knitro can also be used to solve linear programs (LP), and both convex and nonconvex quadratic programs (QCP).

5.23.3 GAMS Options

The following GAMS options are used by the GAMS/Knitro link:

- Option ResLim = x;

  Sets the time limit in seconds. If this limit is exceeded the solver will terminate and pass on the current solution to GAMS. See also reslim in section GAMS options .

- Option SysOut = On;

  This option sends additional Knitro messages to the GAMS listing file. It is useful in case of a solver failure or to get algorithmic details. See also sysout in section GAMS options

- *ModelName*.optCA = x;

  Absolute gap stop criterion for a discrete problem. The Knitro option mip_opt_gap_abs takes its default from this value. See also optca in section GAMS options.

- *ModelName*.optCR = x;

  Relative gap stop criterion for a discrete problem. The Knitro option mip_opt_gap_rel takes its default from this value. See also optcr in section GAMS options.

5.23.4 Summary of Knitro Options

The Knitro options file `knitro.opt` allows the user to easily set options controlling `Knitro`'s behavior. Options are set by specifying a keyword and a corresponding value on a line in the `knitro.opt` file. Lines that begin with a `#` character are treated as comments and blank lines are ignored. For example, to set the maximum allowable number of iterations to 500, one could use the following options file:

```
maxit 500
```

5.23.4.1 General options

Option	Description	Default
algorithm	Indicates which algorithm to use to solve the problem	0
blasoption	Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations	1 or 4 (platform dependent)
blasoptionlib	Specifies a dynamic library name that contains object code for BLAS/LAPACK functions	
bndrange	Specifies max limits on the magnitude of constraint and variable bounds	1e+20
cg_maxit	Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration	-1
cg_pmem	Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner	10
cg_precond	Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms	0
cg_stoptol	Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves	0.01
convex	Declare the problem as convex by setting to 1 or non-convex by setting to 0	-1
cpuplatform	This option can be used to specify the target instruction set architecture for the machine on which Knitro is running	-1
datacheck	Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure)	0
delta	Specifies the initial trust region radius scaling factor used to determine the initial trust region size	1
honorbnds	Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization	-1
initpenalty	Specifies the initial penalty parameter used in the Knitro merit functions	10
initvalues	Enable use of initial guess for levels and marginals (subsequent solves)	1

Option	Description	Default
initvalues0	Enable use of initial guess for levels and marginals (first solve)	2
linesearch	Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate	0
linesearch_maxtrials	Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step	3
linsolver	Indicates which linear solver to use to solve linear systems arising in Knitro algorithms	0
linsolver_maxitref	Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro	2
linsolver_nodeamalg	Controls the node amalgamation setting for the MA57, MA86 and MA97 linear solvers	0
linsolver_ooc	Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when linsolver = mklpardiso	0
linsolver_ordering	Sets the ordering method used for the linear system solver	-1
linsolver_pivottol	Specifies the initial pivot threshold used in factorization routines	1e-08
linsolver_scaling	Enables scaling for the linear system solver	0
names	Enable to pass variable and equation names to Knitro	0
ncvx_qcqp_init	Specifies the initialization strategy used for non-convex QPs and QCQPs	-1
newpoint	Specifies additional action to take after every iteration in a solve of a continuous problem, or after every new incumbent of the NLPBB algorithm	0
objrange	Specifies the extreme limits of the objective function for purposes of determining unboundedness	1e+20
option_file	additional option file name - read only by KNITRO solver lib	
output_time	print output on where time is used	0
qextractalg	quadratic extraction algorithm in GAMS interface	0
restarts	Specifies whether or not to enable automatic restarts in Knitro	-1
restarts_maxit	When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart	0
scale	Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables	1
scale_vars	Specifies the strategy for scaling variables	0
soc	Specifies whether or not to try second order corrections (SOC)	1

Option	Description	Default
strat_warm_start	Specifies whether or not to invoke a warm-start strategy	0

5.23.4.2 Derivative options

Option	Description	Default
bfgs_scaling	Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation	0
findiff_estnoise	This option can be used to enable an estimate of the noise in the model when using finite-difference gradients	0
findiff_relstepsize	Specifies the relative stepsize used for finite-difference gradients during the optimization	0
findiff_terminate	This option specifies the termination criteria when using finite-difference gradients	1
gradopt	Specifies how to compute the gradients of the objective and constraint functions	1
hessopt	Specifies how to compute the (approximate) Hessian of the Lagrangian	0
lmsize	Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option	10

5.23.4.3 Termination options

Option	Description	Default
feastol	Specifies the final relative stopping tolerance for the feasibility error	1e-06
feastolabs	Specifies the final absolute stopping tolerance for the feasibility error	0.001
fstopval	Used to implement a custom stopping condition based on the objective function value	maxdouble
ftol	The optimization process will terminate if the relative change in the objective function is less than ftol for ftol_iters consecutive feasible iterations	1e-15
ftol_iters	The optimization process will terminate if the relative change in the objective function is less than ftol for ftol_iters consecutive feasible iterations	5
infeastol	Specifies the (relative) tolerance used for declaring infeasibility of a model	1e-08
infeastol_iters	The optimization process will terminate if the relative change in the feasibility error is less than infeastol for infeastol_iters consecutive infeasible iterations	50
maxfevals	Specifies the maximum number of function evaluations before termination	-1
maxit	Specifies the maximum number of iterations before termination	GAMS iterlim
maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before termination	100000000
maxtime_real	Specifies, in seconds, the maximum allowable real time before termination	GAMS reslim
opttol	Specifies the final relative stopping tolerance for the KKT (optimality) error	1e-06

Option	Description	Default
opttolabs	Specifies the final absolute stopping tolerance for the KKT (optimality) error	0.001
xtol	The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol_iters	1e-12
xtol_iters	The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol_iters consecutive iterations	0

5.23.4.4 Presolve options

Option	Description	Default
presolve	Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints	1
presolveop_redundant	Determine whether or not to enable the Knitro presolve operation to detect and remove redundant constraints	1
presolveop_substitution	Determine whether or not to enable the Knitro presolve operation to substitute out variables when possible	-1
presolveop_substitution_tol	Tolerance for applying a substitution	0.01
presolveop_tighten	Determine whether or not to enable the Knitro presolve operation to tighten variable bounds or coefficients	-1
presolve_initpt	Control whether the Knitro presolver can shift a user-supplied initial point	-1
presolve_level	Set the level of presolve operations to enable through the Knitro presolver	-1
presolve_passes	Set a maximum limit on the number of passes through the Knitro presolve operations	10
presolve_tol	Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model	1e-06

5.23.4.5 Barrier options

Option	Description	Default
bar_conic_enable	Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm)	-1
bar_directinterval	Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra	-1
bar_feasible	Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms	0
bar_feasmodetol	Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible	0.0001
bar_globalize	Specifies the globalization strategy used in the interior-point algorithms	2
bar_initmu	Specifies the initial value for the barrier parameter μ used with the barrier algorithms	-1
bar_initpi_mpec	Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms	0

Option	Description	Default
bar_initpt	Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm	0
bar_linsys	Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps	-1
bar_linsys_storage	Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps	-1
bar_maxcorrectors	Specifies the maximum number of corrector steps allowed for primal-dual steps	-1
bar_maxcrossit	Specifies the maximum number of crossover iterations before termination	0
bar_maxmu	Specifies the maximum allowable value for the barrier parameter μ used with the barrier algorithms	1e+16
bar_maxrefactor	Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step	-1
bar_mpec_heuristic	Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm	0
bar_murule	Indicates which strategy to use for modifying the barrier parameter mu in the barrier algorithms	0
bar_penaltycons	Indicates whether a penalty approach is applied to the constraints	-1
bar_penaltyrule	Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate	0
bar_refinement	Specifies whether to try to refine the barrier solution for better precision	0
bar_relaxcons	Indicates whether a relaxation approach is applied to the constraints	2
bar_slackboundpush	Specifies the amount by which the barrier slack variables are initially pushed inside the bounds	-1
bar_switchobj	Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase	1
bar_switchrule	Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase	-1
bar_watchdog	Specifies whether to enable watchdog heuristic for barrier algorithms	0

5.23.4.6 Active-set options

Option	Description	Default
act_lpfeastol	Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms	1e-08
act_lppenalty	Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms	1
act_lppresolve	Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms	0
act_parametric	Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms	1
act_qpalg	Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms	0

Option	Description	Default
act_qppenalty	Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm	-1
mip_cut_flowcover	Specifies rules for adding flow cover cuts	-1
mip_cut_probing	Specifies rules for adding probing cuts	-1
mip_heuristic_localsearch	Specifies whether or not to enable the MIP local search heuristic	-1

5.23.4.7 MIP options

Option	Description	Default
mip_branchrule	Specifies which branching rule to use for MIP branch and bound procedure	0
mip_clique	Specifies rules for adding clique cuts	-1
mip_cutfactor	This value specifies a limit on the number of cuts added to a node subproblem	1
mip_cutoff	This value specifies the objective cutoff value for MIP	maxdouble
mip_cutting_plane	Specifies when to apply the cutting plane procedure	1
mip_gomory	Specifies rules for adding Gomory mixed-integer cuts	-1
mip_gub_branch	Specifies whether or not to branch on generalized upper bounds (GUBs)	0
mip_heuristic_diving	Specifies whether or not to enable the MIP diving heuristic	-1
mip_heuristic_feaspump	Specifies whether or not to enable the MIP feasibility pump heuristic	-1
mip_heuristic_lns	Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics	-1
mip_heuristic_maxit	Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled	100
mip_heuristic_misqp	Specifies whether or not to enable the MIP MISQP heuristic	-1
mip_heuristic_mpec	Specifies whether or not to enable the MIP MPEC heuristic	-1
mip_heuristic_strategy	Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point	-1
mip_heuristic_terminate	Specifies the condition for terminating the MIP heuristic	1
mip_implications	Specifies whether or not to add constraints to the MIP derived from logical implications	1
mip_integer_tol	This value specifies the threshold for deciding whether or not a variable is determined to be an integer	1e-08
mip_intvar_strategy	Specifies how to handle integer variables	0
mip_knapsack	Specifies rules for adding MIP knapsack cuts	-1
mip_liftproject	Specifies rules for adding lift and project cuts	-1
mip_lpalg	Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch-and-bound procedure	0

Option	Description	Default
mip_maxnodes	Specifies the maximum number of nodes explored (0 means no limit)	GAMS nodlim
mip_maxsolves	Specifies the maximum number of subproblem solves allowed (0 means no limit)	0
mip_maxtime_cpu	Specifies the maximum allowable CPU time in seconds for the complete MIP solution	100000000
mip_maxtime_real	Specifies the maximum allowable real time in seconds for the complete MIP solution	GAMS reslim
mip_method	Specifies which MIP method to use	0
mip_mir	Specifies rules for adding mixed-integer rounding cuts	-1
mip_multistart	Use to enable MIP multi-start at the branch-and-bound level	0
mip_nodealg	Specifies which algorithm to use for standard node subproblem solves in MIP (same options as algorithm user option)	0
mip_numthreads	Specify the number of threads to use for MIP branch-and-bound (when mip_method = 1)	0
mip_opt_gap_abs	The absolute optimality gap stop tolerance for MIP	GAMS optca
mip_opt_gap_rel	The relative optimality gap stop tolerance for MIP	GAMS optcr
mip_outinterval	Specifies node printing interval for mip_outlevel when mip_outlevel > 0	0
mip_outlevel	Specifies how much MIP information to print	2
mip_pseudoinit	Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method	0
mip_relaxable	Specifies whether integer variables are relaxable	1
mip_restart	Specifies whether to enable the MIP restart procedure	1
mip_rootalg	Specifies which algorithm to use for the root node solve in MIP (same options as algorithm user option)	0
mip_rounding	Specifies the MIP rounding rule to apply	-1
mip_selectdir	Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch-and-bound tree	0
mip_selectrule	Specifies the MIP select rule for choosing the next node in the branch-and-bound tree	0
mip_strong_candlim	Specifies the maximum number of candidates to explore for MIP strong branching	128
mip_strong_level	Specifies the maximum number of tree levels on which to perform MIP strong branching	10
mip_strong_maxit	Specifies the maximum number of iterations to allow for MIP strong branching solves	1000
mip_terminate	Specifies conditions for terminating the MIP algorithm	0
mip_zerohalf	Specifies rules for adding zero-half cuts	-1

5.23.4.8 Multi-algorithm options

Option	Description	Default
ma_maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm ("MA") procedure (algorithm=5)	100000000
ma_maxtime_real	Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm ("MA") procedure (algorithm=5)	100000000
ma_outsub	Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure	0
ma_terminate	Define the termination condition for the multi-algorithm (algorithm=5) procedure	1

5.23.4.9 Multi-start options

Option	Description	Default
ms_deterministic	Indicates whether Knitro multi-start procedure will be deterministic (when ms_terminate = 0)	1
ms_enable	Indicates whether Knitro will solve from multiple start points to find a better local minimum	0
ms_initpt_cluster	The strategy for clustering initial points in multi-start	0
ms_maxbndrange	Specifies the maximum range that an unbounded variable can take when determining new start points	1000
ms_maxsolves	Specifies how many start points to try in multi-start	0
ms_maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before termination	100000000
ms_maxtime_real	Specifies, in seconds, the maximum allowable real time before termination	100000000
ms_numthreads	Specify the number of threads to use for multi-start (when ms_enable = 1)	0
ms_num_to_save	Specifies the number of distinct feasible points to save in a file named knitro_mspoints	0
ms_outsub	Enable writing algorithm output to files for the parallel multi-start procedure	0
ms_savetol	Specifies the tolerance for deciding if two feasible points are distinct	1e-06
ms_seed	Seed value used to generate random initial points in multi-start; should be a non-negative integer	0
ms_startptrange	Specifies the maximum range that each variable can take when determining new start points	1e+20
ms_terminate	Specifies the condition for terminating multi-start	0

5.23.4.10 Parallelism options

Option	Description	Default
blas_numthreads	Specify the number of threads to use for BLAS operations when blasoption = 1	0
conic_numthreads	Specify the number of threads to use for operations in the conic algorithm (when bar_conic_enable = 1)	0
linsolver_numthreads	Specify the number of threads to use for linear system solve operations when linsolver = 6	0
threads	default thread count	GAMS threads

5.23.4.11 Output options

Option	Description	Default
outappend	Specifies whether output should be started in a new file, or appended to existing files	0
outdir	Specifies a single directory as the location to write all output files	
outlev	Controls the level of output produced by Knitro	2
outmode	Specifies where to direct the output from Knitro	0
outname	Use to specify a custom filename when output is written to a file using outmode	
out_csvinfo	Controls whether or not to generates a file knitro_solve	0
out_csvname	Use to specify a custom csv filename when using out_csvinfo	
out_hints	Specifies whether to print diagnostic hints (e.g. about user option settings) after solving	1

5.23.4.12 Tuner options

Option	Description	Default
tuner	Indicates whether to invoke the Knitro-Tuner	0
tuner_maxtime_cpu	Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner	100000000
tuner_maxtime_real	Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner	100000000
tuner_optionsfile	Can be used to specify the location of a Tuner options file	
tuner_outsub	Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure (tuner=1)	0
tuner_terminate	Define the termination condition for the Knitro-Tuner procedure (tuner=1)	0

5.23.5 Detailed Descriptions of Knitro Options

act_lpfeastol *(real)*: Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms ↩

Range: [0, ∞]

Default: 1e-08

act_lppenalty *(integer)*: Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms ↩

Default: 1

value	meaning
1	(all) penalize all constraints.
2	(nonlinear) penalize only nonlinear constraints.
3	(dynamic) dynamically choose which constraints to penalize.

act_lppresolve *(boolean)*: Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms ↩

Default: `0`

value	meaning
`0`	(off) presolve turned off for LP subproblems.
`1`	(on) presolve turned on for LP subproblems.

act_parametric *(integer)*: Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms ↩

Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms. A parametric approach will solve a sequence of closely related LPs instead of one LP. It may increase the cost of an active-set iteration, but perhaps lead to convergence in fewer iterations.

Default: `1`

value	meaning
`0`	(no) do not use a parametric solve (i.e. solve a single LP).
`1`	(maybe) use a parametric solve sometimes.
`2`	(yes) always try a parametric solve.

act_qpalg *(integer)*: Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms ↩

Indicates which algorithm to use to solve quadratic programming (QP) subproblems when using the Knitro Active Set or SQP algorithms. This option has no effect on the Interior/Direct and Interior/CG algorithms.

Default: `0`

value	meaning
`0`	(auto) let Knitro automatically choose an algorithm, based on the problem characteristics.
`1`	(direct) use the Interior/Direct algorithm.
`2`	(cg) use the Interior/CG algorithm.
`3`	(active) use the Active Set algorithm.

act_qppenalty *(integer)*: Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm ↩

Default: `-1`

value	meaning
`-1`	(auto) let Knitro automatically decide.
`0`	(none) do not penalize constraints in QP subproblems.
`1`	(all) penalize all constraints in QP subproblems.

algorithm *(integer)*: Indicates which algorithm to use to solve the problem ↩

Default: 0

value	meaning
0	(auto) let Knitro automatically choose an algorithm, based on the problem characteristics.
1	(direct) use the Interior/Direct algorithm.
2	(cg) use the Interior/CG algorithm.
3	(active) use the Active Set algorithm.
4	(sqp) use the SQP algorithm.
5	(multi) run all algorithms, perhaps in parallel (see Algorithms).

bar_conic_enable *(integer)*: Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm) ↩

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the strategy.
0	(none) Do not apply any special treatment for conic constraints.
1	(soc) Apply special treatments for any Second Order Cone (SOC) constraints identified in the model.

bar_directinterval *(integer)*: Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra ↩

Controls the maximum number of consecutive conjugate gradient (CG) steps before Knitro will try to enforce that a step is taken using direct linear algebra. This option is only valid for the Interior/Direct algorithm and may be useful on problems where Knitro appears to be taking lots of conjugate gradient steps. Setting bar_directinterval to 0 will try to enforce that only direct steps are taken which may produce better results on some problems.

Range: {-1, ..., ∞}

Default: -1

bar_feasible *(integer)*: Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms ↩

Specifies whether special emphasis is placed on getting and staying feasible in the interior-point algorithms. Note This option can only be used with the Interior/Direct and Interior/CG algorithms. If bar_feasible = stay or bar_feasible = get_stay, this will activate the feasible version of Knitro. The feasible version of Knitro will force iterates to strictly satisfy inequalities, but does not require satisfaction of equality constraints at intermediate iterates. This option and the honorbnds option may be useful in applications where functions are undefined outside the region defined by inequalities. The initial point must satisfy inequalities to a sufficient degree; if not, Knitro may generate infeasible iterates and does not switch to the feasible version until a sufficiently feasible point is found. Sufficient satisfaction occurs at a point x if it is true for all inequalities that $cl + tol \leq c(x) \leq cu - tol$ The constant tol is determined by the option bar_feasmodetol. If bar_feasible = get or bar_feasible = get_stay, Knitro will place special emphasis on first trying to get feasible before trying to optimize.

Default: 0

value	meaning
0	(no) No special emphasis on feasibility.
1	(stay) Iterates must satisfy inequality constraints once they become sufficiently feasible.
2	(get) Special emphasis is placed on getting feasible before trying to optimize.
3	(get_stay) Implement both options 1 and 2 above.

bar_feasmodetol *(real)*: Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible ↩

Specifies the tolerance in equation that determines whether Knitro will force subsequent iterates to remain feasible. The tolerance applies to all inequality constraints in the problem. This option only has an effect if option bar_feasible = stay or bar_feasible = get_stay.

Range: [0, ∞]

Default: 0.0001

bar_globalize *(integer)*: Specifies the globalization strategy used in the interior-point algorithms ↩

Default: 2

value	meaning
0	(none) No globalization strategy is applied.
1	(kkt) Apply a globalization strategy based on decreasing the KKT error.
2	(filter) Apply a globalization strategy using a filter based on the objective and constraint violation.

bar_initmu *(real)*: Specifies the initial value for the barrier parameter μ used with the barrier algorithms ↩

Specifies the initial value for the barrier parameter μ used with the barrier algorithms. This option has no effect on the Active Set algorithm.

Range: [-∞, ∞]

Default: -1

bar_initpi_mpec *(real)*: Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms ↩

Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms. If this value is non-positive, then Knitro uses an internal formula to initialize the MPEC penalty parameter.

Range: [0, ∞]

Default: 0

bar_initpt *(integer)*: Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm ↩

Indicates initial point strategy for x, slacks and multipliers when using a barrier algorithm. Note, this option only alters the initial x values if the user does not specify an initial x. This option has no effect on the Active Set algorithm.

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the strategy.
1	(convex) Initialization designed for convex models.
2	(nearbnd) Initialization strategy that stays closer to the bounds.
3	(central) Initialization strategy that is more central on double-bounded variables.

bar_linsys *(integer)*: Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps ↩

Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps. Eliminating more elements results in a smaller dimensional linear system (but also one that is, perhaps, less numerically stable). The bounds option may be preferable for very large problems with many bounded variables. The ineq option may generate significant speedups on models where the number of variables is small, but the number of inequality constraints is large.

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the linear system form.
0	(full) Use the full linear system.
1	(slacks) Eliminate the slack variables.
2	(bounds) Eliminate the slack variables and bounds.
3	(ineqs) Eliminate the slack variables, bounds, and some inequalities.

bar_linsys_storage *(integer)*: Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps ↩

Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps. The lowmem option uses one storage location for multiple linear systems. As a result it may use much less memory, but also may be less efficient when the Interior/Direct algorithm takes a lot of CG steps. The normal option uses separate storage for different linear systems.

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the linear system storage approach.
1	(lowmem) Use common storage for multiple linear systems.
2	(normal) Use separate storage for different linear systems.

bar_maxcorrectors *(integer)*: Specifies the maximum number of corrector steps allowed for primal-dual steps ↩

Specifies the maximum number of corrector steps allowed for primal-dual steps. If the value is positive and the algorithm used is Interior/Direct, then Knitro may add at most bar_maxcorrectors corrector steps to the primal-dual step to try to stay closer to the central path. This may speedup convergence on some models (although it may make the cost per iteration a little more expensive). If the value is negative, Knitro automatically determines the maximum number of corrector steps to apply.

Range: {-∞, ..., ∞}

Default: -1

bar_maxcrossit *(integer)*: Specifies the maximum number of crossover iterations before termination ↩

Specifies the maximum number of crossover iterations before termination. If the value is positive and the algorithm in operation is Interior/Direct or Interior/CG, then Knitro will crossover to the Active Set algorithm near the solution. The Active Set algorithm will then perform at most bar_maxcrossit iterations to get a more exact solution. If the value is 0, no Active Set crossover occurs and the interior-point solution is the final result. If Active Set crossover is unable to improve the approximate interior-point solution, then Knitro will restore the interior-point solution. In some cases (especially on large-scale problems or difficult degenerate problems) the cost of the crossover procedure may be significant – for this reason, crossover is disabled by default. Enabling crossover generally provides a more accurate solution than Interior/Direct or Interior/CG.

Range: {0, ..., ∞}

Default: 0

bar_maxmu *(real)*: Specifies the maximum allowable value for the barrier parameter μ used with the barrier algorithms ↩

Range: [2.08157871384174e-07, 1e+16]

Default: 1e+16

bar_maxrefactor *(integer)*: Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step ↩

Indicates the maximum number of refactorizations of the KKT system per iteration of the Interior/Direct algorithm before reverting to a CG step. If this value is set to -1, it will use a dynamic strategy. These refactorizations are performed if negative curvature is detected in the model. Rather than reverting to a CG step, the Hessian matrix is modified in an attempt to make the subproblem convex and then the KKT system is refactorized. Increasing this value will make the Interior/Direct algorithm less likely to take CG steps. If the Interior/Direct algorithm is taking a large number of CG steps (as indicated by a positive value for "CGits" in the output), this may improve performance. This option has no effect on the Active Set algorithm.

Range: {-1, ..., ∞}

Default: -1

bar_mpec_heuristic *(boolean)*: Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm ↩

Specifies whether or not to use a heuristic approach when solving MPEC models with the barrier algorithm. In some cases enabling this heuristic can speedup the convergence to the solution and provide a more precise solution on MPEC models (i.e., models with complementarity constraints).

Default: 0

value	meaning
0	(no) Do not enable the heuristic for MPEC models.
1	(yes) Enable the heuristic for MPEC models.

bar_murule *(integer)*: Indicates which strategy to use for modifying the barrier parameter *mu* in the barrier algorithms ↩

Indicates which strategy to use for modifying the barrier parameter *mu* in the barrier algorithms. Not all strategies are available for both barrier algorithms, as described below. This option has no effect on the Active Set algorithm.

Default: `0`

value	meaning
`0`	(auto) Let Knitro automatically choose the strategy.
`1`	(monotone) Monotonically decrease the barrier parameter. Available for both barrier algorithms.
`2`	(adaptive) Use an adaptive rule based on the complementarity gap to determine the value of the barrier parameter. Available for both barrier algorithms.
`3`	(probing) Use a probing (affine-scaling) step to dynamically determine the barrier parameter. Available only for the Interior/Direct algorithm.
`4`	(dampmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, with safeguards on the corrector step. Available only for the Interior/Direct algorithm.
`5`	(fullmpc) Use a Mehrotra predictor-corrector type rule to determine the barrier parameter, without safeguards on the corrector step. Available only for the Interior/Direct algorithm.
`6`	(quality) Minimize a quality function at each iteration to determine the barrier parameter. Available only for the Interior/Direct algorithm.

bar_penaltycons *(integer)*: Indicates whether a penalty approach is applied to the constraints ↩

Indicates whether a penalty approach is applied to the constraints. Using a penalty approach may be helpful when the problem has degenerate or difficult constraints. It may also help to more quickly identify infeasible problems, or achieve feasibility in problems with difficult constraints. This option has no effect on the Active Set algorithm.

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro automatically choose the strategy.
`0`	(none) No constraints are penalized.
`2`	(all) A penalty approach is applied to all general constraints.
`3`	(equalities) Apply a penalty approach to equality constraints only.

bar_penaltyrule *(integer)*: Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate ↩

Indicates which penalty parameter strategy to use for determining whether or not to accept a trial iterate. This option has no effect on the Active Set algorithm.

Default: `0`

value	meaning
`0`	(auto) Let Knitro automatically choose the strategy.

value	meaning
1	(single) Use a single penalty parameter in the merit function to weight feasibility versus optimality.
2	(flex) Use a more tolerant and flexible step acceptance procedure based on a range of penalty parameter values.

bar_refinement *(boolean)*: Specifies whether to try to refine the barrier solution for better precision ↩

Specifies whether to try to refine the barrier solution for better precision. If enabled, once the optimality conditions are satisfied, Knitro will apply an additional refinement/postsolve phase to try to obtain more precision in the barrier solution. The effect is similar to the effect of enabling bar_maxcrossit, but it is usually much more efficient since it does not involve switching to the Active Set algorithm.

Default: 0

bar_relaxcons *(integer)*: Indicates whether a relaxation approach is applied to the constraints ↩

Indicates whether a relaxation approach is applied to the constraints. Using a relaxation approach may be helpful when the problem has degenerate or difficult constraints. This option has no effect on the Active Set algorithm.

Default: 2

value	meaning
0	(none) No constraints are relaxed.
1	(eqs) A relaxation approach is applied to general equality constraints.
2	(ineqs) A relaxation approach is applied to general inequality constraints.
3	(all) A relaxation approach is applied to all general constraints.

bar_slackboundpush *(real)*: Specifies the amount by which the barrier slack variables are initially pushed inside the bounds ↩

Specifies the amount by which the barrier slack variables are initially pushed inside the bounds. A smaller value may be preferable when warm-starting from a point close to the solution.

Range: [-∞, ∞]

Default: -1

bar_switchobj *(integer)*: Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase ↩

Default: 1

value	meaning
0	(none) No (or zero) objective.
1	(scalarprox) Proximal point objective with scalar weighting.
2	(diagprox) Proximal point objective with diagonal weighting.

bar_switchrule *(integer)*: Indicates whether or not the barrier algorithms will allow switching from an

optimality phase to a pure feasibility phase ↩

Indicates whether or not the barrier algorithms will allow switching from an optimality phase to a pure feasibility phase. This option has no effect on the Active Set algorithm.

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro determine the switching procedure.
`0`	(never) Never switch to feasibility phase.
`2`	(moderate) Allow switches to feasibility phase.
`3`	(aggressive) Use a more aggressive switching rule.

bar_watchdog *(boolean)*: Specifies whether to enable watchdog heuristic for barrier algorithms ↩

Specifies whether to enable watchdog heuristic for barrier algorithms. In general, enabling the watchdog heuristic makes the barrier algorithms more likely to accept trial points. Specifically, the watchdog heuristic may occasionally accept trial points that increase the merit function, provided that subsequent iterates decrease the merit function.

Default: `0`

bfgs_scaling *(integer)*: Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation ↩

Default: `0`

value	meaning
`0`	(dynamic) Dynamically choose which scaling to use.
`1`	(invhess) The scaling approximates the scale of the inverse Hessian.
`2`	(hess) The scaling approximates the scale of the Hessian.

blasoption *(integer)*: Specifies the BLAS/LAPACK function library to use for basic vector and matrix computations ↩

Default: `1 or 4 (platform dependent)`

value	meaning
`-1`	(auto) Let Knitro automatically choose which BLAS to use.
`0`	(knitro) Use Knitro built-in functions.
`1`	(intel) Use Intel Math Kernel Library (MKL) functions on available platforms.
`2`	(dynamic) Use the dynamic library specified with option blasoptionlib.
`3`	(blis) Use BLIS functions on available platforms (currently not available on Windows OS).
`4`	(apple) Use Apple Accelerate (only available on Mac with M1 processor).

blasoptionlib *(string)*: Specifies a dynamic library name that contains object code for BLAS/LAPACK functions ↩

Specifies a dynamic library name that contains object code for BLAS/LAPACK functions. The library must implement all the functions declared in the file include/blas_lapack.h.

blas_numthreads *(integer)*: Specify the number of threads to use for BLAS operations when blasoption = 1 ↩

Range: {0, ..., ∞}

Default: 0

bndrange *(real)*: Specifies max limits on the magnitude of constraint and variable bounds ↩

Specifies max limits on the magnitude of constraint and variable bounds. Any constraint or variable bounds whose magnitude is greater than or equal to bndrange will be treated as infinite by Knitro. Using very large, finite bounds is discouraged (and is generally an indication of a poorly scaled model).

Range: [0, ∞]

Default: 1e+20

cg_maxit *(integer)*: Determines the maximum allowable number of inner conjugate gradient (CG) iterations per Knitro minor iteration ↩

Default: -1

value	meaning
-1	Let Knitro automatically determine a value.
0	Knitro will set a maximum value based on the problem size.
n	At most n>0 CG iterations may be performed during one minor iteration of Knitro.

cg_pmem *(integer)*: Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner ↩

Default: 10

value	meaning
n	At most n>0 nonzero elements per column.

cg_precond *(boolean)*: Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms ↩

Default: 0

value	meaning
0	(no) Not applied.
1	(chol) Preconditioner is applied.

cg_stoptol *(real)*: Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves ↩

Range: [0, ∞]

Default: 0.01

conic_numthreads *(integer)*: Specify the number of threads to use for operations in the conic algorithm (when bar_conic_enable = 1) ↩

Specify the number of threads to use for operations in the conic algorithm (when bar_conic_enable = 1). 0 Let Knitro choose the number of threads (currently sets conic_numthreads based on numthreads). n>0 Use n threads for the conic solver.

Range: {0, ..., ∞}

Default: 0

convex *(integer)*: Declare the problem as convex by setting to 1 or non-convex by setting to 0 ↩

Declare the problem as convex by setting to 1 or non-convex by setting to 0. Otherwise, Knitro will try to determine this automatically, but may only be able to do so for simple model forms such as QPs or QCQPs. If your model is specified as (or automatically determined to be) convex, this will cause Knitro to apply specializations and tunings that are often beneficial for convex models to speed up the solution. Currently this option is only active for the Interior/Direct algorithm, but may be applied to other algorithms in the future.

Range: {-1, ..., 1}

Default: -1

cpuplatform *(integer)*: This option can be used to specify the target instruction set architecture for the machine on which Knitro is running ↩

This option can be used to specify the target instruction set architecture for the machine on which Knitro is running. This can be used, for example , to try to produce more consistent Knitro performance across various architectures (at the expense of, perhaps, slower performance on some platforms). This option is currently only used for the Intel Math Kernel Library (MKL) functions used inside Knitro.

Range: {-1, ..., 5}

Default: -1

datacheck *(boolean)*: Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure) ↩

Specifies whether to perform more extensive data checks to look for errors in the problem input to Knitro (in particular, this option looks for errors in the sparse Jacobian and/or sparse Hessian structure). The datacheck may have a non- trivial cost for large problems.

Default: 0

delta *(real)*: Specifies the initial trust region radius scaling factor used to determine the initial trust region size ↩

Range: [1e-14, ∞]

Default: 1

feastol *(real)*: Specifies the final relative stopping tolerance for the feasibility error ↩

Specifies the final relative stopping tolerance for the feasibility error. Smaller values of feastol result in a higher degree of accuracy in the solution with respect to feasibility.

Range: [0, ∞]

Default: 1e-06

feastolabs *(real)*: Specifies the final absolute stopping tolerance for the feasibility error ↩

Synonym: feastol_abs

Specifies the final absolute stopping tolerance for the feasibility error. Smaller values of feastol_abs result in a higher degree of accuracy in the solution with respect to feasibility.

Range: [0, ∞]

Default: 0.001

findiff_estnoise *(integer)*: This option can be used to enable an estimate of the noise in the model when using finite-difference gradients ↩

This option can be used to enable an estimate of the noise in the model when using finite-difference gradients. This noise estimate can then be used to set a finite-difference steplength appropriate for the estimated noise level. This can improve performance on models with noise (e.g. noisy black-box optimization models). The cost of the noise estimation procedure is usually a few extra function evaluations.

Default: 0

value	meaning
0	(no) Do not enable any noise estimation procedure for finite-difference gradients.
1	(yes) Enable noise estimation procedure for finite-difference gradients.
2	(withcurv) Enable noise estimation and curvature factor for finite-difference gradients.

findiff_relstepsize *(real)*: Specifies the relative stepsize used for finite-difference gradients during the optimization ↩

Specifies the relative stepsize used for finite-difference gradients during the optimization. This option sets the stepsize for all variables. Note that this option has no affect on the finite-difference derivatives computed for the derivative checker (default values are always used here). It is only used for the finite-difference derivatives computed during the optimization.

Range: [-∞, ∞]

Default: 0

findiff_terminate *(boolean)*: This option specifies the termination criteria when using finite-difference gradients ↩

This option specifies the termination criteria when using finite-difference gradients. The optimality (or KKT) conditions for nonlinear optimization depend on gradient values of the nonlinear objective and constraint functions . When using finite-difference gradients (e.g. gradopt > 1), there will typically be small errors in the computed gradients that will limit the precision in the solution (and the ability to satisfy the optimality conditions). By default,

Knitro will try to estimate these finite-difference gradient errors and terminate when it seems that no more accuracy in the solution is possible. The solution will be treated as optimal as long as it is feasible and the optimality conditions are satisfied either by the optimality tolerances (opttol and opttol_abs) or the error estimates. On some problems, the error estimates may result in extra function evaluations on some iterations, but will often prevent extra iterations that produce no significant improvement in the solution. This special termination can be disabled by setting findiff_terminate = 0 (none).

Default: 1

value	meaning
0	(none) No special criteria; use the standard stopping conditions.
1	(errest) Allow termination based on estimates of the finite-difference error (when no more significant progress is likely).

fstopval *(real)*: Used to implement a custom stopping condition based on the objective function value ↩

Used to implement a custom stopping condition based on the objective function value. Knitro will stop and declare that a satisfactory solution was found if a feasible objective function value at least as good as the value specified by fstopval is achieved. This stopping condition is only active when the absolute value of fstopval is less than objrange.

Range: [-∞, ∞]

Default: maxdouble

ftol *(real)*: The optimization process will terminate if the relative change in the objective function is less than ftol for ftol_iters consecutive feasible iterations ↩

Range: [0, ∞]

Default: 1e-15

ftol_iters *(integer)*: The optimization process will terminate if the relative change in the objective function is less than ftol for ftol_iters consecutive feasible iterations ↩

Range: {1, ..., ∞}

Default: 5

gradopt *(integer)*: Specifies how to compute the gradients of the objective and constraint functions ↩

Default: 1

value	meaning
1	(exact) User provides a routine for computing the exact gradients.
2	(forward) Knitro computes gradients by forward finite differences.
3	(central) Knitro computes gradients by central finite differences.

hessopt *(integer)*: Specifies how to compute the (approximate) Hessian of the Lagrangian ↩

Default: 0

value	meaning
0	(auto)
1	(exact) User provides a routine for computing the exact Hessian.
2	(bfgs) Knitro computes a (dense) quasi-Newton BFGS Hessian.
3	(sr1) Knitro computes a (dense) quasi-Newton SR1 Hessian.
4	(product_findiff) Knitro computes Hessian-vector products using finite-differences.
5	(product) User provides a routine to compute the Hessian-vector products.
6	(lbfgs) Knitro computes a limited-memory quasi-Newton BFGS Hessian (its size is determined by the option lmsize).
7	(gauss_newton) Knitro computes a Gauss-Newton approximation of the hessian (available for least-squares only, and default value for least-squares)

honorbnds *(integer)*: Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization ↩

Indicates whether or not to enforce satisfaction of simple variable bounds throughout the optimization. This option and the bar_feasible option may be useful in applications where functions are undefined outside the region defined by inequalities.

Default: `-1`

value	meaning
-1	(auto) Knitro automatically determine the best setting.
0	(no) Knitro does not require that the bounds on the variables be satisfied at intermediate iterates.
1	(always) Knitro enforces that the initial point and all subsequent solution estimates satisfy the bounds on the variables.
2	(initpt) Knitro enforces that the initial point satisfies the bounds on the variables.

infeastol *(real)*: Specifies the (relative) tolerance used for declaring infeasibility of a model ↩

Specifies the (relative) tolerance used for declaring infeasibility of a model. Smaller values of infeastol make it more difficult to satisfy the conditions Knitro uses for detecting infeasible models. If you believe Knitro incorrectly declares a model to be infeasible, then you should try a smaller value for infeastol.

Range: [0, ∞]

Default: `1e-08`

infeastol_iters *(integer)*: The optimization process will terminate if the relative change in the feasibility error is less than infeastol for infeastol_iters consecutive infeasible iterations ↩

Range: {1, ..., ∞}

Default: `50`

initpenalty *(real)*: Specifies the initial penalty parameter used in the Knitro merit functions ↩

Specifies the initial penalty parameter used in the Knitro merit functions. The Knitro merit functions are used to balance improvements in the objective function versus improvements in feasibility. A larger initial penalty value places more weight initially on feasibility in the merit function.

Range: [0, ∞]

Default: 10

initvalues *(integer)*: Enable use of initial guess for levels and marginals (subsequent solves) ↩

In case of a MI(NL)P, the initial levels are added as primal initial point for the root relaxation and as primal MIP initial guess. From the primal MIP initial guess Knitro will try to construct a feasible solution.

Default: 1

value	meaning
0	Using no initial values
1	Using all initial values
2	Using only non-default initial values

initvalues0 *(integer)*: Enable use of initial guess for levels and marginals (first solve) ↩

In case of a MI(NL)P, the initial levels are added as primal initial point for the root relaxation and as primal MIP initial guess. From the primal MIP initial guess Knitro will try to construct a feasible solution.

Default: 2

value	meaning
0	Using no initial values
1	Using all initial values
2	Using only non-default initial values

linesearch *(integer)*: Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate ↩

Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate. This option has no effect on the Interior/CG or Active Set algorithm.

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the strategy.
1	(backtrack) Use a simple backtracking scheme.
2	(interpolate) Use a cubic interpolation scheme.
3	(weakwolfe) Use a linesearch that satisfies the weak Wolfe conditions (unconstrained only).

linesearch_maxtrials *(integer)*: Indicates the maximum allowable number of trial points during the

linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step ↩

Indicates the maximum allowable number of trial points during the linesearch of the Interior/Direct or SQP algorithm before treating the linesearch step as a failure and generating a new step. This option has no effect on the Interior/CG or Active Set algorithm.

Range: {0, ..., ∞}

Default: 3

linsolver *(integer)*: Indicates which linear solver to use to solve linear systems arising in Knitro algorithms ↩

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the linear solver.
1	(internal) Not currently used; reserved for future use. Same as auto for now.
2	(hybrid) Use a hybrid approach where the solver chosen depends on the particular linear system which needs to be solved.
3	(qr) Use a dense QR method. This approach uses LAPACK QR routines. Since it uses a dense method, it is only efficient for small problems. It may often be the most efficient method for small problems with dense Jacobians or Hessian matrices.
4	(ma27) Use the HSL MA27 sparse symmetric indefinite solver.
5	(ma57) Use the HSL MA57 sparse symmetric indefinite solver.
6	(mklpardiso) Use the Intel MKL PARDISO (parallel, deterministic) sparse symmetric indefinite solver.
7	(ma97) Use the HSL MA97 (parallel, deterministic) sparse symmetric indefinite solver.
8	(ma86) Use the HSL MA86 (parallel, non-deterministic) sparse symmetric indefinite solver.

linsolver_maxitref *(integer)*: Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro ↩

Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro. Iterative refinement steps may be applied when there are significant errors (e.g. large residuals) in the linear system solves. Applying more iterative refinement steps may improve the numerical accuracy of the linear solves at extra cost.

Range: {0, ..., ∞}

Default: 2

linsolver_nodeamalg *(integer)*: Controls the node amalgamation setting for the MA57, MA86 and MA97 linear solvers ↩

Controls the node amalgamation setting for the MA57, MA86 and MA97 linear solvers. A value of 0 indicates that the default value should be used for the given linear solver, while a positive value sets the node amalgamation parameter for the linear solver to that specific value.

Range: {0, ..., ∞}

Default: 0

linsolver_numthreads *(integer)*: Specify the number of threads to use for linear system solve operations when linsolver = 6 ↩

Range: {0, ..., ∞}

Default: 0

linsolver_ooc *(integer)*: Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when linsolver = mklpardiso ↩

Indicates whether to use Intel MKL PARDISO out-of-core solve of linear systems when linsolver = mklpardiso. This option is only active when linsolver = mklpardiso.

Default: 0

value	meaning
0	(no) Do not use Intel MKL PARDISO out-of-core option.
1	(maybe) Maybe solve out-of-core depending on how much space is needed.
2	(yes) Solve linear systems out-of-core when using Intel MKL PARDISO.

linsolver_ordering *(integer)*: Sets the ordering method used for the linear system solver ↩

Default: -1

value	meaning
-1	(auto) Let Knitro automatically choose the ordering strategy.
0	(best) Choose the best between AMD and METIS (try both).
1	(amd) Use AMD ordering (minimum degree for MKL PARDISO).
2	(metis) Use METIS ordering.

linsolver_pivottol *(real)*: Specifies the initial pivot threshold used in factorization routines ↩

Specifies the initial pivot threshold used in factorization routines. The value should be in the range [0, . . . , 0.5] with higher values resulting in more pivoting (more stable factorizations). Values less than 0 will be set to 0 and values larger than 0.5 will be set to 0.5. If linsolver_pivottol is non-positive, initially no pivoting will be performed. Smaller values may improve the speed of the code but higher values are recommended for more stability (for example, if the problem appears to be very ill-conditioned).

Range: [0, 0.5]

Default: 1e-08

linsolver_scaling *(integer)*: Enables scaling for the linear system solver ↩

Enables scaling for the linear system solver. Applying scaling may allow for more accuracy in the linear system solves, but will generally make the linear system solves more expensive.

Default: 0

value	meaning
0	(none) Do not apply scaling in the linear system solves.
1	(always) Always apply scaling in the linear system solves.

lmsize *(integer)*: Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option ↩

Specifies the number of limited memory pairs stored when approximating the Hessian using the limited-memory quasi-Newton BFGS option. The value must be between 1 and 100 and is only used with hessopt = 6. Larger values may give a more accurate, but more expensive, Hessian approximation. Smaller values may give a less accurate, but faster, Hessian approximation. When using the limited memory BFGS approach it is recommended to experiment with different values of this parameter.

Range: {1, ..., 100}

Default: 10

maxfevals *(integer)*: Specifies the maximum number of function evaluations before termination ↩

Specifies the maximum number of function evaluations before termination. Values less than zero imply no limit.

Range: {-∞, ..., ∞}

Default: -1

maxit *(integer)*: Specifies the maximum number of iterations before termination ↩

Synonym: iterlim

Default: GAMS iterlim

value	meaning
0	Let Knitro automatically choose a value based on the problem type. Currently Knitro sets this value to 10000 for LPs/NLPs and 3000 for MIP problems.
n	At most n>0 iterations may be performed before terminating.

maxtime_cpu *(real)*: Specifies, in seconds, the maximum allowable CPU time before termination ↩

Range: [0, 100000000]

Default: 100000000

maxtime_real *(real)*: Specifies, in seconds, the maximum allowable real time before termination ↩

Synonym: reslim

Range: [0, 100000000]

Default: GAMS reslim

ma_maxtime_cpu *(real)*: Specifies, in seconds, the maximum allowable CPU time before termination for the multi-algorithm ("MA") procedure (algorithm=5) ↩

Range: [0, ∞]

Default: 100000000

ma_maxtime_real *(real)*: Specifies, in seconds, the maximum allowable real time before termination for the multi-algorithm ("MA") procedure (algorithm=5) ↩

Range: [0, ∞]

Default: 100000000

ma_outsub *(boolean)*: Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure ↩

Default: 0

value	meaning
0	Do not write detailed algorithm output to files.
1	Write detailed algorithm output to files named knitro_ma_*.log.

ma_terminate *(integer)*: Define the termination condition for the multi-algorithm (algorithm=5) procedure ↩

Default: 1

value	meaning
0	Terminate after all algorithms have completed.
1	Terminate at first locally optimal solution.
2	Terminate at first feasible solution estimate.
3	Terminate at first solution estimate of any type.

mip_branchrule *(integer)*: Specifies which branching rule to use for MIP branch and bound procedure ↩

Default: 0

value	meaning
0	(auto) Let Knitro automatically choose the branching rule.
1	(most_frac) Use most fractional (most infeasible) branching.
2	(pseudcost) Use pseudo-cost branching.
3	(strong) Use strong branching (see options mip_strong_candlim, mip_strong_level and mip_strong_maxit for further control of strong branching procedure).

mip_clique *(integer)*: Specifies rules for adding clique cuts ↩

Default: -1

value	meaning
-1	(auto) Automatically determine whether to add clique cuts.
0	(none) Do not add clique cuts.
1	(root) Add clique cuts derived from the root node only.
2	(tree) Add clique cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

mip_cutfactor *(real)*: This value specifies a limit on the number of cuts added to a node subproblem ↩

This value specifies a limit on the number of cuts added to a node subproblem. If non-negative, a maximum of mip_cutfactor times the number of constraints is possibly appended.

Range: [0, ∞]

Default: 1

mip_cutoff *(real)*: This value specifies the objective cutoff value for MIP ↩

Range: [-∞, ∞]

Default: `maxdouble`

mip_cutting_plane *(boolean)*: Specifies when to apply the cutting plane procedure ↩

Default: `1`

value	meaning
`0`	(none) No cutting plane procedure enabled.
`1`	(root) Perform cutting plane procedure at the root node only.

mip_cut_flowcover *(integer)*: Specifies rules for adding flow cover cuts ↩

Default: `-1`

value	meaning
`-1`	(auto) Automatically determine whether to add flow cover cuts.
`0`	(none) Do not add flow cover cuts.
`1`	(root) Add flow cover cuts derived from the root node only.
`2`	(tree) Add flow cover cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

mip_cut_probing *(integer)*: Specifies rules for adding probing cuts ↩

Default: `-1`

value	meaning
`-1`	(auto) Automatically determine whether to add probing cuts.
`0`	(none) Do not add probing cuts.
`1`	(root) Add probing cuts derived from the root node only.
`2`	(tree) Add probing cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

mip_gomory *(integer)*: Specifies rules for adding Gomory mixed-integer cuts ↩

Default: `-1`

value	meaning
`-1`	(auto) Automatically determine whether to add Gomory cuts.
`0`	(none) Do not add Gomory cuts.
`1`	(root) Add Gomory cuts derived from the root node only.
`2`	(tree) Add Gomory cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

mip_gub_branch *(boolean)*: Specifies whether or not to branch on generalized upper bounds (GUBs) ↩

Default: `0`

value	meaning
0	(no) Do not branch on GUBs.
1	(yes) Allow branching on GUBs.

mip_heuristic_diving *(integer)*: Specifies whether or not to enable the MIP diving heuristic ↩

Specifies whether or not to enable the MIP diving heuristic. This option is a bit-valued option where various diving heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all diving heuristics. Otherwise, set this parameter value to the sum of the values for the individual diving heuristics you wish to enable. For example, to enable only the "fractional" and "linesearch" diving heuristics, you would set this option value to 9 (summing 1 for fractional and 8 for linesearch).

Default: -1

value	meaning
-1	(auto) Let Knitro determine automaticallyfrom mip_heuristic_strategy.
1	(bit 0) Enable fractional diving heuristic.
2	(bit 1) Enable vector length diving heuristic.
4	(bit 2) Enable coefficient diving heuristic.
8	(bit 3) Enable linesearch diving heuristic.
16	(bit 4) Enable guided diving heuristic.

mip_heuristic_feaspump *(integer)*: Specifies whether or not to enable the MIP feasibility pump heuristic ↩

Default: -1

value	meaning
-1	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
0	(off) Feasibility pump heuristic is not applied.
1	(on) Feasibility pump heuristic is enabled.

mip_heuristic_lns *(integer)*: Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics ↩

Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics. This option is a bit-valued option where various LNS heuristics can be enabled by activating the corresponding bit value as described below. Setting this option to -1 will use an automatic setting and setting the value to 0 will disable all LNS heuristics. Otherwise, set this parameter value to the sum of the values for the individual LNS heuristics you wish to enable. For example, to enable both the "RENS" and "RINS" LNS heuristics, you would set this option value to 3 (summing 1 for RENS and 2 for RINS).

Default: -1

value	meaning
-1	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
1	(bit 0) Enable relaxation enforced neighborhood search (RENS) heuristic.
2	(bit 1) Enable relaxation induced neighborhood search (RINS) heuristic.

mip_heuristic_localsearch *(integer)*: Specifies whether or not to enable the MIP local search heuristic ↩

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
`0`	(off) Local search heuristic is not applied.
`1`	(on) Local search heuristic is enabled.

mip_heuristic_maxit *(integer)*: Specifies the maximum number of iterations to allow for MIP heuristic, if one is enabled ↩

Range: {`0`, ..., ∞}

Default: `100`

mip_heuristic_misqp *(integer)*: Specifies whether or not to enable the MIP MISQP heuristic ↩

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
`0`	(off) MISQP heuristic is not applied.
`1`	(on) MISQP heuristic is enabled.

mip_heuristic_mpec *(integer)*: Specifies whether or not to enable the MIP MPEC heuristic ↩

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro determine automatically from mip_heuristic_strategy.
`0`	(off) MPEC heuristic is not applied.
`1`	(on) MPEC heuristic is enabled.

mip_heuristic_strategy *(integer)*: Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point ↩

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro choose the heuristic strategy to apply (if any).
`0`	(none) No heuristic search applied.
`1`	(basic) Apply basic heuristics.
`2`	(advanced) Apply more advanced heuristics.
`3`	(extensive) Apply most extensive heuristics.

mip_heuristic_terminate *(integer)*: Specifies the condition for terminating the MIP heuristic ↩

Default: `1`

value	meaning
1	(feasible) Terminate at first feasible point or iteration limit (whichever comes first).
2	(limit) Always run to the iteration limit.

mip_implications *(boolean)*: Specifies whether or not to add constraints to the MIP derived from logical implications ↩

Default: 1

value	meaning
0	(no) Do not add constraints from logical implications.
1	(yes) Knitro adds constraints from logical implications.

mip_integer_tol *(real)*: This value specifies the threshold for deciding whether or not a variable is determined to be an integer ↩

Range: [0, 1]

Default: 1e-08

mip_intvar_strategy *(integer)*: Specifies how to handle integer variables ↩

Default: 0

value	meaning
0	(none) No special treatment applied.
1	(relax) Relax all integer variables.
2	(mpec) Convert all binary variables to complementarity constraints.

mip_knapsack *(integer)*: Specifies rules for adding MIP knapsack cuts ↩

Default: -1

value	meaning
-1	(auto) Automatically determine whether to add knapsack cuts.
0	(none) Do not add knapsack cuts.
1	(root) Add knapsack cuts derived from the root node only.
2	(tree) Add knapsack cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

mip_liftproject *(integer)*: Specifies rules for adding lift and project cuts ↩

Default: -1

value	meaning
-1	(auto) Automatically determine whether to add lift and project cuts.
0	(none) Do not add lift and project cuts.
1	(root) Add lift and project cuts at the root node only.

mip_lpalg *(integer)*: Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch-and-bound procedure ↩

Specifies which algorithm to use for any linear programming (LP) subproblem solves that may occur in the MIP branch-and-bound procedure. LP subproblems may arise if the problem is a mixed integer linear program (MILP), or if using mip_method = HQG. (Nonlinear programming subproblems use the algorithm specified by the algorithm option.)

Default: `0`

value	meaning
`0`	(auto) Let Knitro automatically choose an algorithm, based on the problem characteristics.
`1`	(direct) Use the Interior/Direct (barrier) algorithm.
`2`	(cg) Use the Interior/CG (barrier) algorithm.
`3`	(active) Use the Active Set (simplex) algorithm.

mip_maxnodes *(integer)*: Specifies the maximum number of nodes explored (0 means no limit) ↩

Synonym: nodlim

Range: {`0`, ..., ∞}

Default: `GAMS nodlim`

mip_maxsolves *(integer)*: Specifies the maximum number of subproblem solves allowed (0 means no limit) ↩

Range: {`0`, ..., ∞}

Default: `0`

mip_maxtime_cpu *(real)*: Specifies the maximum allowable CPU time in seconds for the complete MIP solution ↩

Specifies the maximum allowable CPU time in seconds for the complete MIP solution. Use maxtime_cpu to additionally limit time spent per subproblem solve.

Range: [`0`, ∞]

Default: `100000000`

mip_maxtime_real *(real)*: Specifies the maximum allowable real time in seconds for the complete MIP solution ↩

Specifies the maximum allowable real time in seconds for the complete MIP solution. Use maxtime_real to additionally limit time spent per subproblem solve.

Range: [`0`, ∞]

Default: `GAMS reslim`

mip_method *(integer)*: Specifies which MIP method to use ↩

Default: `0`

value	meaning
0	(auto) Let Knitro automatically choose the method.
1	(BB) Use the standard branch-and-bound method.
2	(HQG) Use the hybrid Quesada-Grossman method (for convex, nonlinear problems only).
3	(MISQP) Use mixed-integer SQP method (allows for non-relaxable integer variables).

mip_mir *(integer)*: Specifies rules for adding mixed-integer rounding cuts ↩

Default: -1

value	meaning
-1	(auto) Let Knitro decide whether to add mixed-integer rounding cuts.
0	(none) Do not add mixed-integer rounding cuts.
1	(root) Add mixed-integer rounding cuts derived from the root node only.
2	(tree) Add mixed-integer rounding cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

mip_multistart *(boolean)*: Use to enable MIP multi-start at the branch-and-bound level ↩

Default: 0

value	meaning
0	(off) Do not enable MIP multi-start for branch-and-bound.
1	(on) Enable MIP multi-start for branch-and-bound.

mip_nodealg *(integer)*: Specifies which algorithm to use for standard node subproblem solves in MIP (same options as algorithm user option) ↩

Range: {0, ..., 5}

Default: 0

mip_numthreads *(integer)*: Specify the number of threads to use for MIP branch-and-bound (when mip_method = 1) ↩

Specify the number of threads to use for MIP branch-and-bound (when mip_method = 1). 0 Let Knitro choose the number of threads. n>0 Use n threads for the MIP branch-and-bound.

Range: {0, ..., ∞}

Default: 0

mip_opt_gap_abs *(real)*: The absolute optimality gap stop tolerance for MIP ↩

Synonym: optca

Range: [-1, ∞]

Default: GAMS optca

mip_opt_gap_rel *(real)*: The relative optimality gap stop tolerance for MIP ↩

Synonym: optcr

Range: [-1, ∞]

Default: `GAMS optcr`

mip_outinterval *(integer)*: Specifies node printing interval for mip_outlevel when mip_outlevel > 0 ↩

Default: `0`

value	meaning
0	Let Knitro decide.
1	Print output every node.
2	Print output every 2nd node.
n	Print output every Nth node.

mip_outlevel *(integer)*: Specifies how much MIP information to print ↩

Default: `2`

value	meaning
0	(none) Do not print any MIP node information.
1	(iters) Print one line of output for every node.
2	(iterstime) Also print accumulated time for every node.
3	(root) Also print detailed log from root node solve.

mip_pseudoinit *(integer)*: Specifies the method used to initialize pseudo-costs corresponding to variables that have not yet been branched on in the MIP method ↩

Default: `0`

value	meaning
0	Let Knitro automatically choose the method.
1	Initialize using the average value of computed pseudo-costs.
2	Initialize using strong branching.

mip_relaxable *(boolean)*: Specifies whether integer variables are relaxable ↩

Default: `1`

value	meaning
0	(none) Integer variables are not relaxable.
1	(all) All integer variables are relaxable.

mip_restart *(boolean)*: Specifies whether to enable the MIP restart procedure ↩

Default: `1`

value	meaning
0	(off) Do not enable the MIP restart procedure.
1	(on) Enable the MIP restart procedure.

mip_rootalg *(integer)*: Specifies which algorithm to use for the root node solve in MIP (same options as algorithm user option) ↩

Range: {0, ..., 5}

Default: 0

mip_rounding *(integer)*: Specifies the MIP rounding rule to apply ↩

Default: -1

value	meaning
-1	(auto) Let Knitro choose the rounding rule.
0	(none) No rounding heuristic is used.
2	(heur_only) Round using a fast heuristic only.
3	(nlp_sometimes) Round and solve a subproblem if likely to succeed.
4	(nlp_always) Always round and solve a subproblem.

mip_selectdir *(boolean)*: Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch-and-bound tree ↩

Default: 0

value	meaning
0	(down) Choose the down (i.e. <=) node first.
1	(up) Choose the up (i.e. >=) node first.

mip_selectrule *(integer)*: Specifies the MIP select rule for choosing the next node in the branch-and-bound tree ↩

Default: 0

value	meaning
0	(auto) Let Knitro choose the node selection rule.
1	(depth_first) Search the tree using a depth first procedure.
2	(best_bound) Select the node with the best relaxation bound.
3	(combo_1) Use depth first unless pruned, then best bound.

mip_strong_candlim *(integer)*: Specifies the maximum number of candidates to explore for MIP strong branching ↩

Range: {-∞, ..., ∞}

Default: 128

mip_strong_level *(integer)*: Specifies the maximum number of tree levels on which to perform MIP strong branching ↩

Range: {-∞, ..., ∞}

Default: `10`

mip_strong_maxit *(integer)*: Specifies the maximum number of iterations to allow for MIP strong branching solves ↩

Range: {-∞, ..., ∞}

Default: `1000`

mip_terminate *(integer)*: Specifies conditions for terminating the MIP algorithm ↩

Default: `0`

value	meaning
`0`	(optimal) Terminate at optimum.
`1`	(feasible) Terminate at first integer feasible point.

mip_zerohalf *(integer)*: Specifies rules for adding zero-half cuts ↩

Default: `-1`

value	meaning
`-1`	(auto) Automatically determine whether to add zero-half cuts.
`0`	(none) Do not add zero-half cuts.
`1`	(root) Add zero-half cuts derived from the root node only.
`2`	(tree) Add zero-half cuts derived at every node depending on the solution of the relaxation and the cut generation strategy.

ms_deterministic *(boolean)*: Indicates whether Knitro multi-start procedure will be deterministic (when ms_terminate = 0) ↩

Default: `1`

value	meaning
`0`	(no) multithreaded multi-start is non-deterministic.
`1`	(yes) multithreaded multi-start is deterministic (when ms_terminate = 0).

ms_enable *(boolean)*: Indicates whether Knitro will solve from multiple start points to find a better local minimum ↩

Default: `0`

value	meaning
`0`	(no) Knitro solves from a single initial point.
`1`	(yes) Knitro solves using multiple start points.

ms_initpt_cluster *(boolean)*: The strategy for clustering initial points in multi-start ↩

Default: 0

value	meaning
0	(none) Do not apply clustering.
1	(sl) Apply single linkage based clustering.

ms_maxbndrange *(real)*: Specifies the maximum range that an unbounded variable can take when determining new start points ↩

Specifies the maximum range that an unbounded variable can take when determining new start points. If a variable is unbounded in one or both directions, then new start point values are restricted by the option. If x_i is such a variable, then all initial values satisfy $\max\{b_i^L, x_i^0 - \texttt{ms\_maxbndrange}/2\} \leq x_i \leq \min\{b_i^U, x_i^0 + \texttt{ms\_maxbndrange}/2\}$, where x_i^0 is the initial value of x_i provided by the user, and b_i^L and b_i^U are the variable bounds (possibly infinite) on x_i . This option has no effect unless ms_enable = yes.

Range: [-∞, ∞]

Default: 1000

ms_maxsolves *(integer)*: Specifies how many start points to try in multi-start ↩

Specifies how many start points to try in multi-start. This option has no effect unless ms_enable = yes.

Default: 0

value	meaning
0	Let Knitro automatically choose a value based on the problem size and context.
n	Try n>0 start points.

ms_maxtime_cpu *(real)*: Specifies, in seconds, the maximum allowable CPU time before termination ↩

Specifies, in seconds, the maximum allowable CPU time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of maxtime_cpu limits how long Knitro iterates from a single start point. Therefore, ms_maxtime_cpu should be greater than maxtime_cpu. This option has no effect unless ms_enable = yes.

Range: [-∞, ∞]

Default: 100000000

ms_maxtime_real *(real)*: Specifies, in seconds, the maximum allowable real time before termination ↩

Specifies, in seconds, the maximum allowable real time before termination. The limit applies to the operation of Knitro since multi-start began; in contrast, the value of maxtime_real limits how long Knitro iterates from a single start point. Therefore, ms_maxtime_real should be greater than maxtime_real. This option has no effect unless ms_enable = yes.

Range: [-∞, ∞]

Default: 100000000

ms_numthreads *(integer)*: Specify the number of threads to use for multi-start (when ms_enable = 1) ↩

Specify the number of threads to use for multi-start (when ms_enable = 1). 0 Let Knitro choose the number of threads (currently sets ms_numthreads based on numthreads). n>0 Use n threads for the multi-start (solve n problems in parallel).

Range: {0, ..., ∞}

Default: 0

ms_num_to_save *(integer)*: Specifies the number of distinct feasible points to save in a file named knitro_mspoints ↩

Specifies the number of distinct feasible points to save in a file named knitro_mspoints.log. Each point results from a Knitro solve from a different starting point, and must satisfy the absolute and relative feasibility tolerances. The file stores points in order from best objective to worst. Points are distinct if they differ in objective value or some component by the value of ms_savetol using a relative tolerance test. This option has no effect unless ms_enable = yes.

Range: {0, ..., ∞}

Default: 0

ms_outsub *(boolean)*: Enable writing algorithm output to files for the parallel multi-start procedure ↩

Default: 0

value	meaning
0	Do not write detailed algorithm output to files.
1	Write detailed algorithm output to files named knitro_ms_∗.log.

ms_savetol *(real)*: Specifies the tolerance for deciding if two feasible points are distinct ↩

Specifies the tolerance for deciding if two feasible points are distinct. Points are distinct if they differ in objective value or some component by the value of ms_savetol using a relative tolerance test. A large value can cause the saved feasible points in the file knitro_mspoints.log to cluster around more widely separated points. This option has no effect unless ms_enable = yes. and ms_num_to_save is positive.

Range: [-∞, ∞]

Default: 1e-06

ms_seed *(integer)*: Seed value used to generate random initial points in multi-start; should be a non-negative integer ↩

Range: {0, ..., ∞}

Default: 0

ms_startptrange *(real)*: Specifies the maximum range that each variable can take when determining new start points ↩

Specifies the maximum range that each variable can take when determining new start points. If a variable has upper and lower bounds and the difference between them is less than or equal to ms_startptrange, then new start point values for the variable can be any number between its upper and lower bounds. If the variable is unbounded in one or both directions, or the difference between bounds is greater than ms_startptrange, then new start point values are restricted by the option. If x_i is such a variable, then all initial values satisfy $\max\{b_i^L, x_i^0 - \tau\} \leq x_i \leq \min\{b_i^U, x_i^0 + \tau\}, \tau = \min\{\texttt{ms\_startptrange}/2, \texttt{ms\_maxbndrange}/2\}$ where x_i^0 is the initial value of x_i provided by the user, and b_i^L and b_i^U are the variable bounds (possibly infinite) on x_i . This option has no effect unless ms_enable = yes.

Range: [-∞, ∞]

Default: `1e+20`

ms_terminate *(integer)*: Specifies the condition for terminating multi-start ↩

Specifies the condition for terminating multi-start. This option has no effect unless ms_enable = yes.

Default: `0`

value	meaning
`0`	(maxsolves) Terminate after ms_maxsolves.
`1`	(optimal) Terminate after the first local optimal solution is found or ms_maxsolves, whichever comes first.
`2`	(feasible) Terminate after the first feasible solution estimate is found or ms_maxsolves, whichever comes first.
`3`	(any) Terminate after the first solution estimate of any type is found or ms_maxsolves, whichever comes first.
`4`	(rulebased) Terminate using rules that estimate when the probability of finding new local solutions is low.

names *(boolean)*: Enable to pass variable and equation names to Knitro ↩

Default: `0`

ncvx_qcqp_init *(integer)*: Specifies the initialization strategy used for non-convex QPs and QCQPs ↩

Specifies the initialization strategy used for non-convex QPs and QCQPs. In particular, these strategies may be more likely to cause Knitro to find global or better local solutions on non-convex quadratic programs (QPs) or non-convex quadratically constrained quadratic programs (QCQPs).

Default: `-1`

value	meaning
`-1`	(auto) Knitro will automatically determine the strategy.
`0`	(none) No special initialization strategy is used.
`1`	(linear) Initialize by solving a linear relaxation.
`2`	(hybrid) Initialize by solving a hybrid formulation.
`3`	(penalty) Initialize by solving a penalty formulation.
`4`	(cvxquad) Initialize by solving a convex quadratic relaxation.

newpoint *(integer)*: Specifies additional action to take after every iteration in a solve of a continuous problem, or after every new incumbent of the NLPBB algorithm ↩

Specifies additional action to take after every iteration in a solve of a continuous problem, or after every new incumbent of the NLPBB algorithm. For a continuous problem, an iteration of Knitro results in a new point that is closer to a solution. The new point includes values of x and Lagrange multipliers lambda. For the NLPBB algorithm, the new incumbent includes values of x.

Default: `0`

value	meaning
`0`	(none) Knitro takes no additional action.
`1`	(saveone) Knitro writes x and lambda to the file knitro_newpoint.log. Previous contents of the file are overwritten.
`2`	(saveall) Knitro appends x and lambda to the file knitro_newpoint.log. Warning: this option can generate a very large file. All iterates, including the start point, crossover points, and the final solution are saved.

objrange *(real)*: Specifies the extreme limits of the objective function for purposes of determining unboundedness ↩

Specifies the extreme limits of the objective function for purposes of determining unboundedness. If the magnitude of the objective function becomes greater than objrange for a feasible iterate, then the problem is determined to be unbounded and Knitro proceeds no further.

Range: [0, ∞]

Default: `1e+20`

option_file *(string)*: additional option file name - read only by KNITRO solver lib ↩

opttol *(real)*: Specifies the final relative stopping tolerance for the KKT (optimality) error ↩

Specifies the final relative stopping tolerance for the KKT (optimality) error. Smaller values of opttol result in a higher degree of accuracy in the solution with respect to optimality.

Range: [0, ∞]

Default: `1e-06`

opttolabs *(real)*: Specifies the final absolute stopping tolerance for the KKT (optimality) error ↩

Synonym: opttol_abs

Specifies the final absolute stopping tolerance for the KKT (optimality) error. Smaller values of opttol_abs result in a higher degree of accuracy in the solution with respect to optimality.

Range: [0, ∞]

Default: `0.001`

outappend *(boolean)*: Specifies whether output should be started in a new file, or appended to existing files ↩

Specifies whether output should be started in a new file, or appended to existing files. The option affects knitro.log. It does not affect knitro_newpoint.log, which is controlled by option newpoint.

Default: `0`

value	meaning
0	(no) Erase any existing files when opening for output.
1	(yes) Append output to any existing files.

outdir *(string)*: Specifies a single directory as the location to write all output files ↩

Specifies a single directory as the location to write all output files. The option should be a full pathname to the directory, and the directory must already exist.

outlev *(integer)*: Controls the level of output produced by Knitro ↩

Default: 2

value	meaning
0	(none) Printing of all output is suppressed.
1	(summary) Print only summary information.
2	(iter_10) Print basic information every 10 iterations.
3	(iter) Print basic information at each iteration.
4	(iter_verbose) Print basic information and the function count at each iteration.
5	(iter_x) Print all the above, and the values of the solution vector x.
6	(all) Print all the above, and the values of the constraints c at x and the Lagrange multipliers lambda.

outmode *(integer)*: Specifies where to direct the output from Knitro ↩

Default: 0

value	meaning
0	(screen) Output is directed to standard out (e.g., screen).
1	(file) Output is sent to a file named knitro.log.
2	(both) Output is directed to both the screen and file knitro.log.

outname *(string)*: Use to specify a custom filename when output is written to a file using outmode ↩

output_time *(boolean)*: print output on where time is used ↩

Default: 0

out_csvinfo *(boolean)*: Controls whether or not to generates a file knitro_solve ↩

Controls whether or not to generates a file knitro_solve.csv containing solve information in comma separated format.

Default: 0

value	meaning
0	(no) No solution information file is generated.
1	(yes) The knitro_solve.csv solution file is generated.

out_csvname *(string)*: Use to specify a custom csv filename when using out_csvinfo ↩

out_hints *(boolean)*: Specifies whether to print diagnostic hints (e.g. about user option settings) after solving ↩

Default: 1

value	meaning
0	(no) Do not print any hints.
1	(yes) Print diagnostic hints on occasion.

presolve *(boolean)*: Determine whether or not to use the Knitro presolver to try to simplify the model by removing variables or constraints ↩

Default: 1

value	meaning
0	(no) Do not use the Knitro presolver.
1	(yes) Enable the Knitro presolver.

presolveop_redundant *(integer)*: Determine whether or not to enable the Knitro presolve operation to detect and remove redundant constraints ↩

Default: 1

value	meaning
0	(none) Do not remove redundant constraints.
1	(dupcon) Detect and remove duplicate constraints.
2	(depcon) Detect and remove linearly dependent constraints.

presolveop_substitution *(integer)*: Determine whether or not to enable the Knitro presolve operation to substitute out variables when possible ↩

Default: -1

value	meaning
-1	(auto) Automatically determined (may depend on the algorithm).
0	(none) Do not perform any variable substitution.
1	(simple) Enable simple substitutions involving doubleton equality constraints.
2	(all) Enable all possible variable substitutions.

presolveop_substitution_tol *(real)*: Tolerance for applying a substitution ↩

Tolerance for applying a substitution. This is a relative tolerance on coefficients involved with the substituted variable. Higher values mean that less reductions will be applied (potentially improving numerical focus). Zero value means all possible substitutions are applied.

Range: [0, ∞]

Default: `0.01`

presolveop_tighten *(integer)*: Determine whether or not to enable the Knitro presolve operation to tighten variable bounds or coefficients ↩

Default: `-1`

value	meaning
`-1`	(auto) Automatically determined (may depend on the algorithm).
`0`	(none) Do not tighten variable bounds (unless it removes a constraint).
`1`	(varbnd) Enable tightening variable bounds always.
`2`	(coef) Enable tightening coefficients in linear constraints.
`3`	(all) Enable tightening variable bounds and coefficients.

presolve_initpt *(integer)*: Control whether the Knitro presolver can shift a user-supplied initial point ↩

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro automatically choose whether to allow shifting.
`0`	(noshift) Do not allow presolver to shift user-supplied initial point.
`1`	(linshift) Allow presolver to shift user-supplied initial point if it only appears in linear constraints.
`2`	(anyshift) Allow presolver to shift any user-supplied initial point.

presolve_level *(integer)*: Set the level of presolve operations to enable through the Knitro presolver ↩

Set the level of presolve operations to enable through the Knitro presolver. A higher presolve level enables more complex presolve operations.

Default: `-1`

value	meaning
`-1`	(auto) Let Knitro automatically choose the presolve level.
`1`	(level1) Enable the most basic presolve operations.
`2`	(level2) Enable more advanced presolve operations.

presolve_passes *(integer)*: Set a maximum limit on the number of passes through the Knitro presolve operations ↩

Range: {`0`, ..., ∞}

Default: `10`

presolve_tol *(real)*: Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model ↩

Determines the tolerance used by the Knitro presolver to remove variables and constraints from the model. If you believe the Knitro presolver is incorrectly modifying the model, use a smaller value for this tolerance (or turn the presolver off).

Range: [`0`, ∞]

Default: `1e-06`

qextractalg *(integer)*: quadratic extraction algorithm in GAMS interface ↩

Default: `0`

value	meaning
0	Automatic
1	ThreePass: Uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage.
2	DoubleForward: Uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.
3	Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.

restarts *(integer)*: Specifies whether or not to enable automatic restarts in Knitro ↩

Specifies whether or not to enable automatic restarts in Knitro. When enabled, if a Knitro algorithm seems to be converging slowly or not converging, the algorithm will automatically restart, which may help with convergence.

Default: `-1`

value	meaning
0	No automatic restarts allowed.
n	At most n>0 automatic restarts may be performed.

restarts_maxit *(integer)*: When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart ↩

Default: `0`

value	meaning
0	No iteration limit on restarts enforced.
n	At most n>0 iterations are allowed without convergence before enforcing an automatic restart, if restarts are enabled.

scale *(integer)*: Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables ↩

Specifies whether to perform problem scaling of the objective function, constraint functions, or possibly variables. If scaling is performed, internal computations, including some aspects of the optimality tests, are based on the scaled values, though the feasibility error is always computed in terms of the original, unscaled values.

Default: `1`

value	meaning
0	(no) No scaling is performed.
1	(user_internal) User provided scaling is used if defined, otherwise Knitro internal scaling is applied.
2	(user_none) User provided scaling is used if defined, otherwise no scaling is applied.
3	(internal) Knitro internal scaling is applied.

scale_vars *(boolean)*: Specifies the strategy for scaling variables ↩

Specifies the strategy for scaling variables. If scaling is performed, internal computations, including some aspects of the optimality tests, are based on the scaled values, though the feasibility error is always computed in terms of the original, unscaled values.

Default: `0`

value	meaning
`0`	(none) No variable scaling is performed.
`1`	(bnds) Scaling of variables is applied based on their bound values.

soc *(integer)*: Specifies whether or not to try second order corrections (SOC) ↩

Specifies whether or not to try second order corrections (SOC). A second order correction may be beneficial for problems with highly nonlinear constraints.

Default: `1`

value	meaning
`0`	(no) No second order correction steps are attempted.
`1`	(maybe) Second order correction steps may be attempted on some iterations.
`2`	(yes) Second order correction steps are always attempted if the original step is rejected and there are nonlinear constraints.

strat_warm_start *(boolean)*: Specifies whether or not to invoke a warm-start strategy ↩

Specifies whether or not to invoke a warm-start strategy. A warm-start strategy may be beneficial when an initial point close to the solution can be provided. For example, this may occur when solving a sequence of closely related problems, and the solution from one problem can be used to initialize (or warm-start) the next problem in the sequence. The Knitro warm-start strategy will use this information to tune the algorithms to try to converge more quickly in this case. If the initial point is not sufficiently close to the solution, or is too infeasible, the warm-start strategy may not be helpful. This option is currently only used for the Knitro barrier/interior-point algorithms. In this case it may also be useful to experiment with different (smaller than default) values for the initial barrier parameter bar_initmu. In general, the closer the initial point is to the solution, the smaller this value should be (Knitro will try by default to initialize this to a good value when applying a warm-start strategy).

Default: `0`

value	meaning
`0`	(no) No warm-start strategy is applied.
`1`	(yes) Knitro will apply a warm-start strategy with special tunings.

threads *(integer)*: default thread count ↩

Synonyms: gthreads numthreads

Controls the number of threads to use. Non-positive values are interpreted as the number of cores to leave free so setting `threads` to 0 uses all available cores while setting `threads` to -1 leaves one core free for other tasks.

By default, Knitro decides automatically how to use the threads specified. For example, if the multi-start method is enabled, it can run in parallel threads. If the multi-algorithm `algorithm=5` is selected, the different algorithms can be run in parallel threads if threads are allocated. In case only one algorithm is running, multiple threads can be allocated to the MKL BLAS library or to the PARDISO linear solver via the `threads` option: see the `blasoption`, `par_blasnumthreads`, and `par_lsnumthreads` options for details.

Range: {-∞, ..., ∞}

Default: `GAMS threads`

tuner *(boolean)*: Indicates whether to invoke the Knitro-Tuner ↩

Default: `0`

value	meaning
`0`	(off) Do not invoke the Knitro-Tuner.
`1`	(on) Invoke the Knitro-Tuner.

tuner_maxtime_cpu *(real)*: Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner ↩

Specifies, in seconds, the maximum allowable CPU time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro- Tuner began. In contrast, the value of maxtime_cpu places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, tuner_maxtime_cpu should be greater than maxtime_cpu. This option has no effect unless tuner = on.

Range: [0, ∞]

Default: `100000000`

tuner_maxtime_real *(real)*: Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner ↩

Specifies, in seconds, the maximum allowable real time before terminating the Knitro-Tuner. The limit applies to the operation of Knitro since the Knitro- Tuner began. In contrast, the value of maxtime_real places a time limit on each individual Knitro-Tuner solve for a particular option setting. Therefore, tuner_maxtime_real should be greater than maxtime_real. This option has no effect unless tuner = on.

Range: [0, ∞]

Default: `100000000`

tuner_optionsfile *(string)*: Can be used to specify the location of a Tuner options file ↩

tuner_outsub *(integer)*: Enable writing additional Tuner subproblem solve output to files for the Knitro-Tuner procedure (tuner=1) ↩

Default: `0`

value	meaning
`0`	Do not write detailed solve output to files.
`1`	Write summary solve output to a file named knitro_tuner_summary.log.
`2`	Write detailed individual solve output to files named knitro_tuner_*.log.

tuner_terminate *(integer)*: Define the termination condition for the Knitro-Tuner procedure (tuner=1) ↩

Default: `0`

value	meaning
`0`	Terminate after all solves have completed.
`1`	Terminate at first locally optimal solution.
`2`	Terminate at first feasible solution estimate.
`3`	Terminate at first solution estimate of any type.

xtol *(real)*: The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol_iters ↩

The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol_iters. consecutive iterations. If using the Interior/Direct or Interior/CG algorithm and the barrier parameter is still large, Knitro will first try decreasing the barrier parameter before terminating.

Range: [`0`, ∞]

Default: `1e-12`

xtol_iters *(integer)*: The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol_iters consecutive iterations ↩

The optimization process will terminate if the relative change in the solution estimate is less than xtol for xtol_iters consecutive iterations. If set to 0, Knitro chooses this value based on the solver and context. Currently Knitro sets this value to 3 unless the MISQP algorithm is being used, in which case the value is set to 1 by default.

Range: {`0`, ..., ∞}

Default: `0`

5.23.6 Knitro Termination Test and Optimality

5.23.6.1 Continuous problems

The first-order conditions for identifying a locally optimal solution of the problem (1) are:

$$\begin{aligned}
\nabla_x \mathcal{L}(x,\lambda) = \nabla f(x) + \sum_{i=1\ldots m} \lambda_i^c \nabla c_i(x) + \sum_{j=1\ldots n} \lambda_j^b \quad &= 0 \\
\lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))] \quad &= 0, \quad i = 1\ldots m \\
\lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)] \quad &= 0, \quad j = 1\ldots n \\
c_i^L \leq c_i(x) \quad &\leq c_i^U, \quad i = 1\ldots m \\
b_j^L \leq x_j \quad &\leq b_j^U, \quad j = 1\ldots n \\
\lambda_i^c \quad &\geq 0, \quad i \in \mathcal{I},\ c_i^L = -\infty,\ c_i^U \text{ finite} \\
\lambda_i^c \quad &\leq 0, \quad i \in \mathcal{I},\ c_i^U = +\infty,\ c_i^L \text{ finite} \\
\lambda_j^b \quad &\geq 0, \quad j \in \mathcal{B},\ b_j^L = -\infty,\ b_j^U \text{ finite} \\
\lambda_j^b \quad &\leq 0, \quad j \in \mathcal{B},\ b_j^U = +\infty,\ b_j^L \text{ finite}
\end{aligned} \tag{3}$$

where $\mathcal{I}$ and $\mathcal{B}$ represent the sets of indices corresponding to the general inequality constraints and non-fixed variable bound constraints respectively, λ_i^c is the Lagrange multiplier corresponding to constraint

$c_i(x)$, and λ_j^b is the Lagrange multiplier corresponding to the simple bounds on x_j. There is exactly one Lagrange multiplier for each constraint and variable. The Lagrange multiplier may be restricted to take on a particular sign depending on the corresponding constraint or variable bounds.

In Knitro we define the feasibility error (`FeasErr`) at a point x^k to be the maximum violation of the constraints of (1), i.e.,

$$\text{FeasErr} = \max_{i=1\ldots m,\ j=1\ldots n}(0, (c_i^L - c_i(x^k)), (c_i(x^k) - c_i^U), (b_j^L - x_j^k), (x_j^k - b_j^U)),$$

while the optimality error (`OptErr`) is defined as the maximum violation of the first three conditions of (3)

$$\text{OptErr} = \max_{i=1\ldots m,\ j=1\ldots n}(\|\nabla_x \mathcal{L}(x^k, \lambda^k)\|_\infty, \lambda_i^c \min[(c_i(x) - c_i^L), (c_i^U - c_i(x))], \lambda_j^b \min[(x_j - b_j^L), (b_j^U - x_j)]).$$

The remaining conditions on the sign of the multipliers are enforced explicitly throughout the optimization. In order to take into account problem scaling in the termination test, the following scaling factors are defined In order to take into account problem scaling in the termination test, the following scaling factors are defined

$$\tau_1 = \max(1, (c_i^L - c_i(x^0)), (c_i(x^0) - c_i^U), (b_j^L - x_j^0), , (x_j^0 - b_j^U))),$$
$$\tau_2 = \begin{cases} \max(1, \|\nabla f(x^k)\|_\infty), & \text{for constrained problems,} \\ \max(1, \min(|f(x^k)|, \|\nabla f(x^0)\|_\infty)), & \text{for unconstrained problems,} \end{cases}$$

where x^0 represents the initial point. The special treatment for unconstraints problems is necessary, as for these problems, $\|\nabla f(x^k)\|_\infty \to 0$ as a solution is approached, thus $\max(1, \|\nabla f(x^k)\|_\infty)$ would not be effective.

Knitro stops and declares `Locally optimal solution found` if the following stopping conditions are satisfied:

$$\text{FeasErr} \leq \max(\tau_1 * \text{feastol}, \text{feastolabs}) \tag{4}$$

$$\text{OptErr} \leq \max(\tau_2 * \text{opttol}, \text{opttolabs}) \tag{5}$$

where feastol, opttol, feastolabs and opttolabs are user-defined options (see section Usage).

This stopping test is designed to give the user much flexibility in deciding when the solution returned by Knitro is accurate enough. One can use a purely scaled stopping test (which is the recommended and default option) by setting feastolabs and opttolabs equal to `0.0e0`. Likewise, an absolute stopping test can be enforced by setting feastol and opttol equal to `0.0e0`.

Unbounded problems

Since by default Knitro uses a relative/scaled stopping test it is possible for the optimality conditions to be satisfied for an unbounded problem. For example, if $\tau_2 \to \infty$ while the optimality error `OptErr` stays bounded, condition (5) will eventually be satisfied for some `opttol`>0. If you suspect that your problem may be unbounded, using an absolute stopping test will allow Knitro to detect this.

5.23.6.2 Discrete problems

Algorithms for solving versions of (1) where one or more of the variables are restricted to take on only discrete values, proceed by solving a sequence of continuous relaxations, where the discrete variables are *relaxed* such that they can take on any continuous value. The *global* solutions $f(x_R)$ of these relaxed problems provide a lower bound on the optimal objective value for problem (1) (upper bound if maximizing). If a feasible point is found for problem (1) that satisfies the discrete restrictions on the variables, then this provides an upper bound on the optimal objective value of problem (1) (lower bound if maximizing). We will refer to these feasible points as *incumbent* points and denote the objective value at an incumbent point by $f(x_I)$. Assuming all the continuous subproblems have been solved to global optimality (if the problem is convex, all local solutions are global solutions), an optimal solution of problem (1) is verified when the lower bound and upper bound are equal.

Knitro declares optimality for a discrete problem when the gap between the best (i.e., largest) lower bound $f(x_R)$ and the best (i.e., smallest) upper bound $f(x_I)$ is less than a threshold determined by the user options mip_opt_gap_abs and mip_opt_gap_rel. Specifically, Knitro declares optimality when either

$$f(x_I) - f(x_R) \leq mip\_integral\_gap\_abs$$

or

$$f(x_I) - f(x_R) \leq mip\_integral\_gap\_rel \cdot \max(1, |f(x_I)|),$$

where mip_opt_gap_abs and mip_opt_gap_rel are typically small positive numbers. Since these termination conditions assume that the continuous subproblems are solved to global optimality and Knitro only finds local solutions of nonconvex, continuous optimization problems, they are only reliable when solving convex, mixed integer problems. The integrality gap $f(x_I) - f(x_R)$ should be non-negative although it may become slightly negative from roundoff error, or if the continuous subproblems are not solved to sufficient accuracy. If the integrality gap becomes largely negative, this may be an indication that the model is nonconvex, in which case `Knitro` may not converge to the optimal solution, and will be unable to verify optimality (even if it claims otherwise).

Note that the default values for mip_opt_gap_abs and mip_opt_gap_rel are taken from the GAMS options optCA and optCR, but an explicit setting of mip_opt_gap_abs or mip_opt_gap_rel will override those.

5.23.7 Knitro Output

If `outlev=0` then all printing of output is suppressed. The description below assumes the default output level (`outlev=2`) except where indicated:

Nondefault Options:

This output lists all user options (see section Usage) which are different from their default values. If nothing is listed in this section then all user options are set to their default values.

Problem Characteristics:

The output begins with a description of the problem characteristics.

Iteration Information - Continuous Problems:

An iteration, in the context of Knitro, is defined as a step which generates a new solution estimate (i.e., a successful step). The columns of the iteration log are as follows:

- `Iter` Iteration number.

- `fCount` The cumulative number of function evaluations, only included if (`outlev>3`)
- `Objective` Gives the value of the objective function at the current iterate.
- `FeasErr` Gives a measure of the feasibility violation at the current iterate.
- `OptErr` Gives a measure of the violation of the Karush-Kuhn-Tucker (KKT) (first-order) optimality conditions (not including feasibility) at the current iterate.
- ||`Step`|| The 2-norm length of the step (i.e., the distance between the new iterate and the previous iterate).
- `CG its` The number of Projected Conjugate Gradient (CG) iterations required to compute the step.

If `outlev=2`, information is printed every 10 major iterations. If `outlev=3` information is printed at each major iteration. If `outlev>4` addition information is included in the log.

Iteration Information - Discrete Problems:

By default, the GAMS/Knitro link prints a log line at every 10'th node. This frequency can be changed via the mip_outinterval option. To turn off the node log completely, set the mip_outlevel option to 0. The columns of the iteration log for discrete models are as follows:

- `Node` The node number. If an integer feasible point was found at a given node, it is marked with a $*$
- `Left` The current number of active nodes left in the branch and bound tree.
- `Iinf` The current number of active nodes left in the branch and bound tree.
- `Objective` Gives the value of the objective function at the solution of the relaxed subproblem solved at the current node. If the subproblem was infeasible or failed, this is indicated. Additional symbols may be printed at some nodes if the node was pruned (`pr`), integer feasible (`f`), or an integer feasible point was found through rounding (`r`).
- `Best relaxatn` The value of the current best relaxation (lower bound on the solution if minimizing).
- `Best incumbent` The value of the current best integer feasible point (upper bound on the solution if minimizing).

Termination Message: At the end of the run a termination message is printed indicating whether or not the optimal solution was found and if not, why the solver terminated. Below is a list of some possible termination messages.

- `EXIT: Locally optimal solution found.`

  Knitro found a locally optimal point which satisfies the stopping criterion (see section Knitro Termination Test and Optimality) for more detail on

  how this is defined). If the problem is convex (for example, a linear

  program), then this point corresponds to a globally optimal solution.

- `EXIT: Iteration limit reached.`

  The iteration limit was reached before being able to satisfy the required stopping criteria.

- `EXIT: Convergence to an infeasible point. Problem appears to be locally infeasible.`

  The algorithm has converged to an infeasible point from which it cannot further decrease the infeasibility measure. This happens when the problem is infeasible, but may also occur on occasion for feasible problems with nonlinear constraints or badly scaled problems. It is recommended to try various initial points. If this occurs for a variety of initial points, it is likely the problem is infeasible.

- `EXIT: Problem appears to be unbounded.`

  The objective function appears to be decreasing without bound, while satisfying the constraints.

- `EXIT: Current point cannot be improved.`

  No more progress can be made. If the current point is feasible it is likely it may be optimal, however the stopping tests cannot be satisfied perhaps because of degeneracy, ill-conditioning or bad scaling).

- `EXIT: Current point cannot be improved. Point appears to be optimal, but desired accuracy could not be achieved.`

  No more progress can be made, but the stopping tests are close to being satisfied (within a factor of 100) and so the current approximate solution is believed to be optimal.

- `EXIT: Time limit reached.`

  The time limit was reached before being able to satisfy the required stopping criteria.

- `EXIT: Evaluation error.`

  This termination value indicates that an evaluation error occurred (e.g., divide by 0, taking the square root of a negative number), preventing the optimization from continuing.

- `EXIT: Not enough memory available to solve problem.`

  This termination value indicates that there was not enough memory available to solve the problem.

Final Statistics:

Following the termination message some final statistics on the run are printed. Both relative and absolute error values are printed.

Solution Vector/Constraints:

If `outlev=5`, the values of the solution vector are printed after the final statistics. If `outlev=6`, the final constraint values are also printed before the solution vector and the values of the Lagrange multipliers (or dual variables) are printed next to their corresponding constraint or bound.

5.23.8 Algorithm Options

5.23.8.1 Automatic

By default, `Knitro` will automatically try to choose the best optimizer for the given problem based on the problem characteristics.

5.23.8.2 Interior/Direct

If the Hessian of the Lagrangian is ill-conditioned or the problem does not have a large-dense Hessian, it may be advisable to compute a step by directly factoring the KKT (primal-dual) matrix rather than using an iterative approach to solve this system. Knitro offers the Interior/Direct optimizer which allows the algorithm to take direct steps by setting `algorithm=1`. This option will try to take a direct step at each iteration and will only fall back on the iterative step if the direct step is suspected to be of poor quality, or if negative curvature is detected.

Using the Interior/Direct optimizer may result in substantial improvements over Interior/CG when the problem is ill-conditioned (as evidenced by Interior/CG taking a large number of Conjugate Gradient iterations). We encourage the user to try both options as it is difficult to predict in advance which one will be more effective on a given problem. In each case, also experiment with the bar_murule option, as it is difficult to predict which update rule will work best.

NOTE: Since the Interior/Direct algorithm in Knitro requires the explicit storage of a Hessian matrix, this version can only be used with Hessian options, `hessopt=1, 2, 3` or `6`. It may not be used with Hessian options, `hessopt=4` or `5`, which only provide Hessian-vector products. Both the Interior/Direct and Interior/CG methods can be used with the bar_feasible option.

5.23.8.3 Interior/CG

Since Knitro was designed with the idea of solving large problems, the Interior/CG optimizer in Knitro offers an iterative Conjugate Gradient approach to compute the step at each iteration. This approach has proven to be efficient in most cases and allows Knitro to handle problems with large, dense Hessians, since it does not require factorization of the Hessian matrix. The Interior/CG algorithm can be chosen by setting `algorithm=2`. It can use any of the Hessian options as well as the bar_feasible option.

5.23.8.4 Active Set

Knitro includes an active-set Sequential Linear-Quadratic Programing (SLQP) optimizer. This optimizer is particular advantageous when "warm starting" (i.e., when the user can provide a good initial solution estimate, for example, when solving a sequence of closely related problems). This algorithm is also the preferred algorithm for detecting infeasible problems quickly. The Active Set algorithm can be chosen by setting `algorithm=3`. It can use any of the Hessian options.

5.23.9 Other Knitro special features

This section describes in more detail some of the more important special features of Knitro and provides some guidance on how use them so that Knitro runs most efficiently for the problem at hand.

5.23.9.1 Second derivative options

The default version of Knitro assumes that exact second derivatives of the objective function and constraint functions can be computed. If this is possible and the cost of computing the second derivatives is not overly expensive, it is highly recommended to use exact second derivatives. However, Knitro also offers other options which are described in detail below.

(Dense) Quasi-Newton BFGS
The quasi-Newton BFGS option uses gradient information to compute a symmetric, *positive-definite* approximation to the Hessian matrix. Typically this method requires more iterations to converge than the exact Hessian version. However, since it is only computing gradients rather than Hessians, this approach may be more efficient in many cases. This option stores a *dense* quasi-Newton Hessian approximation so it is only recommended for small to medium problems ($n < 1000$). The quasi-Newton BFGS option can be chosen by setting options value `hessopt=2`.

(Dense) Quasi-Newton SR1
As with the BFGS approach, the quasi-Newton SR1 approach builds an approximate Hessian using gradient information. However, unlike the BFGS approximation, the SR1 Hessian approximation is not restricted to be positive-definite. Therefore the quasi-Newton SR1 approximation may be a better approach, compared to the BFGS method, if there is a lot of negative curvature in the problem since it may be able to maintain a better approximation to the true Hessian in this case. The quasi-Newton SR1 approximation maintains a *dense* Hessian approximation and so is only recommended for small to medium problems ($n < 1000$). The quasi-Newton SR1 option can be chosen by setting options value `hessopt=3`.

Finite-difference Hessian-vector product option
If the problem is large and gradient evaluations are not the dominate cost, then Knitro can internally compute Hessian-vector products using finite-differences. Each Hessian-vector product in this case requires one additional gradient evaluation. This option can be chosen by setting options value `hessopt=4`. This option is generally only recommended if the exact gradients are provided.

NOTE: This option may not be used when `algorithm=1`.

Exact Hessian-vector products
In some cases the problem which the user wishes to solve may have a large, dense Hessian which makes it impractical to store or work with the Hessian directly.

The performance of this option should be nearly identical to the exact Hessian option but requires much less storage. This option can be chosen by setting options value `hessopt=5`.

NOTE: This option may not be used when `algorithm=1`.

Limited-memory Quasi-Newton BFGS
The limited-memory quasi-Newton BFGS option is similar to the dense quasi-Newton BFGS option described above. However, it is better suited for large-scale problems since, instead of storing a dense Hessian approximation, it only stores a limited number of gradient vectors used to approximate the Hessian. In general it requires more iterations to converge than the dense quasi-Newton BFGS approach but will be much more efficient on large-scale problems. This option can be chosen by setting options value `hessopt=6`.

5.23.9.2 Feasible version

Knitro offers the user the option of forcing intermediate iterates to stay feasible with respect to the *inequality* constraints (it does not enforce feasibility with respect to the *equality* constraints however). Given an initial point which is *sufficiently* feasible with respect to all inequality constraints and selecting `bar_feasible = 1`, forces all the iterates to strictly satisfy the inequality constraints throughout the solution process. For the feasible mode to become active the iterate x must satisfy

$$cl + tol \leq c(x) \leq cu - tol \tag{21}$$

for *all* inequality constraints (i.e., for $cl \neq cu$). The tolerance $tol > 0$ by which an iterate must be strictly feasible for entering the feasible mode is determined by the parameter `bar_feasmodetol` which is `1.0e-4` by default. If the initial point does not satisfy (21) then the default infeasible version of Knitro will run until it obtains a point which is sufficiently feasible with respect to all the inequality constraints. At this point it will switch to the feasible version of Knitro and all subsequent iterates will be forced to satisfy the inequality constraints.

For a detailed description of the feasible version of Knitro see [32] .

NOTE: This option may only be used when `algorithm=2`.

5.23.9.3 Honor Bounds

By default Knitro does not enforce that the simple bounds on the variables (1c) are satisfied throughout the optimization process. Rather, satisfaction of these bounds is only enforced at the solution. In some applications, however, the user may want to enforce that the initial point and all intermediate iterates satisfy the bounds $bl \leq x \leq bu$. This can be enforced by setting `honorbnds=1`.

5.23.9.4 Crossover

Interior-point (or barrier) methods are a powerful tool for solving large-scale optimization problems. However, one drawback of these methods is that they do not always provide a clear picture of which constraints are active at the solution. In general they return a less exact solution and less exact sensitivity information. For this reason, Knitro offers a crossover feature in which the interior-point method switches to the Active Set method at the interior-point solution estimate, in order to "clean up" the solution and provide more exact sensitivity and active set information. The crossover procedure is controlled by the bar_maxcrossit option. If this option is greater than 0, then Knitro will attempt to perform bar_maxcrossit Active Set crossover iterations after the interior-point method has finished, to see if it can provide a more exact solution. This can be viewed as a form of post-processing. If bar_maxcrossit is not positive, then no crossover iterations are attempted.

The crossover procedure will not always succeed in obtaining a more exact solution compared with the interior-point solution. If crossover is unable to improve the solution within bar_maxcrossit crossover iterations, then it will restore the interior-point solution estimate and terminate. By default, Knitro will then print a message indicating that it was unable to improve the solution within the iterations allowed. In this case, you may want to increase the value of bar_maxcrossit and try again. If Knitro determines that the crossover procedure will not succeed, no matter how many iterations are tried, then a message of the form `Crossover mode unable to improve solution.` will be printed.

The extra cost of performing crossover is problem dependent. In most small or medium scale problems, the crossover cost is a small fraction of the total solve cost. In these cases it may be worth using the crossover procedure to obtain a more exact solution. On some large scale or difficult degenerate problems, however, the cost of performing crossover may be significant. It is recommended to experiment with this option to see whether improvement in the exactness of the solution is worth the additional cost.

5.23.9.5 Tuner

The Knitro-Tuner can help you identify some non-default options settings that may improve performance on a particular model or set of models. The Knitro tuner is enabled with the tuner option and controlled via the tuner_ family of options. If you are unsure about what Knitro options should be tuned to try to improve performance, you can run the default Knitro-Tuner by simply setting the option tuner=1 when solving with Knitro. This will cause Knitro to run your model with a variety of automatically determined option settings, and report some statistics at the end. Any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

If you have some ideas about which Knitro options you want to tune, you can tell Knitro which options you want it to tune, as well as specify the values for particular options that you want Knitro to explore. This can be done by specifying a Tuner options file. A Tuner options file is a simple text file that is similar to a standard Knitro options file, with some important differences:

- You can define multiple values (separated by spaces) for each option. This tells Knitro the values you want it to explore.
- You can specify an option name without any values. This will tell Knitro to explore all possible option values for that option. This only works for options that have a finite set of possible option value settings.
- A Tuner options file is loaded via the tuner_optionsfile option.

All possible combinations of options/values specified in a Tuner options file will be explored by Knitro, while any Knitro options that have been set in the usual way will remain fixed throughout the tuning procedure.

5.23.9.6 Solving Systems of Nonlinear Equations

Knitro is quite effective at solving systems of nonlinear equations. To solve a square system of nonlinear equations using Knitro one should specify the nonlinear equations as equality constraints (i.e., constraints with $cl = cu$), and specify the objective function (1a) as zero (i.e., $f(x) = 0$).

5.23.9.7 Solving Least Squares Problems

There are two ways of using Knitro for solving problems in which the objective function is a sum of squares of the form

$$f(x) = \frac{1}{2}\sum_{j=1}^{q} r_j(x)^2.$$

If the value of the objective function at the solution is not close to zero (the large residual case), the least squares structure of f can be ignored and the problem can be solved as any other optimization problem. Any of the Knitro options can be used.

On the other hand, if the optimal objective function value is expected to be small (small residual case) then Knitro can implement the Gauss-Newton or Levenberg-Marquardt methods which only require first derivatives of the residual functions, $r_j(x)$, and yet converge rapidly. To do so, the user need only define the Hessian of f to be

$$\nabla^2 f(x) = J(x)^T J(x),$$

where

$$J(x) = \left[\frac{\partial r_j}{\partial x_i}\right] \begin{array}{l} j = 1, 2, \ldots, q \\ i = 1, 2, \ldots, n \end{array}.$$

The actual Hessian is given by

$$\nabla^2 f(x) = J(x)^T J(x) + \sum_{j=1}^{q} r_j(x)\nabla^2 r_j(x);$$

the Gauss-Newton and Levenberg-Marquardt approaches consist of ignoring the last term in the Hessian.

Knitro will behave like a Gauss-Newton method by setting `algorithm=1`, and will be very similar to the classical Levenberg-Marquardt method when `algorithm=2`. For a discussion of these methods see, for example, [143] .

5.24 LINDO and LINDOGlobal

Lindo Systems, Inc.

5.24.1 Introduction

GAMS/LINDO finds guaranteed globally optimal solutions to general nonlinear problems with continuous and/or discrete variables. GAMS/LINDO supports most mathematical functions, including functions that are nonsmooth, such as abs(x) and or even discontinuous, such as floor(x). Nonlinear solvers employing methods like successive linear programming (SLP) or generalized reduced gradient (GRG) return a local optimal solution to an NLP problem. However, many practical nonlinear models are non-convex and have more than one local optimal solution. In some applications, the user may want to find a global optimal solution.

The LINDO global optimization procedure(GOP) employs branch-and-cut methods to break an NLP model down into a list of subproblems. Each subproblem is analyzed and either a) is shown to not have

a feasible or optimal solution, or b) an optimal solution to the subproblem is found, e.g., because the subproblem is shown to be convex, or c) the subproblem is further split into two or more subproblems which are then placed on the list. Given appropriate tolerances, after a finite, though possibly large number of steps a solution provably global optimal to tolerances is returned. Traditional nonlinear solvers can get stuck at suboptimal, local solutions. This is no longer the case when using the global solver.

GAMS/LINDO can automatically linearize a number of nonlinear relationships, such as max(x,y), through the addition of constraints and integer variables, so the transformed linearized model is mathematically equivalent to the original nonlinear model. Keep in mind, however, that each of these strategies will require additional computation time. Thus, formulating models, so they are convex and contain a single extremum, is desirable. In order to decrease required computing power and time it is also possible to disable the global solver and use GAMS/LINDO like a regular nonlinear solver.

GAMS/LINDO has a multistart feature that restarts the standard (non-global) nonlinear solver from a number of intelligently generated points. This allows the solver to find a number of locally optimal points and report the best one found. This alternative can be used when global optimization is costly. A user adjustable parameter controls the maximum number of multistarts to be performed.

LINDO automatically detects problem type and uses an appropriate solver, e.g., if you submit an LP model to LINDO, it will be solved as an LP at LP speed, regardless of what you said in the "solve using" statement. With the NLP parameter *NLP_QUADCHK* turned on, LINDO can detect hidden quadratic expressions and automatically recognize convex QCPs, as well as second-order cones (SOCP), like in Value-at-Risk models, allowing dramatically faster solution times via the barrier solver. When such models have integer variables, LINDO would use the barrier solver to solve all subproblems leading to significantly improved solution times when compared to the case with the standard NLP solver.

5.24.1.1 Licensing and software requirements

In order to use GAMS/LINDOGlobal, two licenses are required: a GAMS/LINDOGlobal license and a GAMS/CONOPT license. The additional CONOPT license requirement exists because LINDOGlobal uses CONOPT to solve the nonlinear subproblems. The GAMS/LINDOGlobal license places upper limits on the model size of 3,000 variables and 2,000 constraints.

To use GAMS/LINDO, only a GAMS/LINDO license is required. It imposes no upper limit on the model size and includes the capability to solve stochastic models (see section Stochastic Programming (SP) in GAMS/Lindo).

Neither the GAMS/LINDO nor the GAMS/LINDOGlobal license includes the Barrier solver option. The Barrier option is enabled via a separate license for the GAMS/MOSEK barrier solver.

5.24.1.2 Running GAMS/LINDO

GAMS/LINDO is capable of solving models of the following types: EMP (stochastic), LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP and MINLP. If GAMS/LINDO is not specified as the default solver for these models, it can be invoked by issuing one of the following command before the solve statement:

```
option xxx=lindo;
option xxx=lindoglobal;
```

where xxx is one of: EMP, LP, MIP, RMIP, NLP, DNLP, QCP, MIQCP, RMINLP, or MINLP.

You can also find global optima to math programs with equilibrium or complementarity constraints, type MPEC, by using the GAMS/NLPEC translator in conjunction with LINDO. You use NLPEC to translate complementarities into standard mathematical statements, e.g. $h*y = 0$, and then use LINDO as the DNLP(Discontinuous Nonlinear) solver to solve the translated model. The following little GAMS model illustrates:

```
$TITLE simple mpec example
variable f, x1, x2, y1, y2; positive
variable y1; y2.lo = -1; y2.up = 1;

equations cost, g, h1, h2;

cost..  f =E= x1 + x2;
   g..  sqr(x1) + sqr(x2) =L= 1;
  h1..  x1 =G= y1 - y2 + 1;
  h2..  x2 + y2 =N= 0;

* declare h and y complementary
model example / cost, g, h1.y1, h2.y2 /;

option mpec=nlpec;
option dnlp=lindo;
solve example using mpec min f;
```

5.24.2 Supported nonlinear functions

GAMS/LINDO supports most nonlinear functions in global mode, including +, -, ∗, /, floor, modulo, sign, min, max, sqr, exp, power, ln, log, sqrt, abs, cos, sin, tan, cosh, sinh, tanh, arccos, arcsin, arctan and logic expressions AND, OR, NOT, and IF. Be aware that using highly nonconvex functions may lead to long solve times.

5.24.3 Diagnosis of Infeasible or Unbounded Models

GAMS/LINDO offers two diagnostic tools, that can help users debug infeasible or unbounded optimization models. These tools can be called after the solver reports an infeasible or unbounded status for the model. When activating IIS Lindo finds an irreducible infeasible set (IIS) of constraints, whereas setting IUS, makes Lindo find an irreducible unbounded set (IUS) of variables. An IIS is a set of constraints that are infeasible taken together, but every strict subset is feasible. Similarly, an IUS is a set of unbounded variables such that fixing any one of them would make the model bounded. The IIS or IUS portion of the model will generally be much smaller than the original model. Thus, the user can track down formulation or data entry errors quickly. By isolating the source of infeasibility or unboundedness, the user can correct the model data such as right-hand side values, objective coefficients, senses of the constraints, and column bounds. Note that the IUS option is available for LPs only.

5.24.3.1 Infeasible Models

GAMS/Lindo's IIS option activates the IIS finder, after a model was tried to be solved and the solver returned a "no feasible solution" message. For an LP, if an infeasible basis is not resident in the solver, the IIS finder cannot initiate the process to isolate an IIS. This can occur if the infeasibility is detected in the pre-solver before a basis is created, or the barrier solver has terminated without performing a basis crossover. To obtain an IIS for such cases, the pre-solve option will be turned off automatically and the model gets optimized again.

The constraints and bounds in the IIS are further classified into two disjoint sets: a necessary set and a sufficient set. The *sufficient* set refers to a crucial subset of the IIS in the sense that removing any one of its members from the entire model renders the model feasible. Note that not all infeasible models have *sufficient* sets. The *necessary* set contains those constraints and bounds that are likely to contribute to the overall infeasibility of the entire model. Thus, the *necessary* set requires a correction in at least one member to make the original model feasible. A constraint that has been marked as *sufficient* has a high probability of containing an error. In fact, if the model contains only one bad coefficient, the constraint containing it will be marked as *sufficient*.

To control the level of analysis when locating an IIS, one can set the option IIS_ANALYZE_LEVEL.

5.24.3.2 Unbounded Linear Programs

GAMS/Lindo's IUS option is similar to the IIS option, except that it is used to track down the source of an unbounded solution in a linear program. This tool analyzes the model and isolates an "irreducibly unbounded set" (IUS) of variables. As in the infeasibility case, the IUS is partitioned into *sufficient* and *necessary* sets to indicate the role of the member variables for the unboundedness of the overall model.

The variables in the *sufficient* set are crucial in the sense that fixing any of these variables makes the overall model bounded. However, fixing the variables in the *necessary* set does not ensure that there are no other sets of unbounded variables that cause unboundedness for the overall model.

To control the level of analysis when locating an IUS, one can set the option IUS_ANALYZE_LEVEL.

5.24.4 GAMS/LINDO output

The log output below is obtained for the NLP model mhw4d.gms from the GAMS model library using LINDOs global solver.

```

After determining the different kinds of nonlinear operators LINDO tries to linearize these within the presolving. When a feasible starting point is found the optimization starts and the log provides information about the progress. At the end it is reported if an optimum could be found and then the results as well as the used resources are summarized.

The following flags can be seen in the progress log:

Flag	Description
(∗**FP**)	found a new MIP solution with feasibility pump
(∗**SBB**)	found a new MIP solution in tree reorder
(∗**SE**)	found a new MIP solution in simple enumeration
(∗**AB**)	found a new MIP solution in advanced branching
(∗**AH**)	found a new MIP solution with advanced heuristics
(∗**C**)	found a new MIP solution after cuts added
(∗**T**)	found a new MIP solution on the top
(∗**SRH**)	found a new MIP solution in simple rounding heuristics
(∗**SB**)	found a new MIP solution in strong branching
(∗**K**)	found a new MIP solution in knapsack enumerator
(∗)	found a new MIP solution normal branching
(∗**?-**)	found a new MIP solution with advanced heuristics (level$>$10)
(∗**N**)	found a new incumbent GOP solution

Flag	Description
(∗**I**)	stored a box with the incumbent solution into the GOP solution list
(∗**F**)	determined the final GOP status

5.24.5 The GAMS/LINDO Options

GAMS/LINDO offers a diverse range of user-adjustable parameters to control the behavior of its solvers. While the default values of these parameters work best for most purposes, there may be cases the users prefer to work with different settings for a subset of the available parameters. This section gives a list of available GAMS/LINDO parameters, categorized by type, along with their brief descriptions. A more detailed description is given in the section that follows.

5.24.5.1 GAMS/LINDO Options File

In order to set GAMS/LINDO options, you need to set up an option file *lindo.opt* or *lindoglobal.opt* in your GAMS project directory. You must indicate in the model that you want to use the option file by inserting before the solve statement, the line:

```
<modelname>.optfile = 1;
```

where

```
<modelname>
```

is the name of the model referenced in the model statement. The option file is in plain text format containing a single GAMS/LINDO option per line. Each option identifier is followed by its target value with space or tab characters separating them. The lines starting with ∗ character are treated as comments.

A sample option file *lindo.opt* looks like below

```
* Use(1) or Disable(0) global optimization for NLP/MINLP models
USEGOP               0

* Enable Multistart NLP solver
NLP_SOLVER           9

* Allow a maximum of 3 multistart attempts
NLP_MAXLOCALSEARCH   3

* Set an overall time limit of 200 secs.
SOLVER_TIMLMT      200
```

5.24.6 Summary of GAMS/Lindo Options

5.24.6.1 General Options

Option	Description	Default
DECOMPOSITION_TYPE	decomposition to be performed on a linear or mixed integer model	1
FIND_BLOCK	graph partitioning method to find block structures	0
FIND_SYMMETRY_LEVEL	specifies the symmetry finding level.	-1
FIND_SYMMETRY_PRINT_LEVEL	specifies print level for symmetry finding	0
INSTRUCT_SUBOUT	flag to specify how to deal with fixed variables in the instruction list	-1
MULTITHREAD_MODE	threading mode	-1
NUM_THREADS	number of parallel threads to be used	GAMS Threads
PROFILER_LEVEL	specifies the profiler level to break down the total cpu time into.	0
SOLVER_CONCURRENT_OPTMODE	controls if simplex and interior-point optimizers will run concurrently	0
SOLVER_CUTOFFVAL	solver will exit if optimal solution is worse than this	0
SOLVER_FEASTOL	feasibility tolerance	1e-7
SOLVER_IPMSOL	basis crossover flag for barrier solver	0
SOLVER_IUSOL	flag for computing basic solution for infeasible model	0
SOLVER_METHOD	specifies the method to use when generic solver is invoked	0
SOLVER_MODE	controls some of the advanced strategies when solving LPs	1
SOLVER_OPTTOL	dual feasibility tolerance	1e-7
SOLVER_PRE_ELIM_FILL	fill-in introduced by the eliminations during pre-solve	1000
SOLVER_RESTART	starting basis flag	0
SOLVER_TIMLMT	time limit in seconds for continous solver	GAMS ResLim
SOLVER_USECUTOFFVAL	flag for using cutoff value	0
TUNER_PRINT_LEVEL	specifies the amount of print to do during parameter tuning	1

5.24.6.2 LP Options

Option	Description	Default
LP_AIJ_ZEROTOL	coefficient matrix zero tolerance	2.22045e-16
LP_BIGM	big-M for phase-I	1e6
LP_BNDINF	big-M to truncate lower and upper bounds in single phase dual-simplex	1e15
LP_DPSWITCH	specifies whether LP primal-dual simplex switch is enabled or not	1
LP_DRATIO	controls the dual min-ratio strategy	1
LP_DYNOBJFACT	Dynamic obj factor	0.75

Option	Description	Default
LP_DYNOBJMODE	Dynamic obj mode	0
LP_ITRLMT	simplex iteration limit	infinity
LP_PIV_BIGTOL	simplex maximum pivot tolerance	1e-5
LP_PIV_ZEROTOL	simplex pivot zero tolerance	1e-8
LP_PPARTIAL	primal simplex partial pricing method	0
LP_PRELEVEL	controls the amount and type of LP pre-solving	126
LP_RATRANGE	controls the number of pivot-candidates to consider when searching for a stable pivot in LU decomposition	4
LP_SCALE	scaling flag	1
LP_SPRINT_COLFACT	maximum number of columns in Sprint as a factor of number of rows	10
LP_SPRINT_MAXPASS	maximum number of passes in Sprint method	100
LP_SPRINT_SUB	LP method for subproblem in Sprint method	0
PROB_TO_SOLVE	controls whether the explicit primal or dual form of the given LP problem will be solved	0
SPLEX_DPRICING	pricing option for dual simplex method	-1
SPLEX_DUAL_PHASE	controls the dual simplex strategy	0
SPLEX_PPRICING	pricing option for primal simplex method	-1
SPLEX_REFACFRQ	number of simplex iterations between two consecutive basis re-factorizations	100

5.24.6.3 IPM Options

Option	Description	Default
IPM_BASIS_REL_TOL_S	maximum relative dual bound violation allowed in an optimal basic solution	1e-12
IPM_BASIS_TOL_S	maximum absolute dual bound violation in an optimal basic solution	1e-7
IPM_BASIS_TOL_X	maximum absolute primal bound violation allowed in an optimal basic solution	1e-7
IPM_BI_LU_TOL_REL_PIV	relative pivot tolerance used in the LU factorization in the basis identification procedure	1e-2
IPM_CHECK_CONVEXITY	flag to check convexity of a quadratic program using barrier solver	1
IPM_CO_TOL_DFEAS	dual feasibility tolerance for Conic solver	1e-8
IPM_CO_TOL_INFEAS	maximum bound infeasibility tolerance for Conic solver	1e-12
IPM_CO_TOL_MU_RED	optimality tolerance for Conic solver	1e-8
IPM_CO_TOL_PFEAS	primal feasibility tolerance for Conic solver	1e-8
IPM_MAX_ITERATIONS	ipm iteration limit	1000
IPM_NUM_THREADS	number of threads to run the interiorpoint optimizer on	1
IPM_OFF_COL_TRH	extent for detecting the offending columns in the Jacobian of the constraint matrix	40
IPM_TOL_DFEAS	dual feasibility tolerance	1e-8

Option	Description	Default
IPM_TOL_DSAFE	controls the initial dual starting point	1
IPM_TOL_INFEAS	infeasibility tolerance	1e-10
IPM_TOL_MU_RED	relative complementarity gap tolerance	1e-16
IPM_TOL_PATH	how close to follow the central path	1e-8
IPM_TOL_PFEAS	primal feasibility tolerance	1e-8
IPM_TOL_PSAFE	controls the initial primal starting point	1
IPM_TOL_REL_STEP	relative step size to the boundary	0.9999

5.24.6.4 MIP Options

Option	Description	Default
MIP_ABSCUTTOL	MIP absolute cut tolerance	-1.0
MIP_ABSOPTTOL	MIP absolute optimality tolerance	GAMS OptCA
MIP_ADDCUTOBJTOL	required objective improvement to continue generating cuts	1.5625e-5
MIP_ADDCUTPER	percentage of constraint cuts that can be added	0.75
MIP_ADDCUTPER_TREE	percentage of constraint cuts that can be added at child nodes	0.5
MIP_AGGCUTLIM_TOP	max number of constraints involved in derivation of aggregation cut at root node	-1
MIP_AGGCUTLIM_TREE	max number of constraints involved in derivation of aggregation cut at tree nodes	-1
MIP_ANODES_SWITCH_DF	threshold on active nodes for switching to depth-first search	50000
MIP_AOPTTIMLIM	time in seconds beyond which the relative optimality tolerance will be applied	100
MIP_BIGM_FOR_INTTOL	threshold for which coefficient of a binary variable would be considered as big-M	1e8
MIP_BRANCHDIR	first branching direction	0
MIP_BRANCHRULE	rule for choosing the variable to branch	0
MIP_BRANCH_LIMIT	limit on the total number of branches to be created during branch and bound	-1
MIP_BRANCH_PRIO	controls how variable selection priorities are set and used	0
MIP_CONCURRENT_REOPTMODE	specifies the concurrent optimization mode with warm start	0
MIP_CONCURRENT_STRATEGY	controls the concurrent MIP strategy	-1
MIP_CONCURRENT_TOPOPTMODE	specifies the concurrent optimization mode with cold start	0
MIP_CUTDEPTH	threshold value for the depth of nodes in the branch and bound tree	8
MIP_CUTFREQ	frequency of invoking cut generation at child nodes	10
MIP_CUTLEVEL_TOP	combination of cut types to try at the root node when solving a MIP	57342

Option	Description	Default
MIP_CUTLEVEL_TREE	combination of cut types to try at child nodes in the branch and bound tree when solving a MIP	53246
MIP_CUTOFFOBJ	defines limit for branch and bound	1e30
MIP_CUTTIMLIM	time to be spent in cut generation	-1
MIP_DELTA	near-zero value used in linearizing nonlinear expressions	1e-6
MIP_DUAL_SOLUTION	flag for computing dual solution of LP relaxation	0
MIP_FP_HEU_MODE	specifies the feasibility-pump (FP) heuristic mode	0
MIP_FP_ITRLIM	iteration limit for feasibility pump heuristic	500
MIP_FP_MODE	mode for the feasibility pump heuristic	-1
MIP_FP_OPT_METHOD	optimization and reoptimization method for feasibility pump heuristic	0
MIP_FP_PROJECTION	type of objective function of LPs in projection step of the feasibility pump heuristic	0
MIP_FP_TIMLIM	time limit for feasibility pump heuristic	1800
MIP_FP_WEIGTH	weight of the objective function in the feasibility pump	1
MIP_GENERAL_MODE	general strategy in solving MIPs	0
MIP_HEULEVEL	specifies heuristic used to find integer solution	3
MIP_HEUMINTIMLIM	minimum time in seconds to be spent in finding heuristic solutions	0
MIP_HEU_DROP_OBJ	flag for whether to use without OBJ heuristic	0
MIP_HEU_MODE	heuristic used in MIP solver	0
MIP_INTTOL	absolute integer feasibility tolerance	1e-6
MIP_ITRLIM	iteration limit for branch and bound	infinity
MIP_KBEST_USE_GOP	specifies whether to use gop solver in MIP KBest	0
MIP_KEEPINMEM	flag for keeping LP bases in memory	1
MIP_LBIGM	Big-M value used in linearizing nonlinear expressions	10000
MIP_LSOLTIMLIM	time limit until finding a new integer solution	-1
MIP_MAKECUT_INACTIVE_COUNT	threshold for times a cut could remain active after successive reoptimization	10
MIP_MAXCUTPASS_TOP	number passes to generate cuts on the root node	200
MIP_MAXCUTPASS_TREE	number passes to generate cuts on the child nodes	2
MIP_MAXNONIMP_CUTPASS	number of passes allowed in cut-generation that does not improve current relaxation	3
MIP_MAXNUM_MIP_SOL_STORAGE	maximum number of k-best solutions to store	1

Option	Description	Default
MIP_MINABSOBJSTEP	value to update cutoff value each time a mixed integer solution is found	0
MIP_NODESELRULE	specifies the node selection rule	0
MIP_NUM_THREADS	number of parallel threads to use by the parallel MIP solver	1
MIP_PARA_FP	flag for whether to use parallelization on the feasibility pump heuristic	1
MIP_PARA_FP_MODE	flag for the mode of parallel feasibility pump	0
MIP_PARA_INIT_NODE	number of initial nodes for MIP parallelization	-1
MIP_PARA_ITR_MODE	flag for iteration mode in MIP parallelization	1
MIP_PARA_RND_ITRLMT	iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations	2.0
MIP_PARA_SUB	flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing	1
MIP_PEROPTTOL	MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds	1e-5
MIP_PERSPECTIVE_REFORM	flag for whether to use Perspective Reformulation	1
MIP_POLISH_ALPHA_TARGET	proportion solutions in the pool to initiate a polishing-task at the current node	0.6
MIP_POLISH_MAX_BRANCH_COUNT	maximum number of branches to polish	2000
MIP_POLISH_NUM_BRANCH_NEXT	number of branches to polish in the next round	4000
MIP_PREHEU_DFE_VSTLIM	limit for the variable visit in depth first enumeration	200
MIP_PREHEU_LEVEL	heuristic level for the prerelax solver	0
MIP_PREHEU_TC_ITERLIM	iteration limit for the two change heuristic	30000000
MIP_PREHEU_VAR_SEQ	sequence of the variable considered by the prerelax heuristic	-1
MIP_PRELEVEL	controls the amount and type of MIP presolving at root node	3070
MIP_PRELEVEL_TREE	amount and type of MIP pre-solving at tree nodes	1214
MIP_PRE_ELIM_FILL	controls fill-in introduced by eliminations during pre-solve	100
MIP_PSEUDOCOST_RULE	specifies the rule in pseudocost computations for variable selection	0
MIP_PSEUDOCOST_WEIGT	weight in pseudocost computations for variable selection	1.5625e-05
MIP_REDCOSTFIX_CUTOFF	cutoff value as a percentage of the reduced costs	0.9
MIP_REDCOSTFIX_CUTOFF_TREE	cutoff value as a percentage of the reduced costs at tree nodes	0.9
MIP_RELINTTOL	relative integer feasibility tolerance	8e-6
MIP_RELOPTTOL	MIP relative optimality tolerance	GAMS OptCR

Option	Description	Default
MIP_REOPT	optimization method to use when doing reoptimization	0
MIP_SCALING_BOUND	maximum difference between bounds of an integer variable for enabling scaling	10000
MIP_SOLLIM	integer solution limit for MIP solver	-1
MIP_SOLVERTYPE	optimization method to use when solving mixed-integer models	0
MIP_STRONGBRANCHDONUM	minimum number of variables to try the strong branching on	3
MIP_STRONGBRANCHLEVEL	depth from the root in which strong branching is used	10
MIP_SWITCHFAC_SIM_IPM_ITER	specifies the (positive) factor that multiplies the number of constraints to impose an iteration limit to simplex method and trigger a switch over to the barrier method	-1
MIP_SWITCHFAC_SIM_IPM_TIME	factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method	-1
MIP_SYMMETRY_MODE	specifies mip symmetry handling methods	0
MIP_SYMMETRY_NONZ	limit on number of nonzeros to look for symmetries	50000
MIP_TIMLIM	time limit in seconds for integer solver	GAMS ResLim
MIP_TOPOPT	optimization method to use when there is no previous basis	0
MIP_TREEREORDERLEVEL	tree reordering level	10
MIP_TREEREORDERMODE	tree reordering mode	1
MIP_USECUTOFFOBJ	flag for using branch and bound limit	1
MIP_USE_CUTS_HEU	controls if cut generation is enabled during MIP heuristics	-1
MIP_USE_ENUM_HEU	frequency of enumeration heuristic	4
MIP_USE_INT_ZERO_TOL	controls if all MIP calculations would be based on absolute integer feasibility tolarance	0

5.24.6.5 NLP Options

Option	Description	Default
NLP_AUTODERIV	defining type of computing derivatives	0
NLP_AUTOHESS	flag for using Second Order Automatic Differentiation for solving NLP	0
NLP_CONIC_REFORM	determines if to explore conic reformulation	1
NLP_CONOPT_VER	specifies the CONOPT version to be used in NLP optimizations	3
NLP_CUTOFFOBJ	as soon as any multi-start thread achieves this value all threads stop	-1e30
NLP_DERIV_DIFFTYPE	flag indicating the technique used in computing derivatives with finite differences	0

Option	Description	Default
NLP_FEASCHK	how to report results when solution satisfies tolerance of scaled but not original model	1
NLP_FEASTOL	feasibility tolerance for nonlinear constraints	1e-6
NLP_INF	numeric infinity for nonlinear models	1e30
NLP_IPM2GRG	switch from IPM solver to GRG solver when IPM fails due to numerical errors	1
NLP_ITERS_PER_LOGLINE	number of nonlinear iterations to elapse before next progress message	10
NLP_ITRLMT	nonlinear iteration limit	GAMS IterLim
NLP_LINEARZ	extent to which the solver will attempt to linearize nonlinear models	0
NLP_LINEARZ_WB_CONSISTENT	determines if linearization process is consistent with WB/excel calculation	0
NLP_MAXLOCALSEARCH	maximum number of local searches	5
NLP_MAXLOCALSEARCH_TREE	maximum number of multistarts	1
NLP_MAX_RETRY	maximum number refinement retries to purify the final NLP solution	5
NLP_MSW_EUCDIST_THRES	euclidean distance threshold in multistart search	0.001
NLP_MSW_FILTMODE	filtering mode to exclude certain domains during sampling in multistart search	-1
NLP_MSW_MAXNOIMP	maximum number of consecutive populations to generate without any improvements	-1
NLP_MSW_MAXPOP	maximum number of populations to generate in multistart search	-1
NLP_MSW_MAXREF	maximum number of reference points to generate trial points in multistart search	-1
NLP_MSW_NORM	norm to measure the distance between two points in multistart search	2
NLP_MSW_NUM_THREADS	number of parallel threads to be used when solving an NLP model with the multistart solver	1
NLP_MSW_OVERLAP_RATIO	rate of replacement in successive populations	0.1
NLP_MSW_POXDIST_THRES	penalty function neighborhood threshold in multistart search	0.01
NLP_MSW_PREPMODE	preprocessing strategies in multistart solver	-1
NLP_MSW_RG_SEED	random number generator seed for the multistart solver	1019
NLP_MSW_RMAPMODE	specifies the mode to map reference points in the unit cube into the original space	-1
NLP_MSW_SOLIDX	index of the multistart solution to be loaded	0
NLP_MSW_XKKTRAD_FACTOR	KKT solution neighborhood factor in multistart search	0.85
NLP_MSW_XNULRAD_FACTOR	initial solution neighborhood factor in multistart search	0.5
NLP_PRELEVEL	controls the amount and type of NLP presolving	126
NLP_PSTEP_FINITEDIFF	value of the step length in computing the derivatives using finite differences	5e-7

Option	Description	Default
NLP_QUADCHK	flag for checking if NLP is quadratic	1
NLP_REDGTOL	tolerance for the gradients of nonlinear functions	1e-7
NLP_SOLVER	type of nonlinear solver	7
NLP_SOLVE_AS_LP	flag indicating if the nonlinear model will be solved as an LP	0
NLP_STALL_ITRLMT	iteration limit before a sequence of non-improving NLP iterations is declared as stalling	100
NLP_STARTPOINT	flag for using initial starting solution for NLP	1
NLP_SUBSOLVER	type of nonlinear subsolver	1
NLP_USECUTOFFOBJ	flag to use parameter NLP_CUTOFFOBJ	0
NLP_USE_CRASH	flag for using simple crash routines for initial solution	0
NLP_USE_LINDO_CRASH	flag for using advanced crash routines for initial solution	1
NLP_USE_SDP	flag to use SDP solver for POSD constraint	1
NLP_USE_SELCONEVAL	flag for using selective constraint evaluations for solving NLP	1
NLP_USE_SLP	flag for using sequential linear programming step directions for updating solution	1
NLP_USE_STEEPEDGE	flag for using steepest edge directions for updating solution	0

5.24.6.6 Global Options

Option	Description	Default
GOP_ABSOPTTOL	absolute optimality tolerance	GAMS OptCA
GOP_ALGREFORMMD	algebraic reformulation rule for a GOP	18
GOP_BBSRCHMD	node selection rule in GOP branch-and-bound	1
GOP_BNDLIM	max magnitude of variable bounds used in GOP convexification	1e10
GOP_BOXTOL	minimal width of variable intervals	1e-6
GOP_BRANCHMD	direction to branch first when branching on a variable	5
GOP_BRANCH_LIMIT	limit on the total number of branches to be created in GOP tree	-1
GOP_CMINLP	flag indicating if GOP exploits convex MINLP model	0
GOP_CONIC_REFORM	flag indicating if GOP explore conic reformulation	1
GOP_CORELEVEL	strategy of GOP branch-and-bound	14
GOP_DECOMPPTMD	decomposition point selection rule in GOP branch-and-bound	1
GOP_DELTATOL	delta tolerance in GOP convexification	1e-7
GOP_FLTTOL	floating-point tolerance	1e-10
GOP_HEU_MODE	heuristic used in global solver	0

Option	Description	Default
GOP_ITRLIM	GOP iteration limit	infinity
GOP_ITRLIM_IPM	total barrier iteration limit summed over all branches in GOP	-1
GOP_ITRLIM_NLP	total nonlinear iteration limit summed over all branches in GOP	-1
GOP_ITRLIM_SIM	total simplex iteration limit summed over all branches in GOP	-1
GOP_LIM_MODE	flag indicating which heuristic limit on sub-solver in GOP is based	1
GOP_LINEARZ	flag indicating if GOP exploits linearizable model	1
GOP_LSOLBRANLIM	branch limit until finding a new nonlinear solution	-1
GOP_MAXWIDMD	maximum width flag for the global solution	0
GOP_MULTILINEAR	flag indicating if GOP exploits multi linear feature	1
GOP_NUM_THREADS	number of parallel threads to be used when solving a nonlinear model with the global optimization solver	1
GOP_OBJ_THRESHOLD	threshold of objective value in the GOP solver	-1e+30
GOP_OPTCHKMD	criterion used to certify the global optimality	2
GOP_OPT_MODE	mode for GOP optimization	1
GOP_POSTLEVEL	amount and type of GOP postsolving	6
GOP_PRELEVEL	amount and type of GOP presolving	30
GOP_QUADMD	flag indicating if GOP exploits quadratic feature	-1
GOP_QUAD_METHOD	specifies if the GOP solver should solve the model as a QP when applicable	-1
GOP_RELBRNDMD	reliable rounding in the GOP branch-and-bound	0
GOP_RELOPTTOL	relative optimality tolerance	GAMS OptCR
GOP_SOLLIM	integer solution limit for GOP branch-and-bound	-1
GOP_SUBOUT_MODE	substituting out fixed variables	1
GOP_TIMLIM	time limit in seconds for GOP branch-and-bound	GAMS ResLim
GOP_USEBNDLIM	max magnitude of variable bounds flag for GOP convexification	2
GOP_WIDTOL	maximal width of variable intervals	1e-4
USEGOP	use global optimization	1

5.24.6.7 SP Options

Option	Description	Default
CORE_ORDER_BY_STAGE	order nontemporal models or not	1
EMPINFOFILE	Path and name of file containing additional EMP-SP information as randvar, jrandvar, stage etc.	
REPORTEVSOL	solve and report the expected value solution	0
SAMP_CDSINC	correlation matrix diagonal shift increment	1e-6

Option	Description	Default
SAMP_NCM_CUTOBJ	objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem	1e-30
SAMP_NCM_DSTORAGE	flag to enable or disable sparse mode in NCM computations	-1
SAMP_NCM_ITERLIM	iteration limit for NCM method	100
SAMP_NCM_METHOD	bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem	5
SAMP_NCM_OPTTOL	optimality tolerance for NCM method	1e-7
SAMP_NUM_THREADS	specifies the number of parallel threads to be used when sampling	0
SAMP_RG_BUFFER_SIZE	specifies the buffer size for random number generators in running in parallel mode	0
SAMP_SCALE	flag to enable scaling of raw sample data	0
STOC_ABSOPTTOL	absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver	GAMS OptCA
STOC_ADD_MPI	flag to use add-instructions mode when building deteq	0
STOC_ALD_DUAL_FEASTOL	dual feasibility tolerance for ALD	1e-4
STOC_ALD_DUAL_STEPLEN	dual step length for ALD	0.9
STOC_ALD_INNER_ITER_LIM	inner loop iteration limit for ALD	1000
STOC_ALD_OUTER_ITER_LIM	outer loop iteration limit for ALD	200
STOC_ALD_PRIMAL_FEASTOL	primal feasibility tolerance for ALD	1e-4
STOC_ALD_PRIMAL_STEPLEN	primal step length for ALD	0.5
STOC_AUTOAGGR	flag to enable or disable autoaggregation	1
STOC_BENCHMARK_SCEN	benchmark scenario to compare EVPI and EVMU against	-2
STOC_BIGM	big-M value for linearization and penalty functions	1e7
STOC_BUCKET_SIZE	bucket size in Benders decomposition	-1
STOC_CALC_EVPI	flag to enable or disable calculation of EVPI	1
STOC_CORRELATION_TYPE	correlation type associated with correlation matrix	0
STOC_DEQOPT	method to solve the DETEQ problem	0
STOC_DETEQ_TYPE	type of deterministic equivalent	-1
STOC_DS_SUBFORM	subproblem formulation to use in DirectSearch	-1
STOC_ELIM_FXVAR	flag to enable elimination of fixed variables from deteq MPI	1
STOC_INFBND	value to truncate infinite bounds at non-leaf nodes	1e9
STOC_ITER_LIM	iteration limit for stochastic solver	infinity
STOC_MAP_MPI2LP	flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements	0

Option	Description	Default
STOC_MAX_NUMSCENS	maximum number of scenarios before forcing automatic sampling	40000
STOC_METHOD	stochastic optimization method to solve the model	-1
STOC_NAMEDATA_LEVEL	name data level	1
STOC_NODELP_PRELEVEL	presolve level solving node-models	0
STOC_NSAMPLE_PER_STAGE	list of sample sizes per stage (starting at stage 2)	
STOC_NSAMPLE_SPAR	common sample size per stochastic parameter	-1
STOC_NSAMPLE_STAGE	common sample size per stage	-1
STOC_NUM_THREADS	number of parallel threads	1
STOC_RELOPTTOL	relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver	GAMS OptCR
STOC_REL_DSTEPTOL	dual-step tolerance	1e-7
STOC_REL_PSTEPTOL	primal-step tolerance	1e-8
STOC_REOPT	reoptimization method to solve the node-models	0
STOC_RG_SEED	seed to initialize the random number generator	1031
STOC_SAMP_CONT_ONLY	flag to restrict sampling to continuous stochastic parameters only or not	1
STOC_SBD_MAXCUTS	max cuts to generate for master problem	-1
STOC_SBD_NUMCANDID	maximum number of candidate solutions to generate at SBD root	-1
STOC_SBD_OBJCUTFLAG	flag to enable objective cut in SBD master problem	1
STOC_SBD_OBJCUTVAL	RHS value of objective cut in SBD master problem	1e-30
STOC_SHARE_BEGSTAGE	stage beyond which node-models are shared	-1
STOC_TIME_LIM	time limit for stochastic solver	GAMS ResLim
STOC_TOPOPT	optimization method to solve the root problem	0
STOC_VARCONTROL_METHOD	sampling method for variance reduction	1
STOC_WSBAS	warm start basis for wait-see model	-1
SVR_LS_ANTITHETIC	Sample variance reduction map to Lindo Antithetic algorithm	
SVR_LS_LATINSQUARE	Sample variance reduction map to Lindo Latin Square algorithm	
SVR_LS_MONTECARLO	Sample variance reduction map to Lindo Montecarlo algorithm	

5.24.6.8 IIS and IUS Options

Option	Description	Default
IIS	run the IIS finder if the problem is infeasible	0

Option	Description	Default
IIS_ANALYZE_LEVEL	controls the level of analysis when locating an IIS	1
IIS_GETMODE	flag that controls whether variable bounds in the IIS should be retrieved or the integer restrictions	0
IIS_INFEAS_NORM	specifies the norm to measure infeasibilities in IIS search	0
IIS_ITER_LIMIT	the iteration limit for IIS search	-1
IIS_METHOD	specifies the method to use in analyzing infeasible models to locate an IIS	0
IIS_PRINT_LEVEL	specifies the amount of print to do during IIS search	2
IIS_REOPT	specifies which optimization method to use when starting from a given basis	0
IIS_TIME_LIMIT	the time limit for IIS search	-1
IIS_TOPOPT	specifies which optimization method to use when there is no previous basis	0
IIS_USE_EFILTER	flag that controls whether the Elastic Filter should be enabled as the supplementary filter in analyzing infeasible models	0
IIS_USE_GOP	flag that controls whether the global optimizer should be enabled in analyzing infeasible NLP models	0
IIS_USE_SFILTER	flag indicating is sensitivity filter will be used during IIS search	1
IUS	run the IUS finder if the problem is unbounded	0
IUS_ANALYZE_LEVEL	controls the level of analysis when locating an IUS	2

5.24.6.9 Link Options

Option	Description	Default
CHECKRANGE	calculate feasible range for variables	range.gdx
READPARAMS	read Lindo parameter file	
WRITEDEMPI	write deterministic equivalent in MPI format	
WRITEDEMPS	write deterministic equivalent in MPS format	
WRITEMPI	write (S)MPI file of processed model	
WRITEMPS	write (S)MPS file of processed model	

5.24.7 Detailed Descriptions of GAMS/Lindo Options

CHECKRANGE *(string)*: calculate feasible range for variables ↩

If this option is set, Lindo calculates the feasible range (determined by an upper and lower bound) for every variable in each equation while all other variables are fixed to their level. If set, the value of this option defines the name of the GDX file where the results are written to. For every combination of equation- and variable block there will be one symbol in the format *EquBlock_VarBlock(equ_Ind_1, ..., equ_Ind_M, var_Ind_1, ..., var_Ind_N, directions)*.

Default: `range.gdx`

CORE_ORDER_BY_STAGE *(integer)*: order nontemporal models or not ↩

Order nontemporal models or not.

Default: 1

DECOMPOSITION_TYPE *(integer)*: decomposition to be performed on a linear or mixed integer model ↩

This refers to the type of decomposition to be performed on a linear or mixed integer model.

Default: 1

value	meaning
0	Solver decides which type of decomposition to use
1	Solver does not perform any decompositions and uses the original model
2	Attempt total decomposition
3	Decomposed model will have dual angular structure
4	Decomposed model will have block angular structure
5	Decomposed model will have both dual and block angular structure

EMPINFOFILE *(string)*: Path and name of file containing additional EMP-SP information as randvar, jrandvar, stage etc. ↩

FIND_BLOCK *(integer)*: graph partitioning method to find block structures ↩

Specifies the graph partitioning method to find block structures.

Default: 0

value	meaning
0	Use an edge-weight minimizing graph partitioning heuristic
1	Use a vertex-weight minimizing graph partitioning heuristic

FIND_SYMMETRY_LEVEL *(integer)*: specifies the symmetry finding level. ↩

Default: -1

value	meaning
-1	Solver decides
0	Finding orbit only without MIP preprocessing
1	Finding orbit only with MIP preprocessing
2	Finding generators without MIP preprocessing
3	Finding generators with MIP preprocessing
4	Finding the first generator without MIP preprocessing
5	Finding the first generator with MIP preprocessing

FIND_SYMMETRY_PRINT_LEVEL *(integer)*: specifies print level for symmetry finding ↩

Default: 0

value	meaning
0	Nothing printed
+2	General information
+4	Time information
+8	Orbit information
+16	Partition information

GOP_ABSOPTTOL *(real)*: absolute optimality tolerance ↩

Synonym: ABSOPTTOL

This value is the GOP absolute optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: GAMS OptCA

GOP_ALGREFORMMD *(integer)*: algebraic reformulation rule for a GOP ↩

Synonym: ALGREFORMMD

This controls the algebraic reformulation rule for a GOP. The algebraic reformulation and analysis is very crucial in building a tight convex envelope to enclose the nonlinear/nonconvex functions. A lower degree of overestimation on convex envelopes helps increase the convergence rate to the global optimum.

Default: 18

value	meaning
+2	Rearrange and collect terms
+4	Expand all parentheses
+8	Retain nonlinear functions
+16	Selectively expand parentheses

GOP_BBSRCHMD *(integer)*: node selection rule in GOP branch-and-bound ↩

Synonym: BBSRCHMD

This specifies the node selection rule for choosing between all active nodes in the GOP branch-and-bound tree when solving global optimization programs.

Default: 1

value	meaning
0	Depth first search
1	Choose node with worst bound

GOP_BNDLIM *(real)*: max magnitude of variable bounds used in GOP convexification ↩

Synonym: BNDLIM

This value specifies the maximum magnitude of variable bounds used in the GOP convexification. Any lower bound smaller than the negative of this value will be treated as the negative of this

value. Any upper bound greater than this value will be treated as this value. This helps the global solver focus on more productive domains.

Default: `1e10`

GOP_BOXTOL *(real)*: minimal width of variable intervals ↩

Synonym: BOXTOL

This value specifies the minimal width of variable intervals in a box allowed to branch.

Default: `1e-6`

GOP_BRANCHMD *(integer)*: direction to branch first when branching on a variable ↩

Synonym: BRANCHMD

This specifies the direction to branch first when branching on a variable. The branch variable is selected as the one that holds the largest magnitude in the measure.

Default: `5`

value	meaning
0	Absolute width
1	Locally relative width
2	Globally relative width
3	Globally relative distance from the convex minimum to the bounds
4	Absolute violation between the function and its convex envelope at the convex minimum
5	Relative violation between the function and its convex envelope at the convex minimum

GOP_BRANCH_LIMIT *(integer)*: limit on the total number of branches to be created in GOP tree ↩

Synonym: BRANCH_LIMIT

This is the limit on the total number of branches to be created during branch-and- bound in GOP tree. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible solution was found, it will be installed as the incumbent (best known) solution.

Range: {-1, ..., ∞}

Default: `-1`

GOP_CMINLP *(integer)*: flag indicating if GOP exploits convex MINLP model ↩

Default: `0`

value	meaning
0	Off
1	On

GOP_CONIC_REFORM *(integer)*: flag indicating if GOP explore conic reformulation ↩

Default: `1`

value	meaning
`0`	Off
`1`	On

GOP_CORELEVEL *(integer)*: strategy of GOP branch-and-bound ↩

Synonym: CORELEVEL

This controls the strategy of GOP branch-and-bound procedure.

Default: `14`

value	meaning
`+2`	LP convex relaxation
`+4`	NLP solving
`+8`	Box Branching

GOP_DECOMPPTMD *(integer)*: decomposition point selection rule in GOP branch-and-bound ↩

Synonym: DECOMPPTMD

This specifies the decomposition point selection rule. In the branch step of GOP branch-and-bound, a branch point M is selected to decompose the selected variable interval [Lb, Ub] into two subintervals, [Lb, M] and [M, Ub].

Default: `1`

value	meaning
`0`	Mid-point
`1`	Local minimum or convex minimum

GOP_DELTATOL *(real)*: delta tolerance in GOP convexification ↩

Synonym: DELTATOL

This value is the delta tolerance in the GOP convexification. It is a measure of how closely the additional constraints added as part of convexification should be satisfied.

Default: `1e-7`

GOP_FLTTOL *(real)*: floating-point tolerance ↩

Synonym: FLTTOL

This value is the GOP floating-point tolerance. It specifies the maximum rounding errors in the floating-point computation.

Default: `1e-10`

GOP_HEU_MODE *(integer)*: heuristic used in global solver ↩

Synonym: HEU_MODE

This specifies the heuristic used in the global solver to find a good solution. Typically, if a heuristic is used, this will put more efforts in searching for good solutions, and less in bound tightening.

Default: `0`

value	meaning
0	No heuristic is used
1	A simple heuristic is used

GOP_ITRLIM *(real)*: GOP iteration limit ↩

Synonym: ITRLIM

This is the total iteration limit (including simplex, barrier and nonlinear iteration) summed over branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: [-1, ∞]

Default: `infinity`

GOP_ITRLIM_IPM *(real)*: total barrier iteration limit summed over all branches in GOP ↩

Synonym: ITRLIM_IPM

This is the total barrier iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: [-1, ∞]

Default: `-1`

GOP_ITRLIM_NLP *(real)*: total nonlinear iteration limit summed over all branches in GOP ↩

Synonym: ITRLIM_NLP

This is the total nonlinear iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: [-1, ∞]

Default: `-1`

GOP_ITRLIM_SIM *(real)*: total simplex iteration limit summed over all branches in GOP ↩

Synonym: ITRLIM_SIM

This is the total simplex iteration limit summed over all branches in GOP. The default value is -1, which means no iteration limit is imposed. If this limit is reached, GOP will stop.

Range: [-1, ∞]

Default: `-1`

GOP_LIM_MODE *(integer)*: flag indicating which heuristic limit on sub-solver in GOP is based ↩

Synonym: LIM_MODE

This is a flag indicating which heuristic limit on sub-solver in GOP is based.

Default: `1`

value	meaning
0	No limit
1	Time based limit
2	Iteration based limit
3	Both time and iteration based limit

GOP_LINEARZ *(integer)*: flag indicating if GOP exploits linearizable model ↩

This is a flag indicating if GOP exploits linearizable model.

Default: 1

value	meaning
0	Exploit lineariable model
1	Do not exploit lineariable model

GOP_LSOLBRANLIM *(integer)*: branch limit until finding a new nonlinear solution ↩

Synonym: LSOLBRANLIM

This value controls the branch limit until finding a new nonlinear solution since the last nonlinear solution is found. The default value is -1, which means no branch limit is imposed.

Range: {-1, ..., ∞}

Default: -1

GOP_MAXWIDMD *(integer)*: maximum width flag for the global solution ↩

Synonym: MAXWIDMD

This is the maximum width flag for the global solution. The GOP branch-and-bound may continue contracting a box with an incumbent solution until its maximum width is smaller than GOP_WIDTOL.

Default: 0

value	meaning
0	The maximum width criterion is suppressed
1	The maximum width criterion is performed

GOP_MULTILINEAR *(integer)*: flag indicating if GOP exploits multi linear feature ↩

This is a flag indicating if GOP exploits multi linear feature.

Default: 1

value	meaning
0	Off
1	On

GOP_NUM_THREADS *(integer)*: number of parallel threads to be used when solving a nonlinear model with the global optimization solver ↩

This value specifies the number of parallel threads to be used when solving a nonlinear model with the global optimization solver.

Default: `1`

GOP_OBJ_THRESHOLD *(real)*: threshold of objective value in the GOP solver ↩

This value specifies the threshold of objective value in the GOP solver. For min problem, if current incumbent solution is less than the threshold GOP solver will stop.

Range: [`-1e+30`, ∞]

Default: `-1e+30`

GOP_OPTCHKMD *(integer)*: criterion used to certify the global optimality ↩

Synonym: OPTCHKMD

This specifies the criterion used to certify the global optimality. When this value is 0, the absolute deviation of objective lower and upper bounds should be smaller than `GOP_ABSOPTTOL` at the global optimum. When its value is 1, the relative deviation of objective lower and upper bounds should be smaller than `GOP_RELOPTTOL` at the global optimum. 2 means either absolute or relative tolerance is satisfied at global optimum.

Default: `2`

GOP_OPT_MODE *(integer)*: mode for GOP optimization ↩

Synonym: OPT_MODE

This specifies the mode for GOP optimization.

Default: `1`

value	meaning
0	Global search for a feasible solution (thus a feasibility certificate)
1	Global search for an optimal solution
2	Global search for an unboundedness certificate

GOP_POSTLEVEL *(integer)*: amount and type of GOP postsolving ↩

Synonym: POSTLEVEL

This controls the amount and type of GOP post-solving. The default value is: 6 = 2+4 meaning to do both of the below options.

Default: `6`

value	meaning
+2	Apply LSgetBestBound
+4	Reoptimize variable bounds

GOP_PRELEVEL *(integer)*: amount and type of GOP presolving ↩

Synonym: PRELEVEL

This controls the amount and type of GOP pre-solving. The default value is: 30 = 2+4+8+16 meaning to do all of the below options.

Default: `30`

value	meaning
`+2`	Initial local optimization
`+4`	Initial linear constraint propagation
`+8`	Recursive linear constraint propagation
`+16`	Recursive nonlinear constraint propagation

GOP_QUADMD *(integer)*: flag indicating if GOP exploits quadratic feature ↩

Default: `-1`

value	meaning
`-1`	Solver decides
`0`	No
`1`	Yes

GOP_QUAD_METHOD *(integer)*: specifies if the GOP solver should solve the model as a QP when applicable ↩

Default: `-1`

value	meaning
`-1`	Solver decides
`0`	General GOP solver
`1`	Specified QP solver

GOP_RELBRNDMD *(integer)*: reliable rounding in the GOP branch-and-bound ↩

Synonym: RELBRNDMD

This controls the reliable rounding rule in the GOP branch-and-bound. The global solver applies many suboptimizations to estimate the lower and upper bounds on the global optimum. A rounding error or numerical instability could unintentionally cut off a good solution. A variety of reliable approaches are available to improve the precision.

Default: `0`

value	meaning
`+2`	Use smaller optimality or feasibility tolerances and appropriate presolving options
`+4`	Apply interval arithmetic to reverify the solution feasibility

GOP_RELOPTTOL *(real)*: relative optimality tolerance ↩

Synonyms: OPTTOL RELOPTTOL

This value is the GOP relative optimality tolerance. Solutions must beat the incumbent by at least this amount to become the new best solution.

Default: `GAMS OptCR`

GOP_SOLLIM *(integer)*: integer solution limit for GOP branch-and-bound ↩

Range: {`-1`, ..., ∞}

Default: `-1`

GOP_SUBOUT_MODE *(integer)*: substituting out fixed variables ↩

Synonym: SUBOUT_MODE

This is a flag indicating whether fixed variables are substituted out of the instruction list used in the global solver.

Default: `1`

value	meaning
0	Do not substitute out fixed variables
1	Substitute out fixed variables

GOP_TIMLIM *(integer)*: time limit in seconds for GOP branch-and-bound ↩

Synonym: TIMLIM

This is the time limit in seconds for GOP branch-and-bound.

Range: {`-1`, ..., ∞}

Default: `GAMS ResLim`

GOP_USEBNDLIM *(integer)*: max magnitude of variable bounds flag for GOP convexification ↩

Synonym: USEBNDLIM

This value is a flag for the parameter GOP_BNDLIM.

Default: `2`

value	meaning
0	Do not use the bound limit on the variables
1	Use the bound limit right at the beginning of global optimization
2	Use the bound limit after the initial local optimization if selected

GOP_WIDTOL *(real)*: maximal width of variable intervals ↩

Synonym: WIDTOL

This value specifies the maximal width of variable intervals for a box to be considered as an incumbent box containing an incumbent solution. It is used when GOP_MAXWIDMD is set at 1.

Default: `1e-4`

IIS *(boolean)*: run the IIS finder if the problem is infeasible ↩

Default: `0`

IIS_ANALYZE_LEVEL *(integer)*: controls the level of analysis when locating an IIS ↩

Default: `1`

value	meaning
+1	Search for necessary rows
+2	Search for necessary columns
+4	Search for sufficient rows
+8	Search for sufficient columns
+16	Consider integrality restrictions as the potential cause of infeasibilities and include it in the analysis
+32	Compute the underlying LTF matrix and use this as the basis of a ranking score to guide the IIS run
+64	If the underlying matrix is totally decomposable, rank blocks w.r.t their sizes and debug the smallest independent infeasible block
+128	Use the nonzero structure of the underlying matrix to compute a ranking score to guide the IIS run
+256	Treat iter/time limits as intractability

IIS_GETMODE *(integer)*: flag that controls whether variable bounds in the IIS should be retrieved or the integer restrictions ↩

Default: `0`

value	meaning
0	Variable bound
1	Integer restrictions

IIS_INFEAS_NORM *(integer)*: specifies the norm to measure infeasibilities in IIS search ↩

Default: `0`

value	meaning
0	Solver decides
1	Use L-1 norm
2	L-infinity norm

IIS_ITER_LIMIT *(integer)*: the iteration limit for IIS search ↩

Range: {-1, ..., ∞}

Default: `-1`

IIS_METHOD *(integer)*: specifies the method to use in analyzing infeasible models to locate an IIS ↩

Default: `0`

value	meaning
0	Default filter
1	Standard deletion filter
2	Standard additive filter
3	Generalized-binary-search filter
4	Depth-first-binary-search filter
5	Fast-scan filter
6	Standard elastic filter

IIS_PRINT_LEVEL *(integer)*: specifies the amount of print to do during IIS search ↩

Default: 2

IIS_REOPT *(integer)*: specifies which optimization method to use when starting from a given basis ↩

Default: 0

value	meaning
0	Free
1	Primal Simplex
2	Dual Simplex
3	Barrier
4	NLP

IIS_TIME_LIMIT *(integer)*: the time limit for IIS search ↩

Range: {-1, ..., ∞}

Default: -1

IIS_TOPOPT *(integer)*: specifies which optimization method to use when there is no previous basis ↩

Default: 0

value	meaning
0	Free
1	Primal Simplex
2	Dual Simplex
3	Barrier
4	NLP

IIS_USE_EFILTER *(integer)*: flag that controls whether the Elastic Filter should be enabled as the supplementary filter in analyzing infeasible models ↩

Default: 0

value	meaning
-1	Solver decides
0	Do not use elastic filter
1	Use elastic filter

IIS_USE_GOP *(integer)*: flag that controls whether the global optimizer should be enabled in analyzing infeasible NLP models ↩

Default: `0`

value	meaning
`-1`	Solver decides
`0`	Do not use GOP
`1`	Use GOP

IIS_USE_SFILTER *(integer)*: flag indicating is sensitivity filter will be used during IIS search ↩

Default: `1`

value	meaning
`-1`	Solver decides
`0`	Do not use sensitivity filter
`1`	Use sensitivity filter

INSTRUCT_SUBOUT *(integer)*: flag to specify how to deal with fixed variables in the instruction list ↩

This is a flag indicating whether 1) fixed variables are substituted out of the instruction list, 2) performing numerical calculation on constant numbers and replacing with the results.

Default: `-1`

value	meaning
`-1`	Solver decides
`0`	Substitutions will not be performed
`1`	Substitutions will be performed

IPM_BASIS_REL_TOL_S *(real)*: maximum relative dual bound violation allowed in an optimal basic solution ↩

Maximum relative dual bound violation allowed in an optimal basic solution.

Default: `1e-12`

IPM_BASIS_TOL_S *(real)*: maximum absolute dual bound violation in an optimal basic solution ↩

Maximum absolute dual bound violation in an optimal basic solution.

Default: `1e-7`

IPM_BASIS_TOL_X *(real)*: maximum absolute primal bound violation allowed in an optimal basic solution ↩

Maximum absolute primal bound violation allowed in an optimal basic solution.

Default: `1e-7`

IPM_BI_LU_TOL_REL_PIV *(real)*: relative pivot tolerance used in the LU factorization in the basis identification procedure ↩

Relative pivot tolerance used in the LU factorization in the basis identification procedure.

Range: [0, 0.999999]

Default: 1e-2

IPM_CHECK_CONVEXITY *(integer)*: flag to check convexity of a quadratic program using barrier solver ↩

This is a flag to check convexity of a quadratic program using barrier solver.

Default: 1

value	meaning
-1	Check convexity only without solving the model
0	Use barrier solver to check convexity
1	Do not use barrier solver to check convexity

IPM_CO_TOL_DFEAS *(real)*: dual feasibility tolerance for Conic solver ↩

Default: 1e-8

IPM_CO_TOL_INFEAS *(real)*: maximum bound infeasibility tolerance for Conic solver ↩

Maximum bound infeasibility tolerance for Conic solver.

Default: 1e-12

IPM_CO_TOL_MU_RED *(real)*: optimality tolerance for Conic solver ↩

Default: 1e-8

IPM_CO_TOL_PFEAS *(real)*: primal feasibility tolerance for Conic solver ↩

Default: 1e-8

IPM_MAX_ITERATIONS *(integer)*: ipm iteration limit ↩

Controls the maximum number of iterations allowed in the interior-point optimizer.

Default: 1000

IPM_NUM_THREADS *(integer)*: number of threads to run the interiorpoint optimizer on ↩

Number of threads to run the interiorpoint optimizer on. This value should be less than or equal to the actual number of processors or cores on a multi-core system.

Default: 1

IPM_OFF_COL_TRH *(integer)*: extent for detecting the offending columns in the Jacobian of the constraint matrix ↩

Controls the extent for detecting the offending columns in the Jacobian of the constraint matrix. 0 means no offending columns will be detected. 1 means offending columns will be detected. In general, increasing the parameter value beyond the default value of 40 does not improve the result.

Default: `40`

IPM_TOL_DFEAS *(real)*: dual feasibility tolerance ↩

Dual feasibility tolerance used for linear and quadratic optimization problems.

Default: `1e-8`

IPM_TOL_DSAFE *(real)*: controls the initial dual starting point ↩

Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the dual variables associated with constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [`1e-4`, ∞]

Default: `1`

IPM_TOL_INFEAS *(real)*: infeasibility tolerance ↩

This is the tolerance to declare the model primal or dual infeasible using the interior-point optimizer. A smaller number means the optimizer gets more conservative about declaring the model infeasible.

Default: `1e-10`

IPM_TOL_MU_RED *(real)*: relative complementarity gap tolerance ↩

Relative complementarity gap tolerance.

Default: `1e-16`

IPM_TOL_PATH *(real)*: how close to follow the central path ↩

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central path is followed very closely. For numerically unstable problems it might help to increase this parameter.

Range: [`0`, `0.5`]

Default: `1e-8`

IPM_TOL_PFEAS *(real)*: primal feasibility tolerance ↩

Primal feasibility tolerance used for linear and quadratic optimization problems.

Default: `1e-8`

IPM_TOL_PSAFE *(real)*: controls the initial primal starting point ↩

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [`1e-2`, ∞]

Default: `1`

IPM_TOL_REL_STEP *(real)*: relative step size to the boundary ↩

Relative step size to the boundary for linear and quadratic optimization problems.

Range: [`0`, `0.999999`]

Default: `0.9999`

IUS *(boolean)*: run the IUS finder if the problem is unbounded ↩

Default: `0`

IUS_ANALYZE_LEVEL *(integer)*: controls the level of analysis when locating an IUS ↩

Default: `2`

value	meaning
+2	Search for necessary columns
+8	Search for sufficient columns

LP_AIJ_ZEROTOL *(real)*: coefficient matrix zero tolerance ↩

Default: 2.22045e-16

LP_BIGM *(real)*: big-M for phase-I ↩

Default: 1e6

LP_BNDINF *(real)*: big-M to truncate lower and upper bounds in single phase dual-simplex ↩

Default: 1e15

LP_DPSWITCH *(integer)*: specifies whether LP primal-dual simplex switch is enabled or not ↩

Range: {0, ..., 1}

Default: 1

LP_DRATIO *(integer)*: controls the dual min-ratio strategy ↩

Range: {0, ..., 2}

Default: 1

LP_DYNOBJFACT *(real)*: Dynamic obj factor ↩

Range: [0, 1]

Default: 0.75

LP_DYNOBJMODE *(integer)*: Dynamic obj mode ↩

Default: 0

LP_ITRLMT *(integer)*: simplex iteration limit ↩

Synonym: SPLEX_ITRLMT

Range: {-1, ..., ∞}

Default: infinity

LP_PIV_BIGTOL *(real)*: simplex maximum pivot tolerance ↩

Default: 1e-5

LP_PIV_ZEROTOL *(real)*: simplex pivot zero tolerance ↩

Default: 1e-8

LP_PPARTIAL *(integer)*: primal simplex partial pricing method ↩

Range: {0, ..., 3}

Default: 0

LP_PRELEVEL *(integer)*: controls the amount and type of LP pre-solving ↩

This controls the amount and type of LP pre-solving to be used.

Default: 126

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+512	Maximum pass

LP_RATRANGE *(integer)*: controls the number of pivot-candidates to consider when searching for a stable pivot in LU decomposition ↩

Range: {1, ..., ∞}

Default: 4

LP_SCALE *(integer)*: scaling flag ↩

Synonym: SPLEX_SCALE

Default: 1

value	meaning
0	Scaling is suppressed
1	Scaling is performed

LP_SPRINT_COLFACT *(integer)*: maximum number of columns in Sprint as a factor of number of rows ↩

Range: {1, ..., ∞}

Default: 10

LP_SPRINT_MAXPASS *(integer)*: maximum number of passes in Sprint method ↩

Range: {1, ..., ∞}

Default: 100

LP_SPRINT_SUB *(integer)*: LP method for subproblem in Sprint method ↩

Default: 0

MIP_ABSCUTTOL *(real)*: MIP absolute cut tolerance ↩

This is the MIP absolute cut tolerance. If the value is less than or equal to zero, it will use the internal decided tolerace, otherwise it will use this value as the abolute tolerace for adding cuts.

Range: [-1.0, ∞]

Default: -1.0

MIP_ABSOPTTOL *(real)*: MIP absolute optimality tolerance ↩

This is the MIP absolute optimality tolerance. Solutions must beat the incumbent by at least this absolute amount to become the new, best solution.

Default: `GAMS OptCA`

MIP_ADDCUTOBJTOL *(real)*: required objective improvement to continue generating cuts ↩

This specifies the minimum required improvement in the objective function for the cut generation phase to continue generating cuts.

Default: `1.5625e-5`

MIP_ADDCUTPER *(real)*: percentage of constraint cuts that can be added ↩

This determines how many constraint cuts can be added as a percentage of the number of original rows in an integer programming model.

Default: `0.75`

MIP_ADDCUTPER_TREE *(real)*: percentage of constraint cuts that can be added at child nodes ↩

This determines how many constraint cuts can be added at child nodes as a percentage of the number of original rows in an integer programming model.

Default: `0.5`

MIP_AGGCUTLIM_TOP *(integer)*: max number of constraints involved in derivation of aggregation cut at root node ↩

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the root node. The default is .1, which means that the solver will decide.

Range: {`-1`, ..., ∞}

Default: `-1`

MIP_AGGCUTLIM_TREE *(integer)*: max number of constraints involved in derivation of aggregation cut at tree nodes ↩

This specifies an upper limit on the number of constraints to be involved in the derivation of an aggregation cut at the tree nodes. The default is .1, which means that the solver will decide.

Range: {`-1`, ..., ∞}

Default: `-1`

MIP_ANODES_SWITCH_DF *(integer)*: threshold on active nodes for switching to depth-first search ↩

This specifies the threshold on active nodes for switching to depth-first search rule.

Default: `50000`

MIP_AOPTTIMLIM *(integer)*: time in seconds beyond which the relative optimality tolerance will be applied ↩

This is the time in seconds beyond which the relative optimality tolerance, `MIP_PEROPTTOL` will be applied.

Default: `100`

MIP_BIGM_FOR_INTTOL *(real)*: threshold for which coefficient of a binary variable would be considered as big-M ↩

This value specifies the threshold for which the coefficient of a binary variable would be considered as big-M (when applicable).

Default: `1e8`

MIP_BRANCHDIR *(integer)*: first branching direction ↩

This specifies the direction to branch first when branching on a variable.

Default: `0`

value	meaning
0	Solver decides
1	Always branch up first
2	Always branch down first

MIP_BRANCHRULE *(integer)*: rule for choosing the variable to branch ↩

This specifies the rule for choosing the variable to branch on at the selected node.

Default: 0

value	meaning
0	Solver decides
1	Basis rounding with pseudo reduced costs
2	Maximum infeasibility
3	Pseudo reduced costs only
4	Maximum coefficient only
5	Previous branching only

MIP_BRANCH_LIMIT *(integer)*: limit on the total number of branches to be created during branch and bound ↩

This is the limit on the total number of branches to be created during branch-and- bound. The default value is -1, which means no limit is imposed. If the branch limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: {-1, ..., ∞}

Default: -1

MIP_BRANCH_PRIO *(integer)*: controls how variable selection priorities are set and used ↩

This controls how variable selection priorities are set and used.

Default: 0

value	meaning
0	If the user has specified priorities then use them Otherwise let LINDO API decide
1	If user has specified priorities then use them Overwrite users choices if necessary
2	If user has specified priorities then use them Otherwise do not use any priorities
3	Let LINDO API set the priorities and ignore any user specified priorities
4	Binaries always have higher priority over general integers

MIP_CONCURRENT_REOPTMODE *(integer)*: specifies the concurrent optimization mode with warm start ↩

Default: 0

value	meaning
0	no concurrent runs
1	run concurrently if at least 2 threads exist
2	run concurrently

MIP_CONCURRENT_STRATEGY *(integer)*: controls the concurrent MIP strategy ↩

Default: `-1`

value	meaning
`-1`	Solver decides
`1`	Defines built-in priority lists for each thread
`3`	Defines heuristic based strategies for each thread

MIP_CONCURRENT_TOPOPTMODE *(integer)*: specifies the concurrent optimization mode with cold start ↩

Default: `0`

value	meaning
`0`	no concurrent runs
`1`	run concurrently if at least 2 threads exist
`2`	run concurrently

MIP_CUTDEPTH *(integer)*: threshold value for the depth of nodes in the branch and bound tree ↩

This controls a threshold value for the depth of nodes in the B&B tree, so cut generation will be less likely at those nodes deeper than this threshold.

Default: `8`

MIP_CUTFREQ *(integer)*: frequency of invoking cut generation at child nodes ↩

This controls the frequency of invoking cut generation at child nodes. The default value is 10, indicating that the MIP solver will try to generate cuts at every 10 nodes.

Default: `10`

MIP_CUTLEVEL_TOP *(integer)*: combination of cut types to try at the root node when solving a MIP ↩

This controls the combination of cut types to try at the root node when solving a MIP. Bit settings are used to enable the various cut types.

Default: `57342`

value	meaning
`+2`	GUB cover
`+4`	Flow cover
`+8`	Lifting
`+16`	Plant location
`+32`	Disaggregation
`+64`	Knapsack cover
`+128`	Lattice
`+256`	Gomory
`+512`	Coefficient reduction
`+1024`	GCD
`+2048`	Obj integrality
`+4096`	Basis Cuts
`+8192`	Cardinality Cuts
`+16384`	Disjunk Cuts
`+32768`	Soft Knapsack Cuts

MIP_CUTLEVEL_TREE *(integer)*: combination of cut types to try at child nodes in the branch and bound tree when solving a MIP ↩

This controls the combination of cut types to try at child nodes in the B&B tree when solving a MIP.

Default: `53246`

value	meaning
+2	GUB cover
+4	Flow cover
+8	Lifting
+16	Plant location
+32	Disaggregation
+64	Knapsack cover
+128	Lattice
+256	Gomory
+512	Coefficient reduction
+1024	GCD
+2048	Obj integrality
+4096	Basis Cuts
+8192	Cardinality Cuts
+16384	Disjunk Cuts
+32768	Soft Knapsack Cuts

MIP_CUTOFFOBJ *(real)*: defines limit for branch and bound ↩

If this is specified, then any part of the branch-and-bound tree that has a bound worse than this value will not be considered. This can be used to reduce the running time if a good bound is known.

Default: `1e30`

MIP_CUTTIMLIM *(integer)*: time to be spent in cut generation ↩

This controls the total time to be spent in cut generation throughout the solution of a MIP. The default value is -1, indicating that no time limits will be imposed when generating cuts.

Range: {`-1`, ..., ∞}

Default: `-1`

MIP_DELTA *(real)*: near-zero value used in linearizing nonlinear expressions ↩

This refers to a near-zero value used in linearizing nonlinear expressions.

Default: `1e-6`

MIP_DUAL_SOLUTION *(integer)*: flag for computing dual solution of LP relaxation ↩

This flag controls whether the dual solution to the LP relaxation that yielded the optimal MIP solution will be computed or not.

Default: `0`

value	meaning
0	Do not calculate dual solution for LP relaxation
1	Calculate dual solution for LP relaxation

MIP_FP_HEU_MODE *(integer)*: specifies the feasibility-pump (FP) heuristic mode ↩

Default: 0

value	meaning
0	FP is disabled
1	Solver decides
2	Enable FP if no cutoff value or initial mip solution was defined
3	Enable FP independent of cutoff values and initial mip solutions
4	Same as 2 but also enable FP on child nodes in branch-bound tree
5	Same as 3 but also enable FP on child nodes in branch-bound tree

MIP_FP_ITRLIM *(integer)*: iteration limit for feasibility pump heuristic ↩

This is the iteration limit in seconds for feasibility pump heuristic. A value of -1 means no iteration limit is imposed.

Default: 500

MIP_FP_MODE *(integer)*: mode for the feasibility pump heuristic ↩

Controls the mode for the feasibility pump heuristic.

Default: -1

value	meaning
-1	Solver decides
0	Off
1	On until the first solution
2	Try to get more than one solution

MIP_FP_OPT_METHOD *(integer)*: optimization and reoptimization method for feasibility pump heuristic ↩

This specifies optimization and reoptimization method for feasibility pump heuristic.

Default: 0

value	meaning
0	Solver decides
1	Primal simplex
2	Dual simplex
3	Barrier

MIP_FP_PROJECTION *(integer)*: type of objective function of LPs in projection step of the feasibility pump heuristic ↩

Range: {0, ..., 1}

Default: 0

MIP_FP_TIMLIM *(real)*: time limit for feasibility pump heuristic ↩

This is the time limit in seconds for feasibility pump heuristic. A value of -1 implies no time limit is imposed.

Default: 1800

MIP_FP_WEIGTH *(real)*: weight of the objective function in the feasibility pump ↩

Controls the weight of the objective function in the feasibility pump.

Range: [0, 1]

Default: 1

MIP_GENERAL_MODE *(integer)*: general strategy in solving MIPs ↩

This value specifies the general strategy in solving MIPs.

Default: 0

value	meaning
0	Solver decides
+2	Disable all time-driven events for reproducibility of runs
+16	Disable cut generation before branching

MIP_HEULEVEL *(integer)*: specifies heuristic used to find integer solution ↩

This specifies the heuristic used to find the integer solution. Possible values are: 0: No heuristic is used. 1: A simple heuristic is used. Typically, this will find integer solutions only on problems with a certain structure. However, it tends to be fast. 2: This is an advanced heuristic that tries to find a "good" integer solution fast. In general, a value of 2 seems to not increase the total solution time and will find an integer solution fast on many problems. A higher value may find an integer solution faster, or an integer solution where none would have been found with a lower level. Try level 3 or 4 on "difficult" problems where 2 does not help. Higher values cause more time to be spent in the heuristic. The value may be set arbitrarily high. However, >20 is probably not worthwhile. MIP_HEUMINTIMLIM controls the time to be spent in searching heuristic solutions.

Default: 3

MIP_HEUMINTIMLIM *(integer)*: minimum time in seconds to be spent in finding heuristic solutions ↩

This specifies the minimum time in seconds to be spent in finding heuristic solutions to the MIP model. MIP_HEULEVEL controls the heuristic used to find the integer solution.

Default: 0

MIP_HEU_DROP_OBJ *(integer)*: flag for whether to use without OBJ heuristic ↩

This is a flag for whether to use without OBJ heuristic.

Default: 0

value	meaning
0	Off
1	On

MIP_HEU_MODE *(integer)*: heuristic used in MIP solver ↩

This controls the MIP heuristic mode.

Default: 0

value	meaning
0	Solver decides when to stop the heuristic
1	Solver uses a pre-specified time limit to stop the heuristic.
2	Solver uses a pre-specified iteration limit to stop the heuristic

MIP_INTTOL *(real)*: absolute integer feasibility tolerance ↩

An integer variable is considered integer feasible if the absolute difference from the nearest integer is smaller than this.

Default: 1e-6

MIP_ITRLIM *(real)*: iteration limit for branch and bound ↩

This is the total LP iteration limit summed over all branches for branch-and-bound. Range for The default value is -1, which means no iteration limit is imposed. If this iteration limit is reached, branch-and-bound will stop and the best feasible integer solution found will be installed as the incumbent (best known) solution.

Range: [-1, ∞]

Default: infinity

MIP_KBEST_USE_GOP *(integer)*: specifies whether to use gop solver in MIP KBest ↩

Default: 0

value	meaning
0	No
1	Yes

MIP_KEEPINMEM *(integer)*: flag for keeping LP bases in memory ↩

If this is set to 1, the integer pre-solver will try to keep LP bases in memory. This typically gives faster solution times, but uses more memory. Setting this parameter to 0 causes the pre-solver to erase bases from memory.

Default: 1

value	meaning
0	Do not keep LP bases in memory
1	Keep LP bases in memory

MIP_LBIGM *(real)*: Big-M value used in linearizing nonlinear expressions ↩

This refers to the Big-M value used in linearizing nonlinear expressions.

Default: `10000`

MIP_LSOLTIMLIM *(integer)*: time limit until finding a new integer solution ↩

Range: {`-1`, ..., ∞}

Default: `-1`

MIP_MAKECUT_INACTIVE_COUNT *(integer)*: threshold for times a cut could remain active after successive reoptimization ↩

This value specifies the threshold for the times a cut could remain active after successive reoptimization during branch-and-bound. If the count is larger than the specified level the solver will inactive the cut.

Default: `10`

MIP_MAXCUTPASS_TOP *(integer)*: number passes to generate cuts on the root node ↩

This controls the number passes to generate cuts on the root node. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: `200`

MIP_MAXCUTPASS_TREE *(integer)*: number passes to generate cuts on the child nodes ↩

This controls the number passes to generate cuts on the child nodes. Each of these passes will be followed by a reoptimization and a new batch of cuts will be generated at the new solution.

Default: `2`

MIP_MAXNONIMP_CUTPASS *(integer)*: number of passes allowed in cut-generation that does not improve current relaxation ↩

This controls the maximum number of passes allowed in cut-generation that does not improve the current relaxation.

Default: `3`

MIP_MAXNUM_MIP_SOL_STORAGE *(integer)*: maximum number of k-best solutions to store ↩

This specifies the maximum number of k-best solutions to store. Possible values are positive integers.

Default: `1`

MIP_MINABSOBJSTEP *(real)*: value to update cutoff value each time a mixed integer solution is found ↩

This specifies the value to update the cutoff value each time a mixed integer solution is found.

Default: `0`

MIP_NODESELRULE *(integer)*: specifies the node selection rule ↩

This specifies the node selection rule for choosing between all active nodes in the branch-and-bound tree when solving integer programs.Possible selections are: 0: Solver decides (default). 1: Depth first search. 2: Choose node with worst bound. 3: Choose node with best bound. 4: Start with best bound. If no improvement in the gap between best bound and best integer solution is obtained for some time, switch to: if (number of active nodes<10000) Best estimate node selection (5). else Worst bound node selection (2). 5: Choose the node with the best estimate, where the new objective estimate is obtained using pseudo costs. 6: Same as (4), but start with the best estimate.

Default: `0`

value	meaning
0	Solver decides
1	Depth first search
2	Choose node with worst bound
3	Choose node with best bound
4	Start with best bound
5	Choose the node with the best estimate
6	Same as 4 but start with the best estimate

MIP_NUM_THREADS *(integer)*: number of parallel threads to use by the parallel MIP solver ↩

This parameter specifies the number of parallel threads to use by the parallel MIP solver. Possible values are positive integers. The default is 1 implying that the parallel solver is disabled.

Range: {1, ..., ∞}

Default: 1

MIP_PARA_FP *(integer)*: flag for whether to use parallelization on the feasibility pump heuristic ↩

This is a flag for whether to use parallelization on the feasibility pump heuristic.

Default: 1

value	meaning
0	Off
1	On

MIP_PARA_FP_MODE *(integer)*: flag for the mode of parallel feasibility pump ↩

This is a flag for the mode of parallel feasibility pump.

Default: 0

value	meaning
0	Terminate when all threads finish
1	Terminate as soon as the master thread finishes

MIP_PARA_INIT_NODE *(real)*: number of initial nodes for MIP parallelization ↩

This value specifies the number of initial nodes for MIP parallelization.

Range: [-1, ∞]

Default: -1

MIP_PARA_ITR_MODE *(integer)*: flag for iteration mode in MIP parallelization ↩

This is a flag for iteration mode in MIP parallelization.

Default: 1

value	meaning
0	Each thread terminates as soon as arrives iteration limit
1	Each thread terminates until all threads get iteration limit

MIP_PARA_RND_ITRLMT *(real)*: iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations ↩

This value specifies the iteration limit of each round in MIP parallelization, it is a weighted combination of simplex and barrier iterations.

Default: 2.0

MIP_PARA_SUB *(integer)*: flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing ↩

This is a flag for whether to use MIP parallelization on subproblems solved in MIP preprocessing.

Default: 1

value	meaning
0	Off
1	On

MIP_PEROPTTOL *(real)*: MIP relative optimality tolerance in effect after MIP_AOPTTIMLIM seconds ↩

This is the MIP relative optimality tolerance that will be in effect after T seconds following the start. The value T should be specified using the MIP_AOPTTIMLIM parameter.

Default: 1e-5

MIP_PERSPECTIVE_REFORM *(integer)*: flag for whether to use Perspective Reformulation ↩

This is the flag for wether to use Persective Reformulation.

Default: 1

value	meaning
0	Off
1	On

MIP_POLISH_ALPHA_TARGET *(real)*: proportion solutions in the pool to initiate a polishing-task at the current node ↩

This value specifies the proportion solutions in the pool to initiate a polishing-task at the current node.

Range: [0.01, 0.99]

Default: 0.6

MIP_POLISH_MAX_BRANCH_COUNT *(integer)*: maximum number of branches to polish ↩

This value specifies the maximum number of branches to polish.

Default: 2000

MIP_POLISH_NUM_BRANCH_NEXT *(integer)*: number of branches to polish in the next round ↩

This value specifies the number of branches to polish in the next round.

Default: 4000

MIP_PREHEU_DFE_VSTLIM *(integer)*: limit for the variable visit in depth first enumeration ↩

Limit for the variable visit in depth first enumeration.

Default: 200

MIP_PREHEU_LEVEL *(integer)*: heuristic level for the prerelax solver ↩

The heuristic level for the prerelax solver.

Default: 0

value	meaning
0	Nothing
1	One-change
2	One-change and two-change
3	Depth first enumeration

MIP_PREHEU_TC_ITERLIM *(integer)*: iteration limit for the two change heuristic ↩

Iteration limit for the two change heuristic.

Default: 30000000

MIP_PREHEU_VAR_SEQ *(integer)*: sequence of the variable considered by the prerelax heuristic ↩

The sequence of the variable considered by the prerelax heuristic.

Default: -1

value	meaning
-1	Backward
1	Forward

MIP_PRELEVEL *(integer)*: controls the amount and type of MIP pre-solving at root node ↩

This controls the amount and type of MIP pre-solving at root node.

Default: 3070

value	meaning
+2	Simple pre-solving
+4	Probing

value	meaning
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+128	Binary row presolving
+256	Row aggregation
+512	Coef Probe Lifting
+1024	Maximum pass
+2048	Similar row

MIP_PRELEVEL_TREE *(integer)*: amount and type of MIP pre-solving at tree nodes ↩

This controls the amount and type of MIP pre-solving at tree nodes.

Default: 1214

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+128	Binary row presolving
+256	Row aggregation
+512	Coef Probe Lifting
+1024	Maximum pass

MIP_PRE_ELIM_FILL *(integer)*: controls fill-in introduced by eliminations during pre-solve ↩

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: 100

MIP_PSEUDOCOST_RULE *(integer)*: specifies the rule in pseudocost computations for variable selection ↩

This specifies the rule in pseudocost computations for variable selection.

Default: 0

value	meaning
0	Solver decides
1	Only use min pseudo cost
2	Only use max pseudo cost
3	Use quadratic score function and the pseudo cost weigth
4	Same as 3 without quadratic score

MIP_PSEUDOCOST_WEIGT *(real)*: weight in pseudocost computations for variable selection ↩

This specifies the weight in pseudocost computations for variable selection.

Default: `1.5625e-05`

MIP_REDCOSTFIX_CUTOFF *(real)*: cutoff value as a percentage of the reduced costs ↩

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic.

Default: `0.9`

MIP_REDCOSTFIX_CUTOFF_TREE *(real)*: cutoff value as a percentage of the reduced costs at tree nodes ↩

This specifies the cutoff value as a percentage of the reduced costs to be used in fixing variables when using the reduced cost fixing heuristic at tree nodes.

Default: `0.9`

MIP_RELINTTOL *(real)*: relative integer feasibility tolerance ↩

An integer variable is considered integer feasible if the difference between its value and the nearest integer value divided by the value of the nearest integer is less than this.

Default: `8e-6`

MIP_RELOPTTOL *(real)*: MIP relative optimality tolerance ↩

This is the MIP relative optimality tolerance. Solutions must beat the incumbent by at least this relative amount to become the new, best solution.

Default: `GAMS OptCR`

MIP_REOPT *(integer)*: optimization method to use when doing reoptimization ↩

This specifies which optimization method to use when doing reoptimization from a given basis.

Default: `0`

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver

MIP_SCALING_BOUND *(integer)*: maximum difference between bounds of an integer variable for enabling scaling ↩

This controls the maximum difference between the upper and lower bounds of an integer variable that will enable the scaling in the simplex solver when solving a subproblem in the branch-and-bound tree.

Default: `10000`

MIP_SOLLIM *(integer)*: integer solution limit for MIP solver ↩

Range: {-1, ..., ∞}

Default: -1

MIP_SOLVERTYPE *(integer)*: optimization method to use when solving mixed-integer models ↩

This specifies the optimization method to use when solving mixed-integer models.

Default: 0

value	meaning
0	Solver decides
1	Use Branch and Bound only
2	Use Enumeration and Knapsack solver only

MIP_STRONGBRANCHDONUM *(integer)*: minimum number of variables to try the strong branching on ↩

This value specifies the minimum number of variables, among all the candidates, to try the strong branching on.

Default: 3

MIP_STRONGBRANCHLEVEL *(integer)*: depth from the root in which strong branching is used ↩

This specifies the depth from the root in which strong branching is used. The default value of 10 means that strong branching is used on a level of 1 to 10 measured from the root. Strong branching finds the real bound for branching on a given variable, which, in most cases, requires a solution of a linear program and may therefore also be quite expensive in computing time. However, if used on nodes close to the root node of the tree, it also gives a much better bound for that part of the tree and can therefore reduce the size of the branch-and-bound tree.

Default: 10

MIP_SWITCHFAC_SIM_IPM_ITER *(integer)*: specifies the (positive) factor that multiplies the number of constraints to impose an iteration limit to simplex method and trigger a switch over to the barrier method ↩

Range: {-1, ..., ∞}

Default: -1

MIP_SWITCHFAC_SIM_IPM_TIME *(real)*: factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method ↩

This specifies the (positive) factor that multiplies the number of constraints to impose a time limit to simplex method and trigger a switch over to the barrier method. A value of -1.0 means that no time limit is imposed.

Range: [-1, ∞]

Default: -1

MIP_SYMMETRY_MODE *(integer)*: specifies mip symmetry handling methods ↩

Default: 0

value	meaning
0	Do not use symmetries
1	Adding symmetry breaking cuts
2	Orbital fixing

MIP_SYMMETRY_NONZ *(integer)*: limit on number of nonzeros to look for symmetries ↩

Range: {0, ..., ∞}

Default: 50000

MIP_TIMLIM *(integer)*: time limit in seconds for integer solver ↩

This is the time limit in seconds for branch-and-bound. The default value is -1, which means no time limit is imposed. However, the value of SOLVER_TIMLMT will be applied to each continuous subproblem solve. If the value of this parameter is greater than 0, then the value of SOLVER_TIMLMT will be disregarded. If this time limit is reached and a feasible integer solution was found, it will be installed as the incumbent (best known) solution.

Range: {-1, ..., ∞}

Default: GAMS ResLim

MIP_TOPOPT *(integer)*: optimization method to use when there is no previous basis ↩

This specifies which optimization method to use when there is no previous basis.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver

MIP_TREEREORDERLEVEL *(integer)*: tree reordering level ↩

This specifies the tree reordering level.

Default: 10

MIP_TREEREORDERMODE *(integer)*: tree reordering mode ↩

This specifies the tree reordering mode.

Default: 1

value	meaning
1	Use tree reordering only for subproblems
2	Use tree reordering for subproblems and the main bnb loop only when LP status is infeasible
3	Not use tree reordering
4	Use tree reordering based on MIP_TREEREORDERLEVEL

MIP_USECUTOFFOBJ *(integer)*: flag for using branch and bound limit ↩

This is a flag for the parameter MIP_CUTOFFOBJ. If you do not want to lose the value of the parameter MIP_CUTOFFOBJ, this provides an alternative to disabling the cutoff objective.

Default: 1

value	meaning
0	Do not use current cutoff value
1	Use current cutoff value

MIP_USE_CUTS_HEU *(integer)*: controls if cut generation is enabled during MIP heuristics ↩

This flag controls if cut generation is enabled during MIP heuristics. The default is -1 (i.e. the solver decides).

Default: -1

value	meaning
-1	Solver decides
0	Do not use cut heuristic
1	Use cut heuristic

MIP_USE_ENUM_HEU *(integer)*: frequency of enumeration heuristic ↩

This specifies the frequency of enumeration heuristic.

Default: 4

value	meaning
0	Off
1	Only at top (root) node without cuts
2	Both at top (root) and tree nodes without cuts
3	Same as 1 with cuts
4	Same as 2 with cuts

MIP_USE_INT_ZERO_TOL *(integer)*: controls if all MIP calculations would be based on absolute integer feasibility tolarance ↩

This flag controls if all MIP calculations would be based on the integrality tolarance specified by MIP_INTTOL.

Default: 0

value	meaning
0	Do not base MIP calculations on MIP_INTTOL
1	Base MIP calculations on MIP_INTTOL

MULTITHREAD_MODE *(integer)*: threading mode ↩

This parameter controls the threading mode for solvers with multithreading support.

Default: `-1`

value	meaning
-1	Solver decides
1	Try parallel mode but if it is not available try concurrent mode
2	Try parallel mode only
3	Try concurrent mode but if it is not available try parallel mode
4	Try concurrent mode only

NLP_AUTODERIV *(integer)*: defining type of computing derivatives ↩

This is a flag to indicate if automatic differentiation is the method of choice for computing derivatives and select the type of differentiation.

Default: 0

value	meaning
0	Finite Differences approach will be used
1	Forward type of Automatic Differentiation will be used
2	Backward type of Automatic Differentiation will be used

NLP_AUTOHESS *(integer)*: flag for using Second Order Automatic Differentiation for solving NLP ↩

This is a flag to indicate if Second Order Automatic Differentiation will be performed in solving a nonlinear model. The second order derivatives provide an exact/precise Hessian matrix to the SQP algorithm, which may lead to less iterations and better solutions, but may also be quite expensive in computing time for some cases.

Default: 0

value	meaning
0	Do not use Second Order Automatic Differentiation
1	Use Second Order Automatic Differentiation

NLP_CONIC_REFORM *(integer)*: determines if to explore conic reformulation ↩

Default: 1

value	meaning
0	No
1	Yes

NLP_CONOPT_VER *(integer)*: specifies the CONOPT version to be used in NLP optimizations ↩

Range: {3, ..., 4}

Default: 3

NLP_CUTOFFOBJ *(real)*: as soon as any multi-start thread achieves this value all threads stop ↩

If the current best objective of the NLP being solved in a multistart run is better than this value, the solver will terminate early without exhausting the maximum number of multistarts. This is a way of saving computer time if the current best solution is sufficiently attractive.

Range: [-1e30, ∞]

Default: -1e30

NLP_DERIV_DIFFTYPE *(integer)*: flag indicating the technique used in computing derivatives with finite differences ↩

This is a flag indicating the technique used in computing derivatives with Finite Differences.

Default: 0

value	meaning
0	The solver decides
1	Use forward differencing method
2	Use backward differencing method
3	Use center differencing method

NLP_FEASCHK *(integer)*: how to report results when solution satisfies tolerance of scaled but not original model ↩

This input parameter specifies how the NLP solver reports the results when an optimal or local-optimal solution satisfies the feasibililty tolerance (NLP_FEASTOL) of the scaled model but not the original (descaled) one.

Default: 1

value	meaning
0	Perform no action accept the final solution
1	Declare the model status as FEASIBLE if maximum violation in the unscaled model is not higher than 10 times NLP_FEASTOL
2	Declare the model status as UNKNOWN if maximum violation in the unscaled model is higher than NLP_FEASTOL

NLP_FEASTOL *(real)*: feasibility tolerance for nonlinear constraints ↩

This is the feasibility tolerance for nonlinear constraints. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: 1e-6

NLP_INF *(real)*: numeric infinity for nonlinear models ↩

Specifies the numeric infinity for nonlinear models. Possible values are positive real numbers. Smaller values could cause numerical problems.

nlp_ipm2grg This is a flag to switch from IPM solver to the standard NLP (GRG) solver when IPM fails due to numerical errors.

Default: 1e30

NLP_IPM2GRG *(integer)*: switch from IPM solver to GRG solver when IPM fails due to numerical errors ↩

Default: 1

value	meaning
0	Do not switch
1	Switch

NLP_ITERS_PER_LOGLINE *(integer)*: number of nonlinear iterations to elapse before next progress message ↩

Number of nonlinear iterations to elapse before next progress message.

Range: {1, ..., ∞}

Default: 10

NLP_ITRLMT *(integer)*: nonlinear iteration limit ↩

This controls the iteration limit on the number of nonlinear iterations performed.

Range: {-1, ..., ∞}

Default: GAMS IterLim

NLP_LINEARZ *(integer)*: extent to which the solver will attempt to linearize nonlinear models ↩

This determines the extent to which the solver will attempt to linearize nonlinear models.

Default: 0

value	meaning
0	Solver decides
1	No linearization occurs
2	Linearize ABS MAX and MIN functions
3	Same as option 2 plus IF AND OR NOT and all logical operators are linearized

NLP_LINEARZ_WB_CONSISTENT *(integer)*: determines if linearization process is consistent with WB/excel calculation ↩

Default: 0

value	meaning
0	No
1	Yes

NLP_MAXLOCALSEARCH *(integer)*: maximum number of local searches ↩

This controls the maximum number of local searches (multistarts) when solving a NLP using the multistart solver.

Default: 5

NLP_MAXLOCALSEARCH_TREE *(integer)*: maximum number of multistarts ↩

Maximum number of multistarts (at tree nodes)

Default: 1

NLP_MAX_RETRY *(integer)*: maximum number refinement retries to purify the final NLP solution ↩

Maximum number refinement retries to purify the final NLP solution.

Range: {-1, ..., ∞}

Default: 5

NLP_MSW_EUCDIST_THRES *(real)*: euclidean distance threshold in multistart search ↩

Euclidean distance threshold in multistart search

Default: 0.001

NLP_MSW_FILTMODE *(integer)*: filtering mode to exclude certain domains during sampling in multistart search ↩

Filtering mode to exclude certain domains during sampling in multistart search.

Default: -1

value	meaning
-1	Solver decides
+1	Filter-out the points around known KKT or feasible points previously visited
+2	Filter-out the points whose p are in the vicinity of p(x)
+4	Filter-out the points in the vicinity of x where x are initial points of all previous local optimizations
+8	Filter-out the points whose p(.) values are below a dynamic threshold tolerance

NLP_MSW_MAXNOIMP *(integer)*: maximum number of consecutive populations to generate without any improvements ↩

Maximum number of consecutive populations to generate without any improvements.

Range: {-1, ..., ∞}

Default: -1

NLP_MSW_MAXPOP *(integer)*: maximum number of populations to generate in multistart search ↩

Maximum number of populations to generate in multistart search.

Range: {-1, ..., ∞}

Default: -1

NLP_MSW_MAXREF *(integer)*: maximum number of reference points to generate trial points in multistart search ↩

Maximum number of reference points in the solution space to generate trial points in multistart search.

Range: {-1, ..., ∞}

Default: -1

NLP_MSW_NORM *(integer)*: norm to measure the distance between two points in multistart search ↩

Norm to measure the distance between two points in multistart search.

Range: {-1, ..., ∞}

Default: 2

NLP_MSW_NUM_THREADS *(integer)*: number of parallel threads to be used when solving an NLP model with the multistart solver ↩

This value specifies the number of parallel threads to be used when solving an NLP model with the multistart solver.

Default: 1

NLP_MSW_OVERLAP_RATIO *(real)*: rate of replacement in successive populations ↩

This value specifies the rate of replacement in successive populations. Higher values favors survival of points in the parent population.

Range: [0.0, 1.0]

Default: 0.1

NLP_MSW_POXDIST_THRES *(real)*: penalty function neighborhood threshold in multistart search ↩

Penalty function neighborhood threshold in multistart search

Default: 0.01

NLP_MSW_PREPMODE *(integer)*: preprocessing strategies in multistart solver ↩

This value specifies the preprocessing strategies in multistart solver.

Default: -1

value	meaning
-1	Solver decides
+1	Truncate free variables
+2	Scale reference points to origin
+4	Enable expansive scaling of radius[k] by hit[k]
+8	Skewed sampling allowing values in the vicinity of origin.
+16	Get best bounds by presolver
+32	Get best bounds using GOP
+64	Enable sampling of free variables (not recommended)
+128	Collect sufficiently many trial points prior to local solves
+256	Enable power solver, trying several different local strategies

NLP_MSW_RG_SEED *(integer)*: random number generator seed for the multistart solver ↩

This value specified the random number generator seed for the multistart solver.

Default: 1019

NLP_MSW_RMAPMODE *(integer)*: specifies the mode to map reference points in the unit cube into the original space ↩

Default: `-1`

value	meaning
`-1`	Solver decides
`0`	Use original variable bounds
`1`	Use min-max values over all sample points per each dimension
`2`	Use min-max values over all sample points over all dimensions

NLP_MSW_SOLIDX *(integer)*: index of the multistart solution to be loaded ↩

Index of the multistart solution to be loaded main solution structures.

Default: `0`

NLP_MSW_XKKTRAD_FACTOR *(real)*: KKT solution neighborhood factor in multistart search ↩

KKT solution neighborhood factor in multistart search

Default: `0.85`

NLP_MSW_XNULRAD_FACTOR *(real)*: initial solution neighborhood factor in multistart search ↩

Initial solution neighborhood factor in multistart search

Default: `0.5`

NLP_PRELEVEL *(integer)*: controls the amount and type of NLP pre-solving ↩

This controls the amount and type of NLP pre-solving.

Default: `126`

value	meaning
`+2`	Simple pre-solving
`+4`	Probing
`+8`	Coefficient reduction
`+16`	Elimination
`+32`	Dual reductions
`+64`	Use dual information
`+512`	Maximum pass

NLP_PSTEP_FINITEDIFF *(real)*: value of the step length in computing the derivatives using finite differences ↩

This controls the value of the step length in computing the derivatives using finite differences.

Default: `5e-7`

NLP_QUADCHK *(integer)*: flag for checking if NLP is quadratic ↩

This is a flag indicating if the nonlinear model should be examined to check if it is a quadratic model.

Default: `1`

value	meaning
0	Do not check if NLP is quadratic
1	Check if NLP is quadratic

NLP_REDGTOL *(real)*: tolerance for the gradients of nonlinear functions ↩

This is the tolerance for the gradients of nonlinear functions. The (projected) gradient of a function is considered to be the zero-vector if its norm is below this tolerance.

Default: 1e-7

NLP_SOLVER *(integer)*: type of nonlinear solver ↩

This value determines the type of nonlinear solver.

Default: 7

value	meaning
4	Solver decides
5	Uses Levenberg-Marquardt method to solve nonlinear least-squares problem
6	Uses Barrier solver for convex QCP models
7	Uses CONOPTs reduced gradient solver
8	Uses SLP solver
9	Uses CONOPT with multistart feature enabled

NLP_SOLVE_AS_LP *(integer)*: flag indicating if the nonlinear model will be solved as an LP ↩

This is a flag indicating if the nonlinear model will be solved as an LP. 1 means that an LP using first order approximations of the nonlinear terms in the model will be used when optimizing the model with the LSoptimize() function.

Default: 0

value	meaning
0	NLP will not be solved as LP
1	NLP will be solved as LP

NLP_STALL_ITRLMT *(integer)*: iteration limit before a sequence of non-improving NLP iterations is declared as stalling ↩

This specifies the iteration limit before a sequence of non-improving NLP iterations is declared as stalling, thus causing the solver to terminate.

Default: 100

NLP_STARTPOINT *(integer)*: flag for using initial starting solution for NLP ↩

This is a flag indicating if the nonlinear solver should accept initial starting solutions.

Default: 1

value	meaning
0	Do not use initial starting solution for NLP
1	Use initial starting solution for NLP

NLP_SUBSOLVER *(integer)*: type of nonlinear subsolver ↩

This controls the type of linear solver to be used for solving linear subproblems when solving nonlinear models.

Default: 1

value	meaning
1	Primal simplex method
2	Dual simplex method
3	Barrier solver with or without crossover

NLP_USECUTOFFOBJ *(integer)*: flag to use parameter NLP_CUTOFFOBJ ↩

This is a flag for the parameter NLP_CUTOFFOBJ. The value of 0 means NLP_CUTOFFOBJ will be ignored, else it will be used as specified.

Default: 0

value	meaning
-1	Solver decides
0	No
1	Yes

NLP_USE_CRASH *(integer)*: flag for using simple crash routines for initial solution ↩

This is a flag indicating if an initial solution will be computed using simple crash routines.

Default: 0

value	meaning
0	Do not use simple crash routines
1	Use simple crash routines

NLP_USE_LINDO_CRASH *(integer)*: flag for using advanced crash routines for initial solution ↩

This is a flag indicating if an initial solution will be computed using advanced crash routines.

Default: 1

value	meaning
0	Do not use advanced crash routines
1	Use advanced crash routines

NLP_USE_SDP *(integer)*: flag to use SDP solver for POSD constraint ↩

Default: 1

value	meaning
0	No
1	Yes

NLP_USE_SELCONEVAL *(integer)*: flag for using selective constraint evaluations for solving NLP ↩

This is a flag indicating if selective constraint evaluations will be performed in solving a nonlinear model.

Default: 1

value	meaning
0	Do not use selective constraint evaluations
1	Use selective constraint evaluations

NLP_USE_SLP *(integer)*: flag for using sequential linear programming step directions for updating solution ↩

This is a flag indicating if sequential linear programming step directions should be used in updating the solution.

Default: 1

value	meaning
-1	Solver decides
0	Do not use sequential linear programming step directions
1	Use sequential linear programming step directions

NLP_USE_STEEPEDGE *(integer)*: flag for using steepest edge directions for updating solution ↩

This is a flag indicating if steepest edge directions should be used in updating the solution.

Default: 0

value	meaning
0	Do not use steepest edge directions
1	Use steepest edge directions

NUM_THREADS *(integer)*: number of parallel threads to be used ↩

Synonym: gthreads

Number of threads to use in the solver routine to be called. It is a solver-independent parameter which internally sets solver-specific threading parameters automatically. If the GAMS `threads` parameter is set to 0, the Lindo default will be used, which is 1.

Range: {1, ..., ∞}

Default: `GAMS Threads`

PROB_TO_SOLVE *(integer)*: controls whether the explicit primal or dual form of the given LP problem will be solved ↩

This flag controls whether the explicit primal or dual form of the given LP problem will be solved.

Default: `0`

value	meaning
0	Solver decides
1	Explicit primal form
2	Explicit dual form

PROFILER_LEVEL *(integer)*: specifies the profiler level to break down the total cpu time into. ↩

Specifies the profiler level to break down the total cpu time into.

Default: `0`

value	meaning
0	Profiler is off
+1	Enable for simplex solver
+2	Enable for integer solver
+4	Enable for multistart solver
+8	Enable for global solver

READPARAMS *(string)*: read Lindo parameter file ↩

REPORTEVSOL *(no value)*: solve and report the expected value solution ↩

Default: `0`

SAMP_CDSINC *(real)*: correlation matrix diagonal shift increment ↩

Correlation matrix diagonal shift increment.

Default: `1e-6`

SAMP_NCM_CUTOBJ *(real)*: objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem ↩

Objective cutoff (target) value to stop the nearest correlation matrix (NCM) subproblem.

Default: `1e-30`

SAMP_NCM_DSTORAGE *(integer)*: flag to enable or disable sparse mode in NCM computations ↩

Flag to enable/disable sparse mode in NCM computations.

Range: {`-1`, ..., ∞}

Default: `-1`

SAMP_NCM_ITERLIM *(integer)*: iteration limit for NCM method ↩

Iteration limit for NCM method.

Default: `100`

SAMP_NCM_METHOD *(integer)*: bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem ↩

Bitmask to enable methods for solving the nearest correlation matrix (NCM) subproblem.

Default: `5`

SAMP_NCM_OPTTOL *(real)*: optimality tolerance for NCM method ↩

Optimality tolerance for NCM method.

Default: `1e-7`

SAMP_NUM_THREADS *(integer)*: specifies the number of parallel threads to be used when sampling ↩

Default: `0`

SAMP_RG_BUFFER_SIZE *(integer)*: specifies the buffer size for random number generators in running in parallel mode ↩

Default: `0`

SAMP_SCALE *(integer)*: flag to enable scaling of raw sample data ↩

Flag to enable scaling of raw sample data.

Default: `0`

SOLVER_CONCURRENT_OPTMODE *(integer)*: controls if simplex and interior-point optimizers will run concurrently ↩

Controls if simplex and interior-point optimizers will run concurrently, 0 means no concurrent runs will be performed, 1 means both optimizers will run concurrently if at least two threads exist in system, 2 means both optimizers will run concurrently.

Default: `0`

value	meaning
0	no concurrent runs
1	run concurrently if at least 2 threads exist
2	run concurrently

SOLVER_CUTOFFVAL *(real)*: solver will exit if optimal solution is worse than this ↩

If the optimal objective value of the LP being solved is shown to be worse than this (e.g., if the dual simplex method is being used), then the solver will exit without finding a feasible solution. This is a way of saving computer time if there is no sufficiently attractive solution. SOLVER_USECUTOFFVAL needs to be set to 1 to activate this value.

Default: `0`

SOLVER_FEASTOL *(real)*: feasibility tolerance ↩

This is the feasibility tolerance. A constraint is considered violated if the artificial, slack, or surplus variable associated with the constraint violates its lower or upper bounds by the feasibility tolerance.

Default: `1e-7`

SOLVER_IPMSOL *(integer)*: basis crossover flag for barrier solver ↩

This flag controls whether a basis crossover will be performed when solving LPs with the barrier solver. A value of 0 indicates that a crossover to a basic solution will be performed. If the value is 1, then the barrier solution will be left intact. For example, if alternate optima exist, the barrier method will return a solution that is, loosely speaking, the average of all alternate optima.

Default: `0`

value	meaning
0	Perform crossover to basis solution
1	Leave barrier solution intact

SOLVER_IUSOL *(integer)*: flag for computing basic solution for infeasible model ↩

This is a flag that, when set to 1, will force the solver to compute a basic solution to an infeasible model that minimizes the sum of infeasibilities and a basic feasible solution to an unbounded problem from which an extreme direction originates. When set to the default of 0, the solver will return with an appopriate status flag as soon as infeasibility or unboundedness is detected. If infeasibility or unboundedness is declared with presolver's determination, no solution will be computed.

Default: `0`

value	meaning
0	Return appropriate status if infeasibility is encountered
1	Force the solver to compute a basic solution to an infeasible model

SOLVER_METHOD *(integer)*: specifies the method to use when generic solver is invoked ↩

Default: `0`

value	meaning
0	FREE
1	PSIMPLEX
2	DSIMPLEX
3	BARRIER
4	NLP
5	MIP
6	MULTIS
7	GOP
8	IIS
9	IUS
10	SBD
11	SPRINT
12	GA

SOLVER_MODE *(integer)*: controls some of the advanced strategies when solving LPs ↩

Default: `1`

value	meaning
`+1`	add distinct basic solutions to the pool of alternate optimal solutions
`+2`	add edge/nonbasic solutions to the pool of alternate optimal solutions
`+4`	favor basic solutions with integer values when choosing solutions to add to the pool of alternate optimal solutions

SOLVER_OPTTOL *(real)*: dual feasibility tolerance ↩

This is the optimality tolerance. It is also referred to as the dual feasibility tolerance. A dual slack (reduced cost) is considered violated if it violates its lower bound by the optimality tolerance.

Default: `1e-7`

SOLVER_PRE_ELIM_FILL *(integer)*: fill-in introduced by the eliminations during pre-solve ↩

This is a nonnegative value that controls the fill-in introduced by the eliminations during pre-solve. Smaller values could help when the total nonzeros in the presolved model is significantly more than the original model.

Default: `1000`

SOLVER_RESTART *(integer)*: starting basis flag ↩

This is the starting basis flag. 1 means LINDO API will perform warm starts using any basis currently in memory. 0 means LINDO API will perform cold starts discarding any basis in memory and starting from scratch.

Default: `0`

value	meaning
`0`	Perform cold start
`1`	Perform warm start

SOLVER_TIMLMT *(integer)*: time limit in seconds for continous solver ↩

This is a time limit in seconds for the LP solver. The default value of -1 imposes no time limit.

Range: {`-1`, ..., ∞}

Default: `GAMS ResLim`

SOLVER_USECUTOFFVAL *(integer)*: flag for using cutoff value ↩

This is a flag for the parameter SOLVER_CUTOFFVAL

Default: `0`

value	meaning
`0`	Do not use cutoff value
`1`	Use cutoff value

SPLEX_DPRICING *(integer)*: pricing option for dual simplex method ↩

This is the pricing option to be used by the dual simplex method.

Default: `-1`

value	meaning
`-1`	Solver decides the dual pricing method
`0`	Partial pricing
`1`	Steepest edge

SPLEX_DUAL_PHASE *(integer)*: controls the dual simplex strategy ↩

This controls the dual simplex strategy, single-phase versus two-phase.

Default: `0`

value	meaning
`0`	Solver decides
`1`	Single-phase
`2`	Two-phase

SPLEX_PPRICING *(integer)*: pricing option for primal simplex method ↩

This is the pricing option to be used by the primal simplex method.

Default: `-1`

value	meaning
`-1`	Solver decides the primal pricing method
`0`	Partial pricing
`1`	Devex

SPLEX_REFACFRQ *(integer)*: number of simplex iterations between two consecutive basis re-factorizations ↩

This is a positive integer scalar referring to the simplex iterations between two consecutive basis re-factorizations. For numerically unstable models, setting this parameter to smaller values may help.

Default: `100`

STOC_ABSOPTTOL *(real)*: absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ↩

Absolute optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. . Possible values are reals in (0,1) interval.

Default: `GAMS OptCA`

STOC_ADD_MPI *(integer)*: flag to use add-instructions mode when building deteq ↩

Flag to use add-instructions mode when building deteq.

Default: `0`

STOC_ALD_DUAL_FEASTOL *(real)*: dual feasibility tolerance for ALD ↩

Dual feasibility tolerance for ALD.

Default: `1e-4`

STOC_ALD_DUAL_STEPLEN *(real)*: dual step length for ALD ↩

Dual step length for ALD.

Default: `0.9`

STOC_ALD_INNER_ITER_LIM *(integer)*: inner loop iteration limit for ALD ↩

Inner loop iteration limit for ALD.

Default: `1000`

STOC_ALD_OUTER_ITER_LIM *(integer)*: outer loop iteration limit for ALD ↩

Outer loop iteration limit for ALD.

Default: `200`

STOC_ALD_PRIMAL_FEASTOL *(real)*: primal feasibility tolerance for ALD ↩

Primal feasibility tolerance for ALD.

Default: `1e-4`

STOC_ALD_PRIMAL_STEPLEN *(real)*: primal step length for ALD ↩

Primal step length for ALD.

Default: `0.5`

STOC_AUTOAGGR *(integer)*: flag to enable or disable autoaggregation ↩

Flag to enable or disable autoaggregation.

Default: `1`

STOC_BENCHMARK_SCEN *(integer)*: benchmark scenario to compare EVPI and EVMU against ↩

Benchmark scenario to compare EVPI and EVMU against.

Range: {`-2`, ..., ∞}

Default: `-2`

STOC_BIGM *(real)*: big-M value for linearization and penalty functions ↩

Big-M value for linearization and penalty functions.

Default: `1e7`

STOC_BUCKET_SIZE *(integer)*: bucket size in Benders decomposition ↩

Bucket size in Benders decomposition. Possible values are positive integers or (-1) for solver decides.

Range: {`-1`, ..., ∞}

Default: `-1`

STOC_CALC_EVPI *(integer)*: flag to enable or disable calculation of EVPI ↩

Flag to enable/disable calculation of lower bounds on EVPI.

Default: `1`

value	meaning
0	disable
1	enable

STOC_CORRELATION_TYPE *(integer)*: correlation type associated with correlation matrix ↩

Correlation type associated with the correlation matrix.

Default: 0

value	meaning
-1	Target correlation
0	Pearson correlation
1	Kendall correlation
2	Spearman correlation

STOC_DEQOPT *(integer)*: method to solve the DETEQ problem ↩

This specifies the method to use when solving the deterministic equivalent.

Default: 0

value	meaning
0	Solver decides
10	Use simple Benders Decomposition

STOC_DETEQ_TYPE *(integer)*: type of deterministic equivalent ↩

Type of deterministic equivalent to be used by the solver. Implicit determinisitc equivalent is valid for linear and integer models only.

Default: -1

value	meaning
-1	Solver decides
0	Implicit determinisitc equivalent
1	Explicit determinisitc equivalent

STOC_DS_SUBFORM *(integer)*: subproblem formulation to use in DirectSearch ↩

This parameter specifies the type of subproblem formulation to be used in heuristic search.

Default: -1

value	meaning
-1	Solver decides
0	Perform heuristic search in the original solution space
1	Perform heuristic search in the space of discrete variables coupled with optimizations in the linear space

STOC_ELIM_FXVAR *(integer)*: flag to enable elimination of fixed variables from deteq MPI ↩

Flag to enable elimination of fixed variables from deteq MPI.

Default: `1`

STOC_INFBND *(real)*: value to truncate infinite bounds at non-leaf nodes ↩

Value to truncate infinite bounds at nonleaf nodes.

Default: `1e9`

STOC_ITER_LIM *(integer)*: iteration limit for stochastic solver ↩

Iteration limit for stochastic solver. Possible values are positive integers or (-1) no limit.

Range: {`-1`, ..., ∞}

Default: `infinity`

STOC_MAP_MPI2LP *(integer)*: flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements ↩

Flag to specify whether stochastic parameters in MPI will be mapped as LP matrix elements.

Default: `0`

STOC_MAX_NUMSCENS *(integer)*: maximum number of scenarios before forcing automatic sampling ↩

Maximum number of scenarios before forcing automatic sampling. Possible values are positive integers.

Default: `40000`

STOC_METHOD *(integer)*: stochastic optimization method to solve the model ↩

Stochastic optimization method to solve the model.

Default: `-1`

value	meaning
`-1`	Solve with the method chosen by the solver
`0`	Solve the deterministic equivalent (DETEQ)
`1`	Solve with the Nested Benders Decomposition (NBD) method

STOC_NAMEDATA_LEVEL *(integer)*: name data level ↩

Name data level.

Default: `1`

STOC_NODELP_PRELEVEL *(integer)*: presolve level solving node-models ↩

Presolve level solving node-models.

Default: `0`

value	meaning
+2	Simple pre-solving
+4	Probing
+8	Coefficient reduction
+16	Elimination
+32	Dual reductions
+64	Use dual information
+512	Maximum pass

STOC_NSAMPLE_PER_STAGE *(string)*: list of sample sizes per stage (starting at stage 2) ↩

Comma separated list of sample sizes per stage. The sample size of stage 1 is assumed to be 1 so that this list starts with stage stage 2.

STOC_NSAMPLE_SPAR *(integer)*: common sample size per stochastic parameter ↩

Common sample size per stochastic parameter. Possible values are positive integers.

Range: {-1, ..., ∞}

Default: -1

STOC_NSAMPLE_STAGE *(integer)*: common sample size per stage ↩

Common sample size per stage.

Range: {-1, ..., ∞}

Default: -1

STOC_NUM_THREADS *(integer)*: number of parallel threads ↩

This value specifies the number of parallel threads to be used when solving a stochastic programming model.

Default: 1

STOC_RELOPTTOL *(real)*: relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver ↩

Relative optimality tolerance (w.r.t lower and upper bounds on the true objective) to stop the solver. Possible values are reals in (0,1) interval.

Default: GAMS OptCR

STOC_REL_DSTEPTOL *(real)*: dual-step tolerance ↩

This value specifies the dual-step tolerance in decomposition based algorithms.

Default: 1e-7

STOC_REL_PSTEPTOL *(real)*: primal-step tolerance ↩

This value specifies the primal-step tolerance in decomposition based algorithms.

Default: 1e-8

STOC_REOPT *(integer)*: reoptimization method to solve the node-models ↩

Reoptimization method to solve the node-models.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver
4	Use NLP solver

STOC_RG_SEED *(integer)*: seed to initialize the random number generator ↩

Seed to initialize the random number generator. Possible values are positive integers.

Default: 1031

STOC_SAMP_CONT_ONLY *(integer)*: flag to restrict sampling to continuous stochastic parameters only or not ↩

Flag to restrict sampling to continuous stochastic parameters only or not.

Default: 1

value	meaning
0	disable
1	enable

STOC_SBD_MAXCUTS *(integer)*: max cuts to generate for master problem ↩

Max cuts to generate for master problem.

Range: {-1, ..., ∞}

Default: -1

STOC_SBD_NUMCANDID *(integer)*: maximum number of candidate solutions to generate at SBD root ↩

Maximum number of candidate solutions to generate at SBD root.

Range: {-1, ..., ∞}

Default: -1

STOC_SBD_OBJCUTFLAG *(integer)*: flag to enable objective cut in SBD master problem ↩

Flag to enable objective cut in SBD master problem.

Default: 1

STOC_SBD_OBJCUTVAL *(real)*: RHS value of objective cut in SBD master problem ↩

RHS value of objective cut in SBD master problem.

Default: 1e-30

STOC_SHARE_BEGSTAGE *(integer)*: stage beyond which node-models are shared ↩

Stage beyond which node-models share the same model structure. Possible values are positive integers less than or equal to number of stages in the model or (-1) for solver decides.

Range: {-1, ..., ∞}

Default: -1

STOC_TIME_LIM *(real)*: time limit for stochastic solver ↩

Time limit for stochastic solver. Possible values are nonnegative real numbers or -1 for solver decides.

Range: [-1, ∞]

Default: GAMS ResLim

STOC_TOPOPT *(integer)*: optimization method to solve the root problem ↩

Optimization method to solve the root problem.

Default: 0

value	meaning
0	Solver decides
1	Use primal method
2	Use dual simplex
3	Use barrier solver
4	Use NLP solver
6	Use multi-start solver
7	Use global solver

STOC_VARCONTROL_METHOD *(integer)*: sampling method for variance reduction ↩

Sampling method for variance reduction.

Default: 1

value	meaning
0	Montecarlo sampling
1	Latinsquare sampling
2	Antithetic sampling

STOC_WSBAS *(integer)*: warm start basis for wait-see model ↩

Warm start basis for wait-see model .

Range: {-1, ..., ∞}

Default: -1

SVR_LS_ANTITHETIC *(string)*: Sample variance reduction map to Lindo Antithetic algorithm ↩

SVR_LS_LATINSQUARE *(string)*: Sample variance reduction map to Lindo Latin Square algorithm ↩

SVR_LS_MONTECARLO *(string)*: Sample variance reduction map to Lindo Montecarlo algorithm ↩

TUNER_PRINT_LEVEL *(integer)*: specifies the amount of print to do during parameter tuning ↩

Default: 1

value	meaning
0	Do not print anything default
>0	Print more information

USEGOP *(integer)*: use global optimization ↩

This value determines whether the global optimization will be used.

Default: 1

value	meaning
0	Do not use global optimization
1	Use global optimization

WRITEDEMPI *(string)*: write deterministic equivalent in MPI format ↩

WRITEDEMPS *(string)*: write deterministic equivalent in MPS format ↩

WRITEMPI *(string)*: write (S)MPI file of processed model ↩

If this option is set, Lindo write an MPI file of processed model. If set, the value of this option defines the name of the MPI file.

WRITEMPS *(string)*: write (S)MPS file of processed model ↩

5.24.8 Stochastic Programming (SP) in GAMS/Lindo

GAMS/Lindo can also solve stochastic programming models. The syntax to set up an SP problem in GAMS is explained in the chapter Stochastic Programming (SP) with EMP. The options to control LINDOs stochastic solver are described in the subsection SP Options.

5.25 MILES

Thomas F. Rutherford, University of Colorado

5.25.1 Abstract

MILES is a solver for nonlinear complementarity problems and nonlinear systems of equations. The solver can be accessed through GAMS to solve MPSGE or MCP models. This paper documents the solution algorithm, user options, and solver output. The purpose of the paper is to provide users of MILES an overview of how the solver works so that they can use it effectively.

5.25.2 Introduction

MILES is a Fortran-based solver for nonlinear complementarity problems and nonlinear systems of equations. The solution procedure is a generalized Newton method with a backtracking line search. This code is based on an algorithm investigated by Mathiesen (1985) who proposed a modeling format and sequential method for solving economic equilibrium models. The method is closely related to algorithms proposed by Robinson (1975), Hogan (1977), Eaves (1978) and Josephy (1979). In this implementation, subproblems are solved as linear complementarity problems (LCPs), using an extension of Lemke's almost-complementary pivoting scheme in which upper and lower bounds are represented implicitly. The linear solver employs the basis factorization package LUSOL, developed by Gill et al. (1991).

The class of problems for which MILES may be applied are referred to as "generalized" or "mixed" complementarity problems, which is defined as follows:

$$\begin{aligned} \text{Given:} \quad & F : R^n \to R^n \ , \quad \ell, u \in R^n \\ \text{Find:} \quad & z, w, v \in R^n \\ \text{such that} \quad & F(z) = w - v \\ & \ell \le z \le u, \quad w \ge 0, \quad v \ge 0 \\ & w^T(z - \ell) = 0 \ , \quad v^T(u - z) = 0. \end{aligned}$$

When $\ell = -\infty$ and $u = \infty$ MCP reduces to a nonlinear system of equations. When $\ell = 0$ and $u = +\infty$, the MCP is a nonlinear complementarity problem. Finite dimensional variational inequalities are also MCP. MCP includes inequality-constrained linear, quadratic and nonlinear programs as special cases, although for these problems standard optimization methods may be preferred. MCP models which are not optimization problems encompass a large class of interesting mathematical programs. Specific examples of MCP formulations are not provided here. See Rutherford (1992a) for MCP formulations arising in economics. Other examples are provided by Harker and Pang (1990) and Dirkse (1993).

There are two types of GAMS models which can be presented to MILES:

1. MILES may be used to solve computable general equilibrium models generated by MPSGE as a GAMS subsystem. In the MPSGE language, a model-builder specifies classes of nonlinear functions using a specialized tabular input format embedded within a GAMS program. Using benchmark quantities and prices, MPSGE automatically calibrates function coefficients and generates nonlinear equations and Jacobian matrices. Large, complicated systems of nonlinear equations may be implemented and analyzed very easily using this interface to MILES. An introduction to general equilibrium modeling with GAMS/MPSGE is provided by Rutherford (1992a).

2. MILES may be accessed as a GAMS solver for mixed complementarity problems (MCP). If more than one MCP solver is available [3], the statement `OPTION MCP = MILES;` tells GAMS to use MILES as the MCP solution system. When problems are presented to MILES using the MCP format, the user specifies nonlinear functions using GAMS matrix algebra and the GAMS compiler automatically generates the Jacobian functions. An introduction to the GAMS/MCP modeling format is provided by Rutherford (1992b).

The purpose of this document is to provide users of MILES with an overview of how the solver works so that they can use the program more effectively. Section The Newton Algorithm introduces the Newton algorithm. Section Lemke's Method with Implicit Bounds describes the implementation of Lemke's algorithm which is used to solve linear subproblems. Section The Options File defines switches and tolerances which may be specified using the options file. Section Log File Output interprets the run-time log file which is normally directed to the screen. Section Status File Output interprets the status file and the detailed iteration reports which may be generated. Section Termination Messages lists and suggests remedies for abnormal termination conditions.

5.25.3 The Newton Algorithm

The iterative procedure applied within MILES to solve nonlinear complementarity problems is closely related to the classical Newton algorithm for nonlinear equations. This first part of this section reviews the classical procedure. A thorough introduction to these ideas is provided by Dennis and Schnabel (1983). For a practical perspective, see Press et al. (1986).

Newton algorithms for nonlinear equations begin with a local (Taylor series) approximation of the system of nonlinear equations. For a point z in the neighborhood of $\hat{z}$, the system of nonlinear functions is linearized:

$$LF(z) = F(\bar{z}) + \nabla F(\bar{z})(z - \bar{z}).$$

Solving the linear system $LF(z) = 0$ provides the Newton direction from $\bar{z}$ which is given by $d = -\nabla F^{-1}\ F(\bar{z})$.

Newton iteration k begins at point z^k. First, the linear model formed at z^k is solved to determine the associated "Newton direction", d^k. Second, a line search in direction d^k determines the scalar steplength and the subsequent iterate: $z^{k+1} = z^k + \lambda d^k$. An Armijo or "back-tracking" line search initially considers $\lambda = 1$. If $\|F(z^z + \lambda d^k)\| \leq \|F(z^k)\|$, the step size λ is adopted,otherwise is multiplied by a positive factor α, $\alpha < 1$, and the convergence test is reapplied. This procedure is repeated until either an improvement results or $\lambda < \underline{\lambda}$. When $\underline{\lambda} = 0$, a positive step is taken provided that [4]

$$\frac{d}{d\lambda}\|F(z^k + \lambda d^k)\| < 0.$$

Convergence theory for this algorithm is quite well developed. See, for example, Ortega and Rheinbolt (1970) or Dennis and Schnabel (1983). The most attractive aspect of the Newton scheme with the backtracking line search is that in the neighborhood of a well-behaved fixed point, $\lambda = 1$ is the optimal step length and the rate of convergence can be quadratic. If this method finds a solution, it does so very quickly.

The application of Newton methods to nonlinear complementarity problems involves a modification of the search direction. Here, d solves a *linear complementarity problem* (LCP) rather than a linear system of equations. For iteration k, d solves:

[3] There is one other MCP solver available through GAMS: PATH (Ferris and Dirkse,1992)
[4] α and $\underline{\lambda}$ correspond to user-specified tolerances 'DMPFAC' and 'MINSTP', respectively

$$F(z^k) + \nabla F(z^k)d - w + v = 0$$

$$\ell \leq d + z^k \leq u, \quad w \geq 0, \quad v \geq 0$$

$$w^T(d + z^k - \ell) = v^T(u - d - z^k) = 0.$$

Conceptually, we are solving for d, but in practice MILES solves the linear problem in terms of the original variables $z = z^k + d$:

$$F(z^k) - \nabla F(z^k)z_k + \nabla F(z^k)z = w - v$$

$$\ell \leq z \leq u, \quad w \geq 0, \quad v \geq 0$$

$$w^T(z - \ell) = 0\ , \quad v^T(u - z) = 0.$$

After computing the solution z, MILES sets $d^k = z - z^k$.

The linear subproblem incorporates upper and lower bounds on any or all of the variables, assuring that the iterative sequence always remains within the bounds: ($\ell \leq z^k \leq u$). This can be helpful when, as is often the case, $F()$ is undefined for some $z \in R^n$.

Convergence of the Newton algorithm applied to MCP hinges on three questions:

1. Does the linearized problem always have a solution?
2. If the linearized problem has a solution, does Lemke's algorithm find it?
3. Is it possible to show that the computed direction d^k will provide an "improvement" in the solution?

Only for a limited class of functions $F()$ can all three questions be answered in the affirmative. For a much larger class of functions, the algorithm converges in practice but convergence is not "provable" [5]

The answer to question 3. depends on the choice of a norm by which an improvement is measured. The introduction of bounds and complementarity conditions makes the calculation of an error index more complicated. In MILES, the deviation associated with a candidate solution $z, \epsilon(z)$, is based on a measure of the extent to which z, w and v violate applicable upper and lower bounds and complementarity conditions.

[5] Kaneko (1978) provides some convergence theory for the linearized subproblem

5.25.3.1 Evaluating Convergence

Let δ_i^L and δ_i^U be indicator variables for whether z_i is off its lower or upper bound. These are defined as [6]

$$\delta_i^L = min(1, (z_i - \ell_i)^+) \quad \text{and} \quad \delta_i^U = min(1, (u_i - z_i)^+).$$

Given z, MILES uses the value of $F(z)$ to implicitly define the slack variables w and v:

$$w_i = F_i(z)^+ \ , \quad v_i = \Big(-F_i(z)\Big)^+ .$$

There are two components to the error term associated with index i, one corresponding to z_i's violation of upper and lower bounds:

$$\varepsilon_i^B = (z_i - u_i)^+ + (\ell_i - z_i)^+$$

and another corresponding to violations of complementarity conditions:

$$\varepsilon_i^C = \delta_i^L w_i + \delta_i^U v_i.$$

The error assigned to point z is then taken:

$$\varepsilon(z) = \|\varepsilon^B(z) + \varepsilon^C(z)\|_p$$

for a pre-specified value of $p = 1, 2$ or $+\infty$. [7]

5.25.4 Lemke's Method with Implicit Bounds

A mixed linear complementarity problem has the form:

$$\begin{array}{rl} \text{Given:} & M \in R^{n\times n}, \qquad q, \ell, u \in R^n \\ \text{Find:} & z, w, v \in R^n \\ \text{such that} & Mz + q = w - v, \\ & \ell \le z \le u, \quad w \ge 0, \quad v \ge 0, \\ & w^T(z - \ell) = 0 \ , \quad v^T(u - z) = 0. \end{array}$$

In the Newton subproblem at iteration k, the LCP data are given by $q = F(z^k) - \nabla F(z^k) z^k$ and $M = \nabla F(z^k)$.

[6] In the following $x^+ = max(x, 0)$

[7] Parameter p may be selected with input parameter 'NORM'. The default value for p is $+\infty$.

5.25.4.1 The Working Tableau

In MILES, the pivoting scheme for solving the linear problem works with a re-labeled linear system of the form:

```
\f[  B x^B + N x^N = q , \f]
```

where $x^B \in R^n$, $x^N \in R^{2n}$, and the tableau $[B|N]$ is a conformal "complementary permutation" of $[-M|\ I\ |-I]$. That is, every column i in B must either be the ith column of M, I or $-I$, while the corresponding columns i and $i+n$ in N must be the two columns which were not selected for B.

To move from the problem defined in terms of z, w and v to the problem defined in terms of x^B and x^N, we assign upper and lower bounds for the x^B variables as follows:

$$\underline{x}_i^B = \begin{cases} \ell_i, & \texttt{if} \quad x_i^B = z_i \\ 0, & \texttt{if} \quad x_i^B = w_i \ \texttt{or} \ v_i, \end{cases}$$

$$\overline{x}_i^B = \begin{cases} u_i, & \texttt{if} \quad x_i^B = z_i \\ \infty, & \texttt{if} \quad x_i^B = w_i \ \texttt{or} \ v_i \end{cases}$$

The values of the non-basic variables x_i^N and x_{i+n}^N are determined by the assignment of x_i^B:

$$x_i^B = \begin{cases} z_i \ \Rightarrow \ \begin{cases} x_i^N = w_i = 0 \\ x_{i+n}^N = v_i = 0 \end{cases} \\ w_i \ \Rightarrow \ \begin{cases} x_i^N = z_i = \ell_i \\ x_{i+n}^N = v_i = 0 \end{cases} \\ v_i \ \Rightarrow \ \begin{cases} x_i^N = w_i = 0 \\ x_{i+n}^N = z_i = u_i. \end{cases} \end{cases}$$

In words: if z_i is basic then both w_i and v_i equal zero. If z_i is non-basic at its lower bound, then w_i is possibly non-zero and v_i is non-basic at zero. If z_i is non-basic at its upper bound, then v_i is possibly non-zero and w_i is non-basic at zero.

Conceptually, we could solve the LCP by evaluating 3^n linear systems of the form:

$$x^B = B^{-1}\Big(q - Nx^N\Big).$$

Lemke's pivoting algorithm provides a procedure for finding a solution by sequentially evaluating some (hopefully small) subset of these 3^n alternative linear systems.

5.25.4.2 Initialization

Let B^0 denote the initial basis matrix [8] The initial values for basic variables are then:

$$\hat{x}^B = (B^0)^{-1}(q - N\ \hat{x}^N).$$

If $\underline{x}^B \leq \hat{x}^B \leq \bar{x}^B$, then the initial basis is feasible and the complementarity problem is solved [9] Otherwise, MILES introduces an artificial variable z_0 and an artificial column h. Basic variables are then expressed as follows:

$$x^B = \hat{x}^B - \tilde{h}z_0,$$

where $\tilde{h}$ is the "transformed artificial column" (the untransformed column is $h = B^0\tilde{h}$). The coefficients of $\tilde{h}$ are selected so that:

1. The values of "feasible" basis variables are unaffected by z_0: ($\underline{x}_i^B \leq x_i^B \leq \bar{x}_i^B \Longrightarrow \tilde{h}_i = 0$).
2. The "most infeasible" basic variable ($i = p$) is driven to its upper or lower bound when $z_0 = 1$:
$$\tilde{h}_p = \begin{cases} \hat{x}_p^B - \bar{x}_p^B, & if \quad \tilde{x}_p^B > \bar{x}_p^B \\ \hat{x}_p^B - \underline{x}_p^B, & if \quad \tilde{x}_p^B < \underline{x}_p^B \ . \end{cases}$$
3. All other *infeasible* basic variables assume values between their upper and lower bounds when z_0 increases to 1:
$$x_i^B = \begin{cases} 1 + \underline{x}_i^B, & if \quad \underline{x}_i^B > -\infty, \quad \bar{x}_i^B = +\infty \\ \frac{\bar{x}_i^B + \underline{x}_i^B}{2}, & if \quad \underline{x}_i^B > -\infty, \quad \bar{x}_i^B < +\infty \\ \bar{x}_i^B - 1, & if \quad \underline{x}_i^B = -\infty, \quad \bar{x}_i^B < +\infty \ . \end{cases}$$

5.25.4.3 Pivoting Rules

When z_0 enters the basis, it assumes a value of unity, and at this point (barring degeneracy), the subsequent pivot sequence is entirely determined. The entering variable in one iteration is determined by the exiting basic variable in the previous iteration. For example, if z_i were in B^0 and introducing z_0 caused z_i to move onto its lower bound, then the subsequent iteration introduces w_i. Conversely, if w_i were in B^0 and z_0 caused w_i to fall to zero, the subsequent iteration increases z_i from ℓ_i. Finally, if v_i were in B^0 and z_0's introduction caused v_i to fall to zero, the subsequent iteration *decreases* z_i from u_i.

Table 1 Pivot Sequence Rules for Lemke's Algorithm with Implicit Bounds

N	Exiting Variable	Entering Variable	Change in Non-basic Values
I	z_i at lower bound	w_i increases from 0	$x_i^N = z_i = \ell_i$
II	z_i at upper bound	v_i increases from 0	$x_{i+n}^N = z_i = u_i$
III	w_i at 0	z_i increases from ℓ_i	$x_i^N = x_{i+n}^N = 0$
IV	v_i at 0	z_i decreases from u_i	$x_i^N = x_{i+n}^N = 0$

[8] In Miles, B^0 is chosen using the initially assigned values for z. When $z_i \leq \ell_i$, then $x_i^B = w_i$; when $z_i \geq u_i$, then $x_i^B = v_i$; otherwise $x_i^B = z_i$.

[9] The present version of the code simply sets $B^0 = -I$ and $x^B = w$ when the user-specified basis is singular. A subsequent version of the code will incorporate the algorithm described by Anstreicher, Lee, and Rutherford [1992] for coping with singularity.

The full set of pivoting rules is displayed in Table 1. One difference between this algorithm and the original Lemke (type III) pivoting scheme (see Lemke (1965), Garcia and Zangwill (1981), or Cottle and Pang (1992)) is that structural variables (z_i's) may enter or exit the basis at their upper bound values. The algorithm, therefore, must distinguish between pivots in which the entering variable increases from a lower bound and those in which the entering variable decreases from an upper bound.

Another difference with the "usual" Lemke pivot procedure is that an entering structural variable may move from one bound to another. When this occurs, the subsequent pivot introduces the corresponding slack variable. For example, if z_i is increased from ℓ_i to u_i without driving a basic variable infeasible, then z_i becomes non-basic at u_i, and the subsequent pivot introduces v_i. This type of pivot may be interpreted as z_i entering and exiting the basis in a single step [10]

In theory it is convenient to ignore degeneracy, while in practice degeneracy is unavoidable. The present algorithm does not incorporate a lexicographic scheme to avoid cycling, but it does implement a ratio test procedure which assures that when there is more than one candidate, priority is given to the most stable pivot. The admissible set of pivots is determined on both an absolute pivot tolerance (`ZTOLPV`) and a relative pivot tolerance (`ZTOLRP`). No pivot with absolute value smaller than min (`ZTOLPV`, `ZTOLRP` $\|V\|$) is considered, where $\|V\|$ is the norm of the incoming column.

5.25.4.4 Termination on a Secondary Ray

Lemke's algorithm terminates normally when the introduction of a new variable drives z_0 to zero. This is the desired outcome, but it does not always happen. The algorithm may be interrupted prematurely when no basic variable "blocks" an incoming variable, a condition known as "termination on a secondary ray". In anticipation of such outcomes, MILES maintains a record of the value of z_0 for successive iterations, and it saves basis information associated with the smallest observed value, z_0^*. (In Lemke's algorithm, the pivot sequence is determined without regard for the effect on z_0, and the value of the artificial variable may follow an erratic (non-monotone) path from its initial value of one to the final value of zero.)

When MILES encounters a secondary ray, a restart procedure is invoked in which the set of basic variables associated with z_0^* are reinstalled. This basis (augmented with one column from the non-basic triplet to replace z_0) serves as B^0, and the algorithm is restarted. In some cases this procedure permits the pivot sequence to continue smoothly to a solution, while in other cases may only lead to another secondary ray.

5.25.5 The Options File

The standard GAMS options (e.g. iterlim, reslim) can be used to control MILES. For more details, see section Controlling a Solver via GAMS Options.

In addition, MILES-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

The following is a typical MILES options file:

```
ITLIMT = 50
CONTOL = 1.0E-8
LUSIZE = 16
```

In the remainder of this section we describe the MILES options and give their default values.

[10] If all structural variables are subject to finite upper and lower bounds, then no z_i variables may be part of a homogeneous solution adjacent to a secondary ray. This does not imply, however, that secondary rays are impossible when all z_i variables are bounded, as a ray may then be comprised of w_i and v_i variables.

Option	Description	Default
contol	convergence tolerance Whenever an iterate is encountered for which `epsilon(z)` < `CONTOL`, the algorithm terminates. This corresponds to the GAMS/MINOS parameter "Row tolerance".	`1e-6`
dens1	LUSOL: density to start searching maxcol columns The density at which the Markowitz strategy should search `maxcol` columns and no rows. Range: [`0`, `1`]	`0.3`
dens2	LUSOL: density to start searching 1 column The density at which the Markowitz strategy should search only 1 column or (preferably) use a dense LU for all the remaining rows and columns. Range: [`0`, `1`]	`0.6`
dmpfac	damping factor in backtracking linesearch	`0.5`
elmax1	LUSOL: max multiplier allowed in L during factor	`10`
elmax2	LUSOL: max multiplier allowed in L during update	`10`
factim	basis reinversion time Indicates the maximum number of CPU seconds between recalculation of the basis factors.	`120`
invfrq	basis reinversion frequency Determines the maximum number of Lemke iterations between recalculation of the basis factors. This corresponds to the GAMS/MINOS parameter "Factorization frequency".	`200`
invlog	toggle Lemke inversion logging A switch which requests LUSOL to generate a report with basis statistics following each refactorization.	`1`
itch	iteration refinement frequency Indicates the frequency with which the factorization is checked. The number refers to the number of basis replacement operations between refinements. This corresponds to the GAMS/MINOS parameter "Check frequency".	`25`
iterlim	minor (Lemke) iterations limit Can also be set with the GAMS IterLim option, and takes its default from that. This corresponds to the GAMS/MINOS parameter "Iterations Limit".	`GAMS IterLim`
itlimt	major (Newton) iterations limit An upper bound on the number of Newton iterations. This corresponds to the GAMS/MINOS parameter "Major iterations". Range: {`0`, ..., `1000`}	`100`
lcpdmp	LCP dump (post-scaling) A switch to generate a printout of the LCP data after scaling.	`0`
lcpech	LCP echo print (pre-scaling) A switch to generate a printout of the LCP data before scaling, as evaluated.	`0`
levout	set output level Sets the level of debug output written to the log and status files. The lowest meaningful value is -1 and the highest is 3. This corresponds, roughly, to the GAMS/MINOS parameter "Print level".	`1`

Option	Description	Default
lprint	LUSOL: print level Controls the amount of logging from the LUSOL routines. <0: suppresses output 0: gives error messages 1: gives debug output from some of the routines in LUSOL >=2: gives the pivot row and column and the no. of rows and columns involved at each elimination step in lu1fac	0
lusize	LUSOL: multiplier for estimating memory requirements Used to estimate the number of LU nonzeros which will be stored, as a multiple of the number of nonzeros in the Jacobian matrix. Range: {3, ..., ∞}	5
maxcol	LUSOL: max cols to search for pivot element Sets the maximum number of columns to search in a Markowitz-type search for the next pivot element. For some of the factorization, the number of rows searched is maxrow = maxcol - 1.	5
minstp	minimum step length in backtracking linesearch	0.01
norm	norm to use in measuring deviation Defines the vector norm to be used for evaluating epsilon(z). Acceptable values are 1, 2 or 3 which correspond to p = 1, 2 and +INF.	1
nrsmax	restart limit Sets an upper bound on the number of restarts which the linear subproblem solver will undertake before giving up.	1
pivlog	toggle Lemke pivot logging A switch to generate a status file listing of the Lemke pivot sequence.	0
plinfy	infinity used by the solver The value assigned for "plus infinity" ("+INF" in GAMS notation).	1e20
scale	turn on scaling at every iteration Invokes row and column scaling of the LCP tableau in every iteration. This corresponds, roughly, to the GAMS/MINOS switch "scale all variables".	1
small	LUSOL: absolute zero tolerance The absolute tolerance for treating reals as zero.	3.0e-13
uspace	LUSOL: factor limiting waste space in U The row or column lists are compressed if their length exceeds this value times the length of either file after the last compression. Range: [1, ∞]	3
utol1	LUSOL: absolute tolerance U diagonal The absolute tol for flagging small diagonals of U.	3.64e-11
utol2	LUSOL: relative tolerance U diagonal The relative tol for flagging small diagonals of U.	3.64e-11
ztolda	zero tolerance on matrix coefficients, default: sqrt(machEps)	1.48e-08
ztolpv	absolute zero tolerance on pivots, default: machEps**(2/3) The absolute pivot tolerance. This corresponds, roughly, to the GAMS/MINOS parameter "Pivot tolerance" as it applies for nonlinear problems.	3.64e-11
ztolrp	relative zero tolerance on pivots, default: machEps**(2/3) The relative pivot tolerance. This corresponds, roughly, to the GAMS/MINOS parameter "Pivot tolerance" as it applies for nonlinear problems.	3.64e-11
ztolz0	absolute tolerance for installing covering vector elements	1e-6

Option	Description	Default
ztolze	feasibility tolerance Used in the subproblem solution to determine when any variable has exceeded an upper or lower bound. This corresponds to GAMS/MINOS parameter "Feasibility tolerance".	1e-6

5.25.6 Log File Output

The log file is intended for display on the screen in order to permit monitoring progress. Relatively little output is generated.

A sample iteration log is displayed in Table 2. This output is from two cases solved in succession. This and subsequent output comes from program `TRNSP.FOR` which calls the MILES library directly. (When MILES is invoked from within GAMS, at most one case is processed at a time.)

The first line of the log output gives the MILES program date and version information. This information is important for bug reports.

The line beginning "Work space..." reports the amount of memory which has been allocated to solve the model - 10K for this example. Thereafter is reported the initial deviation together with the name of the variable associated with the largest imbalance ($\epsilon_i^B + \epsilon_i^C$). The next line reports the convergence tolerance.

The lines beginning 0 and 1 are the major iteration reports for those iterations. the number following the iteration number is the current deviation, and the third number is the Armijo step length. The name of the variable complementary to the equation with the largest associated deviation is reported in parenthesis at the end of the line.

Following the final iteration is a summary of iterations, refactorizations, amd final deviation. The final message reports the solution status. In this case, the model has been successfully processed ("Solved.").

Table 2 Sample Iteration Log

5.25.7 Status File Output

The status file reports more details regarding the solution process than are provided in the log file. Typically, this file is written to disk and examined only if a problem arises. Within GAMS, the status file appears in the listing only following the GAMS statement `OPTION SYSOUT=ON;`.

The level of output to the status file is determined by the options passed to the solver. In the default configuration, the status file receives all information written to the log file together with a detailed listing of all switches and tolerances and a report of basis factorization statistics.

When output levels are increased from their default values using the options file, the status file can receive considerably more output to assist in debugging. Table 3 - Table 6 present a status file generated with `LEVOUT=3` (maximum), `PIVLOG=T`, and `LCPECH=T`.

The status file begins with the same header as the log file. Thereafter is a complete echo-print of the user-supplied option file when one is provided. Following the core allocation report is a full echo-print of control parameters, switches and tolerance as specified for the current run.

Table 4 continues the status file. The iteration-by- iteration report of variable and function values is produced whenever `LEVOUT >= 2`. Table 4 also contains an LCP echo-print. This report has two sections: $ROWS and $COLUMNS. The four columns of numbers in the $ROWS section are the constant vector (q), the current estimate of level values for the associated variables (z), and the lower and upper bounds vectors (ℓ and u). The letters L and U which appear between the ROW and Z columns are used to identify variables which are non-basic at their lower and upper bounds, respectively. In this example, all upper bounds equal $+\infty$, so no variables are non-basic at their upper bound.

By convention, only variable (and not equation names) appear in the status file. An equation is identified by the corresponding variable. We therefore see in the $COLUMNS: section of the matrix echo-print, the row names correspond to the names of z variables. The names assigned to variables z_i, w_i and v_i are

$z-$ <name i >, $w-$ <name i >, and $v-$ <name i >, as shown in the $COLUMNS section. The nonzeros for $w-$ <> and $v-$ <> variables are not shown because they are assumed to be $-/+I$.

The status file output continues on Table 5 where the first half of the table reports output from the matrix scaling procedure, and the second half reports the messages associated with initiation of Lemke's procedure.

The "lu6chk warning" is a LUSOL report. Thereafter are two factorization reports. Two factorizations are undertaken here because the first basis was singular, so the program installs all the lower bound slacks in place of the matrix defined by the initial values, z.

Following the second factorization report, at the bottom of Table 5 is a summary of the initial pivot. "Infeasible in 3 rows." indicates that $\tilde{h}$ contains 3 nonzero elements. "Maximum infeasibility" reports the largest amount by which a structural variable violates an upper or lower bound. "Artificial column with 3 elements." indicates that the vector $h = B^0\tilde{h}$ contains 3 elements (note that in this case $B^0 = -I$ because the initial basis was singular, hence the equivalence between the number of nonzeros in $\tilde{h}$ and h.).

Table 6 displays the final section of the status file. At the top of the table is the Lemke iteration log. The columns are interpreted as follows:

- `ITER` is the iteration index beginning with 0.
- `STATUS` is a statistic representing the efficiency of the Lemke path. Formally, status is the ratio of the minimum number of pivots from B_0 to the current basis divided by the actual number of pivots. When the status is 1, Lemke's algorithm is performing virtually as efficiently as a direct factorization (apart from the overhead of basis factor updates.)
- `Z%` indicates the percentage of columns in the basis are "structural" (z's).
- `Z0` indicates the value of the artificial variable. Notice that in this example, the artificial variable declines monotonically from its initial value of unity.
- `ERROR` is a column in which the factorization error is reported, when it is computed. For this run, ITCH=30 and hence no factorization errors are computed.
- `INFEAS` is a column in which the magnitude of the infeasibility introduced by the artificial column (defined using the box-norm) is reported. (In MILES the cover vector h contains many different nonzero values, not just 1's; so there may be a large difference between the magnitude of the artificial variable and the magnitude of the induced infeasibility.
- `PIVOTS` reports the pivot magnitude in both absolute terms (the first number) and relative terms (the second number). The relative pivot size is the ratio of the pivot element to the norm of the incoming column.
- `IN/OUT` report the indices (not names) of the incoming and outgoing columns for every iteration. Notice that Lemke's iteration log concludes with variable z_0 exiting the basis.

The convergence report for iteration 1 is no different from the report written to the log file, and following this is a second report of variable and function values. We see here that a solution has been obtained following a single subproblem. This is because the underlying problem is, in fact, linear.

The status file (for this case) concludes with an iteration summary identical to the log file report and a summary of how much CPU time was employed overall and within various subtasks. (Don't be alarmed if the sum of the last five numbers does not add up to the first number - some cycles are not monitored precisely.)

5.25.8 Termination Messages

Basis factorization error in INVERT. An unexpected error code returned by LUSOL. This should normally not occur. Examine the status file for a message from LUSOL [11] .

[11] Within GAMS, insert the line "OPTION SYSOUT=ON;" prior to the solve statement and resubmit the program in order to pass the MILES solver status file through to the listing.

Failure to converge. Two successive iterates are identical - the Newton search direction is not defined. This should normally not occur.

Inconsistent parameters `ZTOLZ0`**,** `ZTOLZE`**.** `ZTOLZ0` determines the smallest value loaded into the cover vector h, whereas `ZTOLZE` is the feasibility tolerance employed in the Harris pivot selection procedure. If `ZTOLZ0` $<$ `-ZTOLZE`, Lemke's algorithm cannot be executed because the initial basis is infeasible.

Insufficient space for linearization. Available memory is inadequate for holding the nonzeros in the Jacobian. More memory needs to be allocated. If there is insufficient space for the {Jacobi} matrix, there is far too little memory for holding the LU factors of the same matrix.

Insufficient space to invert. More memory needs to be allocated for basis factors. Increase the value of `LUSIZE` in the options file, or assign a larger value to `<model>.workspace`.

Iteration limit exceeded. This can result from either exceeding the major (Newton) or minor (Lemke) iterations limit. When MILES is invoked from GAMS, the cumulative Lemke iteration limit can be set with the statement `<model>.iterlim = xx};`. The Newton iteration limit is 100 by default, and it can be modified only through the `ITLIMT` option.

Resource interrupt. Elapsed CPU time exceeds options parameter `RESLIM`. To increase this limit, either add `RESLIM` = xxx in the options file or add a GAMS statement `<model>.RESLIM = xxx;`.

Singular matrix encountered. Lemke's algorithm has been interrupted due to a singularity arising in the basis factorization, either during a column replacement or during a refactorization. For some reason, a restart is not possible.

Termination on a secondary ray. Lemke's algorithm terminated on a secondary ray. For some reason, a restart is not possible.

Unknown termination status. The termination status flag has not been set, but the code has interrupted. Look in the status file for a previous message. This termination code should not happen often.

5.26 MINOS and QUADMINOS

Bruce A. Murtagh; Graduate School of Management, Macquarie University, Sydney, Australia

Michael A. Saunders, Walter Murray; Department of EESOR, Stanford University, CA

Philip E. Gill; Department of Mathematics, University of California, San Diego, La Jolla, CA

5.26.1 Introduction

This document describes the GAMS interface to MINOS which is a general purpose nonlinear programming solver. For a quad-precision MINOS, see quadMINOS.

GAMS/MINOS is a specially adapted version of the solver that is used for solving linear and nonlinear programming problems in a GAMS environment.

GAMS/MINOS is designed to find solutions that are *locally optimal*. The nonlinear functions in a problem must be *smooth* (i.e., their first derivatives must exist).The functions need not be separable. Integer restrictions cannot be imposed directly.

A certain region is defined by the linear constraints in a problem and by the bounds on the variables. If the nonlinear objective and constraint functions are convex within this region, any optimal solution obtained will be a *global optimum*. Otherwise there may be several local optima, and some of these may not be global. In such cases the chances of finding a global optimum are usually increased by choosing a staring point that is "sufficiently close", but there is no general procedure for determining what "close" means, or for verifying that a given local optimum is indeed global.

Linearly constrained models are solved with a very efficient and reliable reduced gradient technique that takes advantage of the sparsity of the model. Models with nonlinear constraints are solved with a method that iteratively solves subproblems with linearized constraints and an augmented Lagrangian objective function. This iterative scheme implies that only the final, optimal solution is sure to be feasible w.r.t the nonlinear constraints. This is in contrast to the feasible path method used by some other NLP solvers, e.g., CONOPT. MINOS and CONOPT are very complementary to each other as they employ very different algorithms. See MINOS vs CONOPT for a comparison of the two solvers.

GAMS allows you to specify values for many parameters that control GAMS/MINOS, and with careful experimentation you may be able to influence the solution process in a helpful way. All MINOS options available through GAMS/MINOS are summarized at the end of this document.

5.26.2 How to Run a Model with GAMS/MINOS

MINOS is capable of solving many types of models, including LP, NLP, DNLP and QCP. If MINOS is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select MINOS:

```
option nlp=minos;
```

The option statement should appear before the `solve` statement.

To be complete, we mention that the solver can be also specified on the command line, as in:

```
> gams camcge nlp=minos
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

5.26.3 Overview of GAMS/MINOS

GAMS/MINOS is a system designed to solve large-scale optimization problems expressed in the following form:

$$\begin{array}{lllll} \text{NLP}: & & \text{minimize} & F(x) + c^T x + d^T y & (1) \\ & & \text{subject to} & f(x) + A_1 y \sim b_1 & (2) \\ & & & A_2 x + A_3 y \sim b_2 & (3) \\ & & & \ell \leq \begin{pmatrix} x \\ y \end{pmatrix} \leq u & (4) \end{array}$$

where the vectors c, d, b_1, b_2, ℓ, u and the matrices A_1, A_2, A_3 are constant, $F(x)$ is a smooth scalar function, and $f(x)$ is a vector of smooth functions. The $\sim$ signs mean that individual constraints may be defined using $\leq$, $=$ or $\geq$ corresponding to the GAMS constructs `=L=` , `=E=` and `=G=`.

The components of x are called the nonlinear variables, and the components of y are the linear variables. Similarly, the equations in (2) are called the nonlinear constraints, and the equations in (3) are the linear constraints. Equations (2) and (3) together are called the general constraints.

Let m_1 and n_1 denote the number of nonlinear constraints and variables, and let m and n denote the total number of (general) constraints and variables. Thus, A_3 has $m - m_1$ rows and $n - n_1$ columns. The constraints (4) specify upper and lower bounds on all variables. These are fundamental to many problem formulations and are treated specially by the solution algorithms in GAMS/MINOS. Some of the components of ℓ and u may be $-\infty$ or $+\infty$ respectively, in accordance with the GAMS use of `-INF` and `+INF`.

The vectors b_1 and b_2 are called the right-hand side, and together are denoted by b.

5.26.3.1 Linear Programming

If the functions $F(x)$ and $f(x)$ are absent, the problem becomes a *linear program*. Since there is no need to distinguish between linear and nonlinear variables, we use x rather than y. GAMS/MINOS converts all general constraints into equalities, and the only remaining inequalities are simple bounds on the variables. Thus, we write linear programs in the form

$$\begin{array}{lll} \text{LP}: & \text{minimize} & c^T x \\ & \text{subject to} & Ax + Is = 0 \\ & & \ell \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u \end{array}$$

where the elements of x are your own GAMS variables, and s is a set of *slack variables*: one for each general constraint. For computational reasons, the right-hand side b is incorporated into the bounds on s.

In the expression $Ax + Is = 0$ we write the identity matrix explicitly if we are concerned with columns of the associated matrix $\begin{pmatrix} A & I \end{pmatrix}$. Otherwise we will use the equivalent notation $Ax + s = 0$.

GAMS/MINOS solves linear programs using a reliable implementation of the *primal simplex method* [41] , in which the constraints $Ax + Is = 0$ are partitioned into the form

$$Bx_B + Nx_N = 0,$$

where the *basis matrix* is square and nonsingular. The elements of x_B and x_N are called the basic or nonbasic variables respectively. Together they are a permutation of the vector

$$\begin{pmatrix} x \\ s \end{pmatrix}.$$

Normally, each nonbasic variable is equal to one of its bounds, and the basic variables take on whatever values are needed to satisfy the general constraints. (The basic variables may be computed by solving the linear equations $Bx_B = Nx_N$.) It can be shown that if an optimal solution to a linear program exists, then it has this form.

The simplex method reaches such a solution by performing a sequence of *iterations*, in which one column of B is replaced by one column of N (and vice versa), until no such interchange can be found that will reduce the value of $c^T x$.

As indicated nonbasic variables usually satisfy their upper and lower bounds. If any components of x_B lie significantly outside their bounds, we say that the current point is *infeasible*. In this case, the simplex method uses a Phase 1 procedure to reduce the sum of infeasibilities to zero. This is similar to the subsequent Phase 2 procedure that optimizes the true objective function $c^T x$.

If the solution procedures are interrupted, some of the nonbasic variables may lie strictly *between* their bounds $\ell_j < x_j < u_j$. In addition, at a "feasible" or "optimal" solution, some of the basic variables may lie slightly outside their bounds: $\ell_j - \delta < x_j < \ell_j$ or $u_j < x_j < u_j + \delta$ where δ is a *feasibility tolerance* (typically 10^{-6}). In rare cases, even nonbasic variables might lie outside their bounds by as much as δ.

GAMS/MINOS maintains a sparse LU factorization of the basis matrix B, using a Markowitz ordering scheme and Bartels-Golub updates, as implemented in the Fortran package LUSOL [82] (see [16] [17] [147] [148]). The basis factorization is central to the efficient handling of sparse linear and nonlinear constraints.

5.26.3.2 Problems with a Nonlinear Objective

When nonlinearities are confined to the term $F(x)$ in the objective function, the problem is a linearly constrained nonlinear program. GAMS/MINOS solves such problems using a *reduced-gradient* algorithm [203] combined with a *quasi-Newton* algorithm that is described in [139] . In the reduced-gradient method, the constraints $Ax + Is = 0$ are partitioned into the form

$$Bx_B + Sx_S + Nx_N = 0$$

where x_s is a set of *superbasic variables*. At a solution, the basic and superbasic variables will lie somewhere between their bounds (to within the feasibility tolerance δ, while nonbasic variables will normally be equal to one of their bounds, as before. Let the number of superbasic variables be s, the number of columns in S. (The context will always distinguish s from the vector of slack variables.) At a solution, s will be no more than n_1, the number of nonlinear variables. In many practical cases we have found that s remains reasonably small, say 200 or less, even if n_1 is large.

In the reduced-gradient algorithm, x_s is regarded as a set of "independent variables" or "free variables" that are allowed to move in any desirable direction, namely one that will improve the value of the objective function (or reduce the sum of infeasibilities). The basic variables can then be adjusted in order to continue satisfying the linear constraints.

If it appears that no improvement can be made with the current definition of B, S and N, some of the nonbasic variables are selected to be added to S, and the process is repeated with an increased value of s. At all stages, if a basic or superbasic variable encounters one of its bounds, the variable is made nonbasic and the value of s is reduced by one.

A step of the reduced-gradient method is called a *minor iteration*. For linear problems, we may interpret the simplex method as being the same as the reduced-gradient method, with the number of superbasic variable oscillating between 0 and 1.

A certain matrix Z is needed now for descriptive purposes. It takes the form

$$\begin{pmatrix} -B^{-1}S \\ I \\ 0 \end{pmatrix}$$

though it is never computed explicitly. Given an LU factorization of the basis matrix B, it is possible to compute products of the form Zq and Z^Tg by solving linear equations involving B or B^T. This in turn allows optimization to be performed on the superbasic variables, while the basic variables are adjusted to satisfy the general linear constraints.

An important feature of GAMS/MINOS is a stable implementation of a quasi-Newton algorithm for optimizing the superbasic variables. This can achieve superlinear convergence during any sequence of iterations for which the B, S, N partition remains constant. A *search direction* q for the superbasic variables is obtained by solving a system of the form

$$R^TRq = -Z^Tg$$

where g is a gradient of $F(x)$, Z^Tg is the *reduced gradient*, and R is a dense upper triangular matrix. GAMS computes the gradient vector g analytically, using automatic differentiation. The matrix R is updated in various ways in order to approximate the *reduced Hessian* according to $R^TR \approx Z^THZ$ where H is the matrix of second derivatives of $F(x)$ (the *Hessian*).

Once q is available, the search direction for all variables is defined by $p = Zq$. A *ine search* is then performed to find an approximate solution to the one-dimensional (w.r.t. α) problem

$$\begin{aligned} &\text{minimize } F(x + \alpha p) \\ &\text{subject to } 0 < \alpha < \beta \end{aligned}$$

where β is determined by the bounds on the variables. Another important piece in GAMS/MINOS is a step-length procedure used in the linesearch to determine the step-length α (see [80]). The number of nonlinear function evaluations required may be influenced by setting the **Linesearch tolerance**, as discussed in Section Detailed Description of MINOS Options .

As in a linear programming solver, an equation $B^T\pi = gB$ is solved to obtain the *dual variables* or *shadow prices* π where gB is the gradient of the objective function associated with basic variables. It follows that $gB - B^T\pi = 0$. The analogous quantity for superbasic variables is the reduced-gradient vector $Z^T g = gs - s^T\pi$; this should also be zero at an optimal solution. (In practice its components will be of order $r||\pi||$ where r is the optimality tolerance, typically 10^{-6}, and $||\pi||$ is a measure of the size of the elements of π.)

5.26.3.3 Problems with Nonlinear Constraints

If any of the constraints are nonlinear, GAMS/MINOS employs a *project Lagrangian* algorithm, based on a method due to [150] , see [140] . This involves a sequence of *major iterations*, each of which requires the solution of a *linearly constrained subproblem*. Each subproblem contains linearized versions of the nonlinear constraints, as well as the original linear constraints and bounds.

At the start of the k^{th} major iteration, let x_k be an estimate of the nonlinear variables, and let λ_k be an estimate of the Lagrange multipliers (or dual variables) associated with the nonlinear constraints. The constraints are linearized by changing $f(x)$ in equation (2) to its linear approximation:

$$f'(x, x_k) = f(x_k) + J(x_k)(x - x_k)$$

or more briefly

$$f' = f_k + J_k(x - x_k)$$

where $J(x_k)$ is the *Jacobian matrix* evaluated at x_k. (The i-th row of the Jacobian is the gradient vector of the i-th nonlinear constraint function. As with the objective gradient, GAMS calculates the Jacobian using automatic differentiation).

The subproblem to be solved during the k-th major iteration is then

$$\begin{aligned}
&\text{minimize} && F(x) + c^T x + d^T y - \lambda_k^T(f - f') + 0.5\rho(f - f')^T(f - f') && (5)\\
&\text{subject to} && f' + A_1 y \sim b_1 && (6)\\
& && A_2 x + A_3 y \sim b_2 && (7)\\
& && \ell \le \begin{pmatrix} x \\ y \end{pmatrix} \le u && (8)
\end{aligned}$$

The objective function (5) is called an *augmented Lagrangian*. The scalar ρ is a *penalty parameter*, and the term involving ρ is a modified *quadratic penalty function*.

GAMS/MINOS uses the reduced-gradient algorithm to minimize (5) subject to (6) – (8). As before, slack variables are introduced and b_1 and b_2 are incorporated into the bounds on the slacks. The linearized constraints take the form

$$\begin{pmatrix} J_k & A_1 \\ A_2 & A_3 \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} s_1 \\ s_2 \end{pmatrix} = \begin{pmatrix} J_k x_k - f_k \\ 0 \end{pmatrix}$$

This system will be referred to as $Ax + Is = 0$ as in the linear case. The Jacobian J_k is treated as a sparse matrix, the same as the matrices A_1, A_2, and A_3.

In the output from GAMS/MINOS, the term *Feasible subproblem* indicates that the *linearized constraints* have been satisfied. In general, the nonlinear constraints are satisfied only in the limit, so that *feasibility* and *optimality* occur at essentially the same time. The nonlinear constraint violation is printed every major iteration. Even if it is zero early on (say at the initial point), it may increase and perhaps fluctuate before tending to zero. On "well behaved problems", the constraint violation will decrease quadratically (i.e., very quickly) during the final few major iterations.

5.26.4 Modeling Issues

Formulating nonlinear models requires that the modeler pays attention to some details that play no role when dealing with linear models.

5.26.4.1 Starting Points

The first issue is specifying a *starting point*. It is advised to specify a good starting point for as many nonlinear variables as possible. The GAMS default of zero is often a very poor choice, making this even more important.

As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points (x_i, y_i):

$$\begin{array}{lll} \text{Example :} & \text{minimize} & r \\ & \text{subject to} & (x_i - a)^2 + (y_i - b)^2 \leq r^2,\ r \geq 0. \end{array}$$

This problem can be modeled in GAMS as follows.

```
set i 'points' /p1*p10/;

parameters
    x(i)    'x coordinates',
    y(i)    'y coordinates';

* fill with random data
x(i) = uniform(1,10);
y(i) = uniform(1,10);

variables
    a       'x coordinate of center of circle'
    b       'y coordinate of center of circle'
    r       'radius';

equations
    e(i)    'points must be inside circle';

e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);

r.lo = 0;

model m /all/;
option nlp=minos;
solve m using nlp minimizing r;
```

Without help, MINOS will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

$$\begin{aligned} x_{\min} &= \min_i x_i, \\ y_{\min} &= \min_i y_i, \\ x_{\max} &= \max_i x_i, \\ y_{\max} &= \max_i y_i, \end{aligned}$$

then good estimates are

$$\begin{aligned} a &= (x_{\min} + x_{\max})/2, \\ b &= (y_{\min} + y_{\max})/2, \\ r &= \sqrt{(a - x_{\min})^2 + (b - y_{\min})^2}. \end{aligned}$$

Thus we include in our model:

```
parameters xmin,ymin,xmax,ymax;
xmin = smin(i, x(i));
ymin = smin(i, y(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqr(a.l-xmin) + sqr(b.l-ymin) );
```

and now the model solves very easily.

Level values can also be set away from zero implicitly as a result of assigning bounds. When a variable is bounded away from zero, for instance by the statement `Y.LO = 1;`, the implicit projection of variable levels onto their bounds that occurs when a model is solved will initialize `Y` away from zero.

5.26.4.2 Bounds

Setting appropriate bounds can be very important to steer the algorithm away from uninteresting areas, and to prevent *function evaluation errors* from happening.

If your model contains a real power of the form `x**y` it is important to add a bound $x > 0.001$, as real exponentation is evaluated in GAMS as $\exp(y \log(x))$. In some cases one cannot write a bound directly, e.g. if the equation is $z = x^{f(y)}$. In that case it is advised to introduce an extra variable and equation:

$$\begin{aligned} z &= x^{\vartheta} \\ \vartheta &= f(y) \\ \vartheta &\geq \varepsilon \end{aligned}$$

(Note that the functions `SQR(x)` and `POWER(x,k)` are integer powers and do not require x to be positive).

If the model produces *function evaluation errors* adding bounds is prefered to raising the `DOMLIM` limit.

Bounds in GAMS are specified using `X.LO(i)=0.001` and `X.UP(i) = 1000`.

5.26.4.3 Scaling

Although MINOS has some facilities to scale the problem before starting to optimize it, it remains an important task for the modeler to provide a well-scaled model. This is especially the case for nonlinear models. GAMS has special syntax features to specify row and column scales that allow the modeler to keep the equations in a most natural form. For more information consult the GAMS User's Guide.

5.26.4.4 The Objective Function

The first step GAMS/MINOS performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. MINOS however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```
obj.. z =e= sum(i, sqr(resid(i)));

model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form NLP (equations $(1)-(4)$) by saying minimize z subject to $z = \sum_i resid_i^2$ and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize $\sum_i resid_i^2$ directly. This can be achieved by a simple reformulation: z can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable z is a free continuous variable (no bounds are defined on z),
- z appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- z is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by MINOS. For instance the model **[CHEM]** from the model library solves in 21 iterations. When we add the bound

```
energy.lo = 0;
```

to the objective variable `energy` and thus prevent it from being substituted out, MINOS will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```
Variables x,y,z;
Equations e1,e2;

e1..z =e= y;
e2..y =e= sqr(1+x);

model m /all/;

option nlp=minos;
solve m using nlp minimizing z;
```

will be reformulated as an *unconstrained* optimization problem

$$\text{minimize} \quad \text{f(x)} \quad = (1+x)^2.$$

These additional reformulations can be turned off by using the statement `option reform = 0;` (see Section GAMS Options).

5.26.5 GAMS Options

The standard GAMS options (e.g. iterlim, domlim) can be used to control GAMS/MINOS. For more details, see section Controlling a Solver via GAMS Options. We highlight some of the details of this usage below for cases of special interest.

iterlim

Sets the *minor* iteration limit. MINOS will stop as soon as the number of *minor iterations* exceeds the iteration limit and report the current solution.

domlim

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate $\sqrt{x}$ for $x < 0$. Other examples include taking logs of negative numbers, and evaluating the real power x^y for $x < \varepsilon$ (x^y is evaluated as $\exp(y \log x)$). When such an error occurs the count of domain errors is incremented: MINOS will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and MINOS continues. For example, in the case of $\sqrt{x}, x < 0$ a zero is passed back for the function value and a large value for the derivative. In many cases MINOS will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don't occur. For example, when an expression $\log(x)$ is present in the model, add a statement like `x.lo = 0.001;`.

bratio

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to MINOS so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead *crash* a new basis. The `bratio` determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

workfactor

By default, GAMS/MINOS computes an estimate of the amount of workspace needed by MINOS, and passes this workspace on to MINOS for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeroes, etc. In most cases this is sufficient to solve the model. In some rare cases MINOS may need more memory, and the user can provide this by specifying a value of `workfactor` greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to MINOS for the solve.

workspace

The `workspace` option is *deprecated*: use the `workfactor` option instead. The `workspace` option specifies the amount of memory, in MB, that MINOS will use.

reform

This option controls the objective reformulation mechanism described in Section The Objective Function The default value of 100 will cause GAMS/MINOS to try further substitutions along the diagonal after the objective variable has been removed. Any other value will disable this diagonal procedure.

5.26.6 Summary of MINOS Options

The performance of GAMS/MINOS is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-standard values for some or all of the options through the MINOS option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

Note that the option file is not case sensitive. Examples for using the option file can be found at the end of this section. The tables below contain summary information about the MINOS options, default values, and links to more detailed explanations.

5.26.6.1 Output related options

Option	Description	Default
debug level	Controls amount of debug information written	0
log frequency	Controls iteration logging to listing file	100
print level	Controls amount of information printed during optimization	0
scale print	Print scaling factors	
solution	Prints MINOS solution	NO
summary frequency	Controls iteration logging to summary (log file)	100

5.26.6.2 Tolerances

Option	Description	Default
crash tolerance	Allow crash procedure to ignore small elements in eligible columns	0.1
feasibility tolerance	Feasibility tolerance for linear constraints	1.0e-6
linesearch tolerance	Controls accuracy of steplength selected	0.1
LU density tolerance	When to use dense factorization	0.5
LU factor tolerance	Trade-off between stability and sparsity in basis factorization	100.0
LU singularity tolerance	Protection against ill-conditioned basis matrices	1.0e-11
LU update tolerance	Trade-off between stability and sparsity in basis updating	10.0
optimality tolerance	Reduced gradient optimality check	1.0e-6
row tolerance	Accuracy requirement for nonlinear rows	1.0e-6
scale print tolerance	Scale print flag and set tolerance	0.9
scale tolerance	Scale tolerance	0.9
subspace tolerance	Determines when nonbasics becomes superbasic	0.5

5.26.6.3 Limits

Option	Description	Default
hessian dimension	Size of Hessian matrix	1
iterations limit	Minor iteration limit	GAMS iterlim
major iterations	Max number of major iterations	50
minor iterations	Max number of minor iterations between linearizations of nonlinear constraints	40
superbasics limit	Maximum number of superbasics	1
unbounded objective value	Determines when a problem is called unbounded	1.0e20
unbounded step size	Determines when a problem is called unbounded	1.0e10

5.26.6.4 Other algorithmic options

Option	Description	Default
check frequency	Controls frequency of linear constraint satisfaction test	60
completion	Completion level for subproblems (full/partial)	FULL
crash option	Controls the basis crash algorithm	3
expand frequency	Setting for anti-cycling mechanism	10000
factorization frequency	Number of iterations between basis factorizations	100
lagrangian	Determines form of objection function in the linearized subproblems	YES
LU complete pivoting	LUSOL pivoting strategy	
LU partial pivoting	LUSOL pivoting strategy	
LU rook pivoting	LUSOL pivoting strategy	
major damping parameter	Prevents large relative changes between subproblem solutions	2.0
minor damping parameter	Limit change in x during linesearch	2.0
multiple price	Multiple pricing	1
partial price	Number of segments in partial pricing strategy	10
penalty parameter	Used in modified augmented Lagrangian	automatic
radius of convergence	controls final reduction of penalty parameter	0.01
scale all variables	Synonym to scale option 2	
scale linear variables	Synonym to scale option 1	
scale no	Synonym to scale option 0	
scale nonlinear variables	Synonym to scale option 2	
scale option	Scaling	1
scale yes	Synonym to scale option 1	
start assigned nonlinears	Starting strategy when there is no basis	SUPERBASIC

Option	Description	Default
verify constraint gradients	Synonym to verify level 2	
verify gradients	Synonym to verify level 3	
verify level	Controls verification of gradients	0
verify no	Synonym to verify level 0	
verify objective gradients	Synonym to verify level 1	
verify yes	Synonym to verify level 3	
weight on linear objective	Composite objective weight	0.0

5.26.6.5 Examples of GAMS/MINOS Option File

The following example illustrates the use of certain options that might be helpful for "difficult" models involving nonlinear constraints. Experimentation may be necessary with the values specified, particularly if the sequence of major iterations does not converge using default values.

```
* These options might be relevant for very nonlinear models.
Major damping parameter  0.2   * may prevent divergence.
Minor damping parameter  0.2   * if there are singularities
                               * in the nonlinear functions.
Penalty parameter       10.0   * or 100.0 perhaps-a value
                               * higher than the default.
Scale linear variables         * (This is the default.)
```

Conversely, nonlinearly constrained models that are very nearly linear may optimize more efficiently if some of the cautious defaults are relaxed:

```
* Suggestions for models with MILDLY nonlinear constraints
Completion   Full
Penalty parameter        0.0  * or 0.1 perhaps-a value
                              * smaller than the default.
                              * Scale one of the following
Scale all variables           * if starting point is VERY GOOD.
Scale linear variables        * if they need it.
Scale No                      * otherwise.
```

Most of the options should be left at their default values for any given model. If experimentation is necessary, we recommend changing just one option at a time.

5.26.7 Special Notes

5.26.7.1 Modeling Hints

Unfortunately, there is no guarantee that the algorithm just described will converge from an arbitrary starting point. The concerned modeler can influence the likelihood of convergence as follows:

- Specify initial activity levels for the nonlinear variables as carefully as possible (using the GAMS suffix `.L`).
- Include sensible upper and lower bounds on all variables.
- Specify a *Major damping parameter* that is lower than the default value, if the problem is suspected of being highly nonlinear
- Specify a *Penalty parameter* ρ that is higher than the default value, again if the problem is highly nonlinear.

In rare cases it may be safe to request the values $\lambda_k = 0$ and $\rho = 0$ for all subproblems, by specifying *Lagrangian=No*. However, convergence is much more likely with the default setting, *Lagrangian=Yes*. The initial estimate of the Lagrange multipliers is then $\lambda_0 = 0$, but for later subproblems λ_k is taken to be the Lagrange multipliers associated with the (linearized) nonlinear constraints at the end of the previous major iteration.

For the first subproblem, the default value for the penalty parameter is $\rho = 100.0/m_1$ where m_1 is the number of nonlinear constraints. For later subproblems, ρ is reduced in stages when it appears that the sequence $\{x_k, \lambda_k\}$ is converging. In many cases it is safe to specify $\lambda = 0$, particularly if the problem is only mildly nonlinear. This may improve the overall efficiency.

5.26.7.2 Storage

GAMS/MINOS uses one large array of memory for most of its workspace. The implementation places no fixed limit on the size of a problem or on its shape (many constraints and relatively few variables, or *vice versa*). In general, the limiting factor will be the amount of physical memory available on a particular machine, and the amount of computation time one is willing to spend.

Some detailed knowledge of a particular model will usually indicate whether the solution procedure is likely to be efficient. An important quantity is m, the total number of general constraints in (2) and (3). The amount of workspace required by GAMS/MINOS is roughly $100m$ doubles, or $800m$ bytes for workspace. A further 300K bytes, approximately, are needed for the program itself, along with buffer space for several files. Very roughly, then, a model with m general constraints requires about $(m + 300)$ K bytes of memory.

Another important quantity is n, the total number of variables in x and y. The above comments assume that n is not much larger than m, the number of constraints. A typical ratio for n/m is 2 or 3.

If there are many nonlinear variables (i.e., if n_1 is large), much depends on whether the objective function or the constraints are highly nonlinear or not. The degree of nonlinearity affects s, the number of superbasic variables. Recall that s is zero for purely linear problems. We know that s need never be larger than $n_1 + 1$. In practice, s is often very much less than this upper limit.

In the quasi-Newton algorithm, the dense triangular matrix R has dimension s and requires about $s^2/2$ words of storage. If it seems likely that s will be very large, some aggregation or reformulation of the problem should be considered.

5.26.8 The GAMS/MINOS Log File

MINOS writes different logs for LPs, NLPs with linear constraints, and NLPs with non-linear constraints. In this section, a sample log file is shown for each case, and the messages that appear are explained.

5.26.8.1 Linear Programs

MINOS uses a standard two-phase simplex method for LPs. In the first phase, the sum of the infeasibilities at each iteration is minimized. Once feasibility is attained, MINOS switches to phase 2 where it minimizes (or maximizes) the original objective function. The different objective functions are called the phase 1 and phase 2 objectives. Notice that the marginals in phase 1 are with respect to the phase 1 objective. This means that if MINOS interrupts in phase 1, the marginals are "wrong" in the sense that they do not reflect the original objective.

The log for the problem **TURKPOW** is as follows:

The first line that is written by MINOS is the version string: `GAMS/MINOS Aug 18, 2010 23.5.2 WIN 19143.19383 VS8 x86/MS Windows` This line identifies which version of the MINOS libraries and links you are using, and is only to be deciphered by GAMS support personnel.

After some advertisement text we see the amount of work space (i.e. memory) that is allocated: *1.60 Mb*. When MINOS is loaded, the amount of memory needed is first estimated. This estimate is based on

statistics like the number of rows, columns and non-zeros. This amount of memory is then allocated and the problem loaded into MINOS.

The columns have the following meaning:

Itn

Iteration number.

ninf

Number of infeasibilities. If nonzero the current iterate is still infeasible.

sinf

The sum of the infeasibilities. This number is minimized during Phase I. Once the model is feasible this number is zero.

objective

The value of the objective function: $z = \sum c_i x_i$. In phase II this number is maximized or minimized. In phase I it may move in the wrong direction.

The final line indicates the exit status of MINOS.

5.26.8.2 Linearly Constrained NLP's

The log is basically the same as for linear models. The only difference is that not only matrix rows and columns need to be loaded, but also instructions for evaluating functions and gradients.

The log for the problem **WEAPONS** is as follows:

Two sets of iterations, *major* and *minor*, are now reported. A description of the various columns present in this log file follows:

Major

A major iteration involves linearizing the nonlinear constraints and performing a number of minor iterations on the resulting subproblem. The objective for the subproblem is an augmented Lagrangian, not the true objective function.

minor

The number of minor iterations performed on the linearized subproblem. If it is a simple number like 90, then the subproblem was solved to optimality. Here, $2T$ means that the subproblem was terminated. In general the T is not something to worry about. Other possible flags are I and U, which mean that the subproblem was infeasible or unbounded. MINOS may have difficulty if these keep occurring.

step

The step size taken towards the solution suggested by the last major iteration. Ideally this should be 1.0, especially near an optimum. If the subproblem solutions are widely different, MINOS may reduce the step size under control of the *Major Damping parameter*.

objective

The objective function for the original nonlinear program.

Feasible

Primal infeasibility, indicating the maximum non-linear constraint violation.

Optimal

The maximum dual infeasibility, measured as the maximum departure from complementarity. If we call d_j the reduced cost of variable x_j, then the dual infeasibility of x_j is $d_j \times \min\{x_j - \ell_j, 1\}$ or $-d_j \times \min\{u_j - x_j, 1\}$ depending on the sign of d_j.

nsb

Number of superbasics. If the model is feasible this number cannot exceed the superbasic limit, which may need to be reset to a larger number if the numbers in this column become larger.

ncon

The number of times MINOS has evaluated the nonlinear constraints and their derivatives.

penalty

The current value of the penalty parameter in the augmented Lagrangian (the objective for the subproblems). If the major iterations appear to be converging, MINOS will decrease the penalty parameter. If there appears to be difficulty, such as unbounded subproblems, the penalty parameter will be increased.

BSswp

Number of basis swaps: the number of $\begin{pmatrix} B & S \end{pmatrix}$ (i.e. basic vs. superbasic) changes.

Note: The **CAMCGE** model (like many CGE models or other almost square systems) can better be solved with the MINOS option *Start Assigned Nonlinears Basic*.

5.26.9 Detailed Description of MINOS Options

The following is an alphabetical list of the keywords that may appear in the GAMS/MINOS options file, and a description of their effect. Options not specified will take the default values shown.

check frequency *(integer)*: Controls frequency of linear constraint satisfaction test ↩

Every i^{th} iteration after the most recent basis factorization, a numerical test is made to see if the current solution x satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax+s = 0$ where s is the set of slack variables. To perform the numerical test, the residual vector $r = Ax + s$ is computed. If the largest component of r is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Range: {1, ..., ∞}

Default: 60

completion *(string)*: Completion level for subproblems (full/partial) ↩

When there are nonlinear constraints, this determines whether subproblems should be solved to moderate accuracy (partial completion) or to full accuracy (full completion). GAMS/MINOS implements the option by using two sets of convergence tolerances for the subproblems.
Use of partial completion may reduce the work during early major iterations, unless the Minor iterations limit is active. The optimal set of basic and superbasic variables will probably be determined for any given subproblem, but the reduced gradient may be larger than it would have been with full completion. An automatic switch to full completion occurs when it appears that the sequence of major iterations is converging. The switch is made when the nonlinear constraint error is reduced below 100 $*$ (Row tolerance), the relative change in $Lambda_k$ is 0.1 or less, and the previous subproblem was solved to optimality. Full completion tends to give better Langrange-multiplier estimates. It may lead to fewer major iterations, but may result in more minor iterations.

Default: FULL

value	meaning
FULL	Solve subproblems to full accuracy
PARTIAL	Solve subproblems to moderate accuracy

crash option *(integer)*: Controls the basis crash algorithm ↩

If a restart is not being performed, an initial basis will be selected from certain columns of the constraint matrix *(A I)*. The value of the parameter i determines which columns of A are eligible. Columns of I are used to fill gaps where necessary. If $i > 0$, three passes are made through the relevant columns of A, searching for a basis matrix that is essentially triangular. A column is assigned to pivot on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis). Pass 1 selects pivots from free columns (corresponding to variables with no upper and lower bounds). Pass 2 requires pivots to be in rows associated with equality (=E=) constraints. Pass 3 allows the pivots to be in inequality rows. For remaining (unassigned) rows, the associated slack variables are inserted to complete the basis.

Default: 3

value	meaning
0	Initial basis will be a slack basis

value	meaning
1	All columns are eligible
2	Only linear columns are eligible
3	Columns appearing nonlinearly in the objective are not eligible
4	Columns appearing nonlinearly in the constraints are not eligible

crash tolerance *(real)*: Allow crash procedure to ignore small elements in eligible columns ↩

The *Crash tolerance r* allows the starting procedure *CRASH* to ignore certain small nonzeros in each column of A. If a_{max} is the largest element in column j, other nonzeros a_{ij} in the column are ignored if $|a_{ij}| < a_{max} * r$. To be meaningful, the parameter r should be in the range $0 <= r < 1$. When $r > 0.0$ the basis obtained by *CRASH* may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of A and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems. For example, suppose the first m columns of A are the matrix shown under LU factor tolerance; i.e., a tridiagonal matrix with entries -1, 4, -1. To help *CRASH* choose all m columns for the initial basis, we could specify *Crash tolerance r* for some value of $r > 0.25$.

Range: [0, 1.0]

Default: 0.1

debug level *(integer)*: Controls amount of debug information written ↩

This causes various amounts of information to be output. Most debug levels will not be helpful to GAMS users, but they are listed here for completeness. Note that you will need to use the GAMS statement `OPTION SYSOUT=on;` to echo the MINOS listing to the GAMS listing file.

- **debug level 0**
  No debug output.
- **debug level 2**(or more)
  Output from *M5SETX* showing the maximum residual after a row check.
- **debug level 40**
  Output from *LU8RPC* (which updates the LU factors of the basis matrix), showing the position of the last nonzero in the transformed incoming column.
- **debug level 50**
  Output from *LU1MAR* (which updates the LU factors each refactorization), showing each pivot row and column and the dimensions of the dense matrix involved in the associated elimination.
- **debug level 100**
  Output from *M2BFAC* and *M5LOG* listing the basic and superbasic variables and their values at every iteration.

Default: 0

expand frequency *(integer)*: Setting for anti-cycling mechanism ↩

This option is part of an anti-cycling procedure designed to guarantee progress even on highly degenerate problems. For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose the specified feasibility tolerance is *delta* and the expand frequency is k. Over a period of k iterations, the tolerance actually used by GAMS/MINOS increases from *0.5*delta* to *delta* (in steps *0.5*delta/k*). For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is

at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced. At least every k iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing k helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see Pivot tolerance).

Range: {1, ..., ∞}

Default: `10000`

factorization frequency *(integer)*: Number of iterations between basis factorizations ↩

At most i basis updates will occur between factorizations of the basis matrix. With linear programs, basis updates usually occur at every iteration. The default i is reasonable for typical problems. Higher values up to $i = 200$ (say) may be more efficient on problems that are extremely sparse and well scaled. When the objective function is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the Check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be re-factorized before the limit of i updates is reached. When the constraints are nonlinear, the Minor iterations limit will probably preempt i.

Range: {1, ..., ∞}

Default: `100`

feasibility tolerance *(real)*: Feasibility tolerance for linear constraints ↩

When the constraints are linear, a feasible solution is one in which all variables, including slacks, satisfy their upper and lower bounds to within the absolute tolerance r. (Since slacks are included, this means that the general linear constraints are also satisfied within r.) GAMS/MINOS attempts to find a feasible solution before optimizing the objective function. If the sum of infeasibilities cannot be reduced to zero, the problem is declared infeasible. Let *SINF* be the corresponding sum of infeasibilities. If *SINF* is quite small, it may be appropriate to raise r by a factor of 10 or 100. Otherwise, some error in the data should be suspected. If *SINF* is not small, there may be other points that have a significantly smaller sum of infeasibilities. GAMS/MINOS does not attempt to find a solution that minimizes the sum. If *Scale option* = 1 or 2, feasibility is defined in terms of the scaled problem (since it is then more likely to be meaningful). A nonlinear objective function *F(x)* will be evaluated only at feasible points. If there are regions where *F(x)* is undefined, every attempt should be made to eliminate these regions from the problem. For example, for a function *F(x) = sqrt(x1)+log(x2)*, it should be essential to place lower bounds on both variables. If *Feasibility tolerance* = 10^{-6}, the bounds $x_1 > 10^{-5}$ and $x_2 > 10^{-4}$ might be appropriate. (The log singularity is more serious; in general, keep variables as far away from singularities as possible.) If the constraints are nonlinear, the above comments apply to each major iteration. A feasible solution satisfies the current linearization of the constraints to within the tolerance r. The associated subproblem is said to be feasible. As for the objective function, bounds should be used to keep x more than r away from singularities in the constraint functions *f(x)*. At the start of major iteration k, the constraint functions $f(x_k)$ are evaluated at a certain point x_k. This point always satisfies the relevant bounds ($l < x_k < u$), but may not satisfy the general linear constraints. During the associated minor iterations, *F(x)* and *f(x)* will be evaluated only at points x that satisfy the bound and the general linear constraints (as well as the linearized nonlinear constraints). If a subproblem is infeasible, the bounds on the linearized constraints are relaxed temporarily, in several stages. Feasibility with respect to the nonlinear constraints themselves is measured against the Row tolerance (not against r). The relevant test is made at the start of a major iteration.

Default: `1.0e-6`

hessian dimension *(integer)*: Size of Hessian matrix ↩

This specifies that an $r*r$ triangular matrix R is to be available for use by the quasi-Newton algorithm. The matrix R approximates the reduced Hessian in that R^TR approximates Z^THZ. Suppose there are s superbasic variables at a particular iteration. Whenever possible, r should be greater than s. If $r > s$, the first s columns of R will be used to approximate the reduced Hessian in the normal manner. If there are no further changes to the set of superbasic variables, the rate of convergence will ultimately be superlinear. If $r < s$, a matrix of the form

$R = diag(R_r, D)$

will be used to approximate the reduced Hessian, where R_r is an $r * r$ upper triangular matrix and D is a diagonal matrix of order s - r. The rate of convergence will no longer be superlinear (and may be arbitrarily slow). The storage required is of the order *sqr(r)/2*, i.e. quadratic in r. In general, r should be a slight over-estimate of the final number of superbasic variables, whenever storage permits. It need never be larger than $n_1 + 1$, where n_1 is the number of nonlinear variables. For many problems it can be much smaller than n_1. If *Superbasics limit s* is specified, the default value of r is the same number, s (and conversely). This is a safeguard to ensure super-linear convergence wherever possible. If neither r nor s is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: {1, ..., ∞}

Default: `1`

iterations limit *(integer)*: Minor iteration limit ↩

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the reduced-gradient method). This option, if set, overrides the GAMS *ITERLIM* specification. If $i = 0$, no minor iterations are performed, but the starting point is tested for both feasibility and optimality.

Default: `GAMS iterlim`

lagrangian *(string)*: Determines form of objection function in the linearized subproblems ↩

This determines the form of the objective function used for the linearized subproblems. The default value *yes* is highly recommended. The *Penalty parameter* value is then also relevant. If *No* is specified, the nonlinear constraint functions will be evaluated only twice per major iteration. Hence this option may be useful if the nonlinear constraints are very expensive to evaluate. However, in general there is a great risk that convergence may not occur.

Default: `YES`

value	meaning
`NO`	Nondefault value (not recommended)
`YES`	Default value (recommended)

linesearch tolerance *(real)*: Controls accuracy of steplength selected ↩

For nonlinear problems, this controls the accuracy with which a steplength *alpha* is located in the one-dimensional problem

minimize *F(x+alpha∗p)*
subject to *0 < alpha <= beta*

A linesearch occurs on most minor iterations for which x is feasible. (If the constraints are nonlinear, the function being minimized is the augmented Lagrangian.) r must be a real value in the range $0.0 < r < 1.0$. The default value $r = 0.1$ requests a moderately accurate search. It should be satisfactory in most cases. If the nonlinear functions are cheap to evaluate, a more accurate search may be appropriate: try $r = 0.01$ or $r = 0.001$. The number of iterations should decrease, and this will reduce total run time if there are many linear or nonlinear constraints. If the nonlinear function are expensive to evaluate, a less accurate search may be appropriate; try $r = 0.5$ or perhaps $r = 0.9$. (The number of iterations will probably increase but the total number of function evaluations may decrease enough to compensate.)

Range: [`0`, `1.0`]

Default: `0.1`

log frequency *(integer)*: Controls iteration logging to listing file ↩

In general, one line of the iteration log is printed every i^{th} minor iteration. A heading labels the printed items, which include the current iteration number, the number and sum of feasibilities (if any), the subproblem objective value (if feasible), and the number of evaluations of the nonlinear functions. A value such as $i = 10, 100$ or larger is suggested for those interested only in the final solution. *Log frequency 0* may be used as shorthand for *Log frequency 99999*. If *Print level* > 0, the default value of i is 1. If *Print level* $= 0$, the default value of i is 100. If *Print level* $= 0$ and the constraints are nonlinear, the minor iteration log is not printed (and the *Log frequency* is ignored). Instead, one line is printed at the beginning of each major iteration.

Range: {`1`, ..., ∞}

Default: `100`

LU complete pivoting *(no value)*: LUSOL pivoting strategy ↩

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say < 2.0).

LU density tolerance *(real)*: When to use dense factorization ↩

The density tolerance is used during LUSOL's basis factorization B=LU. Columns of L and rows of U are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds this tolerance, the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense LU procedure. Raising the tolerance towards 1.0 may give slightly sparser factors, with a slight increase in factorization time.

Range: [`0`, `1.0`]

Default: `0.5`

LU factor tolerance *(real)*: Trade-off between stability and sparsity in basis factorization ↩

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during factorization. The value r specified must satisfy $r >= 1.0$.

- The default value $r = 100.0$ usually strikes a good compromise between stability and sparsity.

- For large and relatively dense problems, a larger value may give a useful improvement in sparsity without impairing stability to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to set r to a value smaller than the default in order to achieve stability.

Range: [`1.0`, ∞]

Default: `100.0`

LU partial pivoting *(no value)*: LUSOL pivoting strategy ↩

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say $<$ *2.0*).

LU rook pivoting *(no value)*: LUSOL pivoting strategy ↩

The LUSOL factorization implements a Markowitz-style search for pivots that locally minimize fill-in subject to a threshold pivoting stability criterion. The *rook* and *complete pivoting* options are more expensive than *partial pivoting* but are more stable and better at revealing rank, as long as the *LU factor tolerance* is not too large (say $<$ *2.0*).

LU singularity tolerance *(real)*: Protection against ill-conditioned basis matrices ↩

When the basis is refactorized, the diagonal elements of U are tested as follows: if $|U_{jj}| <= r$ or $|U_{jj}| < r * max_i |U_{ii}|$, the j^{th} column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart, or at the start of a major iteration.) In some cases, the Jacobian matrix may converge to values that make the basis very ill-conditioned, causing the optimization to progress very slowly (if at all). Setting r = *1.0*$^{-5}$, say, may help cause a judicious change of basis.

Default: `1.0e-11`

LU update tolerance *(real)*: Trade-off between stability and sparsity in basis updating ↩

This tolerance affects the stability and sparsity of the basis factorization $B = LU$ during updates. The value r specified must satisfy $r >= 1.0$.

- The default value r = *10.0* usually strikes a good compromise between stability and sparsity.
- For large and relatively dense problems, r = *25.0* (say) may give a useful improvement in sparsity without impairing stability to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to set r to a value smaller than the default in order to achieve stability.

Range: [`1.0`, ∞]

Default: `10.0`

major damping parameter *(real)*: Prevents large relative changes between subproblem solutions ↩

The parameter may assist convergence on problems that have highly nonlinear constraints. It is intended to prevent large relative changes between subproblem solutions *(x_k, $lambda_k$)* and *(x_{k+1}, $lambda_{k+1}$)*. For example, the default value 2.0 prevents the relative change in either x_k or $lambda_k$ from exceeding 200 percent. It will not be active on well behaved problems. The parameter is used to interpolate between the solutions at the beginning and end of each major iteration. Thus x_{k+1} and $lambda_{k+1}$ are changed to x_k + *sigma*(x_{k+1} - x_k)* and $lambda_k$ + *sigma*($lambda_{k+1}$ - $lambda_k$)* for some step-length *sigma* < *1*. In the case of nonlinear equations (where the number of constraints is the same as the number of variables) this gives a damped Newton method. This is a very crude control. If the sequence of major iterations does not appear to be converging, one should first re-run the problem with a higher Penalty parameter (say 10 or 100 times the default *rho*). (Skip this re-run in the case of nonlinear equations: there are no degrees of freedom and the value of *rho* is irrelevant.) If the subproblem solutions continue to change violently, try reducing *r* to 0.2 or 0.1 (say). For implementation reasons, the shortened step to *sigma* applies to the nonlinear variables *x*, but not to the linear variables *y* or the slack variables *s*. This may reduce the efficiency of the control.

Default: `2.0`

major iterations *(integer)*: Max number of major iterations ↩

The maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the nonlinear constraints, since in some cases the sequence of major iterations may not converge. The progress of the major iterations can be best monitored using *Print level 0* (the default).

Default: `50`

minor damping parameter *(real)*: Limit change in x during linesearch ↩

This parameter limits the change in *x* during a linesearch. It applies to all nonlinear problems, once a feasible solution or feasible subproblem has been found. A linesearch of the form

$$minimize_{alpha}\ F(x + alpha*p)$$

is performed over the range $0 < alpha <= beta$, where *beta* is the step to the nearest upper or lower bound on *x*. Normally, the first step length tried is $a_1 = min(1, beta)$. In some cases, such as $F(x) = ae^{bx}$ or $F(x) = ax^b$, even a moderate change in the components of *x* can lead to floating-point overflow. The parameter *r* is therefore used to define a limit

$$beta2 = r(1 + ||x||)/||p||$$

and the first evaluation of *F(x)* is at the potentially smaller steplength $alpha_1 = min(1, beta, beta2)$. Wherever possible, upper and lower bounds on *x* should be used to prevent evaluation of nonlinear functions at meaningless points. The *Minor damping parameter* provides an additional safeguard. The default value *r = 2.0* should not affect progress on well behaved problems, but setting *r = 0.1* or *0.01* may be helpful when rapidly varying functions are present. A good starting point may be required. An important application is to the class of nonlinear least squares problems. In cases where several local optima exist, specifying a small value for *r* may help locate an optimum near the starting point.

Default: `2.0`

minor iterations *(integer)*: Max number of minor iterations between linearizations of nonlinear constraints ↩

The the maximum number of feasible minor iterations allowed between successive linearizations of the nonlinear constraints. A moderate value (e.g., *20 <= i <= 50*) prevents excessive efforts being expended on early major iterations, but allows later subproblems to be solved to completion. The limit applies to both infeasible and feasible iterations. In some cases, a large number of iterations (say *K*) might be required to obtain a feasible subproblem. If good starting values are supplied for variables appearing nonlinearly in the constraints, it may be sensible to specify a limit $> K$, to allow the first major iteration to terminate at a feasible (and perhaps optimal) subproblem solution. If a good initial subproblem is arbitrarily interrupted by a small limit, the subsequent linearization may be less favorable than the first. In general it is unsafe to specify a value as small as *i = 1* or *2*. Even when an optimal solution has been reached, a few minor iterations may be needed for the corresponding subproblem to be recognized as optimal. The *Iteration limit* provides an independent limit on the total minor iterations (across all subproblems). If the constraints are linear, only the *Iteration limit* applies: the minor iterations value is ignored.

Default: `40`

multiple price *(integer)*: Multiple pricing ↩

Pricing refers to a scan of the current non-basic variables to determine which, if any, are eligible to become (super)basic. The multiple pricing parameter *k* controls the number of entering variables to choose: the *k* best non-basic variables are selected for admission to the set of (super)basic variables. The default *k = 1* is best for linear programs, since an optimal solution will have zero superbasic variables. *Warning* : If *k > 1*, GAMS/MINOS will use the reduced-gradient method rather than the simplex method, even on purely linear problems. The subsequent iterations do not correspond to the efficient minor iterations carried out by commercial linear programming systems using multiple pricing. (In the latter systems, the classical simplex method is applied to a tableau involving *k* dense columns of dimension *m*, and *k* is therefore limited for storage reasons typically to the range *2 <= k <= 7*.) GAMS/MINOS varies all superbasic variables simultaneously. For linear problems its storage requirements are essentially independent of *k*. Larger values of *k* are therefore practical, but in general the iterations and time required when *k > 1* are greater than when the simplex method is used (*k = 1*). On large nonlinear problems it may be important to set *k > 1* if the starting point does not contain many superbasic variables. For example, if a problem has 3000 variables and 500 of them are nonlinear, the optimal solution may well have 200 variables superbasic. If the problem is solved in several runs, it may be beneficial to use *k = 10* (say) for early runs, until it seems that the number of superbasics has leveled off. If *Multiple price k* is specified, it is also necessary to specify *Superbasic limit s* for some *s > k*.

Range: {`1`, ..., ∞}

Default: `1`

optimality tolerance *(real)*: Reduced gradient optimality check ↩

This is used to judge the size of the reduced gradients $d_j = g_j$ - pi^T a_j, where g_j is the gradient of the objective function corresponding to the j^{th} variable, a_j is the associated column of the constraint matrix (or Jacobian), and *pi* is the set of dual variables. By construction, the reduced gradients for basic variables are always zero. Optimality will be declared if the reduced gradients for nonbasic variables at their lower or upper bounds satisfy $d_j/||pi|| >=$ *-r* or $d_j/||pi|| <= r$ respectively, and if $d_j/||pi|| <= r$ for superbasic variables. The $||pi||$ is a measure of the size of the dual variables. It is included to make the tests independent of a scale factor on the objective function. The quantity actually used is defined by

sigma = sum(i, abs(pi(i))), ||pi|| = max{sigma/sqrt(m),1}

so that only large scale factors are compensated for. As the objective scale decreases, the optimality test tends to become an absolute (instead of a relative) test.

Default: `1.0e-6`

partial price *(integer)*: Number of segments in partial pricing strategy ↩

This parameter is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each pricing operation (when a nonbasic variable is selected to become basic or superbasic). When $i = 1$, all columns of the constraints matrix *(A I)* are searched. Otherwise, A_j and I are partitioned to give i roughly equal segments A_j, I_j ($j = 1$ to i). If the previous search was successful on A_{j-1}, I_{j-1}, the next search begins on the segments A_j, I_j. (All subscripts here are modulo i.) If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. (Several may be selected if multiple pricing has been specified.) If nothing is found, the search continues on the next segments A_{j+1}, I_{j+1} and so on. *Partial price t* (or *t/2* or *t/3*) may be appropriate for time-stage models having t time periods

Range: {1, ..., ∞}

Default: `10`

penalty parameter *(real)*: Used in modified augmented Lagrangian ↩

This specifies the value of *rho* in the modified augmented Lagrangian. It is used only when *Lagrangian = yes* (the default setting). For early runs on a problem with unknown characteristics, the default value should be acceptable. If the problem is known to be highly nonlinear, specify a large value, such as 10 times the default. In general, a positive value of *rho* may be necessary to ensure convergence, even for convex programs. On the other hand, if *rho* is too large, the rate of convergence may be unnecessarily slow. If the functions are not highly nonlinear or a good starting point is known, it will often be safe to specify *penalty parameter 0.0*. When solving a sequence of related problems, initially, use a moderate value for *rho* (such as the default) and a reasonably low *Iterations* and/or *major iterations limit*. If successive major iterations appear to be terminating with radically different solutions, the *penalty parameter* should be increased. (See also the *Major damping parameter*.) If there appears to be little progress between major iterations, it may help to reduce the *penalty parameter*.

Default: `automatic`

print level *(integer)*: Controls amount of information printed during optimization ↩

This varies the amount of information that will be output during optimization. *Print level 0* sets the default log and summary frequencies to 100. It is then easy to monitor the progress of the run. *Print level 1* (or more) sets the default log and summary frequencies to 1, giving a line of output for every minor iteration. *Print level 1* also produces basis statistics, i.e., information relating to LU factors of the basis matrix whenever the basis is re-factorized. For problems with nonlinear constraints, certain quantities are printed at the start of each major iteration. The option value is best thought of as a binary number of the form

Print level `JFLXB`

where each letter stands for a digit that is either 0 or 1. The quantities referred to are:

- **B** Basis statistics, as mentioned above
- **X** x_k, the nonlinear variables involved in the objective function or the constraints.
- **L** $lambda_k$, the Lagrange-multiplier estimates for the nonlinear constraints. (Suppressed if *Lagrangian=No*, since then $lambda_k = 0$.)
- **F** $f(x_k)$, the values of the nonlinear constraint functions.
- **J** $J(x_k)$, the Jacobian matrix.

To obtain output of any item, set the corresponding digit to 1, otherwise to 0. For example, *Print level 10* sets `X = 1` and the other digits equal to zero; the nonlinear variables will be printed each major iteration. If `J = 1`, the Jacobian matrix will be output column-wise at the start of each major iteration. Column j will be preceded by the value of the corresponding variable x_j and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if `J = 1`, there is no reason to specify `X = 1` unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

```
3 1.250000D+01 BS 1 1.00000D+00 4 2.00000D+00
```

which would mean that x_3 is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4. (Note: the GAMS/MINOS row numbers are usually different from the GAMS row numbers; see the Solution option.)

Default: `0`

radius of convergence *(real)*: controls final reduction of penalty parameter ↩

This determines when the penalty parameter *rho* will be reduced, assuming *rho* was initially positive. Both the nonlinear constraint violation (see *ROWERR* below) and the relative change in consecutive Lagrange multiplier estimates must be less than r at the start of a major iteration before *rho* is reduced or set to zero. A few major iterations later, full completion will be requested if not already set, and the remaining sequence of major iterations should converge quadratically to an optimum.

Default: `0.01`

row tolerance *(real)*: Accuracy requirement for nonlinear rows ↩

This specifies how accurately the nonlinear constraints should be satisfied at a solution. The default value is usually small enough, since model data is often specified to about this accuracy. Let *ROWERR* be the maximum component of the residual vector $f(x) + A_1 y - b_1$, normalized by the size of the solution. Thus

$$ROWERR = ||f(x) + A_1 y - b_1||_{inf}/(1 + XNORM)$$

where *XNORM* is a measure of the size of the current solution (x, y). The solution is considered to be feasible if $ROWERR <= r$. If the problem functions involve data that is known to be of low accuracy, a larger *Row tolerance* may be appropriate.

Default: `1.0e-6`

scale all variables *(no value)*: Synonym to scale option 2 ↩

scale linear variables *(no value)*: Synonym to scale option 1 ↩

scale no *(no value)*: Synonym to scale option 0 ↩

scale nonlinear variables *(no value)*: Synonym to scale option 2 ↩

scale option *(integer)*: Scaling ↩

Scale Yes sets the default. (*Caution*: If all variables are nonlinear, *Scale Yes* unexpectedly does nothing, because there are no linear variables to scale). *Scale No* suppresses scaling (equivalent to *Scale Option 0*). If nonlinear constraints are present, *Scale option 1* or *0* should generally be tried at first. *Scale option 2* gives scales that depend on the initial Jacobian, and should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear.

Default: `1`

value	meaning
0	No scaling If storage is at a premium, this option should be used.
1	Scale linear variables Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see [5]). This will sometimes improve the performance of the solution procedures. *Scale linear variables* is an equivalent option.
2	Scale linear + nonlinear variables All constraints and variables are scaled by the iterative procedure. Also, a certain additional scaling is performed that may be helpful if the right-hand side b or the solution x is large. This takes into account columns of *(A I)* that are fixed or have positive lower bounds or negative upper bounds. *Scale nonlinear variables* or *Scale all variables* are equivalent options.

scale print *(no value)*: Print scaling factors ↩

This causes the row-scales *r(i)* and column-scales *c(j)* to be printed. The scaled matrix coefficients are $\hat{a}_{ij} = a_{ij}c(j)/r(i)$. The scaled bounds on the variables and slacks are $\hat{l}_j = l_j/c(j)$ and $\hat{u}_j = u_j/c(j)$, where $c(j) = r(j - n)$ if $j > n$. If a Scale option has not already been specified, *Scale print* sets the default scaling.

scale print tolerance *(real)*: Scale print flag and set tolerance ↩

See *Scale Tolerance*. This option also turns on printing of the scale factors.

Range: [0, 1.0]

Default: 0.9

scale tolerance *(real)*: Scale tolerance ↩

All forms except *Scale option* may specify a tolerance r where $0 < r < 1$ (for example: *Scale Print Tolerance = 0.99*). This affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$rho_j = max_i\ |a_{ij}|/min_i\ |a_{ij}|\ \ (a_{ij} \neq 0)$$

If $max_j\ rho_j$ is less than r times its previous value, another scaling pass is performed to adjust the row and column scales. Raising r from 0.9 to 0.99 (say) usually increases the number of scaling passes through A. At most 10 passes are made. If a *Scale option* has not already been specified, *Scale tolerance* sets the default scaling.

Range: [0, 1.0]

Default: 0.9

scale yes *(no value)*: Synonym to scale option 1 ↩

solution *(string)*: Prints MINOS solution ↩

This controls whether or not GAMS/MINOS prints the final solution obtained. There is one line of output for each constraint and variable. The lines are in the same order as in the GAMS solution, but the constraints and variables labeled with internal GAMS/MINOS numbers rather than GAMS names. (The numbers at the left of each line are GAMS/MINOS column numbers, and those at the right of each line in the rows section are GAMS/MINOS slacks.) The GAMS/MINOS solution may be useful occasionally to interpret certain messages that occur during the optimization, and to determine the final status of certain variables (basic, superbasic or nonbasic).

Default: NO

value	meaning
NO	Turn off printing of solution
YES	Turn on printing of solution

start assigned nonlinears *(string)*: Starting strategy when there is no basis ↩

This option affects the starting strategy when there is no basis (i.e., for the first solve or when the GAMS statement *option bratio = 1* is used to reject an existing basis.) This option applies to all nonlinear variables that have been assigned nondefault initial values and are strictly between their bounds. Free variables at their default value of zero are excluded. Let K denote the number of such assigned nonlinear variables.

Default: SUPERBASIC

value	meaning
SUPERBASIC	Default Specify *superbasic* for highly nonlinear models, as long as K is not too large (say $K < 100$) and the initial values are good.
BASIC	Good for square systems Specify *basic* for models that are essentially square (i.e., if there are about as many general constraints as variables).
NONBASIC	Specify *nonbasic* if K is large.
ELIGIBLE FOR CRASH	Specify *Eligible for Crash* for linear or nearly linear models. The nonlinear variables will be treated in the manner described under *Crash* option.

subspace tolerance *(real)*: Determines when nonbasics becomes superbasic ↩

This controls the extent to which optimization is confined to the current set of basic and superbasic variables (Phase 4 iterations), before one or more nonbasic variables are added to the superbasic set (Phase 3). The parameter r must be a real number in the range $0 < r <= 1$. When a nonbasic variable x_j is made superbasic, the resulting norm of the reduced-gradient vector (for all superbasics) is recorded. Let this be $||Z^T\ g_0||$. (In fact, the norm will be $|d_j|$, the size of the reduced gradient for the new superbasic variable x_j. Subsequent Phase 4 iterations will continue at least until the norm of the reduced-gradient vector satisfies $||Z^T\ g_0|| <= r||Z^T\ g_0||$ is the size of the largest reduced-gradient component among the superbasic variables.) A smaller value of r is likely to increase the total number of iterations, but may reduce the number of basic changes. A larger value such as $r = 0.9$ may sometimes lead to improved overall efficiency, if the number of superbasic variables has to increase substantially between the starting point and an optimal solution. Other convergence tests on the change in the function being minimized and the change in the variables may prolong Phase 4 iterations. This helps to make the overall performance insensitive to larger values of r.

Range: [0, 1.0]

Default: 0.5

summary frequency *(integer)*: Controls iteration logging to summary (log file) ↩

A brief form of the iteration log is output to the MINOS summary file (i.e. the GAMS log file). In general, one line is output every i^{th} minor iteration. In an interactive environment, the output normally appears at the terminal and allows a run to be monitored. If something looks wrong, the run can be manually terminated. The summary frequency controls summary output in the same way as the log frequency controls output to the print file. A value such as

Summary Frequency = 10 or *100* is often adequate to determine if the solve is making progress. If *Print level = 0*, the default value of *Summary Frequency* is 100. If *Print level > 0*, the default value of *Summary Frequency* is 1. If *Print level = 0* and the constraints are nonlinear, the *Summary Frequency* is ignored. Instead, one line is printed at the beginning of each major iteration.

Range: {1, ..., ∞}

Default: 100

superbasics limit *(integer)*: Maximum number of superbasics ↩

This places a limit on the storage allocated for superbasic variables. Ideally, the parameter i should be set slightly larger than the number of degrees of freedom expected at an optimal solution. For linear problems, an optimum is normally a basic solution with no degrees of freedom. (The number of variables lying strictly between their bounds is not more than m, the number of general constraints.) The default value of i is therefore 1. For nonlinear problems, the number of degrees of freedom is often called the number of independent variables. Normally, i need not be greater than $n_1 + 1$, where n_1 is the number of nonlinear variables. For many problems, i may be considerably smaller than n_1. This will save storage if n_1 is very large. This parameter also sets the Hessian dimension, unless the latter is specified explicitly (and conversely). If neither parameter is specified, GAMS chooses values for both, using certain characteristics of the problem.

Range: {1, ..., ∞}

Default: 1

unbounded objective value *(real)*: Determines when a problem is called unbounded ↩

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$minimize_{alpha}\ F(x + alpha*p)$$

If $|F|$ exceeds the parameter r or if *alpha* exceeds the *unbounded stepsize*, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in *F(x)* may be manifested by a floating-point overflow (during the evaluation of *F(x + alpha∗p)*, before the test against r can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the *Minor damping parameter*.

Default: 1.0e20

unbounded step size *(real)*: Determines when a problem is called unbounded ↩

This parameter is intended to detect unboundedness in nonlinear problems. During a line search of the form

$$minimize_{alpha}\ F(x + alpha*p)$$

If *alpha* exceeds the parameter r or if $|F|$ exceeds the *unbounded objective value*, iterations are terminated with the exit message PROBLEM IS UNBOUNDED (OR BADLY SCALED). If singularities are present, unboundedness in *F(x)* may be manifested by a floating-point overflow (during the evaluation of *F(x + alpha∗p)*, before the test against r can be made. Unboundedness is best avoided by placing finite upper and lower bounds on the variables. See also the *Minor damping parameter*.

Default: 1.0e10

verify constraint gradients *(no value)*: Synonym to verify level 2 ↩

verify gradients *(no value)*: Synonym to verify level 3 ↩

verify level *(integer)*: Controls verification of gradients ↩

This option controls the finite-difference check performed by MINOS on the gradients (first derivatives) computed by GAMS for each nonlinear function. GAMS computes gradients analytically, and the values obtained should normally be taken as correct.

Default: `0`

value	meaning
`0`	Cheap test Only a cheap test is performed, requiring three evaluations of the nonlinear objective and two evaluations of the nonlinear constraints. *Verify No* is an equivalent option.
`1`	Check objective A more reliable check is made on each component of the objective gradient. *Verify objective gradients* is an equivalent option.
`2`	Check Jacobian A check is made on each column of the Jacobian matrix associated with the nonlinear constraints. *Verify constraint gradients* is an equivalent option.
`3`	Check objective and Jacobian A detailed check is made on both the objective and the Jacobian. *Verify*, *Verify gradients*, and *Verify Yes* are equivalent options.
`-1`	No check

verify no *(no value)*: Synonym to verify level 0 ↩

verify objective gradients *(no value)*: Synonym to verify level 1 ↩

verify yes *(no value)*: Synonym to verify level 3 ↩

weight on linear objective *(real)*: Composite objective weight ↩

This option controls the so-called composite objective technique. If the first solution obtained is infeasible, and if the objective function contains linear terms, and the objective weight w is positive, this technique is used. While trying to reduce the sum of infeasibilities, the method also attempts to optimize the linear portion of the objective. At each infeasible iteration, the objective function is defined to be

$$minimize_x\ sigma{*}w(c^T x)\ +\ (sum\ of\ infeasibilities)$$

where *sigma = 1* for minimization and *sigma = -1* for maximization and c is the linear portion of the objective. If an optimal solution is reached while still infeasible, w is reduced by a factor of 10. This helps to allow for the possibility that the initial w is too large. It also provides dynamic allowance for the fact the sum of infeasibilities is tending towards zero. The effect of w is disabled after five such reductions, or if a feasible solution is obtained. This option is intended mainly for linear programs. It is unlikely to be helpful if the objective function is nonlinear.

Default: `0.0`

5.26.10 Exit Conditions

This section discusses the exit codes printed by MINOS at the end of the optimization run.

EXIT – Optimal solution found

This is the message we all hope to see! It is certainly preferable to every other message. Of course it is quite possible that there are model formulation errors, which will (hopefully) lead to unexpected objective values and solutions. The reported optimum may be a local, and other much better optima may exist.

EXIT – The problem is infeasible

When the constraints are linear, this message can probably be trusted. Feasibility is measured with respect to the upper and lower bounds on the variables (the bounds on the slack variables correspond to the GAMS constraints). The message tells us that among all the points satisfying the general constraints $Ax + s = 0$, there is apparently no point that satisfies the bounds on x and s. Violations as small as the `FEASIBILITY TOLERANCE` are ignored, but at least one component of x or s violates a bound by more than the tolerance.

Note: Although the objective function is the sum of the infeasibilities, this sum will usually not have been *minimized* when MINOS recognizes the situation and exits. There may exist other points that have significantly lower sum of infeasibilities.

When nonlinear constraints are present, infeasibility is *much* harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation MINOS may relax the bounds on the slacks associated with nonlinear rows. This perturbation is allowed a fixed number of times. Normally a feasible point will be obtained relative to the perturbed constraints, and optimization can continue on the subproblem. However, if several consecutive subproblems require such perturbation, the problem is terminated and declared `INFEASIBLE`. Clearly this is an ad-hoc procedure. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

EXIT – The problem is unbounded (or badly scaled)

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can apparently be increased by an arbitrary amount without causing a basic variable to violate a bound. A simple way to diagnose such a model is to add an appropriate bound on the objective variable.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the `SCALE` option.

For nonlinear problems, MINOS monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (as judged by the `UNBOUNDED` parameter), the problem is terminated and declared `UNBOUNDED`. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

EXIT – User Interrupt

This exit code is a result of interrupting the optimization process by hitting `Ctrl-C`. Inside the IDE this is accomplished by hitting the `Interrupt` button. The solver will finish its current iteration, and return the current solution. This solution can be still intermediate infeasible or intermediate non-optimal.

EXIT – Too many iterations

The iteration limit was hit. Either the ITERLIM, or in some cases the ITERATIONS LIMIT or MAJOR ITERATION LIMIT was too small to solve the problem. In most cases increasing the GAMS ITERLIM option will resolve the problem. In other cases you will need to create a MINOS option file and set a MAJOR ITERATION LIMIT. The listing file will give more information regarding what limit was hit.

The GAMS iteration limit is displayed in the listing file under the section SOLVE SUMMARY. If the ITERLIM was hit, the message will look like:

```
ITERATION COUNT, LIMIT        10001      10000
```

EXIT – Resource Interrupt

The solver hit the RESLIM resource limit, which is a time limit. It returned the solution at that time, which may be still intermediate infeasible or intermediate non-optimal.

The GAMS resource limit is displayed in the listing file under the section SOLVE SUMMARY. If the GAMS RESLIM was hit, the message will look like:

```
RESOURCE USAGE, LIMIT       1001.570      1000.000
```

EXIT – The objective has not changed for many iterations

This is an emergency measure for the rare occasions when the solution procedure appears to be *cycling*. Suppose that a zero step is taken for several consecutive iterations, with a basis change occurring each time. It is theoretically possible for the set of basic variables to become the same as they were one or more iterations earlier. The same sequence of iterations would then occur *ad infinitum*.

EXIT – The Superbasics Limit is too small

The problem appears to be more non-linear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and an increase in the number of superbasics is needed. You can use the option SUPERBASICS LIMIT to increase the limit. See also option HESSIAN DIMENSION.

EXIT – Constraint and objective function could not be calculated

The function or gradient could not be evaluated. For example, this can occur when MINOS attempts to take a log or a square root of a negative number, when evaluating the expression x^y with $x \leq 0$, or when evaluating *exp(x)* for large x and the result is too large to store. The listing file will contain details about where and why evaluation errors occur. To fix this problem, add bounds so that all functions can be properly evaluated. E.g. if you have an expression x^y, add a lower bound X.LO=0.001 to your model.

In many cases the algorithm can recover from function evaluation errors, for instance if they happen in the line search while evaluating trial points. The message above appears in cases where the algorithm can not recover, and requires a reliable function or gradient evaluation.

EXIT – Function evaluation error limit

The limit of allowed function evaluation errors DOMLIM has been exceeded.

Function evaluation errors occur when MINOS attempts to evaluate the objective and/or constraints at points where these functions or their derivatives are not defined or where overflows occur. Some examples are given above. The listing file contains details about these errors.

The quick and dirty way to solve this is to increase the GAMS DOMLIM setting, but in general it is better to add bounds. E.g. if you have an expression x^y, then add a bound X.LO=0.001 to your model.

EXIT – The current point can not be improved

The line search failed. This can happen if the model is very nonlinear or if the functions are nonsmooth (using a DNLP model type).

If the model is non-smooth, consider a smooth approximation. It may be useful to check the scaling of the model and think more carefully about choosing a good starting point. Sometimes it can help to restart the model with full scaling turned on:

```
option nlp=minos;
solve m minimizing z using nlp; // this one gives "current point cannot be improved"
file fopt /minos.opt/;          // write option file
putclose fopt "scale all variables"/;
m.optfile=1;
solve m minimizing z using nlp; // solve with "scale all variables"
```

EXIT – Numerical error in trying to satisfy the linear constraints (or the linearized constraints)
The basis is very ill-conditioned.

This is often a scaling problem. Try the full scaling option *scale all variables* or, better yet, rescale the model in GAMS via the .scale suffix or by choosing more appropriate units for variables and RHS values.

EXIT – Not enough storage to solve the model

The amount of workspace allocated for MINOS to solve the model is insufficient. Consider increasing the GAMS option workfactor to increase the workspace allocated for MINOS to use. The listing file and log file (screen) will contain information about the current workspace allocation. Increasing the workfactor by 50% is a reasonable strategy.

EXIT– Systems error

This is a catch all return for other serious problems. Check the listing file for more messages. If needed rerun the model with OPTION SYSOUT=ON;.

5.27 MOSEK

MOSEK ApS, C/O Symbion Science Park, Fruebjergvej 3, Box 16, 2100 Copenhagen Ø, Denmark

5.27.1 Introduction

MOSEK is a software package for the solution of linear, mixed-integer linear, quadratic, mixed-integer quadratic, quadratically constraint, conic, and semidefinite mathematical optimization problems. MOSEK is particularly well suited for solving large-scale linear, convex quadratically constraint, and conic programs using an extremely efficient interior point algorithm.

These problem classes can be solved using an appropriate optimizer built into MOSEK. All the optimizers available in MOSEK are built for the solution of large-scale sparse problems. Current optimizers include:

- Interior-point optimizers for continuous and conic problems
- Simplex optimizer for linear problems
- Branch-and-cut optimizer for mixed-integer linear, quadratic, and conic problems

5.27.1.1 Licensing

Licensing of GAMS/MOSEK is similar to other GAMS solvers. MOSEK is licensed in two different ways:

- **GAMS/MOSEK:**
  All model types.
- **GAMS/MOSEK Solver Link:**
  Users must have a separate, licensed MOSEK system. For users who wish to use MOSEK within GAMS and also in other environments.

Attention

The free bare-bone link mode (previously GAMS/OSIMOSEK) that allowed to solve LP and MIP when the user had a separate MOSEK license installed has been removed. If you relied on using this bare-bone link option, then do not hesitate to contact sales@mosek.com to arrange for a GAMS/MOSEK Solver Link license.

For information regarding MOSEK standalone or interfacing MOSEK with other applications contact sales@mosek.com.

5.27.1.2 Solving Problems in Parallel

MOSEK can exploit multiple CPUs (or a CPU with multiple cores) to solve an optimization problem when using the interior-point or the mixed-integer optimizers.

This implies that whenever the MOSEK interior-point optimizer should solve an optimization problem, then it will try to divide the work so each CPU gets a share of the work. The user decides how many CPUs MOSEK should exploit. Unfortunately, it is not always easy to divide the work. Also some of the coordination work must occur in sequential. Therefore, the speed-up obtained when using multiple CPUs is highly problem dependent. However, as a rule of thumb, if the problem solves very quickly, i.e., in less than 60 seconds, then there is no advantage in using the parallel option.

The parameter MSK_IPAR_NUM_THREADS sets the number of threads (and therefore the number of CPU's) that the optimizer will use.

5.27.1.3 Infeasible/Unbounded Models

Farkas Certificates

MOSEK determines if either the primal or the dual problem is infeasible by means of a Farkas certificate. In such a case MOSEK returns a certificate indicating primal or dual infeasibility.

The primal infeasibility certificate indicates a primal infeasible model. For a minimization problem

$$\begin{array}{ll} \text{minimize} & \langle c, x \rangle \\ \text{subject to} & Ax = b, \\ & x \geq 0, \end{array}$$

the primal infeasibility certificate is the solution y satisfying $A'y \leq 0$ and $\langle b, y \rangle > 0$.

A primal infeasibility certificate is reported in the marginal records of the variables and equations. As no primal solution is available in this case, the level values for variables and equations and the objective function value are set to 0 (setting them to NA would be more appropriate, but GAMS does not support this well). At the moment, primal infeasibility certificate are not available for conic programs.

Since GAMS reports all model statuses in the primal space, the notion of dual infeasibility does not exist and GAMS reports a status of unboundedness, which assumes that the primal problem is feasible. Although GAMS reports the primal as unbounded, there is the possibility that both the primal *and* dual problem are infeasible. To check if this is the case, the user can set appropriate lower and upper bounds on the objective variable, using the `(variable).LO` and `(variable).UP` suffixes and resolve.

The dual infeasibility certificate is reported in the level values for the variables. As no dual solution exists, the marginal values for both variables and equations are set to NA.

For more details on primal and dual infeasibility certificates see the MOSEK Modeling Cookbook.

Infeasibility Report

MOSEK has some facilities for diagnosing the cause of a primal or dual infeasibility. They can be turned on using the parameter setting MSK_IPAR_INFEAS_REPORT_AUTO. This causes MOSEK to print a report about an infeasible subset of the constraints, when an infeasibility is encountered. Moreover, the parameter MSK_IPAR_INFEAS_REPORT_LEVEL controls the amount of information presented in the infeasibility report. We will use the **TRNSPORT example from the GAMS Model Library** with increased demand ($b(j) \leftarrow 1.6\, b(j)$) to make the model infeasible. MOSEK produces the following infeasibility report:

```
MOSEK PRIMAL INFEASIBILITY REPORT.

Problem status: The problem is primal infeasible

The following constraints are involved in the primal infeasibility.

Index    Name                  Lower bound      Upper bound      Dual lower       Dual upper
1        supply(seattle)       none             3.500000e+002    0.000000e+000    1.000000e+000
2        supply(san-diego)     none             6.000000e+002    0.000000e+000    1.000000e+000
3        demand(new-york)      5.200000e+002    none             1.000000e+000    0.000000e+000
4        demand(chicago)       4.800000e+002    none             1.000000e+000    0.000000e+000
5        demand(topeka)        4.400000e+002    none             1.000000e+000    0.000000e+000

The following bound constraints are involved in the infeasibility.

Index    Name                  Lower bound      Upper bound      Dual lower       Dual upper
```

The report indicates which constraints and bounds are causing the infeasibility. In this case, the constraints causing infeasibility are `supply` and `demand`. The values in the columns `Dual lower` and `Dual upper` are also useful, because if the dual lower value is different from zero for a constraint, then it implies that the lower bound on the constraint is important for the infeasibility. Similarly, if the dual upper value is different from zero on a constraint, then this implies the upper bound on the constraint is important for infeasibility.

5.27.1.4 Conic Programming

MOSEK is well suited for solving generalized linear programs involving certain conic constraints.

For an overview of quadratic conic programming and how these conic constraints are implemented in GAMS, see the Section Conic Programming in the GAMS User's Guide. Note, that for Mosek no variable can appear in more than one conic constraint.

Additionally, the primal power cone, defined as

$$x_0^{\alpha} x_1^{(1-\alpha)} \geq \sqrt{\sum_{i=2}^{n} x_i^2}, \quad x_0, x_1 \geq 0,$$

with $\alpha \in (0,1)$, and the primal exponential cone, defined as

$$x_0 \geq x_1 \exp(x_2/x_1), \quad x_0, x_1 \geq 0,$$

are available.

Since GAMS does not offer capabilities to directly restrict a variable to one of these cones, the GAMS/MOSEK link tries to detect the above algebra from a general nonlinear equation. For example, the following GAMS code should work with MOSEK:

```
Set i / 0*10 /;
Variable x(i);
Equations e1, e2;
Scalar alpha;
e1.. x('0')**alpha * x('1')**(1-alpha) =G= sqrt(sum(i$(ord(i)>2), sqr(x(i))));
e2.. x('0') =G= x('1') * exp(x('2') / x('1'));
x.lo('0') = 0;
x.lo('1') = 0;
```

See also testlib models **powercone1**, **powercone2**, and **expcone1**.

5.27.2 Solver Options

MOSEK works like other GAMS solvers, and many options can be set in the GAMS model (see GAMS Options). The most relevant GAMS options are reslim, nodlim, iterlim (iteration limit for simplex and interior point algorithms), optca, optcr, and optfile. A description of all available GAMS options can be found in GAMS Options and Solver related options.

We remark that MOSEK contains many complex solver options, many of which require a deep understanding of the algorithms used. For information on how to use a GAMS/Mosek options file, see The Solver Option File. For example, an option file

```
MSK_IPAR_INTPNT_MAX_ITERATIONS                20
MSK_IPAR_INTPNT_SCALING         MSK_SCALING_NONE
```

limits the number of interior-point iterations to 20 and disables scaling.

In the following, we summarize the MOSEK options that are available through the GAMS/MOSEK interface. For details, see Detailed Descriptions of MOSEK Options.

5.27.2.1 General

Option	Description	Default
MSK_DPAR_OPTIMIZER_MAX_TIME	Maximum amount of time the optimizer is allowed to spent on the optimization.	GAMS ResLim
MSK_DPAR_SEMIDEFINITE_TOL_APPROX	Tolerance to define a matrix to be positive semidefinite.	1e-10
MSK_IPAR_AUTO_SORT_A_BEFORE_OPT	Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed.	MSK_OFF
MSK_IPAR_NUM_THREADS	Controls the number of threads employed by the optimizer.	GAMS Threads
MSK_IPAR_OPTIMIZER	The parameter controls which optimizer is used to optimize the task.	MSK_OPTIMIZER_FREE
MSK_IPAR_TIMING_LEVEL	Controls the amount of timing performed inside MOSEK.	1
MSK_SPAR_PARAM_READ_FILE_NAME	Modifications to the parameter database is read from this file.	

5.27.2.2 Problem Data

Option	Description	Default
MSK_DPAR_CHECK_CONVEXITY_REL_TOL	Not in use.	1e-10
MSK_DPAR_DATA_SYM_MAT_TOL	Absolute zero tolerance for elements in in symmetric matrices.	1e-12
MSK_DPAR_DATA_SYM_MAT_TOL_HUGE	An element in a symmetric matrix which is larger than this value in absolute size causes an error.	1e+20
MSK_DPAR_DATA_SYM_MAT_TOL_LARGE	An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.	1e+10
MSK_DPAR_DATA_TOL_AIJ_HUGE	An element in the constraint matrix which is larger than this value in absolute size causes an error.	1e+20
MSK_DPAR_DATA_TOL_AIJ_LARGE	An element in the constraint matrix which is larger than this value in absolute size causes a warning message.	1e+10
MSK_DPAR_DATA_TOL_BOUND_INF	Any bound which in absolute value is greater than this parameter is considered infinite.	1e+16
MSK_DPAR_DATA_TOL_BOUND_WRN	If a bound value is larger than this value in absolute size, then a warning message is issued.	1e+08
MSK_DPAR_DATA_TOL_CJ_LARGE	A coefficient in the objective function which is larger than this value in absolute terms causes a warning message.	1e+08
MSK_DPAR_DATA_TOL_C_HUGE	A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error.	1e+16
MSK_DPAR_DATA_TOL_QIJ	Absolute zero tolerance for coefficients of quadratic terms.	1e-16

Option	Description	Default
MSK_DPAR_DATA_TOL_X	Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical.	1e-08
MSK_DPAR_LOWER_OBJ_CUT	Lower objective limit.	-1e+30
MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH	Lower objective limit threshold.	-5e+29
MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL	This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems.	1e-15
MSK_DPAR_UPPER_OBJ_CUT	Upper objective limit.	1e+30
MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH	Upper objective limit threshold.	5e+29
QEXTRACTALG	Switch to choose extraction algorithm for quadratic equations in GAMS interface.	0
SDPCHECKVARS	Switch to disable checking that for every entry of a PSD matrix variable also a corresponding GAMS variable is present.	1

5.27.2.3 Presolving

Option	Description	Default
MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP	Absolute tolerance employed by the linear dependency checker.	1e-06
MSK_DPAR_PRESOLVE_TOL_AIJ	Absolute zero tolerance employed for constraint coefficients in presolve.	1e-12
MSK_DPAR_PRESOLVE_TOL_PRIMAL_INFEAS_PERTURBATION	The presolve is allowed to perturb a bound on a constraint or variable by this amount if it removes an infeasibility.	1e-06
MSK_DPAR_PRESOLVE_TOL_REL_LINDEP	Relative tolerance employed by the linear dependency checker.	1e-10
MSK_DPAR_PRESOLVE_TOL_S	Absolute zero tolerance employed for dual variables in presolve.	1e-08
MSK_DPAR_PRESOLVE_TOL_X	Absolute zero tolerance employed for primal variables in presolve.	1e-08
MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL	Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve.	-1
MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUM_TRIES	Control the maximum number of times the eliminator is tried.	-1
MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH	Controls the linear dependency check, which is potentially computationally expensive.	100
MSK_IPAR_PRESOLVE_LINDEP_NEW	Controls whether a new experimental linear dependency checker is employed.	MSK_OFF

Option	Description	Default
MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH	Controls the linear dependency check, which is potentially computationally expensive.	100
MSK_IPAR_PRESOLVE_LINDEP_USE	Controls whether the linear constraints are checked for linear dependencies.	MSK_ON
MSK_IPAR_PRESOLVE_MAX_NUM_PASS	Control the maximum number of times presolve passes over the problem.	-1
MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS	Controls the maximum number of reductions performed by the presolve.	-1
MSK_IPAR_PRESOLVE_USE	Controls whether the presolve is applied to a problem before it is optimized.	MSK_PRESOLVE_MODE_FREE

5.27.2.4 Simplex Optimizer

Option	Description	Default
MSK_DPAR_BASIS_REL_TOL_S	Maximum relative dual bound violation allowed in an optimal basic solution.	1e-12
MSK_DPAR_BASIS_TOL_S	Maximum absolute dual bound violation in an optimal basic solution.	1e-06
MSK_DPAR_BASIS_TOL_X	Maximum absolute primal bound violation allowed in an optimal basic solution.	1e-06
MSK_DPAR_SIMPLEX_ABS_TOL_PIV	Absolute pivot tolerance employed by the simplex optimizers.	1e-07
MSK_DPAR_SIM_LU_TOL_REL_PIV	Relative pivot tolerance for LU factorization in simplex optimizers and basis identification.	0.01
MSK_IPAR_SIM_BASIS_FACTOR_USE	Controls whether an LU factorization of the basis is used in a hot-start.	MSK_ON
MSK_IPAR_SIM_DEGEN	Controls how aggressively degeneration is handled.	MSK_SIM_DEGEN_FREE
MSK_IPAR_SIM_DUAL_CRASH	Controls whether crashing is performed in the dual simplex optimizer.	90
MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION	Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex.	50
MSK_IPAR_SIM_DUAL_SELECTION	Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.	MSK_SIM_SELECTION_FREE
MSK_IPAR_SIM_EXPLOIT_DUPVEC	Controls if the simplex optimizers are allowed to exploit duplicated columns.	MSK_SIM_EXPLOIT_DUPVEC_OFF

Option	Description	Default
MSK_IPAR_SIM_HOTSTART	Controls the type of hot-start that the simplex optimizer perform.	MSK_SIM_HOTSTART_FREE
MSK_IPAR_SIM_HOTSTART_LU	Determines if the simplex optimizer should exploit the initial factorization.	MSK_ON
MSK_IPAR_SIM_MAX_ITERATIONS	Maximum number of iterations that can be used by a simplex optimizer.	GAMS IterLim
MSK_IPAR_SIM_MAX_NUM_SETBACKS	Controls how many set-backs are allowed within a simplex optimizer.	250
MSK_IPAR_SIM_NON_SINGULAR	Controls if the simplex optimizer ensures a non-singular basis, if possible.	MSK_ON
MSK_IPAR_SIM_PRIMAL_CRASH	Controls whether crashing is performed in the primal simplex optimizer.	90
MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION	Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex.	50
MSK_IPAR_SIM_PRIMAL_SELECTION	Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.	MSK_SIM_SELECTION_FREE
MSK_IPAR_SIM_REFORMULATION	Controls if the simplex optimizers are allowed to reformulate the problem.	MSK_SIM_REFORMULATION_OFF
MSK_IPAR_SIM_SAVE_LU	Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis.	MSK_OFF
MSK_IPAR_SIM_SCALING	Controls how much effort is used in scaling the problem before a simplex optimizer is used.	MSK_SCALING_FREE
MSK_IPAR_SIM_SCALING_METHOD	Controls how the problem is scaled before a simplex optimizer is used.	MSK_SCALING_METHOD_POW2
MSK_IPAR_SIM_SEED	Sets the random seed used for randomization in the simplex optimizers.	23456
MSK_IPAR_SIM_SOLVE_FORM	Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer.	MSK_SOLVE_FREE
MSK_IPAR_SIM_STABILITY_PRIORITY	Controls how high priority the numerical stability should be given.	50
MSK_IPAR_SIM_SWITCH_OPTIMIZER	Controls the simplex behavior.	MSK_OFF

5.27.2.5 Interior Point Optimizer and Basis Identification

Option	Description	Default
MSK_DPAR_INTPNT_CO_TOL_DFEAS	Dual feasibility tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_CO_TOL_INFEAS	Infeasibility tolerance used by the interior-point optimizer for conic problems.	1e-12
MSK_DPAR_INTPNT_CO_TOL_MU_RED	Relative complementarity gap tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_CO_TOL_NEAR_REL	Termination tolerance multiplier that is used if no accurate solution can be found.	1
MSK_DPAR_INTPNT_CO_TOL_PFEAS	Primal feasibility tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_CO_TOL_REL_GAP	Relative gap termination tolerance used by the interior-point optimizer for conic problems.	1e-08
MSK_DPAR_INTPNT_QO_TOL_DFEAS	Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.	1e-08
MSK_DPAR_INTPNT_QO_TOL_INFEAS	Infeasibility tolerance used by the interior-point optimizer for quadratic problems.	1e-12
MSK_DPAR_INTPNT_QO_TOL_MU_RED	Relative complementarity gap tolerance used by the interior-point optimizer for quadratic problems.	1e-08
MSK_DPAR_INTPNT_QO_TOL_NEAR_REL	Termination tolerance multiplier that is used if no accurate solution can be found.	1
MSK_DPAR_INTPNT_QO_TOL_PFEAS	Primal feasibility tolerance used by the interior-point optimizer for quadratic problems.	1e-08
MSK_DPAR_INTPNT_QO_TOL_REL_GAP	Relative gap termination tolerance used by the interior-point optimizer for quadratic problems.	1e-08
MSK_DPAR_INTPNT_TOL_DFEAS	Dual feasibility tolerance used by the interior-point optimizer for linear problems.	1e-08
MSK_DPAR_INTPNT_TOL_DSAFE	Controls the initial dual starting point used by the interior-point optimizer.	1
MSK_DPAR_INTPNT_TOL_INFEAS	Infeasibility tolerance used by the interior-point optimizer for linear problems.	1e-10
MSK_DPAR_INTPNT_TOL_MU_RED	Relative complementarity gap tolerance used by the interior-point optimizer for linear problems.	1e-16
MSK_DPAR_INTPNT_TOL_PATH	Controls how close the interior-point optimizer follows the central path.	1e-08

Option	Description	Default
MSK_DPAR_INTPNT_TOL_PFEAS	Primal feasibility tolerance used by the interior-point optimizer for linear problems.	1e-08
MSK_DPAR_INTPNT_TOL_PSAFE	Controls the initial primal starting point used by the interior-point optimizer.	1
MSK_DPAR_INTPNT_TOL_REL_GAP	Relative gap termination tolerance used by the interior-point optimizer for linear problems.	1e-08
MSK_DPAR_INTPNT_TOL_REL_STEP	Relative step size to the boundary for linear and quadratic optimization problems.	0.9999
MSK_DPAR_INTPNT_TOL_STEP_SIZE	Step size tolerance.	1e-06
MSK_IPAR_BI_CLEAN_OPTIMIZER	Controls which simplex optimizer is used in the clean-up phase.	MSK_OPTIMIZER_FREE
MSK_IPAR_BI_IGNORE_MAX_ITER	Controls if basis identification is performed under certain conditions.	MSK_OFF
MSK_IPAR_BI_IGNORE_NUM_ERROR	Turns on basis identification if interior-point optimizer is terminated due to a numerical problem.	MSK_ON
MSK_IPAR_BI_MAX_ITERATIONS	Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification.	1000000
MSK_IPAR_INTPNT_BASIS	Controls whether the interior-point optimizer also computes an optimal basis.	MSK_BI_ALWAYS
MSK_IPAR_INTPNT_DIFF_STEP	Controls whether different step sizes are allowed in the primal and dual space.	MSK_ON
MSK_IPAR_INTPNT_MAX_ITERATIONS	Controls the maximum number of iterations allowed in the interior-point optimizer.	GAMS IterLim
MSK_IPAR_INTPNT_MAX_NUM_COR	Controls the maximum number of correctors allowed by the multiple corrector procedure.	-1
MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS	Maximum number of steps to be used by the iterative refinement of the search direction.	-1
MSK_IPAR_INTPNT_OFF_COL_TRH	Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix.	40
MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS	The GP ordering is dependent on a random seed.	0
MSK_IPAR_INTPNT_ORDER_METHOD	Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system.	MSK_ORDER_METHOD_FREE
MSK_IPAR_INTPNT_REGULARIZATION_USE	Controls whether regularization is allowed.	MSK_ON
MSK_IPAR_INTPNT_SCALING	Controls how the problem is scaled before the interior-point optimizer is used.	MSK_SCALING_FREE

Option	Description	Default
MSK_IPAR_INTPNT_SOLVE_FORM	Controls whether the primal or the dual problem is solved.	MSK_SOLVE_FREE
MSK_IPAR_INTPNT_STARTING_POINT	Starting point used by the interior-point optimizer.	MSK_STARTING_POINT_FREE

5.27.2.6 Mixed Integer Optimizer

Option	Description	Default
FIXOPTFILE	Name of option file which is read just before solving the fixed problem.	
MSK_DPAR_MIO_MAX_TIME	This parameter limits the maximum time spent by the mixed-integer optimizer.	-1
MSK_DPAR_MIO_REL_GAP_CONST	This value is used to compute the relative gap for the solution to an integer optimization problem.	1e-10
MSK_DPAR_MIO_TOL_ABS_GAP	Absolute optimality tolerance employed by the mixed-integer optimizer.	GAMS OptCA
MSK_DPAR_MIO_TOL_ABS_RELAX_INT	Absolute relaxation tolerance of the integer constraints.	1e-05
MSK_DPAR_MIO_TOL_FEAS	Feasibility tolerance for mixed integer solver.	1e-06
MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT	If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.	0
MSK_DPAR_MIO_TOL_REL_GAP	Relative optimality tolerance employed by the mixed-integer optimizer.	GAMS OptCR
MSK_IPAR_MIO_BRANCH_DIR	Controls whether the mixed-integer optimizer is branching up or down by default.	MSK_BRANCH_DIR_FREE
MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION	If this option is turned on outer approximation is used when solving relaxations of conic problems; otherwise interior point is used.	MSK_OFF
MSK_IPAR_MIO_CONSTRUCT_SOL	Whether to construct an initial solution from starting point	MSK_OFF
MSK_IPAR_MIO_CUT_CLIQUE	Controls whether clique cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT_CMIR	Controls whether mixed integer rounding cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT_GMI	Controls whether GMI cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT_IMPLIED_BOUND	Controls whether implied bound cuts should be generated.	MSK_ON
MSK_IPAR_MIO_CUT_KNAPSACK_COVER	Controls whether knapsack cover cuts should be generated.	MSK_ON

Option	Description	Default
MSK_IPAR_MIO_CUT_LIPRO	Controls whether lift-and-project cuts should be generated.	MSK_OFF
MSK_IPAR_MIO_CUT_SELECTION_LEVEL	Controls how aggressively generated cuts are selected to be included in the relaxation.	-1
MSK_IPAR_MIO_DATA_PERMUTATION_METHOD	Controls what problem data permutation method is appplied to mixed-integer problems.	MSK_MIO_DATA_PERMUTATION_METHOD_NONE
MSK_IPAR_MIO_DUAL_RAY_ANALYSIS_LEVEL	Controls the amount of symmetry detection and handling employed by the mixed-integer optimizer in presolve.	-1
MSK_IPAR_MIO_FEASPUMP_LEVEL	Controls the way the Feasibility Pump heuristic is employed by the mixed-integer optimizer.	-1
MSK_IPAR_MIO_HEURISTIC_LEVEL	Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution.	-1
MSK_IPAR_MIO_MAX_NUM_BRANCHES	Maximum number of branches allowed during the branch and bound search.	-1
MSK_IPAR_MIO_MAX_NUM_RELAXS	Maximum number of relaxations allowed during the branch and bound search.	GAMS NodLim
MSK_IPAR_MIO_MAX_NUM_RESTARTS	Maximum number of restarts allowed during the branch and bound search.	0
MSK_IPAR_MIO_MAX_NUM_ROOT_CUT_ROUNDS	Maximum number of cut separation rounds at the root node.	100
MSK_IPAR_MIO_MAX_NUM_SOLUTIONS	The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located.	-1
MSK_IPAR_MIO_MEMORY_EMPHASIS_LEVEL	Controls how much emphasis is put on reducing memory usage.	0
MSK_IPAR_MIO_MIN_REL	Number of times a variable must have been branched on for its pseudocost to be considered reliable.	5
MSK_IPAR_MIO_NODE_OPTIMIZER	Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.	MSK_OPTIMIZER_FREE
MSK_IPAR_MIO_NODE_SELECTION	Controls the node selection strategy employed by the mixed-integer optimizer.	MSK_MIO_NODE_SELECTION_FREE
MSK_IPAR_MIO_NUMERICAL_EMPHASIS_LEVEL	Controls how much emphasis is put on reducing numerical problems possibly at the expense of solution speed.	0
MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE	Enables or disables perspective reformulation in presolve.	MSK_ON
MSK_IPAR_MIO_PRESOLVE_AGGREGATOR_USE	Controls if the aggregator should be used.	MSK_ON

Option	Description	Default
MSK_IPAR_MIO_PROBING_LEVEL	Controls the amount of probing employed by the mixed-integer optimizer in presolve.	-1
MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT	Use objective domain propagation.	MSK_OFF
MSK_IPAR_MIO_QCQO_REFORMULATION_METHOD	Controls what reformulation method is applied to mixed-integer quadratic problems.	MSK_MIO_QCQO_REFORMULATION_METHOD_FREE
MSK_IPAR_MIO_RINS_MAX_NODES	Controls the maximum number of nodes allowed in each call to the RINS heuristic.	-1
MSK_IPAR_MIO_ROOT_OPTIMIZER	Controls which optimizer is employed at the root node in the mixed-integer optimizer.	MSK_OPTIMIZER_FREE
MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL	Controls whether presolve can be repeated at root node.	-1
MSK_IPAR_MIO_SEED	Sets the random seed used for randomization in the mixed integer optimizer.	42
MSK_IPAR_MIO_SYMMETRY_LEVEL	Controls the amount of symmetry detection and handling employed by the mixed-integer optimizer in presolve.	-1
MSK_IPAR_MIO_VAR_SELECTION	Controls the variable selection strategy employed by the mixed-integer optimizer.	MSK_MIO_VAR_SELECTION_FREE
MSK_IPAR_MIO_VB_DETECTION_LEVEL	Controls how much effort is put into detecting variable bounds.	-1
SOLVEFINAL	Switch to resolve the problem with fixed discrete variables after the MOSEK optimizer finished.	1

5.27.2.7 Infeasibility Analyser for Continuous Problems

Option	Description	Default
MSK_DPAR_ANA_SOL_INFEAS_TOL	If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer.	1e-06
MSK_IPAR_INFEAS_PREFER_PRIMAL	If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on.	MSK_ON
MSK_IPAR_INFEAS_REPORT_AUTO	Controls whether an infeasibility report is automatically produced after the optimization if the problem is primal or dual infeasible.	MSK_OFF
MSK_IPAR_INFEAS_REPORT_LEVEL	Controls the amount of information presented in an infeasibility report.	1

5.27.2.8 Output

Option	Description	Default
MSK_IPAR_LOG	Controls the amount of log information.	10
MSK_IPAR_LOG_BI	Controls the amount of output printed by the basis identification procedure.	1
MSK_IPAR_LOG_BI_FREQ	Controls logging frequency of the basis identification	2500
MSK_IPAR_LOG_FEAS_REPAIR	Controls the amount of output printed when performing feasibility repair.	1
MSK_IPAR_LOG_INFEAS_ANA	Controls amount of output printed by the infeasibility analyzer procedures.	1
MSK_IPAR_LOG_INTPNT	Controls amount of output printed by the interior-point optimizer.	1
MSK_IPAR_LOG_MIO	Controls the log level for the mixed-integer optimizer.	4
MSK_IPAR_LOG_MIO_FREQ	Controls how frequent the mixed-integer optimizer prints the log line.	10
MSK_IPAR_LOG_ORDER	If turned on, then factor lines are added to the log.	1
MSK_IPAR_LOG_PRESOLVE	Controls amount of output printed by the presolve procedure.	1
MSK_IPAR_LOG_RESPONSE	Controls amount of output printed when response codes are reported.	0
MSK_IPAR_LOG_SIM	Controls amount of output printed by the simplex optimizer.	4
MSK_IPAR_LOG_SIM_FREQ	Controls simplex optimizer logging frequency.	1000
MSK_IPAR_LOG_STORAGE	When turned on, MOSEK prints messages regarding the storage usage and allocation.	0
MSK_IPAR_OPF_WRITE_HEADER	Write a text header with date and MOSEK version in an OPF file.	MSK_ON
MSK_IPAR_OPF_WRITE_HINTS	Write a hint section with problem dimensions in the beginning of an OPF file.	MSK_ON
MSK_IPAR_OPF_WRITE_LINE_LENGTH	Aim to keep lines in OPF files not much longer than this.	80
MSK_IPAR_OPF_WRITE_PARAMETERS	Write a parameter section in an OPF file.	MSK_OFF
MSK_IPAR_OPF_WRITE_PROBLEM	Write objective, constraints, bounds etc.	MSK_ON
MSK_IPAR_OPF_WRITE_SOLUTIONS	Enable inclusion of solutions in the OPF files.	MSK_OFF
MSK_IPAR_OPF_WRITE_SOL_BAS	Whether to include basic solution in OPF files.	MSK_ON
MSK_IPAR_OPF_WRITE_SOL_ITG	Whether to include integer solution in OPF files.	MSK_ON
MSK_IPAR_OPF_WRITE_SOL_ITR	Whether to include interior solution in OPF files.	MSK_ON
MSK_IPAR_PTF_WRITE_PARAMETERS	If enabled, then the parameters section is written.	MSK_OFF

Option	Description	Default
MSK_IPAR_PTF_WRITE_SOLUTIONS	If enabled, then the solution section is written if any solutions are available, otherwise solution section is not written even if solutions are available.	MSK_OFF
MSK_IPAR_PTF_WRITE_TRANSFORM	If enabled, then constraint blocks with identifiable conic slacks are transformed into conic constraints and the slacks are eliminated.	MSK_ON
MSK_IPAR_WRITE_COMPRESSION	Controls whether the data file is compressed while it is written.	9
MSK_IPAR_WRITE_DATA_PARAM	If this option is turned on the parameter settings are written to the data file as parameters.	MSK_OFF
MSK_IPAR_WRITE_GENERIC_NAMES	Controls whether generic names should be used instead of user-defined names when writing to the data file.	MSK_ON
MSK_IPAR_WRITE_GENERIC_NAMES_IO	Index origin used in generic names.	1
MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_ITEMS	Controls if the writer ignores incompatible problem items when writing files.	MSK_OFF
MSK_IPAR_WRITE_JSON_INDENTATION	When set, the JSON task and solution files are written with indentation for better readability.	MSK_OFF
MSK_IPAR_WRITE_LP_FULL_OBJ	Write all variables, including the ones with 0-coefficients, in the objective.	MSK_ON
MSK_IPAR_WRITE_LP_LINE_WIDTH	Maximum width of line in an LP file written by MOSEK.	80
MSK_IPAR_WRITE_MPS_FORMAT	Controls in which format the MPS is written.	MSK_MPS_FORMAT_FREE
MSK_IPAR_WRITE_MPS_INT	Controls if marker records are written to the MPS file to indicate whether variables are integer restricted.	MSK_ON
MSK_IPAR_WRITE_TASK_INC_SOL	Controls whether the solutions are stored in the task file too.	MSK_ON
MSK_IPAR_WRITE_XML_MODE	Controls if linear coefficients should be written by row or column when writing in the XML file format.	MSK_WRITE_XML_MODE_ROW
MSK_SPAR_DATA_FILE_NAME	If set, problem data is written to this file. File extension determines format.	
MSK_SPAR_PARAM_WRITE_FILE_NAME	The parameter database is written to this file.	
MSK_SPAR_WRITE_LP_GEN_VAR_NAME	Sometimes when an LP file is written additional variables must be inserted.	"xmskgen"
SDPSOLUFILE	Name of GDX file to write primal solution of all PSD matrix variables and dual solution for PSD constraints.	

5.27.3 The MOSEK Log File

The MOSEK log output gives much useful information about the current solver progress and individual phases.

5.27.3.1 Log Using the Interior Point Optimizer

The following is a MOSEK log output from running the **TRNSPORT** model from the GAMS Model Library:

```
Optimizer started.
Interior-point optimizer started.
Presolve started.
Linear dependency checker started.
Linear dependency checker terminated.
Eliminator - tries                  : 0                 time                   : 0.00
Lin. dep.  - tries                  : 1                 time                   : 0.00
Lin. dep.  - number                 : 0
Presolve terminated. Time: 0.00
Optimizer  - threads                : 1
Optimizer  - solved problem         : the primal
Optimizer  - Constraints            : 5
Optimizer  - Cones                  : 0
Optimizer  - Scalar variables       : 11                conic                  : 0

```

The last section gives details about the model and solver status, primal and dual feasibilities, as well as solver resource times. Furthermore, the log gives information about the basis identification phase. Some of this information is listed in the GAMS solve summary in the model listing (.LST) file as well.

The fields in the main MOSEK log output are:

Field	Description
ITE	The number of the current iteration.
PFEAS	Primal feasibility.
DFEAS	Dual feasibility.
GFEAS	The numbers in this column should converge monotonically toward to zero but may stall at low level due to rounding errors.
PRSTATUS	This number converges to 1 if the problem has an optimal solution whereas it converges to -1 if that is not the case.
POBJ	Current objective function value of primal problem.
DOBJ	Current objective function value of dual problem.
MU	Relative complementary gap.
TIME	Current elapsed solving time in seconds.

5.27.3.2 Log Using the Simplex Optimizer

Return code - 10004 [MSK_RES_TRM_MIO_NEAR_ABS_GAP]: The mixed-integer optimizer terminated because tl
```

The fields in the main MOSEK log output are:

Field	Description
BRANCHES	Current number of branches in tree.
RELAXS	Current number of nodes in branch and bound tree.
ACT_NDS	Current number of active nodes.
BEST_INT_OBJ	Current best integer solution (primal bound).
BEST_RELAX_OBJ	Current best relaxed solution (dual bound).
REL_GAP(%)	Relative gap between current BEST_INT_OBJ and BEST_RELAX_OBJ.
TIME	Current elapsed solving time in seconds.

The log then gives information about solving the model with discrete variables fixed in order to determine marginals. Option SOLVEFINAL can be used to disable this step. The fixed problem is solved as a

regular LP with warm start information. So the log looks identical to the MOSEK simplex optimizer for linear programs:

```

5.27.4 Semidefinite Programming with GAMS/MOSEK (experimental)

With Version 7, MOSEK introduced a semidefinite programming (SDP) solver into their portfolio. The following introduction is taken from the Mosek Documentation.

Semidefinite programming is a generalization of quadratic conic programming, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

$$\mathcal{S}_r^+ = \left\{ X \in \mathcal{S}_r : z^T X z \geq 0,\ \forall z \in \mathbb{R}^r \right\},$$

where $\mathcal{S}_r$ is the set of $r \times r$ real-valued symmetric matrices. MOSEK can solve semidefinite optimization problems of the form

$$\begin{array}{lccccll} \text{minimize} & & \displaystyle\sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle \overline{C}_j, \overline{X}_j \rangle + c^f & & & & \\ \text{subject to} & l_i^c & \leq & \displaystyle\sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle \overline{A}_{ij}, \overline{X}_j \rangle & \leq & u_i^c, & i = 0, \ldots, m-1, \\ & l_j^x & \leq & x_j & \leq & u_j^x, & j = 0, \ldots, n-1, \\ & & & x \in \mathcal{C}, \overline{X}_j \in \mathcal{S}_{r_j}^+, & & & j = 0, \ldots, p-1, \end{array} \tag{SDP}$$

where the problem has p symmetric positive semidefinite (PSD) variables $\overline{X}_j \in \mathcal{S}_{r_j}^+$ of dimension r_j with symmetric coefficient matrices $\overline{C}_j \in \mathcal{S}_{r_j}$ and $\overline{A}_{i,j} \in \mathcal{S}_{r_j}$. We use the standard notation for the matrix inner product, i.e., for $A, B \in \mathbb{R}^{m \times n}$ we have

$$\langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij}.$$

5.27.4.1 Example

An example for a mixed semidefinite and conic quadratic programming problem with a 3-dimensional PSD matrix variable is the following:

$$
\begin{aligned}
\text{minimize} \quad & \left\langle \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, \bar{X} \right\rangle + x_0 \\
\text{subject to} \quad & \left\langle \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \bar{X} \right\rangle + x_0 = 1 \\
& \left\langle \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \bar{X} \right\rangle + x_1 + x_2 = \frac{1}{2} \\
& x_0 \geq \sqrt{x_1^2 + x_2^2} \\
& \bar{X} \succeq 0
\end{aligned}
$$

The GAMS/MOSEK interface offers an experimental interface to MOSEK's SDP solver. It allows to state SDP's of the form (SDP) in GAMS language. For instance, the example problem from above can be formulated as follows (**sdp01** in the GAMS Test Library):

```
Set i / 0 * 2 /;
alias(i, ip);
Variables barX(i,i) PSDMATRIX
          x(i)      simple vars
          z         objective var
;
x.lo('0') = 0;
Parameters barAobj(i,i)  coefficients of barX in objective
           barAe1(i,i)   coefficients of barX in e1
           barAe2(i,i)   coefficients of barX in e2
;
Table barAobj(i,i)
   0    1    2
0  2.0  1.0  0.0
1  1.0  2.0  1.0
2  0.0  1.0  2.0
;
  identity matrix
barAe1(i,i) = 1.0;
  all-one matrix
barAe2(i,ip) = 1.0;
Equations obj, e1, e2, e3;
obj.. z   =e= sum((i,ip), barAobj(i,ip) * barX(i,ip)) + x('0');
e1..  1   =e= sum((i,ip), barAe1(i,ip)  * barX(i,ip)) + x('0');
e2..  0.5 =e= sum((i,ip), barAe2(i,ip)  * barX(i,ip)) + x('1') + x('2');
e3..  - sqr(x('0')) + sqr(x('1')) + sqr(x('2')) =l= 0;
Model m / all /;
```

We see that the matrix $\bar{X}$ is defined via the 2-dimensional GAMS variable `barX`. Additionally, the keyword `PSDMATRIX` at the beginning of the descriptive text (!) of the variable is used to indicate that the variables belonging to symbol `barX` are *to be interpreted* as a matrix variable with PSD constraint.

The Model shown above can be solved with MOSEK via the statements

```
option qcp = mosek;
Solve m minimizing z using QCP;
```

As GAMS has no native support for conic programming, the modeltype is specified as QCP.

The solve statement produces the following log output (see also Log Using the Interior Point Optimizer):

```

0         EPS         EPS         EPS
1         EPS         EPS         EPS
2         EPS         EPS         EPS
```

5.27.4.2 Usage

The general syntax for defining a symmetric matrix or an (indexed) set of symmetric matrices with PSD constraints in GAMS is

```
Variable X(a,b,c,...,i1,..,ik,i1,...,ik)  "PSDMATRIX_k <explanatory text>";
```

The number k>0 specifies the number of indices that define the row/column dimension of the matrix. Specifying only the term `PSDMATRIX` is equivalent to `PSDMATRIX_1`. For a given k, the 2k-last indices are used to index the rows and columns of the matrix. The dimensions `a`, `b`, `c`, ... are optional and can be used to index a set of matrices. In the GAMS/MOSEK output, a number in parenthesis is used to indicate the number of PSD matrices that have been found for one symbol. For example, the code

```
Set i / a,b /;
Set j / s01 * s42 /;
Variables z, X(j,i,i) PSDMATRIX;
```

generates the output

```
Recognizing SDP variables for symbols X (42)
```

if all matrices `X(j,.,.)` also occur in a model instantiation.

Note

> The current syntax for declaring PSD matrix variables via the explanatory text a variable is a temporary solution that will hopefully be replaced by a GAMS language feature in the future.

Variables that were tagged as belonging to a PSD matrix can only occur in linear constraints. Within these constraints, the coefficient matrix for a PSD matrix needs to be specified in symmetric form. That is, if the parameter matrix `barAobj` in the example above is equivalently specified as

```
Table barAobj(i,i)
   0    1    2
0  2.0  0.0  0.0
1  2.0  2.0  0.0
2  0.0  2.0  2.0
;
```

the GAMS/MOSEK interface will quit with the error message

```
SDP coefficient matrix not symmetric: defObj_z: 2*barX(1,0) != 0*barX(0,1)
```

Bounds on entries in a PSD matrix variable can be specified as usual with `.lo` and `.up` attributes. These bound constraints are translated into linear constraints by the interface. If different bounds are given to symmetric entries of a PSD matrix variable ($\bar{X}_{i,j}$ vs. $\bar{X}_{j,i}$), the stronger bounds are used, which is equivalent to adding constraints for each of the matrix entries. For nonpositive lower bounds on diagonal entries, no extra constraints are added, as they are implied by the PSD constraint.

5.27.4.3 GAMS variables vs. PSD matrix entries

As GAMS is not aware that a indexed variable will be interpreted as PSD matrix variable, it may not generate variables for all matrix entries when instantiating a model. This is especially critical if the modeler specified bounds on matrix entries that do not appear in any of the model equations, as these bounds would not be visible to the GAMS/MOSEK interface.

As an example, consider the SDP relaxation $\max\{-\langle W, \bar{X}\rangle : X_{i,i} = 1 \; \forall i, X \succeq 0\}$ corresponding to the Goemans-Williamson Randomized Approximation Algorithm for MaxCut:

```
Parameter W(i,i)    edge weights;
Variable X(i,j)     PSDMATRIX
         sdpobjvar  objective var;
Equation sdpobj     objective function;
sdpobj.. sum((i,j), -W(i,j)*(X(i,j) + X(j,i))) =e= sdpobjvar;
X.fx(i,i) = 1.0;
model maxcutsdp / all /;
```

As `W(i,i)=0`, GAMS will not create any variables for `X(i,i)` when instantiating the model in a solve statement. As a consequence, the constraints `X(i,i)=1` will not be visible to GAMS/MOSEK. However, as MOSEK will compute values for the full matrix X, it will also compute values for the diagonal entries of `X`.

Further, the GAMS/MOSEK interface can pass primal solution values only for those entries of a PSD matrix variable that have a corresponding GAMS variable. This may make a solution matrix appear not to be PSD in GAMS, because not all entries have been passed back.

To be aware of such problems, the GAMS/MOSEK interface checks that it has a GAMS variable available for every entry of a PSD matrix variable. If not, it will report an error like

```
ERROR: Have 1600 GAMS variables for entries of 400 x 400 PSD Variable X(,), expected 160000 many.
```

This check can be disabled by setting the option SDPCHECKVARS to 0. Note, that the check is not able to alarm the user in situations where no GAMS variables were created for all entries of a row and corresponding column.

A simple workaround for this issue is to force all variables to be generated when a model is instantiated. This can be done by adding something like `eps*sum((i,j),X(i,j))` to one of the equations. Note, that `eps` is numerically equal to a 0.0 in GAMS, but has the effect that the term `sum((i,j),X(i,j))` is passed to the solver with 0.0-coefficient.

5.27.4.4 Dual Values for PSD constraints

The PSD constraint on a matrix variable $\bar{X}$ is associated with a dual PSD matrix variable $\bar{Y}$. As GAMS is not aware of the PSD constraints, it is also not aware of the corresponding dual variables. Thus, there is no native way to pass the duals for the PSD constraints back to GAMS. (Recall, that the marginals for a PSDMATRIX variable `X` are used to store the dual values associated with the bound constraints on matrix entries.)

To work around this issue, the GAMS/MOSEK interface offers the option SDPSOLUFILE. This option allows to specify the name of a GDX file that stores primal values for all entries of a matrix variable and dual values of the corresponding PSD constraint. For a variable `X(i,j)`, the GDX file stores the primal matrix value for all entries (i, j) (i.e., not just the ones for which GAMS variables were created, therefor offering another workaround for the issue discussed in the previous section) as level values of variable `X` and the dual matrix for the PSD constraint as marginal values.

5.27.4.5 Infeasible and Unbounded SDPs

The GAMS/Mosek link currently does not pass on certificates for primal or dual infeasibility from Mosek to GAMS if PSD variables are present.

5.27.5 Detailed Descriptions of MOSEK Options

FIXOPTFILE *(string)*: Name of option file which is read just before solving the fixed problem. ↩

MSK_DPAR_ANA_SOL_INFEAS_TOL *(real)*: If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer. ↩

Default: `1e-06`

MSK_DPAR_BASIS_REL_TOL_S *(real)*: Maximum relative dual bound violation allowed in an optimal basic solution. ↩

Default: `1e-12`

MSK_DPAR_BASIS_TOL_S *(real)*: Maximum absolute dual bound violation in an optimal basic solution. ↩

Range: [`1e-09`, ∞]

Default: `1e-06`

MSK_DPAR_BASIS_TOL_X *(real)*: Maximum absolute primal bound violation allowed in an optimal basic solution. ↩

Range: [`1e-09`, ∞]

Default: `1e-06`

MSK_DPAR_CHECK_CONVEXITY_REL_TOL *(real)*: Not in use. ↩

Default: `1e-10`

MSK_DPAR_DATA_SYM_MAT_TOL *(real)*: Absolute zero tolerance for elements in in symmetric matrices. ↩

If any value in a symmetric matrix is smaller than this parameter in absolute terms MOSEK will treat the values as zero and generate a warning.

Range: [`1e-16`, `1e-06`]

Default: `1e-12`

MSK_DPAR_DATA_SYM_MAT_TOL_HUGE *(real)*: An element in a symmetric matrix which is larger than this value in absolute size causes an error. ↩

Default: `1e+20`

MSK_DPAR_DATA_SYM_MAT_TOL_LARGE *(real)*: An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed. ↩

Default: `1e+10`

MSK_DPAR_DATA_TOL_AIJ_HUGE *(real)*: An element in the constraint matrix which is larger than this value in absolute size causes an error. ↩

Default: `1e+20`

MSK_DPAR_DATA_TOL_AIJ_LARGE *(real)*: An element in the constraint matrix which is larger than this value in absolute size causes a warning message. ↩

Default: `1e+10`

MSK_DPAR_DATA_TOL_BOUND_INF *(real)*: Any bound which in absolute value is greater than this parameter is considered infinite. ↩

Default: `1e+16`

MSK_DPAR_DATA_TOL_BOUND_WRN *(real)*: If a bound value is larger than this value in absolute size, then a warning message is issued. ↩

Default: `1e+08`

MSK_DPAR_DATA_TOL_CJ_LARGE *(real)*: A coefficient in the objective function which is larger than this value in absolute terms causes a warning message. ↩

Default: `1e+08`

MSK_DPAR_DATA_TOL_C_HUGE *(real)*: A coefficient in the objective function which is larger than the value in absolute terms is considered to be huge and generates an error. ↩

Default: `1e+16`

MSK_DPAR_DATA_TOL_QIJ *(real)*: Absolute zero tolerance for coefficients of quadratic terms. ↩

Default: `1e-16`

MSK_DPAR_DATA_TOL_X *(real)*: Zero tolerance for constraints and variables i.e. if the distance between the lower and upper bound is less than this value, then the lower and upper bound is considered identical. ↩

Default: `1e-08`

MSK_DPAR_INTPNT_CO_TOL_DFEAS *(real)*: Dual feasibility tolerance used by the interior-point optimizer for conic problems. ↩

Range: [0, 1]

Default: `1e-08`

See also: MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_CO_TOL_INFEAS *(real)*: Infeasibility tolerance used by the interior-point optimizer for conic problems. ↩

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: [0, 1]

Default: `1e-12`

MSK_DPAR_INTPNT_CO_TOL_MU_RED *(real)*: Relative complementarity gap tolerance used by the interior-point optimizer for conic problems. ↩

Range: [0, 1]

Default: 1e-08

MSK_DPAR_INTPNT_CO_TOL_NEAR_REL *(real)*: Termination tolerance multiplier that is used if no accurate solution can be found. ↩

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: [1, ∞]

Default: 1

MSK_DPAR_INTPNT_CO_TOL_PFEAS *(real)*: Primal feasibility tolerance used by the interior-point optimizer for conic problems. ↩

Range: [0, 1]

Default: 1e-08

See also: MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_CO_TOL_REL_GAP *(real)*: Relative gap termination tolerance used by the interior-point optimizer for conic problems. ↩

Range: [0, 1]

Default: 1e-08

See also: MSK_DPAR_INTPNT_CO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_QO_TOL_DFEAS *(real)*: Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem. ↩

Range: [0, 1]

Default: 1e-08

See also: MSK_DPAR_INTPNT_QO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_QO_TOL_INFEAS *(real)*: Infeasibility tolerance used by the interior-point optimizer for quadratic problems. ↩

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: [0, 1]

Default: 1e-12

MSK_DPAR_INTPNT_QO_TOL_MU_RED *(real)*: Relative complementarity gap tolerance used by the interior-point optimizer for quadratic problems. ↩

Range: [0, 1]

Default: 1e-08

MSK_DPAR_INTPNT_QO_TOL_NEAR_REL *(real)*: Termination tolerance multiplier that is used if no accurate solution can be found. ↩

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Range: [1, ∞]

Default: 1

MSK_DPAR_INTPNT_QO_TOL_PFEAS *(real)*: Primal feasibility tolerance used by the interior-point optimizer for quadratic problems. ↩

Range: [0, 1]

Default: 1e-08

See also: MSK_DPAR_INTPNT_QO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_QO_TOL_REL_GAP *(real)*: Relative gap termination tolerance used by the interior-point optimizer for quadratic problems. ↩

Range: [0, 1]

Default: 1e-08

See also: MSK_DPAR_INTPNT_QO_TOL_NEAR_REL.

MSK_DPAR_INTPNT_TOL_DFEAS *(real)*: Dual feasibility tolerance used by the interior-point optimizer for linear problems. ↩

Range: [0, 1]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_DSAFE *(real)*: Controls the initial dual starting point used by the interior-point optimizer. ↩

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Range: [0.0001, ∞]

Default: 1

MSK_DPAR_INTPNT_TOL_INFEAS *(real)*: Infeasibility tolerance used by the interior-point optimizer for linear problems. ↩

Controls when the interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Range: [0, 1]

Default: 1e-10

MSK_DPAR_INTPNT_TOL_MU_RED *(real)*: Relative complementarity gap tolerance used by the interior-point optimizer for linear problems. ↩

Range: [0, 1]

Default: 1e-16

MSK_DPAR_INTPNT_TOL_PATH *(real)*: Controls how close the interior-point optimizer follows the central path. ↩

A large value of this parameter means the central path is followed very closely. On numerically unstable problems it may be worthwhile to increase this parameter.

Range: [0, 0.9999]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_PFEAS *(real)*: Primal feasibility tolerance used by the interior-point optimizer for linear problems. ↩

Range: [0, 1]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_PSAFE *(real)*: Controls the initial primal starting point used by the interior-point optimizer. ↩

If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Range: [0.0001, ∞]

Default: 1

MSK_DPAR_INTPNT_TOL_REL_GAP *(real)*: Relative gap termination tolerance used by the interior-point optimizer for linear problems. ↩

Range: [1e-14, ∞]

Default: 1e-08

MSK_DPAR_INTPNT_TOL_REL_STEP *(real)*: Relative step size to the boundary for linear and quadratic optimization problems. ↩

Range: [0.0001, 0.999999]

Default: 0.9999

MSK_DPAR_INTPNT_TOL_STEP_SIZE *(real)*: Step size tolerance. ↩

If the step size falls below the value of this parameter, then the interior-point optimizer assumes it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Range: [0, 1]

Default: 1e-06

MSK_DPAR_LOWER_OBJ_CUT *(real)*: Lower objective limit. ↩

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval (MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT), then MOSEK is terminated.

Range: [-∞, ∞]

Default: -1e+30

See also: MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH.

MSK_DPAR_LOWER_OBJ_CUT_FINITE_TRH *(real)*: Lower objective limit threshold. ↩

If the lower objective cut (MSK_DPAR_LOWER_OBJ_CUT) is less than this value, then it is treated as infinity.

Range: [-∞, ∞]

Default: -5e+29

MSK_DPAR_MIO_MAX_TIME *(real)*: This parameter limits the maximum time spent by the mixed-integer optimizer. ↩

A negative number means infinity.

Range: [-∞, ∞]

Default: -1

MSK_DPAR_MIO_REL_GAP_CONST *(real)*: This value is used to compute the relative gap for the solution to an integer optimization problem. ↩

Range: [1e-15, ∞]

Default: 1e-10

MSK_DPAR_MIO_TOL_ABS_GAP *(real)*: Absolute optimality tolerance employed by the mixed-integer optimizer. ↩

Default: GAMS OptCA

MSK_DPAR_MIO_TOL_ABS_RELAX_INT *(real)*: Absolute relaxation tolerance of the integer constraints. ↩

That means if the fractional part of a discrete variable ($\min(|x| - \lfloor x \rfloor, \lceil x \rceil - |x|)$) is less than the tolerance, then the integer restriction is assumed to be satisfied.

Range: [1e-09, ∞]

Default: 1e-05

MSK_DPAR_MIO_TOL_FEAS *(real)*: Feasibility tolerance for mixed integer solver. ↩

Range: [1e-09, 0.001]

Default: 1e-06

MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT *(real)*: If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation. ↩

A value of 0.0 means that the value is selected automatically.

Range: [0, 1]

Default: 0

MSK_DPAR_MIO_TOL_REL_GAP *(real)*: Relative optimality tolerance employed by the mixed-integer optimizer. ↩

Default: GAMS OptCR

MSK_DPAR_OPTIMIZER_MAX_TIME *(real)*: Maximum amount of time the optimizer is allowed to spent on the optimization. ↩

A negative number means infinity.

Range: [-∞, ∞]

Default: GAMS ResLim

MSK_DPAR_PRESOLVE_TOL_ABS_LINDEP *(real)*: Absolute tolerance employed by the linear dependency checker. ↩

Default: 1e-06

MSK_DPAR_PRESOLVE_TOL_AIJ *(real)*: Absolute zero tolerance employed for constraint coefficients in presolve. ↩

Range: [1e-15, ∞]

Default: 1e-12

MSK_DPAR_PRESOLVE_TOL_PRIMAL_INFEAS_PERTURBATION *(real)*: The presolve is allowed to perturb a bound on a constraint or variable by this amount if it removes an infeasibility. ↩

Default: 1e-06

MSK_DPAR_PRESOLVE_TOL_REL_LINDEP *(real)*: Relative tolerance employed by the linear dependency checker. ↩

Default: 1e-10

MSK_DPAR_PRESOLVE_TOL_S *(real)*: Absolute zero tolerance employed for dual variables in presolve. ↩

Default: 1e-08

MSK_DPAR_PRESOLVE_TOL_X *(real)*: Absolute zero tolerance employed for primal variables in presolve. ↩

Default: 1e-08

MSK_DPAR_QCQO_REFORMULATE_REL_DROP_TOL *(real)*: This parameter determines when columns are dropped in incomplete Cholesky factorization during reformulation of quadratic problems. ↩

Default: 1e-15

MSK_DPAR_SEMIDEFINITE_TOL_APPROX *(real)*: Tolerance to define a matrix to be positive semidefinite. ↩

Range: [1e-15, ∞]

Default: 1e-10

MSK_DPAR_SIMPLEX_ABS_TOL_PIV *(real)*: Absolute pivot tolerance employed by the simplex optimizers. ↩

Range: [1e-12, ∞]

Default: 1e-07

MSK_DPAR_SIM_LU_TOL_REL_PIV *(real)*: Relative pivot tolerance for LU factorization in simplex optimizers and basis identification. ↩

A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.

Range: [1e-06, 0.999999]

Default: 0.01

MSK_DPAR_UPPER_OBJ_CUT *(real)*: Upper objective limit. ↩

If either a primal or dual feasible solution is found proving that the optimal objective value is outside the interval (MSK_DPAR_LOWER_OBJ_CUT, MSK_DPAR_UPPER_OBJ_CUT), then MOSEK is terminated.

Range: [-∞, ∞]

Default: 1e+30

See also: MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH.

MSK_DPAR_UPPER_OBJ_CUT_FINITE_TRH *(real)*: Upper objective limit threshold. ↩

If the upper objective cut MSK_DPAR_UPPER_OBJ_CUT is greater than this value, then it is treated as infinity.

Range: [-∞, ∞]

Default: 5e+29

MSK_IPAR_AUTO_SORT_A_BEFORE_OPT *(string)*: Controls whether the elements in each column of the coefficient matrix are sorted before an optimization is performed. ↩

This is not required but makes the optimization insusceptible to reorderings of variables.

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_BI_CLEAN_OPTIMIZER *(string)*: Controls which simplex optimizer is used in the clean-up phase. ↩

Anything else than primal or dual simplex is equivalent to free simplex.

Default: `MSK_OPTIMIZER_FREE`

value	meaning
`MSK_OPTIMIZER_FREE`	The optimizer is chosen automatically.
`MSK_OPTIMIZER_PRIMAL_SIMPLEX`	The primal simplex optimizer is used.
`MSK_OPTIMIZER_DUAL_SIMPLEX`	The dual simplex optimizer is used.
`MSK_OPTIMIZER_FREE_SIMPLEX`	One of the simplex optimizers is used.

MSK_IPAR_BI_IGNORE_MAX_ITER *(string)*: Controls if basis identification is performed under certain conditions. ↩

If the parameter MSK_IPAR_INTPNT_BASIS has the value `MSK_BI_NO_ERROR` and the interior-point optimizer has terminated due to maximum number of iterations, then basis identification is performed if this parameter has the value `MSK_ON`.

Default: `MSK_OFF`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_BI_IGNORE_NUM_ERROR *(string)*: Turns on basis identification if interior-point optimizer is terminated due to a numerical problem. ↩

If the parameter `MSK_IPAR_INTPNT_BASIS` has the value `MSK_BI_NO_ERROR` and the interior-point optimizer has terminated due to a numerical problem, then basis identification is performed if this parameter has the value `MSK_ON`.

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_BI_MAX_ITERATIONS *(integer)*: Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification. ↩

Default: `1000000`

MSK_IPAR_INFEAS_PREFER_PRIMAL *(string)*: If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_INFEAS_REPORT_AUTO *(string)*: Controls whether an infeasibility report is auto-

matically produced after the optimization if the problem is primal or dual infeasible. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INFEAS_REPORT_LEVEL *(integer)*: Controls the amount of information presented in an infeasibility report. ↩

Higher values imply more information.

Default: 1

MSK_IPAR_INTPNT_BASIS *(string)*: Controls whether the interior-point optimizer also computes an optimal basis. ↩

Default: MSK_BI_ALWAYS

value	meaning
MSK_BI_NEVER	Never do basis identification.
MSK_BI_ALWAYS	Basis identification is always performed even if the interior-point optimizer terminates abnormally.
MSK_BI_NO_ERROR	Basis identification is performed if the interior-point optimizer terminates without an error.
MSK_BI_IF_FEASIBLE	Basis identification is not performed if the interior-point optimizer terminates with a problem status saying that the problem is primal or dual infeasible.

See also: MSK_IPAR_BI_CLEAN_OPTIMIZER, MSK_IPAR_BI_IGNORE_MAX_ITER, MSK_IPAR_BI_IGNORE_NUM_ERROR, MSK_IPAR_BI_MAX_ITERATIONS.

MSK_IPAR_INTPNT_DIFF_STEP *(string)*: Controls whether different step sizes are allowed in the primal and dual space. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_INTPNT_MAX_ITERATIONS *(integer)*: Controls the maximum number of iterations allowed in the interior-point optimizer. ↩

Default: GAMS IterLim

MSK_IPAR_INTPNT_MAX_NUM_COR *(integer)*: Controls the maximum number of correctors allowed by the multiple corrector procedure. ↩

A negative value means that MOSEK is making the choice.

Range: {-1, ..., ∞}

Default: -1

MSK_IPAR_INTPNT_MAX_NUM_REFINEMENT_STEPS *(integer)*: Maximum number of steps to be used by the iterative refinement of the search direction. ↩

A negative value implies that the optimizer chooses the maximum number of iterative refinement steps.

Range: {-∞, ..., ∞}

Default: `-1`

MSK_IPAR_INTPNT_OFF_COL_TRH *(integer)*: Controls how aggressively offending columns are detected in the Jacobian of the constraint matrix. ↩

0 means no detection, 1 means aggressive detection, and higher values mean less aggressive detection.

Default: `40`

MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS *(integer)*: The GP ordering is dependent on a random seed. ↩

Therefore, trying several random seeds may lead to a better ordering. This parameter controls the number of random seeds tried. A value of 0 means that MOSEK makes the choice.

Default: `0`

MSK_IPAR_INTPNT_ORDER_METHOD *(string)*: Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system. ↩

Default: `MSK_ORDER_METHOD_FREE`

value	meaning
`MSK_ORDER_METHOD_FREE`	The ordering method is chosen automatically.
`MSK_ORDER_METHOD_APPMINLOC`	Approximate minimum local fill-in ordering is employed.
`MSK_ORDER_METHOD_TRY_GRAPHPAR`	Always try the graph partitioning based ordering.
`MSK_ORDER_METHOD_FORCE_GRAPHPAR`	Always use the graph partitioning based ordering even if it is worse than the approximate minimum local fill ordering.
`MSK_ORDER_METHOD_NONE`	No ordering is used. Note using this value almost always leads to a significantly slow down.

MSK_IPAR_INTPNT_REGULARIZATION_USE *(string)*: Controls whether regularization is allowed. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_INTPNT_SCALING *(string)*: Controls how the problem is scaled before the interior-point optimizer is used. ↩

Default: MSK_SCALING_FREE

value	meaning
MSK_SCALING_FREE	The optimizer chooses the scaling heuristic.
MSK_SCALING_NONE	No scaling is performed.

MSK_IPAR_INTPNT_SOLVE_FORM *(string)*: Controls whether the primal or the dual problem is solved. ↩

Default: MSK_SOLVE_FREE

value	meaning
MSK_SOLVE_FREE	The optimizer is free to solve either the primal or the dual problem.
MSK_SOLVE_PRIMAL	The optimizer should solve the primal problem.
MSK_SOLVE_DUAL	The optimizer should solve the dual problem.

MSK_IPAR_INTPNT_STARTING_POINT *(string)*: Starting point used by the interior-point optimizer. ↩

Default: MSK_STARTING_POINT_FREE

value	meaning
MSK_STARTING_POINT_FREE	The starting point is chosen automatically.
MSK_STARTING_POINT_GUESS	The optimizer guesses a starting point.
MSK_STARTING_POINT_CONSTANT	The optimizer constructs a starting point by assigning a constant value to all primal and dual variables. This starting point is normally robust.

MSK_IPAR_LOG *(integer)*: Controls the amount of log information. ↩

The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Default: 10

MSK_IPAR_LOG_BI *(integer)*: Controls the amount of output printed by the basis identification procedure. ↩

A higher level implies that more information is logged.

Default: 1

MSK_IPAR_LOG_BI_FREQ *(integer)*: Controls logging frequency of the basis identification ↩

Default: 2500

MSK_IPAR_LOG_FEAS_REPAIR *(integer)*: Controls the amount of output printed when performing feasibility repair. ↩

Default: 1

MSK_IPAR_LOG_INFEAS_ANA *(integer)*: Controls amount of output printed by the infeasibility analyzer procedures. ↩

A higher level implies that more information is logged.

Default: `1`

MSK_IPAR_LOG_INTPNT *(integer)*: Controls amount of output printed by the interior-point optimizer. ↩

A higher level implies that more information is logged.

Default: `1`

MSK_IPAR_LOG_MIO *(integer)*: Controls the log level for the mixed-integer optimizer. ↩

A higher level implies that more information is logged.

Default: `4`

MSK_IPAR_LOG_MIO_FREQ *(integer)*: Controls how frequent the mixed-integer optimizer prints the log line. ↩

It will print a line every time `MSK_INTPAR_LOG_MIO_FREQ` relaxations have been solved.

Range: {-∞, ..., ∞}

Default: `10`

MSK_IPAR_LOG_ORDER *(integer)*: If turned on, then factor lines are added to the log. ↩

Default: `1`

MSK_IPAR_LOG_PRESOLVE *(integer)*: Controls amount of output printed by the presolve procedure. ↩

A higher level implies that more information is logged.

Default: `1`

MSK_IPAR_LOG_RESPONSE *(integer)*: Controls amount of output printed when response codes are reported. ↩

A higher level implies that more information is logged.

Default: `0`

MSK_IPAR_LOG_SIM *(integer)*: Controls amount of output printed by the simplex optimizer. ↩

A higher level implies that more information is logged.

Default: `4`

MSK_IPAR_LOG_SIM_FREQ *(integer)*: Controls simplex optimizer logging frequency. ↩

Default: `1000`

MSK_IPAR_LOG_STORAGE *(integer)*: When turned on, MOSEK prints messages regarding the storage usage and allocation. ↩

Default: `0`

MSK_IPAR_MIO_BRANCH_DIR *(string)*: Controls whether the mixed-integer optimizer is branching up or down by default. ↩

Default: `MSK_BRANCH_DIR_FREE`

value	meaning
MSK_BRANCH_DIR_FREE	The mixed-integer optimizer decides which branch to choose.
MSK_BRANCH_DIR_UP	The mixed-integer optimizer always chooses the up branch first.
MSK_BRANCH_DIR_DOWN	The mixed-integer optimizer always chooses the down branch first.
MSK_BRANCH_DIR_NEAR	Branch in direction nearest to selected fractional variable.
MSK_BRANCH_DIR_FAR	Branch in direction farthest from selected fractional variable.
MSK_BRANCH_DIR_ROOT_LP	Chose direction based on root lp value of selected variable.
MSK_BRANCH_DIR_GUIDED	Branch in direction of current incumbent.
MSK_BRANCH_DIR_PSEUDOCOST	Branch based on the pseudocost of the variable.

MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION *(string)*: If this option is turned on outer approximation is used when solving relaxations of conic problems; otherwise interior point is used. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CONSTRUCT_SOL *(string)*: Whether to construct an initial solution from starting point ↩

If enabled and all integer variables have been given a value for which a feasible mixed integer solution exists, then MOSEK generates an initial solution to the mixed integer problem by fixing all integer values and solving the remaining problem.

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_CLIQUE *(string)*: Controls whether clique cuts should be generated. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_CMIR *(string)*: Controls whether mixed integer rounding cuts should be generated. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.

value	meaning
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_GMI *(string)*: Controls whether GMI cuts should be generated. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_IMPLIED_BOUND *(string)*: Controls whether implied bound cuts should be generated. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_KNAPSACK_COVER *(string)*: Controls whether knapsack cover cuts should be generated. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_LIPRO *(string)*: Controls whether lift-and-project cuts should be generated. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_CUT_SELECTION_LEVEL *(integer)*: Controls how aggressively generated cuts are selected to be included in the relaxation. ↩

Default: -1

value	meaning
-1	The optimizer chooses the level of cut selection.
0	Generated cuts less likely to be added to the relaxation.
1	Cuts are more aggressively selected to be included in the relaxation.

MSK_IPAR_MIO_DATA_PERMUTATION_METHOD *(string)*: Controls what problem data permutation method is appplied to mixed-integer problems. ↩

Default: `MSK_MIO_DATA_PERMUTATION_METHOD_NONE`

value	meaning
`MSK_MIO_DATA_PERMUTATION_METHOD_NONE`	No problem data permutation is applied.
`MSK_MIO_DATA_PERMUTATION_METHOD_CYCLIC_SHIFT`	A random cyclic shift is applied to permute the problem data.
`MSK_MIO_DATA_PERMUTATION_METHOD_RANDOM`	A random permutation is applied to the problem data.

MSK_IPAR_MIO_DUAL_RAY_ANALYSIS_LEVEL *(string)*: Controls the amount of symmetry detection and handling employed by the mixed-integer optimizer in presolve. ↩

Default: `-1`

value	meaning
`-1`	The optimizer chooses the level of dual ray analysis employed.
`0`	Dual ray analysis is disabled.
`1`	A lower amount of dual ray analysis is employed.
`2`	A higher amount of dual ray analysis is employed.

MSK_IPAR_MIO_FEASPUMP_LEVEL *(string)*: Controls the way the Feasibility Pump heuristic is employed by the mixed-integer optimizer. ↩

Default: `-1`

value	meaning
`-1`	The optimizer chooses how the Feasibility Pump is used.
`0`	The Feasibility Pump is disabled.
`1`	The Feasibility Pump is enabled with an effort to improve solution quality.
`2`	The Feasibility Pump is enabled with an effort to reach feasibility early.

MSK_IPAR_MIO_HEURISTIC_LEVEL *(integer)*: Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution. ↩

A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Range: {-∞, ..., ∞}

Default: `-1`

MSK_IPAR_MIO_MAX_NUM_BRANCHES *(integer)*: Maximum number of branches allowed during the branch and bound search. ↩

A negative value means infinite.

Range: {-∞, ..., ∞}

Default: `-1`

MSK_IPAR_MIO_MAX_NUM_RELAXS *(integer)*: Maximum number of relaxations allowed during the branch and bound search. ↩

A negative value means infinite.

Range: {-∞, ..., ∞}

Default: `GAMS NodLim`

MSK_IPAR_MIO_MAX_NUM_RESTARTS *(integer)*: Maximum number of restarts allowed during the branch and bound search. ↩

Default: `0`

MSK_IPAR_MIO_MAX_NUM_ROOT_CUT_ROUNDS *(integer)*: Maximum number of cut separation rounds at the root node. ↩

Default: `100`

MSK_IPAR_MIO_MAX_NUM_SOLUTIONS *(integer)*: The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located. ↩

If this parameter has the value $n > 0$, then the mixed-integer optimizer will be terminated when n feasible solutions have been located.

Range: {-∞, ..., ∞}

Default: `-1`

MSK_IPAR_MIO_MEMORY_EMPHASIS_LEVEL *(string)*: Controls how much emphasis is put on reducing memory usage. ↩

Being more conservative about memory usage may come at the cost of decreased solution speed.

Default: `0`

value	meaning
`0`	The optimizer chooses.
`1`	More emphasis is put on reducing memory usage and less on speed.

MSK_IPAR_MIO_MIN_REL *(integer)*: Number of times a variable must have been branched on for its pseudocost to be considered reliable. ↩

Default: `5`

MSK_IPAR_MIO_NODE_OPTIMIZER *(string)*: Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer. ↩

Default: `MSK_OPTIMIZER_FREE`

value	meaning
`MSK_OPTIMIZER_FREE`	The optimizer is chosen automatically.
`MSK_OPTIMIZER_INTPNT`	The interior-point optimizer is used.
`MSK_OPTIMIZER_CONIC`	The optimizer for problems having conic constraints.

value	meaning
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.
MSK_OPTIMIZER_MIXED_INT	The mixed-integer optimizer.

MSK_IPAR_MIO_NODE_SELECTION *(string)*: Controls the node selection strategy employed by the mixed-integer optimizer. ↩

Default: MSK_MIO_NODE_SELECTION_FREE

value	meaning
MSK_MIO_NODE_SELECTION_FREE	The optimizer decides the node selection strategy.
MSK_MIO_NODE_SELECTION_FIRST	The optimizer employs a depth first node selection strategy.
MSK_MIO_NODE_SELECTION_BEST	The optimizer employs a best bound node selection strategy.
MSK_MIO_NODE_SELECTION_PSEUDO	The optimizer employs selects the node based on a pseudo cost estimate.

MSK_IPAR_MIO_NUMERICAL_EMPHASIS_LEVEL *(string)*: Controls how much emphasis is put on reducing numerical problems possibly at the expense of solution speed. ↩

Default: 0

value	meaning
0	The optimizer chooses.
1	More emphasis is put on reducing numerical problems.
2	Even more emphasis.

MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE *(string)*: Enables or disables perspective reformulation in presolve. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_PRESOLVE_AGGREGATOR_USE *(string)*: Controls if the aggregator should be used. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_MIO_PROBING_LEVEL *(integer)*: Controls the amount of probing employed by the

mixed-integer optimizer in presolve. ↩

Default: `-1`

value	meaning
`-1`	The optimizer chooses the level of probing employed
`0`	Probing is disabled
`1`	A low amount of probing is employed
`2`	A medium amount of probing is employed
`3`	A high amount of probing is employed

MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT *(string)*: Use objective domain propagation. ↩

Default: `MSK_OFF`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_MIO_QCQO_REFORMULATION_METHOD *(string)*: Controls what reformulation method is applied to mixed-integer quadratic problems. ↩

Default: `MSK_MIO_QCQO_REFORMULATION_METHOD_FREE`

value	meaning
`MSK_MIO_QCQO_REFORMULATION_METHOD_FREE`	The mixed-integer optimizer decides which reformulation method to apply.
`MSK_MIO_QCQO_REFORMULATION_METHOD_NONE`	No reformulation method is applied.
`MSK_MIO_QCQO_REFORMULATION_METHOD_LINEARIZATION`	Reformulation via linearization is applied.
`MSK_MIO_QCQO_REFORMULATION_METHOD_EIGEN_VAL_METHOD`	The eigenvalue method is applied.
`MSK_MIO_QCQO_REFORMULATION_METHOD_DIAG_SDP`	SDP perturbation of matrix diagonals via the solution of SDPs is applied.
`MSK_MIO_QCQO_REFORMULATION_METHOD_RELAX_SDP`	Reformulation based on the solution of an SDP-relaxation of the problem is applied.

MSK_IPAR_MIO_RINS_MAX_NODES *(integer)*: Controls the maximum number of nodes allowed in each call to the RINS heuristic. ↩

The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Range: {`-1`, ..., ∞}

Default: `-1`

MSK_IPAR_MIO_ROOT_OPTIMIZER *(string)*: Controls which optimizer is employed at the root node in the mixed-integer optimizer. ↩

Default: `MSK_OPTIMIZER_FREE`

value	meaning
MSK_OPTIMIZER_FREE	The optimizer is chosen automatically.
MSK_OPTIMIZER_INTPNT	The interior-point optimizer is used.
MSK_OPTIMIZER_CONIC	The optimizer for problems having conic constraints.
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.

MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL *(integer)*: Controls whether presolve can be repeated at root node. ↩

Default: -1

value	meaning
-1	The optimizer chooses whether presolve is repeated.
0	Never repeat presolve.
1	Always repeat presolve.

MSK_IPAR_MIO_SEED *(integer)*: Sets the random seed used for randomization in the mixed integer optimizer. ↩

Selecting a different seed can change the path the optimizer takes to the optimal solution.

Default: 42

MSK_IPAR_MIO_SYMMETRY_LEVEL *(string)*: Controls the amount of symmetry detection and handling employed by the mixed-integer optimizer in presolve. ↩

Default: -1

value	meaning
-1	The optimizer chooses the level of symmetry detection and handling employed.
0	Symmetry detection and handling is disabled.
1	A low amount of symmetry detection and handling is employed.
2	A medium amount of symmetry detection and handling is employed.
3	A high amount of symmetry detection and handling is employed .
4	An extremely high amount of symmetry detection and handling is employed.

MSK_IPAR_MIO_VAR_SELECTION *(string)*: Controls the variable selection strategy employed by the mixed-integer optimizer. ↩

Default: MSK_MIO_VAR_SELECTION_FREE

value	meaning
MSK_MIO_VAR_SELECTION_FREE	The optimizer decides the variable selection strategy.
MSK_MIO_VAR_SELECTION_PSEUDOCOST	The optimizer employs pseudocost variable selection.
MSK_MIO_VAR_SELECTION_STRONG	The optimizer employs strong branching variable selection.

MSK_IPAR_MIO_VB_DETECTION_LEVEL *(integer)*: Controls how much effort is put into detecting variable bounds. ↩

Default: `-1`

value	meaning
`-1`	The optimizer chooses.
`0`	No variable bounds are detected.
`1`	Only detect variable bounds that are directly represented in the problem.
`2`	Detect variable bounds in probing.

MSK_IPAR_NUM_THREADS *(integer)*: Controls the number of threads employed by the optimizer. ↩

If set to 0 the number of threads used will be equal to the number of cores detected on the machine.

Default: `GAMS Threads`

MSK_IPAR_OPF_WRITE_HEADER *(string)*: Write a text header with date and MOSEK version in an OPF file. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_OPF_WRITE_HINTS *(string)*: Write a hint section with problem dimensions in the beginning of an OPF file. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_OPF_WRITE_LINE_LENGTH *(integer)*: Aim to keep lines in OPF files not much longer than this. ↩

Default: `80`

MSK_IPAR_OPF_WRITE_PARAMETERS *(string)*: Write a parameter section in an OPF file. ↩

Default: `MSK_OFF`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_OPF_WRITE_PROBLEM *(string)*: Write objective, constraints, bounds etc. ↩

to an OPF file.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOLUTIONS *(string)*: Enable inclusion of solutions in the OPF files. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOL_BAS *(string)*: Whether to include basic solution in OPF files. ↩

If MSK_IPAR_OPF_WRITE_SOLUTIONS is MSK_ON and a basic solution is defined, include the basic solution in OPF files.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOL_ITG *(string)*: Whether to include integer solution in OPF files. ↩

If MSK_IPAR_OPF_WRITE_SOLUTIONS is MSK_ON and an integer solution is defined, write the integer solution to OPF files.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPF_WRITE_SOL_ITR *(string)*: Whether to include interior solution in OPF files. ↩

If MSK_IPAR_OPF_WRITE_SOLUTIONS is MSK_ON and an interior solution is defined, write the interior solution to OPF files.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_OPTIMIZER *(string)*: The parameter controls which optimizer is used to optimize the

task. ↩

Default: MSK_OPTIMIZER_FREE

value	meaning
MSK_OPTIMIZER_FREE	The optimizer is chosen automatically.
MSK_OPTIMIZER_INTPNT	The interior-point optimizer is used.
MSK_OPTIMIZER_CONIC	The optimizer for problems having conic constraints.
MSK_OPTIMIZER_PRIMAL_SIMPLEX	The primal simplex optimizer is used.
MSK_OPTIMIZER_DUAL_SIMPLEX	The dual simplex optimizer is used.
MSK_OPTIMIZER_FREE_SIMPLEX	One of the simplex optimizers is used.
MSK_OPTIMIZER_MIXED_INT	The mixed-integer optimizer.

MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL *(integer)*: Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve. ↩

A negative value means the parameter value is selected automatically.

Range: {-∞, ..., ∞}

Default: -1

MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_NUM_TRIES *(integer)*: Control the maximum number of times the eliminator is tried. ↩

A negative value implies MOSEK decides.

Range: {-∞, ..., ∞}

Default: -1

MSK_IPAR_PRESOLVE_LINDEP_ABS_WORK_TRH *(integer)*: Controls the linear dependency check, which is potentially computationally expensive. ↩

Range: {-∞, ..., ∞}

Default: 100

MSK_IPAR_PRESOLVE_LINDEP_NEW *(string)*: Controls whether a new experimental linear dependency checker is employed. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_PRESOLVE_LINDEP_REL_WORK_TRH *(integer)*: Controls the linear dependency check, which is potentially computationally expensive. ↩

Range: {-∞, ..., ∞}

Default: 100

MSK_IPAR_PRESOLVE_LINDEP_USE *(string)*: Controls whether the linear constraints are checked for linear dependencies. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_PRESOLVE_MAX_NUM_PASS *(integer)*: Control the maximum number of times presolve passes over the problem. ↩

A negative value implies MOSEK decides.

Range: {-∞, ..., ∞}

Default: `-1`

MSK_IPAR_PRESOLVE_MAX_NUM_REDUCTIONS *(integer)*: Controls the maximum number of reductions performed by the presolve. ↩

The value of the parameter is normally only changed in connection with debugging. A negative value implies that an infinite number of reductions are allowed.

Range: {-∞, ..., ∞}

Default: `-1`

MSK_IPAR_PRESOLVE_USE *(string)*: Controls whether the presolve is applied to a problem before it is optimized. ↩

Default: `MSK_PRESOLVE_MODE_FREE`

value	meaning
`MSK_PRESOLVE_MODE_OFF`	The problem is not presolved before it is optimized.
`MSK_PRESOLVE_MODE_ON`	The problem is presolved before it is optimized.
`MSK_PRESOLVE_MODE_FREE`	It is decided automatically whether to presolve before the problem is optimized.

MSK_IPAR_PTF_WRITE_PARAMETERS *(string)*: If enabled, then the parameters section is written. ↩

Default: `MSK_OFF`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_PTF_WRITE_SOLUTIONS *(string)*: If enabled, then the solution section is written if any solutions are available, otherwise solution section is not written even if solutions are available. ↩

Default: `MSK_OFF`

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_PTF_WRITE_TRANSFORM *(string)*: If enabled, then constraint blocks with identifiable conic slacks are transformed into conic constraints and the slacks are eliminated. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_BASIS_FACTOR_USE *(string)*: Controls whether an LU factorization of the basis is used in a hot-start. ↩

Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_DEGEN *(string)*: Controls how aggressively degeneration is handled. ↩

Default: MSK_SIM_DEGEN_FREE

value	meaning
MSK_SIM_DEGEN_NONE	The simplex optimizer should use no degeneration strategy.
MSK_SIM_DEGEN_FREE	The simplex optimizer chooses the degeneration strategy.
MSK_SIM_DEGEN_AGGRESSIVE	The simplex optimizer should use an aggressive degeneration strategy.
MSK_SIM_DEGEN_MODERATE	The simplex optimizer should use a moderate degeneration strategy.
MSK_SIM_DEGEN_MINIMUM	The simplex optimizer should use a minimum degeneration strategy.

MSK_IPAR_SIM_DUAL_CRASH *(integer)*: Controls whether crashing is performed in the dual simplex optimizer. ↩

In general if a basis consists of more than (100*MSK_IPAR_SIM_DUAL_CRASH) percent fixed variables, then a crash will be performed.

Default: 90

MSK_IPAR_SIM_DUAL_RESTRICT_SELECTION *(integer)*: Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the dual simplex. ↩

The dual simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: {0, ..., 100}

Default: 50

MSK_IPAR_SIM_DUAL_SELECTION *(string)*: Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer. ↩

Default: MSK_SIM_SELECTION_FREE

value	meaning
MSK_SIM_SELECTION_FREE	The optimizer chooses the pricing strategy.
MSK_SIM_SELECTION_FULL	The optimizer uses full pricing.
MSK_SIM_SELECTION_ASE	The optimizer uses approximate steepest-edge pricing.
MSK_SIM_SELECTION_DEVEX	The optimizer uses devex steepest-edge pricing. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_SE	The optimizer uses steepest-edge selection. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_PARTIAL	The optimizer uses a partial selection approach. The approach is usually beneficial if the number of variables is much larger than the number of constraints.

MSK_IPAR_SIM_EXPLOIT_DUPVEC *(string)*: Controls if the simplex optimizers are allowed to exploit duplicated columns. ↩

Default: MSK_SIM_EXPLOIT_DUPVEC_OFF

value	meaning
MSK_SIM_EXPLOIT_DUPVEC_ON	Allow the simplex optimizer to exploit duplicated columns.
MSK_SIM_EXPLOIT_DUPVEC_OFF	Disallow the simplex optimizer to exploit duplicated columns.
MSK_SIM_EXPLOIT_DUPVEC_FREE	The simplex optimizer can choose freely.

MSK_IPAR_SIM_HOTSTART *(string)*: Controls the type of hot-start that the simplex optimizer perform. ↩

Default: MSK_SIM_HOTSTART_FREE

value	meaning
MSK_SIM_HOTSTART_NONE	The simplex optimizer performs a coldstart.
MSK_SIM_HOTSTART_FREE	The simplex optimize chooses the hot-start type.
MSK_SIM_HOTSTART_STATUS_KEYS	Only the status keys of the constraints and variables are used to choose the type of hot-start.

MSK_IPAR_SIM_HOTSTART_LU *(string)*: Determines if the simplex optimizer should exploit the initial factorization. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_SIM_MAX_ITERATIONS *(integer)*: Maximum number of iterations that can be used by a simplex optimizer. ↩

Default: `GAMS IterLim`

MSK_IPAR_SIM_MAX_NUM_SETBACKS *(integer)*: Controls how many set-backs are allowed within a simplex optimizer. ↩

A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Default: `250`

MSK_IPAR_SIM_NON_SINGULAR *(string)*: Controls if the simplex optimizer ensures a non-singular basis, if possible. ↩

Default: `MSK_ON`

value	meaning
`MSK_ON`	Switch the option on.
`MSK_OFF`	Switch the option off.

MSK_IPAR_SIM_PRIMAL_CRASH *(integer)*: Controls whether crashing is performed in the primal simplex optimizer. ↩

In general if a basis consists of more than `(100*MSK_IPAR_SIM_PRIMAL_CRASH)` percent fixed variables, then a crash will be performed.

Default: `90`

MSK_IPAR_SIM_PRIMAL_RESTRICT_SELECTION *(integer)*: Controls how aggressively a restricted selection/pricing strategy is used to choose the outgoing variable in the primal simplex. ↩

The primal simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the primal simplex optimizer first choose a subset of all the potential incoming variables. Next, for some time it will choose the incoming variable only among the subset. From time to time the subset is redefined. A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Range: {`0`, ..., `100`}

Default: `50`

MSK_IPAR_SIM_PRIMAL_SELECTION *(string)*: Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer. ↩

Default: `MSK_SIM_SELECTION_FREE`

value	meaning
MSK_SIM_SELECTION_FREE	The optimizer chooses the pricing strategy.
MSK_SIM_SELECTION_FULL	The optimizer uses full pricing.
MSK_SIM_SELECTION_ASE	The optimizer uses approximate steepest-edge pricing.
MSK_SIM_SELECTION_DEVEX	The optimizer uses devex steepest-edge pricing. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_SE	The optimizer uses steepest-edge selection. If it is not available an approximate steep-edge selection is chosen.
MSK_SIM_SELECTION_PARTIAL	The optimizer uses a partial selection approach. The approach is usually beneficial if the number of variables is much larger than the number of constraints.

MSK_IPAR_SIM_REFORMULATION *(string)*: Controls if the simplex optimizers are allowed to reformulate the problem. ↩

Default: MSK_SIM_REFORMULATION_OFF

value	meaning
MSK_SIM_REFORMULATION_ON	Allow the simplex optimizer to reformulate the problem.
MSK_SIM_REFORMULATION_OFF	Disallow the simplex optimizer to reformulate the problem.
MSK_SIM_REFORMULATION_FREE	The simplex optimizer can choose freely.
MSK_SIM_REFORMULATION_AGGRESSIVE	The simplex optimizer should use an aggressive reformulation strategy.

MSK_IPAR_SIM_SAVE_LU *(string)*: Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_SIM_SCALING *(string)*: Controls how much effort is used in scaling the problem before a simplex optimizer is used. ↩

Default: MSK_SCALING_FREE

value	meaning
MSK_SCALING_FREE	The optimizer chooses the scaling heuristic.
MSK_SCALING_NONE	No scaling is performed.

MSK_IPAR_SIM_SCALING_METHOD *(string)*: Controls how the problem is scaled before a simplex optimizer is used. ↩

Default: MSK_SCALING_METHOD_POW2

value	meaning
MSK_SCALING_METHOD_POW2	Scales only with power of 2 leaving the mantissa untouched.
MSK_SCALING_METHOD_FREE	The optimizer chooses the scaling heuristic.

MSK_IPAR_SIM_SEED *(integer)*: Sets the random seed used for randomization in the simplex optimizers. ↩

Range: {0, ..., 32749}

Default: 23456

MSK_IPAR_SIM_SOLVE_FORM *(string)*: Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer. ↩

Default: MSK_SOLVE_FREE

value	meaning
MSK_SOLVE_FREE	The optimizer is free to solve either the primal or the dual problem.
MSK_SOLVE_PRIMAL	The optimizer should solve the primal problem.
MSK_SOLVE_DUAL	The optimizer should solve the dual problem.

MSK_IPAR_SIM_STABILITY_PRIORITY *(integer)*: Controls how high priority the numerical stability should be given. ↩

Range: {0, ..., 100}

Default: 50

MSK_IPAR_SIM_SWITCH_OPTIMIZER *(string)*: Controls the simplex behavior. ↩

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_TIMING_LEVEL *(integer)*: Controls the amount of timing performed inside MOSEK. ↩

Default: 1

MSK_IPAR_WRITE_COMPRESSION *(integer)*: Controls whether the data file is compressed while it is written. ↩

0 means no compression while higher values mean more compression.

Default: 9

MSK_IPAR_WRITE_DATA_PARAM *(string)*: If this option is turned on the parameter settings are written to the data file as parameters. ↩

Default: `MSK_OFF`

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_GENERIC_NAMES *(string)*: Controls whether generic names should be used instead of user-defined names when writing to the data file. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_GENERIC_NAMES_IO *(integer)*: Index origin used in generic names. ↩

Default: 1

MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_ITEMS *(string)*: Controls if the writer ignores incompatible problem items when writing files. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_JSON_INDENTATION *(string)*: When set, the JSON task and solution files are written with indentation for better readability. ↩

Default: MSK_OFF

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_LP_FULL_OBJ *(string)*: Write all variables, including the ones with 0-coefficients, in the objective. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_LP_LINE_WIDTH *(integer)*: Maximum width of line in an LP file written by MOSEK. ↩

Range: {40, ..., ∞}

Default: 80

MSK_IPAR_WRITE_MPS_FORMAT *(string)*: Controls in which format the MPS is written. ↩

Default: MSK_MPS_FORMAT_FREE

value	meaning
MSK_MPS_FORMAT_STRICT	It is assumed that the input file satisfies the MPS format strictly.
MSK_MPS_FORMAT_RELAXED	It is assumed that the input file satisfies a slightly relaxed version of the MPS format.
MSK_MPS_FORMAT_FREE	It is assumed that the input file satisfies the free MPS format. This implies that spaces are not allowed in names. Otherwise the format is free.
MSK_MPS_FORMAT_CPLEX	The CPLEX compatible version of the MPS format is employed.

MSK_IPAR_WRITE_MPS_INT *(string)*: Controls if marker records are written to the MPS file to indicate whether variables are integer restricted. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_TASK_INC_SOL *(string)*: Controls whether the solutions are stored in the task file too. ↩

Default: MSK_ON

value	meaning
MSK_ON	Switch the option on.
MSK_OFF	Switch the option off.

MSK_IPAR_WRITE_XML_MODE *(string)*: Controls if linear coefficients should be written by row or column when writing in the XML file format. ↩

Default: MSK_WRITE_XML_MODE_ROW

value	meaning
MSK_WRITE_XML_MODE_ROW	Write in row order.
MSK_WRITE_XML_MODE_COL	Write in column order.

MSK_SPAR_DATA_FILE_NAME *(string)*: If set, problem data is written to this file. File extension determines format. ↩

Synonym: writeprob

MSK_SPAR_PARAM_READ_FILE_NAME *(string)*: Modifications to the parameter database is read from this file. ↩

MSK_SPAR_PARAM_WRITE_FILE_NAME *(string)*: The parameter database is written to this file. ↩

MSK_SPAR_WRITE_LP_GEN_VAR_NAME *(string)*: Sometimes when an LP file is written additional variables must be inserted. ↩

They will have the prefix denoted by this parameter.

Default: `"xmskgen"`

QEXTRACTALG *(integer)*: Switch to choose extraction algorithm for quadratic equations in GAMS interface. ↩

Default: `0`

value	meaning
`0`	Choose automatically.
`1`	ThreePass: uses a three-pass forward / backward / forward AD technique to compute function / gradient / Hessian values and a hybrid scheme for storage
`2`	DoubleForward: uses forward-mode AD to compute and store function, gradient, and Hessian values at each node or stack level as required. The gradients and Hessians are stored in linked lists.
`3`	Concurrent: Uses ThreePass and DoubleForward in parallel. As soon as one finishes, the other one stops.

SDPCHECKVARS *(boolean)*: Switch to disable checking that for every entry of a PSD matrix variable also a corresponding GAMS variable is present. ↩

Default: `1`

SDPSOLUFILE *(string)*: Name of GDX file to write primal solution of all PSD matrix variables and dual solution for PSD constraints. ↩

SOLVEFINAL *(boolean)*: Switch to resolve the problem with fixed discrete variables after the MOSEK optimizer finished. ↩

Default: `1`

value	meaning
`0`	Do not solve the fixed problem.
`1`	Solve the fixed problem and return duals.

5.27.6 Setting up a GAMS/MOSEK-Link license

To use the GAMS/MOSEK solver with a GAMS/MOSEK-Link license you have save a MOSEK standalone license and point to the MOSEK license file via environment variable `MOSEKLM_LICENSE_FILE`.

5.28 NLPEC

5.28.1 Introduction

The GAMS/NLPEC solver, developed jointly by Michael Ferris of UW-Madison and GAMS Development, solves MPEC and MCP models via reformulation of the complementarity constraints. The resulting sequence of NLP models are parameterized by a scalar μ and solved by existing NLP solvers. The resulting solutions are used to recover an MPEC or MCP solution.

GAMS/NLPEC serves a number of purposes. In many cases, it is an effective tool for solving MPEC models, the first such tool available within GAMS. It also serves as a way to experiment with the many reformulation strategies proposed for solving MPEC and MCP models. Without something like NLPEC (and a library of models to test with) a comprehensive and thorough test and comparison of the various reformulation strategies would not be possible. To better serve these purposes, NLPEC has an open architecture. The model reformulations are written out as GAMS source for solution via an NLP solver, so it is possible to view this source and modify it if desired.

A brief note about notation is in order. The GAMS keyword `positive` is used to indicate nonnegative variables. The same holds for nonpositive variables and the GAMS keyword `negative`.

5.28.2 Usage

GAMS/NLPEC can solve models of two types: MPEC and MCP. If you did not specify NLPEC as the default MPEC or MCP solver, use the following statement in your GAMS model before the solve statement:

```
option MPEC=nlpec; { or MCP }
```

You can also make NLPEC the default solver via the command line:

```
gams nash  MPEC=nlpec MCP=nlpec
```

You can use NLPEC with its default strategy and formulation, but most users will want to use an options file (Section Options) after reading about the different types of reformulations possible (Section Reformulation). In addition, an understanding of the architecture of NLPEC (Section Open Architecture) will be helpful in understanding how GAMS options are treated. Although NLPEC doesn't use the GAMS options `workspace`, `workfactor`, `optcr`, `optca`, `reslim`, `iterlim`, and `domlim` directly, it passes these options on in the reformulated model so they are available to the NLP subsolver.

5.28.3 Reformulation

In this section we describe the different ways that the NLPEC solver can reformulate an MPEC as an NLP. The description also applies to MCP models: just consider MCP to be an MPEC with a constant objective. The choice of reformulation, and the subsidiary choices each reformulation entails, are controlled by the options described in the section on Setting the Reformulation Options and referenced throughout this section.

The original MPEC model is given as:

$$\min_{x \in \mathbf{R}^n, y \in \mathbf{R}^m} f(x, y) \tag{1}$$

subject to the constraints

$$g(x,y) \leq 0 \tag{2}$$

and

$$y \text{ solves MCP}(h(x,\cdot),\mathbf{B}). \tag{3}$$

In most of the reformulations, the objective function (1) is included in the reformulated model without change. In some cases, it may be augmented with a penalty function. The variables x are typically called upper level variables (because they are associated with the upper level optimization problem) whereas the variables y are sometimes termed lower level variables.

The constraints (2) are standard nonlinear programming constraints specified in GAMS in the standard fashion. In particular, these constraints may be less than inequalities as shown above, or equalities or greater than inequalities. The constraints will be unaltered by all our reformulations. These constraints may involve both x and y, or just x or just y, or may not be present at all in the problem.

The constraints of interest are the equilibrium constraints (3), where (3) signifies that $y \in \mathbf{R}^m$ is a solution to the mixed complementarity problem (MCP) defined by the function $h(x,\cdot)$ and the box $\mathbf{B}$ containing (possibly infinite) simple bounds on the variables y. A point y with $a_i \leq y_i \leq b_i$ solves (3) if for each i at least one of the following holds:

$$\begin{array}{c} h_i(x,y) = 0 \\ h_i(x,y) \geq 0,\ y_i = a_i; \\ h_i(x,y) \leq 0,\ y_i = b_i. \end{array} \tag{4}$$

As a special case of (4), consider the case where $a = 0$ and $b = +\infty$. Since y_i can never be $+\infty$ at a solution, (4) simplifies to the nonlinear complementarity problem (NCP):

$$0 \leq h_i(x,y), 0 \leq y_i \text{ and } y_i h_i(x,y) = 0, i = 1,\ldots,m \tag{5}$$

namely that h and y are nonnegative vectors with h perpendicular to y. This motivates our shorthand for (4), the "perp to" symbol $\perp$:

$$h_i(x,y) \quad \perp \quad y_i \in [a_i, b_i] \tag{6}$$

The different ways to force (6) to hold using (smooth) NLP constraints are the basis of the NLPEC solver.

We introduce a simple example now that we will use throughout this document for expositional purposes:

$$\begin{array}{cc} \min\limits_{x_1,x_2,y_1,y_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & y_1 - y_2 + 1 \leq x_1 \perp y_1 \geq 0 \\ & x_2 + y_2 \perp y_2 \in [-1,1] \end{array}$$

This problem has the unique solution $x_1 = 0$, $x_2 = -1$, $y_1 = 0$, $y_2 = 1$. Note that $f(x,y) = x_1 + x_2$ and $g(x,y) = x_1^2 + x_2^2 - 1$ are the objective function and the standard nonlinear programming constraints for this problem. The function $h(x,y)$ is given by:

$$h(x,y) = \begin{bmatrix} x_1 - y_1 + y_2 - 1 \\ x_2 + y_2 \end{bmatrix}$$

and

$$a = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \quad b = \begin{bmatrix} \infty \\ 1 \end{bmatrix}.$$

This example is written very succinctly in GAMS notation as:

```
$TITLE simple mpec example

variable f, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up =  1;

equations cost, g, h1, h2;

cost..  f =E= x1 + x2;
g..     sqr(x1) + sqr(x2) =L= 1;
h1..    x1 =G= y1 - y2 + 1;
h2..    x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min f;
```

Note that the equation `cost` is used to define f, the constraint `g` defines the function g, and h is defined by `h1` and `h2`. The complementarity constraints utilize the standard GAMS convention of specifying the orthogonality relationship between h and y in the `model` statement. The interpretation of the "." relies on the bounds a and b that are specified using `positive`, `negative`, or `lo` and `up` keywords in GAMS. Note that since `h2` really specifies a function h_2 and not a constraint $h_2(x, y) = 0$, we use the GAMS syntax `=N=` to ensure this is clear here. Since the relationships satisfied by h_1 and h_2 are determined by the bounds, `=G=` could also be replaced by `=N=` in `h1`.

In describing the various reformulations for (6), it is convenient to partition the y variables into free $\mathcal{F}$, lower bounded $\mathcal{L}$, upper bounded $\mathcal{U}$ and doubly bounded $\mathcal{B}$ variables respectively, that is:

$$\mathbf{B} := \{y = (y_{\mathcal{F}}, y_{\mathcal{L}}, y_{\mathcal{U}}, y_{\mathcal{B}}) : a_{\mathcal{L}} \leq y_{\mathcal{L}},\ y_{\mathcal{U}} \leq b_{\mathcal{U}},\ a_{\mathcal{B}} \leq y_{\mathcal{B}} \leq b_{\mathcal{B}}\}.$$

We will assume (without loss of generality) that $a_{\mathcal{B}} < b_{\mathcal{B}}$. If $a_i = b_i$ then (6) holds trivially for the index i and we can remove the constraint h_i and its corresponding (fixed) variable y_i from the model. The complementarity condition for variables in $y_i \in \mathcal{F}$ is simply the equality $h_i(x, y) = 0$ so these equality constraints are moved directly into the NLP constraints g of the original model as equalities. Thus, NLPEC needs only to treat the singly-bounded variables in $\mathcal{L}$ and $\mathcal{U}$ and the doubly-bounded variables in $\mathcal{B}$. In the above example, $\mathcal{L} = \{1\}$, $\mathcal{U} = \emptyset$ and $\mathcal{B} = \{2\}$.

5.28.3.1 Product reformulations

Product reformulations all involve products of y_i with h_i, or products of y_i with some auxiliary or slack variables that are set equal to h_i. The underlying point is that the constraints (3) are entirely equivalent to the following system of equalities and inequalities:

$$\begin{gathered} w_{\mathcal{L}} = h_{\mathcal{L}}(x, y),\ a_{\mathcal{L}} \leq y_{\mathcal{L}},\ w_{\mathcal{L}} \geq 0 \text{ and } (y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} = 0 \\ v_{\mathcal{U}} = -h_{\mathcal{U}}(x, y),\ y_{\mathcal{U}} \leq b_{\mathcal{U}},\ v_{\mathcal{U}} \geq 0 \text{ and } (b_{\mathcal{U}} - y_{\mathcal{U}})^T v_{\mathcal{U}} = 0 \\ w_{\mathcal{B}} - v_{\mathcal{B}} = h_{\mathcal{B}}(x, y),\ a_{\mathcal{B}} \leq y_{\mathcal{B}} \leq b_{\mathcal{B}},\ w_{\mathcal{B}} \geq 0,\ v_{\mathcal{B}} \geq 0 \\ (y_{\mathcal{B}} - a_{\mathcal{B}})^T w_{\mathcal{B}} = 0,\ (b_{\mathcal{B}} - y_{\mathcal{B}})^T v_{\mathcal{B}} = 0. \end{gathered} \tag{7}$$

Note that each inner product is a summation of products of nonnegative terms: a slack variable and the difference between a variable and its bound. In each of these products, either the slack variable or its complement must be zero in order to have a solution. Complementarity is forced by the multiplication of these two terms. The above reformulation is specified using option `reftype mult`.

There are a number of variations on this theme, all of which can be specified via an options file. All of the inner products could be put into the same equation, left as in (7) above, or broken out into individual products (one for each $i \in \mathcal{L} \cup \mathcal{U}$, two for each $i \in \mathcal{B}$). For example, the complementarity constraints

associated with lower bounded variables involve nonnegativity of $w_{\mathcal{L}}$, $y_{\mathcal{L}} \geq a_{\mathcal{L}}$ and either of the following alternatives:

$$(y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} = \sum (i \in \mathcal{L}(y_i - a_i)w_i = 0$$

or

$$(y_i - a_i)w_i = 0,\ i = 1, \ldots, m$$

These different levels of aggregation are chosen using option `aggregate none|partial|full`.

Since all of the inner products in (7) involve nonnegative terms, we can set the inner products equal to zero or set them ≤ 0 without changing the feasible set. To choose one or the other, use the option `constraint equality|inequality`.

As a concrete example, consider the option file

```
reftype mult
aggregate none
constraint inequality
```

applied to the simple example given above. Such an option file generates the nonlinear programming model:

$$\begin{array}{rc} \min\limits_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\ & w_1 y_1 \leq \mu \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1] \\ & (y_2 + 1)w_2 \leq \mu,\ (1 - y_2)v_2 \leq \mu \end{array} \tag{8}$$

By default, a single model is generated with the value μ set to 0. There are many examples (e.g. interior point codes, many LP and NLP packages, published results on reformulation approaches to MPEC) that illustrate the value of starting with a "nearly-complementary" solution and pushing the complementarity gap down to zero. For this reason, the inner products in (7) above are always set equal to (or $\leq$) a scalar μ instead of zero. By default μ is zero, but options exist to start μ at a positive value (e.g. `InitMu 1e-2`), to decrease it by a constant factor in a series of looped solves (e.g. `NumSolves 4`, `UpdateFac 0.1`), and to solve one last time with a final value for μ (e.g. `FinalMu 0`). If the following lines are added to the option file

```
initmu 1.0
numsolves 4
```

then five consecutive solves of the nonlinear program (8) are performed, the first one using $\mu = 1$ and each subsequent solve dividing μ by 10 (and starting the NLP solver at the solution of the previous model in this sequence).

As a final example, we use a combination of these options to generate a sequence of nonlinear programs whose solutions attempt to trace out the "central path" favored by interior point and barrier algorithms:

```
reftype mult
constraint equality
initmu 1.0
numsolves 4
updatefac 0.1
finalmu 1e-6
```

produces 6 nonlinear programs of the form

$$\begin{array}{rc} \min\limits_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\ & w_1 y_1 = \mu \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1, 1],\ (y_2 + 1)w_2 = \mu,\ (y_2 - 1)v_2 = \mu \end{array}$$

for values of $\mu = 1, 0.1, 0.01, 0.001, 0.0001$ and $1e-6$.

Slacks and doubly bounded variables

Slack variables can be used to reduce the number of times a complex nonlinear expression appears in the nonlinear programming model, as was carried out in (7). For a simpler illustrative example the NCP constraints (5) are equivalent to the constraints:

$$w_i = h_i(x, y), 0 \leq w_i, 0 \leq y_i \text{ and } y_i w_i = 0, i = 1, \ldots, m$$

This reformulation has an additional equality constraint, and additional variables w, but the expression h_i only appears once. There are cases when this formulation will be preferable, and the simple option `slack none|positive` controls the use of the w variables.

When there are doubly bounded variables present, these two slack options work slightly differently. For the `positive` case, the reformulation introduces two nonnegative variables w_i and v_i that take on the positive and negative parts of h_i at the solution as shown in (7). Since this is the default value of the option `slack`, the example (8) shows what ensues to both singly and doubly bounded variables under this setting.

For the case `slack none`, Scholtes proposed a way to use a multiplication to force complementarity that requires no slack variables:

$$h_i \quad \perp \quad a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i,\ (y_i - a_i)h_i \leq \mu,\ (y_i - b_i)h_i \leq \mu \tag{9}$$

Note that unlike the inner products in Section Reformulation, we can expect that one of the inequalities in (9) is unlikely to be binding at a solution (i.e. when h_i is nonzero). Therefore, we cannot use an equality in this reformulation, and furthermore the products must not be aggregated. Thus, if you use this option, the reformulation automatically enforces the additional options `constraint inequality` and `aggregate none` on the doubly bounded variables, even if the user specifies a conflicting option. Thus the option file

```
reftype mult
slack none
```

results in the model

$$\begin{array}{ll} \min\limits_{x_1,x_2,y_1,y_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & x_1 - y_1 + y_2 - 1 \geq 0, y_1 \geq 0 \\ & (x_1 - y_1 + y_2 - 1)y_1 = \mu \\ & y_2 \in [-1, 1],\ (y_2 + 1)(x_2 + y_2) \leq \mu,\ (y_2 - 1)(x_2 + y_2) \leq \mu \end{array}$$

Note that the complementarity constraint associated with y_1 is an equality (the default) while the constraints associated with y_2 are inequalities for the reasons outlined above.

In the case of doubly bounded variables, a third option is available for the slack variables, namely `slack one`. In this case, only one slack is introduced, and this slack removes the need to write the function h_i twice in the reformulated model as follows:

$$h_i(x, y) \quad \perp \quad a_i \leq y_i \leq b_i \iff a_i \leq y_i \leq b_i,\ w_i = h_i(x, y),\ (y_i - a_i)w_i \leq \mu,\ (y_i - b_i)w_i \leq \mu$$

Note that the slack variable w that is introduced is a free variable. It is not known before solving the problem whether w_i will be positive or negative at the solution.

We take this opportunity to introduce a simple extension to our option mechanism, namely the ability to set the options for singly and doubly bounded variables differently. For example, the option file

```
reftype mult
slack positive one
```

sets the option `slack positive` for the singly bounded variables and the option `slack one` for the doubly bounded variables resulting in the model

$$\begin{array}{rc} \min\limits_{x_1,x_2,y_1,y_2,w_1,w_2} & x_1 + x_2 \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0, y_1 \geq 0 \\ & w_1 y_1 = \mu_1 \\ & w_2 = x_2 + y_2,\ y_2 \in [-1, 1],\ (y_2 + 1)w_2 \leq \mu_2,\ (y_2 - 1)w_2 \leq \mu_2 \end{array}$$

Additional options such as

```
initmu 1.0 3.0
numsolves 2
updatefac 0.1 0.2
```

allow the values of μ for the singly and doubly bounded variables to be controlled separately. In this case μ_1 takes on values of 1, 0.1 and 0.01, while μ_2 takes on values 3.0, 0.6 and 0.12 in each of the three nonlinear programming models generated.

5.28.3.2 NCP functions

An NCP-function is a function $\phi(r, s)$ with the following property:

$$\phi(r, s) = 0 \Longleftrightarrow r \geq 0, s \geq 0, rs = 0$$

Clearly, finding a zero of an NCP-function solves a complementarity problem in (r, s). We can replace the inner products of nonnegative vectors in (7) with a vector of NCP functions whose arguments are complementary pairs, e.g. $(y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} = 0$ becomes $\phi(y_i - a_i, w_i) = 0, i \in \mathcal{L}$ and arrive at another way to treat the complementarity conditions. Note that an NCP function forces both nonnegativity and complementarity, so constraints to explicitly force nonnegativity are not required, though they can be included.

Examples of NCP functions include the min function, `min(r,s)`, and the Fischer-Burmeister function

$$\phi(r, s) = \sqrt{r^2 + s^2} - r - s$$

There is no requirement that an NCP function be nonnegative everywhere (it may be strictly negative at some points), so there is little point in setting the option `constraint`; it will automatically take on the value `constraint equality`. NCP functions cannot be aggregated, so the `aggregate` option will always be set to `none`.

Since the arguments to the NCP functions are going to be nonnegative at solution, we cannot use the functions h_i directly in the case of doubly-bounded variables. We must use slacks $w - v = h_i$ to separate h_i into its positive and negative parts (but see Section Doubly bounded variables below). The slacks can be `positive` or `free`, since the NCP function will force positivity at solution. For the singly-bounded variables, slacks are optional, and can also be `positive` or `free`.

Both of the NCP functions mentioned above suffer from being non-differentiable at the origin (and at points where $r = s$ for the min function). Various smoothed NCP-functions have been proposed that are differentiable. These smooth functions are parameterized by μ, and approach the true NCP-function as the smoothing parameter approaches zero. For example, the Fischer-Burmeister function includes a perturbation μ that guarantees differentiability:

$$\phi_{FB}(r, s) := \sqrt{r^2 + s^2 + 2\mu} - (r + s). \tag{10}$$

You can choose these particular NCP functions using option `RefType min|FB|fFB`. The difference between the last two is that `RefType FB` writes out GAMS code to compute the function ϕ_{FB}, while `RefType fFB` makes use of the GAMS intrinsic function NCPFB(r,s,mu) that computes ϕ_{FB} internally. In general, using the GAMS intrinsic function should work better since the intrinsic can guard against overflow, scale the arguments before computing the function, and use alternative formulas that give more accurate results for certain input ranges.

As an example, the option file

```
reftype fFB
slack free
initmu 1e-2
```

generates the reformulation

$$\begin{aligned} \min_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} \quad & x_1 + x_2 \\ \text{subject to} \quad & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1 \\ & \phi_{FB}(w_1, y_1, \mu) = 0 \\ & w_2 - v_2 = x_2 + y_2 \\ & \phi_{FB}(y_2 + 1, w_2, \mu) = 0,\ \phi_{FB}(1 - y_2, v_2, \mu) = 0 \end{aligned}$$

with a value of $\mu = 0.01$. Following a path of solutions for decreasing values of μ is possible using the options discussed above.

Each of the two arguments to the NCP function will be nonnegative at solution, but for each argument we have the option of including a nonnegativity constraint explicitly as well. This results in the 4 values for the option `NCPBounds none|all|function|variable`. When no slacks are present, this option controls whether to bound the function h_i as well as including it in the NCP function, e.g. $h_i \geq 0, \phi(h_i, y_i - a_i) = 0$. When slacks are present, we require that the slack setting be consistent with the bound setting for the function argument to the NCP function, where `NCPBounds none|variable` is consistent with free slack variables and `NCPBounds all|function` is consistent with positive slack variables.

Thus, the option file

```
reftype min
slack positive
NCPBounds function
```

generates the reformulation

$$\begin{aligned} \min_{x_1,x_2,y_1,y_2,w_1,w_2,v_2} \quad & x_1 + x_2 \\ \text{subject to} \quad & x_1^2 + x_2^2 \leq 1 \\ & w_1 = x_1 - y_1 + y_2 - 1, w_1 \geq 0 \\ & \min(w_1, y_1) = \mu \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0 \\ & \min(y_2 + 1, w_2) = \mu,\ \min(1 - y_2, v_2) = \mu \end{aligned}$$

The `NCPBounds function` option means that the variable argument to the NCP function (in this case y) does not have its bounds explicitly enforced. It should be noted that this nonlinear program has nondifferentiable constraints for every value of μ. For this reason, the model is constructed as a `dnlp` model (instead of an `nlp` model) in GAMS.

A smoothed version of the min function was proposed by Chen & Mangasarian:

$$\phi_{CM}(r, s) := r - \mu \log(1 + \exp((r - s)/\mu)). \tag{11}$$

This function is not symmetric in its two arguments, so $\phi_{CM}(r, s) \neq \phi_{CM}(s, r)$. For this reason, we distinguish between the two cases. Unlike the Fischer-Burmeister function ϕ_{FB}, ϕ_{CM} is not defined in the limit (i.e. for $\mu = 0$) if you use GAMS code to compute it. However, the GAMS intrinsic NCPCM(r,s,mu) handles this limit case internally. The option `RefType CMxf|CMfx|fCMxf|fCMfx` chooses a reformulation based on the function ϕ_{CM}. Again, the last two choices use the GAMS intrinsic function.

Doubly bounded variables

Like the mult reformulation (7), reformulations using NCP functions are appropriate as long as we split the function h_i matching a doubly-bounded variable into its positive and negative parts $w_i - v_i = h_i$. To avoid this, Billups has proposed using a composition of NCP functions to treat the doubly-bounded case:

$$h_i \quad \perp \quad a_i \leq y_i \leq b_i \iff \phi_{FB}(y_i - a_i, \phi_{FB}(b_i - y_i, -h_i)) = 0 \tag{12}$$

Use option `RefType Bill|fBill` to choose such a reformulation for the doubly-bounded variables. The first option value writes out the function in explicit GAMS code, while the second writes it out using the GAMS intrinsic function NCPFB.

5.28.3.3 Penalty functions

All of the reformulations discussed so far have reformulated the complementarity conditions as constraints. It is also possible to treat these by moving them into the objective function with a penalty parameter $1/\mu$: as μ goes to zero, the relative weight placed on complementarity increases. Ignoring the NLP constraints, we can rewrite the original MPEC problem as

$$\min_{x \in \mathbf{R}^n, y \in \mathbf{R}^m} f(x,y) + \frac{1}{\mu}((y_{\mathcal{L}} - a_{\mathcal{L}})^T w_{\mathcal{L}} + (b_{\mathcal{U}} - y_{\mathcal{U}})^T v_{\mathcal{U}} + (y_{\mathcal{B}} - a_{\mathcal{B}})^T w_{\mathcal{B}} + (b_{\mathcal{B}} - y_{\mathcal{B}})^T v_{\mathcal{B}}) \tag{13}$$

subject to the constraints

$$\begin{gathered} g(x,y) \leq 0 \\ w_{\mathcal{L}} = h_{\mathcal{L}}(x,y),\ a_{\mathcal{L}} \leq y_{\mathcal{L}},\ w_{\mathcal{L}} \geq 0 \\ v_{\mathcal{U}} = -h_{\mathcal{U}}(x,y),\ y_{\mathcal{U}} \leq b_{\mathcal{U}},\ v_{\mathcal{U}} \geq 0 \\ w_{\mathcal{B}} - v_{\mathcal{B}} = h_{\mathcal{B}}(x,y)\ a_{\mathcal{B}} \leq y_{\mathcal{B}} \leq b_{\mathcal{B}},\ w_{\mathcal{B}} \geq 0, v_{\mathcal{B}} \geq 0 \end{gathered} \tag{14}$$

Choose this treatment using option `refType penalty`. The options `aggregate` and `constraint` are ignored, since the inner products here are all aggregated and there are no relevant constraints. It is possible to do a similar reformulation without using slacks, so the options `slack none|positive` can be used in conjunction with this reformulation type.

The following option file shows the use of the `penalty` reformulation, but also indicates how to use a different reformulation for the singly and doubly bounded variables:

```
reftype penalty mult
slack none *
initmu 1.0
numsolves 2
updatefac 0.1 0.2
```

The "$*$" value allows the `slack` option to take on its existing value, in this case `positive`. Applied to our simple example given above, such an option file generates the nonlinear programming model:

$$\begin{array}{rc} \min\limits_{x_1,x_2,y_1,y_2,w_2,v_2} & x_1 + x_2 + \frac{1}{\mu_1} y_1 (x_1 - y_1 + y_2 - 1) \\ \text{subject to} & x_1^2 + x_2^2 \leq 1 \\ & x_1 - y_1 + y_2 - 1 \geq 0, y_1 \geq 0 \\ & w_2 - v_2 = x_2 + y_2, w_2, v_2 \geq 0, y_2 \in [-1,1] \\ & (y_2 + 1) w_2 \leq \mu_2,\ (1 - y_2) v_2 \leq \mu_2 \end{array}$$

The penalty parameter μ_1 is controlled separately from the doubly bounded constraint parameter μ_2. For consistency with other options, the penalty parameter in the objective is $1/\mu$ meaning that as μ_1 tends to zero, the penalty increases. The option `initmu` has only one value, so both the singly and doubly bounded μ values are initialized to 1. In the above example, three solves are performed with $\mu_1 = 1, 0.1$ and 0.01 and $\mu_2 = 1, 0.2$ and 0.04.

5.28.3.4 Testing for complementarity

In some cases a solution to the reformulated model may not satisfy the complementarity constraints of the original MPEC, e.g. if a large penalty parameter is used in the reformulation. It can also happen that the solution tolerances used in the NLP solver allow solutions with small error in the NLP model but large error in the original MPEC. For example if $x = f(x) = .001$ then the NLP constraint $xf(x) = 0$ may satisfy the NLP feasibility tolerance but it's not so easy to claim that either x or $f(x)$ is zero. The NLPEC solver includes a check that the proposed solution does in fact satisfy the complementarity constraints. The complementarity gap is computed using the definition common to all GAMS MCP solvers in computing the *objval* model attribute for an MCP model. The tolerance used for this complementarity gap can be adjusted using the `testtol` option.

5.28.4 Options

For details on how to create and use an option file, see the introductory chapter on solver usage.

For most GAMS solvers, the use of an options file is discouraged, at least for those unfamiliar with the solver. For NLPEC, however, we expect that most users will want to use an options file from the very beginning. NLPEC is as much a tool for experimentation as it is a solver, and as such use of the options file is encouraged.

Option values can take many different types (e.g. strings, integers, or reals). Perhaps the most important option to remember is one with no value at all: the `help` option. `Help` prints a list of the available options, along with their possible values and some helpful text. The options file is read sequentially, so in case an option value is set twice, the latter value takes precedence. However, any consistency checks performed on the options values (e.g. `RefType fBill` cannot be used with `aggregate full`) are made after the entire options file is read in, so the order in which different options appear is not important, provided the options are not specified twice.

5.28.4.1 Setting the Reformulation Options

While NLPEC has many options, there is a small set of five options that, taken together, serve to define the type of reformulation used. Listed in order of importance (highest priority items first), these *reformulation options* are the `RefType`, `slack`, `constraint`, `aggregate` and `NCPBounds` options. In some cases, setting the highest-priority option `RefType` is enough to completely define a reformulation (e.g. `RefType penalty` in the case of doubly-bounded variables). In most cases though, the lower-priority options play a role in defining or modifying a reformulation. It's useful to consider the reformulation options in priority order when creating option files to define reformulations.

Some of the combinations of the reformulation options don't make sense. For example, the use of an NCP function to force complementarity between its two input arguments requires a separate function for each complementary pair, so setting both `RefType min` and `aggregate full` is inconsistent. NLPEC implements consistency checks on the reformulation options using the priority order: Given a consistent setting of the higher priority options, the next-highest priority option is checked and, if necessary, reset to be consistent with the items of higher priority. The end result is a set of consistent options that will result in a working reformulation. NLPEC prints out the pre- and post-checked sets of reformulation options, as well as warning messages about changes made. In case you want to use an option that NLPEC doesn't think is consistent, you can use the `NoCheck` option: this supresses the consistency checks.

Each of the reformulation options in the table below takes two values - one for the singly-bounded variables in $\mathcal{L} \cup \mathcal{U}$ and another for the doubly-bounded variables in $\mathcal{B}$. If one option value appears, it sets both option values. When setting both option values, use an asterisk "$*$" to indicate no change. So for example, an option file

```
RefType  fCMxf
RefType  *  fBill
```

first sets the `RefType` to `fCMxf` for all variable types, and then resets the `RefType` to `fBill` for doubly-bounded variables.

5.28.4.2 Reformulation Options

Option	Description	Default
aggregate	controls constraint aggregation Determines if certain constraints are aggregated or not. E.g. to force `w >= 0` and `y >= 0` to be complementary we can write either `w^T y <= 0` or `w_i^T y_i <= 0, for all i`. `none`: use no aggregation `partial`: aggregate doubly-bounded variables separately from others `full`: use maximum aggregation possible	`none`
constraint	controls use of equality/inequality Determines if certain constraints are written down using equalities or inequalities. E.g. to force `w >= 0` and `y >= 0` to be complementary we can write either `w^T y <= 0` or `w^T y = 0`. This option only plays a role when bounding a quantity whose sign cannot be both positive and negative and which must be 0 at a solution. `equality`: use =E= constraints `inequality`: use =L= constraints	`equality`
NCPBounds	sets explicit bounds on arguments of NCP functions Determines which of the two arguments to an NCP function `Phi(r,s)` are explicitly constrained to be nonnegative. The explicit constraints are in addition to those imposed by the constraint `Phi(r,s) = 0`, which implies nonnegativity of `r` and `s`. `none`: no explicit bounds `function`: explicit bound on function/slack argument `variable`: explicit bound on variable argument `all`: explicit bound on both function and variable arguments	`none`
refType	reformulation type Determines the type of reformulation used. Our notation and descriptions are taken from a special case of the MPEC, the NCP: find `x >= 0, f(x) >= 0, x^T f(x) = 0`. `mult`: inner product <x,f> = 0 `min`: NCP function min(x,f) `CMxf`: Chen-Mangasarian NCP function, explicit `CMfx`: Chen-Mangasarian NCP function, explicit `fCMxf`: Chen-Mangasarian NCP function, intrinsic `fCMfx`: Chen-Mangasarian NCP function, intrinsic `FB`: Fischer-Burmeister NCP function, explicit `fFB`: Fischer-Burmeister NCP function, intrinsic `FB_neg`: Fischer-Burmeister NCP function negated, explicit `fFB_neg`: Fischer-Burmeister NCP function negated, intrinsic `Bill`: Billups function for doubly-bounded variables, explicit `fBill`: Billups function for doubly-bounded variables, intrinsic `penalty`: weighted penalization of non-complementarity in objective `median`: median function for doubly-bounded variables, explicit `fVUsin`: Veelken-Ulbrich NCP function (smoothed min), intrinsic `fVUpow`: Veelken-Ulbrich NCP function (smoothed min), intrinsic	`mult`
slack	control use of slacks for function values Determines if slacks are used to treat the functions `h_i`. For single-bounded variables, we use at most one slack (either free or positive) for each `h_i`. For doubly-bounded variables, we can have no slacks, one slack (necessarily free), or two slacks (either free or positive) for each `h_i`. `none`: no slacks will be used `free`: free slacks will be used `positive`: non-negative slacks will be used `one`: one free slack will be used for each h_i in the doubly bounded case	`positive`

5.28.4.3 General Options

Option	Description	Default
allSolves	do all solves in a loop regardless of previous failure In case multiple (looped) solves are specified, the default is to skip subsequent solves when any solve terminates without getting a solution. Setting this flag removes the check and all solves are done, regardless of previous failures.	0
dotGams	name of gams source file for scalar model	auto
dumpValid	dump valid reformulation options to a GDX file and exit	0
equReform	outdated and deprecated Range: {0, ..., 33}	0
finalMu	final value of parameter mu If specified, an extra solve is carried out with mu set to this value. Can be set independently for singly and doubly bounded variables.	none
initMu	initial value of parameter mu A single solve of the nonlinear program is carried out for this value. Note that mu must be positive for some settings of reftype, e.g. penalty. Can be set independently for singly and doubly bounded variables.	0
initSLo	lower bound for artificials added to the problem Range: [-∞, ∞]	0
initSUp	upper bound for artificials added to the problem Range: [-∞, ∞]	+inf
noCheck	do not check consistency of reformulation options	0
numSolves	number of looped solves This should be set in conjunction with the updateFac option, so that the mu values are lowered successively.	0
parmFile	extra GAMS options for running scalar model	
subSolver	controls what subsolver to run If this option is not specified, the usual GAMS rules for selecting the solver to run are used.	auto
subSolverOpt	optfile value to pass to the subsolver	0
terminate	terminate after generating scalar GAMS source code	0
testTol	tolerance for complementarity check in MPEC/MCP	1e-005
updateFac	update factor for mu The factor that multiplies mu before each of the extra solves triggered by the numsolves option. Can be set independently for singly and doubly bounded variables. Range: [1e-280, 1.0]	1e-1

5.28.4.4 The Outdated equreform Option

In the early versions of NLPEC the only way to set the reform type was via the equreform option. Each valid equreform value represented a preselected combination of the options from Section Setting the Reformulation Options. This made it difficult to experiment with combinations not preselected, so the options in Section Setting the Reformulation Options were added. Be default, the equreform option has value 0 and is not used. To get the old behavior, set equreform to a positive value - this will force the options in Section Setting the Reformulation Options to be ignored. The general options in Section General Options are used no matter how the reformulation type is selected - via RefType or equreform.

Option	Description	Default
equreform	Old way to set the type of reformulation used.	0

The values allowed for equreform and their implications are given by the following table.

	L/U				B			
equref	reftype	sign	slacks	free-y	reftype	sign	slacks	free-y
1	$<,>_i$	$=\mu$	bnd		$<,>_i$	$=\mu$	bnd

5.28.5 Open Architecture

In this section we describe the architecture of the NLPEC solver, i.e. the way the solver is put together. This should be useful to anybody using NLPEC for experiments or to those wanting to know the details of how NLPEC works.

The foundation for the NLPEC solver is the software library (also used in the GAMS/CONVERT solver) that allows us to write out a scalar GAMS model that is mathematically equivalent to the original, or

to write out selected pieces of such a model. Using this software, NLPEC creates a GAMS NLP model using one of the reformulation strategies from Section Reformulation. This model may contain many new variables and/or equations, but it will surely contain the (non)linear expressions defining the original model as well. Once the scalar model has been created, NLPEC calls GAMS to solve this model, using the current NLP solver. The option parmFile can be used to pass on additional options to this GAMS job. After the model has solved, NLPEC reads the NLP solution, extracts the MPEC solution from it, and passes this MPEC solution back to GAMS as it terminates.

There are a number of advantages to this architecture. First, its openness makes it easy to see exactly what reformulation is being done. The intermediate scalar GAMS NLP model can be made available after the run by either saving the scratch directory (i.e. run with `keep=1`) or using the `dotGams` option to select an alternate file name. This intermediate model contains all the details of the reformulation. It can be used for debugging in case things didn't work out as expected. It is also possible to modify this file to do some quick and dirty experiments with similar reformulation strategies. Another advantage is the variety of NLP solvers that can be plugged in to solve the reformulated model. There is no need to program (and debug) an interface to an NLP package to run experiments with an NLP solver - the existing GAMS link is all that is needed. It is also easy to experiment with non-default solver options that may be more appropriate for reformulated MPEC models or for a particular choice of reformulation.

5.29 ODHCPLEX

5.29.1 Introduction

GAMS/ODHCPLEX is a solver from Optimization Direct Inc. that implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models that uses IBM CPLEX as its underlying solver engine. It is designed for large-scale models which a MIP solver would find intractable: either by it being unable to find feasible solutions at all or; more usually, by being unable to find feasible solutions of adequate quality in the time available to its user.

It is intended for users who are familiar with MIP modelling and have some knowledge of using the GAMS/CPLEX solver. GAMS/ODHCPLEX does not demand expert specialism in this field.

ODHCPLEX can be used in two ways: it is implemented as a stand-alone ODHeuristic engine, which can be used on its own (ODHeuristicMethod=STANDALONE); and also within the CPLEX optimizer, within which it can supply and receive solutions from the main CPLEX caller (ODHeuristicMethod=ODH-CPLEX (default)) thereby accelerating optimization compared with GAMS/CPLEX run on its own.

The ODHeuristic engine has a heuristic method for finding an initial feasible solution that it designed to complement, those of CPLEX. Since its main algorithmic procedure works by improving an incumbent feasible solution, getting an initial one is important and may consume a significant part of its total runtime. When used on its own (i.e. ODHeuristicMethod=STANDALONE), users should experiment to discover whether ODHeuristics' or CPLEX's initial feasible solution methods work best, but within ODH-CPLEX (i.e. ODHeuristicMethod=ODH-CPLEX) both methods are run in parallel and the winner is chosen automatically.

ODHeuristics' principal algorithm works by solving a sequence of sub-models. An innovative aspect of this process is its ability to use the model's symbolic structure to achieve the sub-model decomposition. It does this by analyzing the symbolic names that the user gives to the decision variables and careful specification of how this should be done this is worthwhile. ODHCPLEX can work without this analysis, but it usually takes about twice as much runtime.

5.29.2 Specifying Model Structure

The ODHeuristic method needs to break the model down into sub-models. It can do this in one of three ways:

1. Automatically using its decomposition heuristic;
2. Using information specified by the user in the IndexKey parameter;
3. By simply assigning each variable to a different block (or *key*); or
4. By using the dot option notatation with the option .key.

By default, the program will use information specified by the IndexKey parameter if it is set and its automatic decomposition heuristic otherwise. This may be overridden by the Decomposition parameter. If it is set to 0 (zero), option 3 above is selected. If it is set to 1, its automatic decomposition method is used, and if it is set to 2, option 4 above is selected.

Whilst the automatic decomposition method often works well, there may be an advantage to specifying decomposition through the IndexKey parameter. After performing the decomposition in whatever way, the program analyses the decomposition and displays statistics showing the maximum and minimum number of variables in each key or block and showing a percentage score to the decomposition as a whole. A typical display is of the form:

```
Variables/key 205.58 (+/-304.79), max/min variables/key 933(32) / 60(113).
There are 227 keys (4149 keys were dropped) with 46872 values.
Decomposition score 13.66%, graph score 2074/3135232.
```

Other things (such as the distribution of variables in keys and the number of keys) being equal, the smaller the percentage decomposition score, the better the decomposition is and the more effective the program will be.

5.29.2.1 Using the IndexKey parameter

The program needs to associate sets of variables with distinct values of a single index. The user can specify this association with a pattern to which some or all of the variables conform. The pattern is in standard C scanf format (see, for example, Kernighan and Ritchie's 2nd edition of The C Programming Language, section B1.3 *Formatted Input*). Currently allowable index values must be non-negative integers, so the pattern must include *d*. For example, if we have variables `x` whose first index names starts with a number of letters then an underscore followed by a numeric index value (like `x(firstone_1)`, `x(another_1)`, `x(firstone_2)`, `x(another_2)`, ..) the pattern

```
x(%*[a-z]_%d)
```

associates those variables whose name ends in _1 with index value 1, those whose name ends in _2 with index value 2 and so on. The pattern is called an *index key* referred to by the program as the option parameter IndexKey, for example

```
IndexKey=%*[xy](t_%d)
```

It may, however, be desirable to consider variables whose names are, say, `x(t_2)` and `y(t_2)`, to belong to different index values, i.e. to belong to different groups. One way of doing this is to identify them with separate index keys. These can be supplied to IndexKey as two fields separated by a semi-colon, for example

```
IndexKey=x(t_%d);y(t_%d)
```

Up to 10 fields can be specified in this way.

On the other hand, it may be desirable to consider such variables as having the same index key and their nomenclature may not permit their identification by a single key field. For example, suppose there are variables `john(t_1)`, `john(t_2)`,.., `jane(t_1)`, `jane(t_2)`,.. and `johnny(t_1)`, `johnny(t_2)`,.. and we want to associate `john(t_x)` and `jane(t_x)` as belonging to key value x, but want to ignore `johnny(t_x)`.

Two key fields can be used to do this by

```
INDEXKEY=john(t_%d);jane(t_%d)
```

By default `john(t_2)` and `jane(t_2)` would not share the same index value, but if the option parameter KeyType, is set to 1, the heuristic will group them together so as to share the same index.

If IndexKey is not specified, the program uses a default decomposition.

The program divides the model up into parts associated with different values of the IndexKey (if specified), using an integer interval divisor. Initially this is a number not less than 2 and it is increased as the search progresses. When no improved solution is found after a number, MaxRepeat, of attempts with the maximum interval divisor, MaxInterDiv, the program terminates. Default values are provided for MaxRepeat and MaxInterDiv, so these do not have to be specified by the user.

5.29.3 Heuristic Parameters

There are a number of other parameters which control the behaviour of the heuristic program. These may be left at their default values or specified on the GAMS/ODHCPLEX option file. In addition, many GAMS/CPLEX options can be supplied in the GAMS/ODHCPLEX option file to tweak the CPLEX behavior, see tables below. Note however that - although they can be technically set - these GAMS/CPLEX options may not have any influence on a GAMS/ODHCPLEX solve. For detailed descriptions of the GAMS/CPLEX options, see Detailed Descriptions of CPLEX Options.

Parameter names and their meanings are summarized in the table below.

5.29.3.1 GAMS/ODHCPLEX: General Options

Option	Description	Default
addcuts	Indicator for adding cuts from CPLEX master solve	2
cpxpresolve	Applies CPLEX presolve to full model	0
decompdensity	Matrix density above which automatic decomposition assigns each variable to a separate key	0.3
decomposition	Model decomposition method.	-1
deterministic	Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode	1

Option	Description	Default
divisor	Initial divisor for sub models	automatic
dynamicsearch	Search strategy for CPLEX caller and sub-model solves	-1
extracplexlog	Write addition CPLEX output to log	0
feastol	Feasibility tolerance	1e-6
firstfeas	Use first feasible heuristic for finding an initial feasible solution	-1
firstfeascontinue	Whether first feasible heuristic continues when it achieves feasibility	0
firstfeaseffort	Effort limit on first feasible heuristic	-500
firstfeaslpitlim	Limit on number of relaxed re-solves in first feasible heuristic	10
firstfeasrelaxcrit	Smallest sum of infeasibilites/row where relaxed solution used	0.01
firstfeasshift	First feasible heuristic variable shifting in found solutions	0
globalbounds	Use of global bounds from CPLEX caller	2
ignoresetslvrparams	Flag to control whether solver parameters can be dynamically altered by ODH	0
indexkey	Pattern used to match variable names for grouping into sub-models discussed above	
integeronly	Variables to include in INDEXKEY	-1
integertol	Integrality tolerance for variable values	1e-5
interdiv	Initial divisor value	4
.key	Variable block or key number	0
keypartition	Use of solver partition information	0
keysminimum	Minimum number of keys that the automatic decomposition method attempts to find	512
keytype	Treatment of multiple INDEXKEYs	0
localsearch	Indicator for local search heuristic	1
loosefeastol	Loose feasibility tolerance	1e-5
maxbacktrack	The maximum number of backtracks permitted in sub-model solves	-1
maxbound	The largest(smallest) non infinite bound value ODH will accept for upper(lower) bounds	1e+9
maxinfrepeat	Maximum divisor value when solution is infeasible	0
maxinterdiv	Maximum divisor value	0
maxrepeat	Maximum number of sub-model repeat solves for each divisor value	0
objtarget	Target objective value	0
objthreshold	Threshold for absolute value of objective coefficients	1e99
odheuristicmethod	ODHeuristic method section	ODH-CPLEX
odhfeasopt	Optimization method for sub-models in phaseI	0

Option	Description	Default
odhthreads	The number of heuristic threads used by ODH-CPLEX or STANDALONE	-1
odhtimelimit	Elapsed time limit in seconds	GAMS ResLim
penalty	The objective function coefficient value for penalties	-1
penperturb	Perturbation tolerance for penalties coefficients	0
phase12	Specifies whether to use a phaseI/phaseII method to remove infeasibilities	1
processorlock	Thread allocation	0
quickfirstsolve	Accelerate initial CPLEX solve	0
recurse	Recurse using heuristic to solve sub-models when a feasible solution has been obtained	0
recursedecomp	Recursed model decomposition method	0
recurseiterlim	Recursed heuristic iteration limit for sub-solves	40
recurselog	Write thread log files for recursed sub-solves	0
recurseminiterlim	Recursed heuristic minimum iterations before a solution is found in sub-solves	10
recursesoliterlim	Recursed heuristic sub-solves quit after these iterations if a solution is found	maxint
rejectinfsol	Reject infeasible solutions to sub-models	2
relaxsos2	Treatment of SOS2 members	1
seed	Initial random number seed	12345
sosfind	Automatic detection of Special Ordered Sets (SOSs)	0
sosinkey	Assign each SOS to its own sub-model component (key)	0
sosmember	Automatically detect SOSs whose variable member names match this pattern	
sosovar	Automatically detect SOSs whose output variable name matches this pattern	
sosselect	Select sub-set of SOS members	
sosselect16	Select sub-set of SOS members for sets with 16 or fewer members only	
soswvar	Automatically detect SOSs whose input(weight) variable name matches this pattern	
strategy	ODH-Cplex Strategy	1
strictdeterministic	Terminate ODH deterministically when improvement heuristic finishes	0
subcheckfreq	Frequency with which sub-model LPs are interrupted for mutual communication	10
subnodelimit	Node limit for submodel searches	-1
suborder	Use of priority order in sub-solves	1
sub_cpx_threads	Threads availble for the solves within ODHeuristic	1
syncfreq	Thread synchronization frequency in deterministic parallel mode	1

Option	Description	Default
threadlog	Write thread log files	0
threadzerosync	Which CPLEX threads to use for synchronization	0
tightenprebounds	Level of bound tightening in ODH presolved model	1
trialbound	Trial bound heuristic	0
trialboundfile	The trial bound file	
trialboundsetsize	Size adjustment to automatically generated trial bound sets	0
usehistory	Use of past sub-model selections in current selection	-1
varcleanlpmethod	Method used to solve variable cleaning LPs	-1
variableclean	Clean variable values from sub-models	1
zerotol	Zero tolerance for variable values	1e-9

5.29.3.2 GAMS/CPLEX: Preprocessing and General Options

Option	Description	Default
advind	advanced basis use	1
aggfill	aggregator fill parameter	10
aggind	aggregator on/off	-1
calcqcpduals	calculate the dual values of a quadratically constrained problem	1
clocktype	clock type for computation time	2
coeredind	coefficient reduction on/off	-1
cpumask	switch and mask to bind threads to processors (Linux only)	auto
cutoff	GMO cutoff	0.0
datacheck	controls data consistency checking and modeling assistance	0
depind	dependency checker on/off	-1
dettilim	deterministic time limit	1.0e+75
domlim	domain violation number	0
eprelax	relaxation for feasOpt	1.0e-06
feasoptmode	mode of FeasOpt	0
fixoptfile	name of option file which is read just before solving the fixed problem	
folding	LP folding will be attempted during the preprocessing phase	-1
freegamsmodel	preserves memory by dumping the GAMS model instance representation temporarily to disk	0
indicoptstrict	abort in case of an error in indicator constraint in solver option file	1
lpmethod	algorithm to be used for LP problems	0

Option	Description	Default
memoryemphasis	reduces use of memory	0
multobjdisplay	level of display during multiobjective optimization	1
names	load GAMS names into Cplex	1
numericalemphasis	emphasizes precision in numerically unstable or difficult problems	0
optimalitytarget	type of optimality that Cplex targets	0
parallelmode	parallel optimization mode	0
paramdisplay	display the nondefault parameters before optimization	1
predual	give dual problem to the optimizer	0
preind	turn presolver on/off	1
prelinear	linear reduction indicator	1
prepass	number of presolve applications to perform	-1
prereform	set presolve reformulations	3
printoptions	list values of all options to GAMS listing file	0
qextractalg	quadratic extraction algorithm in GAMS interface	0
qpmethod	algorithm to be used for QP problems	0
qtolin	linearization of the quadratic terms in the objective function of a QP or MIQP model	-1
randomseed	sets the random seed differently for diversity of solutions	202009243
record	Records invocations of Callable Library routines	0
reduce	primal and dual reduction type	3
relaxfixedinfeas	accept small infeasibilties in the solve of the fixed problem	0
relaxpreind	presolve for initial relaxation on/off	-1
rerun	rerun problem if presolve infeasible or unbounded	nono
scaind	matrix scaling on/off	0
solutiontype	type of solution (basic or non basic) for an LP or QP	0
threads	global default thread count	0
tilim	overrides the GAMS ResLim option	1.0e+75
tryint	GMO tryint	0.0
tuningdettilim	tuning deterministic time limit per model or suite	1.0e+75
tuningdisplay	level of information reported by the tuning tool	1
tuningmeasure	measure for evaluating progress for a suite of models	1
tuningrepeat	number of times tuning is to be repeated on perturbed versions	1
tuningtilim	tuning time limit per model or suite	1.0e+75
usebasis	GMO usebasis	0

Option	Description	Default
warninglimit	determines how many times warnings of a specific type (datacheck=2) will be displayed	10
workdir	directory for working files	.
workmem	memory available for working storage	2048.0

5.29.3.3 GAMS/CPLEX: Simplex Algorithmic Options

Option	Description	Default
conflictalg	algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model	0
conflictdisplay	decides how much information CPLEX reports when the conflict refiner is working	1
craind	crash strategy (used to obtain starting basis)	1
dpriind	dual simplex pricing	0
dynamicrows	switch for dynamic management of rows	-1
epper	perturbation constant	1.0e-06
netfind	attempt network extraction	2
netppriind	network simplex pricing	0
perind	force initial perturbation	0
perlim	number of stalled iterations before perturbation	0
ppriind	primal simplex pricing	0
pricelim	pricing candidate list	0
reinv	refactorization frequency	0
sifting	switch for sifting from simplex optimization	1

5.29.3.4 GAMS/CPLEX: Simplex Limit Options

Option	Description	Default
itlim	iteration limit	2147483647
netitlim	iteration limit for network simplex	2147483647
objllim	objective function lower limit	-1.0e+75
objulim	objective function upper limit	1.0e+75
singlim	limit on singularity repairs	10

5.29.3.5 GAMS/CPLEX: Simplex Tolerance Options

Option	Description	Default
epmrk	Markowitz pivot tolerance	0.01
epopt	optimality tolerance	1.0e-06
eprhs	feasibility tolerance	1.0e-06
netepopt	optimality tolerance for the network simplex method	1.0e-06
neteprhs	feasibility tolerance for the network simplex method	1.0e-06

5.29.3.6 GAMS/CPLEX: Barrier Specific Options

Option	Description	Default
baralg	algorithm selection	0
barcolnz	dense column handling	0
barcrossalg	barrier crossover method	0
barepcomp	convergence tolerance	1.0e-08
bargrowth	unbounded face detection	1.0e+12
baritlim	iteration limit	2147483647
barmaxcor	maximum correction limit	-1
barobjrng	maximum objective function	1.0e+20
barorder	row ordering algorithm selection	0
barqcpepcomp	convergence tolerance for the barrier optimizer for QCPs	1.0e-07
barstartalg	barrier starting point algorithm	1

5.29.3.7 GAMS/CPLEX: Sifting Specific Options

Option	Description	Default
siftalg	sifting subproblem algorithm	0
siftitlim	limit on sifting iterations	2147483647

5.29.3.8 GAMS/CPLEX: MIP Algorithmic Options

Option	Description	Default
bbinterval	best bound interval	7
bendersstrategy	Benders decomposition algorithm as a strategy	0
bndstrenind	bound strengthening	-1
bqpcuts	boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality	0

Option	Description	Default
brdir	set branching direction	0
bttol	backtracking limit	1.0
cliques	clique cut generation	0
covers	cover cut generation	0
cutlo	lower cutoff for tree search	-1.0e+75
cuts	default cut generation	0
cutsfactor	cut limit	-1.0
cutup	upper cutoff for tree search	1.0e+75
disjcuts	disjunctive cuts generation	0
divetype	MIP dive strategy	0
eachcutlim	sets a limit for each type of cut	2100000000
flowcovers	flow cover cut generation	0
flowpaths	flow path cut generation	0
fpheur	feasibility pump heuristic	0
fraccuts	Gomory fractional cut generation	0
gubcovers	GUB cover cut generation	0
heurfreq	heuristic frequency	0
heuristiceffort	the effort that CPLEX spends on heuristics during a MIP solve	1.0
implbd	implied bound cut generation	0
.lazy	Lazy constraints activation	0
lazyconstraints	Indicator to use lazy constraints	0
lbheur	local branching heuristic	0
liftprojcuts	lift-and-project cuts	0
localimplied	generation of locally valid implied bound cuts	0
mcfcuts	multi-commodity flow cut generation	0
mipemphasis	MIP solution tactics	0
mipkappastats	MIP kappa computation	0
mipordind	priority list on/off	1
mipordtype	priority order generation	0
mipsearch	search strategy for mixed integer programs	0
mipstart	use mip starting values	0
miqcpstrat	MIQCP relaxation choice	0
mircuts	mixed integer rounding cut generation	0

Option	Description	Default
multimipstart	use multiple mipstarts provided via gdx files	
nodecuts	decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree	0
nodefileind	node storage file indicator	1
nodesel	node selection strategy	1
preslvnd	node presolve selector	0
probe	perform probing before solving a MIP	0
qpmakepsdind	adjust MIQP formulation to make the quadratic matrix positive-semi-definite	1
repeatpresolve	reapply presolve at root after preprocessing	-1
rinsheur	relaxation induced neighborhood search frequency	0
rltcuts	Reformulation Linearization Technique (RLT) cuts	0
solvefinal	switch to solve the problem with fixed discrete variables	1
sos1reform	automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)	0
sos2reform	automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)	0
startalg	MIP starting algorithm	0
strongcandlim	size of the candidates list for strong branching	10
strongitlim	limit on iterations per branch for strong branching	0
subalg	algorithm for subproblems	0
submipnodelim	limit on number of nodes in an RINS subMIP	500
submipscale	scale the problem matrix when CPLEX solves a subMIP during MIP optimization	0
submipstartalg	starting algorithm for a subMIP of a MIP	0
submipsubalg	algorithm for subproblems of a subMIP of a MIP	0
symmetry	symmetry breaking cuts	-1
varsel	variable selection strategy at each node	0
workeralgorithm	set method for optimizing benders subproblems	0
zerohalfcuts	zero-half cuts	0

5.29.3.9 GAMS/CPLEX: MIP Limit Options

Option	Description	Default
aggcutlim	aggregation limit for cut generation	3
auxrootthreads	number of threads for auxiliary tasks at the root node	0
cutpass	maximum number of cutting plane passes	0

Option	Description	Default
fraccand	candidate limit for generating Gomory fractional cuts	200
fracpass	maximum number of passes for generating Gomory fractional cuts	0
intsollim	maximum number of integer solutions	2147483647
nodelim	maximum number of nodes to solve	2147483647
polishafterdettime	deterministic time before starting to polish a feasible solution	1.0e+75
polishafterepagap	absolute MIP gap before starting to polish a feasible solution	0.0
polishafterepgap	relative MIP gap before starting to polish a solution	0.0
polishafterintsol	MIP integer solutions to find before starting to polish a feasible solution	2147483647
polishafternode	nodes to process before starting to polish a feasible solution	2147483647
polishaftertime	time before starting to polish a feasible solution	1.0e+75
probedettime	deterministic time spent probing	1.0e+75
probetime	time spent probing	1.0e+75
repairtries	try to repair infeasible MIP start	0
trelim	maximum space in memory for tree	1.0e+75

5.29.3.10 GAMS/CPLEX: MIP Solution Pool Options

Option	Description	Default
.divflt	solution pool range filter coefficients	0
divfltlo	lower bound on diversity	mindouble
divfltup	upper bound on diversity	maxdouble
populatelim	limit of solutions generated for the solution pool by populate method	20
readflt	reads Cplex solution pool filter file	
solnpool	solution pool file name	
solnpoolagap	absolute tolerance for the solutions in the solution pool	1.0e+75
solnpoolcapacity	limits of solutions kept in the solution pool	2100000000
solnpoolgap	relative tolerance for the solutions in the solution pool	1.0e+75
solnpoolintensity	solution pool intensity for ability to produce multiple solutions	0
solnpoolmerge	solution pool file name for merged solutions	
solnpoolnumsym	maximum number of variable symbols when writing merged solutions	10
solnpoolprefix	file name prefix for GDX solution files	soln
solnpoolreplace	strategy for replacing a solution in the solution pool	0

5.29.3.11 GAMS/CPLEX: MIP Tolerance Options

Option	Description	Default
bendersfeascuttol	Tolerance for whether a feasibility cut has been violated in Benders decomposition	1.0e-06
bendersoptcuttol	Tolerance for optimality cuts in Benders decomposition	1.0e-06
epagap	absolute stopping tolerance	1.0e-06
epgap	relative stopping tolerance	1.0e-04
epint	integrality tolerance	1.0e-05
eplin	degree of tolerance used in linearization	0.001
objdif	overrides GAMS Cheat parameter	0.0
relobjdif	relative cheat parameter	0.0

5.29.3.12 GAMS/CPLEX: Output Options

Option	Description	Default
bardisplay	progress display level	1
clonelog	enable clone logs	0
mipdisplay	progress display level	2
mipinterval	progress display interval	0
mpslongnum	MPS file format precision of numeric output	1
netdisplay	network display level	2
quality	write solution quality statistics	0
siftdisplay	sifting display level	1
simdisplay	simplex display level	1
writeannotation	produce a Cplex annotation file	
writebas	produce a Cplex basis file	
writeflt	produce a Cplex solution pool filter file	
writelp	produce a Cplex LP file	
writemps	produce a Cplex MPS file	
writemst	produce a Cplex mst file	
writeord	produce a Cplex ord file	
writeparam	produce a Cplex parameter file with all active options	
writepre	produce a Cplex LP/MPS/SAV file of the presolved problem	
writeprob	produce a Cplex problem file and inferrs the type from the extension	
writesav	produce a Cplex binary problem file	

5.29.4 Parallel execution using multiple threads

Both ODHeuristicMethods `STANDALONE` and `ODH-CPLEX` can use multiple simultaneous threads. `ODH-CPLEX` must use separate threads for the main CPLEX solve and for the ODHeuristics engine. The `STANDALONE` just uses the ODHeuristics engine which may use multiple simultaneous threads. Thus the processing capability of multi-core hardware can be exploited effectively.

GAMS/ODHCPLEX will ignore the GAMS threads parameter and use its own default. The default ODHeuristic method (i.e. `ODH-CPLEX`) requires multiple threads to works and with the GAMS threads default of 1 this will not work.

Whilst there are good defaults for allocating available threads, it may be worthwhile to give some attention to the allocation of threads between the main CPLEX solver and the ODHeuristics engine for ODH-CPLEX and STANDALONE.

If the option ODHThreads is set to n, n threads are allocated in total, otherwise the total number of threads allocated for both ODH-CPLEX and STANDALONE is set to the number of physical processors available on the computer. If the ODHThreads option is set to a number greater than the number of available processors, multiple threads will have to share the same processor, which may severely degrade performance.

In general, the more threads allocated to the main CPLEX solver, the faster it will run, and similarly, the more allocated to the ODHeuristics engine, the faster it will run. The best balance depends on the model being solved and whether it is intended to run to optimality or to an optimality gap of (say) 0.05 or 0.1. If the GAMS/Cplex Threads is not set, ODH-CPLEX defaults to allocating a quarter of the threads to the ODHeuristics engine and the remainder to the main CPLEX solve. Otherwise it allocates the specified number of threads to the main CPLEX solver and the remainder to the ODHeuristics engine.

Within the ODHeuristics engine, the principal heuristic algorithm can run in parallel on multiple threads. Each algorithmic thread uses CPLEX to solve sub-models and each such instance of CPLEX can itself run on multiple threads. So some attention needs to be given to the allocation of threads between them. If SUB_CPX_THREADS is not set, the CPLEX solver will use one thread for each available logical processor to solve the sub-models. This means that only one thread will be available for the solution improvement heuristic. If the option SUB_CPX_THREADS is set, then by default the heuristic engine sets its number of algorithmic threads to

```
number_of_available_processors / SUB_CPX_THREADS
```

where number_of_available_processors is: the number of logical processors for STANDALONE; and for ODH-CPLEX it is this number less those allocated to the main CPLEX solver.

Many Intel and compatible processors support hyperthreading (where this is enabled on the computer and operating system) and if so there will be two logical processors for every physical core. Using them can severely degrade performance, so if they are enabled it is often a good idea to set ODHThreads to the number of physical processors. Note that on machines with a large number of processors (cores), the principal bottleneck for large scale optimization is usually memory access. In practice it is often better to use only about half of the available cores on (say) a 24 core Intel Xeon system. This is model dependent and some experimentation is worthwhile.

Although the operating system's scheduler usually allocates threads to logical processors so that they run on separate physical cores where possible, it will have more threads to manage than those of the heuristic or CPLEX and so will change this allocation as the heuristic and CPLEX run so as to balance its workload effectively. There is a performance penalty to doing this from the perspective of the heuristic run time. For the ODHeuristics STANDALONE, this can be avoided by locking the heuristic threads to specific processors by setting the heuristic option parameter ProcessorLock to 1. It is not supported for ODH-CPLEX. Under Windows, beware that the threads need to be locked at an above normal priority so this may have a negative impact on other programs concurrently running on the machine.

5.29.5 Determinism

Many users require that repeated runs of their applications under the same conditions give the same results, albeit in slightly variable times. The heuristic runs in this way by default. However, there is a performance penalty that has to be paid for synchronizing the threads. On average, performance can be considerably improved performance at the expense of non-repeatable execution by setting the heuristic option parameter Deterministic to 0. This is often preferred by users with particularly large and difficult models.

5.29.6 Detailed Descriptions of ODHCLPEX Options

addcuts *(integer)*: Indicator for adding cuts from CPLEX master solve ↩

Default: `2`

value	meaning
`0`	Do not add cuts
`1`	Add cuts from CPLEX master solve at root
`2`	Add cuts from CPLEX master solve at root and in tree

advind *(integer)*: advanced basis use ↩

Default: `1`

aggcutlim *(integer)*: aggregation limit for cut generation ↩

Default: `3`

aggfill *(integer)*: aggregator fill parameter ↩

Default: `10`

aggind *(integer)*: aggregator on/off ↩

Default: `-1`

auxrootthreads *(integer)*: number of threads for auxiliary tasks at the root node ↩

Default: `0`

baralg *(integer)*: algorithm selection ↩

Default: `0`

barcolnz *(integer)*: dense column handling ↩

Default: `0`

barcrossalg *(integer)*: barrier crossover method ↩

Default: `0`

bardisplay *(integer)*: progress display level ↩

Default: `1`

barepcomp *(real)*: convergence tolerance ↩

Default: `1.0e-08`

bargrowth *(real)*: unbounded face detection ↩

Default: `1.0e+12`

baritlim *(integer)*: iteration limit ↩

Default: `2147483647`

barmaxcor *(integer)*: maximum correction limit ↩

Default: `-1`

barobjrng *(real)*: maximum objective function ↩

Default: `1.0e+20`

barorder *(integer)*: row ordering algorithm selection ↩

Default: `0`

barqcpepcomp *(real)*: convergence tolerance for the barrier optimizer for QCPs ↩

Default: `1.0e-07`

barstartalg *(integer)*: barrier starting point algorithm ↩

Default: `1`

bbinterval *(integer)*: best bound interval ↩

Default: `7`

bendersfeascuttol *(real)*: Tolerance for whether a feasibility cut has been violated in Benders decomposition ↩

Default: `1.0e-06`

bendersoptcuttol *(real)*: Tolerance for optimality cuts in Benders decomposition ↩

Default: `1.0e-06`

bendersstrategy *(integer)*: Benders decomposition algorithm as a strategy ↩

Default: `0`

bndstrenind *(integer)*: bound strengthening ↩

Default: `-1`

bqpcuts *(integer)*: boolean quadric polytope cuts for nonconvex QP or MIQP solved to global optimality ↩

Default: `0`

brdir *(integer)*: set branching direction ↩

Default: `0`

bttol *(real)*: backtracking limit ↩

Default: `1.0`

calcqcpduals *(integer)*: calculate the dual values of a quadratically constrained problem ↩

Default: `1`

cliques *(integer)*: clique cut generation ↩

Default: `0`

clocktype *(integer)*: clock type for computation time ↩

Default: `2`

clonelog *(integer)*: enable clone logs ↩

Default: `0`

coeredind *(integer)*: coefficient reduction on/off ↩

Default: `-1`

conflictalg *(integer)*: algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model ↩

Default: `0`

conflictdisplay *(integer)*: decides how much information CPLEX reports when the conflict refiner is working ↩

Default: `1`

covers *(integer)*: cover cut generation ↩

Default: `0`

cpumask *(string)*: switch and mask to bind threads to processors (Linux only) ↩

Default: `auto`

cpxpresolve *(integer)*: Applies CPLEX presolve to full model ↩

Default: `0`

value	meaning
`-1`	Apply only for first feasible heuristic
`-2`	Do not apply at all
`0`	Automatically determined
`1`	Always applied

craind *(integer)*: crash strategy (used to obtain starting basis) ↩

Default: `1`

cutlo *(real)*: lower cutoff for tree search ↩

Default: `-1.0e+75`

cutoff *(real)*: GMO cutoff ↩

Default: `0.0`

cutpass *(integer)*: maximum number of cutting plane passes ↩

Default: `0`

cuts *(string)*: default cut generation ↩

Default: `0`

cutsfactor *(real)*: cut limit ↩

Default: `-1.0`

cutup *(real)*: upper cutoff for tree search ↩

Default: `1.0e+75`

datacheck *(integer)*: controls data consistency checking and modeling assistance ↩

Default: `0`

decompdensity *(real)*: Matrix density above which automatic decomposition assigns each variable to a separate key ↩

Default: `0.3`

decomposition *(integer)*: Model decomposition method. ↩

Default: `-1`

value	meaning
-1	Automatically determined
0	Assign each variable to a separate key
1	Use automatic decomosition method
2	Use decomposition based on dot option .key

depind *(integer)*: dependency checker on/off ↩

Default: `-1`

deterministic *(boolean)*: Specifies whether the solution improvement heuristic is run in deterministic or opportunistic (i.e. non-deterministic) mode ↩

Default: `1`

value	meaning
0	Opportunistic
1	Deterministic

dettilim *(real)*: deterministic time limit ↩

Default: 1.0e+75

disjcuts *(integer)*: disjunctive cuts generation ↩

Default: 0

divetype *(integer)*: MIP dive strategy ↩

Default: 0

.divflt *(real)*: solution pool range filter coefficients ↩

Default: 0

divfltlo *(real)*: lower bound on diversity ↩

Default: mindouble

divfltup *(real)*: upper bound on diversity ↩

Default: maxdouble

divisor *(integer)*: Initial divisor for sub models ↩

Initial sub model size is model_size times 1 over Divisor. Ignored if InterDiv is set.

Default: automatic

domlim *(integer)*: domain violation number ↩

Default: 0

dpriind *(integer)*: dual simplex pricing ↩

Default: 0

dynamicrows *(integer)*: switch for dynamic management of rows ↩

Default: -1

dynamicsearch *(integer)*: Search strategy for CPLEX caller and sub-model solves ↩

Default: -1

value	meaning
-1	Automatically determined
0	Use traditional branch & cut
1	Use dynamic search

eachcutlim *(integer)*: sets a limit for each type of cut ↩

Default: `2100000000`

epagap *(real)*: absolute stopping tolerance ↩

Synonym: optca

Default: `1.0e-06`

epgap *(real)*: relative stopping tolerance ↩

Synonym: optcr

Default: `1.0e-04`

epint *(real)*: integrality tolerance ↩

Default: `1.0e-05`

eplin *(real)*: degree of tolerance used in linearization ↩

Default: `0.001`

epmrk *(real)*: Markowitz pivot tolerance ↩

Default: `0.01`

epopt *(real)*: optimality tolerance ↩

Default: `1.0e-06`

epper *(real)*: perturbation constant ↩

Default: `1.0e-06`

eprelax *(real)*: relaxation for feasOpt ↩

Default: `1.0e-06`

eprhs *(real)*: feasibility tolerance ↩

Default: `1.0e-06`

extracplexlog *(boolean)*: Write addition CPLEX output to log ↩

Default: `0`

value	meaning
0	Do not write extra CPLEX informtion
1	Write extra CPLEX information

feasoptmode *(integer)*: mode of FeasOpt ↩

Default: `0`

feastol *(real)*: Feasibility tolerance ↩

Range: [0, 1.0]

Default: 1e-6

firstfeas *(integer)*: Use first feasible heuristic for finding an initial feasible solution ↩

The default for ODH-CPLEX is 1 while for the heuristic engine the default is -1.

Default: -1

value	meaning
-1	Do not use
0	Use if no solution found during initial presolve
1	Always use

firstfeascontinue *(integer)*: Whether first feasible heuristic continues when it achieves feasibility ↩

Default: 0

value	meaning
0	Do not continue
1	Continue
2	Use in sub-model solves

firstfeaseffort *(integer)*: Effort limit on first feasible heuristic ↩

If the option value is positive the exact value is used as the level of effort. If the value is negative no more than the absolute value of the option is used as the level of effort. The larger the effort level, the more effort is expended before giving up.

Default: -500

value	meaning
>0	Use this level of effort
<0	Use no more than -firstfeaseffort effort

firstfeaslpitlim *(integer)*: Limit on number of relaxed re-solves in first feasible heuristic ↩

Default: 10

value	meaning
-1	No limit
0	No relaxed re-solves
>0	Limit

firstfeasrelaxcrit *(real)*: Smallest sum of infeasibilites/row where relaxed solution used ↩

Default: 0.01

firstfeasshift *(integer)*: First feasible heuristic variable shifting in found solutions ↩

Default: `0`

value	meaning
0	Do not shift
1	Moderate shifting
2	Aggressive shifting

fixoptfile *(string)*: name of option file which is read just before solving the fixed problem ↩

flowcovers *(integer)*: flow cover cut generation ↩

Default: 0

flowpaths *(integer)*: flow path cut generation ↩

Default: 0

folding *(integer)*: LP folding will be attempted during the preprocessing phase ↩

Default: -1

fpheur *(integer)*: feasibility pump heuristic ↩

Default: 0

fraccand *(integer)*: candidate limit for generating Gomory fractional cuts ↩

Default: 200

fraccuts *(integer)*: Gomory fractional cut generation ↩

Default: 0

fracpass *(integer)*: maximum number of passes for generating Gomory fractional cuts ↩

Default: 0

freegamsmodel *(boolean)*: preserves memory by dumping the GAMS model instance representation temporarily to disk ↩

Default: 0

globalbounds *(integer)*: Use of global bounds from CPLEX caller ↩

Default: 2

value	meaning
0	Never use
5	Always use
1-4	Intensity of use

gubcovers *(integer)*: GUB cover cut generation ↩

Default: 0

heurfreq *(integer)*: heuristic frequency ↩

Default: `0`

heuristiceffort *(real)*: the effort that CPLEX spends on heuristics during a MIP solve ↩

Default: `1.0`

ignoresetslvrparams *(boolean)*: Flag to control whether solver parameters can be dynamically altered by ODH ↩

Default: `0`

implbd *(integer)*: implied bound cut generation ↩

Default: `0`

indexkey *(string)*: Pattern used to match variable names for grouping into sub-models discussed above ↩

indicoptstrict *(boolean)*: abort in case of an error in indicator constraint in solver option file ↩

Default: `1`

integeronly *(integer)*: Variables to include in INDEXKEY ↩

Default: `-1`

value	meaning
`-1`	Automatically determined
`0`	All variables
`1`	Only non-continuous variables

integertol *(real)*: Integrality tolerance for variable values ↩

Default: `1e-5`

interdiv *(integer)*: Initial divisor value ↩

Default: `4`

intsollim *(integer)*: maximum number of integer solutions ↩

Default: `2147483647`

itlim *(integer)*: iteration limit ↩

Synonym: iterlim

Default: `2147483647`

.key *(integer)*: Variable block or key number ↩

Default: `0`

keypartition *(integer)*: Use of solver partition information ↩

Default: `0`

value	meaning
0	Do not use
1	Use solver partition information to generate keys
2	Use keys to generate sub-solver partition information

keysminimum *(integer)*: Minimum number of keys that the automatic decomposition method attempts to find ↩

Default: 512

keytype *(boolean)*: Treatment of multiple INDEXKEYs ↩

Default: 0

value	meaning
0	Considered separately e.g. INDEXKEY=x_d;y_d means x_2 and y_2 belong to separate groups
1	Considered together e.g. INDEXKEY=x_d;y_d means x_2 and y_2 belong to the same group

.lazy *(boolean)*: Lazy constraints activation ↩

Default: 0

lazyconstraints *(boolean)*: Indicator to use lazy constraints ↩

Default: 0

lbheur *(boolean)*: local branching heuristic ↩

Default: 0

liftprojcuts *(integer)*: lift-and-project cuts ↩

Default: 0

localimplied *(integer)*: generation of locally valid implied bound cuts ↩

Default: 0

localsearch *(boolean)*: Indicator for local search heuristic ↩

Default: 1

loosefeastol *(real)*: Loose feasibility tolerance ↩

Default: 1e-5

lpmethod *(integer)*: algorithm to be used for LP problems ↩

Default: 0

maxbacktrack *(integer)*: The maximum number of backtracks permitted in sub-model solves ↩

Default: -1

value	meaning
-1	Automatically determined
0	Infinite
>0	Use this value if a better solution is available

maxbound *(real)*: The largest(smallest) non infinite bound value ODH will accept for upper(lower) bounds ↩

If this value is positive, bounds exceeding MAXBOUND are reduced to MAXBOUND; if this value is negative, bounds exceeding -MAXBOUND are ignored.

Default: 1e+9

maxinfrepeat *(integer)*: Maximum divisor value when solution is infeasible ↩

Default: 0

value	meaning
0	Automatically determined
>0	Use this value

maxinterdiv *(integer)*: Maximum divisor value ↩

Default: 0

maxrepeat *(integer)*: Maximum number of sub-model repeat solves for each divisor value ↩

Default: 0

value	meaning
0	Automatically determined
>0	Use this value

mcfcuts *(integer)*: multi-commodity flow cut generation ↩

Default: 0

memoryemphasis *(boolean)*: reduces use of memory ↩

Default: 0

mipdisplay *(integer)*: progress display level ↩

Default: 2

mipemphasis *(integer)*: MIP solution tactics ↩

Default: 0

mipinterval *(integer)*: progress display interval ↩

Default: 0

mipkappastats *(integer)*: MIP kappa computation ↩

Default: `0`

mipordind *(boolean)*: priority list on/off ↩

Synonym: prioropt

Default: `1`

mipordtype *(integer)*: priority order generation ↩

Default: `0`

mipsearch *(integer)*: search strategy for mixed integer programs ↩

Default: `0`

mipstart *(integer)*: use mip starting values ↩

Default: `0`

miqcpstrat *(integer)*: MIQCP relaxation choice ↩

Default: `0`

mircuts *(integer)*: mixed integer rounding cut generation ↩

Default: `0`

mpslongnum *(boolean)*: MPS file format precision of numeric output ↩

Default: `1`

multimipstart *(string)*: use multiple mipstarts provided via gdx files ↩

multobjdisplay *(integer)*: level of display during multiobjective optimization ↩

Default: `1`

names *(boolean)*: load GAMS names into Cplex ↩

Default: `1`

netdisplay *(integer)*: network display level ↩

Default: `2`

netepopt *(real)*: optimality tolerance for the network simplex method ↩

Default: `1.0e-06`

neteprhs *(real)*: feasibility tolerance for the network simplex method ↩

Default: `1.0e-06`

netfind *(integer)*: attempt network extraction ↩

Default: 2

netitlim *(integer)*: iteration limit for network simplex ↩

Default: 2147483647

netppriind *(integer)*: network simplex pricing ↩

Default: 0

nodecuts *(integer)*: decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree ↩

Default: 0

nodefileind *(integer)*: node storage file indicator ↩

Default: 1

nodelim *(integer)*: maximum number of nodes to solve ↩

Synonym: nodlim

Default: 2147483647

nodesel *(integer)*: node selection strategy ↩

Default: 1

numericalemphasis *(boolean)*: emphasizes precision in numerically unstable or difficult problems ↩

Default: 0

objdif *(real)*: overrides GAMS Cheat parameter ↩

Synonym: cheat

Default: 0.0

objllim *(real)*: objective function lower limit ↩

Default: -1.0e+75

objtarget *(real)*: Target objective value ↩

ODHeuristics terminates when this value is reached. Defaults to -infinity for minimization or +infinity for maximization models.

Default: 0

objthreshold *(real)*: Threshold for absolute value of objective coefficients ↩

Variables with coefficients greater than this value are always considered for optimization.

Default: 1e99

objulim *(real)*: objective function upper limit ↩

Default: 1.0e+75

odheuristicmethod *(string)*: ODHeuristic method section ↩

Default: ODH-CPLEX

value	meaning
ODH-CPLEX	ODHeuristic within the CPLEX optimizer
STANDALONE	Stand-alone ODHeuristic engine

odhfeasopt *(boolean)*: Optimization method for sub-models in phaseI ↩

Default: 0

odhthreads *(integer)*: The number of heuristic threads used by ODH-CPLEX or STANDALONE ↩

Default: -1

value	meaning
-1	Automatically determined
0	Run in serial mode
>0	Use the specified number of threads

odhtimelimit *(real)*: Elapsed time limit in seconds ↩

Synonym: reslim

Default: GAMS ResLim

optimalitytarget *(integer)*: type of optimality that Cplex targets ↩

Default: 0

parallelmode *(integer)*: parallel optimization mode ↩

Default: 0

paramdisplay *(boolean)*: display the nondefault parameters before optimization ↩

Default: 1

penalty *(real)*: The objective function coefficient value for penalties ↩

The objective function coefficient value for the penalties introduced to deal with infeasibilities in the solution improvement heuristic. It is set by default when required and if not specified.

Default: -1

penperturb *(real)*: Perturbation tolerance for penalties coefficients ↩

Default: 0

perind *(boolean)*: force initial perturbation ↩

Default: 0

perlim *(integer)*: number of stalled iterations before perturbation ↩

Default: 0

phase12 *(boolean)*: Specifies whether to use a phaseI/phaseII method to remove infeasibilities ↩

Default: 1

value	meaning
0	Use composite objective method
1	Use phaseI/phaseII method

polishafterdettime *(real)*: deterministic time before starting to polish a feasible solution ↩

Default: 1.0e+75

polishafterepagap *(real)*: absolute MIP gap before starting to polish a feasible solution ↩

Default: 0.0

polishafterepgap *(real)*: relative MIP gap before starting to polish a solution ↩

Default: 0.0

polishafterintsol *(integer)*: MIP integer solutions to find before starting to polish a feasible solution ↩

Default: 2147483647

polishafternode *(integer)*: nodes to process before starting to polish a feasible solution ↩

Default: 2147483647

polishaftertime *(real)*: time before starting to polish a feasible solution ↩

Default: 1.0e+75

populatelim *(integer)*: limit of solutions generated for the solution pool by populate method ↩

Default: 20

ppriind *(integer)*: primal simplex pricing ↩

Default: 0

predual *(integer)*: give dual problem to the optimizer ↩

Default: 0

preind *(boolean)*: turn presolver on/off ↩

Default: 1

prelinear *(boolean)*: linear reduction indicator ↩

Default: 1

prepass *(integer)*: number of presolve applications to perform ↩

Default: -1

prereform *(integer)*: set presolve reformulations ↩

Default: 3

preslvnd *(integer)*: node presolve selector ↩

Default: 0

pricelim *(integer)*: pricing candidate list ↩

Default: 0

printoptions *(boolean)*: list values of all options to GAMS listing file ↩

Default: 0

probe *(integer)*: perform probing before solving a MIP ↩

Default: 0

probedettime *(real)*: deterministic time spent probing ↩

Default: 1.0e+75

probetime *(real)*: time spent probing ↩

Default: 1.0e+75

processorlock *(boolean)*: Thread allocation ↩

Default: 0

value	meaning
0	Do not lock threads to processors
1	Lock threads to processors

qextractalg *(integer)*: quadratic extraction algorithm in GAMS interface ↩

Default: 0

qpmakepsdind *(boolean)*: adjust MIQP formulation to make the quadratic matrix positive-semi-definite ↩

Default: 1

qpmethod *(integer)*: algorithm to be used for QP problems ↩

Default: 0

qtolin *(integer)*: linearization of the quadratic terms in the objective function of a QP or MIQP model ↩

Default: -1

quality *(boolean)*: write solution quality statistics ↩

Default: 0

quickfirstsolve *(boolean)*: Accelerate initial CPLEX solve ↩

Default: 0

value	meaning
0	Do not unless presolve applied to full model
1	Use existing presolved model

randomseed *(integer)*: sets the random seed differently for diversity of solutions ↩

Default: 202009243

readflt *(string)*: reads Cplex solution pool filter file ↩

record *(boolean)*: Records invocations of Callable Library routines ↩

Default: 0

recurse *(integer)*: Recurse using heuristic to solve sub-models when a feasible solution has been obtained ↩

Default: 0

value	meaning
0	Do not recurse
1	Recurse thread 0 only
2	Recurse odd numbered threads
3	Recurse all threads
<0	Recurse when working with an infeasible solution. values are negated (e.g. -3 = recursion of all threads)

recursedecomp *(integer)*: Recursed model decomposition method ↩

Default: 0

value	meaning
-1	Use initial model decomposition
0	Assign each variable to a separate key
1	Use automatic decomposition method

recurseiterlim *(integer)*: Recursed heuristic iteration limit for sub-solves ↩

Default: 40

recurselog *(boolean)*: Write thread log files for recursed sub-solves ↩

Default: 0

recurseminiterlim *(integer)*: Recursed heuristic minimum iterations before a solution is found in sub-solves ↩

Default: 10

recursesoliterlim *(integer)*: Recursed heuristic sub-solves quit after these iterations if a solution is found ↩

Default: `maxint`

reduce *(integer)*: primal and dual reduction type ↩

Default: `3`

reinv *(integer)*: refactorization frequency ↩

Default: `0`

rejectinfsol *(integer)*: Reject infeasible solutions to sub-models ↩

Default: `2`

value	meaning
0	Do not check feasibility or reject
1	Check feasibility and warn if infeasible, but accept
2	Check feasibility and reject if infeasible

relaxfixedinfeas *(boolean)*: accept small infeasibilties in the solve of the fixed problem ↩

Default: `0`

relaxpreind *(integer)*: presolve for initial relaxation on/off ↩

Default: `-1`

relaxsos2 *(integer)*: Treatment of SOS2 members ↩

Default: `1`

value	meaning
0	Aggressive use in reducing sub-model size
1	Moderate use in reducing sub-model size
2	Ignored in sub-model creation

relobjdif *(real)*: relative cheat parameter ↩

Default: `0.0`

repairtries *(integer)*: try to repair infeasible MIP start ↩

Default: `0`

repeatpresolve *(integer)*: reapply presolve at root after preprocessing ↩

Default: `-1`

rerun *(string)*: rerun problem if presolve infeasible or unbounded ↩

Default: `nono`

rinsheur *(integer)*: relaxation induced neighborhood search frequency ↩

Default: `0`

rltcuts *(integer)*: Reformulation Linearization Technique (RLT) cuts ↩

Default: `0`

scaind *(integer)*: matrix scaling on/off ↩

Default: `0`

seed *(integer)*: Initial random number seed ↩

Default: `12345`

siftalg *(integer)*: sifting subproblem algorithm ↩

Default: `0`

siftdisplay *(integer)*: sifting display level ↩

Default: `1`

sifting *(boolean)*: switch for sifting from simplex optimization ↩

Default: `1`

siftitlim *(integer)*: limit on sifting iterations ↩

Default: `2147483647`

simdisplay *(integer)*: simplex display level ↩

Default: `1`

singlim *(integer)*: limit on singularity repairs ↩

Default: `10`

solnpool *(string)*: solution pool file name ↩

solnpoolagap *(real)*: absolute tolerance for the solutions in the solution pool ↩

Default: `1.0e+75`

solnpoolcapacity *(integer)*: limits of solutions kept in the solution pool ↩

Default: `2100000000`

solnpoolgap *(real)*: relative tolerance for the solutions in the solution pool ↩

Default: `1.0e+75`

solnpoolintensity *(integer)*: solution pool intensity for ability to produce multiple solutions ↩

Default: `0`

solnpoolmerge *(string)*: solution pool file name for merged solutions ↩

solnpoolnumsym *(integer)*: maximum number of variable symbols when writing merged solutions ↩

Default: `10`

solnpoolprefix *(string)*: file name prefix for GDX solution files ↩

Default: `soln`

solnpoolreplace *(integer)*: strategy for replacing a solution in the solution pool ↩

Default: `0`

solutiontype *(integer)*: type of solution (basic or non basic) for an LP or QP ↩

Default: `0`

solvefinal *(boolean)*: switch to solve the problem with fixed discrete variables ↩

Default: `1`

sos1reform *(integer)*: automatic logarithmic reformulation of special ordered sets of type 1 (SOS1) ↩

Default: `0`

sos2reform *(integer)*: automatic logarithmic reformulation of special ordered sets of type 2 (SOS2) ↩

Default: `0`

sosfind *(boolean)*: Automatic detection of Special Ordered Sets (SOSs) ↩

Default: `0`

sosinkey *(integer)*: Assign each SOS to its own sub-model component (key) ↩

Default: `0`

value	meaning
`0`	Treat SOS members as normal i.e. in keys iff declared non-continuous or integeronly =0;
`1`	SOS members always in keys
`2`	SOS members always in keys and members of each SOS to their own key

sosmember *(string)*: Automatically detect SOSs whose variable member names match this pattern ↩

sosovar *(string)*: Automatically detect SOSs whose output variable name matches this pattern ↩

sosselect *(string)*: Select sub-set of SOS members ↩

sosselect16 *(string)*: Select sub-set of SOS members for sets with 16 or fewer members only ↩

soswvar *(string)*: Automatically detect SOSs whose input(weight) variable name matches this pattern ↩

startalg *(integer)*: MIP starting algorithm ↩

Default: 0

strategy *(integer)*: ODH-Cplex Strategy ↩

The aggressive setting attempt to make more progress with each sub-model solve at the cost of more expensive sub solves. Amongst other changes, it sets InterDiv, MaxInterDiv and MaxRepeat if they are not explicitly set by the user.

Default: 1

value	meaning
0	Conservative
1	Normal
2	Aggressiv

strictdeterministic *(integer)*: Terminate ODH deterministically when improvement heuristic finishes ↩

Default: 0

value	meaning
0	Terminate ODH as soon as possible which can violate determinism
1	Terminate ODH deterministically

strongcandlim *(integer)*: size of the candidates list for strong branching ↩

Default: 10

strongitlim *(integer)*: limit on iterations per branch for strong branching ↩

Default: 0

subalg *(integer)*: algorithm for subproblems ↩

Default: 0

subcheckfreq *(integer)*: Frequency with which sub-model LPs are interrupted for mutual communication ↩

Default: 10

value	meaning
0	Do not interrupt sub-model LPs
>0	Interrupt sub-model LPs. The smaller this value then more often they are interrupted.

submipnodelim *(integer)*: limit on number of nodes in an RINS subMIP ↩

Default: 500

submipscale *(integer)*: scale the problem matrix when CPLEX solves a subMIP during MIP optimization ↩

Default: 0

submipstartalg *(integer)*: starting algorithm for a subMIP of a MIP ↩

Default: 0

submipsubalg *(integer)*: algorithm for subproblems of a subMIP of a MIP ↩

Default: 0

subnodelimit *(integer)*: Node limit for submodel searches ↩

Default: -1

value	meaning
-1	Automatically determined
>0	Set node limit to this value

suborder *(integer)*: Use of priority order in sub-solves ↩

Default: 1

value	meaning
0	Do not use any supplied priority order information in sub-solves
1	Use any supplied priority order information in sub-solves

sub_cpx_threads *(integer)*: Threads availble for the solves within ODHeuristic ↩

Default: 1

symmetry *(integer)*: symmetry breaking cuts ↩

Default: -1

syncfreq *(integer)*: Thread synchronization frequency in deterministic parallel mode ↩

Default: 1

value	meaning
0	Low frequency
1	High frequency

threadlog *(boolean)*: Write thread log files ↩

Default: 0

threads *(integer)*: global default thread count ↩

Synonym: gthreads

Default: `0`

threadzerosync *(integer)*: Which CPLEX threads to use for synchronization ↩

Default: `0`

value	meaning
0	Synchronize with multiple CPLEX threads
1	Only synchronize with CPLEX thread 0

tightenprebounds *(integer)*: Level of bound tightening in ODH presolved model ↩

Default: `1`

value	meaning
0	Do not tighten bounds
1	Least aggressive
2	Moderate aggressive
3	Most aggressive

tilim *(real)*: overrides the GAMS ResLim option ↩

Default: `1.0e+75`

trelim *(real)*: maximum space in memory for tree ↩

Default: `1.0e+75`

trialbound *(integer)*: Trial bound heuristic ↩

Default: `0`

value	meaning
-1	As option 1 plus retain trial bounds for whole optimization
-2	As option 2 plus retain trial bounds for whole optimization
0	Read trial bounds from trialboundfile if it is specified
1	Read trial bounds from trialboundfile
2	Auto generate trial bounds and write them to trialboundfile if it is specified

trialboundfile *(string)*: The trial bound file ↩

Bounds are used to attempt finding an initial feasible solution

trialboundsetsize *(integer)*: Size adjustment to automatically generated trial bound sets ↩

Default: `0`

value	meaning
0	Do not adjust set size
>0	Use no more than this number of set members
<0	Decrease set size by this value

tryint *(real)*: GMO tryint ↩

Default: 0.0

tuningdettilim *(real)*: tuning deterministic time limit per model or suite ↩

Default: 1.0e+75

tuningdisplay *(integer)*: level of information reported by the tuning tool ↩

Default: 1

tuningmeasure *(integer)*: measure for evaluating progress for a suite of models ↩

Default: 1

tuningrepeat *(integer)*: number of times tuning is to be repeated on perturbed versions ↩

Default: 1

tuningtilim *(real)*: tuning time limit per model or suite ↩

Default: 1.0e+75

usebasis *(boolean)*: GMO usebasis ↩

Default: 0

usehistory *(integer)*: Use of past sub-model selections in current selection ↩

Default: -1

value	meaning
-1	Automatically determined
0	Never use historical information
1	Always use historical information

varcleanlpmethod *(integer)*: Method used to solve variable cleaning LPs ↩

Default: -1

value	meaning
-1	Automatically determined by solver
0	Primal simplex
1	Dual simplex
2	Barrier

variableclean *(integer)*: Clean variable values from sub-models ↩

Default: `1`

value	meaning
0	No cleaning
1	Quick cleaning and allow feasible uncleaned solutions if unable to clean
2	Quick cleaning and disallow uncleaned solutions
3	Thorough cleaning

varsel *(integer)*: variable selection strategy at each node ↩

Default: `0`

warninglimit *(integer)*: determines how many times warnings of a specific type (datacheck=2) will be displayed ↩

Default: `10`

workdir *(string)*: directory for working files ↩

Default: `.`

workeralgorithm *(integer)*: set method for optimizing benders subproblems ↩

Default: `0`

workmem *(real)*: memory available for working storage ↩

5.30 PATHNLP

5.30.1 Introduction

This document describes the GAMS/PATHNLP solver for non-linear programs and the options unique to this solver.

PATHNLP solves an NLP by internally constructing the Karush-Kuhn-Tucker (KKT) system of first-order optimality conditions associated with the NLP and solving this system using the PATH solver for complementarity problems. The solution to the original NLP is extracted from the KKT solution and returned to GAMS. All of this takes place automatically - no special syntax or user reformulation is required.

Typically, PATHNLP works very well for convex models. It also has a comparative advantage on models whose solution via reduced gradient methods results in a large number of superbasic variables, since the PATH solver won't construct a dense reduced Hessian in the space of the superbasic variables as reduced gradient solvers do. For nonconvex models, however, PATHNLP is not as robust as the reduced gradient methods.

The theory relating NLP to their KKT systems is well-known: assuming differentiability without convexity, and assuming a constraint qualification holds, then a solution to the NLP must also be a solution to the KKT system. If we also assume convexity, then a solution to the KKT system is also a solution to the NLP - no further constraint qualification is required.

In case PATH fails to find a solution to the KKT system for the NLP, a phase I / phase II method is used in which the phase I objective is simply the feasibility error and the original objective is ignored. If a feasible point is found in phase I then phase II, an attempt to solve the KKT system for the NLP using the current feasible point, is entered.

PATHNLP is installed automatically with your GAMS system. With a demo or community license, it will solve small models only). If your GAMS license includes PATH, this size restriction is removed.

5.30.2 Usage

If you have installed the system and configured PATHNLP as the default NLP solver, all NLP models without a specific solver option will be solved with PATHNLP. If you installed another solver as the default, you can explicitly request that a particular model be solved using PATHNLP by inserting the statement

```
option NLP = pathnlp;
```

somewhere before the `solve` statement. Similar comments hold for the other model types (LP, RMINLP, QCP, etc.) PATHNLP can handle.

The standard GAMS model options `iterlim` and `reslim` can be used to control PATHNLP. A description of these options can be found in the GAMS Options section of the chapter on basic solver usage. In general this is enough to use PATHNLP effectively. In some cases, however, you may want to use some of the PATH or PATHNLP options to gain further performance improvements or for other reasons. The rules for using an option file are described in the chapter on basic solver usage. The options used to control PATH can also be used to control PATHNLP. There are also some options unique to PATHNLP.

5.30.3 Options

The tables that follow describe the options unique to PATHNLP as well as the options shared with the PATH solver for MCP models.

5.30.3.1 General options

Option	Description	Default
chen_lambda	lambda parameter for Chen-Chen-Kanzow residual Range: [0, 1]	0.8
convergence_tolerance	stopping criterion	1e-6
crash_iteration_limit	maximum iterations allowed in crash	50
crash_merit_function	merit function used in crash method `normal`: Use the normal map `fischer`: Use the Fischer function	fischer
crash_method	pnewton or none `pnewton`: Use projected Newton method `none`	pnewton
crash_minimum_dimension	minimum problem dimension to perform crash	1
crash_nbchange_limit	number of changes to the basis allowed	1
crash_perturb	perturb the problem using pnewton crash	1
crash_searchtype	search type to use in the crash method `line`: Use a linesearch `arc`: Use an arcsearch	line
cumulative_iteration_limit	maximum minor iterations allowed	10000
gradient_searchtype	search type to use on a gradient step `line`: Use a linesearch `arc`: Use an arcsearch	arc
gradient_step_limit	gradient steps allowed before restarting	5
interrupt_limit	ctrl-C's required before killing job Range: {1, ..., ∞}	5

Option	Description	Default
major_iteration_limit	maximum major iterations allowed	500
merit_function	merit function to use (normal or fischer) `normal`: Use the normal map `fischer`: Use the Fischer function	fischer
minor_iteration_limit	minor iterations allowed in each major iteration	1000
nms	allow line searching, watch-dogging, and nonmonotone descent	1
nms_initial_reference_factor	controls size of initial reference value	20
nms_maximum_watchdogs	maximum number of watchdog steps allowed	5
nms_memory_size	number of reference values kept	10
nms_mstep_frequency	frequency at which m-steps are performed	10
nms_searchtype	search type to use `line`: Use a linesearch `arc`: Use an arcsearch	line
option_file	option file name for PATHLIB to read	
preprocess	turns preprocessing on/off	1
proximal_perturbation	initial perturbation	0
time_limit	number of seconds algorithm is allowed to run	
lemke_rank_deficiency_iterations	number of attempts made to fix rank-deficient basis during Lemke start	10
lemke_start	frequency of lemke starts `always`: Use a Lemke start for each LCP subproblem `automatic`: Determined by algorithm `first`: Use a Lemke start for the first LCP subproblem	automatic
lemke_start_type	type of lemke start `advanced`: Start Lemke method using an advanced basis `slack`: Start Lemke method using and all-slack basis	slack

5.30.3.2 NLP-specific options

Option	Description	Default
allow_reform	substitute out objective var and equ when possible Many models have an objective variable and equation that can be substituted out of the model, e.g. `f(x) =E= z;` If this option is true, PATHNLP will substitute out the objective variable and equation where possible.	1
gmo_hess_factor	maximum multiples of Jacobian size to allow Hessian storage: 0=no limit	0
nlp_lambda	linesearch factor when using the NLP objective If `nlp_objective` is true and `nlp_lambda` is positive, the PATH linesearch will be altered to take the objective function into account.	0
nlp_objective	treat NLP objective differently in PATH linesearch	0
output_memory	output breakdown of where memory is used	0

Option	Description	Default
skip_kkt	go right to Phase I / Phase II method If true, PATHNLP will skip the initial attempt to solve the KKT system for the NLP and go directly into a Phase I / Phase II method that first attempts to get feasible and then attempts to solve the KKT system starting from the feasible point found in Phase I.	0

5.30.3.3 Output options

Option	Description	Default
output_crash_iterations	output information on crash iterations	1
output_crash_iterations_frequency	frequency at which crash iteration log is printed Range: {1, ..., ∞}	1
output_errors	output error messages	1
output_final_degeneracy_statistics	print information regarding degeneracy at the solution	0
output_final_point	output final point returned from PATH	0
output_final_point_statistics	output information about the point, function, and Jacobian at the final point	1
output_final_scaling_statistics	display matrix norms on the Jacobian at the final point	0
output_final_statistics	output evaluation of available merit functions at the final point	1
output_final_summary	output summary information	1
output_initial_point	output initial point given to PATH	0
output_initial_point_statistics	output information about the point, function, and Jacobian at the initial point	1
output_initial_scaling_statistics	display matrix norms on the Jacobian at the initial point	1
output_initial_statistics	output evaluation of available merit functions at the initial point	0
output_linear_model	output linear model at each major iteration	0
output_major_iterations	output information on major iterations	1
output_major_iterations_frequency	frequency at which major iteration log is printed Range: {1, ..., ∞}	1
output_maximum_zero_listing	limits zero columns reported to listing file	1000
output_maximum_zero_log	limits zero columns reported to log file	10
output_minor_iterations	output information on minor iterations	1
output_minor_iterations_frequency	frequency at which minor iteration log is printed Range: {1, ..., ∞}	500
output_options	output all options and their values	0
output	no turns all output off	1
output_preprocess_level	control output of preprocessing information	1
output_restart_log	output options during restarts	1

Option	Description	Default
output_time	output breakdown of where time is spent	0
output_warnings	output warning messages	0

5.31.1 Complementarity

A fundamental problem of mathematics is to find a solution to a square system of nonlinear equations. Two generalizations of nonlinear equations have been developed, a constrained nonlinear system which incorporates bounds on the variables, and the complementarity problem (MCP). This document is primarily concerned with the complementarity problem.

The PATH solver for MCP models is a Newton-based solver that combines a number of the most effective variations, extensions, and enhancements of this powerful technique. See PATH vs MILES for a comparison with MILES. Algorithmic details can also be found in papers and technical reports by Dirkse, Ferris, and Munson on Ferris' Home Page.

The complementarity problem adds a combinatorial twist to the classic square system of nonlinear equations, thus enabling a broader range of situations to be modeled. In its simplest form, the combinatorial problem is to choose from $2n$ inequalities a subset of n that will be satisfied as equations. These problems arise in a variety of disciplines including engineering and economics [60] where we might want to compute Wardropian and Walrasian equilibria, and optimization where we can model the first order optimality conditions for nonlinear programs [102] [114] . Other examples, such as bimatrix games [117] and options pricing [97] , abound.

Our development of complementarity is done by example. We begin by looking at the optimality conditions for a transportation problem and some extensions leading to the nonlinear complementarity problem. We then discuss a Walrasian equilibrium model and use it to motivate the more general mixed complementarity problem. We conclude this chapter with information on solving the models using the PATH solver and interpreting the results.

5.31.1.1 Transportation Problem

The transportation model is a linear program where demand for a single commodity must be satisfied by suppliers at minimal transportation cost. The underlying transportation network is given as a set $\mathcal{A}$ of arcs, where $(i,j) \in \mathcal{A}$ means that there is a route from supplier i to demand center j. The problem variables are the quantities $x_{i,j}$ shipped over each arc $(i,j) \in \mathcal{A}$. The linear program can be written mathematically as

$$\begin{array}{rl} \min_{x \geq 0} & \sum_{(i,j)\in\mathcal{A}} c_{i,j} x_{i,j} \\ \text{subject to} & \sum_{j:(i,j)\in\mathcal{A}} x_{i,j} \leq s_i, \ \forall i \\ & \sum_{i:(i,j)\in\mathcal{A}} x_{i,j} \geq d_j, \ \forall j. \end{array} \tag{1}$$

where $c_{i,j}$ is the unit shipment cost on the arc (i,j), s_i is the available supply at i, and d_j is the demand at j.

The derivation of the optimality conditions for this linear program begins by associating with each constraint a multiplier, alternatively termed a dual variable or shadow price. These multipliers represent the marginal price on changes to the corresponding constraint. We label the prices on the supply constraint p^s and those on the demand constraint p^d. Intuitively, for each supply node i

$$0 \leq p_i^s, \; s_i \geq \sum_{j:(i,j)\in\mathcal{A}} x_{i,j}.$$

Consider the case when $s_i > \sum_{j:(i,j)\in\mathcal{A}} x_{i,j}$, that is there is excess supply at i. Then, in a competitive marketplace, no rational person is willing to pay for more supply at node i; it is already over-supplied. Therefore, $p_i^s = 0$. Alternatively, when $s_i = \sum_{j:(i,j)\in\mathcal{A}} x_{i,j}$, that is node i clears, we might be willing to pay for additional supply of the good. Therefore, $p_i^s \geq 0$. We write these two conditions succinctly as:

$$0 \leq p_i^s \quad \perp \quad s_i \geq \textstyle\sum_{j:(i,j)\in\mathcal{A}} x_{i,j}, \quad \forall i$$

where the $\perp$ notation is understood to mean that at least one of the adjacent inequalities must be satisfied as an equality. For example, either $0 = p_i^s$, the first case, or $s_i = \sum_{j:(i,j)\in\mathcal{A}} x_{i,j}$, the second case.

Similarly, at each node j, the demand must be satisfied in any feasible solution, that is

$$\sum_{i:(i,j)\in\mathcal{A}} x_{i,j} \geq d_j.$$

Furthermore, the model assumes all prices are nonnegative, $0 \leq p_j^d$. If there is too much of the commodity supplied, $\sum_{i:(i,j)\in\mathcal{A}} x_{i,j} > d_j$, then, in a competitive marketplace, the price p_j^d will be driven down to 0. Summing these relationships gives the following complementarity condition:

$$0 \leq p_j^d \quad \perp \quad \textstyle\sum_{i:(i,j)\in\mathcal{A}} x_{i,j} \geq d_j, \quad \forall j.$$

The supply price at i plus the transportation cost $c_{i,j}$ from i to j must exceed the market price at j. That is, $p_i^s + c_{i,j} \geq p_j^d$. Otherwise, in a competitive marketplace, another producer will replicate supplier i increasing the supply of the good in question which drives down the market price. This chain would repeat until the inequality is satisfied. Furthermore, if the cost of delivery strictly exceeds the market price, that is $p_i^s + c_{i,j} > p_j^d$, then nothing is shipped from i to j because doing so would incur a loss and $x_{i,j} = 0$. Therefore,

$$0 \leq x_{i,j} \quad \perp \quad p_i^s + c_{i,j} \geq p_j^d, \quad \forall (i,j) \in \mathcal{A}.$$

We combine the three conditions into a single problem,

$$\begin{array}{rcll} 0 \leq p_i^s & \perp & s_i \geq \sum_{j:(i,j)\in\mathcal{A}} x_{i,j}, & \forall i \\ 0 \leq p_j^d & \perp & \sum_{i:(i,j)\in\mathcal{A}} x_{i,j} \geq d_j, & \forall j \\ 0 \leq x_{i,j} & \perp & p_i^s + c_{i,j} \geq p_j^d, & \forall (i,j) \in \mathcal{A}. \end{array} \tag{2}$$

This model defines a linear complementarity problem that is easily recognized as the complementary slackness conditions [37] of the linear program (1). For linear programs the complementary slackness conditions are both necessary and sufficient for x to be an optimal solution of the problem (1). Furthermore, the conditions (2) are also the necessary and sufficient optimality conditions for a related problem in the variables (p^s, p^d)

$$\begin{array}{rl} \max_{p^s,p^d\geq 0} & \sum_j d_j p_j^d - \sum_i s_i p_i^s \\ \text{subject to} & c_{i,j} \geq p_j^d - p_i^s, \; \forall (i,j) \in \mathcal{A} \end{array}$$

termed the dual linear program (hence the nomenclature "dual variables").

Looking at (2) a bit more closely we can gain further insight into complementarity problems. A solution of (2) tells us the arcs used to transport goods. A priori we do not need to specify which arcs to use, the solution itself indicates them. This property represents the key contribution of a complementarity problem over a system of equations. If we know what arcs to send flow down, we can just solve a simple system of linear equations. However, the key to the modeling power of complementarity is that it chooses which of the inequalities in (2) to satisfy as equations. In economics we can use this property to generate a model with different regimes and let the solution determine which ones are active. A regime shift could, for example, be a back stop technology like windmills that become profitable if a CO_2 tax is increased.

GAMS Code

The GAMS code for the complementarity version of the transportation problem is given in Figure 1; the actual data for the model is assumed to be given in the file `transmcp.dat`. Note that the model written corresponds very closely to (2). In GAMS, the $\perp$ sign is replaced in the `model` statement with a ".". It is precisely at this point that the pairing of variables and equations shown in (2) occurs in the GAMS code. For example, the function defined by `rational` is complementary to the variable `x`. To inform a solver of the bounds, the standard GAMS statements on the variables can be used, namely (for a declared variable $z(i)$):

```
z.lo(i) = 0;
```

or alternatively

```
positive variable z;
```

Further information on the GAMS syntax can be found in [155]. *Note that GAMS requires the modeler to write `F(z) =g= 0` whenever the complementary variable is lower bounded, and does not allow the alternative form `0 =l= F(z)`.*

Figure 1: A simple MCP model in GAMS, `transmcp.gms`

```
sets    i   canning plants,
        j   markets ;

parameter
        s(i)    capacity of plant i in cases,
        d(j)    demand at market j in cases,
        c(i,j)  transport cost in thousands of dollars per case ;

$include transmcp.dat

positive variables
        x(i,j)           shipment quantities in cases
        p_demand(j)      price at market j
        p_supply(i)      price at plant i;

equations
        supply(i)      observe supply limit at plant i
        demand(j)      satisfy demand at market j
        rational(i,j);

supply(i) ..     s(i) =g= sum(j, x(i,j)) ;

demand(j) ..     sum(i, x(i,j))  =g=  d(j) ;

rational(i,j) .. p_supply(i) + c(i,j) =g= p_demand(j) ;

model transport / rational.x, demand.p_demand, supply.p_supply /;

solve transport using mcp;
```

Extension: Model Generalization

While many interior point methods for linear programming exploit this complementarity framework (so-called primal-dual methods [205]), the real power of this modeling format is the new problem instances it enables a modeler to create. We now show some examples of how to extend the simple model (2) to investigate other issues and facets of the problem at hand.

Demand in the model of Figure 1 is independent of the prices p. Since the prices p are variables in the complementarity problem (2), we can easily replace the constant demand d with a function $d(p)$ in the complementarity setting. Clearly, any algebraic function of p that can be expressed in GAMS can now be added to the model given in Figure 1. For example, a linear demand function could be expressed using

$$\sum_{i:(i,j)\in\mathcal{A}} x_{i,j} \geq d_j(1 - p_j^d), \ \forall j.$$

Note that the demand is rather strange if p_j^d exceeds 1. Other more reasonable examples for $d(p)$ are easily derived from Cobb-Douglas or CES utilities. For those examples, the resulting complementarity problem becomes nonlinear in the variables p. Details of complementarity for more general transportation models can be found in [48] , [62] .

Another feature that can be added to this model are tariffs or taxes. In the case where a tax is applied at the supply point, the third general inequality in (2) is replaced by

$$p_i^s(1 + t_i) + c_{i,j} \geq p_j^d, \ \forall (i,j) \in \mathcal{A}.$$

The taxes can be made endogenous to the model, details are found in [155] .

The key point is that with either of the above modifications, the complementarity problem is not just the optimality conditions of a linear program. In many cases, there is no optimization problem corresponding to the complementarity conditions.

Nonlinear Complementarity Problem

We now abstract from the particular example to describe more carefully the complementarity problem in its mathematical form. All the above examples can be cast as nonlinear complementarity problems (NCPs) defined as follows:

(NCP) Given a function $F : \mathbf{R}^n \to \mathbf{R}^n$, find $z \in \mathbf{R}^n$ such that

$$0 \leq z \perp F(z) \geq 0.$$

Recall that the $\perp$ sign signifies that one of the inequalities is satisfied as an equality, so that componentwise, $z_i F_i(z) = 0$. We frequently refer to this property as z_i is *complementary* to F_i. A special case of the NCP that has received much attention is when F is a linear function, the linear complementarity problem [40] .

5.31.1.2 Walrasian Equilibrium

A Walrasian equilibrium can also be formulated as a complementarity problem (see [132]). In this case, we want to find a price $p \in \mathbf{R}^m$ and an activity level $y \in \mathbf{R}^n$ such that

$$\begin{array}{rcrcl} 0 \leq y & \perp & L(p) & := & -A^T p \geq 0 \\ 0 \leq p & \perp & S(p,y) & := & b + Ay - d(p) \geq 0 \end{array} \tag{3}$$

where $S(p, y)$ represents the excess supply function and $L(p)$ represents the loss function. Complementarity allows us to choose the activities y_j to run (i.e. only those that do not make a loss). The second set of inequalities state that the price of a commodity can only be positive if there is no excess supply. These conditions indeed correspond to the standard exposition of Walras' law which states that supply equals demand if we assume all prices p will be positive at a solution. Formulations of equilibria as systems of equations do not allow the model to choose the activities present, but typically make an a priori assumption on this matter.

GAMS Code

A GAMS implementation of (3) is given in Figure 2. Many large scale models of this nature have been developed. An interested modeler could, for example, see how a large scale complementarity problem was used to quantify the effects of the Uruguay round of talks [95] .

Figure 2: Walrasian equilibrium as an NCP, `walras1.gms`

```
$include walras.dat

positive variables p(i), y(j);
equations S(i), L(j);

S(i)..   b(i) + sum(j, A(i,j)*y(j)) - c(i)*sum(k, g(k)*p(k)) / p(i)
         =g= 0;

L(j)..   -sum(i, p(i)*A(i,j)) =g= 0;

model walras / S.p, L.y /;
solve walras using mcp;
```

Extension: Intermediate Variables

In many modeling situations, a key tool for clarification is the use of intermediate variables. As an example, the modeler may wish to define a variable corresponding to the demand function $d(p)$ in the Walrasian equilibrium (3). The syntax for carrying this out is shown in Figure 3 where we use the variables `d` to store the demand function referred to in the excess supply equation. The model `walras` now contains a mixture of equations and complementarity constraints. Since constructs of this type are prevalent in many practical models, the GAMS syntax allows such formulations.

Figure 3: Walrasian equilibrium as an MCP, `walras2.gms`

```
$include walras.dat

positive variables p(i), y(j);
variables d(i);
equations S(i), L(j), demand(i);

demand(i)..
         d(i) =e= c(i)*sum(k, g(k)*p(k)) / p(i) ;

S(i)..   b(i) + sum(j, A(i,j)*y(j)) - d(i) =g= 0 ;

L(j)..   -sum(i, p(i)*A(i,j)) =g= 0 ;

model walras / demand.d, S.p, L.y /;
solve walras using mcp;
```

Note that positive variables are paired with inequalities, while free variables are paired with equations. A crucial point misunderstood by many modelers (new and experienced alike) is that *the bounds on the variable determine the relationships satisfied by the function F*. Thus in Figure 3, d is a free variable and therefore its paired equation `demand` is an equality. Similarly, since p is nonnegative, its paired relationship `S` is a (greater-than) inequality. See the MCP definition below for details.

A simplification is allowed to the model statement in Figure 3. It is not required to match free variables explicitly to equations; we only require that there are the same number of free columns (i.e. single variables) as unmatched rows (i.e. single equations). Thus, in the example of Figure 3, the model statement could be replaced by

```
model walras / demand, S.p, L.y /;
```

This extension allows existing GAMS models consisting of a square system of nonlinear equations to be easily recast as a complementarity problem - the model statement is unchanged. GAMS generates a list of all variables appearing in the equations found in the model statement, performs explicitly defined pairings and then checks that the number of remaining equality rows equals the number of remaining free columns. However, if an explicit match is given, the PATH solver can frequently exploit the information for better solution. Note that all variables that are not free and all inequalities must be explicitly matched.

Mixed Complementarity Problem

A mixed complementarity problem (MCP) is specified by three pieces of data, namely the lower bounds ℓ, the upper bounds u and the function F.

(MCP) Given lower bounds $\ell \in \{\mathbf{R} \cup \{-\infty\}\}^n$, upper bounds $u \in \{\mathbf{R} \cup \{\infty\}\}^n$ and a function $F : \mathbf{R}^n \to \mathbf{R}^n$, find $z \in \mathbf{R}^n$ such that *precisely* one of the following holds for each $i \in \{1, \ldots, n\}$:

$$\begin{array}{lll} F_i(z) = 0 & \text{and} & \ell_i \leq z_i \leq u_i \\ F_i(z) > 0 & \text{and} & z_i = \ell_i \\ F_i(z) < 0 & \text{and} & z_i = u_i. \end{array}$$

These relationships define a general MCP (sometimes termed a rectangular variational inequality [94]). We will write these conditions compactly as

$$\ell \leq x \leq u \quad \perp \quad F(x).$$

As the MCP model type as defined above is the one used in GAMS, there are some consequences of the definition worth emphasizing here. Firstly, the bounds on the variable determine the relationships satisfied by the function F: the constraint type (e.g. `=G=`, `=L=`) chosen plays no role in defining the problem. This being the case, it is acceptable (and perhaps advisable!) to use an `=N=` in the definition of all equations used in complementarity models to highlight the dependence on the variable bounds in defining the MCP. This is not required, however. The constraint types `=G=`, `=L=` and `=E=` are also allowed. If the variable bounds are inconsistent with the constraint type chosen, GAMS will either reject the model (e.g. an `=L=` row matched with a lower-bounded variable) or silently and temporarily ignore the issue (e.g. an `=E=` row matched with a lower-bounded variable). In the latter case, if equality does not hold at solution (allowable if the variable is at lower bound) the is marked in the listing file with a redef.

Secondly, note the contrast between *complementarity conditions* like $g(z) \leq 0, z \geq 0$ and a *complementarity problem* like $F(x) \perp 0 \leq x \leq \infty$. The former requires a trivial transformation in order to fit into the MCP framework: $-g(z) \perp 0 \leq z \leq \infty$. This simple issue is a frequent source of problems and worth looking out for.

The nonlinear complementarity problem of Nonlinear Complementarity Problem is a special case of the MCP. For example, to formulate an NCP in the GAMS/MCP format we set

```
z.lo(I) = 0;
```

or declare

```
positive variable z;
```

Another special case is a square system of nonlinear equations

(NE) Given a function $F : \mathbf{R}^n \to \mathbf{R}^n$ find $z \in \mathbf{R}^n$ such that

$$F(z) = 0.$$

In order to formulate this in the GAMS/MCP format we just declare

```
free variable z;
```

In both the above cases, we *must not* modify the lower and upper bounds on the variables later (unless we wish to drastically change the problem under consideration).

An advantage of the extended formulation described above is the pairing between "fixed" variables (ones with equal upper and lower bounds) and a component of F. If a variable z_i is fixed, then $F_i(z)$ is unrestricted since precisely one of the three conditions in the MCP definition automatically holds when $z_i = \ell_i = u_i$. Thus if a variable is fixed in a GAMS model, the paired equation is completely dropped from the model. This convenient modeling trick can be used to remove particular constraints from a model at generation time. As an example, in economics, fixing a level of production will remove the zero-profit condition for that activity.

Simple bounds on the variables are a convenient modeling tool that translates into efficient mathematical programming tools. For example, specialized codes exist for the bound constrained optimization problem

$$\min f(x) \text{ subject to } \ell \leq x \leq u.$$

The first order optimality conditions for this problem class are precisely MCP($\nabla f(x), [\ell, u]$). We can easily see this condition in a one dimensional setting. If we are at an unconstrained stationary point, then $\nabla f(x) = 0$. Otherwise, if x is at its lower bound, then the function must be increasing as x increases, so $\nabla f(x) \geq 0$. Conversely, if x is at its upper bound, then the function must be increasing as x decreases, so that $\nabla f(x) \leq 0$. The MCP allows such problems to be easily and efficiently processed.

Upper bounds can be used to extend the utility of existing models. For example, in Figure 3 it may be necessary to have an upper bound on the activity level y. In this case, we simply add an upper bound to y in the model statement, and we can replace the loss equation with the following definition:

```
y.up(j) = 10;
L(j)..   -sum(i, p(i)*A(i,j)) =e= 0 ;
```

Here, for bounded variables, we do not know beforehand if the constraint will be satisfied as an equation, less-than inequality or greater-than inequality, since this determination depends on the values of the solution variables. However, let us interpret the relationships that the above change generates. If $y_j = 0$, the loss function can be positive since we are not producing in the jth sector. If y_j is strictly between its bounds, then the loss function must be zero by the definition of complementarity; this is the competitive assumption. Finally, if y_j is at its upper bound, then the loss function can be negative. Of course, if the market does not allow free entry, some firms may operate at a profit (negative loss). For more examples of problems, the interested reader is referred to [45] , [59] , [60] .

5.31.1.3 Solution

We will assume that a file named `transmcp.gms` has been created using the GAMS syntax which defines an MCP model `transport` as developed in Transportation Problem . The modeler has a choice of the complementarity solver to use. We are going to further assume that the modeler wants to use PATH.

There are two ways to ensure that PATH is used as opposed to any other GAMS/MCP solver. These are as follows:

1. Add the following line to the `transmcp.gms` file prior to the `solve` statement

   ```
   option mcp = path;
   ```

   PATH will then be used instead of the default solver provided.

2. Choose PATH as the default solver for MCP (via the IDE on Windows or elsewhere by rerunning `gamsinst` from the GAMS system directory).

To solve the problem, the modeler executes the command:

```
gams transmcp
```

where `transmcp` can be replaced by any filename containing a GAMS model. Many other command line options for GAMS exist; the reader is referred to List of Command Line Parameters for further details.

At this stage, control is handed over to the solver which creates a log providing information on what the solver is doing as time elapses. See Section PATH for details about the log file. After the solver terminates, a listing file is generated containing the solution to the problem. We now describe the listing file output specifically related to complementarity problems.

Listing File

The listing file is the standard GAMS mechanism for reporting model results. This file contains information regarding the compilation process, the form of the generated equations in the model, and a report from the solver regarding the solution process.

We now detail the last part of this output, an example of which is given in Figure 4 . We use "..." to indicate where we have omitted continuing similar output.

After a summary line indicating the model name and type and the solver name, the listing file shows a solver status and a model status. Table 1 and Table 2 display the relevant codes that are returned under different circumstances. A modeler can access these codes within the `transmcp.gms` file using `transport.solveStat` and `transport.modelStat` respectively.

Table 1: Solver Status Codes

Code	String	Meaning
1	Normal completion	Solver finished normally
2	Iteration interrupt	Solver reached the iterations limit
3	Resource interrupt	Solver reached the time limit
4	Terminated by solver	Solver reached an unspecified limit
8	User interrupt	The user interrupted the solution process

Table 2: Model Status Codes

Code	String	Meaning
1	Optimal	Solver found a solution of the problem
6	Intermediate infeasible	Solver failed to solve the problem

After this, a listing of the time and iterations used is given, along with a count on the number of evaluation errors encountered. If the number of evaluation errors is greater than zero, further information can typically be found later in the listing file, prefaced by "****". Information provided by the solver is then displayed.

Next comes the solution listing, starting with each of the equations in the model. For each equation passed to the solver, four columns are reported, namely the lower bound, level, upper bound and marginal.

GAMS moves all parts of a constraint involving variables to the left hand side, and accumulates the constants on the right hand side. The lower and upper bounds correspond to the constants that GAMS generates. For equations, these should be equal, whereas for inequalities one of them should be infinite. The level value of the equation (an evaluation of the left hand side of the constraint at the current point) should be between these bounds, otherwise the solution is infeasible and the equation is marked as follows:

```
seattle  .chicago     -0.153    -2.000     +INF    300.000 INFES
```

The marginal column in the equation contains the value of the variable that was matched with this equation.

For the variable listing, the lower, level and upper columns indicate the lower and upper bounds on the variables and the solution value. The level value returned by PATH will always be between these bounds. The marginal column contains the value of the slack on the equation that was paired with this variable. If a variable appears in one of the constraints in the model statement but is not explicitly paired to a constraint, the slack reported here contains the internally matched constraint slack. The definition of this slack is the minimum of equ.l - equ.lower and equ.l - equ.upper, where equ is the paired equation.

Finally, a summary report is given that indicates how many errors were found. Figure 4 is nicely-solved case; when the model has infeasibilities, these can be found by searching for the string "INFES" as described above.

Redefined Equations

Unfortunately, this is not the end of the story. Some equations may have the following form:

```
                LOWER      LEVEL      UPPER    MARGINAL

new-york    325.000    350.000    325.000    0.225 REDEF
```

This should be construed as a warning from GAMS, as opposed to an error. In principle, the `REDEF` should only occur if the paired variable to the constraint has a finite lower and/or upper bound and the variable is at one of those bounds. In this case, at the solution of the complementarity problem the sense of the constraint (e.g. `=E=`) may not be satisfied. This occurs when GAMS constraints are used to define the function F. The bounds on each component of the function F are derived from the bounds on the matching variable component, and these bounds may be inconsistent with those implied by the constraint type used. GAMS warns the user via the `REDEF` label when the solution found leads to a violated "constraint". To avoid `REDEF` warnings the `=N=` can be used to define all complementarity functions.

Note that a `REDEF` is not an error, just a warning. The solver has solved the complementarity problem specified. GAMS gives this report to ensure that the modeler understands that the complementarity problem derives the relationships on the equations from the variable bounds, not from the equation definition.

5.31.1.4 Pitfalls

As indicated above, the ordering of an equation is important in the specification of an MCP. Since the data of the MCP is the function F and the bounds ℓ and u, it is important for the modeler to pass the solver the function F and not $-F$.

For example, if we have the optimization problem,

$$\min_{x \in [0,2]} (x-1)^2$$

then the first order optimality conditions are

$$0 \leq x \leq 2 \quad \perp \quad 2(x-1)$$

which has a unique solution, $x = 1$. Figure 5 provides correct GAMS code for this problem.

Figure 5: First order conditions as an MCP, `first.gms`

```
variables x;
equations d_f;

x.lo = 0;
x.up = 2;

d_f.. 2*(x - 1) =e= 0;

model first / d_f.x /;
solve first using mcp;
```

However, if we accidentally write the valid equation

```
d_f.. 0 =e= 2*(x - 1);
```

the problem given to the solver is

$$0 \leq x \leq 2 \quad \perp \quad -2(x-1)$$

which has three solutions, $x = 0$, $x = 1$, and $x = 2$. This problem is in fact the stationary conditions for the nonconvex quadratic problem,

$$\max_{x \in [0,2]} (x-1)^2,$$

not the problem we intended to solve.

Continuing with the example, when x is a free variable, we might conclude that the ordering of the equation is irrelevant because we always have the equation, $2(x-1) = 0$, which does not change under multiplication by -1. In most cases, the ordering of equations (which are complementary to free variables) does not make a difference since the equation is internally "substituted out" of the model. In particular, for defining equations, such as that presented in Figure 3, the choice appears to be arbitrary.

However, in difficult (singular or near singular) cases, the substitution cannot be performed, and instead a perturbation is applied to F, in the hope of "(strongly) convexifying" the problem. If the perturbation happens to be in the wrong direction because F was specified incorrectly, the perturbation actually makes the problem less convex, and hence less likely to solve. Note that determining which of the above orderings of the equations makes most sense is typically tricky. One rule of thumb is to check whether if you replace the "=e=" by "=g=", and then increase "x", is the inequality intuitively more likely to be satisfied. If so, you probably have it the right way round, if not, reorder.

Furthermore, underlying model convexity is important. For example, if we have the linear program

$$\begin{array}{rl} \min_x & c^T x \\ \text{subject to} & Ax = b,\ x \geq 0 \end{array}$$

we can write the first order optimality conditions as either

$$\begin{array}{rcl} 0 \leq x & \perp & -A^T\mu + c \\ \mu \text{ free} & \perp & Ax - b \end{array}$$

or, equivalently,

$$\begin{array}{rcl} 0 \leq x & \perp & -A^T\mu + c \\ \mu \text{ free} & \perp & b - Ax \end{array}$$

because we have an equation. The former is a linear complementarity problem with a positive semidefinite matrix, while the latter is almost certainly indefinite. Also, if we need to perturb the problem because of numerical problems, the former system will become positive definite, while the later becomes highly nonconvex and unlikely to solve. The rule of thumb here is to consider what happens when the dual multiplier μ is made non-negative in the KKT system. In the former system, the constraint becomes $Ax \geq b$, which is consistent with a minimization and a positive multiplier. In the latter system, we get $Ax \leq b$, which is backwards.

Finally, users are strongly encouraged to match equations and free variables when the matching makes sense for their application. Structure and convexity can be destroyed if it is left to the solver to perform the matching. For example, in the above example, we could lose the positive semidefinite matrix with an arbitrary matching of the free variables.

5.31.2 PATH

Newton's method, perhaps the most famous solution technique, has been extensively used in practice to solve square systems of nonlinear equations. The basic idea is to construct a local approximation of the nonlinear equations around a given point, x^k, solve the approximation to find the Newton point, x^N, update the iterate, $x^{k+1} = x^N$, and repeat until we find a solution to the nonlinear system. This method works extremely well close to a solution, but can fail to make progress when started far from a solution. To guarantee progress is made, a line search between x^k and x^N is used to enforce sufficient decrease on an appropriately defined merit function. Typically, $\frac{1}{2}\|F(x)\|^2$ is used.

PATH uses a generalization of this method on a nonsmooth reformulation of the complementarity problem. To construct the Newton direction, we use the normal map [151] representation

$$F(\pi(x)) + x - \pi(x)$$

associated with the MCP, where $\pi(x)$ represents the projection of x onto $[\ell, u]$ in the Euclidean norm. We note that if x is a zero of the normal map, then $\pi(x)$ solves the MCP. At each iteration, a linearization of the normal map, a linear complementarity problem, is solved using a pivotal code related to Lemke's method.

Versions of PATH prior to 4.x are based entirely on this formulation using the residual of the normal map

$$\|F(\pi(x)) + x - \pi(x)\|$$

as a merit function. However, the residual of the normal map is not differentiable, meaning that if a subproblem is not solvable then a "steepest descent" step on this function cannot be taken. PATH 4.x considers an alternative nonsmooth system [63] , $\Phi(x) = 0$, where $\Phi_i(x) = \phi(x_i, F_i(x))$ and $\phi(a, b) := \sqrt{a^2 + b^2} - a - b$. The merit function, $\|\Phi(x)\|^2$, in this case is differentiable, and is used for globalization purposes. When the subproblem solver fails, a projected gradient direction for this merit function is searched. It is shown in [61] that this provides descent and a new feasible point to continue PATH, and convergence to stationary points and/or solutions of the MCP is provided under appropriate conditions.

The remainder of this chapter details the interpretation of output from PATH and ways to modify the behavior of the code. To this end, we will assume that the modeler has created a file named `transmcp.gms` which defines an MCP model `transport` as described in Section Transportation Problem and is using PATH 4.x to solve it. See Section Solution for information on changing the solver.

5.31.2.1 Log File

We will now describe the behavior of the PATH algorithm in terms of the output typically produced. An example of the log for a particular run is given in Figure 6 and Figure 7.

The first few lines on this log file are printed by GAMS during its compilation and generation phases. The model is then passed off to PATH at the stage where the "Executing PATH" line is written out. After some basic memory allocation and problem checking, the PATH solver checks if the modeler required an option file to be read. In the example this is not the case. If PATH is directed to read an option file (see PATH Options below), then the following output is generated after the PATH banner.

```
Reading options file PATH.OPT
 > output_linear_model yes;
Options: Read: Line 2 invalid: hi_there;
Read of options file complete.
```

If the option reader encounters an invalid option (as above), it reports this but carries on executing the algorithm. Following this, the algorithm starts working on the problem.

Diagnostic Information

Some diagnostic information is initially generated by the solver at the starting point. Included is information about the initial point and function evaluation. The log file here tells the value of the largest element of the starting point and the variable where it occurs. Similarly, the maximum function value is displayed along with the row producing it. The maximum element in the gradient is also presented with the equation and variable where it is located.

The second block provides more information about the Jacobian at the starting point. This information can be used to help scale the model. See Section Advanced Topics for complete details.

Crash Log

The first phase of the code is a crash procedure attempting to quickly determine which of the inequalities should be active. This procedure is documented fully in [47] , and an example of the Crash Log can be seen in Figure 6. The first column of the crash log is just a label indicating the current iteration number,

the second gives an indication of how many function evaluations have been performed so far. Note that precisely one Jacobian (gradient) evaluation is performed per crash iteration. The number of changes to the active set between iterations of the crash procedure is shown under the "diff" column. The crash procedure terminates if this becomes small. Each iteration of this procedure involves a factorization of a matrix whose size is shown in the next column. The residual is a measure of how far the current iterate is from satisfying the complementarity conditions (MCP); it is zero at a solution. See Merit Functions for further information. The column "step" corresponds to the steplength taken in this iteration - ideally this should be 1. If the factorization fails, then the matrix is perturbed by an identity matrix scaled by the value indicated in the "prox" column. The "label" column indicates which row in the model is furthest away from satisfying the conditions (MCP). Typically, relatively few crash iterations are performed. Section PATH Options gives mechanisms to affect the behavior of these steps.

Major Iteration Log

After the crash is completed, the main algorithm starts as indicated by the "Major Iteration Log" flag (see Figure 7). The columns that have the same labels as in the crash log have precisely the same meaning described above. However, there are some new columns that we now explain. Each major iteration attempts to solve a linear mixed complementarity problem using a pivotal method that is a generalization of Lemke's method [117] . The number of pivots performed `per` major iteration is given in the "minor" column.

The "grad" column gives the cumulative number of Jacobian evaluations used; typically one evaluation is performed per iteration. The "inorm" column gives the value of the error in satisfying the equation indicated in the "label" column.

At each iteration of the algorithm, several different step types can be taken, due to the use of nonmonotone searches [46] , [56] which are used to improve robustness. In order to help the PATH user, we have added two code letters indicating the return code from the linear solver and the step type to the log file. Table 3 explains the return codes for the linear solver and Table 4 explains the meaning of each step type. The ideal output in this column is "SO"; "SD" and "SB" also indicate reasonable progress. Codes different from these are not catastrophic, but typically indicate the solver is having difficulties due to numerical issues or nonconvexities in the model.

Table 3: Linear Solver Codes

Code	Meaning
C	A cycle was detected.
E	An error occurred in the linear solve.
I	The minor iteration limit was reached.
N	The basis became singular.
R	An unbounded ray was encountered.
S	The linear subproblem was solved.
T	Failed to remain within tolerance after factorization was performed.

Table 4: Step Type Codes

Code	Meaning
B	A Backtracking search was performed from the current iterate to the Newton point in order to obtain sufficient decrease in the merit function.
D	The step was accepted because the Distance between the current iterate and the Newton point was small.
G	A gradient step was performed.
I	Initial information concerning the problem is displayed.

Code	Meaning
M	The step was accepted because the Merit function value is smaller than the nonmonotone reference value.
O	A step that satisfies both the distance and merit function tests.
R	A Restart was carried out.
W	A Watchdog step was performed in which we returned to the last point encountered with a better merit function value than the nonmonotone reference value (M, O, or B step), regenerated the Newton point, andperformed a backtracking search.

Minor Iteration Log

If more than 500 pivots are performed, a minor log is output that gives more details of the status of these pivots. A listing from `transmcp` model follows, where we have set the `output_minor_iteration_frequency` option to 1.

```
Minor Iteration Log
minor      t          z     w     v   art ckpts  enter    leave
    1  4.2538e-01     8     2     0     0     0 t[    0] z[   11]
    2  9.0823e-01     8     2     0     0     0 w[   11] w[   10]
    3  1.0000e+00     9     2     0     0     0 z[   10] t[    0]
```

`t` is a parameter that goes from zero to 1 for normal starts in the pivotal code. When the parameter reaches 1, we are at a solution to the subproblem. The `t` column gives the current value for this parameter. The next columns report the current number of problem variables z and slacks corresponding to variables at lower bound w and at upper bound v. Artificial variables are also noted in the minor log, see [57] for further details. Checkpoints are times where the basis matrix is refactorized. The number of checkpoints is indicated in the `ckpts` column. Finally, the minor iteration log displays the entering and leaving variables during the pivot sequence.

Restart Log

The PATH code attempts to fully utilize the resources provided by the modeler to solve the problem. Versions of PATH after 3.0 have been much more aggressive in determining that a stationary point of the residual function has been encountered. When it is determined that no progress is being made, the problem is restarted from the initial point supplied in the GAMS file with a different set of options. These restarts give the flexibility to change the algorithm in the hopes that the modified algorithm leads to a solution. The ordering and nature of the restarts were determined by empirical evidence based upon tests performed on real-world problems.

The exact options set during the restart are given in the restart log, part of which is reproduced below.

```
Restart Log
proximal_perturbation 0
crash_method none
crash_perturb yes
nms_initial_reference_factor 2
proximal_perturbation 1.0000e-01
```

If a particular problem solves under a restart, a modeler can circumvent the wasted computation by setting the appropriate options as shown in the log. Note that sometimes an option is repeated in this log. In this case, it is the last option that is used.

Solution Log

A solution report is now given by the algorithm for the point returned. The first component is an evaluation of several different merit functions. Next, a display of some statistics concerning the final point is given. This report can be used detect problems with the model and solution as detailed in Section Advanced Topics .

At the end of the log file, summary information regarding the algorithm's performance is given. The string "** EXIT - solution found". is an indication that PATH solved the problem. Any other EXIT string indicates a termination at a point that may not be a solution. These strings give an indication of what `modelStat` and `solveStat` will be returned to GAMS. After this, the "Restarting execution" flag indicates that GAMS has been restarted and is processing the results passed back by PATH.

5.31.2.2 Status File

If for some reason the PATH solver exits without writing a solution, or the `sysout` flag is turned on, the status file generated by the PATH solver will be reported in the listing file. The status file is similar to the log file, but provides more detailed information. The modeler is typically not interested in this output.

5.31.2.3 User Interrupts

A user interrupt can be effected by typing Ctrl-C. We only check for interrupts every major iteration. If a more immediate response is wanted, repeatedly typing Ctrl-C will eventually kill the job. The number needed is controlled by the `interrupt_limit` option. In this latter case, when a kill is performed, no solution is written and an execution error will be generated in GAMS.

5.31.2.4 Preprocessing

The purpose of a preprocessor is to reduce the size and complexity of a model to achieve improved performance by the main algorithm. Another benefit of the analysis performed is the detection of some provably unsolvable problems. A comprehensive preprocessor has been incorporated into PATH as developed in [58] .

The preprocessor reports its finding with some additional output to the log file. This output occurs before the initial point statistics. An example of the preprocessing on the `forcebsm` model is presented below.

```
Zero:     0 Single:   112 Double:     0 Forced:     0
Preprocessed size: 72
```

The preprocessor looks for special polyhedral structure and eliminates variables using this structure. These are indicated with the above line of text. Other special structure is also detected and reported.

On exit from the algorithm, we must generate a solution for the original problem. This is done during the postsolve. Following the postsolve, the residual using the original model is reported.

```
Postsolved residual: 1.0518e-10
```

This number should be approximately the same as the final residual reported on the presolved model.

Constrained Nonlinear System

Modelers typically add bounds to their variables when attempting to solve nonlinear problems in order to restrict the domain of interest. For example, many square nonlinear systems are formulated as

$$F(z) = 0,\ \ell \leq z \leq u,$$

where typically, the bounds on z are inactive at the solution. This is *not* an MCP, but is an example of a "constrained nonlinear system" (CNS). It is important to note the distinction between MCP and CNS. The MCP uses the bounds to infer relationships on the function F. If a finite bound is active at a solution, the corresponding component of F is only constrained to be nonnegative or nonpositive in the MCP, whereas in CNS it must be zero. Thus there may be many solutions of MCP that do not satisfy $F(z) = 0$. Only if z^* is a solution of MCP with $\ell < z^* < u$ is it guaranteed that $F(z^*) = 0$.

Internally, PATH reformulates a constrained nonlinear system of equations to an equivalent complementarity problem. The reformulation adds variables, y, with the resulting problem written as:

$$\begin{array}{rcl} \ell \leq x \leq u & \perp & -y \\ y \text{ free} & \perp & F(x). \end{array}$$

This is the MCP model passed on to the PATH solver.

5.31.3 PATH Options

The default options of PATH should be sufficient for most models. If desired, PATH-specific options can be specified by using a solver option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

We give a list of the available PATH options along with their defaults and meaning below. Note that only the first three characters of every word are significant.

5.31.3.1 General options

Option	Description	Default
chen_lambda	lambda parameter for Chen-Chen-Kanzow residual Range: [0, 1]	0.8
convergence_tolerance	stopping criterion When the residual error is within this tolerance, convergence is declared.	1e-6
crash_iteration_limit	maximum iterations allowed in basis crash	50
crash_merit_function	merit function used in crash method normal: Use the normal map fischer: Use the Fischer function	fischer
crash_method	pnewton or none pnewton: Use projected Newton method none	pnewton
crash_minimum_dimension	minimum problem dimension to perform crash	1
crash_nbchange_limit	limit on crash iterations without basis change The basis crashing procedure is stopped if this many successive stagnant iterations occur.	1
crash_perturb	perturb the problem using pnewton crash	1

Option	Description	Default
crash_searchtype	search type to use in the crash method `line`: Use a linesearch `arc`: Use an arcsearch	`line`
cumulative_iteration_limit	maximum minor iterations allowed	`GAMS iterlim`
factorization_library_name	name of factorization library	

factorization_method	basis package to use
	`lusol`
	`blu_lusol`
	`umfpack`
		`lusol`

gradient_searchtype	search type to use on a gradient step `line`: Use a linesearch `arc`: Use an arcsearch	`arc`
gradient_step_limit	gradient steps allowed before restarting	5
interrupt_limit	ctrl-C's required before a hard kill of the solver Range: {1, ..., ∞}	5
major_iteration_limit	maximum major iterations allowed	500
merit_function	merit function to use (normal or fischer) `normal`: Use the normal map `fischer`: Use the Fischer function	`fischer`
minor_iteration_limit	minor iterations allowed in each major iteration: default MIN(2n,iterlim)	`auto`
nms	allow line searching, watch-dogging, and nonmonotone descent	1
nms_initial_reference_factor	controls size of initial reference value	20
nms_maximum_watchdogs	maximum number of watchdog steps allowed	5
nms_memory_size	number of reference values kept	10
nms_mstep_frequency	frequency at which m-steps are performed	10
nms_searchtype	search type to use `line`: Use a linesearch `arc`: Use an arcsearch	`line`
option_file	name of option file for PATHLIB to read If specified, the PATH optimizer will read this file using its internal reader, after the usual options processing is done.	`none`
preprocess	turns preprocessing on/off	1
proximal_perturbation	initial perturbation	0
time_limit	number of seconds algorithm is allowed to run	`GAMS reslim`
lemke_rank_deficiency_iterations	number of attempts made to fix rank-deficient basis during Lemke start	10
lemke_start	frequency of lemke starts `always`: Use a Lemke start for each LCP subproblem `automatic`: Determined by algorithm `first`: Use a Lemke start for the first LCP subproblem	`automatic`

Option	Description	Default
lemke_start_type	type of lemke start `advanced`: Start Lemke method using an advanced basis `slack`: Start Lemke method using an all-slack basis	`slack`

5.31.3.2 Output options

Option	Description	Default
output_crash_iterations	output information on crash iterations	1
output_crash_iterations_frequency	frequency at which crash iteration log is printed Range: {1, ..., ∞}	1
output_errors	output error messages	1
output_final_degeneracy_statistics	print information regarding degeneracy at the solution	0
output_final_point	output final point returned from PATH	0
output_final_point_statistics	output information about the point, function, and Jacobian at the final point	1
output_final_scaling_statistics	display matrix norms on the Jacobian at the final point	0
output_final_statistics	output evaluation of available merit functions at the final point	1
output_final_summary	output summary information	1
output_initial_point	output initial point given to PATH	0
output_initial_point_statistics	output information about the point, function, and Jacobian at the initial point	1
output_initial_scaling_statistics	display matrix norms on the Jacobian at the initial point	1
output_initial_statistics	output evaluation of available merit functions at the initial point	0
output_linear_model	output linear model at each major iteration	0
output_major_iterations	output information on major iterations	1
output_major_iterations_frequency	frequency at which major iteration log is printed Range: {1, ..., ∞}	1
output_maximum_zero_listing	limits zero columns reported to listing file	1000
output_maximum_zero_log	limits zero columns reported to log file	10
output_minor_iterations	output information on minor iterations	1
output_minor_iterations_frequency	frequency at which minor iteration log is printed Range: {1, ..., ∞}	500
output_options	output all options and their values	0
output	turns all output off or on If output is first turned off, selected parts can be turned back on using specific output options.	1
output_preprocess_level	control output of preprocessing information Range: {-1, ..., ∞}	1

Option	Description	Default
output_restart_log	output options during restarts	1
output_time	output breakdown of where time is spent	0
output_warnings	output warning messages	0

GAMS controls the total number of pivots allowed via the `iterlim` option. If more pivots are needed for a particular model then either of the following lines should be added to the `transmcp.gms` file before the solve statement

```
option iterlim = 2000;
transport.iterlim = 2000;
```

Problems with a singular basis matrix can be overcome by using the `proximal_perturbation` option [26] , and linearly dependent columns can be output with the `output_factorization_singularities` option. For more information on singularities, we refer the reader to Section Advanced Topics.

As a special case, PATH can emulate Lemke's method [39] , [117] for LCP with the following options:

```
crash_method none
crash_perturb no
major_iteration_limit 1
lemke_start first
nms no
```

If instead, PATH is to imitate the Successive Linear Complementarity method (SLCP, often called the Josephy Newton method) [101] , [132] , [131] for MCP with an Armijo style linesearch on the normal map residual, then the options to use are:

```
crash_method none
crash_perturb no
lemke_start always
nms_initial_reference_factor 1
nms_memory size 1
nms_mstep_frequency 1
nms_searchtype line
merit_function normal
```

Note that `nms_memory_size 1` and `nms_initial_reference_factor` 1 turn off the nonmonotone linesearch, while `nms_mstep_frequency` 1 turns off watchdogging [35] . `nms_searchtype line` forces PATH to search the line segment between the initial point and the solution to the linear model, while `merit_function normal` tell PATH to use the normal map for calculating the residual.

5.31.4 Advanced Topics

This chapter discusses some of the difficulties encountered when dealing with complementarity problems. We start off with a very formal definition of a complementarity problem (similar to the one given previously) which is used in later sections on merit functions and ill-defined, poorly-scaled, and singular models.

5.31.4.1 Formal Definition of MCP

The mixed complementarity problem is defined by a function, $F : D \to \mathbf{R}^n$ where $D \subseteq \mathbf{R}^n$ is the domain of F, and possibly infinite lower and upper bounds, ℓ and u. Let $C := \{x \in \mathbf{R}^n \mid \ell \leq x \leq u\}$, a Cartesian product of closed (possibly infinite) intervals. The problem is given as

$$MCP : \text{find } x \in C \cap D \text{ s.t. } \langle F(x), y - x\rangle \geq 0, \ \forall y \in C.$$

This formulation is a special case of the variational inequality problem defined by F and a (nonempty, closed, convex) set C. Special choices of ℓ and u lead to the familiar cases of a system of nonlinear equations

$$F(x) = 0$$

(generated by $\ell \equiv -\infty$, $u \equiv +\infty$) and the nonlinear complementarity problem

$$0 \leq x \ \perp \ F(x) \geq 0$$

(generated using $\ell \equiv 0$, $u \equiv +\infty$).

5.31.4.2 Algorithmic Features

We now describe some of the features of the PATH algorithm and the options affecting each.

Merit Functions

A solver for complementarity problems typically employs a merit function to indicate the closeness of the current iterate to the solution set. The merit function is zero at a solution to the original problem and strictly positive otherwise. Numerically, an algorithm terminates when the merit function is approximately equal to zero, thus possibly introducing spurious "solutions".

The modeler needs to be able to determine with some reasonable degree of accuracy whether the algorithm terminated at solution or if it simply obtained a point satisfying the desired tolerances that is not close to the solution set. For complementarity problems, we can provide several indicators with different characteristics to help make such a determination. If one of the indicators is not close to zero, then there is some evidence that the algorithm has not found a solution. We note that if all of the indicators are close to zero, we are reasonably sure we have found a solution. However, the modeler has the final responsibility to evaluate the "solution" and check that it makes sense for their application.

For the NCP, a standard merit function is

$$\|(-x)_+, (-F(x))_+, [(x_i)_+(F_i(x))_+]_i\|$$

with the first two terms measuring the infeasibility of the current point and the last term indicating the complementarity error. In this expression, we use $(\cdot)_+$ to represent the Euclidean projection of x onto the nonnegative orthant, that is $(x)_+ = \max(x, 0)$. For the more general MCP, we can define a similar function:

$$\left\| x - \pi(x), \left[\left(\frac{x_i - \ell_i}{\|\ell_i\| + 1} \right)_+ (F_i(x))_+ \right]_i, \left[\left(\frac{u_i - x_i}{\|u_i\| + 1} \right)_+ (-F_i(x))_+ \right]_i \right\|$$

where $\pi(x)$ represents the Euclidean projection of x onto C. We can see that if we have an NCP, the function is exactly the one previously given and for nonlinear systems of equations, this becomes $\|F(x)\|$.

There are several reformulations of the MCP as a system of nonlinear (nonsmooth) equations for which the corresponding residual is a natural merit function. Some of these are as follows:

- Generalized Minimum Map: $x - \pi(x - F(x))$
- Normal Map: $F(\pi(y)) + y - \pi(y)$
- Fischer Function: $\Phi(x)$, where $\Phi_i(x) := \phi(x_i, F_i(x))$ with

$$\phi(a, b) := \sqrt{a^2 + b^2} - a - b.$$

  Note that $\phi(a, b) = 0$ if and only if $0 \leq a \perp b \geq 0$. A straightforward extension of Φ to the MCP format is given for example in [61] .

In the context of nonlinear complementarity problems the generalized minimum map corresponds to the classic minimum map $\min(x, F(x))$. Furthermore, for NCPs the minimum map and the Fischer function are both local error bounds and were shown to be equivalent in [185] . Figure 10 in the subsequent section plots all of these merit functions for the ill-defined example discussed therein and highlights the differences between them.

The squared norm of Φ, namely $\Psi(x) := \frac{1}{2}\sum \phi(x_i, F_i)^2$, is continuously differentiable on $\mathbf{R}^n$ provided F itself is. Therefore, the first order optimality conditions for the unconstrained minimization of $\Psi(x)$, namely $\nabla\Psi(x) = 0$ give another indication as to whether the point under consideration is a solution of MCP.

The merit functions and the information PATH provides at the solution can be useful for diagnostic purposes. By default, PATH 4.x returns the best point with respect to the merit function because this iterate likely provides better information to the modeler. As detailed in Section PATH Options, the default merit function in PATH 4.x is the Fischer function. To change this behavior the `merit_function` option can be used.

Crashing Method

The crashing technique [47] is used to quickly identify an active set from the user-supplied starting point. At this time, a proximal perturbation scheme [24] , [25] is used to overcome problems with a singular basis matrix. The proximal perturbation is introduced in the crash method, when the matrix factored is determined to be singular. The value of the perturbation is based on the current merit function value.

Even if the crash method is turned off, for example via the option `crash_method none`, perturbation can be added. This is determined by factoring the matrix that crash would have initially formed. This behavior is extremely useful for introducing a perturbation for singular models. It can be turned off by issuing the option `crash_perturb no`.

Nonmontone Searches

The first line of defense against convergence to stationary points is the use of a nonmonotone linesearch [90] , [91] , [56] . In this case we define a reference value, R^k, and we use this value to test for sufficient decrease:

$$\Psi(x^k + t_k d^k) \leq \mathbf{R}^k + t_k \nabla\Psi(x^k)^T d^k.$$

Depending upon the choice of the reference value, this allows the merit function to increase from one iteration to the next. This strategy can not only improve convergence, but can also avoid local minimizers by allowing such increases.

We now need to detail our choice of the reference value. We begin by letting $\{M_1, \ldots, M_m\}$ be a finite set of values initialized to $\kappa\Psi(x^0)$, where κ is used to determine the initial set of acceptable merit function values. The value of κ defaults to 1 in the code and can be modified with the `nms_initial_reference_factor` option; $\kappa = 1$ indicates that we are not going to allow the merit function to increase beyond its initial value.

Having defined the values of $\{M_1, \ldots, M_m\}$ (where the code by default uses $m = 10$), we can now calculate a reference value. We must be careful when we allow gradient steps in the code. Assuming that d^k is the Newton direction, we define $i_0 = \text{argmax } M_i$ and $R^k = M_{i_0}$. After the nonmonotone linesearch rule above finds t_k, we update the memory so that $M_{i_0} = \Psi(x^k + t_k d^k)$, i.e. we remove an element from the memory having the largest merit function value.

When we decide to use a gradient step, it is beneficial to let $x^k = x^{\text{best}}$ where x^{best} is the point with the absolute best merit function value encountered so far. We then recalculate $d^k = -\nabla\Psi(x^k)$ using the best point and let $R^k = \Psi(x^k)$. That is to say that we force decrease from the best iterate found whenever a gradient step is performed. After a successful step we set $M_i = \Psi(x^k + t_k d^k)$ for all $i \in [1, \ldots, m]$. This prevents future iterates from returning to the same problem area.

A watchdog strategy [35] is also available for use in the code.The method employed allows steps to be accepted when they are "close" to the current iterate. Nonmonotonic decrease is enforced every m iterations, where m is set by the `nms_mstep_frequency` option.

Linear Complementarity Problems

PATH solves a linear complementarity problem at each major iteration. Let $M \in \Re^{n\times n}$, $q \in \Re^n$, and $B = [l, u]$ be given. $(\bar{z}, \bar{w}, \bar{v})$ solves the linear mixed complementarity problem defined by M, q, and B if and only if it satisfies the following constrained system of equations:

$$Mz - w + v + q = 0 \tag{4}$$

$$w^T(z - l) = 0 \tag{5}$$

$$v^T(u - z) = 0 \tag{6}$$

$$z \in B, w \in \Re^n_+, v \in \Re^n_+ \tag{7}$$

where $x + \infty = \infty$ for all $x \in \Re$ and $0 \cdot \infty = 0$ by convention. A triple, $(\hat{z}, \hat{w}, \hat{v})$, satisfying equations (4) - (6) is called a complementary triple.

The objective of the linear model solver is to construct a path from a given complementary triple $(\hat{z}, \hat{w}, \hat{v})$ to a solution $(\bar{z}, \bar{w}, \bar{v})$. The algorithm used to solve the linear problem is identical to that given in [44] ; however, artificial variables are incorporated into the model. The augmented system is then:

$$Mz - w + v + Da + \frac{(1-t)}{s}(sr) + q = 0 \tag{8}$$

$$w^T(z - l) = 0 \tag{9}$$

$$v^T(u - z) = 0 \tag{10}$$

$$z \in B, w \in \Re^n_+, v \in \Re^n_+, a \equiv 0, t \in [0, 1] \tag{11}$$

where r is the residual, t is the path parameter, and a is a vector of artificial variables. The residual is scaled by s to improve numerical stability.

The addition of artificial variables enables us to construct an initial invertible basis consistent with the given starting point even under rank deficiency. The procedure consists of two parts: constructing an initial guess as to the basis and then recovering from rank deficiency to obtain an invertible basis. The crash technique gives a good approximation to the active set. The first phase of the algorithm uses this information to construct a basis by partitioning the variables into three sets:

1. $W = \{i \in \{1, \ldots, n\} \mid \hat{z}_i = l_i \text{ and } \hat{w}_i > 0\}$
2. $V = \{i \in \{1, \ldots, n\} \mid \hat{z}_i = u_i \text{ and } \hat{v}_i > 0\}$
3. $Z = \{1, \ldots, n\} \setminus W \cup V$

Since $(\hat{z}, \hat{w}, \hat{v})$ is a complementary triple, $Z \cap W \cap V = \emptyset$ and $Z \cup W \cup V = \{1, \ldots, n\}$. Using the above guess, we can recover an invertible basis consistent with the starting point by defining D appropriately. The technique relies upon the factorization to indicate the linearly dependent rows and columns of the basis matrix. Some of the variables may be nonbasic, but not at their bounds. For such variables, the corresponding artificial will be basic.

We use a modified version of EXPAND [83] to perform the ratio test. Variables are prioritized as follows:

1. t leaving at its upper bound.
2. Any artificial variable.
3. Any z, w, or v variable.

If a choice as to the leaving variable can be made while maintaining numerical stability and sparsity, we choose the variable with the highest priority (lowest number above).

When an artificial variable leaves the basis and a z-type variable enters, we have the choice of either increasing or decreasing that entering variable because it is nonbasic but not at a bound. The determination is made such that t increases and stability is preserved.

If the code is forced to use a ray start at each iteration (`lemke_start always`), then the code carries out Lemke's method, which is known [39] not to cycle. However,by default, we use a regular start to guarantee that the generated path emanates from the current iterate. Under appropriate conditions, this guarantees a decrease in the nonlinear residual. However, it is then possible for the pivot sequence in the linear model to cycle. To prevent this undesirable outcome, we attempt to detect the formation of a cycle with the heuristic that if a variable enters the basis more that a given number of times, we are cycling. The number of times the variable has entered is reset whenever t increases beyond its previous maximum or an artificial variable leaves the basis. If cycling is detected, we terminate the linear solver at the largest value of t and return this point.

Another heuristic is added when the linear code terminates on a ray. The returned point in this case is not the base of the ray. We move a slight distance up the ray and return this new point. If we fail to solve the linear subproblem five times in a row, a Lemke ray start will be performed in an attempt to solve the linear subproblem. Computational experience has shown this to be an effective heuristic and generally results in solving the linear model. Using a Lemke ray start is not the default mode, since typically many more pivots are required.

For times when a Lemke start is actually used in the code, an advanced ray can be used. We basically choose the "closest" extreme point of the polytope and choose a ray in the interior of the normal cone at this point. This helps to reduce the number of pivots required. However, this can fail when the basis corresponding to the cell is not invertible. We then revert to the Lemke start.

Since the EXPAND pivot rules are used, some of the variables may be nonbasic, but slightly infeasible, as the solution. Whenever the linear code finishes, the nonbasic variables are put at their bounds and the basic variables are recomputed using the current factorization. This procedure helps to find the best possible solution to the linear system.

The resulting linear solver as modified above is robust and has the desired property that we start from $(\hat{z}, \hat{w}, \hat{v})$ and construct a path to a solution.

Other Features

Some other heuristics are incorporated into the code. During the first iteration, if the linear solver fails to find a Newton point, a Lemke start is used. Furthermore, under repeated failures during the linear solve, a Lemke start will be attempted. A gradient step can also be used when we fail repeatedly.

The proximal perturbation is reduced at each major iteration. However, when numerical difficulties are encountered, it will be increased to a fraction of the current merit function value. These are determined when the linear solver returns a Reset or Singular status.

Spacer steps are taken every major iteration, in which the iterate is chosen to be the best point for the normal map. The corresponding basis passed into the Lemke code is also updated.

Scaling is done based on the diagonal of the matrix passed into the linear solver.

We finally note, that if the merit function fails to show sufficient decrease over the last 100 iterates, a restart will be performed, as this indicates we are close to a stationary point.

5.31.4.3 Difficult Models

Ill-Defined Models

A problem can be ill-defined for several different reasons. We concentrate on the following particular cases. We will call F well-defined at $\bar{x} \in C$ if $\bar{x} \in D$ and ill-defined at $\bar{x}$ otherwise. Furthermore, we define F to be well-defined near $\bar{x} \in C$ if there exists an open neighborhood of $\bar{x}$, $\mathcal{N}(\bar{x})$, such that $C \cap \mathcal{N}(\bar{x}) \subseteq D$. By saying the function is well-defined near $\bar{x}$, we are simply stating that F is defined for all $x \in C$ sufficiently close to $\bar{x}$. A function not well-defined near $\bar{x}$ is termed ill-defined near $\bar{x}$.

We will say that F has a well-defined Jacobian at $\bar{x} \in C$ if there exists an open neighborhood of $\bar{x}$, $\mathcal{N}(\bar{x})$, such that $\mathcal{N}(\bar{x}) \subseteq D$ and F is continuously differentiable on $\mathcal{N}(\bar{x})$. Otherwise the function has an ill-defined Jacobian at $\bar{x}$. We note that a well-defined Jacobian at $\bar{x}$ implies that the MCP has a well-defined function near $\bar{x}$, but the converse is not true.

PATH uses both function and Jacobian information in its attempt to solve the MCP. Therefore, both of these definitions are relevant. We discuss cases where the function and Jacobian are ill-defined in the next two subsections. We illustrate uses for the merit function information and final point statistics within the context of these problems.

Function Undefined We begin with a one-dimensional problem for which F is ill-defined at $x = 0$ as follows:

$$0 \leq x \quad \perp \quad \tfrac{1}{x} \geq 0.$$

Here x must be strictly positive because $\frac{1}{x}$ is undefined at $x = 0$. This condition implies that $F(x)$ must be equal to zero. Since $F(x)$ is strictly positive for all x strictly positive, this problem has no solution.

We are able to perform this analysis because the dimension of the problem is small. Preprocessing linear problems can be done by the solver in an attempt to detect obviously inconsistent problems, reduce problem size, and identify active components at the solution. Similar processing can be done for nonlinear models, but the analysis becomes more difficult to perform. Currently, PATH only checks the consistency of the bounds and removes fixed variables and the corresponding complementary equations from the model.

A modeler would likely not know a priori that a problem has no solution and would thus attempt to formulate and solve it. GAMS code for the model above is provided in Figure 8. We must specify an initial value for x in the code. If we were to not provide one, GAMS would use $x = 0$ as the default value, notice that F is undefined at the initial point, and terminate before giving the problem to PATH. The error message indicates that the function $\frac{1}{x}$ is ill-defined at $x = 0$, but does not imply that the corresponding MCP problem has no solution.

Figure 8: GAMS Code for Ill-Defined Function

```
positive variable x;
equations F;

F.. 1 / x =g= 0;

model simple / F.x /;

x.l = 1e-6;

solve simple using mcp;
```

After setting the starting point, GAMS generates the model, and PATH proceeds to "solve" it. A portion of the output relating statistics about the solution is given in Figure 9 PATH uses the Fischer Function indicator as its termination criteria by default, but evaluates all of the merit functions given in Section Merit Functions at the final point. The Normal Map merit function, and to a lesser extent, the complementarity error, indicate that the "solution" found does not necessarily solve the MCP.

```

To indicate the difference between the merit functions, Figure 10 plots them all for this simple example. We note that as x approaches positive infinity, numerically, we are at a solution to the problem with respect to all of the merit functions except for the complementarity error, which remains equal to one. As x approaches zero, the merit functions diverge, also indicating that $x = 0$ is not a solution.

The natural residual and Fischer function tend toward 0 as $x \downarrow 0$. From these measures, we might think $x = 0$ is the solution. However, as previously remarked F is ill-defined at $x = 0$. F and ∇F become very large, indicating that the function (and Jacobian) might not be well-defined. We might be tempted to conclude that if one of the merit function indicators is not close to zero, then we have not found a solution. This conclusion is not always warranted. When one of the indicators is non-zero, we have reservations about the solution, but we cannot eliminate the possibility that we are actually close to a solution. If we slightly perturb the original problem to

$$0 \leq x \quad \perp \quad \tfrac{1}{x+\epsilon} \geq 0$$

for a fixed $\epsilon > 0$, the function is well-defined over $C = \mathbf{R}^n_+$ and has a unique solution at $x = 0$. In this case, by starting at $x > 0$ and sufficiently small, all of the merit functions, with the exception of the Normal Map, indicate that we have solved the problem as is shown by the output in Figure 11 for $\epsilon = 1 * 10^{-6}$ and $x = 1 * 10^{-20}$.

In this case, the Normal Map is quite large and we might think that the function and Jacobian are undefined. When only the normal map is non-zero, we may have just mis-identified the optimal basis. By setting the `merit_function normal` option, we can resolve the problem, identify the correct basis, and solve the problem with all indicators being close to zero. This example illustrates the point that all of these tests are not infallible. The modeler still needs to do some detective work to determine if they have found a solution or if the algorithm is converging to a point where the function is ill-defined.

Jacobian Undefined Since PATH uses a Newton-like method to solve the problem, it also needs the Jacobian of F to be well-defined. One model for which the function is well-defined over C, but for which the Jacobian is undefined at the solution is: $0 \leq x \perp -\sqrt{x} \geq 0$. This model has a unique solution at $x = 0$.

Using PATH and starting from the point $x = 1 * 10^{-14}$, PATH generates the output given in Figure 12 .

We can see that the gradient of the Fischer Function is nonzero and the Jacobian is beginning to become large. These conditions indicate that the Jacobian is undefined at the solution. It is therefore important for a modeler to inspect the given output to guard against such problems.

If we start from $x = 0$, PATH correctly informs us that we are at the solution. The large value reported for the Jacobian is an indication that the Jacobian is undefined.

Poorly Scaled Models

Well-defined problems can still have various numerical problems that impede the algorithm's convergence. One particular problem is a badly scaled Jacobian. In such cases, we can obtain a poor "Newton" direction because of numerical problems introduced in the linear algebra performed. This problem can also lead the code to a point from which it cannot recover.

The final model given to the solver should be scaled such that we avoid numerical difficulties in the linear algebra. The output provided by PATH can be used to iteratively refine the model so that we eventually end up with a well-scaled problem. We note that we only calculate our scaling statistics at the starting point provided. For nonlinear problems these statistics may not be indicative of the overall scaling of the model. Model specific knowledge is very important when we have a nonlinear problem because it can be used to appropriately scale the model to achieve a desired result.

We look at the `titan.gms` model in MCPLIB, that has some scaling problems. The relevant output from PATH for the original code is given in Figure 13.

Figure 13: PATH Output - Poorly Scaled Model

```
INITIAL POINT STATISTICS
Maximum of X. . . . . .  4.1279e+06 var: (w.29)
Maximum of F. . . . . .  2.2516e+00 eqn: (a1.33)
Maximum of Grad F . . . . . .  6.7753e+06 eqn: (a1.29)
                                          var: (x1.29)

INITIAL JACOBIAN NORM STATISTICS
Maximum Row Norm. . . . . .  9.4504e+06 eqn: (a2.29)
Minimum Row Norm. . . . . .  2.7680e-03 eqn: (g.10)
Maximum Column Norm . . . . . .  9.4504e+06 var: (x2.29)
Minimum Column Norm . . . . . .  1.3840e-03 var: (w.10)
```

The maximum row norm is defined as

$$\max_{1\le i\le n} \sum_{1\le j\le n} \mid (\nabla F(x))_{ij} \mid$$

and the minimum row norm is

$$\min_{1\le i\le n} \sum_{1\le j\le n} \mid (\nabla F(x))_{ij} \mid .$$

Similar definitions are used for the column norm. The norm numbers for this particular example are not extremely large, but we can nevertheless improve the scaling. We first decided to reduce the magnitude of the `a1` block of equations as indicated by PATH. Using the GAMS modeling language, we can scale particular equations and variables using the .scale attribute. To turn the scaling on for the model we use the .scaleopt model attribute. After scaling the `a1` block, we re-ran PATH and found an additional block of equations that also needed scaling, `a2`. We also scaled some of the variables, `g` and `w`. The code added to the model follows:

```
titan.scaleopt = 1;
a1.scale(i) = 1000;
a2.scale(i) = 1000;
g.scale(i) = 1/1000;
w.scale(i) = 100000;
```

By scaling these equation and variable blocks, we have improved the model scaling. The statistics for the manually scaled model are given in Figure 14.

Figure 14: PATH Output - Well-Scaled Model

```
INITIAL POINT STATISTICS

Minimum Column Norm . . . . . .  1.3840e-01 var: (w.10)
```

For this particular problem PATH cannot solve the unscaled model, while it can find a solution to the scaled model. Using the scaling features of the GAMS language and the information provided by PATH we are able to remove some of the problem's difficulty and obtain better performance from PATH.

It is possible to get even more information on initial point scaling by inspecting the GAMS listing file. The equation row listing gives the values of all the entries of the Jacobian at the starting point. The row norms generated by PATH give good pointers for starting to use the row listing.

Not all of the numerical problems are directly attributable to poorly scaled models. Problems for which the Jacobian of the active constraints is singular or nearly singular can also cause numerical difficulty as illustrated next.

Singular Models

Assuming that the problem is well-defined and properly scaled, we can still have a Jacobian for which the active constraints are singular or nearly singular (i.e. it is ill-conditioned). When problems are singular or nearly singular, we are also likely to have numerical problems. As a result the "Newton" direction obtained from the linear problem solver can be very bad. In PATH, we can use proximal perturbation or add artificial variables to attempt to remove the singularity problems from the model. However, it is most often beneficial for solver robustness to remove singularities if possible.

The easiest problems to detect are those for which the Jacobian has zero rows and columns. A simple problem for which we have zero rows and columns is:

$$-2 \leq x \leq 2 \quad \perp \quad -x^2 + 1.$$

Note that the Jacobian, $-2x$, is non-singular at all three solutions, but singular at the point $x = 0$. Output from PATH on this model starting at $x = 0$ is given in Figure 15.

Figure 15: PATH Output - Zero Rows and Columns

```

We display in the code the variables and equations for which the row/column in the Jacobian is close to zero. These situations are problematic and for nonlinear problems likely stem from the modeler providing an inappropriate starting point or fixing some variables resulting in some equations becoming constant. We note that the solver may perform well in the presence of zero rows and/or columns, but the modeler should make sure that these are what was intended.

Singularities in the model can also be detected by the linear solver. This in itself is a hard problem and prone to error. For matrices which are poorly scaled, we can incorrectly identify "linearly dependent" rows because of numerical problems. Setting `output_factorization_singularities yes` in an options file will inform the user which equations the linear solver thinks are linearly dependent. Typically, singularity does not cause a lot of problems and the algorithm can handle the situation appropriately. However, an excessive number of singularities are cause for concern. A further indication of possible singularities at the solution is a lack of quadratic convergence to the solution.

5.31.5 Case Study: Von Thunen Land Model

We now turn our attention towards using the diagnostic information provided by PATH to improve an actual model. The Von Thunen land model is a problem recognized in the mathematical programming literature for its computational difficulty. We attempt to understand more carefully the facets of the problem that make it difficult to solve. This will enable us to outline and identify these problems and furthermore to extend the model to a more realistic and computationally more tractable form.

5.31.5.1 Classical Model

The problem is cast in the Arrow-Debreu framework as an equilibrium problem.The basic model is a closed economy consisting of three economic agents, a landowner, a worker and a porter. There is a central market, around which concentric regions of land are located. Since the produced goods have to be delivered to the market, this is an example of a spatial price equilibrium. The key variables of the model are the prices of commodities, land, labour and transport. Given these prices, it is assumed that the agents demand certain amounts of the commodities, which are supplied so as to maximize profit in each sector. Walras' law is then a consequence of the assumed competitive paradigm, namely that supply will equal demand in the equilibrium state.

We now describe the problems that the consumers and the producers face. We first look at consumption and derive a demand function for each of the consumer agents in the economy. Each of these agents has a utility function, that they wish to maximize subject to their budgetary constraints. As is typical in such problems, the utility function is assumed to be Cobb-Douglas:

$$u_a(d) = \prod_c d_c^{\alpha_{c,a}}, \quad \alpha_{c,a} \geq 0, \sum_c \alpha_{c,a} = 1,$$

where the $\alpha_{c,a}$ are given parameters dependent only on the agent. For each agent a, the variables d_c represent quantities of the desired commodities c. In the Von Thunen model, the goods are wheat, rice, corn and barley. The agent's endowments determine their budgetary constraint as follows. Given current market prices, an agent's wealth is the value of the initial endowment of goods at those prices. The agent's problem is therefore

$$\max_d u_a(d) \text{ subject to } \langle p, d\rangle \leq \langle p, e_a\rangle, d \geq 0,$$

where e_a is the endowment bundle for agent a. A closed form solution, corresponding to demand from agent a for commodity c is thus

$$d_{c,a}(p) := \frac{\alpha_{c,a}\langle p, e_a\rangle}{p_c}.$$

Note that this assumes the prices of the commodities p_c are positive.

The supply side of the economy is similar. The worker earns a wage w_L for his labour input. The land is distributed around the market in rings with a rental rate w_r associated with each ring r of land. The area of land a_r in each ring is an increasing function of r. The model assumes that labour and land are substitutable via a constant elasticities of substitution (CES) function.

Consider the production $x_{c,r}$ of commodity c in region r. In order to maximize profit (or minimize costs), the labour y_L and land use y_r solve

$$\min w_L y_L + w_r y_r \text{ subject to } \phi_c y_L^{\beta_c} y_r^{1-\beta_c} \geq x_{c,r},\ y_L, y_r \geq 0, \tag{12}$$

where ϕ_c is a given cost function scale parameter, and $\beta_c \in [0, 1]$ is the share parameter. The technology constraint is precisely the CES function allowing a suitable mix of labour and land use. Again, a closed form solution can be calculated. For example, the demand for labour in order to produce $x_{c,r}$ of commodity c in region r is given by

$$x_{c,r} \frac{\beta_c \left(\frac{w_L}{\beta_c}\right)^{\beta_c} \left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}}{\phi_c w_L}.$$

Considering all such demands, this clearly assumes the prices of inputs w_L, w_r are positive. A key point to note is that input commodity (factor) demands to produce $x_{c,r}$ can be determined by first solving (12) for unit demand $x_{c,r} \equiv 1$ and then multiplying these factor demands by the actual amount desired. Let $\bar{y}_L$ and $\bar{y}_r$ denote the optimal solutions of (12) with $x_{c,r} \equiv 1$. Using this fact, the *unit* production cost $\gamma_{c,r}$ for commodity c in region r can be calculated as follows:

$$\begin{aligned}\gamma_{c,r} &= w_L\bar{y}_L + w_r\bar{y}_r \\ &= w_L\frac{\beta_c\left(\frac{w_L}{\beta_c}\right)^{\beta_c}\left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}}{\phi_c w_L} + w_r\frac{(1-\beta_c)\left(\frac{w_L}{\beta_c}\right)^{\beta_c}\left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}}{\phi_c w_r} \\ &= \frac{1}{\phi_c}\left(\frac{w_L}{\beta_c}\right)^{\beta_c}\left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c}.\end{aligned}$$

Transportation is provided by a porter, earning a wage w_p. If we denote the unit cost for transportation of commodity c by t_c, then unit transportation cost to market is

$$T_{c,r}(w_p) := t_c d_r w_p,$$

where d_r is the distance of region r to the market. Spatial price equilibrium arises from the consideration:

$$0 \le x_{c,r} \perp \gamma_{c,r}(w_L, w_r) + T_{c,r}(w_p) \ge p_c.$$

This is intuitively clear; it states that commodity c will be produced in region r only if the combined cost of production and transportation equals the market price.

The above derivations assumed that the producers and consumers acted as price takers. Walras' law is now invoked to determine the prices so that markets clear. The resulting complementarity problem is:

$$\gamma_{c,r} = \frac{1}{\phi_c}\left(\frac{w_L}{\beta_c}\right)^{\beta_c}\left(\frac{w_r}{1-\beta_c}\right)^{1-\beta_c} \tag{13}$$

$$0 \le x_{c,r} \perp \gamma_{c,r} + T_{c,r}(w_p) \ge p_c \tag{14}$$

$$0 \le w_L \perp e_L \ge \sum_{r,c} x_{c,r}\frac{\beta_c\gamma_{c,r}}{w_L} \tag{15}$$

$$0 \le w_r \perp a_r \ge \sum_{c} \frac{x_{c,r}(1-\beta_c)\gamma_{c,r}}{w_r} \tag{16}$$

$$0 \le w_p \perp e_P \ge \sum_{r,c} t_c d_r x_{c,r} \tag{17}$$

$$0 \le p_c \perp \sum_r x_{c,r} \ge \frac{\alpha_{c,P}e_P w_p + \alpha_{c,L}e_L w_L + \alpha_{c,O}\sum_r w_r a_r}{p_c} \tag{18}$$

Note that in (15), (16) and (17), the amounts of labour, land and transport are bounded from above, and hence the prices on these inputs are determined as multipliers (or shadow prices) on the corresponding constraints. The final relationship (18) in the above complementarity problem corresponds to market clearance; prices are nonnegative and can only be positive if supply equals demand. (Some modelers multiply the last inequality throughout by p_c. This removes problems where p_c becomes zero, but can also introduce spurious solutions.)

The Arrow-Debreu theory guarantees that the problem is homogeneous in prices; $(x, \lambda w, \lambda p)$ is also a solution whenever (x, w, p) solves the above. Typically this singularity in the model is removed by fixing a numeraire, that is fixing a price (for example $w_L = 1$) and dropping the corresponding complementary relationship.

Unfortunately, in this formulation even after fixing a numeraire, some of the variables p and w may go to zero, resulting in an ill-defined problem. In the case of the Von Thunen land model, the rental price of land w_r decreases as the distance to market increases, and for remote rings of land, it becomes zero. A standard modeling fix is to put artificial lower bounds on these variables. Even with this fix, the problem typically remains very hard to solve. More importantly, the homogeneity property of the prices used above to fix a numeraire no longer holds, and the corresponding complementary relationship (which was dropped from the problem) may fail to be satisfied. It therefore matters which numeriare is fixed, and many modelers run into difficulty since in many cases the solution found by a solver is invalid for the originally posed model.

In order to test our diagnostic information, we implemented a version of the above model in GAMS. The model corresponds closely to the MCPLIB model pgvon105.gms except we added more regions to make the problem even more difficult. The model file has been documented more fully, and the data rounded to improve clarity.

Our first trial was to solve the model without fixing a numeraire. In this case, PATH 4.x failed to find a solution. At the starting point, the indicators described in Sectiion Ill-Defined Models are reasonable, and there are no zero rows/columns in the Jacobian. At the best point found, all indicators are still reasonable. However, the listing file indicates a large number of division by zero problems occurring in (16). We also note that a nonzero proximal perturbation is used in the first iteration of the crash method. This is an indication of singularities. We therefore added an option to output factorization singularities, and singularities appeared in the first iteration. At this point, we decided to fix a numeraire to see if this alleviated the problem.

We chose to fix the labour wage rate to 1. After increasing the iterations allowed to 100,000, PATH 4.x solved the problem. The statistics at the solution are cause for concern. In particular, the gradient of the Fischer function is 7 orders of magnitude larger than all the other residuals. Furthermore, the Jacobian is very large at the solution point. Looking further in the listing file, a large number of division by zero problems occur in (16).

To track down the problem further, we added an artificial lower bound on the variables w_r of 10^{-5}, that would not be active at the aforementioned solution. Resolving gave the same "solution", but resulted in the domain errors disappearing.

Although the problem is solved, there is concern on two fronts. Firstly, the gradient of the Fischer function should go to zero at the solution. Secondly, if a modeler happens to make the artificial lower bounds on the variables a bit larger, then they become active at the solution, and hence the constraint that has been dropped by fixing the price of labour at 1 is violated at this point. Of course, the algorithm is unable to detect this problem, since it is not part of the model that is passed to it, and the corresponding output looks satisfactory.

We are therefore led to the conclusion that the model as postulated is ill-defined. The remainder of this section outlines two possible modeling techniques to overcome the difficulties with ill-defined problems of this type.

5.31.5.2 Intervention Pricing

The principal difficulty is the fact that the rental prices on land go to zero as proximity to the market decreases, and become zero for sufficiently remote rings. Such a property is unlikely to hold in a practical setting. Typically, a landowner has a minimum rental price (for example, land in fallow increases in value). As outlined above, a fixed lower bound on the rental price violates the well-established homogeneity property. A suggestion postulated by Professor Thomas Rutherford is to allow the landowner to intervene and "purchase-back" his land whenever the rental cost gets smaller than a certain fraction of the labour wage.

The new model adds a (homogeneous in price) constraint

$$0 \leq i_r \quad \perp \quad w_r \geq 0.0001 * w_L$$

and modifies (16) and (18) as follows:

$$0 \leq w_r \perp a_r - i_r \geq \sum_c \frac{x_{c,r}(1-\beta_c)\gamma_{c,r}}{w_r}$$

$$0 \leq p_c \perp \sum_r x_{c,r} \geq \frac{\alpha_{c,P} e_P w_p + \alpha_{c,L} e_L w_L + \alpha_{c,O} \sum_r w_r(a_r - i_r)}{p_c}. \tag{19}$$

Given the intervention purchase, we can now add a lower bound on w_r to avoid division by zero errors. In our model we chose 10^{-5} since this will never be active at the solution and therefore will not affect the positive homogeneity. After this reformulation, PATH 4.x solves the problem. Furthermore, the gradient of the Fischer function, although slightly larger than the other residuals, is quite small, and can be made even smaller by reducing the convergence tolerance of PATH. Inspecting the listing file, the only difficulties mentioned are division by zero errors in the market clearance condition (19), that can be avoided a posteori by imposing an artificial (inactive) lower bound on these prices. We chose not to do this however.

5.31.5.3 Nested Production and Maintenance

Another observation that can be used to overcome the land price going to zero is the fact that land typically requires some maintenance labour input to keep it usable for crop growth. Traditionally, in economics, this is carried out by providing a nested CES function as technology input to the model. The idea is that commodity c in region r is made from labour and an intermediate good, which is "maintained land". Essentially, the following production problem replaces (12):

$$\begin{array}{rc} \min_{y_M, y_L, y_r, g} & w_L(y_M + y_L) + w_r y_r \\ \text{subject to} & y_r \geq (1 - \beta_c - \epsilon)g \\ & y_M \geq \epsilon g \\ & \phi_c y_L^{\beta_c} g^{1-\beta_c} \geq 1, \\ & y_M, y_L, y_r, g \geq 0. \end{array}$$

Note that the variable y_M represents "maintenance labour" and g represents the amount of "maintained land" produced, an intermediate good. The process of generating maintained land uses a Leontieff production function, namely

$$\min(\lambda_r y_r, \lambda_M y_M) \geq g.$$

Here $\lambda_M = \frac{1}{\epsilon}$, ϵ small, corresponds to small amounts of maintenance labour, while $\lambda_r = \frac{1}{1-\beta_c-\epsilon}$ is chosen to calibrate the model correctly. A simple calculus exercise then generates appropriate demand and cost expressions. The resulting complementarity problem comprises (14), (17), (18) and

$$\begin{aligned} \gamma_{c,r} &= \frac{w_L^{\beta_c}}{\phi_c} \left(\frac{w_L \epsilon + w_r(1-\beta_c-\epsilon)}{1-\beta_c} \right)^{1-\beta_c} \\ 0 \leq w_L \quad \perp \quad e_L &\geq \sum_{r,c} x_{c,r}\gamma_{c,r} \left(\frac{\beta_c}{w_L} + \frac{\epsilon(1-\beta_c)}{w_L\epsilon + w_r(1-\beta_c-\epsilon)} \right) \\ 0 \leq w_r \quad \perp \quad a_r &\geq \sum_c \frac{x_{c,r}\gamma_{c,r}(1-\beta_c)(1-\beta_c-\epsilon)}{w_L\epsilon + w_r(1-\beta_c-\epsilon)} \end{aligned}$$

After making the appropriate modifications to the model file, PATH 4.x solved the problem on defaults without any difficulties. All indicators showed the problem and solution found to be well-posed.

5.32 quadMINOS

For LP (and RMIP) models that cause difficulty for the standard solvers, quadMINOS provides considerably greater reliability and accuracy than MINOS by using quadruple-precision floating-point arithmetic. Although it is slower by a factor of 20 or 30 for cold-start runs, you can use standard MINOS or another LP solver first and let them do their best. Warm-starts with quadMINOS may give greatly improved solutions at moderate cost.

To take advantage of quadMINOS, the main requirement is to set a few runtime options to non-default values in order to request higher accuracy. For example, it is reasonable to set

```
Feasibility tolerance  1e-15
Optimality  tolerance  1e-15
```

because IEEE Quad floating-point has nearly 34 digits of precision. For an example of using Double and Quad MINOS together, see **[DQQ]** in the GAMS model library.

Note

GAMS/quadMINOS can only solve LPs and RMIPs at the moment because GAMS does not provide function evaluations in quad-precision.

The documentation of MINOS also refers to quadMINOS.

5.33 SBB

5.33.1 Introduction

SBB is a GAMS solver for Mixed Integer Nonlinear Programming (MINLP) models. It is based on a combination of the standard Branch and Bound (B&B) method known from Mixed Integer Linear Programming and some of the standard NLP solvers already supported by GAMS. SBB can use all GAMS NLP solvers as subsolvers but it works best with NLP solvers that can utilize a near optimal point as a starting point like Conopt, Minos, and Snopt.

SBB supports all types of discrete variables supported by GAMS, including Binary, Integer, Semicont, Semiint, Sos1, and Sos2.

5.33.2 The Branch and Bound Algorithm

The Relaxed Mixed Integer Nonlinear Programming (RMINLP) model is initially solved using the starting point provided by the modeler. SBB will stop immediately if the RMINLP model is unbounded or infeasible, or if it fails (see option `infeasseq` and `failseq` below for an exception). If all discrete variables in the RMINLP model are integer, SBB will return this solution as the optimal integer solution. Otherwise, the current solution is stored and the Branch and Bound procedure will start.

During the Branch and Bound process, the feasible region for the discrete variables is subdivided, and bounds on discrete variables are tightened to new integer values to cut off the current non-integer solutions. Each time a bound is tightened, a new, tighter NLP submodel is solved starting from the optimal solution to the previous looser submodel. The objective function values from the NLP submodel is assumed to be lower bounds on the objective in the restricted feasible space (assuming minimization), even though the local optimum found by the NLP solver may not be a global optimum. If the NLP solver returns a Locally Infeasible status for a submodel, it is usually assumed that there is no feasible solution to the submodel, even though the infeasibility only has been determined locally (see option `infeasseq` below for an exception). If the model is convex, these assumptions will be satisfied and SBB will provide correct bounds. If the model is not convex, the objective bounds may not be correct and better solutions may exist in other, unexplored parts of the search space.

5.33.3 SBB with Pseudo Costs

Over the last decades quite a number of search strategies have been successfully introduced for mixed integer linear programming (for details see e.g. J.T. Linderoth and M.W.P. Savelsbergh, A Computational Study of Search Strategies for Mixed Integer Programming, INFORMS Journal on Computing, 11(2), 1999). Pseudo costs are key elements of sophisticated search strategies. Using pseudo costs, we can estimate the degradation of the objective function if we move a fractional variable to a close integer value. Naturally, the variable selection can be based on pseudo costs (see SBB option `varsel`). Node selection can also make use of pseudo cost: If we can estimate the change of the objective for moving one fractional variable to the closed integer value, we can then aggregate this change for all fractional variables, to estimate the objective of the best integer solution reachable from a particular node (see SBB option `nodesel`).

Unfortunately, the computation of pseudo cost can be a substantial part of the overall computation. Models with a large number of fractional variables in the root node are **not** good candidates for search strategies which require pseudo costs (`varsel 3, nodesel 3,5,6`). The impact (positive or negative) of using pseudo cost depends significantly on the particular model. At this stage, general statements are difficult to make.

Selecting pseudo cost related search strategies (`varsel 3, nodesel 3,5,6`) may use computation time which sometimes does not pay off. However, we encourage the user to try these options for difficult models which require a large number of branch-and-bound nodes to solve.

5.33.4 The SBB Options

SBB works like other GAMS solvers, and many options can be set in the GAMS model. The most relevant GAMS options are IterLim, ResLim, NodLim, OptCA, OptCR, OptfFile, Cheat, and CutOff. A description of all available GAMS options can be found in the GAMS User's Guide Solver related options. GAMS options PriorOpt and TryInt are also accepted by SBB.

SBB uses the `var.prior` information to select the fractional variable with the smallest priority during the variable selection process. SBB uses the TryInt information to set the branching direction in the B&B algorithm. At the beginning, SBB looks at the levels of the discrete variables provided by the user and if Abs(Round(x.l)-x.l) $<$ m.TryInt, SBB will branch on that variable in the direction of Round(x.l). For example, x.l=0.9 and m.TryInt=0.2. We have Abs(Round(0.9)-0.9)=0.1 $<$ 0.2, so when SBB decides to branch on this variable (because it is fractional, lets say with value 0.5), the node explored next will have the additional constraint x $\geq$ 1 (the node with x $\leq$ 0 will be explored later). If everything goes well (there is the chance that we end up in a different local optima in the subsolves for non-convex problems), SBB should reproduce a preset incumbent solution in a couple of nodes.

If you specify <`modelname`>`.OptFile = 1;` before the Solve statement in your GAMS model, SBB will then look for and read an option file with the name `sbb.opt` (see The Solver Option File for general use of solver option files). Unless explicitly specified in the SBB option file, the NLP subsolvers will not read an option file. The syntax for the SBB option file is

```
optname value
```

with one option on each line.

For example,

```
rootsolver conopt.1
subsolver snopt
loginterval 10
```

The first two lines determine the NLP subsolvers for the Branch and Bound procedure. CONOPT with the option file `conopt.opt` will be used for solving the root node. SNOPT with no option file will be used for the remaining nodes. The last option determines the frequency for log line printing. Every 10th node, and each node with a new integer solution, causes a log line to be printed. The following options are implemented:

Option	Description	Default
acceptnonopt	accepts feasible solution from subsolver	0
avgresmult	average resource multiplicator	5
dfsstay	keeps DFS node selection after solution has been found	0
epint	integer feasibility tolerance	1.0e-5
failseq	solver sequence for failed nodes	
infeasseq	solver sequence for infeasible nodes	
intsollim	maximum number of integer solutions	2100000000
loginterval	progress display interval	1
loglevel	level of solver display	1
memnodes	maximum number of nodes in memory	10000
miptrace	filename of MIP trace file	
miptracenode	node interval when a trace record is written	100
miptracetime	time interval when a trace record is written	5.0
nodesel	node selection strategy	0
printbbinfo	prints additional node info	0
rootsolver	solver for the root node	GAMS NLP solver
solvelink	Solvelink for GAMS NLP solver	5
subiter	iteration limit for the subsolve	GAMS iterlim
subres	resource limit for the subsolve	GAMS reslim
subsolver	solver for the subproblems	GAMS NLP solver
usercallparmfile	Command-line parameter include file used in GAMS command-line calls triggered by BCH	
usergdxname	the name of the GDX file exported from the solver with the solution at the node	bchout.gdx
usergdxnameinc	the name of the GDX file exported from the solver with the incumbent solution	bchout_i.gdx
userheurcall	the GAMS command line to call the heuristic	
userheurfirst	calls the cut generator for the first n nodes	10
userheurfreq	determines the frequency of the cut generator model calls	10
userheurinterval	determines the interval when to apply the multiplier for the frequency of the cut generator model calls	100
userheurmult	determines the multiplier for the frequency of the cut generator model calls	2
userheurnewint	calls the heuristic if the solver found a new integer feasible solution	0
userheurobjfirst	Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement	50
varsel	variable selection strategy at each node	0

acceptnonopt *(boolean)*: accepts feasible solution from subsolver ↩

If this option is set to 1 and the subsolver terminates with solver status *Terminated by Solver* and model status *Intermediate Nonoptimal* SBB takes this as a good solution and keeps on going. In default mode such a return is treated as a subsolver failure and the failseq is consulted.

Default: `0`

avgresmult *(integer)*: average resource multiplicator ↩

Similar to subres, this option allows the user to control the time limit spend in a node. SBB keeps track of how much time is spent in the nodes, and builds an average over time. This average multiplied by the factor `avgresmult` is set as a time limit for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure: the node is ignored or the solvers in the failseq are called. The default multiplier `avgresmult` is 5. Setting `avgresmult` to 0 will disable the automatic time limit feature. A multiplier is not very useful for very small node solution times; therefore, independent of each node, SBB grants the solver at least 5 seconds to solve the node. The competing option subres overwrites the automatically generated resource limit.

Default: `5`

dfsstay *(integer)*: keeps DFS node selection after solution has been found ↩

If the node selection is a B∗/DFS mix, SBB switches frequently to DFS node selection mode. It switches back into B∗ node selection mode, if no subnodes were created (new int, pruned, infeasible, fail). It can be advantageous to search the neighborhood of the last node also in a DFS manner. Setting `dfsstay` to n instructs SBB to stay in DFS mode for another n nodes.

Default: `0`

epint *(real)*: integer feasibility tolerance ↩

The integer infeasibility tolerance.

Range: [`1e-9`, `1`]

Default: `1.0e-5`

failseq *(string)*: solver sequence for failed nodes ↩

`solver1[.n1] solver2[.n2] ...` where `solver1` is the name of a GAMS NLP solver to be used if the default solver fails, i.e., if it was not stopped by an iteration, resource, or domain limit and does not return a locally optimal or locally infeasible solution. `n1` is the value of optfile passed to the alternative NLP solver. If `.n1` is left blank it is interpreted as zero. Similarly, `solver2` is the name of a GAMS NLP solver that is used if `solver1` fails, and `n2` is the value of optfile passed to the second NLP solver. If you have a difficult model where solver failures are not unlikely, you may add more `solver.n` pairs. You can use the same solver several times with different options files. `failseq conopt conopt.2 conopt.3` means to try CONOPT with no options file. If this approach also fails, try CONOPT with options file `conopt.op2`, and if it again fails, try CONOPT with options file `conopt.op3`. If all solver and options file combinations fail the node will be labeled *ignored* and the node will not be explored further. The default is to try only one solver (the `rootsolver` or `subsolver`) and to ignore nodes with a solver failure.

infeasseq *(string)*: solver sequence for infeasible nodes ↩

`level solver1[.n1] solver2[.n2] ...` The purpose of `infeasseq` is to avoid cutting parts of the search tree that appear to be infeasible but really are feasible. If the NLP solver labels a node *Locally Infeasible* and the model is not convex a feasible solution may actually exist. If SBB is high in the search tree it can be very drastic to prune the node immediately. SBB is therefore directed to try the solver/option combinations in the list as long as the depth in the search tree is less than the integer value `level`. If the list is exhausted without finding a feasible solution, the node is assumed to be infeasible. The default is to trust that *Locally Infeasible* nodes are indeed infeasible and to remove them from further consideration.

intsollim *(integer)*: maximum number of integer solutions ↩

Maximum number of integer solutions. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: `2100000000`

loginterval *(integer)*: progress display interval ↩

The interval (number of nodes) for which log lines are written.

Default: `1`

loglevel *(integer)*: level of solver display ↩

The level of log output.

Default: `1`

value	meaning
0	only SBB log lines with one line every loginterval nodes
1	NLP solver log for the root node plus SBB loglines as 0
2	NLP solver log for all nodes plus SBB log lines as 0

memnodes *(integer)*: maximum number of nodes in memory ↩

The maximum number of nodes SBB can have in memory. If this number is exceeded, SBB will terminate and return the best solution found so far.

Default: `10000`

miptrace *(string)*: filename of MIP trace file ↩

More info is available in chapter Solve trace

miptracenode *(integer)*: node interval when a trace record is written ↩

More info is available in chapter Solve trace

Default: `100`

miptracetime *(real)*: time interval when a trace record is written ↩

More info is available in chapter Solve trace

Default: `5.0`

nodesel *(integer)*: node selection strategy ↩

Node selection scheme.

Default: `0`

value	meaning
0	automatic
1	Depth First Search (DFS)
2	Best Bound (BB)
3	Best Estimate (BE)
4	DFS/BB mix
5	DFS/BE mix
6	DFS/BB/BE mix

printbbinfo *(integer)*: prints additional node info ↩

Additional info of log output.

Default: `0`

value	meaning
0	print no additional info
1	print variable selection letter The node and variable selection for the current node are indicated by a two letter code at the end of the log line. The first letter represents the node selection: D for DFS, B for Best Bound, and E for Best Estimate. The second letter represents the variable selection: X for maximum infeasibility, N for minimum infeasibility, and P for pseudo cost.
2	print best estimate

rootsolver *(string)*: solver for the root node ↩

`solver[.n]` Solver is the name of the GAMS NLP solver that should be used in the root node, and `n` is the integer corresponding to optfile for the root node. If `.n` is missing, the optfile treated as zero i.e. the NLP solver will not look for an options file. This SBB option can be used to overwrite the default that uses the NLP solver specified with an `Option NLP = solver;` statement or the default GAMS solver for NLP.

Default: `GAMS NLP solver`

solvelink *(integer)*: Solvelink for GAMS NLP solver ↩

Default: `5`

value	meaning
1	Call GAMS NLP solver via script
2	Call GAMS NLP solver via module
5	Call GAMS NLP solver in memory

subiter *(integer)*: iteration limit for the subsolve ↩

The default for `subiter` passed on through `iterlim`. Similar to subres but sets the iteration limit for solving a node in the B&B tree.

Default: `GAMS iterlim`

subres *(real)*: resource limit for the subsolve ↩

The default for `subres` passed on through `reslim`. Sets the time limit in seconds for solving a node in the B&B tree. If the NLP solver exceeds this limit it is handled like a failure and the node is ignored, or the solvers in the failseq are called.

Default: `GAMS reslim`

subsolver *(string)*: solver for the subproblems ↩

`solver[.n]` Similar to rootsolver but applied to the subnodes.

Default: `GAMS NLP solver`

usercallparmfile *(string)*: Command-line parameter include file used in GAMS command-line calls triggered by BCH ↩

usergdxname *(string)*: the name of the GDX file exported from the solver with the solution at the node ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `bchout.gdx`

usergdxnameinc *(string)*: the name of the GDX file exported from the solver with the incumbent solution ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `bchout_i.gdx`

userheurcall *(string)*: the GAMS command line to call the heuristic ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

userheurfirst *(integer)*: calls the cut generator for the first n nodes ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `10`

userheurfreq *(integer)*: determines the frequency of the cut generator model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `10`

userheurinterval *(integer)*: determines the interval when to apply the multiplier for the frequency of the cut generator model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `100`

userheurmult *(integer)*: determines the multiplier for the frequency of the cut generator model calls ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `2`

userheurnewint *(boolean)*: calls the heuristic if the solver found a new integer feasible solution ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `0`

userheurobjfirst *(integer)*: Similar to UserHeurFirst but only calls the heuristic if the relaxed objective promises an improvement ↩

More info is available in chapter The GAMS Branch-and-Cut-and-Heuristic Facility.

Default: `50`

varsel *(integer)*: variable selection strategy at each node ↩

Variable selection scheme.

Default: `0`

value	meaning
0	automatic
1	maximum integer infeasibility
2	minimum integer infeasibility
3	pseudo costs

5.33.5 The SBB Log File

The SBB Log file (usually directed to the screen) can be controlled with the `loginterval` and `loglevel` options in SBB. It will by default first show the iteration output from the NLP solver that solves the root node. This is followed by output from SBB describing the search tree. An example of this search tree output follows:

```
Root node solved locally optimal.
   Node  Act. Lev.  Objective  IInf  Best Int.      Best Bound   Gap  (2 secs)
      0     0   0   8457.6878   3            -       8457.6878       -
      1     1   1   8491.2869   2            -       8457.6878       -
      2     2   2   8518.1779   1            -       8457.6878       -
*     3     3   3   9338.1020   0    9338.1020       8457.6878  0.1041
      4     2   1      pruned   -    9338.1020       8491.2869  0.0997
 Solution satisfies optcr
 Statistics:
    Iterations    :                 90
    NLP Seconds   :           0.110000
    B&B nodes     :                  3

    Relative gap  :           0.099728     optcr :  0.100000
    Model Status  :                  8
    Solver Status :                  1

 NLP Solver Statistics
    Total Number of NLP solves  :           7
    Total Number of NLP failures:           0
    Details:         conopt
      # execs             7
      # failures          0
 Terminating.
```

The fields in the log are:

Field	Description
`Node`	The number of the current node. The root node is node 0.
`Act`	The number of active nodes defined as the number of subnodes that have not yet been solved.
`Lev`	The level in the search tree, i.e., the number of branches needed to reach this node.
`Objective`	The objective function value for the node. A numerical value indicates that the node was solved and the objective was good enough for the node to not be ignored. "pruned" indicates that the objective value was worse than the Best Integer value, "infeasible" indicates that the node was Infeasible or Locally Infeasible, and "ignored" indicates that the node could not be solved (see under failseq above).

Field	Description
IInf	The number of integer infeasibilities, i.e. the number of variables that are supposed to be binary or integer that do not satisfy the integrality requirement. Semi continuous variables and SOS variables may also contribute to IInf.
Best Int	The value of the best integer solution found so far. A dash (-) indicates that an integer solution has not yet been found. A star (∗) in column one indicates that the node is integer and that the solution is better than the best yet found.
Best Bound	The minimum value of "Objective" for the subnodes that have not been solved yet (maximum for maximization models). For convex models, Best Bound will increase monotonically. For nonconvex models, Best Bound may decrease, indicating that the Objective value for a node was not a valid lower bound for that node.
Gap	The relative gap between the Best Integer solution and the Best Bound.

The remaining part of the Log file displays various solution statistics similar to those provided by the MIP solvers. This information can also be found in the Solver Status area of the GAMS listing file.

The following Log file shows cases where the NLP solver fails to solve a subnode. The text "ignored" in the Objective field shows the failure, and the values in parenthesis following the Gap field are the Solve and Model status returned by the NLP solver:

```
Root node solved locally optimal.
Node  Act. Lev.  Objective  IInf  Best Int.      Best Bound   Gap  (2 secs)
   0     0   0    6046.0186  12            -       6046.0186       -
   1     1   1   infeasible   -            -       6046.0186       -
   2     0   1    6042.0995  10            -       6042.0995       -
   3     1   2      ignored   -            -       6042.0995       - (4,6)
   4     0   2    5804.5856   8            -       5804.5856       -
   5     1   3      ignored   -            -       5804.5856       - (4,7)
```

The next Log file shows the effect of the infeasseq and failseq options on the model above. CONOPT with options file *conopt.opt* (the default solver and options file pair for this model) considers the first subnode to be locally infeasible. CONOPT, MINOS, and SNOPT, all with no options file, are therefore tried in sequence. In this case, they all declare the node infeasible and it is considered to be infeasible.

In node 3, CONOPT with option file fails but CONOPT without option file finds a Locally Optimal solution, and this solution is then used for further search. The SBB option file for the following run would be:

```
rootsolver conopt.1
subsolver conopt.1
failseq conopt
infeasseq 100 conopt minos snopt
```

The log looks as follows:

```
Root node solved locally optimal.
Node  Act. Lev.  Objective  IInf  Best Int.      Best Bound   Gap  (2 secs)
   0     0   0    6046.0186  12            -       6046.0186       -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos reports locally infeasible
```

```
Executing snopt
   1     1    1  infeasible   -            -       6046.0186       -
   2     0    1   6042.0995  10            -       6042.0995       -
conopt.1 failed. 4 TERMINATED BY SOLVER, 7 FEASIBLE SOLUTION
Executing conopt
   3     1    2   4790.2373   8            -       6042.0995       -
   4     2    3   4481.4156   6            -       6042.0995       -
conopt.1 reports locally infeasible
Executing conopt
conopt reports locally infeasible
Executing minos
minos failed. 4 TERMINATED BY SOLVER, 6 INTERMEDIATE INFEASIBLE
Executing snopt
   5     3    4  infeasible   -            -       6042.0995       -
   6     2    4   4480.3778   4            -       6042.0995       -
```

The Log file shows a solver statistic at the end, summarizing how many times an NLP was executed and how often it failed:

```
NLP Solver Statistics
   Total Number of NLP solves  :   45
   Total Number of NLP failures:   13
   Details:     conopt     minos   snopt
     # execs        34         3       8
     # failures      4         3       6
```

The solutions found by the NLP solver to the subproblems in the Branch and Bound may not be the global optima. Therefore, the objective can improve even though we restrict the problem by tightening some bounds. These *jumps* of the objective in the *wrong* direction which might also have an impact on the best bound/possible are reported in a separate statistic:

```
Non convex model!
   # jumps in best bound       :           2
   Maximum jump in best bound  :   20.626587 in node 13
   # jumps to better objective :           2
   Maximum jump in objective   :   20.626587 in node 13
```

5.33.6 Comparison of SBB and other MINLP Solvers

GAMS offers a variety of MINLP solvers including local and global MINLP solver. They implement different algorithms and it is usually unclear which solver performs best. Here we give a brief comparison between SBB and the well known solver DICOPT.

DICOPT is based on the outer approximation method. Initially, the RMINLP model is solved just as in SBB. The model is then linearized around this point and a linear MIP model is solved. The discrete variables are then fixed at the optimal values from the MIP model, and the resulting NLP model is solved. If the NLP model is feasible, we have an integer feasible solution.

The model is linearized again and a new MIP model with both the old and new linearized constraints is solved. The discrete variables are again fixed at the optimal values, and a new NLP model is solved.

The process stops when the MIP model becomes infeasible, when the NLP solution becomes worse, or, in some cases, when bounds derived from the MIP model indicate that it is safe to stop.

DICOPT is based on the assumption that MIP models can be solved efficiently while NLP models can be expensive and difficult to solve. The MIP models try to approximate the NLP model over a large area and solve it using much cheaper linear technology. Ideally, only a few NLPs must be solved.

DICOPT can experience difficulties solving models, if many or all the NLP submodels are infeasible. DICOPT can also have problems if the linearizations used for the MIP model create ill-conditioned models. The MIP models may become very difficult to solve, and the results from the MIP models may be poor as initial values for the NLP models. The linearized constraint used by DICOPT may also exclude certain areas of the feasible space from consideration.

SBB uses different assumptions and works very differently. Most of the work in SBB involves solving NLP models. Since the NLP submodels differ only in one or a few bounds, the assumption is that the NLP models can be solved quickly using a good restart procedure. Since the NLP models differ very little and good initial values are available, the solution process will be fairly reliable compared to the solution process in DICOPT, where initial values of good quality seldom are available. Because search space is reduced based on very different grounds than in DICOPT, other solutions may therefore be explored.

Overall, DICOPT should perform better on models that have a significant and difficult combinatorial part, while SBB may perform better on models that have fewer discrete variables but more difficult nonlinearities (and possibly also on models that are fairly non convex).

5.34 SCIP

SCIP (**S**olving **C**onstraint **I**nteger **P**rograms) is a framework for Constraint Integer Programming oriented towards the needs of Mathematical Programming experts who want to have total control of the solution process and access detailed information down to the guts of the solver. SCIP can also be used as a pure MIP or MINLP solver or as a framework for branch-cut-and-price. Within GAMS, the MIP and MINLP solving facilities of SCIP are available.

For more detailed information, we refer to [4] [1] [2] [21] [20] [74] [127] [88] [89] [75] [22] [192] [191] [204] and the SCIP web site.

GAMS/SCIP uses CPLEX, if licensed, and otherwise SOPLEX [206] as LP solver, the COIN-OR Interior Point Optimizer IPOPT [197] as nonlinear solver, and CppAD to compute derivatives of nonlinear functions.

SCIP supports continuous, binary, integer, semi-continuous, semi-integer variables, indicator constraints, special ordered sets, and branching priorities for discrete variables.

5.34.1 Usage

The following statement can be used inside your GAMS program to specify using SCIP

```
Option MIP = SCIP;     { or QCP or NLP or MIQCP or MINLP or ... }
```

The above statement should appear before the Solve statement. If SCIP was specified as the default solver during GAMS installation, the above statement is not necessary.

5.34.1.1 Specification of SCIP Options

GAMS/SCIP supports the GAMS parameters reslim, iterlim, nodlim, optca, optcr, and workspace. Further, the option threads can be used to control the number of threads used in the MILP presolver, the linear algebra routines (e.g., in IPOPT), and for solving LPs if CPLEX' barrier solver is used. Setting threads to 0 (the default) will enable the automatic choice of the number of threads in the MILP presolver and LP solver, but does not enable multithreading for linear algebra routines at the moment.

Options can be specified by a SCIP options file. A SCIP options file consists of one option or comment per line. A pound sign (#) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs). Further, string values have to be enclosed in quotation marks.

A small example for a scip.opt file is:

```
propagating/probing/maxprerounds = 0
separating/maxrounds             = 0
separating/maxroundsroot         = 0
```

It causes GAMS/SCIP to disable probing during presolve and to turn off all cut generators.

5.34.1.2 Specification of Indicators

Indicators are a modeling tool to specify that certain equations in a model must only be satisfied if certain binary variables take a specified value. Indicators are not supported by the GAMS language, but can be passed to SCIP via a separate file, see Indicator Constraints for more details on its syntax. The name of that file is specified via the option gams/indicatorfile in a SCIP option file. Currently, indicators can only be used for linear equations.

5.34.2 Special Features

5.34.2.1 SCIP interactive shell

The interactive shell in SCIP is a powerful tool that allows the user to display various information (e.g., branching statistics, presolved model), load emphasis settings, interrupt a solve to change parameters or trigger a restart, write the model in various file formats, start SCIPs solution counter, and many more things.

When setting the option gams/interactive to a nonempty string, the GAMS/SCIP interface opens the interactive shell of SCIP after having load the GAMS problem and parameters and passes the value of the gams/interactive parameter to the SCIP interactive shell.

By default, SCIP behaves as if `gams/interactive` has been set to `"optimize write gamssol quit"`, that is, SCIP is requested to solve the problem, then to pass the solution back to GAMS, and to quit.

An example use of the SCIP interactive shell feature via GAMS is to add the following line to your SCIP options file:

```
gams/interactive = "write prob orig.lp presolve write transprob presol.mps opt write gamssol quit"
```

This instructs SCIP to write the original problem to the file `orig.lp` in LP format, to presolve the instance, to write the presolved problem to the file `presolved.mps` in MPS format, to solve the instance, to write the solution out to GAMS, and to finish.

By omitting the `quit` command, SCIPs interactive shell remains open and awaits user input. The command `help` prints a list of available commands. Note, that on Windows, GAMS need to be called with the option interactivesolver enabled to allow user input for the solver process.

A tutorial on using the SCIP shell is available at https://www.scipopt.org/doc/html/SHELL.php.

5.34.2.2 Emphasis Settings

SCIP includes various emphasis settings, which are predefined values for a set of SCIP parameters. Such predefined settings are available for setting the effort that SCIP should spend for, e.g., presolving, separation, or heuristics.

The emphasis settings are not available as single parameters, but can be set via SCIPs interactive shell. E.g., writing `set heuristics emphasis` in the shell displays the available emphasis settings for heuristics (`aggressive`, `fast`, `off`) and expects the user to input which setting to use. Further, general emphasis settings are available in the `set emphasis` menu, some of them giving predefined settings similar to the CPLEX option mipemphasis.

Via the gams/interactive option, c.f. Section SCIP interactive shell, emphasis settings can be activated via a SCIP options file. For example, adding the option

```
gams/interactive = "set emphasis feasibility set loadgams optimize write gamssol quit"
```

instructs SCIP to load the emphasis setting `feasibility` prior to optimizing the model and passing the solution back to GAMS. Note, that setting one of the emphasis settings `feasibility`, `hardlp`, and `optimality` resets all previously set parameters to their default values, which includes the ones that are set by the GAMS/SCIP interface or which were loaded from a SCIP options file. Therefore, the command `set loadgams` has been used above to restore these parameter settings.

The following emphasis settings are available in SCIP:

shell command	purpose
`set emphasis easycip`	use for easy problems
`set emphasis feasibility`	emphasize finding a feasible solution
`set emphasis hardlp`	use for problems with a hard LP
`set emphasis optimality`	emphasize proving optimality
`set emphasis numerics`	increase numerical stability
`set emphasis cpsolver`	setup a constraint programming like search
`set heuristic emphasis aggressive`	use primal heuristics aggressively
`set heuristic emphasis fast`	use only fast primal heuristics
`set heuristic emphasis off`	disable all primal heuristics
`set presolving emphasis aggressive`	do aggressive presolving
`set presolving emphasis fast`	use only fast presolving steps
`set presolving emphasis off`	disable presolving
`set separating emphasis aggressive`	use cutting plane separators aggressively
`set separating emphasis fast`	use only fast cutting plane separators
`set separating emphasis off`	disable all cutting plane separators

5.34.2.3 Starting point

Using the completesol heuristic, SCIP can try to find a feasible solution based on values given by the user for all or some of the variables. The values need to be specified as variable levels in the GAMS model. The heuristic solves a copy of the problem where variables for which values have been provided are restricted to be close to that value. When an integral value is specified for a binary or integer variable, the variable is fixed to that value. See also Section 2.3.2 in [127] for a more detailed description of the heuristic.

For which variables the level values are passed from GAMS to SCIP is controlled by the parameter gams/mipstart. The parameter values have the following meaning:

- 0: do not pass any variable values to SCIP, the heuristic will not run
- 1: pass values for all binary and integer variables to SCIP and let SCIP try to find a feasible solution in its neighborhood by using the completesol heuristic
- 2 (default): pass values for all variables to SCIP and let SCIP check feasibility of the given solution, the heuristic will not run
- 3: pass values for all variables to SCIP and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic
- 4: pass values for all binary and integer variables to SCIP which fractionality is at most the value of GAMS option tryint (thus, with default tryint=0, only for variables with integral values, the value is passed to SCIP) and let SCIP try to find a feasible solution in the neighborhood by using the completesol heuristic

Note, that the completesol heuristic will not run if there are too many variables with unknown values. This behavior can be adjusted by setting parameter heuristics/completesol/maxunknownrate.

5.34.2.4 Decomposition Information

SCIP potentially can make use of a user-provided `problem decomposition`, e.g., in primal heuristics PADM or GINS. Note, that SCIP's Benders Decomposition is not available with GAMS at the moment. A GAMS user can inform SCIP about such a decomposition by using the .stage variable suffix.

In an attempt to following the same convention on interpreting the `.stage` variable suffix as the GAMS/CPLEX link, variables which `.stage` suffix is set to an integral value greater than 0 are assigned to a block with this number. Variables which `.stage` suffix is set to a fractional value or a value smaller than 1 are assigned to no block.

Note, that the default value for the `.stage` suffix is 1. Therefore, GAMS/SCIP only passes decomposition information to SCIP if at least one variable has its `.stage` suffix set to a value different than 1. Moreover, in order to receive the `.stage` values, `scaleOpt` and `priorOpt` must be left at their default of 0.

5.34.2.5 Solution Pool

When SCIP solves a problem, it may find several solutions, whereof only the best one is available to the GAMS user via the variable level values in the GAMS model. If the option gams/dumpsolutions is specified, then all alternative solutions found by SCIP are written into GDX files and an index file with the name given by the this option is written. If the option gams/dumpsolutionsmerged is specified, then all alternative solutions found by SCIP are written into a single GDX file, which name is given by the this option.

The GAMS testlib model **dumpsol** shows an example use for this option.

5.34.2.6 Solving process tracing

The option gams/solvetrace/file can be used to specify the name of a file where information about the progress of the branch-and-bound tree search in SCIP is stored. The file is created and updated during the solution process, so it may also be used to monitor the progress of SCIP while it still solves the model.

New entries are written periodically, depending on how many nodes have been processed or how much time has been elapsed since the last entry was written. Each entry contains information on the current primal and dual bound.

5.34.2.7 Notes on solving MINLPs

SCIP includes capabilities to handle nonlinear functions that are specified via algebraic expressions. Therefore, neither external/extrinsic functions nor all GAMS mathematical functions are supported.

Nonconvex MINLPs are solved via a spatial branch-and-bound algorithm using linear relaxations. The tightness of this relaxation depends heavily on the variable bounds, thus tight bounds for the nonlinear variables are crucial for SCIP.

Convex MINLPs are much easier to solve for SCIP, provided it recognizes the convexity of the model. The convexity check implemented in SCIP may not give a conclusive answer in all cases. However, setting the option constraints/nonlinear/assumeconvex to `TRUE` can be used to tell SCIP that it should assume all nonlinear constraints to be of convex type. This may help to improve solving times for convex MINLPs considerably in some cases. However, it can also deteriorate performance as it prevents the use of certain extended formulations.

Another feature that can be especially useful for convex MINLPs is to enable the generation of cuts in feasible solutions, since these supporting hyperplanes can be strong. At the moment, this is only enabled for purely continuous nonlinear programs (QCPs and NLPs), but can be adjusted by parameter constraints/nonlinear/linearizeheursol. In this connection, it may also be beneficial to set separating/poolfreq to 1.

5.34.3 Components

In the following, we list components that are available in SCIP together with some common properties. Many of these properties can be modified with corresponding parameters.

5.34.3.1 Branching Rules

branching rule	priority	maxdepth	maxbounddist	description
relpscost	10000	-1	100	reliability branching on pseudo cost values
pscost	2000	-1	100	branching on pseudo cost values
inference	1000	-1	100	inference history branching
mostinf	100	-1	100	most infeasible branching
leastinf	50	-1	100	least infeasible branching
distribution	0	-1	100	branching rule based on variable influence on cumulative normal distribution of row activities
fullstrong	0	-1	100	full strong branching
cloud	0	-1	100	branching rule that considers several alternative LP optima
lookahead	0	-1	100	full strong branching over multiple levels
multaggr	0	-1	100	fullstrong branching on fractional and multi-aggregated variables
allfullstrong	-1000	-1	100	all variables full strong branching
vanillafullstrong	-2000	-1	100	vanilla full strong branching
random	-100000	-1	100	random variable branching
nodereopt	-9000000	-1	100	branching rule for node reoptimization

See https://www.scipopt.org/doc/html/BRANCH.php for a detailed description of the branching rule properties.

5.34.3.2 Conflict Handler

conflict handler	priority	description
logicor	800000	conflict handler creating logic or constraints
setppc	700000	conflict handler creating set covering constraints
indicatorconflict	200000	replace slack variables and generate logicor constraints
linear	-1000000	conflict handler creating linear constraints
bounddisjunction	-3000000	conflict handler creating bound disjunction constraints

5.34.3.3 Constraint Handler

constraint handler	checkprio	enfoprio	sepaprio	sepafreq	propfreq	eagerfreq	presolvetimings	description
integral	0	0	0	-1	-1	-1	always	integrality constraint
SOS1	-10	100	1000	10	1	100	medium	SOS1 constraint handler
SOS2	-10	100	10	0	1	100	fast	SOS2 constraint handler
varbound	-500000	-500000	900000	0	1	100	fast medium	variable bounds lhs <= x + c*y <= rhs, x non-binary, y non-continuous
knapsack	-600000	-600000	600000	0	1	100	always	knapsack constraint of the form a^T x <= b, x binary and a >= 0
setppc	-700000	-700000	700000	0	1	100	always	set partitioning / packing / covering constraints

constraint handler	checkprio	enfoprio	sepaprio	sepafreq	propfreq	eagerfreq	presolvetimings	description
or	-850000	-850000	850000	0	1	100	medium	constraint handler for or constraints: r = or(x1, ..., xn)
and	-850100	-850100	850100	1	1	100	fast exhaustive	constraint handler for AND-constraints: r = and(x1, ..., xn)
xor	-850200	-850200	850200	0	1	100	always	constraint handler for xor constraints: r = xor(x1, ..., xn)
linear	-1000000	-1000000	100000	0	1	100	fast exhaustive	linear constraints of the form lhs <= a^T x <= rhs
orbisack	-1005200	-1005200	40100	5	5	-1	exhaustive	symmetry breaking constraint handler for orbisacks
orbitope	-1005200	-1005200	40100	-1	1	-1	medium	symmetry breaking constraint handler relying on (partitioning/packing) orbitopes

constraint handler	check-prio	enfo-prio	sepa-prio	sepa-freq	propfreq	eager-freq	presol-vetim-ings	de-scrip-tion
symresack	-1005200	-1005200	40100	5	5	-1	exhaustive	symmetry breaking constraint handler relying on sym-resacks
logicor	-2000000	-2000000	10000	0	1	100	always	logic or con-straints
bounddisjunction	-3000000	-3000000	0	-1	1	100	fast	bound disjunc-tion con-straints
nonlinear	-4000010	-60	10	1	1	100	always	handler for non-linear con-straints specified by al-gebraic expres-sions
indicator	-6000000	-100	10	10	1	100	fast	indicator con-straint handler
components	-9999999	0	0	-1	1	-1		independent compo-nents con-straint handler

See https://www.scipopt.org/doc/html/CONS.php for a detailed description of the constraint handler properties.

5.34.3.4 Display Columns

display column	header	position	width	priority	status	description
solfound		0	1	80000	auto	letter that indi-cates the heuris-tic which found the solution
time	time	50	5	4000	auto	total solution time
nnodes	node	100	7	100000	auto	number of pro-cessed nodes

display column	header	position	width	priority	status	description
nodesleft	left	200	7	90000	auto	number of unprocessed nodes
nrank1nodes	rank1	500	7	40000	off	current number of rank1 nodes left
nnodesbelowinc	nbInc	550	6	40000	off	current number of nodes with an estimate better than the current incumbent
lpiterations	LP iter	1000	7	30000	auto	number of simplex iterations
lpavgiterations	LP it/n	1400	7	25000	auto	average number of LP iterations since the last output line
lpcond	LP cond	1450	7	0	auto	estimate on condition number of LP solution
memused	umem	1500	5	0	auto	total number of bytes used in block memory
memtotal	mem/heur	1500	8	20000	auto	total number of bytes in block memory or the creator name when a new incumbent solution was found
depth	depth	2000	5	500	auto	depth of current node
maxdepth	mdpt	2100	5	5000	auto	maximal depth of all processed nodes
plungedepth	pdpt	2200	5	10	auto	current plunging depth
nfrac	frac	2500	5	700	auto	number of fractional variables in the current solution
nexternbranchcands	extbr	2600	5	650	auto	number of extern branching variables in the current node
vars	vars	3000	5	3000	auto	number of variables in the problem
conss	cons	3100	5	3100	auto	number of globally valid constraints in the problem
curconss	ccons	3200	5	600	auto	number of enabled constraints in current node

display column	header	position	width	priority	status	description
curcols	cols	3300	5	800	auto	number of LP columns in current node
currows	rows	3400	5	900	auto	number of LP rows in current node
cuts	cuts	3500	5	2100	auto	total number of cuts applied to the LPs
separounds	sepa	3600	4	100	auto	number of separation rounds performed at the current node
poolsize	pool	3700	5	50	auto	number of LP rows in the cut pool
conflicts	confs	4000	5	2000	auto	total number of conflicts found in conflict analysis
strongbranchs	strbr	5000	5	1000	auto	total number of strong branching calls
pseudoobj	pseudoobj	6000	14	300	auto	current pseudo objective value
lpobj	lpobj	6500	14	300	auto	current LP objective value
curdualbound	curdualbound	7000	14	400	auto	dual bound of current node
estimate	estimate	7500	14	200	auto	estimated value of feasible solution in current node
avgdualbound	avgdualbound	8000	14	40	auto	average dual bound of all unprocessed nodes
dualbound	dualbound	9000	14	70000	auto	current global dual bound
primalbound	primalbound	10000	14	80000	auto	current primal bound
cutoffbound	cutoffbound	10100	14	10	auto	current cutoff bound
gap	gap	20000	8	60000	auto	current (relative) gap using |primal-dual|/MIN(|dual|,|primal|)
primalgap	primgap	21000	8	20000	off	current (relative) gap using |primal-dual|/|primal|
nsols	nsols	30000	5	0	auto	current number of solutions found

display column	header	position	width	priority	status	description
completed	compl.	30100	8	110000	auto	completion of search in percent (based on tree size estimation)
nobjleaves	objleav	31000	7	0	auto	current number of encountered objective limit leaves
ninfeasleaves	infleav	32000	7	0	auto	number of encountered infeasible leaves
sols	sols	100000	7	110000	off	number of detected feasible solutions
feasST	feasST	110000	6	110000	off	number of detected non trivial feasible subtrees

See https://www.scipopt.org/doc/html/DISP.php for a detailed description of the display column properties.

5.34.3.5 Nonlinear Handler

nonlinear handler	enabled	detect priority	enforce priority	description
default	1	0	0	default handler for expressions
convex	1	50	50	handler that identifies and estimates convex expressions
concave	1	40	40	handler that identifies and estimates concave expressions
bilinear	1	-10	-10	bilinear handler for expressions
perspective	1	-20	125	perspective handler for expressions
quadratic	1	1	100	handler for quadratic expressions
quotient	1	20	20	nonlinear handler for quotient expressions
soc	1	100	100	nonlinear handler for second-order cone structures

5.34.3.6 Node Selectors

node selector	standard priority	memsave priority	description
estimate	200000	100	best estimate search

node selector	standard priority	memsave priority	description
bfs	100000	0	best first search
hybridestim	50000	50	hybrid best estimate / best bound search
restartdfs	10000	50000	depth first search with periodical selection of the best node
uct	10	0	node selector which balances exploration and exploitation
dfs	0	100000	depth first search
breadthfirst	-10000	-1000000	breadth first search

See https://www.scipopt.org/doc/html/NODESEL.php for a detailed description of the node selector properties.

5.34.3.7 Presolvers

presolver	priority	timing	maxrounds	description
milp	9999999	medium	-1	MILP specific presolving methods
trivial	9000000	fast	-1	round fractional bounds on integers, fix variables with equal bounds
boundshift	7900000	fast	0	converts variables with domain [a,b] to variables with domain [0,b-a]
inttobinary	7000000	fast	-1	converts integer variables with domain [a,a+1] to binaries
convertinttobin	6000000	fast	0	converts integer variables to binaries
gateextraction	1000000	exhaustive	-1	presolver extracting gate(and)-constraints
qpkktref	-1	medium	0	adds KKT conditions to (mixed-binary) quadratic programs
dualcomp	-50	exhaustive	-1	compensate single up-/downlocks by singleton continuous variables
stuffing	-100	exhaustive	0	fix redundant singleton continuous variables
domcol	-1000	exhaustive	-1	dominated column presolver
tworowbnd	-2000	exhaustive	0	do bound tigthening by using two rows
dualinfer	-3000	exhaustive	0	exploit dual information for fixings and side changes
implics	-10000	medium	-1	implication graph aggregator
dualagg	-12000	exhaustive	0	aggregate variables by dual arguments
sparsify	-24000	exhaustive	-1	eliminate non-zero coefficients
dualsparsify	-240000	exhaustive	-1	eliminate non-zero coefficients
redvub	-9000000	exhaustive	0	detect redundant variable bound constraints

See https://www.scipopt.org/doc/html/PRESOL.php for a detailed description of the presolver properties.

5.34.3.8 Primal Heuristics

primal heuristic	type	priority	freq	freqoffset	description
actconsdiving	d	-1003700	-1	5	LP diving heuristic that chooses fixings w.r.t. the active constraints
adaptivediving	d	-70000	5	3	diving heuristic that selects adaptively between the existing, public divesets
bound	p	-1107000	-1	0	heuristic which fixes all integer variables to a bound and solves the remaining LP
clique	p	5000	0	0	LNS heuristic using a clique partition to restrict the search neighborhood
coefdiving	d	-1001000	-1	1	LP diving heuristic that chooses fixings w.r.t. the matrix coefficients
completesol	L	0	0	0	primal heuristic trying to complete given partial solutions
conflictdiving	d	-1000100	10	0	LP diving heuristic that chooses fixings w.r.t. conflict locks
crossover	L	-1104000	30	0	LNS heuristic that fixes all variables that are identic in a couple of solutions
dins	L	-1105000	-1	0	distance induced neighborhood search by Ghosh
distributiondiving	d	-1003300	10	3	Diving heuristic that chooses fixings w.r.t. changes in the solution density
dps	L	75000	-1	0	primal heuristic for decomposable MIPs
dualval	L	-10	-1	0	primal heuristic using dual values
farkasdiving	d	-900000	10	0	LP diving heuristic that tries to construct a Farkas-proof
feaspump	o	-1000000	20	0	objective feasibility pump 2.0
fixandinfer	p	-500000	-1	0	iteratively fixes variables and propagates inferences
fracdiving	d	-1003000	10	3	LP diving heuristic that chooses fixings w.r.t. the fractionalities
gins	L	-1103000	20	8	gins works on k-neighborhood in a variable-constraint graph
guideddiving	d	-1007000	10	7	LP diving heuristic that chooses fixings in direction of incumbent solutions
zeroobj	L	100	-1	0	heuristic trying to solve the problem without objective
indicator	L	-20200	1	0	indicator heuristic to create feasible solutions from values for indicator variables
intdiving	d	-1003500	-1	9	LP diving heuristic that fixes binary variables with large LP value to one
intshifting	r	-10000	10	0	LP rounding heuristic with infeasibility recovering and final LP solving
linesearchdiving	d	-1006000	10	6	LP diving heuristic that chooses fixings following the line from root solution to current solution
localbranching	L	-1102000	-1	0	local branching heuristic by Fischetti and Lodi

primal heuristic	type	priority	freq	freqoffset	description
locks	p	3000	0	0	heuristic that fixes variables based on their rounding locks
lpface	L	-1104010	15	0	LNS heuristic that searches the optimal LP face inside a sub-MIP
alns	L	-1100500	20	0	Large neighborhood search heuristic that orchestrates the popular neighborhoods Local Branching, RINS, RENS, DINS etc.
nlpdiving	d	-1003010	10	3	NLP diving heuristic that chooses fixings w.r.t. the fractionalities
mutation	L	-1103010	-1	8	mutation heuristic randomly fixing variables
multistart	L	-2100000	0	0	multistart heuristic for convex and nonconvex MINLPs
mpec	d	-2050000	50	0	regularization heuristic for convex and nonconvex MINLPs
objpscostdiving	o	-1004000	20	4	LP diving heuristic that changes variable's objective values instead of bounds, using pseudo costs as guide
octane	r	-1008000	-1	0	octane primal heuristic for pure {0;1}-problems based on Balas et al.
ofins	L	60000	0	0	primal heuristic for reoptimization, objective function induced neighborhood search
oneopt	i	-20000	1	0	1-opt heuristic which tries to improve setting of single integer variables
padm	L	70000	0	0	penalty alternating direction method primal heuristic
proximity	L	-2000000	-1	0	heuristic trying to improve the incumbent by an auxiliary proximity objective function
pscostdiving	d	-1002000	10	2	LP diving heuristic that chooses fixings w.r.t. the pseudo cost values
randrounding	r	-200	20	0	fast LP rounding heuristic
rens	L	-1100000	0	0	LNS exploring fractional neighborhood of relaxation's optimum
reoptsols	p	40000	0	0	primal heuristic updating solutions found in a previous optimization round
repair	L	-20	-1	0	tries to repair a primal infeasible solution
rins	L	-1101000	25	0	relaxation induced neighborhood search by Danna, Rothberg, and Le Pape
rootsoldiving	o	-1005000	20	5	LP diving heuristic that changes variable's objective values using root LP solution as guide
rounding	r	-1000	1	0	LP rounding heuristic with infeasibility recovering
shiftandpropagate	p	1000	0	0	Pre-root heuristic to expand an auxiliary branch-and-bound tree and apply propagation techniques

primal heuristic	type	priority	freq	freqoffset	description
shifting	r	-5000	10	0	LP rounding heuristic with infeasibility recovering also using continuous variables
simplerounding	r	-30	1	0	simple and fast LP rounding heuristic
subnlp	L	-2000010	1	0	primal heuristic that performs a local search in an NLP after fixing integer variables and presolving
trivial	t	10000	0	0	start heuristic which tries some trivial solutions
trivialnegation	p	39990	0	0	negate solution entries if an objective coefficient changes the sign, enters or leaves the objective.
trustregion	L	-1102010	-1	0	LNS heuristic for Benders' decomposition based on trust region methods
trysol	t	-3000010	1	0	try solution heuristic
twoopt	i	-20100	-1	0	primal heuristic to improve incumbent solution by flipping pairs of variables
undercover	L	-1110000	0	0	solves a sub-CIP determined by a set covering approach
vbounds	p	2500	0	0	LNS heuristic uses the variable lower and upper bounds to determine the search neighborhood
veclendiving	d	-1003100	10	4	LP diving heuristic that rounds variables with long column vectors
zirounding	r	-500	1	0	LP rounding heuristic as suggested by C. Wallace taking row slacks and bounds into account

See https://www.scipopt.org/doc/html/HEUR.php for a detailed description of the primal heuristic properties.

5.34.3.9 Propagators

propagator	propprio	freq	presolveprio	presolvetiming	description
rootredcost	10000000	1	0	always	reduced cost strengthening using root node reduced costs and the cutoff bound
dualfix	8000000	0	8000000	fast	roundable variables dual fixing
genvbounds	3000000	1	-2000000	fast	generalized variable bounds propagator
vbounds	3000000	1	-90000	medium exhaustive	propagates variable upper and lower bounds
pseudoobj	3000000	1	6000000	fast	pseudo objective function propagator
redcost	1000000	1	0	always	reduced cost strengthening propagator

propagator	propprio	freq	presolveprio	presolvetiming	description
probing	-100000d	-1	-100000	exhaustive	probing propagator on binary variables
symmetry	-1000000	1	-10000000	exhaustive	propagator for handling symmetry
obbt	-1000000d	0	0	always	optimization-based bound tightening propagator
nlobbt	-1100000d	-1	0	always	propagator template

See https://www.scipopt.org/doc/html/PROP.php for a detailed description of the propagator properties.

5.34.3.10 Separators

separator	priority	freq	bounddist	description
closecuts	1000000	-1	1	closecuts meta separator
rlt	10	0	1	reformulation-linearization-technique separator
disjunctive	10d	0	0	disjunctive cut separator
gauge	0	-1	1	gauge separator
interminor	0	-1	1	intersection cuts separator to ensure that 2x2 minors of X (= xx') have determinant 0
convexproj	0d	-1	1	separate at projection of point onto convex region
minor	0	10	1	separator to ensure that 2x2 principal minors of X - xx' are positive semi-definite
impliedbounds	-50	10	1	implied bounds separator
mixing	-50	10	1	mixing inequality separator
intobj	-100	-1	0	integer objective value separator
gomory	-1000	10	1	separator for Gomory mixed-integer and strong CG cuts from LP tableau rows
cgmip	-1000	-1	0	Chvatal-Gomory cuts via MIPs separator
aggregation	-3000	10	1	aggregation heuristic for complemented mixed integer rounding cuts and flowcover cuts
clique	-5000	0	0	clique separator of stable set relaxation
zerohalf	-6000	10	1	{0,1/2}-cuts separator
mcf	-10000	0	0	multi-commodity-flow network cut separator
eccuts	-13000	-1	1	separator for edge-concave functions
oddcycle	-15000	-1	1	odd cycle separator
strongcg	-100000	10	0	separator for strong CG cuts
gomorymi	-100000	10	0	separator for Gomory mixed-integer cuts
knapsackcover	-100000	10	0	separator for knapsack cover cuts
flowcover	-100000	10	0	separator for flowcover cuts
cmir	-100000	10	0	separator for cmir cuts
rapidlearning	-1200000	5	1	rapid learning heuristic and separator

See https://www.scipopt.org/doc/html/SEPA.php for a detailed description of the separator properties.

5.34.4 List of SCIP Options

SCIP supports a large set of options. In the following, we give a detailed list of all SCIP options.

5.34.4.1 gams

Option	Description	Default
gams/dumpsolutions	name of solutions index gdx file for writing all alternate solutions Range: string	
gams/dumpsolutionsmerged	name of gdx file for writing all alternate solutions into a single file Range: string	
gams/indicatorfile	name of GAMS options file that contains definitions on indicators Range: string	
gams/infbound	value to use for variable bounds that are missing or exceed numerics/infinity Range: [0, ∞]	∞
gams/interactive	command to be issued to the SCIP shell instead of issuing a solve command Range: string	
gams/mipstart	how to handle initial variable levels, see also section Starting point Range: {0, ..., 4}	2

5.34.4.2 gams/solvetrace

Option	Description	Default
gams/solvetrace/file	name of file where to write branch-and-bound trace information too Range: string	
gams/solvetrace/nodefreq	frequency in number of nodes when to write branch-and-bound trace information, 0 to disable Range: {0, ..., ∞}	100
gams/solvetrace/timefreq	frequency in seconds when to write branch-and-bound trace information, 0.0 to disable Range: [0, ∞]	5

5.34.4.3 branching

Option	Description	Default
branching/clamp	minimal relative distance of branching point to bounds when branching on a continuous variable Range: [0, 0.5]	0.2
branching/delaypscostupdate	should updating pseudo costs for continuous variables be delayed to the time after separation? Range: boolean	1

Option	Description	Default
branching/divingpscost	should pseudo costs be updated also in diving and probing mode? Range: boolean	1
branching/lpgainnormalize	strategy for normalization of LP gain when updating pseudocosts of continuous variables (divide by movement of 'l'p value, reduction in 'd'omain width, or reduction in domain width of 's'ibling) Range: d, l, s	s
branching/midpull	fraction by which to move branching point of a continuous variable towards the middle of the domain; a value of 1.0 leads to branching always in the middle of the domain Range: [0, 1]	0.75
branching/midpullreldomtrig	multiply midpull by relative domain width if the latter is below this value Range: [0, 1]	0.5
branching/preferbinary	should branching on binary variables be preferred? Range: boolean	0
Options for expert users		
branching/checksol	should LP solutions during strong branching with propagation be checked for feasibility? Range: boolean	1
branching/firstsbchild	child node to be regarded first during strong branching (only with propagation): 'u'p child, 'd'own child, 'h'istory-based, or 'a'utomatic Range: a, d, u, h	a
branching/forceallchildren	should all strong branching children be regarded even if one is detected to be infeasible? (only with propagation) Range: boolean	0
branching/roundsbsol	should LP solutions during strong branching with propagation be rounded? (only when checksbsol=TRUE) Range: boolean	1
branching/scorefac	branching score factor to weigh downward and upward gain prediction in sum score function Range: [0, 1]	0.167
branching/scorefunc	branching score function ('s'um, 'p'roduct, 'q'uotient) Range: s, p, q	p
branching/sumadjustscore	score adjustment near zero by adding epsilon (TRUE) or using maximum (FALSE) Range: boolean	0

5.34.4.4 branching/allfullstrong

Option	Description	Default
branching/allfullstrong/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/allfullstrong/maxdepth	maximal depth level, up to which branching rule <allfullstrong> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1

Option	Description	Default
branching/allfullstrong/priority	priority of branching rule <allfullstrong> Range: {-536870912, ..., 536870911}	-1000

5.34.4.5 branching/cloud

Option	Description	Default
branching/cloud/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/cloud/maxdepth	maximal depth level, up to which branching rule <cloud> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/cloud/maxdepthunion	maximum depth for the union Range: {0, ..., 65000}	65000
branching/cloud/maxpoints	maximum number of points for the cloud (-1 means no limit) Range: {-1, ..., ∞}	-1
branching/cloud/minsuccessrate	minimum success rate for the cloud Range: [0, 1]	0
branching/cloud/minsuccessunion	minimum success rate for the union Range: [0, 1]	0
branching/cloud/onlyF2	should only F2 be used? Range: boolean	0
branching/cloud/priority	priority of branching rule <cloud> Range: {-536870912, ..., 536870911}	0
branching/cloud/usecloud	should a cloud of points be used? Range: boolean	1
branching/cloud/useunion	should the union of candidates be used? Range: boolean	0

5.34.4.6 branching/distribution

Option	Description	Default
branching/distribution/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/distribution/maxdepth	maximal depth level, up to which branching rule <distribution> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/distribution/priority	priority of branching rule <distribution> Range: {-536870912, ..., 536870911}	0
Options for expert users		
branching/distribution/onlyactiverows	should only rows which are active at the current node be considered? Range: boolean	0

Option	Description	Default
branching/distribution/scoreparam	the score;largest 'd'ifference, 'l'owest cumulative probability,'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w') Range: d, h, l, v, w	v
branching/distribution/weightedscore	should the branching score weigh up- and down-scores of a variable Range: boolean	0

5.34.4.7 branching/fullstrong

Option	Description	Default
branching/fullstrong/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/fullstrong/maxdepth	maximal depth level, up to which branching rule <fullstrong> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/fullstrong/priority	priority of branching rule <fullstrong> Range: {-536870912, ..., 536870911}	0
Options for expert users		
branching/fullstrong/forcestrongbranch	should strong branching be applied even if there is just a single candidate? Range: boolean	0
branching/fullstrong/maxproprounds	maximum number of propagation rounds to be performed during strong branching before solving the LP (-1: no limit, -2: parameter settings) Range: {-3, ..., ∞}	-2
branching/fullstrong/probingbounds	should valid bounds be identified in a probing-like fashion during strong branching (only with propagation)? Range: boolean	1
branching/fullstrong/reevalage	number of intermediate LPs solved to trigger reevaluation of strong branching value for a variable that was already evaluated at the current node Range: {0, ..., ∞}	10

5.34.4.8 branching/inference

Option	Description	Default
branching/inference/conflictprio	priority value for using conflict weights in lex. order Range: {0, ..., ∞}	1
branching/inference/cutoffprio	priority value for using cutoff weights in lex. order Range: {0, ..., ∞}	1

Option	Description	Default
branching/inference/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/inference/maxdepth	maximal depth level, up to which branching rule <inference> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/inference/priority	priority of branching rule <inference> Range: {-536870912, ..., 536870911}	1000
branching/inference/useweightedsum	should a weighted sum of inference, conflict and cutoff weights be used? Range: boolean	1
Options for expert users		
branching/inference/conflictweight	weight in score calculations for conflict score Range: [0, ∞]	1000
branching/inference/cutoffweight	weight in score calculations for cutoff score Range: [0, ∞]	1
branching/inference/fractionals	should branching on LP solution be restricted to the fractional variables? Range: boolean	1
branching/inference/inferenceweight	weight in score calculations for inference score Range: real	1
branching/inference/reliablescore	weight in score calculations for conflict score Range: [0, ∞]	0.001

5.34.4.9 branching/leastinf

Option	Description	Default
branching/leastinf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/leastinf/maxdepth	maximal depth level, up to which branching rule <leastinf> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/leastinf/priority	priority of branching rule <leastinf> Range: {-536870912, ..., 536870911}	50

5.34.4.10 branching/lookahead

Option	Description	Default
branching/lookahead/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1

Option	Description	Default
branching/lookahead/maxdepth	maximal depth level, up to which branching rule <lookahead> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/lookahead/priority	priority of branching rule <lookahead> Range: {-536870912, ..., 536870911}	0
Options for expert users		
branching/lookahead/abbreviated	toggles the abbreviated LAB. Range: boolean	1
branching/lookahead/abbrevpseudo	if abbreviated: Use pseudo costs to estimate the score of a candidate. Range: boolean	0
branching/lookahead/addbinconsrow	should binary constraints be added as rows to the base LP? (0: no, 1: separate, 2: as initial rows) Range: {0, ..., 2}	0
branching/lookahead/addclique	add binary constraints with two variables found at the root node also as a clique Range: boolean	0
branching/lookahead/addnonviocons	should binary constraints, that are not violated by the base LP, be collected and added? Range: boolean	0
branching/lookahead/applychildbounds	should bounds known for child nodes be applied? Range: boolean	0
branching/lookahead/deeperscoringfunction	scoring function to be used at deeper levels Range: d, f, s, w, l, c, r, x	x
branching/lookahead/enforcemaxdomreds	should the maximum number of domain reductions maxnviolateddomreds be enforced? Range: boolean	0
branching/lookahead/filterbymaxgain	should lookahead branching only be applied if the max gain in level 1 is not uniquely that of the best candidate? Range: boolean	0
branching/lookahead/level2avgscore	should the average score be used for uninitialized scores in level 2? Range: boolean	0
branching/lookahead/level2zeroscore	should uninitialized scores in level 2 be set to 0? Range: boolean	0
branching/lookahead/maxncands	if abbreviated: The max number of candidates to consider at the node. Range: {1, ..., ∞}	4
branching/lookahead/maxndeepercands	if abbreviated: The max number of candidates to consider per deeper node. Range: {0, ..., ∞}	2
branching/lookahead/maxnviolatedbincons	how many binary constraints that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 for unrestricted] Range: {0, ..., ∞}	0

Option	Description	Default
branching/lookahead/maxnviolatedcons	how many constraints that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 for unrestricted] Range: {0, ..., ∞}	1
branching/lookahead/maxnviolateddomreds	how many domain reductions that are violated by the base lp solution should be gathered until the rule is stopped and they are added? [0 for unrestricted] Range: {0, ..., ∞}	1
branching/lookahead/maxproprounds	maximum number of propagation rounds to perform at each temporary node (-1: unlimited, 0: SCIP default) Range: {-1, ..., ∞}	0
branching/lookahead/mergedomainreductions	should domain reductions of feasible siblings should be merged? Range: boolean	0
branching/lookahead/minweight	if scoringfunction is 's', this value is used to weight the min of the gains of two child problems in the convex combination Range: [0, ∞]	0.8
branching/lookahead/onlyvioldomreds	should only domain reductions that violate the LP solution be applied? Range: boolean	0
branching/lookahead/prefersimplebounds	should domain reductions only be applied if there are simple bound changes? Range: boolean	0
branching/lookahead/propagate	should domain propagation be executed before each temporary node is solved? Range: boolean	1
branching/lookahead/recursiondepth	the max depth of LAB. Range: {1, ..., ∞}	2
branching/lookahead/reevalage	max number of LPs solved after which a previous prob branching results are recalculated Range: {0, ..., ∞}	10
branching/lookahead/reevalagefsb	max number of LPs solved after which a previous FSB scoring results are recalculated Range: {0, ..., ∞}	10
branching/lookahead/reusebasis	if abbreviated: Should the information gathered to obtain the best candidates be reused? Range: boolean	1
branching/lookahead/scoringfunction	scoring function to be used at the base level Range: d, f, s, w, p, l, c, r, a	a
branching/lookahead/scoringscoringfunction	scoring function to be used during FSB scoring Range: d, f, s, w, l, c, r	d
branching/lookahead/storeunviolatedsol	if only non violating constraints are added, should the branching decision be stored till the next call? Range: boolean	1

Option	Description	Default
branching/lookahead/updatebranchingresults	should branching results (and scores) be updated w.r.t. proven dual bounds? Range: boolean	0
branching/lookahead/usedomainreduction	should domain reductions be collected and applied? Range: boolean	1
branching/lookahead/useimpliedbincons	should binary constraints be collected and applied? Range: boolean	0
branching/lookahead/uselevel2data	should branching data generated at depth level 2 be stored for re-using it? Range: boolean	1
branching/lookahead/worsefactor	if the FSB score is of a candidate is worse than the best by this factor, skip this candidate (-1: disable) Range: [-1, ∞]	-1

5.34.4.11 branching/mostinf

Option	Description	Default
branching/mostinf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/mostinf/maxdepth	maximal depth level, up to which branching rule <mostinf> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/mostinf/priority	priority of branching rule <mostinf> Range: {-536870912, ..., 536870911}	100

5.34.4.12 branching/multaggr

Option	Description	Default
branching/multaggr/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/multaggr/maxdepth	maximal depth level, up to which branching rule <multaggr> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/multaggr/priority	priority of branching rule <multaggr> Range: {-536870912, ..., 536870911}	0
Options for expert users		
branching/multaggr/maxproprounds	maximum number of propagation rounds to be performed during multaggr branching before solving the LP (-1: no limit, -2: parameter settings) Range: {-2, ..., ∞}	0

Option	Description	Default
branching/multaggr/probingbounds	should valid bounds be identified in a probing-like fashion during multaggr branching (only with propagation)? Range: boolean	1
branching/multaggr/reevalage	number of intermediate LPs solved to trigger reevaluation of strong branching value for a variable that was already evaluated at the current node Range: {0, ..., ∞}	0

5.34.4.13 branching/nodereopt

Option	Description	Default
branching/nodereopt/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/nodereopt/maxdepth	maximal depth level, up to which branching rule <nodereopt> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/nodereopt/priority	priority of branching rule <nodereopt> Range: {-536870912, ..., 536870911}	-9000000

5.34.4.14 branching/pscost

Option	Description	Default
branching/pscost/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/pscost/maxdepth	maximal depth level, up to which branching rule <pscost> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/pscost/narymaxdepth	maximal depth where to do n-ary branching, -1 to turn off Range: {-1, ..., ∞}	-1
branching/pscost/naryminwidth	minimal domain width in children when doing n-ary branching, relative to global bounds Range: [0, 1]	0.001
branching/pscost/narywidthfactor	factor of domain width in n-ary branching when creating nodes with increasing distance from branching value Range: [1, ∞]	2
branching/pscost/nchildren	number of children to create in n-ary branching Range: {2, ..., ∞}	2
branching/pscost/priority	priority of branching rule <pscost> Range: {-536870912, ..., 536870911}	2000

Option	Description	Default
branching/pscost/strategy	strategy for utilizing pseudo-costs of external branching candidates (multiply as in pseudo costs 'u'pdate rule, or by 'd'omain reduction, or by domain reduction of 's'ibling, or by 'v'ariable score) Range: d, s, u, v	u
Options for expert users		
branching/pscost/maxscoreweight	weight for maximum of scores of a branching candidate when building weighted sum of min/max/sum of scores Range: real	1.3
branching/pscost/minscoreweight	weight for minimum of scores of a branching candidate when building weighted sum of min/max/sum of scores Range: real	0.8
branching/pscost/sumscoreweight	weight for sum of scores of a branching candidate when building weighted sum of min/max/sum of scores Range: real	0.1

5.34.4.15 branching/random

Option	Description	Default
branching/random/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/random/maxdepth	maximal depth level, up to which branching rule <random> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/random/priority	priority of branching rule <random> Range: {-536870912, ..., 536870911}	-100000
branching/random/seed	initial random seed value Range: {0, ..., ∞}	41

5.34.4.16 branching/relpscost

Option	Description	Default
branching/relpscost/initcand	maximal number of candidates initialized with strong branching per node Range: {0, ..., ∞}	100
branching/relpscost/inititer	iteration limit for strong branching initializations of pseudo cost entries (0: auto) Range: {0, ..., ∞}	0
branching/relpscost/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1

Option	Description	Default
branching/relpscost/maxdepth	maximal depth level, up to which branching rule <relpscost> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/relpscost/priority	priority of branching rule <relpscost> Range: {-536870912, ..., 536870911}	10000
branching/relpscost/sbiterofs	additional number of allowed strong branching LP iterations Range: {0, ..., ∞}	100000
branching/relpscost/sbiterquot	maximal fraction of strong branching LP iterations compared to node relaxation LP iterations Range: [0, ∞]	0.5
Options for expert users		
branching/relpscost/confidencelevel	the confidence level for statistical methods, between 0 (Min) and 4 (Max). Range: {0, ..., 4}	2
branching/relpscost/conflictlengthweight	weight in score calculations for conflict length score Range: real	0
branching/relpscost/conflictweight	weight in score calculations for conflict score Range: real	0.01
branching/relpscost/cutoffweight	weight in score calculations for cutoff score Range: real	0.0001
branching/relpscost/degeneracyaware	should degeneracy be taken into account to update weights and skip strong branching? (0: off, 1: after root, 2: always) Range: {0, ..., 2}	1
branching/relpscost/dynamicweights	should the weights of the branching rule be adjusted dynamically during solving based on objective and infeasible leaf counters? Range: boolean	1
branching/relpscost/filtercandssym	Use symmetry to filter branching candidates? Range: boolean	0
branching/relpscost/higherrortol	high relative error tolerance for reliability Range: [0, ∞]	1
branching/relpscost/inferenceweight	weight in score calculations for inference score Range: real	0.0001
branching/relpscost/lowerrortol	low relative error tolerance for reliability Range: [0, ∞]	0.05
branching/relpscost/maxbdchgs	maximal number of bound tightenings before the node is reevaluated (-1: unlimited) Range: {-1, ..., ∞}	5
branching/relpscost/maxlookahead	maximal number of further variables evaluated without better score Range: {1, ..., ∞}	9
branching/relpscost/maxproprounds	maximum number of propagation rounds to be performed during strong branching before solving the LP (-1: no limit, -2: parameter settings) Range: {-2, ..., ∞}	-2

Option	Description	Default
branching/relpscost/maxreliable	maximal value for minimum pseudo cost size to regard pseudo cost value as reliable Range: [0, ∞]	5
branching/relpscost/minreliable	minimal value for minimum pseudo cost size to regard pseudo cost value as reliable Range: [0, ∞]	1
branching/relpscost/nlscoreweight	weight in score calculations for nlcount score Range: real	0.1
branching/relpscost/probingbounds	should valid bounds be identified in a probing-like fashion during strong branching (only with propagation)? Range: boolean	1
branching/relpscost/pscostweight	weight in score calculations for pseudo cost score Range: real	1
branching/relpscost/randinitorder	should candidates be initialized in random-ized order? Range: boolean	0
branching/relpscost/skipbadinitcands	should branching rule skip candidates that have a low probability to be better than the best strong-branching or pseudo-candidate? Range: boolean	1
branching/relpscost/startrandseed	start seed for random number generation Range: {0, ..., ∞}	5
branching/relpscost/storesemiinitcosts	should strong branching result be considered for pseudo costs if the other direction was infeasible? Range: boolean	0
branching/relpscost/transsympscost	Transfer pscost information to symmetric variables? Range: boolean	0
branching/relpscost/usedynamicconfidence	should the confidence level be adjusted dy-namically? Range: boolean	0
branching/relpscost/usehyptestforreliability	should the strong branching decision be based on a hypothesis test? Range: boolean	0
branching/relpscost/userelerrorreliability	should reliability be based on relative errors? Range: boolean	0
branching/relpscost/usesblocalinfo	should the scoring function use only local cutoff and inference information obtained for strong branching candidates? Range: boolean	0
branching/relpscost/usesmallweightsitlim	should smaller weights be used for pseudo cost updates after hitting the LP iteration limit? Range: boolean	0

5.34.4.17 branching/treemodel

Option	Description	Default
branching/treemodel/enable	should candidate branching variables be scored using the Treemodel branching rules? Range: boolean	0
branching/treemodel/height	estimated tree height at which we switch from using the low rule to the high rule Range: {0, ..., ∞}	10
branching/treemodel/highrule	scoring function to use at nodes predicted to be high in the tree ('d'efault, 's'vts, 'r'atio, 't'ree sample) Range: d, s, r, t	r
branching/treemodel/lowrule	scoring function to use at nodes predicted to be low in the tree ('d'efault, 's'vts, 'r'atio, 't'ree sample) Range: d, s, r, t	r
Options for expert users		
branching/treemodel/fallbackinf	which method should be used as a fallback if the tree size estimates are infinite? ('d'efault, 'r'atio) Range: d, r	r
branching/treemodel/fallbacknoprim	which method should be used as a fallback if there is no primal bound available? ('d'efault, 'r'atio) Range: d, r	r
branching/treemodel/filterhigh	should dominated candidates be filtered before using the high scoring function? ('a'uto, 't'rue, 'f'alse) Range: a, t, f	a
branching/treemodel/filterlow	should dominated candidates be filtered before using the low scoring function? ('a'uto, 't'rue, 'f'alse) Range: a, t, f	a
branching/treemodel/maxfpiter	maximum number of fixed-point iterations when computing the ratio Range: {1, ..., ∞}	24
branching/treemodel/maxsvtsheight	maximum height to compute the SVTS score exactly before approximating Range: {0, ..., ∞}	100
branching/treemodel/smallpscost	threshold at which pseudocosts are considered small, making hybrid scores more likely to be the deciding factor in branching Range: [0, ∞]	0.1

5.34.4.18 branching/vanillafullstrong

Option	Description	Default
branching/vanillafullstrong/idempotent	should strong branching side-effects be prevented (e.g., domain changes, stat updates etc.)? Range: boolean	0
branching/vanillafullstrong/integralcands	should integral variables in the current LP solution be considered as branching candidates? Range: boolean	0

Option	Description	Default
branching/vanillafullstrong/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying branching rule (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
branching/vanillafullstrong/maxdepth	maximal depth level, up to which branching rule <vanillafullstrong> should be used (-1 for no limit) Range: {-1, ..., 65534}	-1
branching/vanillafullstrong/priority	priority of branching rule <vanillafullstrong> Range: {-536870912, ..., 536870911}	-2000
Options for expert users		
branching/vanillafullstrong/collectscores	should strong branching scores be collected? Range: boolean	0
branching/vanillafullstrong/donotbranch	should candidates only be scored, but no branching be performed? Range: boolean	0
branching/vanillafullstrong/scoreall	should strong branching scores be computed for all candidates, or can we early stop when a variable has infinite score? Range: boolean	0

5.34.4.19 conflict

Option	Description	Default
conflict/conflictgraphweight	the weight the VSIDS score is weight by updating the VSIDS for a variable if it is part of a conflict graph Range: [0, 1]	1
conflict/conflictweight	the weight the VSIDS score is weight by updating the VSIDS for a variable if it is part of a conflict Range: [0, 1]	0
conflict/enable	should conflict analysis be enabled? Range: boolean	1
conflict/preferbinary	should binary conflicts be preferred? Range: boolean	0
conflict/restartfac	factor to increase restartnum with after each restart Range: [0, ∞]	1.5
conflict/restartnum	number of successful conflict analysis calls that trigger a restart (0: disable conflict restarts) Range: {0, ..., ∞}	0
conflict/sepaaltproofs	apply cut generating functions to construct alternative proofs Range: boolean	0
conflict/useboundlp	should bound exceeding LP conflict analysis be used? ('o'ff, 'c'onflict graph, 'd'ual ray, 'b'oth conflict graph and dual ray) Range: o, c, d, b	b

Option	Description	Default
conflict/useinflp	should infeasible LP conflict analysis be used? ('o'ff, 'c'onflict graph, 'd'ual ray, 'b'oth conflict graph and dual ray) Range: o, c, d, b	b
conflict/useprop	should propagation conflict analysis be used? Range: boolean	1
conflict/usepseudo	should pseudo solution conflict analysis be used? Range: boolean	1
conflict/usesb	should infeasible/bound exceeding strong branching conflict analysis be used? Range: boolean	1
Options for expert users		
conflict/allowlocal	should conflict constraints be generated that are only valid locally? Range: boolean	1
conflict/cleanboundexceedings	should conflicts based on an old cutoff bound be removed from the conflict pool after improving the primal bound? Range: boolean	1
conflict/downlockscorefac	score factor for down locks in bound relaxation heuristic Range: real	0
conflict/dynamic	should the conflict constraints be subject to aging? Range: boolean	1
conflict/fuiplevels	number of depth levels up to which first UIP's are used in conflict analysis (-1: use All-FirstUIP rule) Range: {-1, ..., ∞}	-1
conflict/fullshortenconflict	try to shorten the whole conflict set or terminate early (depending on the 'maxvarsdetectimpliedbounds' parameter) Range: boolean	1
conflict/ignorerelaxedbd	should relaxed bounds be ignored? Range: boolean	0
conflict/interconss	maximal number of intermediate conflict constraints generated in conflict graph (-1: use every intermediate constraint) Range: {-1, ..., ∞}	-1
conflict/keepreprop	should constraints be kept for repropagation even if they are too long? Range: boolean	1
conflict/lpiterations	maximal number of LP iterations in each LP resolving loop (-1: no limit) Range: {-1, ..., ∞}	10
conflict/maxconss	maximal number of conflict constraints accepted at an infeasible node (-1: use all generated conflict constraints) Range: {-1, ..., ∞}	10
conflict/maxlploops	maximal number of LP resolving loops during conflict analysis (-1: no limit) Range: {-1, ..., ∞}	2

Option	Description	Default
conflict/maxstoresize	maximal size of conflict store (-1: auto, 0: disable storage) Range: {-1, ..., ∞}	10000
conflict/maxvarsdetectimpliedbounds	maximal number of variables to try to detect global bound implications and shorten the whole conflict set (0: disabled) Range: {0, ..., ∞}	250
conflict/maxvarsfac	maximal fraction of variables involved in a conflict constraint Range: [0, ∞]	0.15
conflict/minimprove	minimal improvement of primal bound to remove conflicts based on a previous incumbent Range: [0, 1]	0.05
conflict/minmaxvars	minimal absolute maximum of variables involved in a conflict constraint Range: {0, ..., ∞}	0
conflict/prefinfproof	prefer infeasibility proof to boundexceeding proof Range: boolean	1
conflict/proofscorefac	score factor for impact on acticity in bound relaxation heuristic Range: real	1
conflict/reconvlevels	number of depth levels up to which UIP reconvergence constraints are generated (-1: generate reconvergence constraints in all depth levels) Range: {-1, ..., ∞}	-1
conflict/removable	should the conflict's relaxations be subject to LP aging and cleanup? Range: boolean	1
conflict/repropagate	should earlier nodes be repropagated in order to replace branching decisions by deductions? Range: boolean	1
conflict/scorefac	factor to decrease importance of variables' earlier conflict scores Range: [1e-06, 1]	0.98
conflict/separate	should the conflict constraints be separated? Range: boolean	1
conflict/settlelocal	should conflict constraints be attached only to the local subtree where they can be useful? Range: boolean	0
conflict/uplockscorefac	score factor for up locks in bound relaxation heuristic Range: real	0
conflict/uselocalrows	use local rows to construct infeasibility proofs Range: boolean	1
conflict/weightrepropdepth	weight of the repropagation depth of a conflict used in score calculation Range: [0, 1]	0.1
conflict/weightsize	weight of the size of a conflict used in score calculation Range: [0, 1]	0.001
conflict/weightvaliddepth	weight of the valid depth of a conflict used in score calculation Range: [0, 1]	1

Option	Description	Default

5.34.4.20 conflict/bounddisjunction

Option	Description	Default
conflict/bounddisjunction/continuousfrac	maximal percantage of continuous variables within a conflict Range: [0, 1]	0.4
Options for expert users		
conflict/bounddisjunction/priority	priority of conflict handler <bounddisjunction> Range: {-2147483648, ..., ∞}	-3000000

5.34.4.21 conflict/graph

Option	Description	Default
Options for expert users		
conflict/graph/depthscorefac	score factor for depth level in bound relaxation heuristic Range: real	1

5.34.4.22 conflict/indicatorconflict

Option	Description	Default
Options for expert users		
conflict/indicatorconflict/priority	priority of conflict handler <indicatorconflict> Range: {-2147483648, ..., ∞}	200000

5.34.4.23 conflict/linear

Option	Description	Default
Options for expert users		
conflict/linear/priority	priority of conflict handler <linear> Range: {-2147483648, ..., ∞}	-1000000

5.34.4.24 conflict/logicor

Option	Description	Default
Options for expert users		
conflict/logicor/priority	priority of conflict handler <logicor> Range: {-2147483648, ..., ∞}	800000

5.34.4.25 conflict/setppc

Option	Description	Default
Options for expert users		
conflict/setppc/priority	priority of conflict handler <setppc> Range: {-2147483648, ..., ∞}	700000

5.34.4.26 constraints

Option	Description	Default
Options for expert users		
constraints/agelimit	maximum age an unnecessary constraint can reach before it is deleted (0: dynamic, -1: keep all constraints) Range: {-1, ..., ∞}	0
constraints/disableenfops	should enforcement of pseudo solution be disabled? Range: boolean	0
constraints/obsoleteage	age of a constraint after which it is marked obsolete (0: dynamic, -1 do not mark constraints obsolete) Range: {-1, ..., ∞}	-1

5.34.4.27 constraints/SOS1

Option	Description	Default
constraints/SOS1/branchnonzeros	Branch on SOS constraint with most number of nonzeros? Range: boolean	0
constraints/SOS1/branchsos	Use SOS1 branching in enforcing (otherwise leave decision to branching rules)? This value can only be set to false if all SOS1 variables are binary Range: boolean	1
constraints/SOS1/branchweight	Branch on SOS cons. with highest nonzero-variable weight for branching (needs branch-nonzeros = false)? Range: boolean	0
constraints/SOS1/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/SOS1/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
constraints/SOS1/addbdsfeas	minimal feasibility value for bound inequalities in order to be added to the branching node Range: real	1
constraints/SOS1/addcomps	if TRUE then add complementarity constraints to the branching nodes (can be used in combination with neighborhood or bipartite branching) Range: boolean	0
constraints/SOS1/addcompsdepth	only add complementarity constraints to branching nodes for predefined depth (-1: no limit) Range: {-1, ..., ∞}	30

Option	Description	Default
constraints/SOS1/addcompsfeas	minimal feasibility value for complementarity constraints in order to be added to the branching node Range: real	-0.6
constraints/SOS1/addextendedbds	should added complementarity constraints be extended to SOS1 constraints to get tighter bound inequalities Range: boolean	1
constraints/SOS1/autocutsfromsos1	if TRUE then automatically switch to separating initial SOS1 constraints if the SOS1 constraints do not overlap Range: boolean	1
constraints/SOS1/autosos1branch	if TRUE then automatically switch to SOS1 branching if the SOS1 constraints do not overlap Range: boolean	1
constraints/SOS1/boundcutsdepth	node depth of separating bound cuts (-1: no limit) Range: {-1, ..., ∞}	40
constraints/SOS1/boundcutsfreq	frequency for separating bound cuts; zero means to separate only in the root node Range: {-1, ..., 65534}	10
constraints/SOS1/boundcutsfromgraph	if TRUE separate bound inequalities from the conflict graph Range: boolean	1
constraints/SOS1/boundcutsfromsos1	if TRUE separate bound inequalities from initial SOS1 constraints Range: boolean	0
constraints/SOS1/branchingrule	which branching rule should be applied ? ('n': neighborhood, 'b': bipartite, 's': SOS1/clique) (note: in some cases an automatic switching to SOS1 branching is possible) Range: n, b, s	n
constraints/SOS1/conflictprop	whether to use conflict graph propagation Range: boolean	1
constraints/SOS1/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/SOS1/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/SOS1/depthimplanalysis	number of recursive calls of implication graph analysis (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/SOS1/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/SOS1/fixnonzero	if neighborhood branching is used, then fix the branching variable (if positive in sign) to the value of the feasibility tolerance Range: boolean	0

Option	Description	Default
constraints/SOS1/implcutsdepth	node depth of separating implied bound cuts (-1: no limit) Range: {-1, ..., ∞}	40
constraints/SOS1/implcutsfreq	frequency for separating implied bound cuts; zero means to separate only in the root node Range: {-1, ..., 65534}	0
constraints/SOS1/implprop	whether to use implication graph propagation Range: boolean	1
constraints/SOS1/maxaddcomps	maximal number of complementarity constraints added per branching node (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/SOS1/maxboundcuts	maximal number of bound cuts separated per branching node Range: {0, ..., ∞}	50
constraints/SOS1/maxboundcutsroot	maximal number of bound cuts separated per iteration in the root node Range: {0, ..., ∞}	150
constraints/SOS1/maxextensions	maximal number of extensions that will be computed for each SOS1 constraint (-1: no limit) Range: {-1, ..., ∞}	1
constraints/SOS1/maximplcuts	maximal number of implied bound cuts separated per branching node Range: {0, ..., ∞}	50
constraints/SOS1/maximplcutsroot	maximal number of implied bound cuts separated per iteration in the root node Range: {0, ..., ∞}	150
constraints/SOS1/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/SOS1/maxsosadjacency	do not create an adjacency matrix if number of SOS1 variables is larger than predefined value (-1: no limit) Range: {-1, ..., ∞}	10000
constraints/SOS1/maxtightenbds	maximal number of bound tightening rounds per presolving round (-1: no limit) Range: {-1, ..., ∞}	5
constraints/SOS1/nstrongiter	maximal number LP iterations to perform for each strong branching round (-2: auto, -1: no limit) Range: {-2, ..., ∞}	10000
constraints/SOS1/nstrongrounds	maximal number of strong branching rounds to perform for each node (-1: auto); only available for neighborhood and bipartite branching Range: {-1, ..., ∞}	0
constraints/SOS1/perfimplanalysis	if TRUE then perform implication graph analysis (might add additional SOS1 constraints) Range: boolean	0
constraints/SOS1/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8

Option	Description	Default
constraints/SOS1/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/SOS1/sosconsprop	whether to use SOS1 constraint propagation Range: boolean	0
constraints/SOS1/strthenboundcuts	if TRUE then bound cuts are strengthened in case bound variables are available Range: boolean	1

5.34.4.28 constraints/SOS2

Option	Description	Default
constraints/SOS2/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/SOS2/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/SOS2/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/SOS2/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/SOS2/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/SOS2/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/SOS2/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4
constraints/SOS2/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.29 constraints/and

Option	Description	Default
constraints/and/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1

Option	Description	Default
constraints/and/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
Options for expert users		
constraints/and/aggrlinearization	should an aggregated linearization be used? Range: boolean	0
constraints/and/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/and/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/and/dualpresolving	should dual presolving be performed? Range: boolean	1
constraints/and/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/and/enforcecuts	should cuts be separated during LP enforcing? Range: boolean	1
constraints/and/linearize	should the AND-constraint get linearized and removed (in presolving)? Range: boolean	0
constraints/and/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/and/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/and/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	20
constraints/and/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/and/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/and/upgraderesultant	should all binary resultant variables be upgraded to implicit binary variables? Range: boolean	1

5.34.4.30 constraints/bounddisjunction

Option	Description	Default
constraints/bounddisjunction/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1

Option	Description	Default
constraints/bounddisjunction/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/bounddisjunction/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/bounddisjunction/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/bounddisjunction/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/bounddisjunction/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/bounddisjunction/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4
constraints/bounddisjunction/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.31 constraints/components

Option	Description	Default
constraints/components/intfactor	the weight of an integer variable compared to binary variables Range: [0, ∞]	1
constraints/components/maxdepth	maximum depth of a node to run components detection (-1: disable component detection during solving) Range: {-1, ..., ∞}	-1
constraints/components/nodelimit	maximum number of nodes to be solved in subproblems during presolving Range: {-1, ..., ∞}	10000
constraints/components/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/components/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/components/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	1

Option	Description	Default
constraints/components/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/components/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/components/feastolfactor	factor to increase the feasibility tolerance of the main SCIP in all sub-SCIPs, default value 1.0 Range: [0, 1e+06]	1
constraints/components/maxintvars	maximum number of integer (or binary) variables to solve a subproblem during presolving (-1: unlimited) Range: {-1, ..., ∞}	500
constraints/components/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/components/minrelsize	minimum relative size (in terms of variables) to solve a component individually during branch-and-bound Range: [0, 1]	0.1
constraints/components/minsize	minimum absolute size (in terms of variables) to solve a component individually during branch-and-bound Range: {0, ..., ∞}	50
constraints/components/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	32
constraints/components/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.32 constraints/indicator

Option	Description	Default
constraints/indicator/maxsepacuts	maximal number of cuts separated per separation round Range: {0, ..., ∞}	100
constraints/indicator/maxsepacutsroot	maximal number of cuts separated per separation round in the root node Range: {0, ..., ∞}	2000
constraints/indicator/maxsepanonviolated	maximal number of separated non violated IISs, before separation is stopped Range: {0, ..., ∞}	3
constraints/indicator/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/indicator/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10

Option	Description	Default
Options for expert users		
constraints/indicator/addcoupling	Add coupling constraints or rows if big-M is small enough? Range: boolean	1
constraints/indicator/addcouplingcons	Add initial variable upper bound constraints, if 'addcoupling' is true? Range: boolean	0
constraints/indicator/addopposite	Add opposite inequality in nodes in which the binary variable has been fixed to 0? Range: boolean	0
constraints/indicator/branchindicators	Branch on indicator constraints in enforcing? Range: boolean	0
constraints/indicator/conflictsupgrade	Try to upgrade bounddisjunction conflicts by replacing slack variables? Range: boolean	0
constraints/indicator/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/indicator/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/indicator/dualreductions	Should dual reduction steps be performed? Range: boolean	1
constraints/indicator/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/indicator/enforcecuts	In enforcing try to generate cuts (only if sepaalternativelp is true)? Range: boolean	0
constraints/indicator/forcerestart	Force restart if absolute gap is 1 or enough binary variables have been fixed? Range: boolean	0
constraints/indicator/generatebilinear	Do not generate indicator constraint, but a bilinear constraint instead? Range: boolean	0
constraints/indicator/genlogicor	Generate logicor constraints instead of cuts? Range: boolean	0
constraints/indicator/maxconditionaltlp	maximum estimated condition of the solution basis matrix of the alternative LP to be trustworthy (0.0 to disable check) Range: [0, ∞]	0
constraints/indicator/maxcouplingvalue	maximum coefficient for binary variable in coupling constraint Range: [0, 1e+09]	10000
constraints/indicator/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
constraints/indicator/nolinconscont	Decompose problem (do not generate linear constraint if all variables are continuous)? Range: boolean	0
constraints/indicator/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4
constraints/indicator/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/indicator/removeindicators	Remove indicator constraint if corresponding variable bound constraint has been added? Range: boolean	0
constraints/indicator/restartfrac	fraction of binary variables that need to be fixed before restart occurs (in forcerestart) Range: [0, 1]	0.9
constraints/indicator/scaleslackvar	Scale slack variable coefficient at construction time? Range: boolean	0
constraints/indicator/sepaalternativelp	Separate using the alternative LP? Range: boolean	0
constraints/indicator/sepacouplingcuts	Should the coupling inequalities be separated dynamically? Range: boolean	1
constraints/indicator/sepacouplinglocal	Allow to use local bounds in order to separate coupling inequalities? Range: boolean	0
constraints/indicator/sepacouplingvalue	maximum coefficient for binary variable in separated coupling constraint Range: [0, 1e+09]	10000
constraints/indicator/sepaperspective	Separate cuts based on perspective formulation? Range: boolean	0
constraints/indicator/sepapersplocal	Allow to use local bounds in order to separate perspective cuts? Range: boolean	1
constraints/indicator/trysolfromcover	Try to construct a feasible solution from a cover? Range: boolean	0
constraints/indicator/trysolutions	Try to make solutions feasible by setting indicator variables? Range: boolean	1
constraints/indicator/updatebounds	Update bounds of original variables for separation? Range: boolean	0
constraints/indicator/upgradelinear	Try to upgrade linear constraints to indicator constraints? Range: boolean	0

Option	Description	Default
constraints/indicator/useobjectivecut	Use objective cut with current best solution to alternative LP? Range: boolean	0
constraints/indicator/useotherconss	Collect other constraints to alternative LP? Range: boolean	0

5.34.4.33 constraints/integral

Option	Description	Default
constraints/integral/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
constraints/integral/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/integral/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/integral/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/integral/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/integral/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	0
constraints/integral/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/integral/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.34 constraints/knapsack

Option	Description	Default
constraints/knapsack/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	5
constraints/knapsack/maxroundsroot	maximal number of separation rounds per node in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
constraints/knapsack/maxsepacuts	maximal number of cuts separated per separation round Range: {0, ..., ∞}	50

Option	Description	Default
constraints/knapsack/maxsepacutsroot	maximal number of cuts separated per separation round in the root node Range: {0, ..., ∞}	200
constraints/knapsack/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/knapsack/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/knapsack/cliqueextractfactor	lower clique size limit for greedy clique extraction algorithm (relative to largest clique) Range: [0, 1]	0.5
constraints/knapsack/clqpartupdatefac	factor on the growth of global cliques to decide when to update a previous (negated) clique partition (used only if updatecliquepartitions is set to TRUE) Range: [1, 10]	1.5
constraints/knapsack/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/knapsack/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/knapsack/detectcutoffbound	should presolving try to detect constraints parallel to the objective function defining an upper bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/knapsack/detectlowerbound	should presolving try to detect constraints parallel to the objective function defining a lower bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/knapsack/disaggregation	should disaggregation of knapsack constraints be allowed in preprocessing? Range: boolean	1
constraints/knapsack/dualpresolving	should dual presolving steps be performed? Range: boolean	1
constraints/knapsack/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/knapsack/maxcardbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for separating knapsack cuts Range: [0, 1]	0
constraints/knapsack/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
constraints/knapsack/negatedclique	should negated clique information be used in solving process Range: boolean	1
constraints/knapsack/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/knapsack/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/knapsack/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/knapsack/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/knapsack/sepacardfreq	multiplier on separation frequency, how often knapsack cuts are separated (-1: never, 0: only at root) Range: {-1, ..., 65534}	1
constraints/knapsack/simplifyinequalities	should presolving try to simplify knapsacks Range: boolean	1
constraints/knapsack/updatecliquepartitions	should clique partition information be updated when old partition seems outdated? Range: boolean	0
constraints/knapsack/usegubs	should GUB information be used for separation? Range: boolean	0

5.34.4.35 constraints/linear

Option	Description	Default
constraints/linear/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	5
constraints/linear/maxroundsroot	maximal number of separation rounds per node in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
constraints/linear/maxsepacuts	maximal number of cuts separated per separation round Range: {0, ..., ∞}	50
constraints/linear/maxsepacutsroot	maximal number of cuts separated per separation round in the root node Range: {0, ..., ∞}	200
constraints/linear/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/linear/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0

Option	Description	Default
constraints/linear/separateall	should all constraints be subject to cardinality cut generation instead of only the ones with non-zero dual value? Range: boolean	0
Options for expert users		
constraints/linear/aggregatevariables	should presolving search for aggregations in equations Range: boolean	1
constraints/linear/checkrelmaxabs	should the violation for a constraint with side 0.0 be checked relative to 1.0 (FALSE) or to the maximum absolute value in the activity (TRUE)? Range: boolean	0
constraints/linear/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/linear/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/linear/detectcutoffbound	should presolving try to detect constraints parallel to the objective function defining an upper bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/linear/detectlowerbound	should presolving try to detect constraints parallel to the objective function defining a lower bound and prevent these constraints from entering the LP? Range: boolean	1
constraints/linear/detectpartialobjective	should presolving try to detect subsets of constraints parallel to the objective function? Range: boolean	1
constraints/linear/dualpresolving	should dual presolving steps be performed? Range: boolean	1
constraints/linear/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/linear/extractcliques	should Cliques be extracted? Range: boolean	1
constraints/linear/maxaggrnormscale	maximal allowed relative gain in maximum norm for constraint aggregation (0.0: disable constraint aggregation) Range: [0, ∞]	0
constraints/linear/maxcardbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for separating knapsack cardinality cuts Range: [0, 1]	0
constraints/linear/maxdualmultaggrquot	maximum coefficient dynamism (ie. maxabsval / minabsval) for dual multiaggregation Range: [1, ∞]	∞

Option	Description	Default
constraints/linear/maxeasyactivitydelta	maximum activity delta to run easy propagation on linear constraint (faster, but numerically less stable) Range: [0, ∞]	1e+06
constraints/linear/maxmultaggrquot	maximum coefficient dynamism (ie. maxabsval / minabsval) for primal multiaggregation Range: [1, ∞]	1000
constraints/linear/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/linear/mingainpernmincomparisons	minimal gain per minimal pairwise presolve comparisons to repeat pairwise comparison round Range: [0, 1]	1e-06
constraints/linear/multaggrremove	should multi-aggregations only be performed if the constraint can be removed afterwards? Range: boolean	0
constraints/linear/nmincomparisons	number for minimal pairwise presolve comparisons Range: {1, ..., ∞}	200000
constraints/linear/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/linear/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	20
constraints/linear/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/linear/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/linear/rangedrowartcons	should presolving and propagation extract sub-constraints from ranged rows and equations? Range: boolean	1
constraints/linear/rangedrowfreq	frequency for applying ranged row propagation Range: {1, ..., 65534}	1
constraints/linear/rangedrowmaxdepth	maximum depth to apply ranged row propagation Range: {0, ..., ∞}	∞
constraints/linear/rangedrowpropagation	should presolving and propagation try to improve bounds, detect infeasibility, and extract sub-constraints from ranged rows and equations? Range: boolean	1
constraints/linear/simplifyinequalities	should presolving try to simplify inequalities Range: boolean	1

Option	Description	Default
constraints/linear/singletonstuffing	should stuffing of singleton continuous variables be performed? Range: boolean	1
constraints/linear/singlevarstuffing	should single variable stuffing be performed, which tries to fulfill constraints using the cheapest variable? Range: boolean	0
constraints/linear/sortvars	apply binaries sorting in decr. order of coeff abs value? Range: boolean	1
constraints/linear/tightenboundsfreq	multiplier on propagation frequency, how often the bounds are tightened (-1: never, 0: only at root) Range: {-1, ..., 65534}	1

5.34.4.36 constraints/linear/upgrade

Option	Description	Default
constraints/linear/upgrade/indicator	enable linear upgrading for constraint handler <indicator> Range: boolean	1
constraints/linear/upgrade/knapsack	enable linear upgrading for constraint handler <knapsack> Range: boolean	1
constraints/linear/upgrade/logicor	enable linear upgrading for constraint handler <logicor> Range: boolean	1
constraints/linear/upgrade/setppc	enable linear upgrading for constraint handler <setppc> Range: boolean	1
constraints/linear/upgrade/varbound	enable linear upgrading for constraint handler <varbound> Range: boolean	1
constraints/linear/upgrade/xor	enable linear upgrading for constraint handler <xor> Range: boolean	1

5.34.4.37 constraints/logicor

Option	Description	Default
constraints/logicor/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/logicor/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/logicor/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0

Option	Description	Default
constraints/logicor/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/logicor/dualpresolving	should dual presolving steps be performed? Range: boolean	1
constraints/logicor/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/logicor/implications	should implications/cliques be used in presolving Range: boolean	1
constraints/logicor/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/logicor/negatedclique	should negated clique information be used in presolving Range: boolean	1
constraints/logicor/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/logicor/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/logicor/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/logicor/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/logicor/strengthen	should pairwise constraint comparison try to strengthen constraints by removing superflous nonzeros? Range: boolean	1

5.34.4.38 constraints/nonlinear

Option	Description	Default
constraints/nonlinear/assumeconvex	whether to assume that any constraint is convex Range: boolean	0
constraints/nonlinear/bilinmaxnauxexprs	maximal number of auxiliary expressions per bilinear term Range: {0, ..., ∞}	10
constraints/nonlinear/linearizeheursol	whether tight linearizations of nonlinear constraints should be added to cutpool when some heuristics finds a new solution ('o'ff, on new 'i'ncumbents, on 'e'very solution) Range: o, i, e	i if QCP or NLP, o otherwise

Option	Description	Default
constraints/nonlinear/maxproprounds	limit on number of propagation rounds for a set of constraints within one round of SCIP propagation Range: {0, ..., ∞}	10
constraints/nonlinear/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/nonlinear/reformbinprods	whether to reformulate products of binary variables during presolving Range: boolean	1
constraints/nonlinear/reformbinprodsand	whether to use the AND constraint handler for reformulating binary products Range: boolean	1
constraints/nonlinear/reformbinprodsfac	minimum number of terms to reformulate bilinear binary products by factorizing variables (≤ 1: disabled) Range: {1, ..., ∞}	50
constraints/nonlinear/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
Options for expert users		
constraints/nonlinear/checkvarlocks	whether variables contained in a single constraint should be forced to be at their lower or upper bounds ('d'isable, change 't'ype, add 'b'ound disjunction) Range: b, d, t	t
constraints/nonlinear/conssiderelaxamount	by how much to relax constraint sides during bound tightening Range: [0, 1]	1e-09
constraints/nonlinear/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/nonlinear/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/nonlinear/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/nonlinear/enfoauxviolfactor	an expression will be enforced if the "auxiliary" violation is at least this factor times the "original" violation Range: [0, 1]	0.01

Option	Description	Default
constraints/nonlinear/forbidmultaggrnlvar	whether to forbid multiaggregation of nonlinear variables Range: boolean	1
constraints/nonlinear/forcestrongcut	whether to force "strong" cuts in enforcement Range: boolean	0
constraints/nonlinear/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/nonlinear/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/nonlinear/propauxvars	whether to check bounds of all auxiliary variable to seed reverse propagation Range: boolean	1
constraints/nonlinear/propinenforce	whether to (re)run propagation in enforcement Range: boolean	0
constraints/nonlinear/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/nonlinear/rownotremovable	whether to make rows to be non-removable in the node where they are added (can prevent some cycling): 'o'ff, in 'e'nforcement only, 'a'lways Range: o, e, a	o
constraints/nonlinear/strongcuteffica	consider efficacy requirement when deciding whether a cut is "strong" Range: boolean	0
constraints/nonlinear/strongcutmaxcoef	"strong" cuts will be scaled to have their maximal coef in [1/strongcutmaxcoef,strongcutmaxcoef] Range: [1, ∞]	1000
constraints/nonlinear/tightenlpfeastol	whether to tighten LP feasibility tolerance during enforcement, if it seems useful Range: boolean	1
constraints/nonlinear/varboundrelax	strategy on how to relax variable bounds during bound tightening: relax (n)ot, relax by (a)bsolute value, relax always by a(b)solute value, relax by (r)relative value Range: n, a, b, r	r

Option	Description	Default
constraints/nonlinear/varboundrelaxamount	by how much to relax variable bounds during bound tightening if strategy 'a', 'b', or 'r' Range: [0, 1]	1e-09
constraints/nonlinear/violscale	method how to scale violations to make them comparable (not used for feasibility check): (n)one, (a)ctivity and side, norm of (g)radient Range: n, a, g	n
constraints/nonlinear/vpadjfacetthresh	adjust computed facet of envelope of vertex-polyhedral function up to a violation of this value times LP feasibility tolerance Range: [0, ∞]	10
constraints/nonlinear/vpdualsimplex	whether to use dual simplex instead of primal simplex for LP that computes facet of vertex-polyhedral function Range: boolean	1
constraints/nonlinear/vpmaxperturb	maximal relative perturbation of reference point when computing facet of envelope of vertex-polyhedral function (dim>2) Range: [0, 1]	0.001
constraints/nonlinear/weakcutminviolfactor	retry enfo of constraint with weak cuts if violation is least this factor of maximal violated constraints Range: [0, 2]	0.5
constraints/nonlinear/weakcutthreshold	threshold for when to regard a cut from an estimator as weak (lower values allow more weak cuts) Range: [0, 1]	0.2

5.34.4.39 constraints/nonlinear/branching

Option	Description	Default
constraints/nonlinear/branching/aux	from which depth on in the tree to allow branching on auxiliary variables (variables added for extended formulation) Range: {0, ..., ∞}	∞
constraints/nonlinear/branching/domainweight	weight by how much to consider the domain width in branching score Range: [0, ∞]	0
constraints/nonlinear/branching/dualweight	weight by how much to consider the dual values of rows that contain a variable for its branching score Range: [0, ∞]	0
constraints/nonlinear/branching/external	whether to use external branching candidates and branching rules for branching Range: boolean	0

Option	Description	Default
constraints/nonlinear/branching/highscorefactor	consider a variable branching score high if its branching score ≥ this factor ∗ maximal branching score among all variables Range: [0, 1]	0.9
constraints/nonlinear/branching/highviolfactor	consider a constraint highly violated if its violation is ≥ this factor ∗ maximal violation among all constraints Range: [0, 1]	0
constraints/nonlinear/branching/pscostreliable	minimum pseudo-cost update count required to consider pseudo-costs reliable Range: [0, ∞]	2
constraints/nonlinear/branching/pscostweight	weight by how much to consider the pseudo cost of a variable for its branching score Range: [0, ∞]	1
constraints/nonlinear/branching/scoreagg	how to aggregate several branching scores given for the same expression: 'a'verage, 'm'aximum, 's'um Range: a, m, s	s
constraints/nonlinear/branching/vartypeweight	weight by how much to consider variable type (continuous: 0, binary: 1, integer: 0.1, impl-integer: 0.01) in branching score Range: [0, ∞]	0.5
constraints/nonlinear/branching/violsplit	method used to split violation in expression onto variables: 'u'niform, 'm'idness of solution, 'd'omain width, 'l'ogarithmic domain width Range: u, m, d, l	m
constraints/nonlinear/branching/violweight	weight by how much to consider the violation assigned to a variable for its branching score Range: [0, ∞]	1

5.34.4.40 constraints/nonlinear/upgrade

Option	Description	Default
constraints/nonlinear/upgrade/linear	enable nonlinear upgrading for constraint handler <linear> Range: boolean	1
constraints/nonlinear/upgrade/setppc	enable nonlinear upgrading for constraint handler <setppc> Range: boolean	1

5.34.4.41 constraints/or

Option	Description	Default
constraints/or/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/or/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0

Option	Description	Default
Options for expert users		
constraints/or/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/or/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/or/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/or/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/or/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8
constraints/or/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.42 constraints/orbisack

Option	Description	Default
constraints/orbisack/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
constraints/orbisack/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
Options for expert users		
constraints/orbisack/checkpporbisack	Upgrade orbisack constraints to packing/partioning orbisacks? Range: boolean	1
constraints/orbisack/coeffbound	Maximum size of coefficients for orbisack inequalities Range: [0, ∞]	1e+06
constraints/orbisack/coverseparation	Separate cover inequalities for orbisacks? Range: boolean	1
constraints/orbisack/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/orbisack/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/orbisack/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1

Option	Description	Default
constraints/orbisack/forceconscopy	Whether orbisack constraints should be forced to be copied to sub SCIPs. Range: boolean	0
constraints/orbisack/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/orbisack/orbiSeparation	Separate orbisack inequalities? Range: boolean	0
constraints/orbisack/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
constraints/orbisack/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.43 constraints/orbitope

Option	Description	Default
constraints/orbitope/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/orbitope/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
constraints/orbitope/checkpporbitope	Strengthen orbitope constraints to packing/partioning orbitopes? Range: boolean	1
constraints/orbitope/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/orbitope/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/orbitope/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/orbitope/forceconscopy	Whether orbitope constraints should be forced to be copied to sub SCIPs. Range: boolean	0
constraints/orbitope/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/orbitope/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8

Option	Description	Default
constraints/orbitope/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/orbitope/sepafullorbitope	Whether we separate inequalities for full orbitopes? Range: boolean	0

5.34.4.44 constraints/setppc

Option	Description	Default
constraints/setppc/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/setppc/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/setppc/addvariablesascliques	should we try to generate extra cliques out of all binary variables to maybe fasten redundant constraint detection Range: boolean	0
constraints/setppc/cliquelifting	should we try to lift variables into other clique constraints, fix variables, aggregate them, and also shrink the amount of variables in clique constraints Range: boolean	0
constraints/setppc/clqueshrinking	should we try to shrink the number of variables in a clique constraints, by replacing more than one variable by only one Range: boolean	1
constraints/setppc/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/setppc/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/setppc/dualpresolving	should dual presolving steps be performed? Range: boolean	1
constraints/setppc/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/setppc/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/setppc/npseudobranches	number of children created in pseudo branching (0: disable pseudo branching) Range: {0, ..., ∞}	2

Option	Description	Default
constraints/setppc/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/setppc/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/setppc/presolusehashing	should hash table be used for detecting redundant constraints in advance Range: boolean	1
constraints/setppc/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.45 constraints/symresack

Option	Description	Default
constraints/symresack/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
constraints/symresack/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
Options for expert users		
constraints/symresack/checkmonotonicity	Check whether permutation is monotone when upgrading to packing/partioning symresacks? Range: boolean	1
constraints/symresack/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/symresack/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/symresack/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	-1
constraints/symresack/forceconscopy	Whether symresack constraints should be forced to be copied to sub SCIPs. Range: boolean	0
constraints/symresack/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/symresack/ppsymresack	Upgrade symresack constraints to packing/partioning symresacks? Range: boolean	1

Option	Description	Default
constraints/symresack/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
constraints/symresack/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.46 constraints/varbound

Option	Description	Default
constraints/varbound/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/varbound/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
constraints/varbound/usebdwidening	should bound widening be used in conflict analysis? Range: boolean	1
Options for expert users		
constraints/varbound/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/varbound/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/varbound/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/varbound/maxlpcoef	maximum coefficient in varbound constraint to be added as a row into LP Range: [0, ∞]	1e+09
constraints/varbound/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/varbound/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/varbound/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	12
constraints/varbound/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1

5.34.4.47 constraints/xor

Option	Description	Default
constraints/xor/propfreq	frequency for propagating domains (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
constraints/xor/sepafreq	frequency for separating cuts (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
Options for expert users		
constraints/xor/addextendedform	should the extended formulation be added in presolving? Range: boolean	0
constraints/xor/addflowextended	should the extended flow formulation be added (non-symmetric formulation otherwise)? Range: boolean	0
constraints/xor/delayprop	should propagation method be delayed, if other propagators found reductions? Range: boolean	0
constraints/xor/delaysepa	should separation method be delayed, if other separators found cuts? Range: boolean	0
constraints/xor/eagerfreq	frequency for using all instead of only the useful constraints in separation, propagation and enforcement (-1: never, 0: only in first evaluation) Range: {-1, ..., 65534}	100
constraints/xor/gausspropfreq	frequency for applying the Gauss propagator Range: {-1, ..., 65534}	5
constraints/xor/maxprerounds	maximal number of presolving rounds the constraint handler participates in (-1: no limit) Range: {-1, ..., ∞}	-1
constraints/xor/presolpairwise	should pairwise constraint comparison be performed in presolving? Range: boolean	1
constraints/xor/presoltiming	timing mask of the constraint handler's presolving method (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	28
constraints/xor/presolusehashing	should hash table be used for detecting redundant constraints in advance? Range: boolean	1
constraints/xor/proptiming	timing when constraint propagation should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS) Range: {1, ..., 15}	1
constraints/xor/separateparity	should parity inequalities be separated? Range: boolean	0

5.34.4.48 cutselection/hybrid

Option	Description	Default
cutselection/hybrid/dircutoffdistweight	weight of directed cutoff distance in cut score calculation Range: [0, ∞]	0
cutselection/hybrid/efficacyweight	weight of efficacy in cut score calculation Range: [0, ∞]	1
cutselection/hybrid/intsupportweight	weight of integral support in cut score calculation Range: [0, ∞]	0.1
cutselection/hybrid/minortho	minimal orthogonality for a cut to enter the LP Range: [0, 1]	0.9
cutselection/hybrid/minorthoroot	minimal orthogonality for a cut to enter the LP in the root node Range: [0, 1]	0.9
cutselection/hybrid/objparalweight	weight of objective parallelism in cut score calculation Range: [0, ∞]	0.1
cutselection/hybrid/priority	priority of cut selection rule <hybrid> Range: {-536870912, ..., 1073741823}	8000

5.34.4.49 decomposition

Option	Description	Default
decomposition/disablemeasures	disable expensive measures Range: boolean	0
decomposition/maxgraphedge	maximum number of edges in block graph computation (-1: no limit, 0: disable block graph computation) Range: {-1, ..., ∞}	10000

5.34.4.50 display

Option	Description	Default
display/allviols	display all violations for a given start solution / the best solution after the solving process? Range: boolean	0
display/freq	frequency for displaying node information lines Range: {-1, ..., ∞}	100
display/headerfreq	frequency for displaying header lines (every n'th node information line) Range: {-1, ..., ∞}	15
display/lpinfo	should the LP solver display status messages? Range: boolean	0
display/relevantstats	should the relevant statistics be displayed at the end of solving? Range: boolean	1
display/statistics	whether to print statistics on a solve and a provided decomposition Range: boolean	0

Option	Description	Default
display/verblevel	verbosity level of output Range: {0, ..., 5}	4
display/width	maximal number of characters in a node information line Range: {0, ..., ∞}	143 (80 for Windows without IDE)

5.34.4.51 display/avgdualbound

Option	Description	Default
display/avgdualbound/active	display activation status of display column <avgdualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.52 display/completed

Option	Description	Default
display/completed/active	display activation status of display column <completed> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.53 display/concdualbound

Option	Description	Default
display/concdualbound/active	display activation status of display column <concdualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.54 display/concgap

Option	Description	Default
display/concgap/active	display activation status of display column <concgap> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.55 display/concmemused

Option	Description	Default
display/concmemused/active	display activation status of display column <concmemused> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.56 display/concprimalbound

Option	Description	Default
display/concprimalbound/active	display activation status of display column <concprimalbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.57 display/concsolfound

Option	Description	Default
display/concsolfound/active	display activation status of display column <concsolfound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.58 display/conflicts

Option	Description	Default
display/conflicts/active	display activation status of display column <conflicts> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.59 display/conss

Option	Description	Default
display/conss/active	display activation status of display column <conss> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.60 display/curcols

Option	Description	Default
display/curcols/active	display activation status of display column <curcols> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.61 display/curconss

Option	Description	Default
display/curconss/active	display activation status of display column <curconss> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.62 display/curdualbound

Option	Description	Default
display/curdualbound/active	display activation status of display column <curdualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.63 display/currows

Option	Description	Default
display/currows/active	display activation status of display column <currows> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.64 display/cutoffbound

Option	Description	Default
display/cutoffbound/active	display activation status of display column <cutoffbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.65 display/cuts

Option	Description	Default
display/cuts/active	display activation status of display column <cuts> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.66 display/depth

Option	Description	Default
display/depth/active	display activation status of display column <depth> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.67 display/dualbound

Option	Description	Default
display/dualbound/active	display activation status of display column <dualbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.68 display/estimate

Option	Description	Default
display/estimate/active	display activation status of display column <estimate> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.69 display/feasST

Option	Description	Default
display/feasST/active	display activation status of display column <feasST> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.34.4.70 display/gap

Option	Description	Default
display/gap/active	display activation status of display column <gap> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.71 display/lpavgiterations

Option	Description	Default
display/lpavgiterations/active	display activation status of display column <lpavgiterations> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1 (0 for Windows without IDE)

5.34.4.72 display/lpcond

Option	Description	Default
display/lpcond/active	display activation status of display column <lpcond> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.73 display/lpiterations

Option	Description	Default
display/lpiterations/active	display activation status of display column <lpiterations> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.74 display/lpobj

Option	Description	Default
display/lpobj/active	display activation status of display column <lpobj> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.75 display/maxdepth

Option	Description	Default
display/maxdepth/active	display activation status of display column <maxdepth> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1 (0 for Windows without IDE)

5.34.4.76 display/memtotal

Option	Description	Default
display/memtotal/active	display activation status of display column <memtotal> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.77 display/memused

Option	Description	Default
display/memused/active	display activation status of display column <memused> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.78 display/nexternbranchcands

Option	Description	Default
display/nexternbranchcands/active	display activation status of display column <nexternbranchcands> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.79 display/nfrac

Option	Description	Default
display/nfrac/active	display activation status of display column <nfrac> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.80 display/ninfeasleaves

Option	Description	Default
display/ninfeasleaves/active	display activation status of display column <ninfeasleaves> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.81 display/nnodes

Option	Description	Default
display/nnodes/active	display activation status of display column <nnodes> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.82 display/nnodesbelowinc

Option	Description	Default
display/nnodesbelowinc/active	display activation status of display column <nnodesbelowinc> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.34.4.83 display/nobjleaves

Option	Description	Default
display/nobjleaves/active	display activation status of display column <nobjleaves> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.84 display/nodesleft

Option	Description	Default
display/nodesleft/active	display activation status of display column <nodesleft> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.85 display/nrank1nodes

Option	Description	Default
display/nrank1nodes/active	display activation status of display column <nrank1nodes> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.34.4.86 display/nsols

Option	Description	Default
display/nsols/active	display activation status of display column <nsols> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.87 display/plungedepth

Option	Description	Default
display/plungedepth/active	display activation status of display column <plungedepth> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.88 display/poolsize

Option	Description	Default
display/poolsize/active	display activation status of display column <poolsize> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.89 display/primalbound

Option	Description	Default
display/primalbound/active	display activation status of display column <primalbound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.90 display/primalgap

Option	Description	Default
display/primalgap/active	display activation status of display column <primalgap> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.34.4.91 display/pseudoobj

Option	Description	Default
display/pseudoobj/active	display activation status of display column <pseudoobj> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.92 display/separounds

Option	Description	Default
display/separounds/active	display activation status of display column <separounds> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.93 display/solfound

Option	Description	Default
display/solfound/active	display activation status of display column <solfound> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.94 display/sols

Option	Description	Default
display/sols/active	display activation status of display column <sols> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	0

5.34.4.95 display/strongbranchs

Option	Description	Default
display/strongbranchs/active	display activation status of display column <strongbranchs> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.96 display/time

Option	Description	Default
display/time/active	display activation status of display column <time> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1 (2 for Windows without IDE)

5.34.4.97 display/vars

Option	Description	Default
display/vars/active	display activation status of display column <vars> (0: off, 1: auto, 2:on) Range: {0, ..., 2}	1

5.34.4.98 estimation

Option	Description	Default
estimation/coefmonossg	coefficient of 1 - SSG in monotone approximation of search completion Range: [0, 1]	0.6333
estimation/coefmonoweight	coefficient of tree weight in monotone approximation of search completion Range: [0, 1]	0.3667
estimation/completiontype	approximation of search tree completion: (a)uto, (g)ap, tree (w)eight, (m)onotone regression, (r)egression forest, (s)sg Range: a, g, m, r, s, w	a
estimation/method	tree size estimation method: (c)ompletion, (e)nsemble, time series forecasts on either (g)ap, (l)eaf frequency, (o)pen nodes, tree (w)eight, (s)sg, or (t)ree profile or w(b)e Range: b, c, e, g, l, o, s, t, w	w
estimation/regforestfilename	user regression forest in RFCSV format Range: string	-
Options for expert users		
estimation/reportfreq	report frequency on estimation: -1: never, 0:always, k $\geq$ 1: k times evenly during search Range: {-1, ..., 1073741823}	-1
estimation/showstats	should statistics be shown at the end? Range: boolean	0
estimation/useleafts	use leaf nodes as basic observations for time series, or all nodes? Range: boolean	1

5.34.4.99 estimation/restarts

Option	Description	Default
estimation/restarts/countonlyleaves	should only leaves count for the minnodes parameter? Range: boolean	0
estimation/restarts/hitcounterlim	limit on the number of successive samples to really trigger a restart Range: {1, ..., ∞}	50
estimation/restarts/minnodes	minimum number of nodes before restart Range: {-1, ..., ∞}	1000
estimation/restarts/restartactpricers	whether to apply a restart when active pricers are used Range: boolean	0
estimation/restarts/restartfactor	factor by which the estimated number of nodes should exceed the current number of nodes Range: [1, ∞]	50
estimation/restarts/restartlimit	restart limit Range: {-1, ..., ∞}	1
estimation/restarts/restartnonlinear	whether to apply a restart when nonlinear constraints are present Range: boolean	0
estimation/restarts/restartpolicy	restart policy: (a)lways, (c)ompletion, (e)stimation, (n)ever Range: a, c, e, n	e

5.34.4.100 estimation/ssg

Option	Description	Default
estimation/ssg/nmaxsubtrees	the maximum number of individual SSG subtrees; -1: no limit Range: {-1, ..., 1073741823}	-1
estimation/ssg/nminnodeslastsplit	minimum number of nodes to process between two consecutive SSG splits Range: {0, ..., ∞}	0

5.34.4.101 estimation/treeprofile

Option	Description	Default
estimation/treeprofile/enabled	should the event handler collect data? Range: boolean	0
estimation/treeprofile/minnodesperdepth	minimum average number of nodes at each depth before producing estimations Range: [1, ∞]	20

5.34.4.102 expr/log

Option	Description	Default
expr/log/minzerodistance	minimal distance from zero to enforce for child in bound tightening Range: [0, 1]	1e-09

5.34.4.103 expr/pow

Option	Description	Default
expr/pow/minzerodistance	minimal distance from zero to enforce for child in bound tightening Range: [0, 1]	1e-09

5.34.4.104 heuristics

Option	Description	Default
Options for expert users		
heuristics/useuctsubscip	should setting of common subscip parameters include the activation of the UCT node selector? Range: boolean	0

5.34.4.105 heuristics/actconsdiving

Option	Description	Default
heuristics/actconsdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/actconsdiving/freq	frequency for calling primal heuristic <actconsdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/actconsdiving/freqofs	frequency offset for calling primal heuristic <actconsdiving> Range: {0, ..., 65534}	5
heuristics/actconsdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/actconsdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/actconsdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/actconsdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/actconsdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	1
Options for expert users		
heuristics/actconsdiving/maxdepth	maximal depth level to call primal heuristic <actconsdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/actconsdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/actconsdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	1
heuristics/actconsdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/actconsdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	1
heuristics/actconsdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/actconsdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/actconsdiving/priority	priority of heuristic <actconsdiving> Range: {-536870912, ..., 536870911}	-1003700

5.34.4.106 heuristics/adaptivediving

Option	Description	Default
heuristics/adaptivediving/bestsolweight	weight of incumbent solutions compared to other solutions in computation of LP iteration limit Range: [0, ∞]	10
heuristics/adaptivediving/epsilon	parameter that increases probability of exploration among divesets (only active if seltype is 'e') Range: [0, ∞]	1
heuristics/adaptivediving/freq	frequency for calling primal heuristic <adaptivediving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	5
heuristics/adaptivediving/freqofs	frequency offset for calling primal heuristic <adaptivediving> Range: {0, ..., 65534}	3
heuristics/adaptivediving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1500
heuristics/adaptivediving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.1
heuristics/adaptivediving/scoretype	score parameter for selection: minimize either average 'n'odes, LP 'i'terations,backtrack/'c'onflict ratio, 'd'epth, 1 / 's'olutions, or 1 / solutions'u'ccess Range: c, d, i, n, s, u	c
heuristics/adaptivediving/selconfidencecoeff	coefficient c to decrease initial confidence (calls + 1.0) / (calls + c) in scores Range: [1, 2.14748e+09]	10
heuristics/adaptivediving/seltype	selection strategy: (e)psilon-greedy, (w)eighted distribution, (n)ext diving Range: e, n, w	w
Options for expert users		
heuristics/adaptivediving/maxdepth	maximal depth level to call primal heuristic <adaptivediving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/adaptivediving/priority	priority of heuristic <adaptivediving> Range: {-536870912, ..., 536870911}	-70000
heuristics/adaptivediving/useadaptivecontext	should the heuristic use its own statistics, or shared statistics? Range: boolean	0

5.34.4.107 heuristics/alns

Option	Description	Default
heuristics/alns/freq	frequency for calling primal heuristic <alns> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20

Option	Description	Default
heuristics/alns/freqofs	frequency offset for calling primal heuristic <alns> Range: {0, ..., 65534}	0
heuristics/alns/nodesofs	offset added to the nodes budget Range: {0, ..., ∞}	500
heuristics/alns/nodesquot	fraction of nodes compared to the main SCIP for budget computation Range: [0, 1]	0.1
heuristics/alns/nodesquotmin	lower bound fraction of nodes compared to the main SCIP for budget computation Range: [0, 1]	0
heuristics/alns/nsolslim	limit on the number of improving solutions in a sub-SCIP call Range: {-1, ..., ∞}	3
heuristics/alns/seed	initial random seed for bandit algorithms and random decisions by neighborhoods Range: {0, ..., ∞}	113
Options for expert users		
heuristics/alns/adjustfixingrate	should the heuristic adjust the target fixing rate based on the success? Range: boolean	1
heuristics/alns/adjustminimprove	should the factor by which the minimum improvement is bound be dynamically updated? Range: boolean	0
heuristics/alns/adjusttargetnodes	should the target nodes be dynamically adjusted? Range: boolean	1
heuristics/alns/alpha	parameter to increase the confidence width in UCB Range: [0, 100]	0.0016
heuristics/alns/banditalgo	the bandit algorithm: (u)pper confidence bounds, (e)xp.3, epsilon (g)reedy Range: u, e, g	u
heuristics/alns/beta	reward offset between 0 and 1 at every observation for Exp.3 Range: [0, 1]	0
heuristics/alns/copycuts	should cutting planes be copied to the sub-SCIP? Range: boolean	0
heuristics/alns/domorefixings	should the ALNS heuristic do more fixings by itself based on variable prioritization until the target fixing rate is reached? Range: boolean	1
heuristics/alns/eps	increase exploration in epsilon-greedy bandit algorithm Range: [0, 1]	0.468584
heuristics/alns/fixtol	tolerance by which the fixing rate may be missed without generic fixing Range: [0, 1]	0.1
heuristics/alns/gamma	weight between uniform (gamma ∼ 1) and weight driven (gamma ∼ 0) probability distribution for exp3 Range: [0, 1]	0.0704146
heuristics/alns/initduringroot	should the heuristic be executed multiple times during the root node? Range: boolean	0

Option	Description	Default
heuristics/alns/maxcallssamesol	number of allowed executions of the heuristic on the same incumbent solution (-1: no limit, 0: number of active neighborhoods) Range: {-1, ..., 100}	-1
heuristics/alns/maxdepth	maximal depth level to call primal heuristic <alns> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/alns/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/alns/minimprovehigh	upper bound for the minimal improvement over the incumbent Range: [0, 1]	0.01
heuristics/alns/minimprovelow	lower threshold for the minimal improvement over the incumbent Range: [0, 1]	0.01
heuristics/alns/minnodes	minimum number of nodes required to start a sub-SCIP Range: {0, ..., ∞}	50
heuristics/alns/priority	priority of heuristic <alns> Range: {-536870912, ..., 536870911}	-1100500
heuristics/alns/resetweights	should the bandit algorithms be reset when a new problem is read? Range: boolean	1
heuristics/alns/rewardbaseline	the reward baseline to separate successful and failed calls Range: [0, 0.99]	0.5
heuristics/alns/rewardcontrol	reward control to increase the weight of the simple solution indicator and decrease the weight of the closed gap reward Range: [0, 1]	0.8
heuristics/alns/rewardfilename	file name to store all rewards and the selection of the bandit Range: string	-
heuristics/alns/scalebyeffort	should the reward be scaled by the effort? Range: boolean	1
heuristics/alns/shownbstats	show statistics on neighborhoods? Range: boolean	0
heuristics/alns/startminimprove	initial factor by which ALNS should at least improve the incumbent Range: [0, 1]	0.01
heuristics/alns/subsciprandseeds	should random seeds of sub-SCIPs be altered to increase diversification? Range: boolean	0
heuristics/alns/targetnodefactor	factor by which target node number is eventually increased Range: [1, 100000]	1.05
heuristics/alns/unfixtol	tolerance by which the fixing rate may be exceeded without generic unfixing Range: [0, 1]	0.1
heuristics/alns/usedistances	distances from fixed variables be used for variable prioritization Range: boolean	1

Option	Description	Default
heuristics/alns/uselocalredcost	should local reduced costs be used for generic (un)fixing? Range: boolean	0
heuristics/alns/usepscost	should pseudo cost scores be used for variable priorization? Range: boolean	1
heuristics/alns/useredcost	should reduced cost scores be used for variable prioritization? Range: boolean	1
heuristics/alns/usesubscipheurs	should the heuristic activate other sub-SCIP heuristics during its search? Range: boolean	0
heuristics/alns/waitingnodes	number of nodes since last incumbent solution that the heuristic should wait Range: {0, ..., ∞}	25

5.34.4.108 heuristics/alns/crossover

Option	Description	Default
Options for expert users		
heuristics/alns/crossover/active	is this neighborhood active? Range: boolean	1
heuristics/alns/crossover/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/crossover/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/crossover/nsols	the number of solutions that crossover should combine Range: {2, ..., 10}	2
heuristics/alns/crossover/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.109 heuristics/alns/dins

Option	Description	Default
Options for expert users		
heuristics/alns/dins/active	is this neighborhood active? Range: boolean	1
heuristics/alns/dins/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/dins/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/dins/npoolsols	number of pool solutions where binary solution values must agree Range: {1, ..., 100}	5
heuristics/alns/dins/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.110 heuristics/alns/localbranching

Option	Description	Default
Options for expert users		
heuristics/alns/localbranching/active	is this neighborhood active? Range: boolean	1
heuristics/alns/localbranching/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/localbranching/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/localbranching/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.111 heuristics/alns/mutation

Option	Description	Default
Options for expert users		
heuristics/alns/mutation/active	is this neighborhood active? Range: boolean	1
heuristics/alns/mutation/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/mutation/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/mutation/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.112 heuristics/alns/proximity

Option	Description	Default
Options for expert users		
heuristics/alns/proximity/active	is this neighborhood active? Range: boolean	1
heuristics/alns/proximity/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/proximity/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/proximity/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.113 heuristics/alns/rens

Option	Description	Default
Options for expert users		
heuristics/alns/rens/active	is this neighborhood active? Range: boolean	1

Option	Description	Default
heuristics/alns/rens/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/rens/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/rens/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.114 heuristics/alns/rins

Option	Description	Default
Options for expert users		
heuristics/alns/rins/active	is this neighborhood active? Range: boolean	1
heuristics/alns/rins/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/rins/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/rins/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.115 heuristics/alns/trustregion

Option	Description	Default
heuristics/alns/trustregion/violpenalty	the penalty for each change in the binary variables from the candidate solution Range: [0, ∞]	100
Options for expert users		
heuristics/alns/trustregion/active	is this neighborhood active? Range: boolean	0
heuristics/alns/trustregion/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/trustregion/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3
heuristics/alns/trustregion/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.116 heuristics/alns/zeroobjective

Option	Description	Default
Options for expert users		
heuristics/alns/zeroobjective/active	is this neighborhood active? Range: boolean	1
heuristics/alns/zeroobjective/maxfixingrate	maximum fixing rate for this neighborhood Range: [0, 1]	0.9
heuristics/alns/zeroobjective/minfixingrate	minimum fixing rate for this neighborhood Range: [0, 1]	0.3

Option	Description	Default
heuristics/alns/zeroobjective/priority	positive call priority to initialize bandit algorithms Range: [0.01, 1]	1

5.34.4.117 heuristics/bound

Option	Description	Default
heuristics/bound/bound	to which bound should integer variables be fixed? ('l'ower, 'u'pper, or 'b'oth) Range: l, u, b	l
heuristics/bound/freq	frequency for calling primal heuristic <bound> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/bound/freqofs	frequency offset for calling primal heuristic <bound> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/bound/maxdepth	maximal depth level to call primal heuristic <bound> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/bound/maxproprounds	maximum number of propagation rounds during probing (-1 infinity, -2 parameter settings) Range: {-1, ..., 536870911}	0
heuristics/bound/onlywithoutsol	Should heuristic only be executed if no primal solution was found, yet? Range: boolean	1
heuristics/bound/priority	priority of heuristic <bound> Range: {-536870912, ..., 536870911}	-1107000

5.34.4.118 heuristics/clique

Option	Description	Default
heuristics/clique/freq	frequency for calling primal heuristic <clique> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/clique/freqofs	frequency offset for calling primal heuristic <clique> Range: {0, ..., 65534}	0
heuristics/clique/minintfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.65
heuristics/clique/minmipfixingrate	minimum percentage of fixed variables in the sub-MIP Range: [0, 1]	0.65
heuristics/clique/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/clique/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		

Option	Description	Default
heuristics/clique/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/clique/maxbacktracks	maximum number of backtracks during the fixing process Range: {-1, ..., 536870911}	10
heuristics/clique/maxdepth	maximal depth level to call primal heuristic <clique> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/clique/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/clique/maxproprounds	maximum number of propagation rounds during probing (-1 infinity) Range: {-1, ..., 536870911}	2
heuristics/clique/minimprove	factor by which clique heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/clique/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	500
heuristics/clique/priority	priority of heuristic <clique> Range: {-536870912, ..., 536870911}	5000
heuristics/clique/uselockfixings	should more variables be fixed based on variable locks if the fixing rate was not reached? Range: boolean	0

5.34.4.119 heuristics/coefdiving

Option	Description	Default
heuristics/coefdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/coefdiving/freq	frequency for calling primal heuristic <coefdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/coefdiving/freqofs	frequency offset for calling primal heuristic <coefdiving> Range: {0, ..., 65534}	1
heuristics/coefdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/coefdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/coefdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/coefdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05

Option	Description	Default
heuristics/coefdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/coefdiving/maxdepth	maximal depth level to call primal heuristic <coefdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/coefdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/coefdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/coefdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/coefdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/coefdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/coefdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/coefdiving/priority	priority of heuristic <coefdiving> Range: {-536870912, ..., 536870911}	-1001000

5.34.4.120 heuristics/completesol

Option	Description	Default
heuristics/completesol/beforepresol	should the heuristic run before presolving? Range: boolean	1
heuristics/completesol/freq	frequency for calling primal heuristic <completesol> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/completesol/freqofs	frequency offset for calling primal heuristic <completesol> Range: {0, ..., 65534}	0
heuristics/completesol/ignorecont	should number of continuous variables be ignored? Range: boolean	0
heuristics/completesol/maxcontvars	maximal number of continuous variables after presolving Range: {-1, ..., ∞}	-1
heuristics/completesol/maxlpiter	maximal number of LP iterations (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
heuristics/completesol/maxproprounds	maximal number of iterations in propagation (-1: no limit) Range: {-1, ..., ∞}	10
heuristics/completesol/maxunknownrate	maximal rate of unknown solution values Range: [0, 1]	0.85
heuristics/completesol/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/completesol/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/completesol/solutions	heuristic stops, if the given number of improving solutions were found (-1: no limit) Range: {-1, ..., ∞}	5
Options for expert users		
heuristics/completesol/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/completesol/boundwidening	bound widening factor applied to continuous variables (0: fix variables to given solution values, 1: relax to global bounds) Range: [0, 1]	0.1
heuristics/completesol/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/completesol/maxdepth	maximal depth level to call primal heuristic <completesol> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/completesol/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/completesol/minimprove	factor by which the incumbent should be improved at least Range: [0, 1]	0.01
heuristics/completesol/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/completesol/objweight	weight of the original objective function (1: only original objective) Range: [0.001, 1]	1
heuristics/completesol/priority	priority of heuristic <completesol> Range: {-536870912, ..., 536870911}	0

5.34.4.121 heuristics/conflictdiving

Option	Description	Default
heuristics/conflictdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1

Option	Description	Default
heuristics/conflictdiving/freq	frequency for calling primal heuristic <conflictdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/conflictdiving/freqofs	frequency offset for calling primal heuristic <conflictdiving> Range: {0, ..., 65534}	0
heuristics/conflictdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/conflictdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/conflictdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/conflictdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.15
heuristics/conflictdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/conflictdiving/likecoef	perform rounding like coefficient diving Range: boolean	0
heuristics/conflictdiving/lockweight	weight used in a convex combination of conflict and variable locks Range: [0, 1]	0.75
heuristics/conflictdiving/maxdepth	maximal depth level to call primal heuristic <conflictdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/conflictdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/conflictdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/conflictdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/conflictdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/conflictdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/conflictdiving/maxviol	try to maximize the violation Range: boolean	1
heuristics/conflictdiving/minconflictlocks	minimal number of conflict locks per variable Range: {0, ..., ∞}	5

Option	Description	Default
heuristics/conflictdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/conflictdiving/priority	priority of heuristic <conflictdiving> Range: {-536870912, ..., 536870911}	-1000100

5.34.4.122 heuristics/crossover

Option	Description	Default
heuristics/crossover/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	-1
heuristics/crossover/freq	frequency for calling primal heuristic <crossover> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	30
heuristics/crossover/freqofs	frequency offset for calling primal heuristic <crossover> Range: {0, ..., 65534}	0
heuristics/crossover/minfixingrate	minimum percentage of integer variables that have to be fixed Range: [0, 1]	0.666
heuristics/crossover/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/crossover/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/crossover/nusedsols	number of solutions to be taken into account Range: {2, ..., ∞}	3
Options for expert users		
heuristics/crossover/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/crossover/dontwaitatroot	should the nwaitingnodes parameter be ignored at the root node? Range: boolean	0
heuristics/crossover/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/crossover/maxdepth	maximal depth level to call primal heuristic <crossover> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/crossover/maxnodes	maximum number of nodes to regard in the sub-problem Range: {0, ..., ∞}	5000
heuristics/crossover/minimprove	factor by which Crossover should at least improve the incumbent Range: [0, 1]	0.01
heuristics/crossover/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50

Option	Description	Default
heuristics/crossover/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/crossover/permute	should the subproblem be permuted to increase diversification? Range: boolean	0
heuristics/crossover/priority	priority of heuristic <crossover> Range: {-536870912, ..., 536870911}	-1104000
heuristics/crossover/randomization	should the choice which sols to take be randomized? Range: boolean	1
heuristics/crossover/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/crossover/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.34.4.123 heuristics/dins

Option	Description	Default
heuristics/dins/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	3
heuristics/dins/freq	frequency for calling primal heuristic <dins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/dins/freqofs	frequency offset for calling primal heuristic <dins> Range: {0, ..., 65534}	0
heuristics/dins/minfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.3
heuristics/dins/minnodes	minimum number of nodes required to start the sub-problem Range: {0, ..., ∞}	50
heuristics/dins/neighborhoodsize	radius (using Manhattan metric) of the incumbent's neighborhood to be searched Range: {1, ..., ∞}	18
heuristics/dins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	5000
heuristics/dins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.05
heuristics/dins/solnum	number of pool-solutions to be checked for flag array update (for hard fixing of binary variables) Range: {1, ..., ∞}	5
Options for expert users		
heuristics/dins/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1

Option	Description	Default
heuristics/dins/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	1.5
heuristics/dins/maxdepth	maximal depth level to call primal heuristic <dins> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/dins/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/dins/minimprove	factor by which dins should at least improve the incumbent Range: [0, 1]	0.01
heuristics/dins/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/dins/priority	priority of heuristic <dins> Range: {-536870912, ..., 536870911}	-1105000
heuristics/dins/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/dins/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.34.4.124 heuristics/distributiondiving

Option	Description	Default
heuristics/distributiondiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/distributiondiving/freq	frequency for calling primal heuristic <distributiondiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/distributiondiving/freqofs	frequency offset for calling primal heuristic <distributiondiving> Range: {0, ..., 65534}	3
heuristics/distributiondiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/distributiondiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/distributiondiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/distributiondiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05

Option	Description	Default
heuristics/distributiondiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	1
Options for expert users		
heuristics/distributiondiving/maxdepth	maximal depth level to call primal heuristic <distributiondiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/distributiondiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/distributiondiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/distributiondiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/distributiondiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/distributiondiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/distributiondiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/distributiondiving/priority	priority of heuristic <distributiondiving> Range: {-536870912, ..., 536870911}	-1003300
heuristics/distributiondiving/scoreparam	the score;largest 'd'ifference, 'l'owest cumulative probability,'h'ighest c.p., 'v'otes lowest c.p., votes highest c.p.('w'), 'r'evolving Range: l, v, d, h, w, r	r

5.34.4.125 heuristics/dps

Option	Description	Default
heuristics/dps/freq	frequency for calling primal heuristic <dps> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/dps/freqofs	frequency offset for calling primal heuristic <dps> Range: {0, ..., 65534}	0
heuristics/dps/maxiterations	maximal number of iterations Range: {1, ..., ∞}	50
heuristics/dps/maxlinkscore	maximal linking score of used decomposition (equivalent to percentage of linking constraints) Range: [0, 1]	1
heuristics/dps/penalty	multiplier for absolute increase of penalty parameters (0: no increase) Range: [0, ∞]	100

Option	Description	Default
heuristics/dps/reoptimize	should the problem get reoptimized with the original objective function? Range: boolean	0
heuristics/dps/reuse	should solutions get reused in subproblems? Range: boolean	0
Options for expert users		
heuristics/dps/maxdepth	maximal depth level to call primal heuristic <dps> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/dps/priority	priority of heuristic <dps> Range: {-536870912, ..., 536870911}	75000

5.34.4.126 heuristics/dualval

Option	Description	Default
heuristics/dualval/dynamicdepth	says if and how the recursion depth is computed at runtime Range: {0, ..., 1}	0
heuristics/dualval/freq	frequency for calling primal heuristic <dualval> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/dualval/freqofs	frequency offset for calling primal heuristic <dualval> Range: {0, ..., 65534}	0
heuristics/dualval/heurverblevel	verblevel of the heuristic, default is 0 to display nothing Range: {0, ..., 4}	0
heuristics/dualval/lambdaobj	scaling factor for the objective function Range: [0, 1]	0
heuristics/dualval/lambdaslack	value added to objective of slack variables, must not be zero Range: [0.1, ∞]	1
heuristics/dualval/maxcalls	maximal number of recursive calls of the heuristic (if dynamicdepth is off) Range: {0, ..., ∞}	25
heuristics/dualval/maxequalranks	maximal number of variables that may have maximal rank, quit if there are more, turn off by setting -1 Range: {-1, ..., ∞}	50
heuristics/dualval/mingap	minimal gap for which we still run the heuristic, if gap is less we return without doing anything Range: [0, 100]	5
heuristics/dualval/nlpverblevel	verblevel of the nlp solver, can be 0 or 1 Range: {0, ..., 1}	0
heuristics/dualval/onlyleaves	disable the heuristic if it was not called at a leaf of the B&B tree Range: boolean	0
heuristics/dualval/rankvalue	number of ranks that should be displayed when the heuristic is called Range: {0, ..., ∞}	10

Option	Description	Default
heuristics/dualval/relaxcontvars	relax the continous variables Range: boolean	0
heuristics/dualval/relaxindicators	relax the indicator variables by introducing continuous copies Range: boolean	0
Options for expert users		
heuristics/dualval/forceimprovements	exit if objective doesn't improve Range: boolean	0
heuristics/dualval/maxdepth	maximal depth level to call primal heuristic <dualval> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/dualval/onlycheaper	add constraint to ensure that discrete vars are improving Range: boolean	1
heuristics/dualval/priority	priority of heuristic <dualval> Range: {-536870912, ..., 536870911}	-10

5.34.4.127 heuristics/farkasdiving

Option	Description	Default
heuristics/farkasdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/farkasdiving/freq	frequency for calling primal heuristic <farkasdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/farkasdiving/freqofs	frequency offset for calling primal heuristic <farkasdiving> Range: {0, ..., 65534}	0
heuristics/farkasdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/farkasdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	1
heuristics/farkasdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/farkasdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/farkasdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/farkasdiving/checkcands	should diving candidates be checked before running? Range: boolean	0

Option	Description	Default
heuristics/farkasdiving/maxdepth	maximal depth level to call primal heuristic <farkasdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/farkasdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/farkasdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/farkasdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/farkasdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/farkasdiving/maxobjocc	maximal occurance factor of an objective coefficient Range: [0, 1]	1
heuristics/farkasdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/farkasdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/farkasdiving/objdynamism	minimal objective dynamism (log) to run Range: [0, ∞]	0.0001
heuristics/farkasdiving/priority	priority of heuristic <farkasdiving> Range: {-536870912, ..., 536870911}	-900000
heuristics/farkasdiving/rootsuccess	should the heuristic only run within the tree if at least one solution was found at the root node? Range: boolean	1
heuristics/farkasdiving/scalescore	should the score be scaled? Range: boolean	1
heuristics/farkasdiving/scaletype	scale score by [f]ractionality or [i]mpact on farkasproof Range: f, i	i

5.34.4.128 heuristics/feaspump

Option	Description	Default
heuristics/feaspump/alpha	initial weight of the objective function in the convex combination Range: [0, 1]	1
heuristics/feaspump/alphadiff	threshold difference for the convex parameter to perform perturbation Range: [0, 1]	1
heuristics/feaspump/beforecuts	should the feasibility pump be called at root node before cut separation? Range: boolean	1

Option	Description	Default
heuristics/feaspump/freq	frequency for calling primal heuristic <feaspump> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/feaspump/freqofs	frequency offset for calling primal heuristic <feaspump> Range: {0, ..., 65534}	0
heuristics/feaspump/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/feaspump/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.01
heuristics/feaspump/neighborhoodsize	radius (using Manhattan metric) of the neighborhood to be searched in stage 3 Range: {1, ..., ∞}	18
heuristics/feaspump/objfactor	factor by which the regard of the objective is decreased in each round, 1.0 for dynamic Range: [0, 1]	0.1
heuristics/feaspump/pertsolfound	should a random perturbation be performed if a feasible solution was found? Range: boolean	1
heuristics/feaspump/stage3	should we solve a local branching sub-MIP if no solution could be found? Range: boolean	0
heuristics/feaspump/usefp20	should an iterative round-and-propagate scheme be used to find the integral points? Range: boolean	0
Options for expert users		
heuristics/feaspump/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/feaspump/cyclelength	maximum length of cycles to be checked explicitly in each round Range: {1, ..., 100}	3
heuristics/feaspump/maxdepth	maximal depth level to call primal heuristic <feaspump> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/feaspump/maxloops	maximal number of pumping loops (-1: no limit) Range: {-1, ..., ∞}	10000
heuristics/feaspump/maxsols	total number of feasible solutions found up to which heuristic is called (-1: no limit) Range: {-1, ..., ∞}	10
heuristics/feaspump/maxstallloops	maximal number of pumping rounds without fractionality improvement (-1: no limit) Range: {-1, ..., ∞}	10
heuristics/feaspump/minflips	minimum number of random variables to flip, if a 1-cycle is encountered Range: {1, ..., ∞}	10
heuristics/feaspump/perturbfreq	number of iterations until a random perturbation is forced Range: {1, ..., ∞}	100

Option	Description	Default
heuristics/feaspump/priority	priority of heuristic <feaspump> Range: {-536870912, ..., 536870911}	-1000000

5.34.4.129 heuristics/fixandinfer

Option	Description	Default
heuristics/fixandinfer/freq	frequency for calling primal heuristic <fixandinfer> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/fixandinfer/freqofs	frequency offset for calling primal heuristic <fixandinfer> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/fixandinfer/maxdepth	maximal depth level to call primal heuristic <fixandinfer> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/fixandinfer/minfixings	minimal number of fixings to apply before dive may be aborted Range: {0, ..., ∞}	100
heuristics/fixandinfer/priority	priority of heuristic <fixandinfer> Range: {-536870912, ..., 536870911}	-500000
heuristics/fixandinfer/proprounds	maximal number of propagation rounds in probing subproblems (-1: no limit, 0: auto) Range: {-1, ..., ∞}	0

5.34.4.130 heuristics/fracdiving

Option	Description	Default
heuristics/fracdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/fracdiving/freq	frequency for calling primal heuristic <fracdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/fracdiving/freqofs	frequency offset for calling primal heuristic <fracdiving> Range: {0, ..., 65534}	3
heuristics/fracdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/fracdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/fracdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/fracdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05

Option	Description	Default
heuristics/fracdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/fracdiving/maxdepth	maximal depth level to call primal heuristic <fracdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/fracdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/fracdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/fracdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/fracdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/fracdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/fracdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/fracdiving/priority	priority of heuristic <fracdiving> Range: {-536870912, ..., 536870911}	-1003000

5.34.4.131 heuristics/gins

Option	Description	Default
heuristics/gins/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	3
heuristics/gins/freq	frequency for calling primal heuristic <gins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/gins/freqofs	frequency offset for calling primal heuristic <gins> Range: {0, ..., 65534}	8
heuristics/gins/maxdistance	maximum distance to selected variable to enter the subproblem, or -1 to select the distance that best approximates the minimum fixing rate from below Range: {-1, ..., ∞}	3
heuristics/gins/minfixingrate	percentage of integer variables that have to be fixed Range: [1e-06, 0.999999]	0.66
heuristics/gins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500

Option	Description	Default
heuristics/gins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.15
Options for expert users		
heuristics/gins/consecutiveblocks	should blocks be treated consecutively (sorted by ascending label?) Range: boolean	1
heuristics/gins/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/gins/fixcontvars	should continuous variables outside the neighborhoods be fixed? Range: boolean	0
heuristics/gins/maxdepth	maximal depth level to call primal heuristic <gins> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/gins/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/gins/minimprove	factor by which gins should at least improve the incumbent Range: [0, 1]	0.01
heuristics/gins/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/gins/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	100
heuristics/gins/overlap	overlap of blocks between runs - 0.0: no overlap, 1.0: shift by only 1 block Range: [0, 1]	0
heuristics/gins/potential	the reference point to compute the neighborhood potential: (r)oot, (l)ocal lp, or (p)seudo solution Range: l, p, r	r
heuristics/gins/priority	priority of heuristic <gins> Range: {-536870912, ..., 536870911}	-1103000
heuristics/gins/relaxdenseconss	should dense constraints (at least as dense as 1 - minfixingrate) be ignored by connectivity graph? Range: boolean	0
heuristics/gins/rollhorizonlimfac	limiting percentage for variables already used in sub-SCIPs to terminate rolling horizon approach Range: [0, 1]	0.4
heuristics/gins/usedecomp	should user decompositions be considered, if available? Range: boolean	1
heuristics/gins/usedecomprollhorizon	should user decompositions be considered for initial selection in rolling horizon, if available? Range: boolean	0
heuristics/gins/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0

Option	Description	Default
heuristics/gins/userollinghorizon	should the heuristic solve a sequence of sub-MIP's around the first selected variable Range: boolean	1
heuristics/gins/useselfallback	should random initial variable selection be used if decomposition was not successful? Range: boolean	1

5.34.4.132 heuristics/guideddiving

Option	Description	Default
heuristics/guideddiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/guideddiving/freq	frequency for calling primal heuristic <guideddiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/guideddiving/freqofs	frequency offset for calling primal heuristic <guideddiving> Range: {0, ..., 65534}	7
heuristics/guideddiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/guideddiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/guideddiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/guideddiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/guideddiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/guideddiving/maxdepth	maximal depth level to call primal heuristic <guideddiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/guideddiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/guideddiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	1
heuristics/guideddiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8

Option	Description	Default
heuristics/guideddiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	1
heuristics/guideddiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/guideddiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/guideddiving/priority	priority of heuristic <guideddiving> Range: {-536870912, ..., 536870911}	-1007000

5.34.4.133 heuristics/indicator

Option	Description	Default
heuristics/indicator/freq	frequency for calling primal heuristic <indicator> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/indicator/freqofs	frequency offset for calling primal heuristic <indicator> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/indicator/improvesols	Try to improve other solutions by one-opt? Range: boolean	0
heuristics/indicator/maxdepth	maximal depth level to call primal heuristic <indicator> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/indicator/oneopt	whether the one-opt heuristic should be started Range: boolean	0
heuristics/indicator/priority	priority of heuristic <indicator> Range: {-536870912, ..., 536870911}	-20200

5.34.4.134 heuristics/intdiving

Option	Description	Default
heuristics/intdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/intdiving/freq	frequency for calling primal heuristic <intdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/intdiving/freqofs	frequency offset for calling primal heuristic <intdiving> Range: {0, ..., 65534}	9
heuristics/intdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/intdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
Options for expert users		

Option	Description	Default
heuristics/intdiving/maxdepth	maximal depth level to call primal heuristic <intdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/intdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/intdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/intdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/intdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/intdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/intdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/intdiving/priority	priority of heuristic <intdiving> Range: {-536870912, ..., 536870911}	-1003500

5.34.4.135 heuristics/intshifting

Option	Description	Default
heuristics/intshifting/freq	frequency for calling primal heuristic <intshifting> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/intshifting/freqofs	frequency offset for calling primal heuristic <intshifting> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/intshifting/maxdepth	maximal depth level to call primal heuristic <intshifting> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/intshifting/priority	priority of heuristic <intshifting> Range: {-536870912, ..., 536870911}	-10000

5.34.4.136 heuristics/linesearchdiving

Option	Description	Default
heuristics/linesearchdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/linesearchdiving/freq	frequency for calling primal heuristic <linesearchdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10

Option	Description	Default
heuristics/linesearchdiving/freqofs	frequency offset for calling primal heuristic <linesearchdiving> Range: {0, ..., 65534}	6
heuristics/linesearchdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/linesearchdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/linesearchdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/linesearchdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/linesearchdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/linesearchdiving/maxdepth	maximal depth level to call primal heuristic <linesearchdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/linesearchdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/linesearchdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/linesearchdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/linesearchdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/linesearchdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/linesearchdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/linesearchdiving/priority	priority of heuristic <linesearchdiving> Range: {-536870912, ..., 536870911}	-1006000

5.34.4.137 heuristics/localbranching

Option	Description	Default
heuristics/localbranching/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	3

Option	Description	Default
heuristics/localbranching/freq	frequency for calling primal heuristic <localbranching> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/localbranching/freqofs	frequency offset for calling primal heuristic <localbranching> Range: {0, ..., 65534}	0
heuristics/localbranching/neighborhoodsize	radius (using Manhattan metric) of the incumbent's neighborhood to be searched Range: {1, ..., ∞}	18
heuristics/localbranching/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	1000
heuristics/localbranching/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.05
Options for expert users		
heuristics/localbranching/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/localbranching/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	1.5
heuristics/localbranching/maxdepth	maximal depth level to call primal heuristic <localbranching> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/localbranching/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	10000
heuristics/localbranching/minimprove	factor by which localbranching should at least improve the incumbent Range: [0, 1]	0.01
heuristics/localbranching/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	1000
heuristics/localbranching/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/localbranching/priority	priority of heuristic <localbranching> Range: {-536870912, ..., 536870911}	-1102000
heuristics/localbranching/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0

5.34.4.138 heuristics/locks

Option	Description	Default
heuristics/locks/freq	frequency for calling primal heuristic <locks> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0

Option	Description	Default
heuristics/locks/freqofs	frequency offset for calling primal heuristic <locks> Range: {0, ..., 65534}	0
heuristics/locks/minfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.65
heuristics/locks/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/locks/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/locks/roundupprobability	probability for rounding a variable up in case of ties Range: [0, 1]	0.67
Options for expert users		
heuristics/locks/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/locks/maxdepth	maximal depth level to call primal heuristic <locks> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/locks/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/locks/maxproprounds	maximum number of propagation rounds to be performed in each propagation call (-1: no limit, -2: parameter settings) Range: {-2, ..., ∞}	2
heuristics/locks/minfixingratelp	minimum fixing rate over all variables (including continuous) to solve LP Range: [0, 1]	0
heuristics/locks/minimprove	factor by which locks heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/locks/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	500
heuristics/locks/priority	priority of heuristic <locks> Range: {-536870912, ..., 536870911}	3000
heuristics/locks/updatelocks	should the locks be updated based on LP rows? Range: boolean	1
heuristics/locks/usefinalsubmip	should a final sub-MIP be solved to costruct a feasible solution if the LP was not roundable? Range: boolean	1

5.34.4.139 heuristics/lpface

Option	Description	Default
heuristics/lpface/freq	frequency for calling primal heuristic <lpface> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	15

Option	Description	Default
heuristics/lpface/freqofs	frequency offset for calling primal heuristic <lpface> Range: {0, ..., 65534}	0
heuristics/lpface/minfixingrate	required percentage of fixed integer variables in sub-MIP to run Range: [0, 1]	0.1
heuristics/lpface/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	200
heuristics/lpface/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/lpface/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/lpface/dualbasisequations	should dually nonbasic rows be turned into equations? Range: boolean	0
heuristics/lpface/keepsubscip	should the heuristic continue solving the same sub-SCIP? Range: boolean	0
heuristics/lpface/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/lpface/maxdepth	maximal depth level to call primal heuristic <lpface> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/lpface/maxnodes	maximum number of nodes to regard in the sub-problem Range: {0, ..., ∞}	5000
heuristics/lpface/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/lpface/minpathlen	the minimum active search tree path length along which lower bound hasn't changed before heuristic becomes active Range: {0, ..., 65531}	5
heuristics/lpface/priority	priority of heuristic <lpface> Range: {-536870912, ..., 536870911}	-1104010
heuristics/lpface/subscipobjective	objective function in the sub-SCIP: (z)ero, (r)oot-LP-difference, (i)nference, LP (f)ractionality, (o)riginal Range: f, o, r, z, i	z
heuristics/lpface/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	1

5.34.4.140 heuristics/mpec

Option	Description	Default
heuristics/mpec/freq	frequency for calling primal heuristic <mpec> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	50
heuristics/mpec/freqofs	frequency offset for calling primal heuristic <mpec> Range: {0, ..., 65534}	0
heuristics/mpec/inittheta	initial regularization right-hand side value Range: [0, 0.25]	0.125
heuristics/mpec/maxiter	maximum number of iterations of the MPEC loop Range: {0, ..., ∞}	100
heuristics/mpec/maxnlpcost	maximum cost available for solving NLPs per call of the heuristic Range: [0, ∞]	1e+08
heuristics/mpec/maxnlpiter	maximum number of NLP iterations per solve Range: {0, ..., ∞}	500
heuristics/mpec/maxnunsucc	maximum number of consecutive calls for which the heuristic did not find an improving solution Range: {0, ..., ∞}	10
heuristics/mpec/mingapleft	minimum amount of gap left in order to call the heuristic Range: [0, ∞]	0.05
heuristics/mpec/minimprove	factor by which heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/mpec/sigma	regularization update factor Range: [0, 1]	0.5
heuristics/mpec/subnlptrigger	maximum number of NLP iterations per solve Range: [0, 1]	0.001
Options for expert users		
heuristics/mpec/maxdepth	maximal depth level to call primal heuristic <mpec> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/mpec/priority	priority of heuristic <mpec> Range: {-536870912, ..., 536870911}	-2050000

5.34.4.141 heuristics/multistart

Option	Description	Default
heuristics/multistart/freq	frequency for calling primal heuristic <multistart> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/multistart/freqofs	frequency offset for calling primal heuristic <multistart> Range: {0, ..., 65534}	0
heuristics/multistart/gradlimit	limit for gradient computations for all improvePoint() calls (0 for no limit) Range: [0, ∞]	5e+06
heuristics/multistart/maxboundsize	maximum variable domain size for unbounded variables Range: [0, ∞]	20000
heuristics/multistart/maxiter	number of iterations to reduce the maximum violation of a point Range: {0, ..., ∞}	300

Option	Description	Default
heuristics/multistart/maxncluster	maximum number of considered clusters per heuristic call Range: {0, ..., ∞}	3
heuristics/multistart/maxreldist	maximum distance between two points in the same cluster Range: [0, ∞]	0.15
heuristics/multistart/minimprfac	minimum required improving factor to proceed in improvement of a single point Range: real	0.05
heuristics/multistart/minimpriter	number of iteration when checking the minimum improvement Range: {1, ..., ∞}	10
heuristics/multistart/nrndpoints	number of random points generated per execution call Range: {0, ..., ∞}	100
heuristics/multistart/onlynlps	should the heuristic run only on continuous problems? Range: boolean	1
Options for expert users		
heuristics/multistart/maxdepth	maximal depth level to call primal heuristic <multistart> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/multistart/priority	priority of heuristic <multistart> Range: {-536870912, ..., 536870911}	-2100000

5.34.4.142 heuristics/mutation

Option	Description	Default
heuristics/mutation/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	-1
heuristics/mutation/freq	frequency for calling primal heuristic <mutation> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/mutation/freqofs	frequency offset for calling primal heuristic <mutation> Range: {0, ..., 65534}	8
heuristics/mutation/minfixingrate	percentage of integer variables that have to be fixed Range: [1e-06, 0.999999]	0.8
heuristics/mutation/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/mutation/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/mutation/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/mutation/maxdepth	maximal depth level to call primal heuristic <mutation> (-1: no limit) Range: {-1, ..., 65534}	-1

Option	Description	Default
heuristics/mutation/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/mutation/minimprove	factor by which mutation should at least improve the incumbent Range: [0, 1]	0.01
heuristics/mutation/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	500
heuristics/mutation/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/mutation/priority	priority of heuristic <mutation> Range: {-536870912, ..., 536870911}	-1103010
heuristics/mutation/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/mutation/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.34.4.143 heuristics/nlpdiving

Option	Description	Default
heuristics/nlpdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/nlpdiving/fixquot	percentage of fractional variables that should be fixed before the next NLP solve Range: [0, 1]	0.2
heuristics/nlpdiving/freq	frequency for calling primal heuristic <nlpdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/nlpdiving/freqofs	frequency offset for calling primal heuristic <nlpdiving> Range: {0, ..., 65534}	3
heuristics/nlpdiving/maxfeasnlps	maximal number of NLPs with feasible solution to solve during one dive Range: {1, ..., ∞}	10
heuristics/nlpdiving/maxnlpiterabs	minimial absolute number of allowed NLP iterations Range: {0, ..., ∞}	200
heuristics/nlpdiving/maxnlpiterrel	additional allowed number of NLP iterations relative to successfully found solutions Range: {0, ..., ∞}	10
heuristics/nlpdiving/minsuccquot	heuristic will not run if less then this percentage of calls succeeded (0.0: no limit) Range: [0, 1]	0.1
heuristics/nlpdiving/nlpfastfail	should the NLP solver stop early if it converges slow? Range: boolean	1

Option	Description	Default
heuristics/nlpdiving/prefercover	should variables in a minimal cover be preferred? Range: boolean	1
heuristics/nlpdiving/solvesubmip	should a sub-MIP be solved if all cover variables are fixed? Range: boolean	0
heuristics/nlpdiving/varselrule	which variable selection should be used? ('f'ractionality, 'c'oefficient, 'p'seudocost, 'g'uided, 'd'ouble, 'v'eclen) Range: f, c, p, g, d, v	d
Options for expert users		
heuristics/nlpdiving/lp	should the LP relaxation be solved before the NLP relaxation? Range: boolean	0
heuristics/nlpdiving/maxdepth	maximal depth level to call primal heuristic <nlpdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/nlpdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/nlpdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/nlpdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/nlpdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/nlpdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/nlpdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/nlpdiving/nlpstart	which point should be used as starting point for the NLP solver? ('n'one, last 'f'easible, from dive's'tart) Range: f, n, s	s
heuristics/nlpdiving/preferlpfracs	prefer variables that are also fractional in LP solution? Range: boolean	0
heuristics/nlpdiving/priority	priority of heuristic <nlpdiving> Range: {-536870912, ..., 536870911}	-1003010

5.34.4.144 heuristics/objpscostdiving

Option	Description	Default
heuristics/objpscostdiving/freq	frequency for calling primal heuristic <objpscostdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20

Option	Description	Default
heuristics/objpscostdiving/freqofs	frequency offset for calling primal heuristic <objpscostdiving> Range: {0, ..., 65534}	4
heuristics/objpscostdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/objpscostdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to total iteration number Range: [0, 1]	0.01
Options for expert users		
heuristics/objpscostdiving/depthfac	maximal diving depth: number of binary/integer variables times depthfac Range: [0, ∞]	0.5
heuristics/objpscostdiving/depthfacnosol	maximal diving depth factor if no feasible solution was found yet Range: [0, ∞]	2
heuristics/objpscostdiving/maxdepth	maximal depth level to call primal heuristic <objpscostdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/objpscostdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/objpscostdiving/maxsols	total number of feasible solutions found up to which heuristic is called (-1: no limit) Range: {-1, ..., ∞}	-1
heuristics/objpscostdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/objpscostdiving/priority	priority of heuristic <objpscostdiving> Range: {-536870912, ..., 536870911}	-1004000

5.34.4.145 heuristics/octane

Option	Description	Default
heuristics/octane/freq	frequency for calling primal heuristic <octane> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/octane/freqofs	frequency offset for calling primal heuristic <octane> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/octane/ffirst	number of 0-1-points to be tested at first whether they violate a common row Range: {1, ..., ∞}	10
heuristics/octane/fmax	number of 0-1-points to be tested as possible solutions by OCTANE Range: {1, ..., ∞}	100
heuristics/octane/maxdepth	maximal depth level to call primal heuristic <octane> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/octane/priority	priority of heuristic <octane> Range: {-536870912, ..., 536870911}	-1008000
heuristics/octane/useavgnbray	should the weighted average of the nonbasic cone be used as one ray direction? Range: boolean	1

Option	Description	Default
heuristics/octane/useavgray	should the average of the basic cone be used as one ray direction? Range: boolean	1
heuristics/octane/useavgwgtray	should the weighted average of the basic cone be used as one ray direction? Range: boolean	1
heuristics/octane/usediffray	should the difference between the root solution and the current LP solution be used as one ray direction? Range: boolean	0
heuristics/octane/usefracspace	execute OCTANE only in the space of fractional variables (TRUE) or in the full space? Range: boolean	1
heuristics/octane/useobjray	should the inner normal of the objective be used as one ray direction? Range: boolean	1

5.34.4.146 heuristics/ofins

Option	Description	Default
heuristics/ofins/freq	frequency for calling primal heuristic <ofins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/ofins/freqofs	frequency offset for calling primal heuristic <ofins> Range: {0, ..., 65534}	0
heuristics/ofins/maxchange	maximal rate of change per coefficient to get fixed Range: [0, 1]	0.04
heuristics/ofins/maxchangerate	maximal rate of changed coefficients Range: [0, 1]	0.5
heuristics/ofins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/ofins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/ofins/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/ofins/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/ofins/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/ofins/maxdepth	maximal depth level to call primal heuristic <ofins> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/ofins/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/ofins/minimprove	factor by which RENS should at least improve the incumbent Range: [0, 1]	0.01

Option	Description	Default
heuristics/ofins/minnodes	minimum number of nodes required to start the sub-problem Range: {0, ..., ∞}	50
heuristics/ofins/priority	priority of heuristic <ofins> Range: {-536870912, ..., 536870911}	60000

5.34.4.147 heuristics/oneopt

Option	Description	Default
heuristics/oneopt/freq	frequency for calling primal heuristic <oneopt> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/oneopt/freqofs	frequency offset for calling primal heuristic <oneopt> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/oneopt/beforepresol	should the heuristic be called before presolving? Range: boolean	0
heuristics/oneopt/duringroot	should the heuristic be called before and during the root node? Range: boolean	1
heuristics/oneopt/forcelpconstruction	should the construction of the LP be forced even if LP solving is deactivated? Range: boolean	0
heuristics/oneopt/maxdepth	maximal depth level to call primal heuristic <oneopt> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/oneopt/priority	priority of heuristic <oneopt> Range: {-536870912, ..., 536870911}	-20000
heuristics/oneopt/useloop	should the heuristic continue to run as long as improvements are found? Range: boolean	1
heuristics/oneopt/weightedobj	should the objective be weighted with the potential shifting value when sorting the shifting candidates? Range: boolean	1

5.34.4.148 heuristics/padm

Option	Description	Default
heuristics/padm/assignlinking	should linking constraints be assigned? Range: boolean	1
heuristics/padm/freq	frequency for calling primal heuristic <padm> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/padm/freqofs	frequency offset for calling primal heuristic <padm> Range: {0, ..., 65534}	0
heuristics/padm/reoptimize	should the problem get reoptimized with the original objective function? Range: boolean	1

Option	Description	Default
heuristics/padm/timing	should the heuristic run before or after the processing of the node? (0: before, 1: after, 2: both) Range: {0, ..., 2}	0
Options for expert users		
heuristics/padm/admiterations	maximal number of ADM iterations in each penalty loop Range: {1, ..., 100}	4
heuristics/padm/gap	mipgap at start Range: [0, 16]	2
heuristics/padm/maxdepth	maximal depth level to call primal heuristic <padm> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/padm/maxnodes	maximum number of nodes to regard in all subproblems Range: {0, ..., ∞}	5000
heuristics/padm/minnodes	minimum number of nodes to regard in one subproblem Range: {0, ..., ∞}	50
heuristics/padm/nodefac	factor to control nodelimits of subproblems Range: [0, 0.99]	0.8
heuristics/padm/original	should the original problem be used? This is only for testing and not recommended! Range: boolean	0
heuristics/padm/penaltyiterations	maximal number of penalty iterations Range: {1, ..., 100000}	100
heuristics/padm/priority	priority of heuristic <padm> Range: {-536870912, ..., 536870911}	70000
heuristics/padm/scaling	enable sigmoid rescaling of penalty parameters Range: boolean	1

5.34.4.149 heuristics/proximity

Option	Description	Default
heuristics/proximity/freq	frequency for calling primal heuristic <proximity> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/proximity/freqofs	frequency offset for calling primal heuristic <proximity> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/proximity/binvarquot	threshold for percentage of binary variables required to start Range: [0, 1]	0.1
heuristics/proximity/lpitersquot	quotient of sub-MIP LP iterations with respect to LP iterations so far Range: [0, 1]	0.2
heuristics/proximity/maxdepth	maximal depth level to call primal heuristic <proximity> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/proximity/maxlpiters	maximum number of LP iterations to be performed in the subproblem Range: {-1, ..., ∞}	100000

Option	Description	Default
heuristics/proximity/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	10000
heuristics/proximity/mingap	minimum primal-dual gap for which the heuristic is executed Range: [0, ∞]	0.01
heuristics/proximity/minimprove	factor by which proximity should at least improve the incumbent Range: [0, 1]	0.02
heuristics/proximity/minlpiters	minimum number of LP iterations performed in subproblem Range: {0, ..., ∞}	200
heuristics/proximity/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	1
heuristics/proximity/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	50
heuristics/proximity/nodesquot	sub-MIP node limit w.r.t number of original nodes Range: [0, ∞]	0.1
heuristics/proximity/priority	priority of heuristic <proximity> Range: {-536870912, ..., 536870911}	-2000000
heuristics/proximity/restart	should the heuristic immediately run again on its newly found solution? Range: boolean	1
heuristics/proximity/usefinallp	should the heuristic solve a final LP in case of continuous objective variables? Range: boolean	0
heuristics/proximity/uselprows	should subproblem be constructed based on LP row information? Range: boolean	0
heuristics/proximity/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0
heuristics/proximity/waitingnodes	waiting nodes since last incumbent before heuristic is executed Range: {0, ..., ∞}	100

5.34.4.150 heuristics/pscostdiving

Option	Description	Default
heuristics/pscostdiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/pscostdiving/freq	frequency for calling primal heuristic <pscostdiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/pscostdiving/freqofs	frequency offset for calling primal heuristic <pscostdiving> Range: {0, ..., 65534}	2

Option	Description	Default
heuristics/pscostdiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/pscostdiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/pscostdiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/pscostdiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/pscostdiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	1
Options for expert users		
heuristics/pscostdiving/maxdepth	maximal depth level to call primal heuristic <pscostdiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/pscostdiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/pscostdiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/pscostdiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/pscostdiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/pscostdiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/pscostdiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/pscostdiving/priority	priority of heuristic <pscostdiving> Range: {-536870912, ..., 536870911}	-1002000

5.34.4.151 heuristics/randrounding

Option	Description	Default
heuristics/randrounding/freq	frequency for calling primal heuristic <randrounding> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/randrounding/freqofs	frequency offset for calling primal heuristic <randrounding> Range: {0, ..., 65534}	0

Option	Description	Default
Options for expert users		
heuristics/randrounding/maxdepth	maximal depth level to call primal heuristic <randrounding> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/randrounding/maxproprounds	limit of rounds for each propagation call Range: {-1, ..., ∞}	1
heuristics/randrounding/oncepernode	should the heuristic only be called once per node? Range: boolean	0
heuristics/randrounding/priority	priority of heuristic <randrounding> Range: {-536870912, ..., 536870911}	-200
heuristics/randrounding/propagateonlyroot	should the probing part of the heuristic be applied exclusively at the root node? Range: boolean	1
heuristics/randrounding/usesimplerounding	should the heuristic apply the variable lock strategy of simple rounding, if possible? Range: boolean	0

5.34.4.152 heuristics/rens

Option	Description	Default
heuristics/rens/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	-1
heuristics/rens/freq	frequency for calling primal heuristic <rens> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/rens/freqofs	frequency offset for calling primal heuristic <rens> Range: {0, ..., 65534}	0
heuristics/rens/minfixingrate	minimum percentage of integer variables that have to be fixable Range: [0, 1]	0.5
heuristics/rens/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/rens/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/rens/startsol	solution that is used for fixing values ('l'p relaxation, 'n'lp relaxation) Range: n, l	l
Options for expert users		
heuristics/rens/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/rens/binarybounds	should general integers get binary bounds [floor(.),ceil(.)] ? Range: boolean	1
heuristics/rens/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1

Option	Description	Default
heuristics/rens/extratime	should the RENS sub-CIP get its own full time limit? This is only for testing and not recommended! Range: boolean	0
heuristics/rens/fullscale	should the RENS sub-CIP be solved with cuts, conflicts, strong branching,... This is only for testing and not recommended! Range: boolean	0
heuristics/rens/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/rens/maxdepth	maximal depth level to call primal heuristic <rens> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/rens/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/rens/minimprove	factor by which RENS should at least improve the incumbent Range: [0, 1]	0.01
heuristics/rens/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/rens/priority	priority of heuristic <rens> Range: {-536870912, ..., 536870911}	-1100000
heuristics/rens/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/rens/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.34.4.153 heuristics/reoptsols

Option	Description	Default
heuristics/reoptsols/freq	frequency for calling primal heuristic <reoptsols> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/reoptsols/freqofs	frequency offset for calling primal heuristic <reoptsols> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/reoptsols/maxdepth	maximal depth level to call primal heuristic <reoptsols> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/reoptsols/maxruns	check solutions of the last k runs. (-1: all) Range: {-1, ..., ∞}	-1
heuristics/reoptsols/maxsols	maximal number solutions which should be checked. (-1: all) Range: {-1, ..., ∞}	1000
heuristics/reoptsols/priority	priority of heuristic <reoptsols> Range: {-536870912, ..., 536870911}	40000

5.34.4.154 heuristics/repair

Option	Description	Default
heuristics/repair/filename	file name of a solution to be used as infeasible starting point, [-] if not available Range: string	-
heuristics/repair/freq	frequency for calling primal heuristic <repair> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/repair/freqofs	frequency offset for calling primal heuristic <repair> Range: {0, ..., 65534}	0
heuristics/repair/minfixingrate	minimum percentage of integer variables that have to be fixed Range: [0, 1]	0.3
heuristics/repair/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/repair/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/repair/roundit	True : fractional variables which are not fractional in the given solution are rounded, FALSE : solving process of this heuristic is stopped. Range: boolean	1
heuristics/repair/useobjfactor	should a scaled objective function for original variables be used in repair subproblem? Range: boolean	0
heuristics/repair/useslackvars	should slack variables be used in repair subproblem? Range: boolean	0
heuristics/repair/usevarfix	should variable fixings be used in repair subproblem? Range: boolean	1
Options for expert users		
heuristics/repair/alpha	factor for the potential of var fixings Range: [0, 100]	2
heuristics/repair/maxdepth	maximal depth level to call primal heuristic <repair> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/repair/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/repair/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/repair/priority	priority of heuristic <repair> Range: {-536870912, ..., 536870911}	-20

5.34.4.155 heuristics/rins

Option	Description	Default
heuristics/rins/freq	frequency for calling primal heuristic <rins> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	25

Option	Description	Default
heuristics/rins/freqofs	frequency offset for calling primal heuristic <rins> Range: {0, ..., 65534}	0
heuristics/rins/minfixingrate	minimum percentage of integer variables that have to be fixed Range: [0, 1]	0.3
heuristics/rins/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/rins/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.3
Options for expert users		
heuristics/rins/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/rins/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	2
heuristics/rins/maxdepth	maximal depth level to call primal heuristic <rins> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/rins/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	5000
heuristics/rins/minimprove	factor by which rins should at least improve the incumbent Range: [0, 1]	0.01
heuristics/rins/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	50
heuristics/rins/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	200
heuristics/rins/priority	priority of heuristic <rins> Range: {-536870912, ..., 536870911}	-1101000
heuristics/rins/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0
heuristics/rins/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.34.4.156 heuristics/rootsoldiving

Option	Description	Default
heuristics/rootsoldiving/freq	frequency for calling primal heuristic <rootsoldiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	20
heuristics/rootsoldiving/freqofs	frequency offset for calling primal heuristic <rootsoldiving> Range: {0, ..., 65534}	5

Option	Description	Default
heuristics/rootsoldiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/rootsoldiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.01
Options for expert users		
heuristics/rootsoldiving/alpha	soft rounding factor to fade out objective coefficients Range: [0, 1]	0.9
heuristics/rootsoldiving/depthfac	maximal diving depth: number of binary/integer variables times depthfac Range: [0, ∞]	0.5
heuristics/rootsoldiving/depthfacnosol	maximal diving depth factor if no feasible solution was found yet Range: [0, ∞]	2
heuristics/rootsoldiving/maxdepth	maximal depth level to call primal heuristic <rootsoldiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/rootsoldiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/rootsoldiving/maxsols	total number of feasible solutions found up to which heuristic is called (-1: no limit) Range: {-1, ..., ∞}	-1
heuristics/rootsoldiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/rootsoldiving/priority	priority of heuristic <rootsoldiving> Range: {-536870912, ..., 536870911}	-1005000

5.34.4.157 heuristics/rounding

Option	Description	Default
heuristics/rounding/freq	frequency for calling primal heuristic <rounding> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/rounding/freqofs	frequency offset for calling primal heuristic <rounding> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/rounding/maxdepth	maximal depth level to call primal heuristic <rounding> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/rounding/oncepernode	should the heuristic only be called once per node? Range: boolean	0
heuristics/rounding/priority	priority of heuristic <rounding> Range: {-536870912, ..., 536870911}	-1000
heuristics/rounding/successfactor	number of calls per found solution that are considered as standard success, a higher factor causes the heuristic to be called more often Range: {-1, ..., ∞}	100

5.34.4.158 heuristics/shiftandpropagate

Option	Description	Default
heuristics/shiftandpropagate/freq	frequency for calling primal heuristic <shiftandpropagate> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/shiftandpropagate/freqofs	frequency offset for calling primal heuristic <shiftandpropagate> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/shiftandpropagate/binlocksfirst	should binary variables with no locks be preferred in the ordering? Range: boolean	0
heuristics/shiftandpropagate/collectstats	should variable statistics be collected during probing? Range: boolean	1
heuristics/shiftandpropagate/cutoffbreaker	The number of cutoffs before heuristic stops Range: {-1, ..., 1000000}	15
heuristics/shiftandpropagate/fixbinlocks	should binary variables with no locks in one direction be fixed to that direction? Range: boolean	1
heuristics/shiftandpropagate/impliscontinuous	should implicit integer variables be treated as continuous variables? Range: boolean	1
heuristics/shiftandpropagate/maxcutoffquot	maximum percentage of allowed cutoffs before stopping the heuristic Range: [0, 2]	0
heuristics/shiftandpropagate/maxdepth	maximal depth level to call primal heuristic <shiftandpropagate> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/shiftandpropagate/minfixingratelp	minimum fixing rate over all variables (including continuous) to solve LP Range: [0, 1]	0
heuristics/shiftandpropagate/normalize	should coefficients and left/right hand sides be normalized by max row coeff? Range: boolean	1
heuristics/shiftandpropagate/nozerofixing	should variables with a zero shifting value be delayed instead of being fixed? Range: boolean	0
heuristics/shiftandpropagate/nproprounds	The number of propagation rounds used for each propagation Range: {-1, ..., 1000}	10
heuristics/shiftandpropagate/onlywithoutsol	Should heuristic only be executed if no primal solution was found, yet? Range: boolean	1
heuristics/shiftandpropagate/preferbinaries	Should binary variables be shifted first? Range: boolean	1
heuristics/shiftandpropagate/priority	priority of heuristic <shiftandpropagate> Range: {-536870912, ..., 536870911}	1000
heuristics/shiftandpropagate/probing	Should domains be reduced by probing? Range: boolean	1

Option	Description	Default
heuristics/shiftandpropagate/relax	Should continuous variables be relaxed? Range: boolean	1
heuristics/shiftandpropagate/selectbest	should the heuristic choose the best candidate in every round? (set to FALSE for static order)? Range: boolean	0
heuristics/shiftandpropagate/sortkey	the key for variable sorting: (n)orms down, norms (u)p, (v)iolations down, viola(t)ions up, or (r)andom Range: n, r, t, u, v	v
heuristics/shiftandpropagate/sortvars	Should variables be sorted for the heuristic? Range: boolean	1
heuristics/shiftandpropagate/stopafterfeasible	Should the heuristic stop calculating optimal shift values when no more rows are violated? Range: boolean	1
heuristics/shiftandpropagate/updateweights	should row weight be increased every time the row is violated? Range: boolean	0

5.34.4.159 heuristics/shifting

Option	Description	Default
heuristics/shifting/freq	frequency for calling primal heuristic <shifting> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/shifting/freqofs	frequency offset for calling primal heuristic <shifting> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/shifting/maxdepth	maximal depth level to call primal heuristic <shifting> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/shifting/priority	priority of heuristic <shifting> Range: {-536870912, ..., 536870911}	-5000

5.34.4.160 heuristics/simplerounding

Option	Description	Default
heuristics/simplerounding/freq	frequency for calling primal heuristic <simplerounding> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/simplerounding/freqofs	frequency offset for calling primal heuristic <simplerounding> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/simplerounding/maxdepth	maximal depth level to call primal heuristic <simplerounding> (-1: no limit) Range: {-1, ..., 65534}	-1

Option	Description	Default
heuristics/simplerounding/oncepernode	should the heuristic only be called once per node? Range: boolean	0
heuristics/simplerounding/priority	priority of heuristic <simplerounding> Range: {-536870912, ..., 536870911}	-30

5.34.4.161 heuristics/subnlp

Option	Description	Default
heuristics/subnlp/expectinfeas	percentage of NLP solves with infeasible status required to tell NLP solver to expect an infeasible NLP Range: [0, 1]	0
heuristics/subnlp/feastolfactor	factor on SCIP feasibility tolerance for NLP solves if resolving when NLP solution not feasible in CIP Range: [0, 1]	0.1
heuristics/subnlp/forbidfixings	whether to add constraints that forbid specific fixings that turned out to be infeasible Range: boolean	0
heuristics/subnlp/freq	frequency for calling primal heuristic <subnlp> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/subnlp/freqofs	frequency offset for calling primal heuristic <subnlp> Range: {0, ..., 65534}	0
heuristics/subnlp/iterinit	number of iterations used for initial NLP solves Range: {0, ..., ∞}	300
heuristics/subnlp/itermin	minimal number of iterations for NLP solves Range: {0, ..., ∞}	20
heuristics/subnlp/maxpresolverounds	limit on number of presolve rounds in sub-SCIP (-1 for unlimited, 0 for no presolve) Range: {-1, ..., ∞}	-1
heuristics/subnlp/ninitsolves	number of successful NLP solves until switching to iterlimit guess and using success rate Range: {0, ..., ∞}	2
heuristics/subnlp/nlpverblevel	verbosity level of NLP solver Range: {0, ..., 65535}	0
heuristics/subnlp/nodesfactor	factor on number of nodes in SCIP (plus nodesoffset) to compute itercontingent (higher value runs heuristics more frequently) Range: [0, ∞]	0.3
heuristics/subnlp/nodesoffset	number of nodes added to the current number of nodes when computing itercontingent (higher value runs heuristic more often in early search) Range: {0, ..., ∞}	1600
heuristics/subnlp/presolveemphasis	presolve emphasis in sub-SCIP (0: default, 1: aggressive, 2: fast, 3: off) Range: {0, ..., 3}	2
heuristics/subnlp/setcutoff	whether to set cutoff in sub-SCIP to current primal bound Range: boolean	1

Option	Description	Default
heuristics/subnlp/successrateexp	exponent for power of success rate to be multiplied with itercontingent (lower value decreases impact of success rate) Range: [0, ∞]	1
Options for expert users		
heuristics/subnlp/keepcopy	whether to keep SCIP copy or to create new copy each time heuristic is applied Range: boolean	1
heuristics/subnlp/maxdepth	maximal depth level to call primal heuristic <subnlp> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/subnlp/opttol	absolute optimality tolerance to use for NLP solves Range: [0, 1]	1e-07
heuristics/subnlp/priority	priority of heuristic <subnlp> Range: {-536870912, ..., 536870911}	-2000010

5.34.4.162 heuristics/trivial

Option	Description	Default
heuristics/trivial/freq	frequency for calling primal heuristic <trivial> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/trivial/freqofs	frequency offset for calling primal heuristic <trivial> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/trivial/maxdepth	maximal depth level to call primal heuristic <trivial> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/trivial/priority	priority of heuristic <trivial> Range: {-536870912, ..., 536870911}	10000

5.34.4.163 heuristics/trivialnegation

Option	Description	Default
heuristics/trivialnegation/freq	frequency for calling primal heuristic <trivialnegation> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/trivialnegation/freqofs	frequency offset for calling primal heuristic <trivialnegation> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/trivialnegation/maxdepth	maximal depth level to call primal heuristic <trivialnegation> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/trivialnegation/priority	priority of heuristic <trivialnegation> Range: {-536870912, ..., 536870911}	39990

5.34.4.164 heuristics/trustregion

Option	Description	Default
heuristics/trustregion/bestsollimit	limit on number of improving incumbent solutions in sub-CIP Range: {-1, ..., ∞}	3
heuristics/trustregion/freq	frequency for calling primal heuristic <trustregion> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/trustregion/freqofs	frequency offset for calling primal heuristic <trustregion> Range: {0, ..., 65534}	0
heuristics/trustregion/minbinvars	the number of binary variables necessary to run the heuristic Range: {1, ..., ∞}	10
heuristics/trustregion/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	1000
heuristics/trustregion/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.05
heuristics/trustregion/objminimprove	the minimum absolute improvement in the objective function value Range: [0, ∞]	0.01
heuristics/trustregion/violpenalty	the penalty for each change in the binary variables from the candidate solution Range: [0, ∞]	100
Options for expert users		
heuristics/trustregion/copycuts	if uselprows == FALSE, should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/trustregion/lplimfac	factor by which the limit on the number of LP depends on the node limit Range: [1, ∞]	1.5
heuristics/trustregion/maxdepth	maximal depth level to call primal heuristic <trustregion> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/trustregion/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	10000
heuristics/trustregion/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	100
heuristics/trustregion/nwaitingnodes	number of nodes without incumbent change that heuristic should wait Range: {0, ..., ∞}	1
heuristics/trustregion/priority	priority of heuristic <trustregion> Range: {-536870912, ..., 536870911}	-1102010
heuristics/trustregion/uselprows	should subproblem be created out of the rows in the LP rows? Range: boolean	0

5.34.4.165 heuristics/trysol

Option	Description	Default
heuristics/trysol/freq	frequency for calling primal heuristic <trysol> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/trysol/freqofs	frequency offset for calling primal heuristic <trysol> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/trysol/maxdepth	maximal depth level to call primal heuristic <trysol> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/trysol/priority	priority of heuristic <trysol> Range: {-536870912, ..., 536870911}	-3000010

5.34.4.166 heuristics/twoopt

Option	Description	Default
heuristics/twoopt/freq	frequency for calling primal heuristic <twoopt> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/twoopt/freqofs	frequency offset for calling primal heuristic <twoopt> Range: {0, ..., 65534}	0
Options for expert users		
heuristics/twoopt/intopt	Should Integer-2-Optimization be applied or not? Range: boolean	0
heuristics/twoopt/matchingrate	parameter to determine the percentage of rows two variables have to share before they are considered equal Range: [0, 1]	0.5
heuristics/twoopt/maxdepth	maximal depth level to call primal heuristic <twoopt> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/twoopt/maxnslaves	maximum number of slaves for one master variable Range: {-1, ..., 1000000}	199
heuristics/twoopt/priority	priority of heuristic <twoopt> Range: {-536870912, ..., 536870911}	-20100
heuristics/twoopt/waitingnodes	user parameter to determine number of nodes to wait after last best solution before calling heuristic Range: {0, ..., 10000}	0

5.34.4.167 heuristics/undercover

Option	Description	Default
heuristics/undercover/fixingalts	prioritized sequence of fixing values used ('l'p relaxation, 'n'lp relaxation, 'i'ncumbent solution) Range: string	li

Option	Description	Default
heuristics/undercover/freq	frequency for calling primal heuristic <undercover> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/undercover/freqofs	frequency offset for calling primal heuristic <undercover> Range: {0, ..., 65534}	0
heuristics/undercover/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/undercover/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
heuristics/undercover/onlyconvexify	should we only fix variables in order to obtain a convex problem? Range: boolean	0
heuristics/undercover/postnlp	should the NLP heuristic be called to polish a feasible solution? Range: boolean	1
Options for expert users		
heuristics/undercover/beforecuts	should the heuristic be called at root node before cut separation? Range: boolean	1
heuristics/undercover/conflictweight	weight for conflict score in fixing order Range: real	1000
heuristics/undercover/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/undercover/coverbd	should bounddisjunction constraints be covered (or just copied)? Range: boolean	0
heuristics/undercover/coveringobj	objective function of the covering problem (influenced nonlinear 'c'onstraints/'t'erms, 'd'omain size, 'l'ocks, 'm'in of up/down locks, 'u'nit penalties) Range: c, d, l, m, t, u	u
heuristics/undercover/cutoffweight	weight for cutoff score in fixing order Range: [0, ∞]	1
heuristics/undercover/fixingorder	order in which variables should be fixed (increasing 'C'onflict score, decreasing 'c'onflict score, increasing 'V'ariable index, decreasing 'v'ariable index Range: C, c, V, v	v
heuristics/undercover/fixintfirst	should integer variables in the cover be fixed first? Range: boolean	0
heuristics/undercover/inferenceweight	weight for inference score in fixing order Range: real	1
heuristics/undercover/locksrounding	shall LP values for integer vars be rounded according to locks? Range: boolean	1

Option	Description	Default
heuristics/undercover/maxbacktracks	maximum number of backtracks in fix-and-propagate Range: {0, ..., ∞}	6
heuristics/undercover/maxcoversizeconss	maximum coversize (as ratio to the percentage of non-affected constraints) Range: [0, ∞]	∞
heuristics/undercover/maxcoversizevars	maximum coversize (as fraction of total number of variables) Range: [0, 1]	1
heuristics/undercover/maxdepth	maximal depth level to call primal heuristic <undercover> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/undercover/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	500
heuristics/undercover/maxrecovers	maximum number of recoverings Range: {0, ..., ∞}	0
heuristics/undercover/maxreorders	maximum number of reorderings of the fixing order Range: {0, ..., ∞}	1
heuristics/undercover/mincoveredabs	minimum number of nonlinear constraints in the original problem Range: {0, ..., ∞}	5
heuristics/undercover/mincoveredrel	minimum percentage of nonlinear constraints in the original problem Range: [0, 1]	0.15
heuristics/undercover/minimprove	factor by which the heuristic should at least improve the incumbent Range: [-1, 1]	0
heuristics/undercover/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	500
heuristics/undercover/priority	priority of heuristic <undercover> Range: {-536870912, ..., 536870911}	-1110000
heuristics/undercover/recoverdiv	fraction of covering variables in the last cover which need to change their value when recovering Range: [0, 1]	0.9
heuristics/undercover/reusecover	shall the cover be reused if a conflict was added after an infeasible subproblem? Range: boolean	0

5.34.4.168 heuristics/vbounds

Option	Description	Default
heuristics/vbounds/freq	frequency for calling primal heuristic <vbounds> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	0
heuristics/vbounds/freqofs	frequency offset for calling primal heuristic <vbounds> Range: {0, ..., 65534}	0

Option	Description	Default
heuristics/vbounds/minintfixingrate	minimum percentage of integer variables that have to be fixed Range: [0, 1]	0.65
heuristics/vbounds/minmipfixingrate	minimum percentage of variables that have to be fixed within sub-SCIP (integer and continuous) Range: [0, 1]	0.65
heuristics/vbounds/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	500
heuristics/vbounds/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/vbounds/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
heuristics/vbounds/feasvariant	which variants of the vbounds heuristic that try to stay feasible should be called? (0: off, 1: w/o looking at obj, 2: only fix to best bound, 4: only fix to worst bound Range: {0, ..., 7}	6
heuristics/vbounds/maxbacktracks	maximum number of backtracks during the fixing process Range: {-1, ..., 536870911}	10
heuristics/vbounds/maxdepth	maximal depth level to call primal heuristic <vbounds> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/vbounds/maxnodes	maximum number of nodes to regard in the sub-problem Range: {0, ..., ∞}	5000
heuristics/vbounds/maxproprounds	maximum number of propagation rounds during probing (-1 infinity) Range: {-1, ..., 536870911}	2
heuristics/vbounds/minimprove	factor by which vbounds heuristic should at least improve the incumbent Range: [0, 1]	0.01
heuristics/vbounds/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	500
heuristics/vbounds/priority	priority of heuristic <vbounds> Range: {-536870912, ..., 536870911}	2500
heuristics/vbounds/tightenvariant	which tightening variants of the vbounds heuristic should be called? (0: off, 1: w/o looking at obj, 2: only fix to best bound, 4: only fix to worst bound Range: {0, ..., 7}	7
heuristics/vbounds/uselockfixings	should more variables be fixed based on variable locks if the fixing rate was not reached? Range: boolean	0

5.34.4.169 heuristics/veclendiving

Option	Description	Default
heuristics/veclendiving/backtrack	use one level of backtracking if infeasibility is encountered? Range: boolean	1
heuristics/veclendiving/freq	frequency for calling primal heuristic <veclendiving> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	10
heuristics/veclendiving/freqofs	frequency offset for calling primal heuristic <veclendiving> Range: {0, ..., 65534}	4
heuristics/veclendiving/lpresolvedomchgquot	percentage of immediate domain changes during probing to trigger LP resolve Range: [0, ∞]	0.15
heuristics/veclendiving/lpsolvefreq	LP solve frequency for diving heuristics (0: only after enough domain changes have been found) Range: {0, ..., ∞}	0
heuristics/veclendiving/maxlpiterofs	additional number of allowed LP iterations Range: {0, ..., ∞}	1000
heuristics/veclendiving/maxlpiterquot	maximal fraction of diving LP iterations compared to node LP iterations Range: [0, ∞]	0.05
heuristics/veclendiving/onlylpbranchcands	should only LP branching candidates be considered instead of the slower but more general constraint handler diving variable selection? Range: boolean	0
Options for expert users		
heuristics/veclendiving/maxdepth	maximal depth level to call primal heuristic <veclendiving> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/veclendiving/maxdiveavgquot	maximal quotient (curlowerbound - lowerbound)/(avglowerbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, ∞]	0
heuristics/veclendiving/maxdiveavgquotnosol	maximal AVGQUOT when no solution was found yet (0.0: no limit) Range: [0, ∞]	0
heuristics/veclendiving/maxdiveubquot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where diving is performed (0.0: no limit) Range: [0, 1]	0.8
heuristics/veclendiving/maxdiveubquotnosol	maximal UBQUOT when no solution was found yet (0.0: no limit) Range: [0, 1]	0.1
heuristics/veclendiving/maxreldepth	maximal relative depth to start diving Range: [0, 1]	1
heuristics/veclendiving/minreldepth	minimal relative depth to start diving Range: [0, 1]	0
heuristics/veclendiving/priority	priority of heuristic <veclendiving> Range: {-536870912, ..., 536870911}	-1003100

5.34.4.170 heuristics/zeroobj

Option	Description	Default
heuristics/zeroobj/freq	frequency for calling primal heuristic <zeroobj> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	-1
heuristics/zeroobj/freqofs	frequency offset for calling primal heuristic <zeroobj> Range: {0, ..., 65534}	0
heuristics/zeroobj/nodesofs	number of nodes added to the contingent of the total nodes Range: {0, ..., ∞}	100
heuristics/zeroobj/nodesquot	contingent of sub problem nodes in relation to the number of nodes of the original problem Range: [0, 1]	0.1
Options for expert users		
heuristics/zeroobj/addallsols	should all subproblem solutions be added to the original SCIP? Range: boolean	0
heuristics/zeroobj/maxdepth	maximal depth level to call primal heuristic <zeroobj> (-1: no limit) Range: {-1, ..., 65534}	0
heuristics/zeroobj/maxlpiters	maximum number of LP iterations to be performed in the subproblem Range: {-1, ..., ∞}	5000
heuristics/zeroobj/maxnodes	maximum number of nodes to regard in the subproblem Range: {0, ..., ∞}	1000
heuristics/zeroobj/minimprove	factor by which zeroobj should at least improve the incumbent Range: [0, 1]	0.01
heuristics/zeroobj/minnodes	minimum number of nodes required to start the subproblem Range: {0, ..., ∞}	100
heuristics/zeroobj/onlywithoutsol	should heuristic only be executed if no primal solution was found, yet? Range: boolean	1
heuristics/zeroobj/priority	priority of heuristic <zeroobj> Range: {-536870912, ..., 536870911}	100
heuristics/zeroobj/useuct	should uct node selection be used at the beginning of the search? Range: boolean	0

5.34.4.171 heuristics/zirounding

Option	Description	Default
heuristics/zirounding/freq	frequency for calling primal heuristic <zirounding> (-1: never, 0: only at depth freqofs) Range: {-1, ..., 65534}	1
heuristics/zirounding/freqofs	frequency offset for calling primal heuristic <zirounding> Range: {0, ..., 65534}	0

Option	Description	Default
Options for expert users		
heuristics/zirounding/maxdepth	maximal depth level to call primal heuristic <zirounding> (-1: no limit) Range: {-1, ..., 65534}	-1
heuristics/zirounding/maxroundingloops	determines maximum number of rounding loops Range: {-1, ..., ∞}	2
heuristics/zirounding/minstopncalls	determines the minimum number of calls before percentage-based deactivation of Zirounding is applied Range: {1, ..., ∞}	1000
heuristics/zirounding/priority	priority of heuristic <zirounding> Range: {-536870912, ..., 536870911}	-500
heuristics/zirounding/stoppercentage	if percentage of found solutions falls below this parameter, Zirounding will be deactivated Range: [0, 1]	0.02
heuristics/zirounding/stopziround	flag to determine if Zirounding is deactivated after a certain percentage of unsuccessful calls Range: boolean	1

5.34.4.172 history

Option	Description	Default
history/allowmerge	should variable histories be merged from sub-SCIPs whenever possible? Range: boolean	0
history/allowtransfer	should variable histories be transferred to initialize SCIP copies? Range: boolean	0
history/valuebased	should statistics be collected for variable domain value pairs? Range: boolean	0

5.34.4.173 limits

Option	Description	Default
limits/absgap	solving stops, if the absolute gap = |primalbound - dualbound| is below the given value Range: [0, ∞]	GAMS optca
limits/autorestartnodes	if solve exceeds this number of nodes for the first time, an automatic restart is triggered (-1: no automatic restart) Range: {-1, ..., ∞}	-1
limits/bestsol	solving stops, if the given number of solution improvements were found (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
limits/gap	solving stops, if the relative gap = |primal - dual|/MIN(|dual|,|primal|) is below the given value, the gap is 'Infinity', if primal and dual bound have opposite signs Range: [0, ∞]	GAMS optcr
limits/maxorigsol	maximal number of solutions candidates to store in the solution storage of the original problem Range: {0, ..., ∞}	10
limits/maxsol	maximal number of solutions to store in the solution storage Range: {1, ..., ∞}	100
limits/memory	maximal memory usage in MB; reported memory usage is lower than real memory usage! Range: [0, 8.79609e+12]	GAMS workspace
limits/nodes	maximal number of nodes to process (-1: no limit) Range: {-1, ..., ∞}	GAMS nodlim, if > 0, otherwise -1
limits/restarts	solving stops, if the given number of restarts was triggered (-1: no limit) Range: {-1, ..., ∞}	-1
limits/softtime	soft time limit which should be applied after first solution was found (-1.0: disabled) Range: [-1, ∞]	-1
limits/solutions	solving stops, if the given number of solutions were found; this limit is first checked in presolving (-1: no limit) Range: {-1, ..., ∞}	-1
limits/stallnodes	solving stops, if the given number of nodes was processed since the last improvement of the primal solution value (-1: no limit) Range: {-1, ..., ∞}	-1
limits/time	maximal time in seconds to run Range: [0, ∞]	GAMS reslim
limits/totalnodes	maximal number of total nodes (incl. restarts) to process (-1: no limit) Range: {-1, ..., ∞}	-1

5.34.4.174 lp

Option	Description	Default
lp/alwaysgetduals	should the Farkas duals always be collected when an LP is found to be infeasible? Range: boolean	0

Option	Description	Default
lp/initalgorithm	LP algorithm for solving initial LP relaxations (automatic 's'implex, 'p'rimal simplex, 'd'ual simplex, 'b'arrier, barrier with 'c'rossover) Range: s, p, d, b, c	s
lp/pricing	LP pricing strategy ('l'pi default, 'a'uto, 'f'ull pricing, 'p'artial, 's'teepest edge pricing, 'q'uickstart steepest edge pricing, 'd'evex pricing) Range: l, a, f, p, s, q, d	l
lp/resolvealgorithm	LP algorithm for resolving LP relaxations if a starting basis exists (automatic 's'implex, 'p'rimal simplex, 'd'ual simplex, 'b'arrier, barrier with 'c'rossover) Range: s, p, d, b, c	s
lp/solvedepth	maximal depth for solving LP at the nodes (-1: no depth limit) Range: {-1, ..., 65534}	-1
lp/solvefreq	frequency for solving LP at the nodes (-1: never; 0: only root LP) Range: {-1, ..., 65534}	1
lp/solver	LP solver to use (clp, cplex, soplex) Range: string	cplex, if licensed, otherwise soplex
Options for expert users		
lp/checkdualfeas	should LP solutions be checked for dual feasibility, resolving LP when numerical troubles occur? Range: boolean	1
lp/checkfarkas	should infeasibility proofs from the LP be checked? Range: boolean	1
lp/checkprimfeas	should LP solutions be checked for primal feasibility, resolving LP when numerical troubles occur? Range: boolean	1
lp/checkstability	should LP solver's return status be checked for stability? Range: boolean	1
lp/cleanupcols	should new non-basic columns be removed after LP solving? Range: boolean	0
lp/cleanupcolsroot	should new non-basic columns be removed after root LP solving? Range: boolean	0
lp/cleanuprows	should new basic rows be removed after LP solving? Range: boolean	1
lp/cleanuprowsroot	should new basic rows be removed after root LP solving? Range: boolean	1

Option	Description	Default
lp/clearinitialprobinglp	should lp state be cleared at the end of probing mode when lp was initially unsolved, e.g., when called right after presolving? Range: boolean	1
lp/colagelimit	maximum age a dynamic column can reach before it is deleted from the LP (-1: don't delete columns due to aging) Range: {-1, ..., ∞}	10
lp/conditionlimit	maximum condition number of LP basis counted as stable (-1.0: no limit) Range: [-1, ∞]	-1
lp/disablecutoff	disable the cutoff bound in the LP solver? (0: enabled, 1: disabled, 2: auto) Range: {0, ..., 2}	2
lp/fastmip	which FASTMIP setting of LP solver should be used? 0: off, 1: low Range: {0, ..., 1}	1
lp/freesolvalbuffers	should the buffers for storing LP solution values during diving be freed at end of diving? Range: boolean	0
lp/iterlim	iteration limit for each single LP solve (-1: no limit) Range: {-1, ..., ∞}	-1
lp/lexdualalgo	should the lexicographic dual algorithm be used? Range: boolean	0
lp/lexdualbasic	choose fractional basic variables in lexicographic dual algorithm? Range: boolean	0
lp/lexdualmaxrounds	maximum number of rounds in the lexicographic dual algorithm (-1: unbounded) Range: {-1, ..., ∞}	2
lp/lexdualrootonly	should the lexicographic dual algorithm be applied only at the root node Range: boolean	1
lp/lexdualstalling	turn on the lex dual algorithm only when stalling? Range: boolean	1
lp/minmarkowitz	minimal Markowitz threshold to control sparsity/stability in LU factorization Range: [0.0001, 0.9999]	0.01
lp/presolving	should presolving of LP solver be used? Range: boolean	1
lp/refactorinterval	LP refactorization interval (0: auto) Range: {0, ..., ∞}	0

Option	Description	Default
lp/resolveiterfac	factor of average LP iterations that is used as LP iteration limit for LP resolve (-1: unlimited) Range: [-1, ∞]	-1
lp/resolveitermin	minimum number of iterations that are allowed for LP resolve Range: {1, ..., ∞}	1000
lp/resolverestore	should the LP be resolved to restore the state at start of diving (if FALSE we buffer the solution values)? Range: boolean	0
lp/rootiterlim	iteration limit for initial root LP solve (-1: no limit) Range: {-1, ..., ∞}	-1
lp/rowagelimit	maximum age a dynamic row can reach before it is deleted from the LP (-1: don't delete rows due to aging) Range: {-1, ..., ∞}	10
lp/rowrepswitch	simplex algorithm shall use row representation of the basis if number of rows divided by number of columns exceeds this value (-1.0 to disable row representation) Range: [-1, ∞]	1.2
lp/scaling	LP scaling (0: none, 1: normal, 2: aggressive) Range: {0, ..., 2}	1
lp/solutionpolishing	LP solution polishing method (0: disabled, 1: only root, 2: always, 3: auto) Range: {0, ..., 3}	3
lp/threads	number of threads used for solving the LP (0: automatic) Range: {0, ..., 64}	GAMS threads

5.34.4.175 memory

Option	Description	Default
memory/savefac	fraction of maximal memory usage resulting in switch to memory saving mode Range: [0, 1]	0.8
Options for expert users		
memory/arraygrowfac	memory growing factor for dynamically allocated arrays Range: [1, 10]	1.2
memory/arraygrowinit	initial size of dynamically allocated arrays Range: {0, ..., ∞}	4
memory/pathgrowfac	memory growing factor for path array Range: [1, 10]	2
memory/pathgrowinit	initial size of path array Range: {0, ..., ∞}	256

Option	Description	Default
memory/treegrowfac	memory growing factor for tree array Range: [1, 10]	2
memory/treegrowinit	initial size of tree array Range: {0, ..., ∞}	65536

5.34.4.176 misc

Option	Description	Default
misc/allowstrongdualreds	should strong dual reductions be allowed in propagation and presolving? Range: boolean	1
misc/allowweakdualreds	should weak dual reductions be allowed in propagation and presolving? Range: boolean	1
misc/avoidmemout	try to avoid running into memory limit by restricting plugins like heuristics? Range: boolean	1
misc/calcintegral	should SCIP calculate the primal dual integral value? Range: boolean	1
misc/catchctrlc	should the CTRL-C interrupt be caught by SCIP? Range: boolean	1
misc/estimexternmem	should the usage of external memory be estimated? Range: boolean	1
misc/finitesolutionstore	should SCIP try to remove infinite fixings from solutions copied to the solution store? Range: boolean	0
misc/improvingsols	should only solutions be checked which improve the primal bound Range: boolean	0
misc/outputorigsol	should the best solution be transformed to the orignal space and be output in command line run? Range: boolean	1
misc/printreason	should the reason be printed if a given start solution is infeasible Range: boolean	0
misc/referencevalue	objective value for reference purposes Range: real	∞
misc/resetstat	should the statistics be reset if the transformed problem is freed (in case of a Benders' decomposition this parameter should be set to FALSE) Range: boolean	1
misc/scaleobj	should the objective function be scaled so that it is always integer? Range: boolean	1
misc/showdivingstats	should detailed statistics for diving heuristics be shown? Range: boolean	0
misc/transorigsols	should SCIP try to transfer original solutions to the transformed space (after presolving)? Range: boolean	1
misc/transsolsorig	should SCIP try to transfer transformed solutions to the original space (after solving)? Range: boolean	1

Option	Description	Default
misc/useconstable	should a hashtable be used to map from constraint names to constraints? Range: boolean	1
misc/usesmalltables	should smaller hashtables be used? yields better performance for small problems with about 100 variables Range: boolean	0
misc/usesymmetry	bitset describing used symmetry handling technique (0: off; 1: polyhedral (orbitopes and/or symresacks); 2: orbital fixing; 3: orbitopes and orbital fixing; 4: Schreier Sims cuts; 5: Schreier Sims cuts and orbitopes); 6: Schreier Sims cuts and orbital fixing; 7: Schreier Sims cuts, orbitopes, and orbital fixing Range: {0, ..., 7}	7
misc/usevartable	should a hashtable be used to map from variable names to variables? Range: boolean	1

5.34.4.177 nlhdlr/bilinear

Option	Description	Default
nlhdlr/bilinear/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/bilinear/maxsepadepth	maximum depth to apply separation Range: {0, ..., ∞}	∞
nlhdlr/bilinear/maxseparounds	maximum number of separation rounds in a local node Range: {0, ..., ∞}	1
nlhdlr/bilinear/maxseparoundsroot	maximum number of separation rounds in the root node Range: {0, ..., ∞}	10
nlhdlr/bilinear/useinteval	whether to use the interval evaluation callback of the nlhdlr Range: boolean	1
nlhdlr/bilinear/usereverseprop	whether to use the reverse propagation callback of the nlhdlr Range: boolean	1

5.34.4.178 nlhdlr/concave

Option	Description	Default
nlhdlr/concave/detectsum	whether to run convexity detection when the root of an expression is a sum Range: boolean	0
nlhdlr/concave/enabled	should this nonlinear handler be used Range: boolean	1
Options for expert users		
nlhdlr/concave/cvxprodcomp	whether to use convexity check on product composition f(h)$*$h Range: boolean	1
nlhdlr/concave/cvxquadratic	whether to use convexity check on quadratics Range: boolean	0

Option	Description	Default
nlhdlr/concave/cvxsignomial	whether to use convexity check on signomials Range: boolean	1
nlhdlr/concave/handletrivial	whether to also handle trivial convex expressions Range: boolean	0

5.34.4.179 nlhdlr/convex

Option	Description	Default
nlhdlr/convex/detectsum	whether to run convexity detection when the root of an expression is a non-quadratic sum Range: boolean	0
nlhdlr/convex/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/convex/extendedform	whether to create extended formulations instead of looking for maximal convex expressions Range: boolean	1
Options for expert users		
nlhdlr/convex/cvxprodcomp	whether to use convexity check on product composition f(h)∗h Range: boolean	1
nlhdlr/convex/cvxquadratic	whether to use convexity check on quadratics Range: boolean	1
nlhdlr/convex/cvxsignomial	whether to use convexity check on signomials Range: boolean	1
nlhdlr/convex/handletrivial	whether to also handle trivial convex expressions Range: boolean	0

5.34.4.180 nlhdlr/default

Option	Description	Default
nlhdlr/default/enabled	should this nonlinear handler be used Range: boolean	1

5.34.4.181 nlhdlr/perspective

Option	Description	Default
nlhdlr/perspective/adjrefpoint	whether to adjust the reference point Range: boolean	1
nlhdlr/perspective/convexonly	whether perspective cuts are added only for convex expressions Range: boolean	0
nlhdlr/perspective/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/perspective/maxproprounds	maximal number of propagation rounds in probing Range: {-1, ..., ∞}	1
nlhdlr/perspective/mindomreduction	minimal relative reduction in a variable's domain for applying probing Range: [0, 1]	0.1

Option	Description	Default
nlhdlr/perspective/minviolprobing	minimal violation w.r.t. auxiliary variables for applying probing Range: [0, ∞]	1e-05
nlhdlr/perspective/probingfreq	probing frequency (-1 - no probing, 0 - root node only) Range: {-1, ..., ∞}	1
nlhdlr/perspective/probingonlyinsepa	whether to do probing only in separation Range: boolean	1
nlhdlr/perspective/tightenbounds	whether variable semicontinuity is used to tighten variable bounds Range: boolean	1

5.34.4.182 nlhdlr/quadratic

Option	Description	Default
nlhdlr/quadratic/atwhichnodes	determines at which nodes cut is used (if it's -1, it's used only at the root node, if it's n ≥ 0, it's used at every multiple of n Range: {-1, ..., ∞}	1
nlhdlr/quadratic/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/quadratic/ignorebadrayrestriction	should cut be generated even with bad numerics when restricting to ray? Range: boolean	1
nlhdlr/quadratic/ignorenhighre	should cut be added even when range / efficacy is large? Range: boolean	1
nlhdlr/quadratic/maxrank	maximal rank a slackvar can have Range: {0, ..., ∞}	∞
nlhdlr/quadratic/mincutviolation	minimal cut violation the generated cuts must fulfill to be added to the LP Range: [0, ∞]	0.0001
nlhdlr/quadratic/minviolation	minimal violation the constraint must fulfill such that a cut is generated Range: [0, ∞]	0.0001
nlhdlr/quadratic/ncutslimit	limit for number of cuts generated consecutively Range: {0, ..., ∞}	2
nlhdlr/quadratic/ncutslimitroot	limit for number of cuts generated at root node Range: {0, ..., ∞}	20
nlhdlr/quadratic/nstrengthlimit	limit for number of rays we do the strengthening for Range: {0, ..., ∞}	∞
nlhdlr/quadratic/useboundsasrays	use bounds of variables in quadratic as rays for intersection cuts Range: boolean	0
nlhdlr/quadratic/useintersectioncuts	whether to use intersection cuts for quadratic constraints to separate Range: boolean	0
nlhdlr/quadratic/usestrengthening	whether the strengthening should be used Range: boolean	0

5.34.4.183 nlhdlr/quotient

Option	Description	Default
nlhdlr/quotient/enabled	should this nonlinear handler be used Range: boolean	1

5.34.4.184 nlhdlr/soc

Option	Description	Default
nlhdlr/soc/compeigenvalues	Should Eigenvalue computations be done to detect complex cases in quadratic constraints? Range: boolean	1
nlhdlr/soc/enabled	should this nonlinear handler be used Range: boolean	1
nlhdlr/soc/mincutefficacy	Minimum efficacy which a cut needs in order to be added. Range: [0, ∞]	1e-05

5.34.4.185 nlp

Option	Description	Default
nlp/disable	should the NLP relaxation be always disabled (also for NLPs/MINLPs)? Range: boolean	0

5.34.4.186 nlpi/ipopt

Option	Description	Default
nlpi/ipopt/hessian_approximation	Indicates what Hessian information is to be used. Valid values if not empty: exact limited-memory Range: string	
nlpi/ipopt/hsllib	Name of library containing HSL routines for load at runtime Range: string	
nlpi/ipopt/linear_solver	Linear solver used for step computations. Valid values if not empty: ma27 ma57 ma77 ma86 ma97 pardiso pardisomkl mumps custom Range: string	ma27, if IpoptH licensed, mumps otherwise
nlpi/ipopt/linear_system_scaling	Method for scaling the linear system. Valid values if not empty: none mc19 slack-based Range: string	mc19, if IpoptH licensed, empty otherwise
nlpi/ipopt/mu_strategy	Update strategy for barrier parameter. Valid values if not empty: monotone adaptive Range: string	

Option	Description	Default
nlpi/ipopt/nlp_scaling_method	Select the technique used for scaling the NLP. Valid values if not empty: none user-scaling gradient-based equilibration-based Range: string	
nlpi/ipopt/optfile	name of Ipopt options file Range: string	
nlpi/ipopt/pardisolib	Name of library containing Pardiso routines (from pardiso-project.org) for load at runtime Range: string	
nlpi/ipopt/print_level	Output verbosity level. -1 to use NLPI or Ipopt default. Range: {-1, ..., 12}	-1
nlpi/ipopt/priority	priority of NLPI <ipopt> Range: {-536870912, ..., 536870911}	1000
nlpi/ipopt/warm_start_push	amount (relative and absolute) by which starting point is moved away from bounds in warmstarts Range: [0, 1]	1e-09

5.34.4.187 nodeselection

Option	Description	Default
nodeselection/childsel	child selection rule ('d'own, 'u'p, 'p'seudo costs, 'i'nference, 'l'p value, 'r'oot LP value difference, 'h'ybrid inference/root LP value difference) Range: d, u, p, i, l, r, h	h

5.34.4.188 nodeselection/bfs

Option	Description	Default
nodeselection/bfs/stdpriority	priority of node selection rule <bfs> in standard mode Range: {-536870912, ..., 1073741823}	100000
Options for expert users		
nodeselection/bfs/maxplungedepth	maximal plunging depth, before new best node is forced to be selected (-1 for dynamic setting) Range: {-1, ..., ∞}	-1
nodeselection/bfs/maxplungequot	maximal quotient (curlowerbound - lowerbound)/(cutoffbound - lowerbound) where plunging is performed Range: [0, ∞]	0.25
nodeselection/bfs/memsavepriority	priority of node selection rule <bfs> in memory saving mode Range: {-536870912, ..., 536870911}	0
nodeselection/bfs/minplungedepth	minimal plunging depth, before new best node may be selected (-1 for dynamic setting) Range: {-1, ..., ∞}	-1

5.34.4.189 nodeselection/breadthfirst

Option	Description	Default
nodeselection/breadthfirst/stdpriority	priority of node selection rule <breadthfirst> in standard mode Range: {-536870912, ..., 1073741823}	-10000
Options for expert users		
nodeselection/breadthfirst/memsavepriority	priority of node selection rule <breadthfirst> in memory saving mode Range: {-536870912, ..., 536870911}	-1000000

5.34.4.190 nodeselection/dfs

Option	Description	Default
nodeselection/dfs/stdpriority	priority of node selection rule <dfs> in standard mode Range: {-536870912, ..., 1073741823}	0
Options for expert users		
nodeselection/dfs/memsavepriority	priority of node selection rule <dfs> in memory saving mode Range: {-536870912, ..., 536870911}	100000

5.34.4.191 nodeselection/estimate

Option	Description	Default
nodeselection/estimate/bestnodefreq	frequency at which the best node instead of the best estimate is selected (0: never) Range: {0, ..., ∞}	10
nodeselection/estimate/breadthfirstdepth	depth until breadth-first search is applied Range: {-1, ..., ∞}	-1
nodeselection/estimate/plungeoffset	number of nodes before doing plunging the first time Range: {0, ..., ∞}	0
nodeselection/estimate/stdpriority	priority of node selection rule <estimate> in standard mode Range: {-536870912, ..., 1073741823}	200000
Options for expert users		
nodeselection/estimate/maxplungedepth	maximal plunging depth, before new best node is forced to be selected (-1 for dynamic setting) Range: {-1, ..., ∞}	-1
nodeselection/estimate/maxplungequot	maximal quotient (estimate - lowerbound)/(cutoffbound - lowerbound) where plunging is performed Range: [0, ∞]	0.25
nodeselection/estimate/memsavepriority	priority of node selection rule <estimate> in memory saving mode Range: {-536870912, ..., 536870911}	100

Option	Description	Default
nodeselection/estimate/minplungedepth	minimal plunging depth, before new best node may be selected (-1 for dynamic setting) Range: {-1, ..., ∞}	-1

5.34.4.192 nodeselection/hybridestim

Option	Description	Default
nodeselection/hybridestim/bestnodefreq	frequency at which the best node instead of the hybrid best estimate / best bound is selected (0: never) Range: {0, ..., ∞}	1000
nodeselection/hybridestim/stdpriority	priority of node selection rule <hybridestim> in standard mode Range: {-536870912, ..., 1073741823}	50000
Options for expert users		
nodeselection/hybridestim/estimweight	weight of estimate value in node selection score (0: pure best bound search, 1: pure best estimate search) Range: [0, 1]	0.1
nodeselection/hybridestim/maxplungedepth	maximal plunging depth, before new best node is forced to be selected (-1 for dynamic setting) Range: {-1, ..., ∞}	-1
nodeselection/hybridestim/maxplungequot	maximal quotient (estimate - lowerbound)/(cutoffbound - lowerbound) where plunging is performed Range: [0, ∞]	0.25
nodeselection/hybridestim/memsavepriority	priority of node selection rule <hybridestim> in memory saving mode Range: {-536870912, ..., 536870911}	50
nodeselection/hybridestim/minplungedepth	minimal plunging depth, before new best node may be selected (-1 for dynamic setting) Range: {-1, ..., ∞}	-1

5.34.4.193 nodeselection/restartdfs

Option	Description	Default
nodeselection/restartdfs/countonlyleaves	count only leaf nodes (otherwise all nodes)? Range: boolean	1
nodeselection/restartdfs/selectbestfreq	frequency for selecting the best node instead of the deepest one Range: {0, ..., ∞}	100
nodeselection/restartdfs/stdpriority	priority of node selection rule <restartdfs> in standard mode Range: {-536870912, ..., 1073741823}	10000
Options for expert users		

Option	Description	Default
nodeselection/restartdfs/memsavepriority	priority of node selection rule <restartdfs> in memory saving mode Range: {-536870912, ..., 536870911}	50000

5.34.4.194 nodeselection/uct

Option	Description	Default
nodeselection/uct/stdpriority	priority of node selection rule <uct> in standard mode Range: {-536870912, ..., 1073741823}	10
Options for expert users		
nodeselection/uct/memsavepriority	priority of node selection rule <uct> in memory saving mode Range: {-536870912, ..., 536870911}	0
nodeselection/uct/nodelimit	maximum number of nodes before switching to default rule Range: {0, ..., 1000000}	31
nodeselection/uct/useestimate	should the estimate (TRUE) or lower bound of a node be used for UCT score? Range: boolean	0
nodeselection/uct/weight	weight for visit quotient of node selection rule Range: [0, 1]	0.1

5.34.4.195 numerics

Option	Description	Default
numerics/checkfeastolfac	feasibility tolerance factor; for checking the feasibility of the best solution Range: [0, ∞]	1
numerics/dualfeastol	feasibility tolerance for reduced costs in LP solution Range: [1e-17, 0.001]	1e-07
numerics/epsilon	absolute values smaller than this are considered zero Range: [1e-20, 0.001]	1e-09
numerics/feastol	feasibility tolerance for constraints Range: [1e-17, 0.001]	1e-06
numerics/lpfeastolfactor	factor w.r.t. primal feasibility tolerance that determines default (and maximal) primal feasibility tolerance of LP solver Range: [1e-06, 1]	1
numerics/sumepsilon	absolute values of sums smaller than this are considered zero Range: [1e-17, 0.001]	1e-06
Options for expert users		
numerics/barrierconvtol	LP convergence tolerance used in barrier algorithm Range: [1e-17, 0.001]	1e-10
numerics/boundstreps	minimal relative improve for strengthening bounds Range: [1e-17, ∞]	0.05
numerics/hugeval	values larger than this are considered huge and should be handled separately (e.g., in activity computation) Range: [0, ∞]	1e+15

Option	Description	Default
numerics/pseudocostdelta	minimal objective distance value to use for branching pseudo cost updates Range: [0, ∞]	0.0001
numerics/pseudocosteps	minimal variable distance value to use for branching pseudo cost updates Range: [1e-17, 1]	0.1
numerics/recomputefac	minimal decrease factor that causes the recomputation of a value (e.g., pseudo objective) instead of an update Range: [0, ∞]	1e+07

5.34.4.196 presolving

Option	Description	Default
presolving/maxrestarts	maximal number of restarts (-1: unlimited) Range: {-1, ..., ∞}	-1
presolving/maxrounds	maximal number of presolving rounds (-1: unlimited, 0: off) Range: {-1, ..., ∞}	-1
Options for expert users		
presolving/abortfac	abort presolve, if at most this fraction of the problem was changed in last presolve round Range: [0, 1]	0.0008
presolving/clqtablefac	limit on number of entries in clique table relative to number of problem nonzeros Range: [0, ∞]	2
presolving/donotaggr	should aggregation of variables be forbidden? Range: boolean	0
presolving/donotmultaggr	should multi-aggregation of variables be forbidden? Range: boolean	0
presolving/immrestartfac	fraction of integer variables that were fixed in the root node triggering an immediate restart with preprocessing Range: [0, 1]	0.1
presolving/restartfac	fraction of integer variables that were fixed in the root node triggering a restart with preprocessing after root node evaluation Range: [0, 1]	0.025
presolving/restartminred	minimal fraction of integer variables removed after restart to allow for an additional restart Range: [0, 1]	0.1
presolving/subrestartfac	fraction of integer variables that were globally fixed during the solving process triggering a restart with preprocessing Range: [0, 1]	1

5.34.4.197 presolving/boundshift

Option	Description	Default
presolving/boundshift/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		

Option	Description	Default
presolving/boundshift/flipping	is flipping allowed (multiplying with -1)? Range: boolean	1
presolving/boundshift/integer	shift only integer ranges? Range: boolean	1
presolving/boundshift/maxshift	absolute value of maximum shift Range: {0, ..., ∞}	∞
presolving/boundshift/priority	priority of presolver <boundshift> Range: {-536870912, ..., 536870911}	7900000
presolving/boundshift/timing	timing mask of presolver <boundshift> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.34.4.198 presolving/convertinttobin

Option	Description	Default
presolving/convertinttobin/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		
presolving/convertinttobin/maxdomainsize	absolute value of maximum domain size for converting an integer variable to binaries variables Range: {0, ..., ∞}	∞
presolving/convertinttobin/onlypoweroftwo	should only integer variables with a domain size of 2^p - 1 be converted(, there we don't need an knapsack-constraint for restricting the sum of the binaries) Range: boolean	0
presolving/convertinttobin/priority	priority of presolver <convertinttobin> Range: {-536870912, ..., 536870911}	6000000
presolving/convertinttobin/samelocksinbothdirections	should only integer variables with uplocks equals downlocks be converted Range: boolean	0
presolving/convertinttobin/timing	timing mask of presolver <convertinttobin> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.34.4.199 presolving/domcol

Option	Description	Default
presolving/domcol/continuousred	should reductions for continuous variables be performed? Range: boolean	1
presolving/domcol/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
presolving/domcol/nummaxpairs	maximal number of pair comparisons Range: {1024, ..., 1000000000}	1048576

Option	Description	Default
presolving/domcol/numminpairs	minimal number of pair comparisons Range: {100, ..., 1048576}	1024
presolving/domcol/predbndstr	should predictive bound strengthening be applied? Range: boolean	0
Options for expert users		
presolving/domcol/priority	priority of presolver <domcol> Range: {-536870912, ..., 536870911}	-1000
presolving/domcol/timing	timing mask of presolver <domcol> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.200 presolving/dualagg

Option	Description	Default
presolving/dualagg/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		
presolving/dualagg/priority	priority of presolver <dualagg> Range: {-536870912, ..., 536870911}	-12000
presolving/dualagg/timing	timing mask of presolver <dualagg> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.201 presolving/dualcomp

Option	Description	Default
presolving/dualcomp/componlydisvars	should only discrete variables be compensated? Range: boolean	0
presolving/dualcomp/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
presolving/dualcomp/priority	priority of presolver <dualcomp> Range: {-536870912, ..., 536870911}	-50
presolving/dualcomp/timing	timing mask of presolver <dualcomp> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.202 presolving/dualinfer

Option	Description	Default
presolving/dualinfer/maxdualbndloops	maximal number of dual bound strengthening loops Range: {-1, ..., ∞}	12
presolving/dualinfer/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0

Option	Description	Default
presolving/dualinfer/maxrowsupport	Maximum number of row's non-zeros for changing inequality to equality Range: {2, ..., ∞}	3
presolving/dualinfer/twocolcombine	use convex combination of columns for determining dual bounds Range: boolean	1
Options for expert users		
presolving/dualinfer/maxcombinefails	maximal number of consecutive useless column combines Range: {-1, ..., ∞}	1000
presolving/dualinfer/maxconsiderednonzeros	maximal number of considered non-zeros within one column (-1: no limit) Range: {-1, ..., ∞}	100
presolving/dualinfer/maxhashfac	Maximum number of hashlist entries as multiple of number of columns in the problem (-1: no limit) Range: {-1, ..., ∞}	10
presolving/dualinfer/maxpairfac	Maximum number of processed column pairs as multiple of the number of columns in the problem (-1: no limit) Range: {-1, ..., ∞}	1
presolving/dualinfer/maxretrievefails	maximal number of consecutive useless hashtable retrieves Range: {-1, ..., ∞}	1000
presolving/dualinfer/priority	priority of presolver <dualinfer> Range: {-536870912, ..., 536870911}	-3000
presolving/dualinfer/timing	timing mask of presolver <dualinfer> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.203 presolving/dualsparsify

Option	Description	Default
presolving/dualsparsify/maxbinfillin	maximal fillin for binary variables (-1: unlimited) Range: {-1, ..., ∞}	1
presolving/dualsparsify/maxcontfillin	maximal fillin for continuous variables (-1: unlimited) Range: {-1, ..., ∞}	1
presolving/dualsparsify/maxintfillin	maximal fillin for integer variables including binaries (-1: unlimited) Range: {-1, ..., ∞}	1
presolving/dualsparsify/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
presolving/dualsparsify/mineliminatednonzeros	minimal eliminated nonzeros within one column if we need to add a constraint to the problem Range: {0, ..., ∞}	100
Options for expert users		

Option	Description	Default
presolving/dualsparsify/enablecopy	should dualsparsify presolver be copied to sub-SCIPs? Range: boolean	1
presolving/dualsparsify/maxconsiderednonzeros	maximal number of considered nonzeros within one column (-1: no limit) Range: {-1, ..., ∞}	70
presolving/dualsparsify/maxretrievefac	limit on the number of useless vs. useful hashtable retrieves as a multiple of the number of constraints Range: [0, ∞]	100
presolving/dualsparsify/preservegoodlocks	should we preserve good locked properties of variables (at most one lock in one direction)? Range: boolean	0
presolving/dualsparsify/preserveintcoefs	should we forbid cancellations that destroy integer coefficients? Range: boolean	0
presolving/dualsparsify/priority	priority of presolver <dualsparsify> Range: {-536870912, ..., 536870911}	-240000
presolving/dualsparsify/timing	timing mask of presolver <dualsparsify> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
presolving/dualsparsify/waitingfac	number of calls to wait until next execution as a multiple of the number of useless calls Range: [0, ∞]	2

5.34.4.204 presolving/gateextraction

Option	Description	Default
presolving/gateextraction/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
presolving/gateextraction/onlysetpart	should we only try to extract set-partitioning constraints and no and-constraints Range: boolean	0
presolving/gateextraction/priority	priority of presolver <gateextraction> Range: {-536870912, ..., 536870911}	1000000
presolving/gateextraction/searchequations	should we try to extract set-partitioning constraint out of one logicor and one corresponding set-packing constraint Range: boolean	1
presolving/gateextraction/sorting	order logicor contraints to extract big-gates before smaller ones (-1), do not order them (0) or order them to extract smaller gates at first (1) Range: {-1, ..., 1}	1
presolving/gateextraction/timing	timing mask of presolver <gateextraction> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.205 presolving/implics

Option	Description	Default
presolving/implics/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
presolving/implics/priority	priority of presolver <implics> Range: {-536870912, ..., 536870911}	-10000
presolving/implics/timing	timing mask of presolver <implics> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8

5.34.4.206 presolving/inttobinary

Option	Description	Default
presolving/inttobinary/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
presolving/inttobinary/priority	priority of presolver <inttobinary> Range: {-536870912, ..., 536870911}	7000000
presolving/inttobinary/timing	timing mask of presolver <inttobinary> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.34.4.207 presolving/milp

Option	Description	Default
presolving/milp/hugebound	absolute bound value that is considered too huge for activitity based calculations Range: [0, ∞]	1e+08
presolving/milp/markowitztolerance	the markowitz tolerance used for substitutions Range: [0, 1]	0.01
presolving/milp/maxbadgesizepar	maximal badge size in Probing in PaPILO if PaPILO is executed in parallel mode Range: {-1, ..., ∞}	-1
presolving/milp/maxbadgesizeseq	maximal badge size in Probing in PaPILO if PaPILO is executed in sequential mode Range: {-1, ..., ∞}	15000
presolving/milp/maxfillinpersubstitution	maximal possible fillin for substitutions to be considered Range: {-2147483648, ..., ∞}	3
presolving/milp/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
presolving/milp/modifyconsfac	modify SCIP constraints when the number of nonzeros or rows is at most this factor times the number of nonzeros or rows before presolving Range: [0, 1]	0.8
presolving/milp/randomseed	the random seed used for randomization of tie breaking Range: {-2147483648, ..., ∞}	0
presolving/milp/threads	maximum number of threads presolving may use (0: automatic) Range: {0, ..., ∞}	GAMS threads
Options for expert users		
presolving/milp/enabledomcol	should the dominated column presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enabledualinfer	should the dualinfer presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enablemultiaggr	should the multi-aggregation presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enableparallelrows	should the parallel rows presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enableprobing	should the probing presolver be enabled within the presolve library? Range: boolean	1
presolving/milp/enablesparsify	should the sparsify presolver be enabled within the presolve library? Range: boolean	0
presolving/milp/maxshiftperrow	maximal amount of nonzeros allowed to be shifted to make space for substitutions Range: {0, ..., ∞}	10
presolving/milp/priority	priority of presolver <milp> Range: {-536870912, ..., 536870911}	9999999
presolving/milp/probfilename	filename to store the problem before MILP presolving starts Range: string	-
presolving/milp/timing	timing mask of presolver <milp> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8

5.34.4.208 presolving/qpkktref

Option	Description	Default
presolving/qpkktref/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		

Option	Description	Default
presolving/qpkktref/addkktbinary	if TRUE then allow binary variables for KKT update Range: boolean	0
presolving/qpkktref/priority	priority of presolver <qpkktref> Range: {-536870912, ..., 536870911}	-1
presolving/qpkktref/timing	timing mask of presolver <qpkktref> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	8
presolving/qpkktref/updatequadbounded	if TRUE then only apply the update to QPs with bounded variables; if the variables are not bounded then a finite optimal solution might not exist and the KKT conditions would then be invalid Range: boolean	1
presolving/qpkktref/updatequadindef	if TRUE then apply quadratic constraint update even if the quadratic constraint matrix is known to be indefinite Range: boolean	0

5.34.4.209 presolving/redvub

Option	Description	Default
presolving/redvub/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		
presolving/redvub/priority	priority of presolver <redvub> Range: {-536870912, ..., 536870911}	-9000000
presolving/redvub/timing	timing mask of presolver <redvub> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.210 presolving/sparsify

Option	Description	Default
presolving/sparsify/maxbinfillin	maximal fillin for binary variables (-1: unlimited) Range: {-1, ..., ∞}	0
presolving/sparsify/maxcontfillin	maximal fillin for continuous variables (-1: unlimited) Range: {-1, ..., ∞}	0
presolving/sparsify/maxintfillin	maximal fillin for integer variables including binaries (-1: unlimited) Range: {-1, ..., ∞}	0
presolving/sparsify/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		

Option	Description	Default
presolving/sparsify/cancellinear	should we cancel nonzeros in constraints of the linear constraint handler? Range: boolean	1
presolving/sparsify/enablecopy	should sparsify presolver be copied to sub-SCIPs? Range: boolean	1
presolving/sparsify/maxconsiderednonzeros	maximal number of considered non-zeros within one row (-1: no limit) Range: {-1, ..., ∞}	70
presolving/sparsify/maxnonzeros	maximal support of one equality to be used for cancelling (-1: no limit) Range: {-1, ..., ∞}	-1
presolving/sparsify/maxretrievefac	limit on the number of useless vs. useful hashtable retrieves as a multiple of the number of constraints Range: [0, ∞]	100
presolving/sparsify/preserveintcoefs	should we forbid cancellations that destroy integer coefficients? Range: boolean	1
presolving/sparsify/priority	priority of presolver <sparsify> Range: {-536870912, ..., 536870911}	-24000
presolving/sparsify/rowsort	order in which to process inequalities ('n'o sorting, 'i'ncreasing nonzeros, 'd'ecreasing nonzeros) Range: n, i, d	d
presolving/sparsify/timing	timing mask of presolver <sparsify> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16
presolving/sparsify/waitingfac	number of calls to wait until next execution as a multiple of the number of useless calls Range: [0, ∞]	2

5.34.4.211 presolving/stuffing

Option	Description	Default
presolving/stuffing/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		
presolving/stuffing/priority	priority of presolver <stuffing> Range: {-536870912, ..., 536870911}	-100
presolving/stuffing/timing	timing mask of presolver <stuffing> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.212 presolving/trivial

Option	Description	Default
presolving/trivial/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
presolving/trivial/priority	priority of presolver <trivial> Range: {-536870912, ..., 536870911}	9000000
presolving/trivial/timing	timing mask of presolver <trivial> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	4

5.34.4.213 presolving/tworowbnd

Option	Description	Default
presolving/tworowbnd/maxcombinefails	maximal number of consecutive useless row combines Range: {-1, ..., ∞}	1000
presolving/tworowbnd/maxconsiderednonzeros	maximal number of considered non-zeros within one row (-1: no limit) Range: {-1, ..., ∞}	100
presolving/tworowbnd/maxhashfac	Maximum number of hashlist entries as multiple of number of rows in the problem (-1: no limit) Range: {-1, ..., ∞}	10
presolving/tworowbnd/maxpairfac	Maximum number of processed row pairs as multiple of the number of rows in the problem (-1: no limit) Range: {-1, ..., ∞}	1
presolving/tworowbnd/maxretrievefails	maximal number of consecutive useless hashtable retrieves Range: {-1, ..., ∞}	1000
presolving/tworowbnd/maxrounds	maximal number of presolving rounds the presolver participates in (-1: no limit) Range: {-1, ..., ∞}	0
Options for expert users		
presolving/tworowbnd/enablecopy	should tworowbnd presolver be copied to sub-SCIPs? Range: boolean	1
presolving/tworowbnd/priority	priority of presolver <tworowbnd> Range: {-536870912, ..., 536870911}	-2000
presolving/tworowbnd/timing	timing mask of presolver <tworowbnd> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {4, ..., 60}	16

5.34.4.214 propagating

Option	Description	Default
propagating/abortoncutoff	should propagation be aborted immediately? setting this to FALSE could help conflict analysis to produce more conflict constraints Range: boolean	1
propagating/maxrounds	maximal number of propagation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	100
propagating/maxroundsroot	maximal number of propagation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	1000

5.34.4.215 propagating/dualfix

Option	Description	Default
propagating/dualfix/freq	frequency for calling propagator <dualfix> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
propagating/dualfix/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
propagating/dualfix/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/dualfix/presolpriority	presolving priority of propagator <dualfix> Range: {-536870912, ..., 536870911}	8000000
propagating/dualfix/presoltiming	timing mask of the presolving method of propagator <dualfix> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	4
propagating/dualfix/priority	priority of propagator <dualfix> Range: {-536870912, ..., 536870911}	8000000
propagating/dualfix/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	1

5.34.4.216 propagating/genvbounds

Option	Description	Default
propagating/genvbounds/freq	frequency for calling propagator <genvbounds> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/genvbounds/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		

Option	Description	Default
propagating/genvbounds/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/genvbounds/global	apply global propagation? Range: boolean	1
propagating/genvbounds/presolpriority	presolving priority of propagator <genvbounds> Range: {-536870912, ..., 536870911}	-2000000
propagating/genvbounds/presoltiming	timing mask of the presolving method of propagator <genvbounds> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	4
propagating/genvbounds/priority	priority of propagator <genvbounds> Range: {-536870912, ..., 536870911}	3000000
propagating/genvbounds/propasconss	should genvbounds be transformed to (linear) constraints? Range: boolean	0
propagating/genvbounds/propinrootnode	apply genvbounds in root node if no new incumbent was found? Range: boolean	1
propagating/genvbounds/sort	sort genvbounds and wait for bound change events? Range: boolean	1
propagating/genvbounds/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	15

5.34.4.217 propagating/nlobbt

Option	Description	Default
propagating/nlobbt/addlprows	should non-initial LP rows be used? Range: boolean	1
propagating/nlobbt/freq	frequency for calling propagator <nlobbt> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
propagating/nlobbt/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
propagating/nlobbt/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	1
propagating/nlobbt/feastolfac	factor for NLP feasibility tolerance Range: [0, 1]	0.01
propagating/nlobbt/itlimitfactor	LP iteration limit for nlobbt will be this factor times total LP iterations in root node Range: [0, ∞]	2
propagating/nlobbt/minlinearfrac	minimum (convex nlrows)/(linear nlrows) threshold to apply propagator Range: [0, ∞]	0.02

Option	Description	Default
propagating/nlobbt/minnonconvexfrac	(convex nlrows)/(nonconvex nlrows) threshold to apply propagator Range: [0, ∞]	0.2
propagating/nlobbt/nlpiterlimit	iteration limit of NLP solver; 0 for no limit Range: {0, ..., ∞}	500
propagating/nlobbt/nlptimelimit	time limit of NLP solver; 0.0 for no limit Range: [0, ∞]	0
propagating/nlobbt/nlpverblevel	verbosity level of NLP solver Range: {0, ..., 5}	0
propagating/nlobbt/presolpriority	presolving priority of propagator <nlobbt> Range: {-536870912, ..., 536870911}	0
propagating/nlobbt/presoltiming	timing mask of the presolving method of propagator <nlobbt> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	28
propagating/nlobbt/priority	priority of propagator <nlobbt> Range: {-536870912, ..., 536870911}	-1100000
propagating/nlobbt/relobjtolfac	factor for NLP relative objective tolerance Range: [0, 1]	0.01
propagating/nlobbt/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	4

5.34.4.218 propagating/obbt

Option	Description	Default
propagating/obbt/boundstreps	minimal relative improve for strengthening bounds Range: [0, 1]	0.001
propagating/obbt/conditionlimit	maximum condition limit used in LP solver (-1.0: no limit) Range: [-1, ∞]	-1
propagating/obbt/dualfeastol	feasibility tolerance for reduced costs used in obbt; this value is used if SCIP's dual feastol is greater Range: [0, ∞]	1e-09
propagating/obbt/freq	frequency for calling propagator <obbt> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
propagating/obbt/itlimitfactor	multiple of root node LP iterations used as total LP iteration limit for obbt (≤ 0: no limit) Range: real	10
propagating/obbt/itlimitfactorbilin	multiple of OBBT LP limit used as total LP iteration limit for solving bilinear inequality LPs (< 0 for no limit) Range: real	3
propagating/obbt/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
propagating/obbt/minitlimit	minimum LP iteration limit Range: {0, ..., ∞}	5000
propagating/obbt/minnonconvexity	minimum absolute value of nonconvex eigenvalues for a bilinear term Range: [0, ∞]	0.1
Options for expert users		
propagating/obbt/applyfilterrounds	try to filter bounds in so-called filter rounds by solving auxiliary LPs? Range: boolean	0
propagating/obbt/applytrivialfilter	try to filter bounds with the LP solution after each solve? Range: boolean	1
propagating/obbt/createbilinineqs	solve auxiliary LPs in order to find valid inequalities for bilinear terms? Range: boolean	1
propagating/obbt/creategenvbounds	should obbt try to provide genvbounds if possible? Range: boolean	1
propagating/obbt/createlincons	create linear constraints from inequalities for bilinear terms? Range: boolean	0
propagating/obbt/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	1
propagating/obbt/genvbdsduringfilter	should we try to generate genvbounds during trivial and aggressive filtering? Range: boolean	1
propagating/obbt/genvbdsduringsepa	try to create genvbounds during separation process? Range: boolean	1
propagating/obbt/minfilter	minimal number of filtered bounds to apply another filter round Range: {1, ..., ∞}	2
propagating/obbt/normalize	should coefficients in filtering be normalized w.r.t. the domains sizes? Range: boolean	1
propagating/obbt/onlynonconvexvars	only apply obbt on non-convex variables Range: boolean	1
propagating/obbt/orderingalgo	select the type of ordering algorithm which should be used (0: no special ordering, 1: greedy, 2: greedy reverse) Range: {0, ..., 2}	1
propagating/obbt/presolpriority	presolving priority of propagator <obbt> Range: {-536870912, ..., 536870911}	0
propagating/obbt/presoltiming	timing mask of the presolving method of propagator <obbt> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	28
propagating/obbt/priority	priority of propagator <obbt> Range: {-536870912, ..., 536870911}	-1000000
propagating/obbt/propagatefreq	trigger a propagation round after that many bound tightenings (0: no propagation) Range: {0, ..., ∞}	0

Option	Description	Default
propagating/obbt/sepamaxiter	maximum number of iteration spend to separate an obbt LP solution Range: {0, ..., ∞}	10
propagating/obbt/sepaminiter	minimum number of iteration spend to separate an obbt LP solution Range: {0, ..., ∞}	0
propagating/obbt/separatesol	should the obbt LP solution be separated? Range: boolean	0
propagating/obbt/tightcontboundsprobing	should continuous bounds be tightened during the probing mode? Range: boolean	0
propagating/obbt/tightintboundsprobing	should integral bounds be tightened during the probing mode? Range: boolean	1
propagating/obbt/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	4

5.34.4.219 propagating/probing

Option	Description	Default
propagating/probing/freq	frequency for calling propagator <probing> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
propagating/probing/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
propagating/probing/maxruns	maximal number of runs, probing participates in (-1: no limit) Range: {-1, ..., ∞}	1
Options for expert users		
propagating/probing/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	1
propagating/probing/maxdepth	maximal depth until propagation is executed(-1: no limit) Range: {-1, ..., ∞}	-1
propagating/probing/maxfixings	maximal number of fixings found, until probing is interrupted (0: don't iterrupt) Range: {0, ..., ∞}	25
propagating/probing/maxsumuseless	maximal number of probings without fixings, until probing is aborted (0: don't abort) Range: {0, ..., ∞}	0
propagating/probing/maxtotaluseless	maximal number of successive probings without fixings, bound changes, and implications, until probing is aborted (0: don't abort) Range: {0, ..., ∞}	50
propagating/probing/maxuseless	maximal number of successive probings without fixings, until probing is aborted (0: don't abort) Range: {0, ..., ∞}	1000

Option	Description	Default
propagating/probing/presolpriority	presolving priority of propagator <probing> Range: {-536870912, ..., 536870911}	-100000
propagating/probing/presoltiming	timing mask of the presolving method of propagator <probing> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	16
propagating/probing/priority	priority of propagator <probing> Range: {-536870912, ..., 536870911}	-100000
propagating/probing/proprounds	maximal number of propagation rounds in probing subproblems (-1: no limit, 0: auto) Range: {-1, ..., ∞}	-1
propagating/probing/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	4

5.34.4.220 propagating/pseudoobj

Option	Description	Default
propagating/pseudoobj/freq	frequency for calling propagator <pseudoobj> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/pseudoobj/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
propagating/pseudoobj/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/pseudoobj/force	should the propagator be forced even if active pricer are present? Range: boolean	0
propagating/pseudoobj/maximplvars	maximum number of binary variables the implications are used if turned on (-1: unlimited)? Range: {-1, ..., ∞}	50000
propagating/pseudoobj/maxnewvars	number of variables added after the propagator is reinitialized? Range: {0, ..., ∞}	1000
propagating/pseudoobj/maxvarsfrac	maximal fraction of non-binary variables with non-zero objective without a bound reduction before aborted Range: [0, 1]	0.1
propagating/pseudoobj/minuseless	minimal number of successive non-binary variable propagations without a bound reduction before aborted Range: {0, ..., ∞}	100
propagating/pseudoobj/presolpriority	presolving priority of propagator <pseudoobj> Range: {-536870912, ..., 536870911}	6000000

Option	Description	Default
propagating/pseudoobj/presoltiming	timing mask of the presolving method of propagator <pseudoobj> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	4
propagating/pseudoobj/priority	priority of propagator <pseudoobj> Range: {-536870912, ..., 536870911}	3000000
propagating/pseudoobj/propcutoffbound	propagate new cutoff bound directly globally Range: boolean	1
propagating/pseudoobj/propfullinroot	whether to propagate all non-binary variables when we are propagating the root node Range: boolean	1
propagating/pseudoobj/propuseimplics	use implications to strengthen the propagation of binary variable (increasing the objective change)? Range: boolean	1
propagating/pseudoobj/respropuseimplics	use implications to strengthen the resolve propagation of binary variable (increasing the objective change)? Range: boolean	1
propagating/pseudoobj/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	7

5.34.4.221 propagating/redcost

Option	Description	Default
propagating/redcost/continuous	should reduced cost fixing be also applied to continuous variables? Range: boolean	0
propagating/redcost/freq	frequency for calling propagator <redcost> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/redcost/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
propagating/redcost/useimplics	should implications be used to strength the reduced cost for binary variables? Range: boolean	0
Options for expert users		
propagating/redcost/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/redcost/force	should the propagator be forced even if active pricer are present? Range: boolean	0
propagating/redcost/presolpriority	presolving priority of propagator <redcost> Range: {-536870912, ..., 536870911}	0
propagating/redcost/presoltiming	timing mask of the presolving method of propagator <redcost> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	28

Option	Description	Default
propagating/redcost/priority	priority of propagator <redcost> Range: {-536870912, ..., 536870911}	1000000
propagating/redcost/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	6

5.34.4.222 propagating/rootredcost

Option	Description	Default
propagating/rootredcost/freq	frequency for calling propagator <rootredcost> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/rootredcost/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
Options for expert users		
propagating/rootredcost/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/rootredcost/force	should the propagator be forced even if active pricer are present? Range: boolean	0
propagating/rootredcost/onlybinary	should only binary variables be propagated? Range: boolean	0
propagating/rootredcost/presolpriority	presolving priority of propagator <rootredcost> Range: {-536870912, ..., 536870911}	0
propagating/rootredcost/presoltiming	timing mask of the presolving method of propagator <rootredcost> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	28
propagating/rootredcost/priority	priority of propagator <rootredcost> Range: {-536870912, ..., 536870911}	10000000
propagating/rootredcost/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	5

5.34.4.223 propagating/symmetry

Option	Description	Default
propagating/symmetry/freq	frequency for calling propagator <symmetry> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/symmetry/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1

Option	Description	Default
Options for expert users		
propagating/symmetry/addconflictcuts	Should Schreier Sims constraints be added if we use a conflict based rule? Range: boolean	1
propagating/symmetry/addconsstiming	timing of adding constraints (0 = before presolving, 1 = during presolving, 2 = after presolving) Range: {0, ..., 2}	2
propagating/symmetry/addstrongsbcs	Should strong SBCs for enclosing orbit of symmetric subgroups be added if orbitopes are not used? Range: boolean	0
propagating/symmetry/addsymresacks	Add inequalities for symresacks for each generator? Range: boolean	0
propagating/symmetry/addweaksbcs	Should we add weak SBCs for enclosing orbit of symmetric subgroups? Range: boolean	1
propagating/symmetry/checksymmetries	Should all symmetries be checked after computation? Range: boolean	0
propagating/symmetry/compresssymmetries	Should non-affected variables be removed from permutation to save memory? Range: boolean	1
propagating/symmetry/compressthreshold	Compression is used if percentage of moved vars is at most the threshold. Range: [0, 1]	0.5
propagating/symmetry/conssaddlp	Should the symmetry breaking constraints be added to the LP? Range: boolean	1
propagating/symmetry/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/symmetry/detectorbitopes	Should we check whether the components of the symmetry group can be handled by orbitopes? Range: boolean	1
propagating/symmetry/detectsubgroups	Should we try to detect symmetric subgroups of the symmetry group on binary variables? Range: boolean	1
propagating/symmetry/displaynorbitvars	Should the number of variables affected by some symmetry be displayed? Range: boolean	0
propagating/symmetry/doubleequations	Double equations to positive/negative version? Range: boolean	0
propagating/symmetry/maxgenerators	limit on the number of generators that should be produced within symmetry detection (0 = no limit) Range: {0, ..., ∞}	1500

Option	Description	Default
propagating/symmetry/maxnconsssubgroup	maximum number of constraints up to which subgroup structures are detected Range: {0, ..., ∞}	500000
propagating/symmetry/ofsymcomptiming	timing of symmetry computation for orbital fixing (0 = before presolving, 1 = during presolving, 2 = at first call) Range: {0, ..., 2}	2
propagating/symmetry/onlybinarysymmetry	Is only symmetry on binary variables used? Range: boolean	1
propagating/symmetry/performpresolving	run orbital fixing during presolving? Range: boolean	0
propagating/symmetry/preferlessrows	Shall orbitopes with less rows be preferred in detection? Range: boolean	1
propagating/symmetry/presolpriority	presolving priority of propagator <symmetry> Range: {-536870912, ..., 536870911}	-10000000
propagating/symmetry/presoltiming	timing mask of the presolving method of propagator <symmetry> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	16
propagating/symmetry/priority	priority of propagator <symmetry> Range: {-536870912, ..., 536870911}	-1000000
propagating/symmetry/recomputerestart	recompute symmetries after a restart has occured? (0 = never) Range: {0, ..., 0}	0
propagating/symmetry/sstaddcuts	Should Schreier Sims constraints be added? Range: boolean	1
propagating/symmetry/sstleaderrule	rule to select the leader in an orbit (0: first var; 1: last var; 2: var having most conflicting vars in orbit; 3: var having most conflicting vars in problem) Range: {0, ..., 3}	0
propagating/symmetry/sstleadervartype	bitset encoding which variable types can be leaders (1: binary; 2: integer; 4: impl. int; 8: continuous);if multiple types are allowed, take the one with most affected vars Range: {1, ..., 15}	14
propagating/symmetry/sstmixedcomponents	Should Schreier Sims constraints be added if a symmetry component contains variables of different types? Range: boolean	1
propagating/symmetry/ssttiebreakrule	rule to select the orbit in Schreier Sims inequalities (variable in 0: minimum size orbit; 1: maximum size orbit; 2: orbit with most variables in conflict with leader) Range: {0, ..., 2}	1
propagating/symmetry/symfixnonbinaryvars	Whether all non-binary variables shall be not affected by symmetries if OF is active? Range: boolean	0

Option	Description	Default
propagating/symmetry/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	1
propagating/symmetry/usecolumnsparsity	Should the number of conss a variable is contained in be exploited in symmetry detection? Range: boolean	0
propagating/symmetry/usedynamicprop	whether dynamic propagation should be used for full orbitopes Range: boolean	1

5.34.4.224 propagating/vbounds

Option	Description	Default
propagating/vbounds/detectcycles	should cycles in the variable bound graph be identified? Range: boolean	0
propagating/vbounds/dotoposort	should the bounds be topologically sorted in advance? Range: boolean	1
propagating/vbounds/freq	frequency for calling propagator <vbounds> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	1
propagating/vbounds/maxcliquesexhaustive	maximum number of cliques per variable to run clique table analysis in exhaustive presolving Range: [0, ∞]	100
propagating/vbounds/maxcliquesmedium	maximum number of cliques per variable to run clique table analysis in medium presolving Range: [0, ∞]	50
propagating/vbounds/maxprerounds	maximal number of presolving rounds the propagator participates in (-1: no limit) Range: {-1, ..., ∞}	-1
propagating/vbounds/minnewcliques	minimum percentage of new cliques to trigger another clique table analysis Range: [0, 1]	0.1
propagating/vbounds/usebdwidening	should bound widening be used to initialize conflict analysis? Range: boolean	1
Options for expert users		
propagating/vbounds/delay	should propagator be delayed, if other propagators found reductions? Range: boolean	0
propagating/vbounds/presolpriority	presolving priority of propagator <vbounds> Range: {-536870912, ..., 536870911}	-90000
propagating/vbounds/presoltiming	timing mask of the presolving method of propagator <vbounds> (4:FAST, 8:MEDIUM, 16:EXHAUSTIVE, 32:FINAL) Range: {2, ..., 60}	24

Option	Description	Default
propagating/vbounds/priority	priority of propagator <vbounds> Range: {-536870912, ..., 536870911}	3000000
propagating/vbounds/sortcliques	should cliques be regarded for the topological sort? Range: boolean	0
propagating/vbounds/timingmask	timing when propagator should be called (1:BEFORELP, 2:DURINGLPLOOP, 4:AFTERLPLOOP, 15:ALWAYS)) Range: {1, ..., 15}	5
propagating/vbounds/usecliques	should cliques be propagated? Range: boolean	0
propagating/vbounds/useimplics	should implications be propagated? Range: boolean	0
propagating/vbounds/usevbounds	should vbounds be propagated? Range: boolean	1

5.34.4.225 randomization

Option	Description	Default
randomization/lpseed	random seed for LP solver, e.g. for perturbations in the simplex (0: LP default) Range: {0, ..., ∞}	0
randomization/permutationseed	seed value for permuting the problem after reading/transformation (0: no permutation) Range: {0, ..., ∞}	0
randomization/randomseedshift	global shift of all random seeds in the plugins and the LP random seed Range: {0, ..., ∞}	0
Options for expert users		
randomization/permuteconss	should order of constraints be permuted (depends on permutationseed)? Range: boolean	1
randomization/permutevars	should order of variables be permuted (depends on permutationseed)? Range: boolean	0

5.34.4.226 separating

Option	Description	Default
separating/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separation (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/maxcoefratio	maximal ratio between coefficients in strongcg, cmir, and flowcover cuts Range: [1, ∞]	10000
separating/maxcoefratiofacrowprep	maximal ratio between coefficients (as factor of 1/feastol) to ensure in rowprep cleanup Range: [0, ∞]	10

Option	Description	Default
separating/maxcuts	maximal number of cuts separated per separation round (0: disable local separation) Range: {0, ..., ∞}	100
separating/maxcutsroot	maximal number of separated cuts at the root node (0: disable root node separation) Range: {0, ..., ∞}	2000
separating/maxlocalbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying local separation (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/maxstallrounds	maximal number of consecutive separation rounds without objective or integrality improvement in local nodes (-1: no additional restriction) Range: {-1, ..., ∞}	1
separating/maxstallroundsroot	maximal number of consecutive separation rounds without objective or integrality improvement in the root node (-1: no additional restriction) Range: {-1, ..., ∞}	10
separating/minactivityquot	minimum cut activity quotient to convert cuts into constraints during a restart (0.0: all cuts are converted) Range: [0, 1]	0.8
separating/minefficacy	minimal efficacy for a cut to enter the LP Range: [0, ∞]	0.0001
separating/minefficacyroot	minimal efficacy for a cut to enter the LP in the root node Range: [0, ∞]	0.0001
separating/poolfreq	separation frequency for the global cut pool (-1: disable global cut pool, 0: only separate pool at the root) Range: {-1, ..., 65534}	10
Options for expert users		
separating/cutagelimit	maximum age a cut can reach before it is deleted from the global cut pool, or -1 to keep all cuts Range: {-1, ..., ∞}	80
separating/cutselrestart	cut selection during restart ('a'ge, activity 'q'uotient) Range: a, q	a
separating/cutselsubscip	cut selection for sub SCIPs ('a'ge, activity 'q'uotient) Range: a, q	a
separating/efficacynorm	row norm to use for efficacy calculation ('e'uclidean, 'm'aximum, 's'um, 'd'iscrete) Range: e, m, s, d	e
separating/filtercutpoolrel	should cutpool separate only cuts with high relative efficacy? Range: boolean	1

Option	Description	Default
separating/maxaddrounds	maximal additional number of separation rounds in subsequent price-and-cut loops (-1: no additional restriction) Range: {-1, ..., ∞}	1
separating/maxroundsrootsubrun	maximal number of separation rounds in the root node of a subsequent run (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/maxruns	maximal number of runs for which separation is enabled (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/orthofunc	function used for calc. scalar prod. in orthogonality test ('e'uclidean, 'd'iscrete) Range: e, d	e

5.34.4.227 separating/aggregation

Option	Description	Default
separating/aggregation/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/aggregation/freq	frequency for calling separator <aggregation> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/aggregation/maxrounds	maximal number of cmir separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/aggregation/maxroundsroot	maximal number of cmir separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/aggregation/maxsepacuts	maximal number of cmir cuts separated per separation round Range: {0, ..., ∞}	100
separating/aggregation/maxsepacutsroot	maximal number of cmir cuts separated per separation round in the root node Range: {0, ..., ∞}	500
Options for expert users		
separating/aggregation/aggrtol	tolerance for bound distances used to select continuous variable in current aggregated constraint to be eliminated Range: [0, ∞]	0.01
separating/aggregation/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/aggregation/densityoffset	additional number of variables allowed in row on top of density Range: {0, ..., ∞}	100
separating/aggregation/densityscore	weight of row density in the aggregation scoring of the rows Range: [0, ∞]	0.0001

Option	Description	Default
separating/aggregation/expbackoff	base for exponential increase of frequency at which separator <aggregation> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/aggregation/fixintegralrhs	should an additional variable be complemented if f0 = 0? Range: boolean	1
separating/aggregation/maxaggdensity	maximal density of aggregated row Range: [0, 1]	0.2
separating/aggregation/maxaggrs	maximal number of aggregations for each row per separation round Range: {0, ..., ∞}	3
separating/aggregation/maxaggrsroot	maximal number of aggregations for each row per separation round in the root node Range: {0, ..., ∞}	6
separating/aggregation/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <aggregation> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/aggregation/maxfails	maximal number of consecutive unsuccessful aggregation tries (-1: unlimited) Range: {-1, ..., ∞}	20
separating/aggregation/maxfailsroot	maximal number of consecutive unsuccessful aggregation tries in the root node (-1: unlimited) Range: {-1, ..., ∞}	100
separating/aggregation/maxrowdensity	maximal density of row to be used in aggregation Range: [0, 1]	0.05
separating/aggregation/maxrowfac	maximal row aggregation factor Range: [0, ∞]	10000
separating/aggregation/maxslack	maximal slack of rows to be used in aggregation Range: [0, ∞]	0
separating/aggregation/maxslackroot	maximal slack of rows to be used in aggregation in the root node Range: [0, ∞]	0.1
separating/aggregation/maxtestdelta	maximal number of different deltas to try (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/aggregation/maxtries	maximal number of rows to start aggregation with per separation round (-1: unlimited) Range: {-1, ..., ∞}	200
separating/aggregation/maxtriesroot	maximal number of rows to start aggregation with per separation round in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/aggregation/priority	priority of separator <aggregation> Range: {-536870912, ..., 536870911}	-3000

Option	Description	Default
separating/aggregation/slackscore	weight of slack in the aggregation scoring of the rows Range: [0, ∞]	0.001
separating/aggregation/trynegscaling	should negative values also be tested in scaling? Range: boolean	1

5.34.4.228 separating/cgmip

Option	Description	Default
separating/cgmip/addviolationcons	add constraint to subscip that only allows violated cuts (otherwise add obj. limit)? Range: boolean	0
separating/cgmip/addviolconshdlr	add constraint handler to filter out violated cuts? Range: boolean	0
separating/cgmip/cmirownbounds	tell CMIR-generator which bounds to used in rounding? Range: boolean	0
separating/cgmip/conshdlrusenorm	should the violation constraint handler use the norm of a cut to check for feasibility? Range: boolean	1
separating/cgmip/contconvert	Convert some integral variables to be continuous to reduce the size of the sub-MIP? Range: boolean	0
separating/cgmip/contconvfrac	fraction of integral variables converted to be continuous (if contconvert) Range: [0, 1]	0.1
separating/cgmip/contconvmin	minimum number of integral variables before some are converted to be continuous Range: {-1, ..., ∞}	100
separating/cgmip/decisiontree	Use decision tree to turn separation on/off? Range: boolean	0
separating/cgmip/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/cgmip/earlyterm	terminate separation if a violated (but possibly sub-optimal) cut has been found? Range: boolean	1
separating/cgmip/freq	frequency for calling separator <cgmip> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/cgmip/genprimalsols	Try to generate primal solutions from Gomory cuts? Range: boolean	0
separating/cgmip/intconvert	Convert some integral variables attaining fractional values to have integral value? Range: boolean	0
separating/cgmip/intconvfrac	fraction of frac. integral variables converted to have integral value (if intconvert) Range: [0, 1]	0.1
separating/cgmip/intconvmin	minimum number of integral variables before some are converted to have integral value Range: {-1, ..., ∞}	100

Option	Description	Default
separating/cgmip/maxdepth	maximal depth at which the separator is applied (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/cgmip/maxnodelimit	maximum number of nodes considered for sub-MIP (-1: unlimited) Range: {-1, ..., ∞}	5000
separating/cgmip/maxrounds	maximal number of cgmip separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	5
separating/cgmip/maxroundsroot	maximal number of cgmip separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	50
separating/cgmip/maxrowage	maximal age of rows to consider if onlyactiverows is false Range: {-1, ..., ∞}	-1
separating/cgmip/minnodelimit	minimum number of nodes considered for sub-MIP (-1: unlimited) Range: {-1, ..., ∞}	500
separating/cgmip/objlone	Should the objective of the sub-MIP minimize the l1-norm of the multipliers? Range: boolean	0
separating/cgmip/objweightsize	Weight each row by its size? Range: boolean	1
separating/cgmip/onlyactiverows	Use only active rows to generate cuts? Range: boolean	0
separating/cgmip/onlyintvars	Generate cuts for problems with only integer variables? Range: boolean	0
separating/cgmip/onlyrankone	Separate only rank 1 inequalities w.r.t. CG-MIP separator? Range: boolean	0
separating/cgmip/output	Should information about the sub-MIP and cuts be displayed? Range: boolean	0
separating/cgmip/primalseparation	only separate cuts that are tight for the best feasible solution? Range: boolean	1
separating/cgmip/skipmultbounds	Skip the upper bounds on the multipliers in the sub-MIP? Range: boolean	1
separating/cgmip/subscipfast	Should the settings for the sub-MIP be optimized for speed? Range: boolean	1
separating/cgmip/usecmir	use CMIR-generator (otherwise add cut directly)? Range: boolean	1
separating/cgmip/usecutpool	use cutpool to store CG-cuts even if the are not efficient? Range: boolean	1
separating/cgmip/useobjlb	Use lower bound on objective function (via primal solution)? Range: boolean	0

Option	Description	Default
separating/cgmip/useobjub	Use upper bound on objective function (via primal solution)? Range: boolean	0
separating/cgmip/usestrongcg	use strong CG-function to strengthen cut? Range: boolean	0
Options for expert users		
separating/cgmip/cutcoefbnd	bounds on the values of the coefficients in the CG-cut Range: [0, ∞]	1000
separating/cgmip/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/cgmip/expbackoff	base for exponential increase of frequency at which separator <cgmip> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/cgmip/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <cgmip> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/cgmip/memorylimit	memory limit for sub-MIP Range: [0, ∞]	∞
separating/cgmip/objweight	weight used for the row combination coefficient in the sub-MIP objective Range: [0, ∞]	0.001
separating/cgmip/priority	priority of separator <cgmip> Range: {-536870912, ..., 536870911}	-1000
separating/cgmip/timelimit	time limit for sub-MIP Range: [0, ∞]	∞

5.34.4.229 separating/clique

Option	Description	Default
separating/clique/freq	frequency for calling separator <clique> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/clique/maxsepacuts	maximal number of clique cuts separated per separation round (-1: no limit) Range: {-1, ..., ∞}	10
Options for expert users		
separating/clique/backtrackfreq	frequency for premature backtracking up to tree level 1 (0: no backtracking) Range: {0, ..., ∞}	1000
separating/clique/cliquedensity	minimal density of cliques to use a dense clique table Range: [0, 1]	0
separating/clique/cliquetablemem	maximal memory size of dense clique table (in kb) Range: [0, 2.09715e+06]	20000
separating/clique/delay	should separator be delayed, if other separators found cuts? Range: boolean	0

Option	Description	Default
separating/clique/expbackoff	base for exponential increase of frequency at which separator <clique> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/clique/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <clique> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/clique/maxtreenodes	maximal number of nodes in branch and bound tree (-1: no limit) Range: {-1, ..., ∞}	10000
separating/clique/maxzeroextensions	maximal number of zero-valued variables extending the clique (-1: no limit) Range: {-1, ..., ∞}	1000
separating/clique/priority	priority of separator <clique> Range: {-536870912, ..., 536870911}	-5000
separating/clique/scaleval	factor for scaling weights Range: [1, ∞]	1000

5.34.4.230 separating/closecuts

Option	Description	Default
separating/closecuts/freq	frequency for calling separator <closecuts> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
separating/closecuts/closethres	threshold on number of generated cuts below which the ordinary separation is started Range: {-1, ..., ∞}	50
separating/closecuts/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/closecuts/expbackoff	base for exponential increase of frequency at which separator <closecuts> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/closecuts/inclobjcutoff	include an objective cutoff when computing the relative interior? Range: boolean	0
separating/closecuts/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <closecuts> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/closecuts/maxlpiterfactor	factor for maximal LP iterations in relative interior computation compared to node LP iterations (negative for no limit) Range: [-1, ∞]	10
separating/closecuts/maxunsuccessful	turn off separation in current node after unsuccessful calls (-1 never turn off) Range: {-1, ..., ∞}	0

Option	Description	Default
separating/closecuts/priority	priority of separator <closecuts> Range: {-536870912, ..., 536870911}	1000000
separating/closecuts/recomputerelint	recompute relative interior point in each separation call? Range: boolean	0
separating/closecuts/sepacombvalue	convex combination value for close cuts Range: [0, 1]	0.3
separating/closecuts/separelint	generate close cuts w.r.t. relative interior point (best solution otherwise)? Range: boolean	1

5.34.4.231 separating/cmir

Option	Description	Default
separating/cmir/freq	frequency for calling separator <cmir> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/cmir/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/cmir/expbackoff	base for exponential increase of frequency at which separator <cmir> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/cmir/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <cmir> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/cmir/priority	priority of separator <cmir> Range: {-536870912, ..., 536870911}	-100000

5.34.4.232 separating/convexproj

Option	Description	Default
separating/convexproj/freq	frequency for calling separator <convexproj> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/convexproj/maxdepth	maximal depth at which the separator is applied (-1: unlimited) Range: {-1, ..., ∞}	-1
Options for expert users		
separating/convexproj/delay	should separator be delayed, if other separators found cuts? Range: boolean	1
separating/convexproj/expbackoff	base for exponential increase of frequency at which separator <convexproj> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4

Option	Description	Default
separating/convexproj/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <convexproj> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/convexproj/nlpiterlimit	iteration limit of NLP solver; 0 for no limit Range: {0, ..., ∞}	250
separating/convexproj/priority	priority of separator <convexproj> Range: {-536870912, ..., 536870911}	0

5.34.4.233 separating/disjunctive

Option	Description	Default
separating/disjunctive/freq	frequency for calling separator <disjunctive> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/disjunctive/maxrank	maximal rank of a disj. cut that could not be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞}	20
separating/disjunctive/maxrankintegral	maximal rank of a disj. cut that could be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞}	-1
Options for expert users		
separating/disjunctive/delay	should separator be delayed, if other separators found cuts? Range: boolean	1
separating/disjunctive/expbackoff	base for exponential increase of frequency at which separator <disjunctive> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/disjunctive/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <disjunctive> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/disjunctive/maxconfsdelay	delay separation if number of conflict graph edges is larger than predefined value (-1: no limit) Range: {-1, ..., ∞}	100000
separating/disjunctive/maxdepth	node depth of separating bipartite disjunctive cuts (-1: no limit) Range: {-1, ..., ∞}	-1
separating/disjunctive/maxinvcuts	maximal number of cuts investigated per iteration in a branching node Range: {0, ..., ∞}	50
separating/disjunctive/maxinvcutsroot	maximal number of cuts investigated per iteration in the root node Range: {0, ..., ∞}	250

Option	Description	Default
separating/disjunctive/maxrounds	maximal number of separation rounds per iteration in a branching node (-1: no limit) Range: {-1, ..., ∞}	25
separating/disjunctive/maxroundsroot	maximal number of separation rounds in the root node (-1: no limit) Range: {-1, ..., ∞}	100
separating/disjunctive/maxweightrange	maximal valid range max(|weights|)/min(|weights|) of row weights Range: [1, ∞]	1000
separating/disjunctive/priority	priority of separator <disjunctive> Range: {-536870912, ..., 536870911}	10
separating/disjunctive/strengthen	strengthen cut if integer variables are present. Range: boolean	1

5.34.4.234 separating/eccuts

Option	Description	Default
separating/eccuts/cutmaxrange	maximal coef. range of a cut (max coef. divided by min coef.) in order to be added to LP relaxation Range: [0, ∞]	1e+07
separating/eccuts/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/eccuts/freq	frequency for calling separator <eccuts> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/eccuts/maxdepth	maximal depth at which the separator is applied (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/eccuts/maxrounds	maximal number of eccuts separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/eccuts/maxroundsroot	maximal number of eccuts separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	250
separating/eccuts/maxsepacuts	maximal number of edge-concave cuts separated per separation round Range: {0, ..., ∞}	10
separating/eccuts/maxsepacutsroot	maximal number of edge-concave cuts separated per separation round in the root node Range: {0, ..., ∞}	50
separating/eccuts/minviolation	minimal violation of an edge-concave cut to be separated Range: [0, 0.5]	0.3
Options for expert users		
separating/eccuts/delay	should separator be delayed, if other separators found cuts? Range: boolean	0

Option	Description	Default
separating/eccuts/expbackoff	base for exponential increase of frequency at which separator <eccuts> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/eccuts/maxaggrsize	search for edge-concave aggregations of at most this size Range: {3, ..., 5}	4
separating/eccuts/maxbilinterms	maximum number of bilinear terms allowed to be in a quadratic constraint Range: {0, ..., ∞}	500
separating/eccuts/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <eccuts> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/eccuts/maxstallrounds	maximum number of unsuccessful rounds in the edge-concave aggregation search Range: {0, ..., ∞}	5
separating/eccuts/minaggrsize	search for edge-concave aggregations of at least this size Range: {3, ..., 5}	3
separating/eccuts/priority	priority of separator <eccuts> Range: {-536870912, ..., 536870911}	-13000

5.34.4.235 separating/flowcover

Option	Description	Default
separating/flowcover/freq	frequency for calling separator <flowcover> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/flowcover/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/flowcover/expbackoff	base for exponential increase of frequency at which separator <flowcover> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/flowcover/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <flowcover> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/flowcover/priority	priority of separator <flowcover> Range: {-536870912, ..., 536870911}	-100000

5.34.4.236 separating/gauge

Option	Description	Default
separating/gauge/freq	frequency for calling separator <gauge> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
separating/gauge/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/gauge/expbackoff	base for exponential increase of frequency at which separator <gauge> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/gauge/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <gauge> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/gauge/nlpiterlimit	iteration limit of NLP solver; 0 for no limit Range: {0, ..., ∞}	1000
separating/gauge/priority	priority of separator <gauge> Range: {-536870912, ..., 536870911}	0

5.34.4.237 separating/gomory

Option	Description	Default
separating/gomory/away	minimal integrality violation of a basis variable in order to try Gomory cut Range: [0.0001, 0.5]	0.01
separating/gomory/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/gomory/freq	frequency for calling separator <gomory> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/gomory/maxrank	maximal rank of a gomory cut that could not be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/gomory/maxrankintegral	maximal rank of a gomory cut that could be scaled to integral coefficients (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/gomory/maxrounds	maximal number of gomory separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	5
separating/gomory/maxroundsroot	maximal number of gomory separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/gomory/maxsepacuts	maximal number of gomory cuts separated per separation round Range: {0, ..., ∞}	50
separating/gomory/maxsepacutsroot	maximal number of gomory cuts separated per separation round in the root node Range: {0, ..., ∞}	200

Option	Description	Default
Options for expert users		
separating/gomory/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/gomory/delayedcuts	should cuts be added to the delayed cut pool? Range: boolean	0
separating/gomory/expbackoff	base for exponential increase of frequency at which separator <gomory> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/gomory/forcecuts	if conversion to integral coefficients failed still consider the cut Range: boolean	1
separating/gomory/genbothgomscg	Should both Gomory and strong CG cuts be generated (otherwise take best)? Range: boolean	1
separating/gomory/makeintegral	try to scale cuts to integral coefficients Range: boolean	0
separating/gomory/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <gomory> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/gomory/priority	priority of separator <gomory> Range: {-536870912, ..., 536870911}	-1000
separating/gomory/separaterows	separate rows with integral slack Range: boolean	1
separating/gomory/sidetypebasis	choose side types of row (lhs/rhs) based on basis information? Range: boolean	1
separating/gomory/trystrongcg	try to generate strengthened Chvatal-Gomory cuts? Range: boolean	1

5.34.4.238 separating/gomorymi

Option	Description	Default
separating/gomorymi/freq	frequency for calling separator <gomorymi> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/gomorymi/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/gomorymi/expbackoff	base for exponential increase of frequency at which separator <gomorymi> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4

Option	Description	Default
separating/gomorymi/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <gomorymi> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/gomorymi/priority	priority of separator <gomorymi> Range: {-536870912, ..., 536870911}	-100000

5.34.4.239 separating/impliedbounds

Option	Description	Default
separating/impliedbounds/freq	frequency for calling separator <impliedbounds> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/impliedbounds/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/impliedbounds/expbackoff	base for exponential increase of frequency at which separator <impliedbounds> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/impliedbounds/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <impliedbounds> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/impliedbounds/priority	priority of separator <impliedbounds> Range: {-536870912, ..., 536870911}	-50
separating/impliedbounds/usetwosizecliques	should violated inequalities for cliques with 2 variables be separated? Range: boolean	1

5.34.4.240 separating/interminor

Option	Description	Default
separating/interminor/freq	frequency for calling separator <interminor> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/interminor/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/interminor/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/interminor/mincutviol	minimum required violation of a cut Range: [0, ∞]	0.0001

Option	Description	Default
separating/interminor/usebounds	whether to also enforce nonegativity bounds of principle minors Range: boolean	0
separating/interminor/usestrengthening	whether to use strengthened intersection cuts to separate minors Range: boolean	0
Options for expert users		
separating/interminor/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/interminor/expbackoff	base for exponential increase of frequency at which separator <interminor> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/interminor/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <interminor> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/interminor/priority	priority of separator <interminor> Range: {-536870912, ..., 536870911}	0

5.34.4.241 separating/intobj

Option	Description	Default
separating/intobj/freq	frequency for calling separator <intobj> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
Options for expert users		
separating/intobj/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/intobj/expbackoff	base for exponential increase of frequency at which separator <intobj> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/intobj/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <intobj> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/intobj/priority	priority of separator <intobj> Range: {-536870912, ..., 536870911}	-100

5.34.4.242 separating/knapsackcover

Option	Description	Default
separating/knapsackcover/freq	frequency for calling separator <knapsackcover> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/knapsackcover/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/knapsackcover/expbackoff	base for exponential increase of frequency at which separator <knapsackcover> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/knapsackcover/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <knapsackcover> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/knapsackcover/priority	priority of separator <knapsackcover> Range: {-536870912, ..., 536870911}	-100000

5.34.4.243 separating/mcf

Option	Description	Default
separating/mcf/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/mcf/freq	frequency for calling separator <mcf> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/mcf/maxsepacuts	maximal number of mcf cuts separated per separation round Range: {-1, ..., ∞}	100
separating/mcf/maxsepacutsroot	maximal number of mcf cuts separated per separation round in the root node – default separation Range: {-1, ..., ∞}	200
Options for expert users		
separating/mcf/checkcutshoreconnectivity	should we separate only if the cuts shores are connected? Range: boolean	1
separating/mcf/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/mcf/expbackoff	base for exponential increase of frequency at which separator <mcf> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/mcf/fixintegralrhs	should an additional variable be complemented if f0 = 0? Range: boolean	1

Option	Description	Default
separating/mcf/maxarcinconsistencyratio	maximum inconsistency ratio of arcs not to be deleted Range: [0, ∞]	0.5
separating/mcf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <mcf> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/mcf/maxinconsistencyratio	maximum inconsistency ratio for separation at all Range: [0, ∞]	0.02
separating/mcf/maxtestdelta	maximal number of different deltas to try (-1: unlimited) – default separation Range: {-1, ..., ∞}	20
separating/mcf/maxweightrange	maximal valid range max(|weights|)/min(|weights|) of row weights Range: [1, ∞]	1e+06
separating/mcf/modeltype	model type of network (0: auto, 1:directed, 2:undirected) Range: {0, ..., 2}	0
separating/mcf/nclusters	number of clusters to generate in the shrunken network – default separation Range: {2, ..., 32}	5
separating/mcf/priority	priority of separator <mcf> Range: {-536870912, ..., 536870911}	-10000
separating/mcf/separateflowcutset	should we separate flowcutset inequalities on the network cuts? Range: boolean	1
separating/mcf/separateknapsack	should we separate knapsack cover inequalities on the network cuts? Range: boolean	1
separating/mcf/separatesinglenodecuts	should we separate inequalities based on single-node cuts? Range: boolean	1
separating/mcf/trynegscaling	should negative values also be tested in scaling? Range: boolean	0

5.34.4.244 separating/minor

Option	Description	Default
separating/minor/freq	frequency for calling separator <minor> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/minor/ignorepackingconss	whether to ignore circle packing constraints during minor detection Range: boolean	1
separating/minor/maxminorsconst	constant for the maximum number of minors, i.e., max(const, fac ∗ # quadratic terms) Range: {0, ..., ∞}	3000

Option	Description	Default
separating/minor/maxminorsfac	factor for the maximum number of minors, i.e., max(const, fac $*$ # quadratic terms) Range: [0, ∞]	10
separating/minor/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/minor/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/minor/mincutviol	minimum required violation of a cut Range: [0, ∞]	0.0001
Options for expert users		
separating/minor/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/minor/expbackoff	base for exponential increase of frequency at which separator <minor> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/minor/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <minor> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/minor/priority	priority of separator <minor> Range: {-536870912, ..., 536870911}	0

5.34.4.245 separating/mixing

Option	Description	Default
separating/mixing/freq	frequency for calling separator <mixing> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/mixing/maxnunsuccessful	maximal number of consecutive unsuccessful iterations Range: {-1, ..., ∞}	10
separating/mixing/maxrounds	maximal number of mixing separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/mixing/maxroundsroot	maximal number of mixing separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	-1
Options for expert users		
separating/mixing/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/mixing/expbackoff	base for exponential increase of frequency at which separator <mixing> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4

Option	Description	Default
separating/mixing/iscutsonints	Should general integer variables be used to generate cuts? Range: boolean	0
separating/mixing/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <mixing> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/mixing/priority	priority of separator <mixing> Range: {-536870912, ..., 536870911}	-50
separating/mixing/uselocalbounds	Should local bounds be used? Range: boolean	0

5.34.4.246 separating/oddcycle

Option	Description	Default
separating/oddcycle/freq	frequency for calling separator <oddcycle> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	-1
separating/oddcycle/liftoddcycles	Should odd cycle cuts be lifted? Range: boolean	0
separating/oddcycle/maxrounds	maximal number of oddcycle separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/oddcycle/maxroundsroot	maximal number of oddcycle separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/oddcycle/maxsepacuts	maximal number of oddcycle cuts separated per separation round Range: {0, ..., ∞}	5000
separating/oddcycle/maxsepacutsroot	maximal number of oddcycle cuts separated per separation round in the root node Range: {0, ..., ∞}	5000
separating/oddcycle/usegls	Should the search method by Groetschel, Lovasz, Schrijver be used? Otherwise use levelgraph method by Hoffman, Padberg. Range: boolean	1
Options for expert users		
separating/oddcycle/addselfarcs	add links between a variable and its negated Range: boolean	1
separating/oddcycle/allowmultiplecuts	Even if a variable is already covered by a cut, still allow another cut to cover it too? Range: boolean	1
separating/oddcycle/cutthreshold	maximal number of other cuts s.t. separation is applied (-1 for direct call) Range: {-1, ..., ∞}	-1
separating/oddcycle/delay	should separator be delayed, if other separators found cuts? Range: boolean	0

Option	Description	Default
separating/oddcycle/expbackoff	base for exponential increase of frequency at which separator <oddcycle> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/oddcycle/includetriangles	separate triangles found as 3-cycles or repaired larger cycles Range: boolean	1
separating/oddcycle/lpliftcoef	Choose lifting candidate by coef∗lpvalue or only by coef? Range: boolean	0
separating/oddcycle/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <oddcycle> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/oddcycle/maxcutslevel	maximal number of oddcycle cuts generated in every level of the level graph Range: {0, ..., ∞}	50
separating/oddcycle/maxcutsroot	maximal number of oddcycle cuts generated per chosen variable as root of the level graph Range: {0, ..., ∞}	1
separating/oddcycle/maxnlevels	maximal number of levels in level graph Range: {0, ..., ∞}	20
separating/oddcycle/maxpernodeslevel	percentage of nodes allowed in the same level of the level graph [0-100] Range: {0, ..., 100}	100
separating/oddcycle/maxreference	minimal weight on an edge (in level graph or bipartite graph) Range: {0, ..., ∞}	0
separating/oddcycle/maxunsucessfull	number of unsuccessful calls at current node Range: {0, ..., ∞}	3
separating/oddcycle/multiplecuts	Even if a variable is already covered by a cut, still try it as start node for a cycle search? Range: boolean	0
separating/oddcycle/offsetnodeslevel	offset of nodes allowed in the same level of the level graph (additional to the percentage of levelnodes) Range: {0, ..., ∞}	10
separating/oddcycle/offsettestvars	offset of variables to try the chosen method on (additional to the percentage of testvars) Range: {0, ..., ∞}	100
separating/oddcycle/percenttestvars	percentage of variables to try the chosen method on [0-100] Range: {0, ..., 100}	0
separating/oddcycle/priority	priority of separator <oddcycle> Range: {-536870912, ..., 536870911}	-15000
separating/oddcycle/recalcliftcoef	Calculate lifting coefficient of every candidate in every step (or only if its chosen)? Range: boolean	1
separating/oddcycle/repaircycles	try to repair violated cycles with double appearance of a variable Range: boolean	1

Option	Description	Default
separating/oddcycle/scalingfactor	factor for scaling of the arc-weights Range: {1, ..., ∞}	1000
separating/oddcycle/sortrootneighbors	sort level of the root neighbors by fractionality (maxfrac) Range: boolean	1
separating/oddcycle/sortswitch	use sorted variable array (unsorted(0), maxlp(1), minlp(2), maxfrac(3), minfrac(4)) Range: {0, ..., 4}	3

5.34.4.247 separating/rapidlearning

Option	Description	Default
separating/rapidlearning/freq	frequency for calling separator <rapidlearning> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	5
Options for expert users		
separating/rapidlearning/applybdchgs	should the found global bound deductions be applied in the original SCIP? Range: boolean	1
separating/rapidlearning/applyconflicts	should the found conflicts be applied in the original SCIP? Range: boolean	1
separating/rapidlearning/applyinfervals	should the inference values be used as initialization in the original SCIP? Range: boolean	1
separating/rapidlearning/applyprimalsol	should the incumbent solution be copied to the original SCIP? Range: boolean	1
separating/rapidlearning/applysolved	should a solved status be copied to the original SCIP? Range: boolean	1
separating/rapidlearning/checkdegeneracy	should local LP degeneracy be checked? Range: boolean	1
separating/rapidlearning/checkdualbound	should the progress on the dual bound be checked? Range: boolean	0
separating/rapidlearning/checkexec	check whether rapid learning should be executed Range: boolean	1
separating/rapidlearning/checkleaves	should the ratio of leaves proven to be infeasible and exceeding the cutoff bound be checked? Range: boolean	0
separating/rapidlearning/checknsols	should the number of solutions found so far be checked? Range: boolean	1
separating/rapidlearning/checkobj	should the (local) objective function be checked? Range: boolean	0
separating/rapidlearning/contvars	should rapid learning be applied when there are continuous variables? Range: boolean	0

Option	Description	Default
separating/rapidlearning/contvarsquot	maximal portion of continuous variables to apply rapid learning Range: [0, 1]	0.3
separating/rapidlearning/copycuts	should all active cuts from cutpool be copied to constraints in subproblem? Range: boolean	1
separating/rapidlearning/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/rapidlearning/expbackoff	base for exponential increase of frequency at which separator <rapidlearning> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/rapidlearning/lpiterquot	maximal fraction of LP iterations compared to node LP iterations Range: [0, ∞]	0.2
separating/rapidlearning/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <rapidlearning> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/rapidlearning/maxcalls	maximum number of overall calls Range: {0, ..., ∞}	100
separating/rapidlearning/maxnconss	maximum problem size (constraints) for which rapid learning will be called Range: {0, ..., ∞}	10000
separating/rapidlearning/maxnodes	maximum number of nodes considered in rapid learning run Range: {0, ..., ∞}	5000
separating/rapidlearning/maxnvars	maximum problem size (variables) for which rapid learning will be called Range: {0, ..., ∞}	10000
separating/rapidlearning/mindegeneracy	minimal degeneracy threshold to allow local rapid learning Range: [0, 1]	0.7
separating/rapidlearning/mininflpratio	minimal threshold of inf/obj leaves to allow local rapid learning Range: [0, ∞]	10
separating/rapidlearning/minnodes	minimum number of nodes considered in rapid learning run Range: {0, ..., ∞}	500
separating/rapidlearning/minvarconsratio	minimal ratio of unfixed variables in relation to basis size to allow local rapid learning Range: [1, ∞]	2
separating/rapidlearning/nwaitingnodes	number of nodes that should be processed before rapid learning is executed locally based on the progress of the dualbound Range: {0, ..., ∞}	100
separating/rapidlearning/priority	priority of separator <rapidlearning> Range: {-536870912, ..., 536870911}	-1200000

Option	Description	Default
separating/rapidlearning/reducedinfer	should the inference values only be used when rapidlearning found other reductions? Range: boolean	0

5.34.4.248 separating/rlt

Option	Description	Default
separating/rlt/addtopool	if set to true, globally valid RLT cuts are added to the global cut pool Range: boolean	1
separating/rlt/detecthidden	if set to true, hidden products are detected and separated by McCormick cuts Range: boolean	0
separating/rlt/freq	frequency for calling separator <rlt> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	0
separating/rlt/hiddenrlt	whether RLT cuts (TRUE) or only McCormick inequalities (FALSE) should be added for hidden products Range: boolean	0
separating/rlt/maxncuts	maximal number of rlt-cuts that are added per round (-1: unlimited) Range: {-1, ..., ∞}	-1
separating/rlt/maxrounds	maximal number of separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	1
separating/rlt/maxroundsroot	maximal number of separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	10
separating/rlt/maxunknownterms	maximal number of unknown bilinear terms a row is still used with (-1: unlimited) Range: {-1, ..., ∞}	0
separating/rlt/maxusedvars	maximal number of variables used to compute rlt cuts (-1: unlimited) Range: {-1, ..., ∞}	100
separating/rlt/onlycontrows	if set to true, only continuous rows are used for rlt cuts Range: boolean	0
separating/rlt/onlyeqrows	if set to true, only equality rows are used for rlt cuts Range: boolean	0
separating/rlt/onlyoriginal	if set to true, only original rows and variables are used Range: boolean	1
separating/rlt/useinsubscip	if set to true, rlt is also used in sub-scips Range: boolean	0
separating/rlt/useprojection	if set to true, projected rows are checked first Range: boolean	0
Options for expert users		
separating/rlt/badscore	threshold for score of cut relative to best score to be discarded Range: [0, 1]	0.5

Option	Description	Default
separating/rlt/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/rlt/dircutoffdistweight	weight of directed cutoff distance in cut score calculation Range: [0, 1]	0
separating/rlt/efficacyweight	weight of efficacy in cut score calculation Range: [0, 1]	1
separating/rlt/expbackoff	base for exponential increase of frequency at which separator <rlt> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/rlt/goodmaxparall	maximum parallelism for good cuts Range: [0, 1]	0.1
separating/rlt/goodscore	threshold for score of cut relative to best score to be considered good, so that less strict filtering is applied Range: [0, 1]	1
separating/rlt/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <rlt> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/rlt/maxparall	maximum parallelism for non-good cuts Range: [0, 1]	0.1
separating/rlt/objparalweight	weight of objective parallelism in cut score calculation Range: [0, 1]	0
separating/rlt/priority	priority of separator <rlt> Range: {-536870912, ..., 536870911}	10

5.34.4.249 separating/strongcg

Option	Description	Default
separating/strongcg/freq	frequency for calling separator <strongcg> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
Options for expert users		
separating/strongcg/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/strongcg/expbackoff	base for exponential increase of frequency at which separator <strongcg> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/strongcg/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <strongcg> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	0
separating/strongcg/priority	priority of separator <strongcg> Range: {-536870912, ..., 536870911}	-100000

5.34.4.250 separating/zerohalf

Option	Description	Default
separating/zerohalf/dynamiccuts	should generated cuts be removed from the LP if they are no longer tight? Range: boolean	1
separating/zerohalf/freq	frequency for calling separator <zerohalf> (-1: never, 0: only in root node) Range: {-1, ..., 65534}	10
separating/zerohalf/initseed	initial seed used for random tie-breaking in cut selection Range: {0, ..., ∞}	24301
separating/zerohalf/maxcutcands	maximal number of zerohalf cuts considered per separation round Range: {0, ..., ∞}	2000
separating/zerohalf/maxrounds	maximal number of zerohalf separation rounds per node (-1: unlimited) Range: {-1, ..., ∞}	5
separating/zerohalf/maxroundsroot	maximal number of zerohalf separation rounds in the root node (-1: unlimited) Range: {-1, ..., ∞}	20
separating/zerohalf/maxsepacuts	maximal number of zerohalf cuts separated per separation round Range: {0, ..., ∞}	20
separating/zerohalf/maxsepacutsroot	maximal number of zerohalf cuts separated per separation round in the root node Range: {0, ..., ∞}	100
Options for expert users		
separating/zerohalf/badscore	threshold for score of cut relative to best score to be discarded Range: [0, 1]	0.5
separating/zerohalf/delay	should separator be delayed, if other separators found cuts? Range: boolean	0
separating/zerohalf/densityoffset	additional number of variables allowed in row on top of density Range: {0, ..., ∞}	100
separating/zerohalf/dircutoffdistweight	weight of directed cutoff distance in cut score calculation Range: [0, 1]	0
separating/zerohalf/efficacyweight	weight of efficacy in cut score calculation Range: [0, 1]	1
separating/zerohalf/expbackoff	base for exponential increase of frequency at which separator <zerohalf> is called (1: call at each multiple of frequency) Range: {1, ..., 100}	4
separating/zerohalf/goodmaxparall	maximum parallelism for good cuts Range: [0, 1]	0.1
separating/zerohalf/goodscore	threshold for score of cut relative to best score to be considered good, so that less strict filtering is applied Range: [0, 1]	1

Option	Description	Default
separating/zerohalf/maxbounddist	maximal relative distance from current node's dual bound to primal bound compared to best node's dual bound for applying separator <zerohalf> (0.0: only on current best node, 1.0: on all nodes) Range: [0, 1]	1
separating/zerohalf/maxparall	maximum parallelism for non-good cuts Range: [0, 1]	0.1
separating/zerohalf/maxrowdensity	maximal density of row to be used in aggregation Range: [0, 1]	0.05
separating/zerohalf/maxslack	maximal slack of rows to be used in aggregation Range: [0, ∞]	0
separating/zerohalf/maxslackroot	maximal slack of rows to be used in aggregation in the root node Range: [0, ∞]	0
separating/zerohalf/minviol	minimal violation to generate zerohalfcut for Range: [0, ∞]	0.1
separating/zerohalf/objparalweight	weight of objective parallelism in cut score calculation Range: [0, 1]	0
separating/zerohalf/priority	priority of separator <zerohalf> Range: {-536870912, ..., 536870911}	-6000

5.34.4.251 solvingphases

Option	Description	Default
solvingphases/enabled	should the event handler adapt the solver behavior? Range: boolean	0
solvingphases/fallback	should the event handler fall back from optimal phase? Range: boolean	0
solvingphases/feassetname	settings file for feasibility phase – precedence over emphasis settings Range: string	-
solvingphases/improvesetname	settings file for improvement phase – precedence over emphasis settings Range: string	-
solvingphases/interruptoptimal	should the event handler interrupt the solving process after optimal solution was found? Range: boolean	0
solvingphases/nodeoffset	node offset for rank-1 and estimate transitions Range: {1, ..., ∞}	50
solvingphases/optimalvalue	optimal solution value for problem Range: real	∞
solvingphases/proofsetname	settings file for proof phase – precedence over emphasis settings Range: string	-
solvingphases/testmode	should the event handler test all phase transitions? Range: boolean	0
solvingphases/transitionmethod	transition method: Possible options are 'e'stimate,'l'ogarithmic regression,'o'ptimal-value based,'r'ank-1 Range: e, l, o, r	r

Option	Description	Default
solvingphases/useemphsettings	should emphasis settings for the solving phases be used, or settings files? Range: boolean	1
solvingphases/userestart1to2	should a restart be applied between the feasibility and improvement phase? Range: boolean	0
solvingphases/userestart2to3	should a restart be applied between the improvement and the proof phase? Range: boolean	0
solvingphases/xtype	x-type for logarithmic regression - (t)ime, (n)odes, (l)p iterations Range: l, n, t	n

5.34.4.252 table/branchrules

Option	Description	Default
table/branchrules/active	is statistics table <branchrules> active Range: boolean	1

5.34.4.253 table/compression

Option	Description	Default
table/compression/active	is statistics table <compression> active Range: boolean	1

5.34.4.254 table/concurrentsolver

Option	Description	Default
table/concurrentsolver/active	is statistics table <concurrentsolver> active Range: boolean	1

5.34.4.255 table/conflict

Option	Description	Default
table/conflict/active	is statistics table <conflict> active Range: boolean	1

5.34.4.256 table/cons_nonlinear

Option	Description	Default
table/cons_nonlinear/active	is statistics table <cons_nonlinear> active Range: boolean	0

5.34.4.257 table/constiming

Option	Description	Default
table/constiming/active	is statistics table <constiming> active Range: boolean	1

5.34.4.258 table/constraint

Option	Description	Default
table/constraint/active	is statistics table <constraint> active Range: boolean	1

5.34.4.259 table/cutsel

Option	Description	Default
table/cutsel/active	is statistics table <cutsel> active Range: boolean	1

5.34.4.260 table/estim

Option	Description	Default
table/estim/active	is statistics table <estim> active Range: boolean	1

5.34.4.261 table/exprhdlr

Option	Description	Default
table/exprhdlr/active	is statistics table <exprhdlr> active Range: boolean	1

5.34.4.262 table/heuristics

Option	Description	Default
table/heuristics/active	is statistics table <heuristics> active Range: boolean	1

5.34.4.263 table/lp

Option	Description	Default
table/lp/active	is statistics table <lp> active Range: boolean	1

5.34.4.264 table/neighborhood

Option	Description	Default
table/neighborhood/active	is statistics table <neighborhood> active Range: boolean	1

5.34.4.265 table/nlhdlr

Option	Description	Default
table/nlhdlr/active	is statistics table <nlhdlr> active Range: boolean	1

5.34.4.266 table/nlhdlr_bilinear

Option	Description	Default
table/nlhdlr_bilinear/active	is statistics table <nlhdlr_bilinear> active Range: boolean	0

5.34.4.267 table/nlhdlr_quadratic

Option	Description	Default
table/nlhdlr_quadratic/active	is statistics table <nlhdlr_quadratic> active Range: boolean	0

5.34.4.268 table/nlp

Option	Description	Default
table/nlp/active	is statistics table <nlp> active Range: boolean	1

5.34.4.269 table/nlpi

Option	Description	Default
table/nlpi/active	is statistics table <nlpi> active Range: boolean	1

5.34.4.270 table/orbitalfixing

Option	Description	Default
table/orbitalfixing/active	is statistics table <orbitalfixing> active Range: boolean	1

5.34.4.271 table/origprob

Option	Description	Default
table/origprob/active	is statistics table <origprob> active Range: boolean	1

5.34.4.272 table/presolvedprob

Option	Description	Default
table/presolvedprob/active	is statistics table <presolvedprob> active Range: boolean	1

5.34.4.273 table/presolver

Option	Description	Default
table/presolver/active	is statistics table <presolver> active Range: boolean	1

5.34.4.274 table/pricer

Option	Description	Default
table/pricer/active	is statistics table <pricer> active Range: boolean	1

5.34.4.275 table/propagator

Option	Description	Default
table/propagator/active	is statistics table <propagator> active Range: boolean	1

5.34.4.276 table/relaxator

Option	Description	Default
table/relaxator/active	is statistics table <relaxator> active Range: boolean	1

5.34.4.277 table/root

Option	Description	Default
table/root/active	is statistics table <root> active Range: boolean	1

5.34.4.278 table/separator

Option	Description	Default
table/separator/active	is statistics table <separator> active Range: boolean	1

5.34.4.279 table/solution

Option	Description	Default
table/solution/active	is statistics table <solution> active Range: boolean	1

5.34.4.280 table/status

Option	Description	Default
table/status/active	is statistics table <status> active Range: boolean	1

5.34.4.281 table/timing

Option	Description	Default
table/timing/active	is statistics table <timing> active Range: boolean	1

5.34.4.282 table/tree

Option	Description	Default
table/tree/active	is statistics table <tree> active Range: boolean	1

5.34.4.283 timing

Option	Description	Default
timing/clocktype	default clock type (1: CPU user seconds, 2: wall clock time) Range: {1, ..., 2}	2
timing/enabled	is timing enabled? Range: boolean	1
timing/nlpieval	should time for evaluation in NLP solves be measured? Range: boolean	0
timing/rareclockcheck	should clock checks of solving time be performed less frequently (note: time limit could be exceeded slightly) Range: boolean	0
timing/reading	belongs reading time to solving time? Range: boolean	0
timing/statistictiming	should timing for statistic output be performed? Range: boolean	1

5.35 SHOT

SHOT (**S**upporting **H**yperplane **O**ptimization **T**oolkit) is a deterministic solver for mixed-integer nonlinear programming problems (MINLPs).

Originally, SHOT was intended for convex MINLP problems only, but now also has functionality to solve nonconvex MINLP problems as a heuristic method without providing any guarantees of global optimality. SHOT can solve certain nonconvex problem types to global optimality as well.

SHOT has mainly been developed by Andreas Lundell (Åbo Akademi University, Finland) and Jan Kronqvist (Imperial College London, UK). For more details, see [126] [122] [112] [113] [121].

SHOT supports GAMS equations that use the following intrinsic functions: abs, cos, cvPower, div, exp, log, log10, log2, pi, power, rPower, sin, sqr, sqrt, vcPower.

5.35.1 Algorithm

SHOT is based on iteratively creating a tighter polyhedral approximation of the nonlinear feasible set by generating supporting hyperplanes or cutting planes. These linearized problems are then solved with a mixed-integer linear programming (MIP) solver. GAMS/SHOT uses CPLEX, if a GAMS/CPLEX license is available, and otherwise CBC. Users with a license from Gurobi can also select Gurobi as MIP solver. If CPLEX or Gurobi is used, the subproblems can also include quadratic and bilinear nonlinearities directly.

The solution to the outer approximation problem provides a dual bound (i.e., a lower bound when solving a minimization problem) to the optimal value of the original problem if it is convex. If the problem is nonconvex, convergence to the global optimal solution cannot be guaranteed (but might be achieved for certain classes of problems, cf. [122]).

To get a primal bound (i.e., an upper bound when solving a minimization problem) on the optimal value, SHOT utilizes the following heuristics:

- Solving nonlinear programming (NLP) problems where the integer variables have been fixed to valid values. This is done by calling an NLP solver, which is either Ipopt, one of the GAMS NLP solvers, or SHOT itself.
- By checking solutions from the MIP solver's solution pool for points that fulfill also the nonlinear constraints in the original MINLP problem.
- By performing root searches.

When a termination criterion like a tolerance on the relative or absolute objective gap or a time limit is fulfilled, SHOT terminates and returns the current primal solution to GAMS. If the original problem is convex and SHOT could close the objective gap, then this is a global optimal solution to the problem. If it is nonconvex, then there is normally no guarantee that such a solution can be found. However, SHOT will always, in addition to a primal solution, return a valid dual bound on the solution in model attribute objest, unless Model.Convexity.AssumeConvex has been enabled.

5.35.2 Usage

The following statement can be used inside your GAMS program to specify using SHOT

```
Option MINLP = SHOT;     { or MIQCP }
```

The above statement should appear before the Solve statement. If SHOT was specified as the default MINLP or MIQCP solver during GAMS installation, the above statement is not necessary.

5.35.2.1 Specification of SHOT Options

GAMS/SHOT supports the GAMS parameters reslim, iterlim, nodlim, optcr, optca, cutoff, and threads.

Options can be specified by a SHOT options file. A SHOT options file consists of one option or comment per line. An asterik (∗) at the beginning of a line causes the entire line to be ignored. Otherwise, the line will be interpreted as an option name and value separated by an equal sign (=) and any amount of white space (blanks or tabs).

A small example for a shot.opt file is:

```
Dual.CutStrategy = 1
Dual.MIP.Solver = 2
Output.Console.DualSolver.Show = true
```

It causes GAMS/SHOT to use the Extended Cutting Plane (ECP) method instead of the Extended Supporting Hyperplane (EHP) method, changes the MIP solver to CBC, and enables showing the output of the solver that computes dual bounds (typically the MIP solver).

Attention

SHOT requires options to be specified using exactly the names as specified in the documentation. That is, also casing matters.

5.35.3 List of SHOT Options

In the following, we give a detailed list of all SHOT options.

5.35.3.1 Solver output

These settings control how much and what output is shown to the user from the solver.

Option	Description	Default
Output.Debug.Path	The folder where to save the debug information Range: string	
Output.GAMS.AlternateSolutionsFile	Name of GAMS GDX file to write alternative solutions to Range: string	
Output.Console.Iteration.Detail	When should the fixed strategy be used 0: Full 1: On objective gap update 2: On objective gap update and all primal NLP calls	1
Output.Console.LogLevel	Log level for console output 0: Trace 1: Debug 2: Info 3: Warning 4: Error 5: Critical 6: Off	2
Output.Console.DualSolver.Show	Show output from dual solver on console Range: boolean	0
Output.Console.PrimalSolver.Show	Show output from primal solver on console Range: boolean	0
Output.Debug.Enable	Use debug functionality Range: boolean	0

5.35.3.2 Subsolver functionality

These settings allow for more direct control of the different subsolvers utilized in SHOT.

Option	Description	Default
Subsolver.Cplex.WorkDirectory	Directory for swap file Range: string	
Subsolver.GAMS.NLP.OptionsFilename	Options file for the NLP solver in GAMS Range: string	
Subsolver.GAMS.NLP.Solver	NLP solver to use in GAMS (auto: SHOT chooses) Range: string	auto
Subsolver.Cbc.NodeStrategy	Node strategy 0: depth 1: downdepth 2: downfewest 3: fewest 4: hybrid 5: updepth 6: upfewest	4
Subsolver.Cbc.Scaling	Whether to scale problem 0: automatic 1: dynamic 2: equilibrium 3: geometric 4: off 5: rowsonly	4
Subsolver.Cbc.Strategy	This turns on newer features 0: easy problems 1: default 2: aggressive	1
Subsolver.Cplex.FeasOptMode	Strategy to use for the feasibility repair 0: Minimize the sum of all required relaxations in first phase only 1: Minimize the sum of all required relaxations in first phase and execute second phase to find optimum among minimal relaxations 2: Minimize the number of constraints and bounds requiring relaxation in first phase only 3: Minimize the sum of squares of required relaxations in first phase only 4: Minimize the sum of squares of required relaxations in first phase and execute second phase to find optimum among minimal relaxations	0
Subsolver.Cplex.MIPEmphasis	Sets the MIP emphasis 0: Balanced 1: Feasibility 2: Optimality 3: Best bound 4: Hidden feasible	1
Subsolver.Cplex.MemoryEmphasis	Try to conserve memory when possible Range: {0, ..., 1}	0

Option	Description	Default
Subsolver.Cplex.NodeFile	Where to store the node file 0: No file 1: Compressed in memory 2: On disk 3: Compressed on disk	1
Subsolver.Cplex.NumericalEmphasis	Emphasis on numerical stability Range: {0, ..., 1}	1
Subsolver.Cplex.OptimalityTarget	Specifies how CPLEX treats nonconvex quadratics 0: Automatic 1: Searches for a globally optimal solution to a convex model 2: Searches for a solution that satisfies first-order optimality conditions, but is not necessarily globally optimal 3: Searches for a globally optimal solution to a nonconvex model	0
Subsolver.Cplex.ParallelMode	Controls how much time and memory should be used when filling the solution pool -1: Opportunistic 0: Automatic 1: Deterministic	0
Subsolver.Cplex.Probe	Sets the MIP probing level -1: No probing 0: Automatic 1: Moderate 2: Aggressive 3: Very aggressive	0
Subsolver.Cplex.SolutionPoolIntensity	Controls how much time and memory should be used when filling the solution pool 0: Automatic 1: Mild 2: Moderate 3: Aggressive 4: Very aggressive	0
Subsolver.Cplex.SolutionPoolReplace	How to replace solutions in the solution pool when full 0: Replace oldest 1: Replace worst 2: Find diverse	0
Subsolver.Gurobi.MIPFocus	MIP focus 0: Automatic 1: Feasibility 2: Optimality 3: Best bound	0
Subsolver.Gurobi.NumericFocus	MIP focus 0: Automatic 1: Mild 2: Moderate 3: Aggressive	1
Subsolver.Gurobi.PoolSearchMode	Finds extra solutions 0: No extra effort 1: Try to find solutions 2: Find n best solutions	0

Option	Description	Default
Subsolver.Gurobi.PoolSolutions	Determines how many MIP solutions are stored Range: {1, ..., 2000000000}	10
Subsolver.Gurobi.ScaleFlag	Controls model scaling -1: Automatic 0: Off 1: Mild 2: Moderate 3: Aggressive	-1
Subsolver.Ipopt.LinearSolver	Ipopt linear subsolver 0: Default 1: MA27 2: MA57 3: MA86 4: MA97 5: MUMPS	5
Subsolver.Ipopt.MaxIterations	Maximum number of iterations Range: {0, ..., ∞}	1000
Subsolver.Rootsearch.MaxIterations	Maximal root search iterations Range: {0, ..., ∞}	100
Subsolver.Rootsearch.Method	Root search method to use 0: TOMS748 1: Bisection	0
Subsolver.Cplex.SolutionPoolGap	Sets the relative gap filter on objective values in the solution pool Range: [0, 1e+75]	1e+75
Subsolver.Cplex.WorkMemory	Memory limit for when to start swapping to disk Range: [0, 1e+75]	0
Subsolver.Gurobi.Heuristics	The relative amount of time spent in MIP heuristics. Range: [0, 1]	0.05
Subsolver.Ipopt.ConstraintViolationTolerance	Constraint violation tolerance in Ipopt Range: real	1e-08
Subsolver.Ipopt.RelativeConvergenceTolerance	Relative convergence tolerance Range: real	1e-08
Subsolver.Rootsearch.ActiveConstraintTolerance	Epsilon constraint tolerance for root search Range: [0, ∞]	0
Subsolver.Rootsearch.TerminationTolerance	Epsilon lambda tolerance for root search Range: [0, ∞]	1e-16
Subsolver.SHOT.ReuseHyperplanes.Fraction	The fraction of generated hyperplanes to reuse. Range: [0, 1]	0.1
Subsolver.Cbc.AutoScale	Whether to scale objective, rhs and bounds of problem if they look odd (experimental) Range: boolean	0
Subsolver.Cbc.DeterministicParallelMode	Run Cbc with multiple threads in deterministic mode Range: boolean	0
Subsolver.Cplex.AddRelaxedLazyConstraintsAsLocal	Whether to add lazy constraints generated in relaxed points as local or global Range: boolean	0

Option	Description	Default
Subsolver.Cplex.UseGenericCallback	Use the new generic callback in the single-tree strategy Range: boolean	0
Subsolver.SHOT.ReuseHyperplanes.Use	Reuse valid generated hyperplanes in main dual model. Range: boolean	1
Subsolver.SHOT.UseFBBT	Do FBBT on NLP problem. Range: boolean	1

5.35.3.3 Dual strategy

These settings control the various functionality of the dual strategy in SHOT, i.e., the polyhedral outer approximation utilizing the ESH or ECP algorithms.

Option	Description	Default
Dual.CutStrategy	Dual cut strategy 0: ESH 1: ECP	0
Dual.ESH.InteriorPoint.CuttingPlane.IterationLimit	Iteration limit for minimax cutting plane solver Range: {1, ..., ∞}	100
Dual.ESH.InteriorPoint.CuttingPlane.IterationLimitSubsolver	Iteration limit for minimization subsolver Range: {0, ..., ∞}	100
Dual.ESH.InteriorPoint.UsePrimalSolution	Utilize primal solution as interior point 0: No 1: Add as new 2: Replace old 3: Use avarage	1
Dual.HyperplaneCuts.MaxPerIteration	Maximal number of hyperplanes to add per iteration Range: {0, ..., ∞}	200
Dual.HyperplaneCuts.ObjectiveRootSearch	When to use the objective root search 0: Always 1: IfConvex 2: Never	1
Dual.MIP.InfeasibilityRepair.IterationLimit	Max number of infeasible problems repaired without primal objective value improvement Range: {0, ..., ∞}	100
Dual.MIP.NumberOfThreads	Number of threads to use in MIP solver: 0: Automatic Range: {0, ..., 999}	GAMS threads
Dual.MIP.Presolve.Frequency	When to call the MIP presolve 0: Never 1: Once 2: Always	1
Dual.MIP.SolutionLimit.ForceOptimal.Iteration	Iterations without dual bound updates for forcing optimal MIP solution Range: {0, ..., ∞}	10000

Option	Description	Default
Dual.MIP.SolutionLimit.IncreaseIterations	Max number of iterations between MIP solution limit increases Range: {0, ..., ∞}	50
Dual.MIP.SolutionLimit.Initial	Initial MIP solution limit Range: {1, ..., ∞}	1
Dual.MIP.SolutionPool.Capacity	The maximum number of solutions in the solution pool Range: {0, ..., ∞}	100
Dual.MIP.Solver	Which MIP solver to use 0: Cplex 1: Gurobi 2: Cbc	Cplex, if licensed, otherwise Cbc
Dual.ReductionCut.MaxIterations	Max number of primal cut reduction without primal improvement Range: {0, ..., ∞}	5
Dual.Relaxation.Frequency	The frequency to solve an LP problem: 0: Disable Range: {0, ..., ∞}	0
Dual.Relaxation.IterationLimit	The max number of relaxed LP problems to solve initially Range: {0, ..., ∞}	200
Dual.Relaxation.MaxLazyConstraints	Max number of lazy constraints to add in relaxed solutions in single-tree strategy Range: {0, ..., ∞}	0
Dual.TreeStrategy	The main strategy to use 0: Multi-tree 1: Single-tree	1
Dual.ESH.InteriorPoint.CuttingPlane.ConstraintSelectionFactor	The fraction of violated constraints to generate cutting planes for Range: [0, 1]	0.25
Dual.ESH.InteriorPoint.CuttingPlane.TerminationToleranceAbs	Absolute termination tolerance between LP and linesearch objective Range: [0, ∞]	1
Dual.ESH.InteriorPoint.CuttingPlane.TerminationToleranceRel	Relative termination tolerance between LP and linesearch objective Range: [0, ∞]	1
Dual.ESH.InteriorPoint.CuttingPlane.TimeLimit	Time limit for minimax solver Range: [0, ∞]	10
Dual.ESH.InteriorPoint.MinimaxObjectiveLowerBound	Lower bound for minimax objective variable Range: [-∞, 0]	-1e+12
Dual.ESH.InteriorPoint.MinimaxObjectiveUpperBound	Upper bound for minimax objective variable Range: real	0.1

Option	Description	Default
Dual.ESH.Rootsearch.ConstraintTolerance	Constraint tolerance for when not to add individual hyperplanes Range: [0, ∞]	1e-08
Dual.HyperplaneCuts.ConstraintSelectionFactor	The fraction of violated constraints to generate supporting hyperplanes / cutting planes for Range: [0, 1]	0.5
Dual.HyperplaneCuts.MaxConstraintFactor	Rootsearch performed on constraints with values larger than this factor times the maximum value Range: [1e-06, 1]	0.1
Dual.MIP.CutOff.InitialValue	Initial cutoff value to use Range: real	GAMS cutoff
Dual.MIP.CutOff.Tolerance	An extra tolerance for the objective cutoff value (to prevent infeasible subproblems) Range: real	1e-05
Dual.MIP.InfeasibilityRepair.TimeLimit	Time limit when reparing infeasible problem Range: [0, ∞]	10
Dual.MIP.NodeLimit	Node limit to use for MIP solver in single-tree strategy Range: [0, ∞]	GAMS nodlim
Dual.MIP.OptimalityTolerance	The reduced-cost tolerance for optimality in the MIP solver Range: [1e-09, 0.01]	1e-06
Dual.MIP.SolutionLimit.ForceOptimal.Time	Time (s) without dual bound updates for forcing optimal MIP solution Range: [0, ∞]	1000
Dual.MIP.SolutionLimit.UpdateTolerance	The constraint tolerance for when to update MIP solution limit Range: [0, ∞]	0.001
Dual.ReductionCut.ReductionFactor	The factor used to reduce the cutoff value Range: [0, 1]	0.001
Dual.Relaxation.TerminationTolerance	Time limit (s) when solving LP problems initially Range: real	0.5
Dual.Relaxation.TimeLimit	Time limit (s) when solving LP problems initially Range: [0, ∞]	30
Dual.ESH.InteriorPoint.CuttingPlane.Reuse	Reuse valid cutting planes in main dual model Range: boolean	0
Dual.ESH.Rootsearch.UniqueConstraints	Allow only one hyperplane per constraint per iteration Range: boolean	0

Option	Description	Default
Dual.ESH.Rootsearch.UseMaxFunction	Perform rootsearch on max function, otherwise on individual constraints Range: boolean	0
Dual.HyperplaneCuts.Delay	Add hyperplane cuts to model only after optimal MIP solution Range: boolean	1
Dual.HyperplaneCuts.SaveHyperplanePoints	Whether to save the points in the generated hyperplanes list Range: boolean	0
Dual.HyperplaneCuts.UseIntegerCuts	Add integer cuts for infeasible integer-combinations for binary problems Range: boolean	0
Dual.MIP.CutOff.UseInitialValue	Use the initial cutoff value Range: boolean	1, if cutoff is set
Dual.MIP.InfeasibilityRepair.IntegerCuts	Allow feasibility repair of integer cuts Range: boolean	1
Dual.MIP.InfeasibilityRepair.Use	Enable the infeasibility repair strategy for nonconvex problems Range: boolean	1
Dual.MIP.Presolve.RemoveRedundantConstraints	Remove redundant constraints (as determined by presolve) Range: boolean	0
Dual.MIP.Presolve.UpdateObtainedBounds	Update bounds (from presolve) to the MIP model Range: boolean	1
Dual.MIP.UpdateObjectiveBounds	Update nonlinear objective variable bounds to primal/dual bounds Range: boolean	0
Dual.ReductionCut.Use	Enable the dual reduction cut strategy for nonconvex problems Range: boolean	1
Dual.Relaxation.Use	Initially solve continuous dual relaxations Range: boolean	1

5.35.3.4 Optimization model

These settings control various aspects of SHOT's representation for and handling of the provided optimization model.

Option	Description	Default
Model.BoundTightening.FeasibilityBased.MaxIterations	Maximal number of bound tightening iterations Range: {0, ..., ∞}	5
Model.BoundTightening.InitialPOA.CutStrategy	Dual cut strategy 0: ESH 1: ECP	1
Model.BoundTightening.InitialPOA.IterationLimit	Iteration limit for POA Range: {0, ..., ∞}	50

Option	Description	Default
Model.BoundTightening.InitialPOA.StagnationIterationLimit	Limit for iterations without significant progress Range: {0, ..., ∞}	5
Model.Reformulation.Bilinear.IntegerFormulation	Reformulate integer bilinear terms 0: No 1: No if nonconvex quadratic terms allowed by MIP solver 2: Yes	1
Model.Reformulation.Bilinear.IntegerFormulation.MaxDomain	Do not reformulate integer variables in bilinear terms which can assume more than this number of discrete values Range: {2, ..., ∞}	100
Model.Reformulation.Constraint.PartitionNonlinearTerms	When to partition nonlinear sums in constraints 0: Always 1: If result is convex 2: Never	1
Model.Reformulation.Constraint.PartitionQuadraticTerms	When to partition quadratic sums in constraints 0: Always 1: If result is convex 2: Never	1
Model.Reformulation.Monomials.Formulation	How to reformulate binary monomials 0: None 1: Simple 2: Costa and Liberti	1
Model.Reformulation.ObjectiveFunction.PartitionNonlinearTerms	When to partition nonlinear sums in objective function 0: Always 1: If result is convex 2: Never	1
Model.Reformulation.ObjectiveFunction.PartitionQuadraticTerms	When to partition quadratic sums in objective function 0: Always 1: If result is convex 2: Never	1
Model.Reformulation.Quadratics.EigenValueDecomposition.Formulation	Which formulation to use in eigenvalue decomposition 0: Term coefficient is included in reformulation 1: Term coefficient remains	0
Model.Reformulation.Quadratics.ExtractStrategy	How to extract quadratic terms from nonlinear expressions 0: Do not extract 1: Extract to same objective or constraint 2: Extract to quadratic equality constraint if nonconvex 3: Extract to quadratic equality constraint even if convex	1
Model.Reformulation.Quadratics.Strategy	How to treat quadratic functions 0: All nonlinear 1: Use quadratic objective 2: Use convex quadratic objective and constraints 3: Use nonconvex quadratic objective and constraints	2

Option	Description	Default
Model.BoundTightening.FeasibilityBased.TimeLimit	Time limit for bound tightening Range: [0, ∞]	2
Model.BoundTightening.InitialPOA.ConstraintTolerance	Constraint termination tolerance Range: real	0.1
Model.BoundTightening.InitialPOA.ObjectiveConstraintTolerance	Objective constraint termination tolerance Range: real	0.001
Model.BoundTightening.InitialPOA.ObjectiveGapAbsolute	Absolute objective gap termination level Range: real	0.1
Model.BoundTightening.InitialPOA.ObjectiveGapRelative	Relative objective gap termination level Range: real	0.1
Model.BoundTightening.InitialPOA.StagnationConstraintTolerance	Tolerance factor for when no progress is made Range: real	0.01
Model.BoundTightening.InitialPOA.TimeLimit	Time limit for initial POA Range: real	5
Model.Convexity.Quadratics.EigenValueTolerance	Convexity tolerance for the eigenvalues of the Hessian matrix for quadratic terms Range: [0, ∞]	1e-05
Model.Reformulation.Quadratics.EigenValueDecomposition.Tolerance	Variables with eigenvalues smaller than this value will be ignored Range: [0, ∞]	1e-06
Model.Variables.Continuous.MaximumUpperBound	Maximum upper bound for continuous variables Range: real	1e+50
Model.Variables.Continuous.MinimumLowerBound	Minimum lower bound for continuous variables Range: real	-1e+50
Model.Variables.Integer.MaximumUpperBound	Maximum upper bound for integer variables Range: real	2e+09
Model.Variables.Integer.MinimumLowerBound	Minimum lower bound for integer variables Range: real	-2e+09
Model.Variables.NonlinearObjectiveVariable.Bound	Max absolute bound for the auxiliary nonlinear objective variable Range: real	1e+12
Model.BoundTightening.FeasibilityBased.Use	Peform feasibility-based bound tightening Range: boolean	1
Model.BoundTightening.FeasibilityBased.UseNonlinear	Peform feasibility-based bound tightening on nonlinear expressions Range: boolean	1
Model.BoundTightening.InitialPOA.Use	Create an initial polyhedral outer approximation Range: boolean	0
Model.Convexity.AssumeConvex	Assume that the problem is convex Range: boolean	0
Model.Reformulation.Bilinear.AddConvexEnvelope	Add convex envelopes (subject to original bounds) to bilinear terms Range: boolean	0
Model.Reformulation.Monomials.Extract	Extract monomial terms from nonlinear expressions Range: boolean	1
Model.Reformulation.ObjectiveFunction.Epigraph.Use	Reformulates a nonlinear objective as an auxiliary constraint Range: boolean	0

Option	Description	Default
Model.Reformulation.Quadratics.EigenValueDecomposition.Method	Whether to use the eigen value decomposition of convex quadratic functions Range: boolean	0
Model.Reformulation.Quadratics.EigenValueDecomposition.Use	Whether to use the eigenvalue decomposition of convex quadratic functions Range: boolean	0
Model.Reformulation.Signomials.Extract	Extract signomial terms from nonlinear expressions Range: boolean	1

5.35.3.5 Modeling system

These settings control functionality used in the interfaces to different modeling environments.

Option	Description	Default
ModelingSystem.GAMS.QExtractAlg	Extraction algorithm for quadratic equations in GAMS interface 0: automatic 1: threepass 2: doubleforward 3: concurrent	0

5.35.3.6 Primal heuristics

These settings control the primal heuristics used in SHOT.

Option	Description	Default
Primal.FixedInteger.CallStrategy	When should the fixed strategy be used 0: Use each iteration 1: Based on iteration or time 2: Based on iteration or time, and for all feasible MIP solutions	2
Primal.FixedInteger.Frequency.Iteration	Max number of iterations between calls Range: {0, ..., ∞}	10
Primal.FixedInteger.IterationLimit	Max number of iterations per call Range: {0, ..., ∞}	10000000
Primal.FixedInteger.Solver	NLP solver to use 0: Ipopt 1: GAMS 2: SHOT	1
Primal.FixedInteger.Source	Source of fixed MIP solution point 0: All 1: First 2: All feasible 3: First and all feasible 4: With smallest constraint deviation	3
Primal.FixedInteger.SourceProblem	Which problem formulation to use for NLP problem 0: Original problem 1: Reformulated problem 2: Both	0

Option	Description	Default
Primal.FixedInteger.DualPointGap.Relative	If the objective gap between the MIP point and dual solution is less than this the fixed strategy is activated Range: [0, ∞]	0.001
Primal.FixedInteger.Frequency.Time	Max duration (s) between calls Range: [0, ∞]	5
Primal.FixedInteger.TimeLimit	Time limit (s) per NLP problem Range: [0, ∞]	10
Primal.Tolerance.Integer	Integer tolerance for accepting primal solutions Range: real	1e-05
Primal.Tolerance.LinearConstraint	Linear constraint tolerance for accepting primal solutions Range: real	1e-06
Primal.Tolerance.NonlinearConstraint	Nonlinear constraint tolerance for accepting primal solutions Range: real	1e-05
Primal.FixedInteger.CreateInfeasibilityCut	Create a cut from an infeasible solution point Range: boolean	0
Primal.FixedInteger.Frequency.Dynamic	Dynamically update the call frequency based on success Range: boolean	1
Primal.FixedInteger.OnlyUniqueIntegerCombinations	Whether to resolve with the same integer combination, e.g. for nonconvex problems with different continuous variable starting points Range: boolean	1
Primal.FixedInteger.Use	Use the fixed integer primal strategy Range: boolean	1
Primal.FixedInteger.Warmstart	Warm start the NLP solver Range: boolean	1
Primal.Rootsearch.Use	Use a rootsearch to find primal solutions Range: boolean	1
Primal.Tolerance.TrustLinearConstraintValues	Trust that subsolvers (NLP, MIP) give primal solutions that respect linear constraints Range: boolean	1

5.35.3.7 Termination

These settings control when SHOT will terminate the solution process.

Option	Description	Default
Termination.DualStagnation.IterationLimit	Max number of iterations without significant dual objective value improvement Range: {0, ..., ∞}	∞
Termination.IterationLimit	Iteration limit for main strategy Range: {1, ..., ∞}	GAMS iterlim
Termination.PrimalStagnation.IterationLimit	Max number of iterations without significant primal objective value improvement Range: {0, ..., ∞}	50

Option	Description	Default
Termination.ConstraintTolerance	Termination tolerance for nonlinear constraints Range: [0, ∞]	1e-08
Termination.DualStagnation.ConstraintTolerance	Min absolute difference between max nonlinear constraint errors in subsequent iterations for termination Range: [0, ∞]	1e-06
Termination.ObjectiveConstraintTolerance	Termination tolerance for the nonlinear objective constraint Range: [0, ∞]	1e-08
Termination.ObjectiveGap.Absolute	Absolute gap termination tolerance for objective function Range: [0, ∞]	GAMS optca
Termination.ObjectiveGap.Relative	Relative gap termination tolerance for objective function Range: [0, ∞]	GAMS optcr
Termination.TimeLimit	Time limit (s) for solver Range: [0, ∞]	GAMS reslim

5.35.3.8 Strategy

Overall strategy parameters used in SHOT.

Option	Description	Default
Strategy.UseRecommendedSettings	Modifies some settings to their recommended values based on the strategy Range: boolean	1

5.36 SNOPT

Author

Philip E. Gill; Department of Mathematics, University of California, San Diego, La Jolla, CA

Walter Murray, Michael A. Saunders; Department of EESOR, Stanford University, Stanford, CA

5.36.1 Introduction

This section describes the GAMS interface to the general-purpose NLP solver SNOPT, (Sparse Nonlinear Optimizer) which implements a sequential quadratic programming (SQP) method for solving constrained optimization problems with smooth nonlinear functions in the objective and constraints. The optimization problem is assumed to be stated in the form

$$\begin{aligned} \text{NP}: \quad & \text{minimize or maximize } f_0(x) \\ & f(x) \sim b_1 \\ \text{subject to} \quad & A_L x \sim b_2 \\ & l \leq x \leq u, \end{aligned} \tag{1}$$

where $x \in \Re^n$, $f_0(x)$ is a linear or nonlinear smooth objective function, l and u are constant lower and upper bounds, $f(x)$ is a set of nonlinear constraint functions, A_L is a sparse matrix, $\sim$ is a vector of relational operators ($\leq$, $\geq$ or $=$), and b_1 and b_2 are right-hand side constants. $f(x) \sim b_1$s are the nonlinear constraints of the model and $A_L x \sim b_2$ form the linear constraints.

The gradients of f_0 and f_i are automatically provided by GAMS, using its automatic differentiation engine.

The bounds may include special values `-INF` or `+INF` to indicate $l_j = -\infty$ or $u_j = +\infty$ for appropriate j. Free variables have both bounds infinite and fixed variables have $l_j = u_j$.

SNOPT uses a sequential quadratic programming (SQP) algorithm that obtains search directions from a sequence of quadratic programming subproblems. Each QP subproblem minimizes a quadratic model of a certain Lagrangian function subject to a linearization of the constraints. An augmented Lagrangian merit function is reduced along each search direction to ensure convergence from any starting point.

SNOPT is most efficient if only some of the variables enter nonlinearly, or if the number of active constraints (including simple bounds) is nearly as large as the number of variables. SNOPT requires relatively few evaluations of the problem functions.

5.36.1.1 Problem Types

If the nonlinear functions are absent, the problem is a *linear program* (LP) and SNOPT applies the primal simplex method [41] . Sparse basis factors are maintained by LUSOL [82] as in MINOS [141] .

If only the objective is nonlinear, the problem is *linearly constrained* (LC) and tends to solve more easily than the general case with nonlinear constraints (NC). Note that GAMS models have an objective variable instead of an objective function. The GAMS/SNOPT link will try to substitute out the objective variable and reformulate the model such that SNOPT will see a true objective function.

For both linearly and nonlinearly constrained problems SNOPT applies a sparse sequential quadratic programming (SQP) method [85] using limited-memory quasi-Newton approximations to the Hessian of the Lagrangian. The merit function for steplength control is an augmented Lagrangian, as in the dense SQP solver NPSOL [81] [84] .

In general, SNOPT requires less matrix computation than NPSOL and fewer evaluations of the functions than the nonlinear algorithms in MINOS [139] [140] . It is suitable for nonlinear problems with thousands of constraints and variables, and is most efficient if only some of the variables enter nonlinearly, or there are relatively few degrees of freedom at a solution (i.e., many constraints are active). However, unlike previous versions of SNOPT, there is no limit on the number of degrees of freedom.

5.36.1.2 Selecting the SNOPT Solver

If SNOPT is not specified as the default solver for the desired model type (e.g. NLP), then the following statement can be used in your GAMS model to select SNOPT:

```
option nlp=SNOPT;
```

The option statement should appear before the `solve` statement. To be complete, we mention that the solver can be also specified on the command line, as in:

```
> gams camcge nlp=snopt
```

This will override the global default, but if an algorithm option has been specified inside the model, then that specification takes precedence.

If the model contains non-smooth functions like abs (x), or $\max(x, y)$ you can try to get it solved by SNOPT using

```
option dnlp=SNOPT;
```

These models have discontinuous derivatives however, and SNOPT was not designed for solving such models. Discontinuities in the gradients can sometimes be tolerated if they appear away from an optimum.

5.36.2 Description of the method

Here we briefly describe the main features of the SQP algorithm used in SNOPT and introduce some terminology. The SQP algorithm is fully described by by Gill, Murray and Saunders [86] .

5.36.2.1 Objective function reconstruction

The first step GAMS/SNOPT performs is to try to reconstruct the objective function. In GAMS, optimization models minimize or maximize an objective variable. SNOPT however works with an objective function. One way of dealing with this is to add a dummy linear function with just the objective variable. Consider the following GAMS fragment:

```
obj.. z =e= sum(i, sqr[r(i)]);

model m /all/;
solve m using nlp minimizing z;
```

This can be cast in form (1) by saying minimize z subject to $z = \sum_i r_i^2$ and the other constraints in the model. Although simple, this approach is not always preferable. Especially when all constraints are linear it is important to minimize the nonlinear expression $\sum_i r_i^2$ directly. This can be achieved by a simple reformulation: z can be substituted out. The substitution mechanism carries out the formulation if all of the following conditions hold:

- the objective variable z is a free continuous variable (no bounds are defined on z),
- z appears linearly in the objective function,
- the objective function is formulated as an equality constraint,
- z is only present in the objective function and not in other constraints.

For many models it is very important that the nonlinear objective function be used by SNOPT. For instance the model `chem.gms` from the model library solves in 16 iterations. When we add the bound

```
energy.lo = 0;
```

on the objective variable `energy` and thus preventing it from being substituted out, SNOPT will not be able to find a feasible point for the given starting point.

This reformulation mechanism has been extended for substitutions along the diagonal. For example, the GAMS model

```
variables x,y,z;
equations e1,e2;
e1..z =e= y;
e2..y =e= sqr(1+x);
model m /all/;
option nlp=snopt;
solve m using nlp minimizing z;
```

will be reformulated as an *unconstrained* optimization problem

$$\min f(x) = (1+x)^2.$$

5.36.2.2 Constraints and slack variables

Problem (1) contains n variables in x. Let m be the number of components of $f(x)$ and $A_L x$ combined. The upper and lower bounds on those terms define the general constraints of the problem. SNOPT converts the general constraints to equalities by introducing a set of slack variables $s = (s_1, s_2, ..., s_m)^T$. For example, the linear constraint $5 \leq 2x_1 + 3x_2 \leq +\infty$ is replaced by $2x_1 + 3x_2 - s_1 = 0$ together with the bounded slack $5 \leq s_1 \leq +\infty$. Problem (1) can be written in the equivalent form

$$\begin{array}{ll} \text{minimize} & f_0(x) \\ \text{subject to} & \begin{pmatrix} f(x) \\ A_L x \end{pmatrix} - s = 0, \quad l \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u. \end{array}$$

where a maximization problem is cast into a minimization by multiplying the objective function by -1.

The linear and nonlinear general constraints become equalities of the form $f(x) - s_N = 0$ and $A_L x - s_L = 0$, where s_L and s_N are known as the *linear* and *nonlinear* slacks.

5.36.2.3 Major iterations

The basic structure of SNOPT's solution algorithm involves *major* and *minor* iterations. The major iterations generate a sequence of iterates (x_k) that satisfy the linear constraints and converge to a point that satisfies the first-order conditions for optimality. At each iterate $\{x_k\}$ a QP subproblem is used to generate a search direction towards the next iterate $\{x_{k+1}\}$. The constraints of the subproblem are formed from the linear constraints $A_L x - s_L = 0$ and the nonlinear constraint linearization

$$f(x_k) + f'(x_k)(x - x_k) - s_N = 0,$$

where $f'(x_k)$ denotes the *Jacobian*: a matrix whose rows are the first derivatives of $f(x)$ evaluated at x_k. The QP constraints therefore comprise the m linear constraints

$$\begin{array}{rrrl} f'(x_k)x & -s_N & = & -f(x_k) + f'(x_k)x_k, \\ A_L x & -s_L & = & 0, \end{array}$$

where x and s are bounded by l and u as before. If the $m \times n$ matrix A and m-vector b are defined as

$$A = \begin{pmatrix} f'(x_k) \\ A_L \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} -f(x_k) + f'(x_k)x_k \\ 0 \end{pmatrix},$$

then the QP subproblem can be written as

$$\begin{array}{lll} \text{QP}_k : & \min\limits_{x,s} & q(x, x_k) = g_k^T(x - x_k) + \dfrac{1}{2}(x - x_k)^T H_k (x - x_k) \\ & \text{subject to} & Ax - s = b, \quad l \leq \begin{pmatrix} x \\ s \end{pmatrix} \leq u, \end{array} \tag{2}$$

where $q(x, x_k)$ is a quadratic approximation to a modified Lagrangian function [85] . The matrix H_k is a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration. If some of the variables enter the Lagrangian linearly the Hessian will have some zero rows and columns. If the nonlinear variables appear first, then only the leading n_1 rows and columns of the Hessian need be approximated, where n_1 is the number of nonlinear variables.

5.36.2.4 Minor iterations

Solving the QP subproblem is itself an iterative procedure. Here, the iterations of the QP solver SQOPT [87] form the *minor* iterations of the SQP method.

SQOPT uses a reduced-Hessian active-set method implemented as a reduced-gradient method similar to that in MINOS [139] .

At each minor iteration, the constraints $Ax - s = b$ are partitioned into the form

$$Bx_B + Sx_S + Nx_N = b,$$

where the *basis matrix* B is square and nonsingular and the matrices S, N are the remaining columns of $(A\ -I)$. The vectors x_B, x_S, x_N are the associated basic, superbasic, and nonbasic components of the variables (x, s).

The term *active-set method* arises because the nonbasic variables x_N are temporarily frozen at their upper or lower bounds, and their bounds are considered to be active. Since the general constraints are satisfied also, the set of active constraints takes the form

$$\begin{pmatrix} B & S & N \\ & & I \end{pmatrix} \begin{pmatrix} x_B \\ x_S \\ x_N \end{pmatrix} = \begin{pmatrix} b \\ x_N \end{pmatrix},$$

where x_N represents the current values of the nonbasic variables. (In practice, nonbasic variables are sometimes frozen at values strictly between their bounds.) The reduced-gradient method chooses to move the superbasic variables in a direction that will improve the objective function. The basic variables "tag along" to keep $Ax - s = b$ satisfied, and the nonbasic variables remain unaltered until one of them is chosen to become superbasic.

At a nonoptimal feasible point (x, s) we seek a search direction p such that $(x, s) + p$ remains on the set of active constraints yet improves the QP objective. If the new point is to be feasible, we must have $Bp_B + Sp_S + Np_N = 0$ and $p_N = 0$. Once p_S is specified, p_B is uniquely determined from the system $Bp_B = -Sp_S$. It follows that the superbasic variables may be regarded as independent variables that are free to move in any desired direction. The number of superbasic variables (n_S say) therefore indicates the number of degrees of freedom remaining after the constraints have been satisfied. In broad terms, n_S is a measure of how nonlinear the problem is. In particular, n_S need not be more than one for linear problems.

5.36.2.5 The reduced Hessian and reduced gradient

The dependence of p on p_S may be expressed compactly as $p = Zp_S$, where Z is a matrix that spans the null space of the active constraints:

$$Z = P \begin{pmatrix} -B^{-1}S \\ I \\ 0 \end{pmatrix} \tag{3}$$

where P permutes the columns of $(A\ -I)$ into the order $(B\ S\ N)$. Minimizing $q(x, x_k)$ with respect to p_S now involves a quadratic function of p_S:

$$g^T Zp_S + \frac{1}{2} p_S^T Z^T HZp_S, \tag{4}$$

where g and H are expanded forms of g_k and H_k defined for all variables (x, s). This is a quadratic with Hessian $Z^T HZ$ (the reduced Hessian) and constant vector $Z^T g$ (the reduced gradient). If the reduced Hessian is nonsingular, p_S is computed from the system

$$Z^T HZp_S = -Z^T g. \tag{5}$$

The matrix Z is used only as an operator, i.e., it is not stored explicitly. Products of the form Zv or $Z^T g$ are obtained by solving with B or B^T . The package LUSOL [82] is used to maintain sparse LU factors of B as the BSN partition changes. From the definition of Z, we see that the reduced gradient can be computed from

$$B^T\pi = g_B, \;\; Z^T g = g_S - S^T\pi,$$

where π is an estimate of the *dual variables* associated with the m equality constraints $Ax - s = b$, and g_B is the basic part of g.

By analogy with the elements of $Z^T g$, we define a vector of reduced gradients (or reduced costs) for all variables in (x, s):

$$d = g - \begin{pmatrix} A^T \\ -I \end{pmatrix}\pi, \;\; \text{so that } d_S = Z^T g.$$

At a feasible point, the reduced gradients for the slacks s are the dual variables π.

The optimality conditions for subproblem QP $_k$ (2) may be written in terms of d. The current point is optimal if $d_j \geq 0$ for all nonbasic variables at their lower bounds, $d_j \leq 0$ for all nonbasic variables at their upper bounds, and $d_j = 0$ for all superbasic variables ($d_S = 0$). In practice, SNOPT requests an *approximate* QP solution $(\widehat{x}_k, \widehat{s}_k, \widehat{\pi}_k)$ with slightly relaxed conditions on d_j.

If $d_S = 0$, no improvement can be made with the current BSN partition, and a nonbasic variable with non-optimal reduced gradient is selected to be added to S. The iteration is then repeated with n_S increased by one. At all stages, if the step $(x, s) + p$ would cause a basic or superbasic variable to violate one of its bounds, a shorter step $(x, s) + \alpha p$ is taken, one of the variables is made nonbasic, and n_S is decreased by one.

The process of computing and testing reduced gradients d_N is known as *pricing* (a term introduced in the context of the simplex method for linear programming). Pricing the jth variable means computing $d_j = g_j - a_j^T\pi$, where a_j is the jth column of $(A - I)$. If there are significantly more variables than general constraints (i.e., $n \gg m$), pricing can be computationally expensive. In this case, a strategy known as *partial pricing* can be used to compute and test only a subset of d_N.

Solving the reduced Hessian system (5) is sometimes expensive. With the option `QPSolver Cholesky`, an upper-triangular matrix R is maintained satisfying $R^T R = Z^T H Z$. Normally, R is computed from $Z^T H Z$ at the start of phase 2 and is then updated as the BSN sets change. For efficiency the dimension of R should not be excessive (say, $n_S \leq 1000$). This is guaranteed if the number of nonlinear variables is "moderate". Other `QPSolver` options are available for problems with many degrees of freedom.

5.36.2.6 The merit function

After a QP subproblem has been solved, new estimates of the NLP solution are computed using a linesearch on the augmented Lagrangian merit function

$$\mathcal{M}(x, s, \pi) = f(x) - \pi^T\big(F(x) - s_N\big) + \frac{1}{2}\big(F(x) - s_N\big)^T D\big(F(x) - s_N\big), \tag{6}$$

where D is a diagonal matrix of penalty parameters. If (x_k, s_k, π_k) denotes the current solution estimate and $(\widehat{x}_k, \widehat{s}_k, \widehat{\pi}_k)$ denotes the optimal QP solution, the linesearch determines a step α_k ($0 < \alpha_k \leq 1$) such that the new point

$$\begin{pmatrix} x_{k+1} \\ s_{k+1} \\ \pi_{k+1} \end{pmatrix} = \begin{pmatrix} x_k \\ s_k \\ \pi_k \end{pmatrix} + \alpha_k \begin{pmatrix} \widehat{x}_k - x_k \\ \widehat{s}_k - s_k \\ \widehat{\pi}_k - \pi_k \end{pmatrix} \tag{7}$$

gives a *sufficient decrease* in the merit function. When necessary, the penalties in D are increased by the minimum-norm perturbation that ensures descent for $\mathcal{M}$ [84] . As in NPSOL, s_N is adjusted to minimize the merit function as a function of s prior to the solution of the QP subproblem. For more details, see [81] [54] .

5.36.2.7 Treatment of constraint infeasibilities

SNOPT makes explicit allowance for infeasible constraints. Infeasible *linear* constraints are detected first by solving a problem of the form

$$\begin{aligned} \text{FLP}: \qquad & \text{minimize} \quad e^T(v+w) \\ & \text{subject to} \quad \ell \le \begin{pmatrix} x \\ A_L x - v + w \end{pmatrix} \le u,\ v \ge 0,\ w \ge 0, \end{aligned}$$

where e is a vector of ones. This is equivalent to minimizing the sum of the general linear constraint violations subject to the simple bounds. (In the linear programming literature, the approach is often called *elastic programming*. We also describe it as minimizing the ℓ_1 norm of the infeasibilities.)

If the linear constraints are infeasible ($v \neq 0$ or $w \neq 0$), SNOPT terminates without computing the nonlinear functions.

If the linear constraints are feasible, all subsequent iterates satisfy the linear constraints. (Such a strategy allows linear constraints to be used to define a region in which the functions can be safely evaluated.) SNOPT proceeds to solve NP (1) as given, using search directions obtained from a sequence of quadratic programming subproblems (2).

If a QP subproblem proves to be infeasible or unbounded (or if the dual variables π for the nonlinear constraints become large), SNOPT enters "elastic" mode and solves the problem

$$\begin{aligned} \text{NP}(\gamma): \qquad & \text{minimize} \quad f_0(x) + \gamma e^T(v+w) \\ & \text{subject to} \quad \ell \le \begin{pmatrix} x \\ f(x) - v + w \\ A_L x \end{pmatrix} \le u,\ v \ge 0,\ w \ge 0, \end{aligned}$$

where γ is a nonnegative parameter (the *elastic weight*), and $f(x) + \gamma e^T(v+w)$ is called a *composite objective*. If γ is sufficiently large, this is equivalent to minimizing the sum of the nonlinear constraint violations subject to the linear constraints and bounds. A similar ℓ_1 formulation of NP is fundamental to the S ℓ_1QP algorithm of Fletcher [64] . See also Conn [38] .

The initial value of γ is controlled by the optional parameter elastic weight.

5.36.3 Starting points and advanced bases

A good starting point may be essential for solving nonlinear models. We show how such a starting point can be specified in a GAMS environment, and how SNOPT will use this information.

A related issue is the use of "restart" information in case a number of related models are solved in a row. Starting from an optimal point of a previous solve statement is in such situations often beneficial. In a GAMS environment this means reusing primal and dual information, which is stored in the `.L` and `.M` fields of variables and equations.

5.36.3.1 Starting points

To specify a starting point for SNOPT use the `.L` level values in GAMS. For example, to set all variables $x_{i,j} := 1$ use `x.l(i,j)=1;`. The default values for level values are zero.

Setting a good starting point can be crucial for getting good results. As an (artificial) example consider the problem where we want to find the smallest circle that contains a number of points (x_i, y_i):

$$\begin{array}{lll} \text{Example :} & \text{minimize} & r \\ & \text{subject to} & (x_i - a)^2 + (y_i - b)^2 \leq r^2,\ r \geq 0. \end{array}$$

This problem can be modeled in GAMS as follows.

```
set i points /p1*p10/;

parameters
    x(i)    x coordinates,
    y(i)    y coordinates;

* fill with random data
x(i) = uniform(1,10);
y(i) = uniform(1,10);

variables
    a       x coordinate of center of circle
    b       y coordinate of center of circle
    r       radius;

equations
    e(i)    points must be inside circle;

e(i).. sqr(x(i)-a) + sqr(y(i)-b) =l= sqr(r);

r.lo = 0;

model m /all/;
option nlp=snopt;
solve m using nlp minimizing r;
```

Without help, SNOPT will not be able to find an optimal solution. The problem will be declared infeasible. In this case, providing a good starting point is very easy. If we define

$$\begin{aligned} x_{\min} &= \min_i x_i, \\ y_{\min} &= \min_i y_i, \\ x_{\max} &= \max_i x_i, \\ y_{\max} &= \max_i y_i, \end{aligned}$$

then good estimates are

$$\begin{aligned} a &= (x_{\min} + x_{\max})/2, \\ b &= (y_{\min} + y_{\max})/2, \\ r &= \sqrt{(a - x_{\min})^2 + (b - y_{\min})^2}. \end{aligned}$$

Thus we include in our model:

```
parameters xmin,ymin,xmax,ymax;
xmin = smin(i, x(i));
ymin = smin(i, x(i));
xmax = smax(i, x(i));
ymax = smax(i, y(i));

* set starting point
a.l = (xmin+xmax)/2;
b.l = (ymin+ymax)/2;
r.l = sqrt( sqr(a.l-xmin) + sqr(b.l-ymin) );
```

and now the model solves very easily.

Level values can also be set implicitly as a result of assigning bounds, since GAMS will project variable levels onto their bounds as part of executing a solve statement. For example, when a variable is bounded away from zero by a statement like `Y.LO = 1;` and `Y` is at its default level of zero, the `SOLVE` statement will set the level `Y.L` to 1.

Note: another way to formulate the model would be to minimize r^2 instead of r. This allows SNOPT to solve the problem even with the default starting point.

5.36.3.2 Advanced basis

GAMS automatically passes on level values and basis information from one solve to the next. Thus, when we have two solve statements in a row, with just a few changes in between SNOPT will typically need very few iterations to find an optimal solution in the second solve. For instance, when we add a second solve to the `fawley.gms` model from the model library:

```
Model exxon /all/;
...
Solve exxon maximizing profit using lp;
Solve exxon maximizing profit using lp;
```

we observe the following iteration counts:

```
               S O L V E      S U M M A R Y

     MODEL   exxon               OBJECTIVE  profit
     TYPE    LP                  DIRECTION  MAXIMIZE
     SOLVER  SNOPT               FROM LINE  278

**** SOLVER STATUS     1 NORMAL COMPLETION
**** MODEL STATUS      1 OPTIMAL
**** OBJECTIVE VALUE             2899.2528

 RESOURCE USAGE, LIMIT          0.016      1000.000
 ITERATION COUNT, LIMIT        24         10000

.....

               S O L V E      S U M M A R Y

     MODEL   exxon               OBJECTIVE  profit
     TYPE    LP                  DIRECTION  MAXIMIZE
```

```
     SOLVER  SNOPT               FROM LINE  279

**** SOLVER STATUS     1 NORMAL COMPLETION
**** MODEL STATUS      1 OPTIMAL
**** OBJECTIVE VALUE              2899.2528

 RESOURCE USAGE, LIMIT          0.000      1000.000
 ITERATION COUNT, LIMIT         0         10000
```

The first `solve` takes 24 iterations, while the second `solve` needs exactly zero iterations.

Basis information is passed on using the marginals of the variables and equations. In general the rule is:

- `X.M = 0`: basic
- `X.M` $\neq 0$: nonbasic if level value is at bound, superbasic otherwise

A marginal value of `EPS` means that the numerical value of the marginal is zero, but that the status is nonbasic or superbasic. The user can specify a basis by assigning zero or nonzero values to the `.M` values. It is further noted that if too many `.M` values are zero, the basis is rejected. This happens for instance when two subsequent models are too different. This decision is made based on the value of the GAMS bratio option.

5.36.4 GAMS Options

The usual GAMS options (e.g. reslim, sysout) can be used to control GAMS/SNOPT. For more details, see section Controlling a Solver via GAMS Options. We highlight some of the details of this usage below for cases of special interest.

iterlim

Sets the *minor* iteration limit. SNOPT will stop as soon as the number of *minor iterations* exceeds the iteration limit, in which case the current solution will be reported.

domlim

Sets the domain error limit. Domain errors are evaluation errors in the nonlinear functions. An example of a domain error is trying to evaluate $\sqrt{x}$ for $x < 0$. Other examples include taking logs of negative numbers, and evaluating the real power x^y for $x < \varepsilon$ (x^y is evaluated as $\exp(y \log x)$). When such an error occurs the count of domain errors is incremented: SNOPT will stop if this count exceeds the limit. If the limit has not been reached, reasonable estimates for the function (and derivatives, if requested) are returned and SNOPT continues. For example, in the case of $\sqrt{x}, x < 0$ a zero is passed back for the function value and a large value for the derivative. In many cases SNOPT will be able to recover from these domain errors, especially when they happen at some intermediate point. Nevertheless it is best to add appropriate bounds or linear constraints to ensure that these domain errors don't occur. For example, when an expression $\log(x)$ is present in the model, add a statement like `x.lo = 0.001;`.

bratio

Ratio used in basis acceptance test. When a previous solution or solution estimate exists, GAMS automatically passes this solution to SNOPT so that it can reconstruct an advanced basis. When too many new (i.e. uninitialized with level and/or marginal values) variables or constraints enter the model, it may be better not to use existing basis information, but to instead *crash* a new basis. The `bratio` determines how quickly an existing basis is discarded. A value of 1.0 will discard any basis, while a value of 0.0 will retain any basis.

workfactor

By default, GAMS/SNOPT computes an estimate of the amount of workspace needed by SNOPT, and passes this workspace on to SNOPT for use in solving the model. This estimate is based on the model statistics: number of (nonlinear) equations, number of (nonlinear) variables, number of (nonlinear) nonzeroes, etc. In most cases this is sufficient to solve the model. In some rare cases SNOPT may need more memory, and the user can provide this by specifying a value of workfactor greater than 1. The computed memory estimate is multiplied by the workfactor to determine the amount of workspace made available to SNOPT for the solve.

5.36.5 SNOPT Options

The performance of GAMS/SNOPT is controlled by a number of parameters or "options." Each option has a default value that should be appropriate for most problems. For special situations it is possible to specify non-default values for some or all of the options via the SNOPT option file. While the content of an option file is solver-specific, the details of how to create an option file and instruct the solver to use it are not. This topic is covered in section The Solver Options File.

Note that the option file is not case sensitive. The tables below contain summary information about the SNOPT options, default values, and links to more detailed explanations.

5.36.5.1 Printing

Option	Description	Default
major print level	Amount of information printed during optimization (listing file)	1
minor print level	Amount of information printed during optimization (listing file)	1
print frequency	Number of iterations between each log line (listing file)	100
solution	Prints SNOPT solution (listing file)	NO
summary frequency	Number of iterations between each log line (log file)	100
suppress parameters	Suppress printing of parameters (listing file)	
system information	Provides additional information on the progress of the iterations (listing file)	NO
timing level	Amount of timing information (listing file)	3

5.36.5.2 Problem specification

Option	Description	Default
feasible point	Ignore objective function and find a feasible point	
infinite bound	Bounds larger than this number are considered Infinity	1.0e20

5.36.5.3 Convergence tolerances

Option	Description	Default
major feasibility tolerance	Feasibility tolerance for nonlinear constraints	1.0e-6
major optimality tolerance	Specifies the final accuracy of the dual variables	1.0e-6
minor feasibility tolerance	Feasibility tolerance for all variables and linear constraints	1.0e-6

5.36.5.4 Derivative checking

Option	Description	Default
verify level	Finite-difference checks on the derivatives	-1

5.36.5.5 Scaling

Option	Description	Default
scale option	Controls problem scaling	auto
scale print	Print scaling factors (listing file)	
scale tolerance	Scale tolerance	0.9

5.36.5.6 Other tolerances

Option	Description	Default
crash tolerance	Allow crash procedure to ignore small elements in eligible columns	0.1
linesearch tolerance	Controls accuracy of steplength selected	0.9
pivot tolerance	Used to keep the basis non-singular	3.67e-11

5.36.5.7 QP subproblems

Option	Description	Default
crash option	Controls the basis crash algorithm	auto: 0 or 3
elastic weight	Control for elastic mode	1.0e4
iterations limit	Minor iteration limit	GAMS iterlim
partial price	Number of segments in partial pricing strategy	auto
qpsolver	Controls method used for QP subproblems	Cholesky

5.36.5.8 SQP method

Option	Description	Default
central difference interval	Not applicable: GAMS provides analytic derivatives	6.0e-6

Option	Description	Default
cold start	Ignore advanced basis and use CRASH procedure	
derivative linesearch	Linesearch method (safeguarded cubic interpolation) with use of derivatives	
difference interval	Not applicable: GAMS provides analytic derivatives	1.5e-8
function precision	Relative accuracy with which the nonlinear functions are evaluated	3.00e-13
major iterations limit	Max number of major iterations	GAMS iterlim
major step limit	Limits the change in x during a linesearch	2.0
minor iterations limit	Max number of minor iterations between linearizations of nonlinear constraints	500
new superbasics limit	Limit on new superbasics when a QP subproblem is solved	99
nonderivative linesearch	Linesearch method (safeguarded quadratic interpolation) without use of derivatives	
penalty parameter	Initial penalty parameter	0
proximal point method	Controls promimal point method used for solving linear constraints	1
reduced hessian dimension	Size of Hessian matrix	auto
superbasics limit	Maximum number of superbasics	1
unbounded objective value	Determines when a problem is called unbounded	1.0e15
unbounded step size	Determines when a problem is called unbounded	1.0e18
violation limit	Limit on maximum constraint violation after the linesearch	10
warm start	Use advanced basis provided by GAMS	

5.36.5.9 Hessian approximation

Option	Description	Default
hessian frequency	How often the full Hessian is reset to the identity matrix	999999
hessian full memory	Approximate Hessian is treated as a dense matrix	
hessian limited memory	Limited-memory procedure is used to update a diagonal Hessian approximation	
hessian updates	How often the limited memory Hessian is reset	10

5.36.5.10 Frequencies

Option	Description	Default
check frequency	Controls frequency of linear constraint satisfaction test	60
expand frequency	Setting for anti-cycling mechanism	10000
factorization frequency	Number of iterations between basis factorizations	auto: 100 or 50

5.36.5.11 LUSOL options

Option	Description	Default
LU complete pivoting	LUSOL pivoting strategy	
LU density tolerance	Controls when to move to a dense factorization	0.6
LU factor tolerance	Trade-off between stability and sparsity in basis factorization	auto
LU partial pivoting	LUSOL pivoting strategy	yes
LU rook pivoting	LUSOL pivoting strategy	
LU singularity tolerance	Protection against ill-conditioned basis matrices	3.2e-11
LU update tolerance	Trade-off between stability and sparsity in basis factorization	auto

central difference interval *(real)*: Not applicable: GAMS provides analytic derivatives ↩

Default: `6.0e-6`

check frequency *(integer)*: Controls frequency of linear constraint satisfaction test ↩

Every i^{th} minor iteration after the most recent basis factorization, a numerical test is made to see if the current solution x satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form $Ax - s = b$, where s is the set of slack variables. To perform the numerical test, the residual vector $r = b - Ax + s$ is computed. If the largest component of r is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

`Check frequency 1` is useful for debugging purposes, but otherwise this option should not be needed.

Range: {1, ..., ∞}

Default: `60`

cold start *(no value)*: Ignore advanced basis and use CRASH procedure ↩

Requests that the CRASH procedure be used to choose an initial basis. This option takes precedence over the GAMS bratio option.

crash option *(integer)*: Controls the basis crash algorithm ↩

Except on restarts, a CRASH procedure is used to select an initial basis from certain rows and columns of the constraint matrix ($A \quad -I$). The `Crash option` i determines which rows and columns of A are eligible initially, and how many times CRASH is called. Columns of $-I$ are used to pad the basis where necessary.

If $i \geq 1$, certain slacks on inequality rows are selected for the basis first. (If $i \geq 2$, numerical values are used to exclude slacks that are close to a bound.) CRASH then makes several passes through the columns of A, searching for a basis matrix that is essentially triangular. A column is assigned to "pivot" on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis.) For the remaining unassigned rows, slack variables are inserted to complete the basis.

By default, `crash option 3` is used for linearly constrained problems and `crash option 0` for problems with nonlinear constraints.

Default: `auto: 0 or 3`

value	meaning
0	Initial basis will be a slack basis. The initial basis contains only slack variables: $B = I$.
1	One phase CRASH. CRASH is called once, looking for a triangular basis in all rows and columns of the matrix A.
2	Two phase CRASH. CRASH is called twice (if there are nonlinear constraints). The first call looks for a triangular basis in linear rows, and the iteration proceeds with simplex iterations until the linear constraints are satisfied. The Jacobian is then evaluated for the first major iteration and CRASH is called again to find a triangular basis in the nonlinear rows (retaining the current basis for linear rows).
3	Three phase CRASH. CRASH is called up to three times (if there are nonlinear constraints). The first two calls treat *linear equalities* and *linear inequalities* separately. As before, the last call treats nonlinear rows before the first major iteration.

crash tolerance *(real)*: Allow crash procedure to ignore small elements in eligible columns ↩

The `Crash tolerance` r allows the starting procedure CRASH to ignore certain small nonzeros in each column of A. If $a_{\max}$ is the largest element in column j, other nonzeros a_{ij} in the column are ignored if $|a_{ij}| \leq a_{\max} \times r$. (To be meaningful, r should be in the range $0 \leq r < 1$.)

When $r > 0.0$, the basis obtained by CRASH may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of A and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems.

For example, suppose the first m columns of A are the matrix shown under LU_factor_tolerance, i.e. a tridiagonal matrix with entries $-1, 2, -1$. To help CRASH choose all m columns for the initial basis, we would specify `Crash tolerance` r for some value of $r > 0.5$.

Range: [`0`, `1`]

Default: `0.1`

derivative linesearch *(no value)*: Linesearch method (safeguarded cubic interpolation) with use of derivatives ↩

At each major iteration a linesearch is used to improve the merit function. A `Derivative linesearch` uses safeguarded cubic interpolation and requires both function and gradient values to compute estimates of the step size α_k.

difference interval *(real)*: Not applicable: GAMS provides analytic derivatives ↩

This alters the interval h_1 that is used to estimate gradients by forward differences in the following circumstances:

- In the initial ("cheap") phase of verifying the problem derivatives.
- For verifying the problem derivatives.
- For estimating missing derivatives.

In all cases, a derivative with respect to x_j is estimated by perturbing that component of x to the value $x_j + h_1(1 + |x_j|)$, and then evaluating $f_0(x)$ or $f(x)$ at the perturbed point. The resulting gradient estimates should be accurate to $O(h_1)$ unless the functions are badly scaled. Judicious alteration of h_1 may sometimes lead to greater accuracy. This option has limited use in a GAMS environment as GAMS provides analytical gradients.

Default: `1.5e-8`

elastic weight *(real)*: Control for elastic mode ↩

The *elastic_weight* ω determines the initial weight γ associated with problem NP(γ).

At any given major iteration k, elastic mode is started if the QP subproblem is infeasible or if the QP dual variables are larger in magnitude than $\omega(1 + \|g(x_k)\|_2)$, where g is the objective gradient. In either case, the QP is re-solved in elastic mode with $\gamma = \omega(1 + \|g(x_k)\|_2)$.

Thereafter, γ is increased (subject to a maximum allowable value) at any point that is optimal for problem NP(γ), but not feasible for NP. After the rth such increase, $\gamma = \omega 10^r(1+\|g(x_{k1})\|_2)$, where x_{k1} is the iterate at which γ was first needed.

Default: `1.0e4`

expand frequency *(integer)*: Setting for anti-cycling mechanism ↩

This option is part of the EXPAND anti-cycling procedure [83] designed to make progress even on highly degenerate problems.

For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose that the minor feasibility tolerance is δ and the expand frequency is k. Over a period of k iterations, the tolerance actually used by SNOPT increases from 0.5δ to δ (in steps of $0.5\delta/k$).

For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced.

At least every k iterations, a resetting procedure eliminates any infeasible nonbasic variables. Increasing k helps to reduce the number of these slightly infeasible nonbasic variables. However, it also diminishes the freedom to choose a large pivot element (see pivot tolerance).

Range: {1, ..., ∞}

Default: `10000`

factorization frequency *(integer)*: Number of iterations between basis factorizations ↩

At most k basis changes will occur between factorizations of the basis matrix.

- With linear programs, the basis factors are usually updated every iteration. The default k is reasonable for typical problems. Smaller values (say $k = 75$ or $k = 50$) may be more efficient on problems that are rather dense or poorly scaled.
- When the problem is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be refactorized before the limit of k updates is reached.

By default, the frequency is set to 100 for linear models and 50 otherwise.

Range: {1, ..., ∞}

Default: `auto: 100 or 50`

feasible point *(no value)*: Ignore objective function and find a feasible point ↩

The keyword `feasible point` means "Ignore the objective function" while finding a feasible point for the linear and nonlinear constraints. It can be used to check that the nonlinear constraints are feasible.

Default: turned off.

function precision *(real)*: Relative accuracy with which the nonlinear functions are evaluated ↩

The *relative function precision* ϵ_R is intended to be a measure of the relative accuracy with which the nonlinear functions can be computed. For example, if $f(x)$ is computed as 1000.56789 for some relevant x and if the first 6 significant digits are known to be correct, the appropriate value for ϵ_R would be `1.0e-6`.

(Ideally the functions $f_0(x)$ or $f_i(x)$ should have magnitude of order 1. If all functions are substantially less than 1 in magnitude, ϵ_R should be the absolute precision. For example, if $f(x) =$ `1.23456789e-4` at some point and if the first 6 significant digits are known to be correct, the appropriate value for ϵ_R would be `1.0e-10`.)

- The default value of ϵ_R is appropriate for simple analytic functions.
- In some cases the function values will be the result of extensive computation, possibly involving an iterative procedure that can provide rather few digits of precision at reasonable cost. Specifying an appropriate `Function precision` may lead to savings, by allowing the linesearch procedure to terminate when the difference between function values along the search direction becomes as small as the absolute error in the values.

Default: `3.00e-13`

hessian frequency *(integer)*: How often the full Hessian is reset to the identity matrix ↩

This option sets the frequency i for resetting the full memory Hessian. For example, if hessian full memory is selected and i BFGS updates have already been carried out, the Hessian approximation is reset to the identity matrix. (For certain problems, occasional resets may improve convergence, but in general they should not be necessary.)

`Hessian Full Memory` and `Hessian Frequency = 20` have a similar effect to `Hessian Limited Memory` and `Hessian Updates = 20`, except that the latter retains the current diagonal during resets.

Default: `999999`

hessian full memory *(no value)*: Approximate Hessian is treated as a dense matrix ↩

This option selects the full storage method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

If `Hessian Full Memory` is specified, the approximate Hessian is treated as a dense matrix and the BFGS updates are applied explicitly. This option is most efficient when the number of nonlinear variables n_1 is not too large. In this case, the storage requirement is fixed and one can expect Q-superlinear convergence to the solution.

By default, this storage method is chosen when the number of nonlinear variables $n_1 \leq 75$.

hessian limited memory *(no value)*: Limited-memory procedure is used to update a diagonal Hessian approximation ↩

This option selects the limited memory storage method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

`Hessian Limited Memory` should be used on problems where the number of nonlinear variables n_1 is large. In this case a limited-memory procedure is used to update a diagonal Hessian approximation H_r a limited number of times. (Updates are accumulated as a list of vector pairs. They are discarded at regular intervals after H_r has been reset to their diagonal.)

By default, this storage method is chosen when the number of nonlinear variables $n_1 > 75$.

hessian updates *(integer)*: How often the limited memory Hessian is reset ↩

If hessian limited memory is selected and i BFGS updates have already been carried out, all but the diagonal elements of the accumulated updates are discarded and the updating process starts again.

Broadly speaking, the more updates stored, the better the quality of the approximate Hessian. However, the cost of each QP iteration also increases with the number of updates. The default value is likely to give a robust algorithm without significant expense, but faster convergence can sometimes be obtained with significantly fewer updates (e.g., $i = 5$).

Default: `10`

infinite bound *(real)*: Bounds larger than this number are considered Infinity ↩

If $r > 0$, r defines the "infinite" bound `infBnd` in the definition of the problem constraints. Any upper bound greater than or equal to `infBnd` will be regarded as plus infinity (and similarly for a lower bound less than or equal to `-infBnd`). If $r \leq 0$, the default value is used.

Default: `1.0e20`

iterations limit *(integer)*: Minor iteration limit ↩

The maximum number of minor iterations allowed (i.e., iterations of the simplex method or the QP algorithm), summed over all major iterations. This option, if set, overrides the GAMS iterlim specification.

Default: `GAMS iterlim`

linesearch tolerance *(real)*: Controls accuracy of steplength selected ↩

This controls the accuracy with which a steplength will be located along the direction of search at each iteration. At the start of each linesearch a target directional derivative for the merit function is identified. The `linesearch tolerance` t determines the accuracy to which this target value is approximated.

- Larger values like $t = 0.9$ request just moderate accuracy in the linesearch.
- If the nonlinear functions are cheap to evaluate, as is usually the case for GAMS models, a more accurate search may be appropriate; try $t = 0.1$, 0.01 or 0.001. The number of major iterations might decrease.
- If the nonlinear functions are expensive to evaluate, a less accurate search may be appropriate. In the case of running under GAMS where all gradients are known, try $t = 0.99$. The number of major iterations might increase, but the total number of function evaluations may decrease enough to compensate.

Range: [0, 1]

Default: 0.9

LU complete pivoting *(no value)*: LUSOL pivoting strategy ↩

See LU_partial_pivoting.

LU density tolerance *(real)*: Controls when to move to a dense factorization ↩

The density tolerance r_1 is used during LUSOL's basis factorization $B = LU$. Columns of L and rows of U are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds r_1, the Markowitz strategy for choosing pivots is terminated and the remaining matrix is factored by a dense LU procedure. Raising the density tolerance towards 1.0 may give slightly sparser LU factors, with a slight increase in factorization time.

See also LU_singularity_tolerance.

Range: [0, 1]

Default: 0.6

LU factor tolerance *(real)*: Trade-off between stability and sparsity in basis factorization ↩

`LU factor tolerance` r_1

`LU update tolerance` r_2

These tolerances affect the stability and sparsity of the basis factorization $B = LU$ during refactorization and updating, respectively. They must satisfy $r_1, r_2 \geq 1.0$. The matrix L is a product of matrices of the form

$$\begin{pmatrix} 1 & \\ \mu & 1 \end{pmatrix},$$

where the multipliers μ satisfy $|\mu| \leq r_i$. Smaller values of r_i favor stability, while larger values favor sparsity.

- For large and relatively dense problems, smaller values of r_1 (e.g. $r_1 = 3.0$) may give a useful improvement in stability without impairing sparsity to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to reduce r_1 and/or r_2 in order to achieve stability. For example, if the columns of A include a submatrix of the form

$$\begin{pmatrix} 2 & -1 & & & & \\ -1 & 2 & -1 & & & \\ & -1 & 2 & -1 & & \\ & & \ddots & \ddots & \ddots & \\ & & & -1 & 2 & -1 \\ & & & & -1 & 2 \end{pmatrix},$$

  both r_1 and r_2 should be in the range $1.0 \leq r_i < 2.0$.

For linear models, the defaults are $r_1 = 100$ and $r_2 = 10$, while for nonlinear models both tolerances default to 3.99.

See also LU_update_tolerance.

Range: [1, ∞]

Default: auto

LU partial pivoting *(no value)*: LUSOL pivoting strategy ↩

The LUSOL factorization implements a Markowitz-type search for pivots that locally minimizes fill-in subject to a threshold pivoting stability criterion. The `rook pivoting` and `complete pivoting` options are more expensive than `partial pivoting` but are more stable and better at revealing rank, as long as the LU_factor_tolerance is not too large (say $r_1 < 2.0$).

When numerical difficulties are encountered, SNOPT automatically reduces the LU tolerances toward 1.0 and switches (if necessary) to rook or complete pivoting before reverting to the default or specified options at the next refactorization. (With sysout on and system information enabled, relevant messages are output to the listing file.)

Default: `yes`

LU rook pivoting *(no value)*: LUSOL pivoting strategy ↩

See LU_partial_pivoting.

LU singularity tolerance *(real)*: Protection against ill-conditioned basis matrices ↩

The singularity tolerance r_2 helps guard against ill-conditioned basis matrices. After B is refactorized, the diagonal elements of U are tested as follows: if $|U_{jj}| \leq r_2$ or $|U_{jj}| < r_2 \max_i |U_{ij}|$, the jth column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart.)

See also LU_density_tolerance.

Default: `3.2e-11`

LU update tolerance *(real)*: Trade-off between stability and sparsity in basis factorization ↩

See LU_factor_tolerance for details.

Range: [1, ∞]

Default: `auto`

major feasibility tolerance *(real)*: Feasibility tolerance for nonlinear constraints ↩

This tolerance ϵ_r specifies how accurately the nonlinear constraints should be satisfied. The default value of `1.0e-6` is appropriate when the constraints are expected to have at least that accuracy.

Let `rowerr` be the maximum nonlinear constraint violation, normalized by the size of the solution. It is required to satisfy

$$\text{rowerr} = \max_i \ \text{viol}_i / \|x\| \leq \ \epsilon_r, \tag{8}$$

where viol_i is the violation of the ith nonlinear constraint.

In the GAMS/SNOPT iteration log, `rowerr` appears as the quantity labeled `"Feasibl"`. If some of the problem functions are known to be of low accuracy, a larger `Major feasibility tolerance` may be appropriate.

Default: `1.0e-6`

major iterations limit *(integer)*: Max number of major iterations ↩

This is the maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the constraints. By default it is set to `max(1000,m)`.

Default: `GAMS iterlim`

major optimality tolerance *(real)*: Specifies the final accuracy of the dual variables ↩

This tolerance ϵ_d specifies the final accuracy of the dual variables. On successful termination, SNOPT will have computed a solution (x, s, π) such that

$$\text{maxComp} = \max_j \ \text{Comp}_j/\|\pi\| \ \leq \ \epsilon_d, \tag{9}$$

where $Comp_j$ is an estimate of the complementarity slackness for variable j. The values $Comp_j$ are computed from the final QP solution using the reduced gradients $d_j = g_j - \pi^T a_j$ (where g_j is the jth component of the objective gradient, a_j is the associated column of the constraint matrix $(A \quad -I)$ and π is the set of QP dual variables):

$$\text{Comp}_j = \begin{cases} d_j \min\{x_j - l_j, 1\} & \text{if } d_j \geq 0; \\ -d_j \min\{u_j - x_j, 1\} & \text{if } d_j < 0. \end{cases}$$

In the GAMS/SNOPT iteration log, *maxComp* appears as the quantity labeled `"Optimal"`.

Default: `1.0e-6`

major print level *(integer)*: Amount of information printed during optimization (listing file) ↩

This controls the amount of output to the GAMS listing file at each major iteration. This output is only visible if the sysout option is turned on. `Major print level 1` gives normal output for linear and nonlinear problems, and `Major print level 11` gives additional details of the Jacobian factorization that commences each major iteration. In general, the value specified may be thought of as a binary number of the form

```
Major print level   JFDXbs
```

where each letter stands for a digit that is either `0` or `1` as follows:

- `s` single line that gives a summary of each major iteration. (This entry in `JFDXbs` is not strictly binary since the summary line is printed whenever JFDXbs ≥ 1).
- `b` BASIS statistics, i.e., information relating to the basis matrix whenever it is refactorized. (This output is always provided if JFDXbs ≥ 10).
- `X` x_k, the nonlinear variables involved in the objective function or the constraints.
- `D` π_k, the dual variables for the nonlinear constraints.
- `F` $F(x_k)$, the values of the nonlinear constraint functions.
- `J` $J(x_k)$, the Jacobian.

To obtain output of any items `JFDXbs`, set the corresponding digit to `1`, otherwise to `0`.

If `J=1`, the Jacobian will be output column-wise at the start of each major iteration. Column j will be preceded by the value of the corresponding variable x_j and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if `J=1`, there is no reason to specify `X=1` unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

```
3  1.250000D+01 BS      1  1.00000E+00      4  2.00000E+00
```

which would mean that x_3 is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4.

`Major print level 0` suppresses most output, except for error messages.

Default: `1`

major step limit *(real)*: Limits the change in x during a linesearch ↩

This parameter r limits the change in x during a linesearch. It applies to all nonlinear problems, once a "feasible solution" or "feasible subproblem" has been found.

1. A linesearch determines a step α over the range $0 < \alpha \leq \beta$, where β is 1 if there are nonlinear constraints, or the step to the nearest upper or lower bound on x if all the constraints are linear. Normally, the first steplength tried is $\alpha_1 = \min(1, \beta)$.
2. In some cases, such as $f(x) = ae^{bx}$ or $f(x) = ax^b$, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to define a limit $\bar{\beta} = r(1 + \|x\|)/\|p\|$ (where p is the search direction), and the first evaluation of $f(x)$ is at the potentially smaller steplength $\alpha_1 = \min(1, \bar{\beta}, \beta)$.
3. Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at meaningless points. The `Major step limit` provides an additional safeguard. The default value $r = 2.0$ should not affect progress on well behaved problems, but setting $r = 0.1$ or 0.01 may be helpful when rapidly varying functions are present. A "good" starting point may be required. An important application is to the class of nonlinear least-squares problems.
4. In cases where several local optima exist, specifying a small value for r may help locate an optimum near the starting point.

Default: `2.0`

minor feasibility tolerance *(real)*: Feasibility tolerance for all variables and linear constraints ↩

SNOPT tries to ensure that all variables eventually satisfy their upper and lower bounds to within this tolerance t. This includes slack variables, so general linear constraints should also be satisfied to within t.

Feasibility with respect to nonlinear constraints is judged by the major feasibility tolerance.

- If the bounds and linear constraints cannot be satisfied to within t, the problem is declared `infeasible`. Let `sInf` be the corresponding sum of infeasibilities. If `sInf` is quite small, it may be appropriate to raise t by a factor of 10 or 100. Otherwise, some error in the data should be suspected.
- Nonlinear functions will be evaluated only at points that satisfy the bounds and linear constraints. If there are regions where a function is undefined, every attempt should be made to eliminate these regions from the problem. For example, if $f(x) = \sqrt{x_1} + \log x_2$, it is essential to place lower bounds on both variables. If $t = 1.0e-6$, the bounds $x_1 \geq 10^{-5}$ and $x_2 \geq 10^{-4}$ might be appropriate. (The log singularity is more serious. In general, keep x as far away from singularities as possible.)
- If the model is scaled (see scale option), feasibility is defined in terms of the `scaled` problem.
- In reality, SNOPT uses t as a feasibility tolerance for satisfying the bounds on x and s in each QP subproblem. If the sum of infeasibilities cannot be reduced to zero, the QP subproblem is declared infeasible. SNOPT is then in *elastic mode* thereafter (with only the linearized nonlinear constraints defined to be elastic). See elastic weight for details.

Default: `1.0e-6`

minor iterations limit *(integer)*: Max number of minor iterations between linearizations of nonlinear constraints ↩

Minor iterations limit k. If the number of minor iterations for the optimality phase of the QP subproblem exceeds k, then all nonbasic QP variables that have not yet moved are frozen at their current values and the reduced QP is solved to optimality. Note that more than k minor iterations may be necessary to solve the reduced QP to optimality. These extra iterations are necessary to ensure that the terminated point gives a suitable direction for the linesearch. In the major iteration log, a `t` at the end of a line indicates that the corresponding QP was artificially terminated using the limit k. Note that iterations limit defines an independent absolute limit on the total number of minor iterations (summed over all QP subproblems).

Default: `500`

minor print level *(integer)*: Amount of information printed during optimization (listing file) ↩

This controls the amount of output to the GAMS listing file during solution of the QP subproblems. It is only useful if the GAMS sysout option is turned on. The value of k has the following effect:

- 0 No minor iteration output except error messages.
- ≥ 1 A single line of output each minor iteration (controlled by print frequency).
- ≥ 10 Basis factorization statistics generated during the periodic refactorization of the basis (see factorization frequency). Statistics for the *first factorization* of each major iteration are controlled by the major print level.

Default: `1`

new superbasics limit *(integer)*: Limit on new superbasics when a QP subproblem is solved ↩

This option causes early termination of the QP subproblems if the number of free variables has increased significantly since the first feasible point. If the number of new superbasics is greater than `new superbasics limit` the nonbasic variables that have not yet moved are frozen and the resulting smaller QP is solved to optimality. In the major iteration log, a `"T"` at the end of a line indicates that the QP was terminated early in this way.

Default: `99`

nonderivative linesearch *(no value)*: Linesearch method (safeguarded quadratic interpolation) without use of derivatives ↩

A `nonderivative linesearch` can be slightly less robust on difficult problems, and it is recommended that the default derivative linesearch be used if the functions and derivatives can be computed at approximately the same cost. If the gradients are very expensive relative to the functions, a nonderivative linesearch may give a significant decrease in computation time. In a GAMS environment derivative linesearch (the default) is more appropriate.

partial price *(integer)*: Number of segments in partial pricing strategy ↩

This parameter sets the number of segments k using in partial pricing and is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each "pricing" operation (i.e. when a nonbasic variable is selected to become superbasic).

- When $k = 1$, all columns of the constraint matrix $(A \quad -I)$ are searched.

- Otherwise, A and I are partitioned to give k roughly equal segments A_j, I_j ($j = 1$ to k). If the previous pricing search was successful on A_j, I_j, the next search begins on the segments A_{j+1}, I_{j+1}. (All subscripts here are modulo k.)
- If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. If nothing is found, the search continues on the next segments A_{j+2}, I_{j+2}, and so on.
- `Partial price` t (or $t/2$ or $t/3$) may be appropriate for time-stage models having t time periods.

The default is `10` for linear models and `1` for nonlinear models.

Range: {`1`, ..., ∞}

Default: `auto`

penalty parameter *(real)*: Initial penalty parameter ↩

After a QP subproblem has been solved, new estimates of the NLP solution are computed using a linesearch on the augmented Lagrangian merit function. This functions contains penalty parameters, which may be increased to ensure descent.

Default: `0`

pivot tolerance *(real)*: Used to keep the basis non-singular ↩
