GAMS – Documentation

Contents

Chapter 1

GAMS Documentation Center

The GAMS Documentation Center provides you with the technical information on getting started, using and maintaining our GAMS (General Algebraic Modeling System) products.

- Preface
- Release Notes - 46.4.1 Maintenance release (April 16, 2024)
- User's Guide
  - Installation and Licensing - Guides on installing GAMS for various platforms and using a GAMS license
  - Tutorials and Examples - Step-by-step guides including a number of examples
  - GAMS Language and Environment - Guide through components of GAMS Language and the environment for executing a GAMS model
- Solver Manuals - Manuals of solvers available in the distribution
- Tools Manuals - Manuals of tools available in the distribution
- Application Programming Interfaces - Manuals of Application Programming Interfaces
- Appendix - Glossary, bibliography, and list of third-party codes

1.1 Model Libraries

From the early stages of the development of GAMS we have collected models to be used in libraries of examples. Many of these are standard textbook examples and can be used in classes on problem formulation or to illustrate points about GAMS. Others are models that have been used in policy or sector analysis and are interesting for both the methods and the data they use. These model libraries are included with all GAMS systems and are also available online.

The following model libraries are available:

- **GAMS Model Library** - includes GAMS models representing interesting and sometimes classic problems, ranged from production and shipment by firms, investment planning, cropping patterns in agriculture, operation of oil refineries and petrochemical plants, macroeconomics stabilization, applied general equilibrium, international trade in aluminum and in copper, water distribution networks, and many more.

- **GAMS Test Library** - includes GAMS models developed for testing and quality control, both for the GAMS base module and the many solvers distributed with the GAMS system.
- **GAMS Data Library** - includes GAMS models demonstrating various utilities to interface GAMS with other tools and applications such as spreadsheets and database interface.
- **GAMS EMP Library** - includes GAMS Extended Mathematical Programming (EMP) models that illustrate and test the capabilities of GAMS/EMP.
- **GAMS API Library** - includes GAMS Models used as scripts to compile and execute application programs in various programming languages interfacing to GAMS.
- **FIN Library** - includes GAMS practical financial optimization models described in the book Practical Financial Optimization: Decision Making for Financial Engineers by Consiglio, Nielsen and Zenios,
- **NOA Library** - includes GAMS nonlinear optimization applications models based on the book Nonlinear Optimization Applications Using the GAMS Technology by Neculai Andrei.
- **PSOPT Library** - includes GAMS optimization models based on the book Power System Optimization Modelling in GAMS by by Alireza Soroudi.

See Accessing Model Libraries on how to access a GAMS model from the model libraries.

For large parts of the documentation, references to models from the model libraries are enclosed in square parenthesis (for example, [**TRNSPORT**]).

1.2 Further Help

If you have a further question which is not answered by the documentation above, you can get further help from our GAMS-FAQ which contains materials collected from various support activities or post your question to GAMS World Forum. You can also sign up to our Newsletters to get the latest information from GAMS. There is also GAMS Lessons, a YouTube Video Channel providing you with some tutorials on how to use our system.

There are a number of contributed documentations that have been contributed by GAMS users as well as presentations, books, posters, and advertisements contributed by people working with GAMS.

You can also visit our upcoming courses and workshops.

If you experience a problem using GAMS please contact our Technical Support. If you have a confidential model that you cannot share as is, please read the information on conversion of models before submitting your models to our technical support.

Chapter 2

Preface

The GAMS documentation has changed considerably since it was first released in 1988: in format, in scope and content, and in how it is distributed and accessed. At the same time, it maintains many elements of the original style: part tutorial, part user's guide, and part reference manual. We describe here the evolution of the GAMS documentation and related topics.

Figure 2.1 Covers of GAMS User's Guide and Solver Manual

The first published GAMS documentation is the book *GAMS: A User's Guide* (aka the "red book") by Brooke, Kendrick, and Meeraus, published in 1988 by The Scientific Press. Copies were sold in bookstores and included a chapter on the model library (100 models at that time), a much-appreciated and well-used index, appendices describing the solvers available (MINOS and ZOOM), and a 5.25 inch floppy disk containing a student version of "PC-GAMS version 2.05". This was followed up in 1992 with *GAMS: A User's Guide, Release 2.25* (aka the "blue book") by a different publisher (Boyd & Fraser), a soft cover, and no floppy disk: by this time the software was available directly from GAMS. The final section of installation notes in the red book was replaced in the blue book by notes on the new features in GAMS 2.25, but the content was otherwise unchanged.

As the pace of development increased, it became clear that we needed a new documentation scheme, one that would allow us to update the document continuously as language features, models and model libraries, solvers, and tools/utilities were added to or updated in the system. Consequently, we converted the existing documentation to MS Word, expanded, updated, and edited it as appropriate, and sent it to the copy shop to be printed. This was a group effort spearheaded by Ramesh Raman, whose name was included as an author in the User's Guide first included (along with a CD) in shipments of our 18.0 release in Feb 1999. The solver manuals in this release were collected from various sources (with varying styles, content, and organization) and put into a separate binder. A further push was required to unify this solver documentation (using LaTeX) to use a common style and organization: this unified Solver Manual was included with the 21.0 release of May 2003. In addition to hard-copy, all of these documents were included as PDF in the GAMS system and freely available via the Web. Thus, the shift away from published documentation to manuals produced in-house went hand-in-hand with a shift from printed documents to viewing and searching PDF documents.

During this time Bruce McCarl had been regularly teaching GAMS courses: basic and advanced, targeting a general audience but with a distinct flavor of agricultural economics. As part of this he developed course material to use in his classes, and he was in a good position to notice that the GAMS User Guide was not keeping up with all the updates to the software. With some encouragement from GAMS, Bruce started the ambitious project of creating a new GAMS User's Guide, one that would be more complete, more to his taste with an increase in tutorial flavor, and designed to take full advantage of being a Web document: linked, cross-referenced, searchable, and indexed. The end result was the McCarl Guide that emerged as a PDF based on a Word document in 2002. This was redone in the more convenient CHM format with the 22.1 release of Mar 2006 and renamed as the *Expanded GAMS Guide (McCarl)* in release 22.3 of Nov 2006. We also kept the original GAMS User's Guide, by this time as PDF generated from LaTeX source. With its improved content, organization, and navigability, Bruce's new guide was a boon to all GAMS users, not just those taking his courses. We owe a debt of gratitude to Bruce for this and many other contributions.

The *Expanded GAMS Guide (McCarl)* was never intended to be printed and was not shipped as hard-copy with GAMS. In 2013, GAMS stopped making physical shipments altogether and moved to an online order-fulfillment system. For those who still wanted printed documentation, the documents were also made available via Amazon's CreateSpace, but most users browsed the documents online or as part of an installed GAMS system, often via the GAMS IDE, so the need for printable documents was small and growing smaller.

Having two user's guides was counter-intuitive or confusing for some users, especially when the content for some topics was different, missing, or even contradictory. The additional effort required to maintain two documents became more noticeable, especially since the *Expanded User Guide (McCarl)* was implemented using a Windows-only product that did not lend itself to version control via SVN or git. When we documented our object-oriented APIs in Feb 2013, we used the opportunity to experiment with a doxygen-based authoring process that uses text files as source, is platform-independent, and produces output in multiple formats. The results were good, and in 2015 we hired a consultant, Martha Loewe, to research what it would take to convert all of the GAMS documentation to use the doxygen-based process and to set up a framework for this. We eventually committed fully to this process and produced a unified set of documentation as of release 24.9 in Aug 2017. This involved reorganizing things somewhat to better fit a linked document, merging the two user guides into one (while trying to maintain the best qualities of each), adding links throughout, and submitting everything to review and editing by internal subject matter experts so the content is accurate, updated, and complete. The end result is something we believe is an improvement over its predecessors, but it is also something we are committed to maintaining and improving. The current system allows and encourages immediate updates by the whole GAMS team and has helped foster a culture and attitude where this takes place.

Chapter 3

Release Notes

3.1 Release Types

Major releases contain substantial changes to the GAMS system. The License Check date is set to the release date of the major release.

Minor releases are mainly issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. Additionally, they can provide a few new features that do not change existing behavior. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this minor release.

Maintenance releases do not provide any new features. They are issued to provide bug fixes, performance improvements, and maintenance releases of solver libraries. The License Check Date remains the same as for the prior major release. This means that any license file that worked with the prior major release will also work with this maintenance release.

3.2 Release History

3.3 46 Distribution

3.3.1 46.1.0 Major release (February 17, 2024)

3.3.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Simon Wesley Bowen, Ruud Egging-Bratseth, Wolfgang Britz, Katja Jensen, Bruce McCarl, Scott McDonald, Evangelos Panos, Hailie Petrick, Alfonso Rodriguez Osuna, and Tom Rutherford.

3.3.1.2 Platforms

- As announced, dropped support for macOS 11 (Big Sur).

3.3.1.3 GAMS System

GAMS

- Added new put_utility commands `stdOut` and `stdErr` to send a message to standard output and error streams independent of the GAMS log file.
- Added new command line parameter gdxSymbols to select symbols that get exported when command line parameter GDX is set.
- Print warning to the log if execute_load or execute_loaddc is called without specifying any symbols to be loaded.
- Changed default for option threads to 0. The new meaning of setting `threads=0` is that the solver will decide on the number of processors to use. In particular, the following changes in behavior can be observed for `threads=0`:
  - MIP solvers called by BARON no longer use multiple processors.
  - CBC may use multiple processors in linear algebra subroutines, but not for parallelization in root node processing or the tree search.
  - COPT, CPLEX, GUROBI, KNITRO, and XPRESS now decide automatically on the number of processors to use.
  - IPOPT(H) and LINDO / LINDOGlobal use 1 processor.
  - MOSEK now uses the number of processor cores instead of the number of virtual processors to determine the number of threads (i.e., hyperthreading is disregarded).
  - SCIP now decides automatically on the number of processors to use in MILP presolving and LP solving. It uses 1 thread for some linear algebra routines.
  - MIP solvers called by SHOT now decide automatically how many processors to use.
- Added new option value 22 for dumpOpt that writes processed input with all comments into a separate dump file for each block.
- Removed misleading message about matched rows for CNS models.
- Fixed a potentially wrong result of a sameAs statement, when it is used in a loop construct with a singleton set which gets changed in the loop execution.
- Fixed a wrong dump file, when $onVerbatim was used with $onPut or EmbeddedCode.
- Fixed a potential crash with dumpOpt and dumpOptGdx.

3.3.1.4 Documentation

- The McCarl GAMS User Guide will be dropped with the next major release.

Embedded Python Code Facility

- As announced, the command line parameter `pyMultInst` has been dropped.
- Fixed a problem with empty code blocks.

GAMS Connect

- Added new option skip for the Concatenate agent that allows to indicate if sets or parameters should be skipped.
- Added new ExcelReader and ExcelWriter agents for reading and writing Excel files.
- `PandasExcelReader` and `PandasExcelWriter` are deprecated and will be removed in a future release. Use ExcelReader and ExcelWriter instead.
- Harmonized the sorting behavior of Connect agents. Please check the Usage section for details.
- Improved exception handling for GDXWriter with better error message in case of duplicate records and `duplicateRecords` set to `all`.
- Fixed a bug where GAMSWriter would not raise an error in case of duplicate records and `duplicateRecords` set to `all`.
- Fixed that GAMSWriter and GDXWriter agents were changing the Connect database when dropping duplicate records.

GMSPython

- The Python version of GMSPython has been upgraded to `3.12.1`.
- Added the package `scipy` to GMSPython.

3.3.1.5 Solvers

Antigone, CBC, Ipopt, SCIP, SHOT

- Updated MKL to version 2024.0 on Linux and version 2023.0.0 on Windows.

BARON

- New libraries 24.1.30.
  - Improved algorithms for integer linear and nonlinear programs, including local search, reformulations, relaxations, cutting planes, and presolve.

CBC

- New libraries nauty 2.8.8.

CONOPT

- New libraries 4.32.
  - Bounds larger than Lim_Variable will now be reset to inf (analogously for -inf). Previously, CONOPT terminated with an error.
  - Fixed projection of initial point into bounded interval after linear infeasibility model.
  - Fixed issue with Hessian evaluation when multithreading is enabled.
- Solver alias `conopt` now equals `conopt4`. Use `conopt3` to solve with CONOPT 3.

CPLEX

- Added possibility to define multiple mipstopexpr in one option file. If any of the given stop expressions is true, the algorithm stops.

GUROBI

- New libraries 11.0.0.
  - MINLP: Can now use spatial branching and outer approximation to solve models with non-linear constraints in a form that is supported by Gurobi, instead of using static piecewise-linear (PWL) approximations.
  - New option concurrentmethod: Chooses continuous solvers to run concurrently.
  - New option tunedynamicjobs: Enables distributed tuning using a dynamic set of workers.
  - New option mixingcuts: Mixing cut generation.
  - New option funcnonlinear: Controls whether general function constraints are treated as nonlinear functions or via PWL approximation.
  - New option solutiontarget: Specify the solution target for LP.
  - New option value `-2` for tuneresults.
  - Changed both upper bound and default for option tunetimelimit to infinity.
  - Changed default for option nonconvex to accept models with non-convex objective or constraints.
  - Changed default for option dofuncpieces to use the relative error approach.
- New option nlreform: Reform nonlinear equations to Gurobi general constraints.
- Added possibility to define multiple mipstopexpr in one option file. If any of the given stop expressions is true, the algorithm stops.

GUSS

- In rare (mostly internal) places GUSS was previously called `SCENSOLVER`, e.g. in `gmscmpun.txt` files or the system attribute `solverNames`. This synonym has been removed and replaced by `GUSS`.

JAMS

- Update solution reporting for VI agents: for VI functions that have been flipped, the value of the matching variable is now returned in the equation marginal, instead of its negative.
- Fixed model reformulation for VI agents: corrected reformulation in cases where VI constraints were flipped.

KESTREL

- The client-side implementation now strictly enforces TLS 1.2 or later.

KNITRO

- New libraries 14.0.0.
  - Performance improvements on mixed-integer and QP/QCQP problems.
  - Improvemed presolve.
  - Improvemed quasi-Newton Hessian approximations.
  - New option linsolver_nodeamalg: Controls the node amalgamation setting for the MA57, MA86, and MA97 linear solvers.
  - New option linsolver_ordering: Sets the ordering method used for the linear system solver.
  - New option linsolver_scaling: Enables scaling for the linear system solver.
  - New option scale_vars: Specifies the strategy for scaling variables.
  - New option presolveop_substitution_tol: Tolerance for applying a substitution.
  - New option presolveop_substitution: Determine whether or not to enable the Knitro presolve operation to substitute out variables when possible.
  - New option bar_globalize: Specifies the globalization strategy used in the interior-point algorithms.
  - New option bar_maxmu: Specifies the maximum allowable value for the barrier parameter μ used with the barrier algorithms.
  - New option mip_cut_flowcover: Specifies rules for adding flow cover cuts.
  - New option mip_cut_probing: Specifies rules for adding probing cuts.
  - New option mip_heuristic_localsearch: Specifies whether or not to enable the MIP local search heuristic.
  - New option ms_initpt_cluster: The strategy for clustering initial points in multi-start.
  - New option value `4` for ms_terminate.
  - New option values `-1` and `4` for blasoption.
- For discrete models the initial point is now added as MIP start in addition to the root relaxation start.

Octeract

- As announced, Octeract has been removed.

PATH

- Avoid multi-threaded Jacobian evaluation for models with external equations (aka `=X=` rows) as thread-safe external evaluation cannot be assumed.

SCIP

- Added sassy 1.1 (9847fa1) as graph preprocessor for symmetry detection.

XPRESS

- Added possibility to define multiple mipstopexpr in one option file. If any of the given stop expressions is true, the algorithm stops.

3.3.1.6 Tools

$LibInclude files

- As announced, the libinclude files `gdxservice`, `linalg`, and `win32` have been removed. Please use the corresponding tools from the GAMS tools library instead.

Cholesky, Eigenvalue, Eigenvector, Invert

- As announced, the tools cholesky, eigenvalue, eigenvector, and invert have been removed. Please use the linear algebra tools from the GAMS tools library instead.

GAMS IDE

- Fixed an error reading certain reference files.

GAMS Studio

- New version 1.17.2.
  - Added install license button for the "GAMS Licensing" dialog.
  - Added highlighting of the system log tab when new messages are available. In case of warnings and errors the tab will be focused.
  - Added new options "Compare Defaults", "Compare Domains", and "Ignore Order" to the GDX Diff dialog.
  - Added the ability to resume to an ongoing GAMS Engine job after Studio is restarted.
  - Added symbol sub types to the "Type" column of the symbol table in the GDXViewer.
  - GDXViewer export improvements:
    - The dialog now uses the ExcelReader instead of the PandasExcelReader (deprecated). This changes the following aspects:
      - All GAMS special values are exported as string representation per default.
      - Visual appearance of the generated Excel files has changed.

        - Exported data does not contain the "value" and "element_text" headers anymore.
        - No extra blank row between column header and data anymore.
        - Labels are not written into merged cells anymore.
    - Added support for specifying custom values for GAMS special values.
- Navigator improvements:
    - Improved performance after large searches.
    - Fixed duplicate entries for files that are also opened in a tab.
    - Fixed file navigation when starting path with ...
    - Fixed problem handling long path names.
    - Fixed directories being listed as files.
    - Fixed filesystem navigation for absolute path on Windows.
    - Fixed filesystem navigation improperly handling file switching.
    - Fixed that unnecessary spaces broke Navigator modes.
- Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Added Esc as a shortcut to abort the search.
    - Added abort of ongoing search when search dialog is closed (but not hidden).
    - Improved LST viewer performance.
    - Improved performance when searching very large folders.
    - Improved file handling for unexpected events while writing a file, i.e., write to temporary file and rename after success.
    - Fixed crash when closing a project during a GAMS debug run.
    - Fixed crash when opening file from welcome page.
    - Fixed crash when loading an empty lxi/lst file.
    - Fixed crash in lxiViewer with invalid model index.
    - Fixed crash in project explorer on macOS with invalid model index.
    - Fixed crash in Connect Editor when adding ExcelWriter schema data.
    - Fixed problem where "Replace All" in unopened files appended extra characters.
    - Fixed stop and interrupt button for macOS and Linux.
    - Fixed LST viewer sometimes jumping to wrong position in file.
    - Fixed help view showing empty page when document linked to a page in new tab or new window.
    - Fixed unresponsive `Abort` button in Search Dialog.
    - Fixed that search was not properly interrupted when pressing `Abort`.
    - Fixed deactivated search elements when project settings are focussed.
    - Fixed unwanted partial matches in the Search Dialog file filter section.
    - Fixed project explorer not updated when using "save as".
    - Fixed encoding resets to UTF-8 after restart.
    - Fixed Windows interrupt not working in some cases.
    - Fixed `Open As Text` button in Connect Editor not showing file contents in text editor.
    - Fixed `Save` for newly added data by drag and drop schema in Connect Editor.
    - Fixed overwritten clp when moving/copying a file from one project to another.

GDX2HAR/HAR2GDX

- As announced, the tools gdx2har and har2gdx have been removed. The tools can be accessed from the `CoPS web site`.

GDXRank, GDXRename

- As announced, the tools gdxrank and gdxrename have been removed. Please use the GDX service tools from the GAMS tools library instead.
- The `$libInclude rank` functionality now uses `executeTool 'alg.rank'` to sort a one dimensional parameter instead of the gdxrank tool.

MCFilter

- As announced, the tool mcfilter has been removed. This discussion at the GAMS World Forum gives an alternative.

MOO

- A new LibInclude tool moo has been added. It provides methods for multi-objective optimization in GAMS (e.g. Augmented Epsilon Constraint).

MSAppAvail and Shellexecute

- As announced, the tools msappavail and shellexecute have been removed. Please use the Windows only tools from the GAMS tools library instead.

3.3.1.7 APIs

C++

- Added client-side enforcement of TLS 1.2 or later in `GAMSJob::runEngine`.
- New libraries curl 8.6.0.

C4U

- As announced, the C4U API has been removed from the distribution.

GAMS Transfer Matlab

Attention

GAMS Transfer Matlab has been moved and restructured! The API

- is located in `api/matlab` (previously: `apifiles/Matlab/api`) and
- comes as the Matlab package `gams.transfer` (previously: `GAMSTransfer`).

- Now available for macOS on ARM64 CPUs.
- Added `gams.transfer.setup` and `*.c` MEX source files of internal interface to `gams.transfer.cmex`. Calling `gams.transfer.setup` allows to build GAMS Transfer Matlab from source. Check with `mex -setup` which C compiler is enabled in Matlab.

GAMS Transfer Python

- Symbol property `.container` now holds a reference to the `Container` instead of a `weakref`.
- Relaxed axis uniqueness requirement when setting records with `uels_on_axes=True`.
- Fixed error encountered with non-unique axis elements when setting records with `uels_on_axes=True`.
- Fixed that the `pivot` method failed for DataFrames with non-`str` column names.
- Fixed failure with `getSparsity` by adding new `isValid` test to efficiently detect domain violations in certain situations.
- Fixed bug that did not allow mixed case `gdx` file extensions.

GAMS Transfer R

- New libraries 3.0.0.
  - GDX API changed to the new GDX C++ API, which allows for significant performance improvements.
  - Performance improvements in reading GDX file.
  - The `systemDirectory` argument in the `Container` constructor is deprecated and will be removed in the future.
  - Bug fix: `Container` property `summary` changed from a method to active binding.
  - Bug fix: `Symbol` method `equals` incorrectly returned `FALSE` when the symbol records contain `NA`.
  - Fixed overriding `PKG_CXXFLAGS` in Makevars.

GDX

- New libraries 7.10.1 (synchronized with open-source release of GDX expert-level API):
  - Added `gdxAllowBogusDomains` as boolean option to toggle allowing potentially unsafe writing of records to symbols with one dimensional sets as domain, when GDX has no lookup table for the elements of this set. This can happen when `gdxStoreDomainSets` was disabled by the user to save memory. For backwards compatibility, this is enabled by default. When the user explicitly disables it, e.g. via `gdxAllowBogusDomainsSet(false)`, then using a one dimensional set as domain will cause a GDX error (`ERR_NODOMAINDATA`).
  - Added boolean property `gdxMapAcronymsToNaN` (disabled by default) that maps all acronym values to special value "Not a Number" (NaN).

GEV

- Add alternative function `gevSwitchLogStatEx` to better handle cases where the current log/status destination is independent of the one switched to.

GMO

- Added `gmoObj_None` to enum `gmoObjectiveSense` for model instances without objective. This return value of `gmoSense()` was possible before, but is used more consistently now.

Matlab

Attention

The (object-oriented) Matlab API has been renamed, moved and restructured! The API

- is now called GAMS Control (previously: object-oriented GAMS API),
- is located in `api/matlab` (previously: `apifiles/Matlab/api`),
- comes as the Matlab package `gams.control` or its alias `gc` (previously: `GAMS`),
- now has sub-packages `gams.control.engine`, `gams.control.globals` and `gams.control.options`, and
- removed `GAMS` from class names. For example, use `gams.control.Workspace` (or the alias `gc.Workspace`) instead of `GAMS.GAMSWorkspace`. The old class names are still available as aliases to the new names, but are deprecated and may be removed in an upcoming release. See also mapping of old to new class names.

Furthermore, the enumeration classes have changed. They are now normal classes that behave like enumeration classes for better support of software products that do not support enumerations, e.g., Octave. This has changed:

- Enumeration values are now constant properties of the class. Syntax for using those values does not change.
- The new enumeration-like classes have properties `select` and `value` that store the current selection (name of the enumeration value) and value of the enumeration, respectively. These properties can be changed to other enumeration selections or values. Use `select` when printing the enumeration.
- Removed method `lookup`. Use the class constructor instead.
- Removed method `value`. Use the property `value` instead.
- Setting the environment variable `GAMS_MATLAB_ENUM_ALT` has no effect anymore.

- Added option value `SplitBlocksDumpWithComments` to option `DumpOpt`: Write processed input with all comments into a separate dump file for each block.
- Removed option `PyMultInst`.

.Net

- Changed the `TargetFramework` of the GAMS .Net API and all dependent examples from 4.5 to 4.6.2.

PAL

- Added routine `palExistingConfigFiles()` that returns an ordered list of GAMS configuration files.

Python

- The `gams.transfer.numpy` API has been moved to `gams.core.numpy`.
- Added new value `KeepFilesOnError` to **DebugLevel** which keeps temporary files only in case of an error. Its internal numerical value is `1` and all values for `DebugLevel.KeepFiles` or greater have been increased by one.
- Changed the default of **GamsWorkspace** from `DebugLevel.Off` to `DebugLevel.KeepFilesOnError` with the effect that temporary files do not get deleted anymore in case of an error.
- The client-side implementation of `gams.control.GamsJob.run_engine()` now enforces TLS 1.2 or later when using `urllib3` prior to version 2.0.
- Improved log output of **GamsJob.run()** to be always live (per line).
- Fixed log output of **GamsJob.run()** containing duplicate carriage returns for line endings on Windows.
- Fixed **GamsOptions.optdir** property used with **GamsModelInstance.instantiate()** having no effect in **GamsModelInstance.solve()**.

3.3.1.8 Model Libraries

FIN Library

- Updated **CreditImmunization : Factor Immunization model for corporate bonds.**.
- Updated **MeanVar : Mean-variance efficient portfolios**.
- Updated **MeanVarShort : Mean-variance model allowing short sales**.
- Updated **PutCall : Put/Call efficient frontier model.**.
- Updated **ReadData : Reads excel files and converts them to gdx format**.
- Updated **SelectiveHedging : Scenario Optimization for selective hedging**.
- Updated **ThreeStageSPDA : A three stage stochastic programming model for SPDA**.

GAMS Data Library

- Removed `embeddedMultiInstance`.
- Added **EngineSolve.gms : Demonstrate how to submit just a solve statement to Engine**.
- Added **EngineSolveAsync.gms : Demonstrate how to asynchronously submit solve statements to Engine**.
- Added **moo01.gms : Solve scalable multi-objective knapsack model**.
- Added **moo02.gms : Solve multi-objective power generation model**.
- Updated **connect01.gms : Complex Connect Example with Spreadsheets**.
- Updated **connect05.gms : Simple Connect Example for Excel**.

GAMS Model Library

- **dice** and **dicex**: Fixed big-M and ensured `fval` to be integral after solve in `dice`.
- Added **boxpacking.gms : Container Packing Problem**.
- Added **cvrp.gms : Capacitated Vehicle Routing Problem**.
- Updated **cta.gms : Controlled Tabular Adjustments**.
- Updated **herves.gms : Herves (Transposable Element) Activity Calculations**.
- Updated **qmeanvar.gms : Financial Optimization: Risk Management using MIQCP**.
- Updated **sddp.gms : Multi-stage Stochastic Water Reservoir Model solved with SDDP**.

GAMS Test Library

- Removed `har1`.
- Added **unload16.gms : Test command line parameter gdxSymbols**.
- Added **emp34.gms : JAMS: test of flipping functions with VI**.
- Added **emp35.gms : JAMS: test of flipping constraints with VI**.
- Added **moo1.gms : Test libInclude tool moo**.
- Added **caxlsr.gms : Test Connect agent ExcelReader**.
- Added **caxlsrw.gms : Test Connect agents ExcelReader and ExcelWriter**.
- Added **gamsincr.gms : Test GAMS incrementalMode**.
- Updated **capcode.gms : Test Connect agent PythonCode**.

PSOPT Library

- Updated **DED-PB : Price based Dynamic Economic Load Dispatch**.
- Updated **DED-wind : Dynamic Economic Load Dispatch considering Wind generation**.
- Updated **DED : Dynamic Economic Load Dispatch**.
- Updated **DEDESS : Cost based Dynamic Economic Dispatch integrated with Energy Storage**.
- Updated **DEDESSwind : Cost based Dynamic Economic Dispatch integrated with Energy Storage and Wind**.
- Updated **ESSDCOPFwind : DC-OPF integrated with Energy Storage and Wind**.
- Updated **MultiperiodACOPF24bus : Multi-period AC-OPF for IEEE 24-bus network considering wind and load shedding**.
- Updated **MultiperiodDCOPF24bus : Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding**.
- Updated **PBUC : Price based Unit commitment**.
- Updated **RampSenDED : Ramp rate sensitivity analysis for Dynamic Economic Load Dispatch**.

3.3.2 46.2.0 Minor release (March 05, 2024)

3.3.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jinggang Guo, Scott McDonald, and Anne Sofie Skak-Iversen.

3.3.2.2 GAMS System

Embedded Code Facility

- Fixed error if embedded Python/Connect code arguments (`gams.arguments`) contain single quotes.

GAMS Connect

- Fixed ExcelReader error when reading from empty sheet.
- Fixed ExcelWriter error when writing an empty symbol.
- Improved ExcelReader error messages for insufficient ranges.

3.3.2.3 Solvers

BARON

- New libraries 24.3.1.
  - Performance improvements for QCQPs.

CONOPT

- New libraries 4.33.

MOSEK

- New libraries 10.1.27.

3.3.2.4 Tools

GAMS Studio

- New version 1.17.3 with bug fixes and minor enhancements:
  - Added "Last Projects" to the welcome page.
  - Added close button to remove an entry from the welcome page.
  - Added search and replace for block-edit.
  - Fixed that project file got cleared when opening a file of the same base name.

3.3.2.5 APIs

DCT

- Fixed a wrong error message in case of an overflow in `dctSetBasicCountsEx`.

3.3.2.6 Model Libraries

GAMS Test Library

- Updated **caxlsr.gms : Test Connect agent ExcelReader**.
- Updated **caxlsrw.gms : Test Connect agents ExcelReader and ExcelWriter**.
- Updated **connectsub.gms : Test substitution for Connect**.
- Updated **embpy01.gms : Test for embedded code facility**.
- Updated **embpy02.gms : Test for embedded code facility**.

3.3.3 46.3.0 Minor release (March 19, 2024)

3.3.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Nick Sahinidis, and Feng-Sheng Wang.

3.3.3.2 GAMS System

GAMS

- New Put_Utility `xsave`: Writes a compressed save file of the current state of execution.
- New dollar control option $xsave[.keepCode] to create a compressed work file during compilation.

Embedded Python Code Facility

- Fixed a problem with code blocks with comments only.
- Fixed `%` character not being diplayed correctly when using `gams.printLog`.

GAMS Connect

- Added a warning to the `ExcelWriter` agent in case `openpyxl<3.1.0` is used which can lead to wrong data being exported.
- Fixed bug where `Concatenate` agent would not preserve the UEL order.

3.3.3.3 Installer

- Fixed incorrect capitalization in macOS uninstall script when asking for confirmation to remove GAMS.

3.3.3.4 Solvers

BARON

- New libraries 24.3.10.

CONOPT

- New libraries 3.17P.
- Fixed error with too large threadf value in CONOPT 4. Will be clipped at 64 now.
- Fixed interfaces for solving model instances without equations but bound constraints (only relevant when calling solver directly via GMO API).

COPT

- Fixed library load problems on some Linux systems.

GUROBI

- New libraries 11.0.1.

HiGHS

- Variable level values are no longer passed as initial solution to an LP solve, as this disabled LP presolving.

MOSEK

- New libraries 10.1.28.

3.3.3.5 Tools

GDXDUMP

- Fixed a problem with long element text when writing in CSV format.

MOO

- The tool will now throw an error in case of an empty dynamic objective set.
- Fixed bug where objective values of zero would not be fixed while calculating the payoff table.
- In addition to raising a warning, the tool will now skip objectives with min=max after the payoff table calculation. If there is not more than one objective without min=max left, the methods are skipped and the pareto points from the payoff table are returned.
- Fixed bug where sandwiching returned incorrect savepoint files for anchor points.

GAMS Studio

- New version 1.17.4.
  - Fixed crash on close a tab with active block edit selection.
  - Fixed font initialization error.
  - Fixed project not created when using "Open File".
  - Fixed behavior of running GAMS Engine job on Studio exit.
  - Fixed keep file modified when saving the file fails.

3.3.3.6 APIs

Python

- Added minimum version `3.1.0` for `openpyxl` in `pip` extras for `connect`.

3.3.3.7 Model Libraries

GAMS Test Library

- Updated **caconcat.gms : Test Connect agent Concatenate**.
- Updated **connectsub.gms : Test substitution for Connect**.
- Updated **embpy01.gms : Test for embedded code facility**.
- Updated **embpy02.gms : Test for embedded code facility**.
- Updated **moo1.gms : Test libInclude tool moo**.

3.3.4 46.4.0 Minor release (April 02, 2024)

3.3.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Torbjoern Jansson, Daniel Oliveira, and Evangelos Panos.

3.3.4.2 GAMS System

GAMS

- Modified behavior of dumpOpt for value 22 to not split into further dump files when processing an include file.

Embedded GAMS Code Facility

- Fixed bug with embedded GAMS code when executing in a directory with a long path name.

GAMS Connect

- Fixed bug in `SQLReader` agent where `indexSubstitutions` on stacked indices in case of more than one value column would result into `NaN`.

3.3.4.3 Solvers

Convert

- Fixed issue writing opening parenthesis for function arguments in new line.

3.3.4.4 Tools

GAMS Studio

- New version 1.17.5.
  - Fixed: Prevent Alt keys from closing GDX Viewer filter dialogs.

GDXDUMP

- Fixed bug when writing symbol text that starts with `(`.

3.3.4.5 Model Libraries

GAMS Data Library

- Updated **GMSPythonCheck.gms : Consistency check for GMSPython**.

GAMS Test Library

- Updated **casqlr.gms : Test Connect agent SQLReader**.

3.3.5 46.4.1 Maintenance release (April 16, 2024)

3.3.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.3.5.2 GAMS System

GAMS

- Fixed a bug causing $declareAndLoad to throw an error when an alias to the universe should be declared.

3.3.5.3 Solvers

CBC

- New libraries CoinUtils 2.11.11.

CONOPT

- Fixed default setting of LFITER and RVTIME to solver default.

KESTREL

- Removed EMP from the list of supported model types since Kestrel currently does not support `EMP` models.

3.3.5.4 APIs

.NET

- Fixed `GAMS.GAMSOptions.OptDir` property used with `GAMS.GAMSModelInstance.Instantiate` having no effect in `GAMS.GAMSModelInstance.Solve`.

3.4 45 Distribution

3.4.1 45.1.0 Major release (October 14, 2023)

3.4.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Saran Chanpuang, Aidana Ermatova, Michael Ferris, Adderly Huerta, Auke Greijdanus, Mogens Bech Laursen, and Christoph Pahmeyer.

3.4.1.2 Platforms

- We will drop support for macOS 11 (Big Sur) with the next major release.
- Added support for macOS 14 (Sonoma).

3.4.1.3 GAMS System

GAMS

- Added an additional note to the log about the expiration date of the license used.
- Extended the $declareAndLoad capability to also declare new acronyms found in the input GDX file.
- Minor performance improvement for execute_unload.
- Fixed a bug which caused a wrong dump file when $onEmpty is active.
- Fixed a broken message in the log when a $call gets executed with a command that exceeds 255 characters.
- Fixed a data-dependent bug that resulted in an unexpected execution error and was triggered by re-loading data at execution time in a loop via Embedded Code.
- Fixed sys15 being ignored in option statements.

Embedded Python Code Facility

- We plan to drop the command line parameter `pyMultInst` with a future major release. The ability to maintain independent Python sessions can not be maintained in a reliable way.

GAMS Connect

- The CSVWriter now supports unstacking multiple dimensions to header rows.

GMSPython

- The Python version of GMSPython has been updated to `3.8.17`.

3.4.1.4 Documentation

- Added list of 156 third-party codes that are redistributed with GAMS.

3.4.1.5 Installer

- The Windows installer does not create the `GAMS` sub directory in the users documents directory anymore.

3.4.1.6 Solvers

CONOPT

- New libraries 4.31.
  - Added option Flg_AdjIniP to disable sometimes expensive adjustments to initial point.
  - Added option Flg_NoDefc to disable definitional constraints.
  - Added evaluation of post-triangular constraints if a CNS model was interrupted.
  - Improved AttemptCNS.
  - Changed the logic for improving the conditioning of the basis to fix problems with superbasic slacks.
  - Function evaluation errors are made silent after ill-conditioned steps.
  - Reset reduced Hessian and superbasis after singularities or numerical problems.
  - Fixed a problem in SQP when a critical bound was infinite. This could have given huge steps and domain errors.
  - Fixed an error in the pre-processor where minimax constraints could be converted into an incorrect equality.

CONVERT

- Fixed writing `eps` for `0` as variable coefficients in GAMS format.

COPT

- New libraries 7.0.1.
  - Performance improvements.
  - New option BarStart: method to compute starting point for Barrier solver.
  - New option FAPHeurLevel: level of fix-and-propagate heuristic.

CPLEX, GUROBI, MOSEK, FICO XPRESS

Attention

The bare-bone link mode (previously OsiCplex, OsiGurobi, OsiMosek, OsiXpress), which required only a GAMS base license and a standalone solver license to solve LP or MIP, has been **removed**. Please contact `sales@gams.com` to arrange for a solver-link license to be added to your GAMS license.

GUROBI

- New libraries 10.0.3.

HiGHS

- New libraries 1.6 (c070f1253).
  - Improved handling of user-interrupt.
  - New option mip_min_logging_interval.
- Added functionality to write solve trace files. New options solvetrace, solvetracenodefreq, and solvetracetimefreq.

Ipopt

- New libraries METIS 5.2.1.
- Fix in METIS adapter code used by HSL linear solvers.

MOSEK

- New libraries 10.1.13.
  - Improved branching variable selection: Automatic choice of variable selection method and adjustment of strong branching work limits. New options MSK_IPAR_MIO_VAR_SELECTION and MSK_IPAR_MIO_MIN_REL.
  - Knapsack cover cuts are now enabled by default, that is, changed default of option MSK_IPAR_MIO_CUT_KNAPSACK_COVER from `MSK_OFF` to `MSK_ON`.
  - Added conflict analysis based on dual rays. New option MSK_IPAR_MIO_DUAL_RAY_ANALYSIS_LEVEL.
  - New option MSK_IPAR_MIO_MAX_NUM_RESTARTS.
  - New option MSK_IPAR_PRESOLVE_LINDEP_NEW.
  - Removed options `MSK_IPAR_CHECK_CONVEXITY` and `MSK_IPAR_LOG_CHECK_CONVEXITY`.
  - Removed value `MSK_STARTING_POINT_SATISFY_BOUNDS` for option MSK_IPAR_INTPNT_STARTING_POINT.

SCIP Optimization Suite

- New libraries PaPILO 2.1 (9ef45bfa).
- New libraries SoPlex 6.0 (5a9b664d).
- New libraries SCIP 8.0 (6c8c7c8d90).

SHOT

- New libraries 1.1 (424b5e48).

3.4.1.7 Tools

GAMS Studio

- New version 1.16.1.
  - Removed the "Go To" dialog, as the functionality is integrated into the Navigator.
  - Improvements for the GDX Viewer:
    - Added support for `Shift + Left Click` to select/deselect multiple labels in the GDX Viewer filters.
    - Added thousands separator to symbol record count and symbol number in GDX Viewer.
  - Added HTTPS support to check for update feature, removed dependency on C4U library.
  - Added authorization provider support to GAMS Engine.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Improved performance of the Navigator for sessions with a lot of files.
    - Fixed check for GAMS license.
    - Fixed crash when reading a corrupted Reference File.
    - Fixed crash on using nested `$echo` commands.
    - Fixed partly saved auto-save files.
    - Fixed recovering outdated auto-save files.

Info-ZIP

- Updated `gmszip` to Zip `3.0-13` on Linux and macOS.
- Updated `gmsunzip` to UnZip `6.0-28` on Linux and macOS.

3.4.1.8 APIs

C

- As announced, removed `gcmt.h`, `gcmt.c`, `gclgms.c`, and `gcdllinit.h` from `apifiles/C/api`.

C++

- Added function `GAMSJob::runEngine` to run jobs on GAMS Engine, rather than locally.
- Adjusted `GAMSJob::run` public function signature.
- Added `transportEngine` example to show usage of new Engine feature.

C4U

- We plan to remove the C4U API from the distribution with an upcoming major release.

GDX

- The user-specified special value mapping set via `gdxSetReadSpecialValues` now also affects the type-specific default values (level, lower, upper, marginal, scale) for empty 0-dimensional (scalar) variables and equations.
- Reverted `gdxSetDomain` to write `0` instead of `-1` as domain index for unknown domains.
- Adjust default behavior to store negative zero as zero. This is more space-efficient due to our internal storage scheme and is consistent with pre-GAMS-38 behavior.
- Fixed incorrect default record for empty equation symbols with equation type different than "equals".

GMD

- Added new function `gmdFindUel` (counterpart for `gmdGetUelByIndex`) which queries the UEL index for a given UEL label. Returns false on failure. UEL index is set to -1 in case the UEL label is not found in the UEL table.
- Performance improvements when dealing with larger datasets due to more efficient symbol and UEL handling.

GMO

- Fixed a bug in functions `gmoGNLNZ64` and `gmoGNLNZ`: they computed counts incorrectly in case of degenerate quadratic forms like `x * (1 + eps*y)`.

GAMS Transfer Matlab

- **Breaking**: Renamed records field `text` of Sets to `element_text`.
- Added symbol `UniverseAlias` to represent aliases to the universe set.
- Added possibility to change symbol name case with `Container.renameSymbol`.
- Added possibility to reorder UELs by record order with `Symbol.reorderUELs` (passing no arguments).
- Added `Container.getSets`, `Container.getParameters`, `Container.getVariables`, `Container.getEquations`, and `Container.getAliases` to get list of symbol objects of corresponding type.
- Added possibility to get/remove all symbols with `Container.getSymbols` or `Container.removeSymbols`, respectively.
- Added `Container.lowerUELs`, `Container.upperUELs`, `Symbol.lowerUELs`, and `Symbol.upperUELs` to convert (all) UELs to lower or upper case, respectively.
- Added columns `where_min` and `where_max` to output of `Container.describeParameters`.
- Changed column names in output of `Container.describe*` methods: `dim` → `dimension`, `num_recs` → `number_records`, `num_vals` → `number_values`, `min_value` → `min`, `max_value` → `max`, `mean_value` → `mean`.
- Removed `*_marginal`, `count_*`, `where_max_abs_value`, and `is_alias` columns in output of `Container.describe*` methods.
- Removed `ConstContainer`.
- Added GDX library unload before each read/write operation.
- Changed used GDX library to `gdxcclib64`.
- Fixed bug that limited the number of used UELs in `Symbol.transformRecords` and `Symbol.getUELs`.
- Fixed `Container.eq` in case of containers with different number of symbols.

GAMS Transfer Python

- Officially removing the beta label.
- Improved performance for both reading/writing of GAMS data from/to GDX and GMD.
- Allow users to update symbol records by repeating calls to the symbol constructor (new objects will not be created).
- Added new symbol/container methods to easily modify UEL strings (`lowerUELs`, `upperUELs`, `lstripUELs`, `rstripUELs`, `stripUELs`, `capitalizeUELs`, `casefoldUELs`, `titleUELs`, `ljustUELs`, and `rjustUELs`).
- Added new container methods to retrieve symbol objects (`getSets`, `getAliases`, `getParameters`, `getVariables`, and `getEquations`).
- Added support for reading data that originated with different encodings.
- Enabled different GDX/GMD `read`/`write` modes (defaults should be used to maintain performance, except in rare instances).
- Passing `None` (new default) to <`container`>`.removeSymbols()` will remove all symbols.
- Passing `None` (new default) to <`container`>`.getSymbols()` will return a list of all symbol objects.
- Renamed symbol property `ref_container` to `container`.
- Added `eps_to_zero=True` (changes default behavior) argument to <`container`>`.write()` to control writing all GAMS EPS (i.e., `-0.0` in GTP) special values to `0.0`.
- Enabled the symbol property `name` (and <`container`>`.renameSymbol()`) to change the casing of a symbol name.
- `Container` property `system_directory` can now accept either `str` or `PathLike` objects.
- Added `symbols` argument to `Container` methods (`getDomainViolations`, `hasDomainViolations`, `countDomainViolations`, `dropDomainViolations`, `getDuplicateRecords`, `hasDuplicateRecords`, `countDuplicateRecords`, `dropDuplicateRecords`, `isValid`).
- Reorganized the `describe`$*$ tables for clarity and brevity.
- Added `Container.hasSymbols()` method to test for symbols in a container (can also use the `in` operator).
- Updated the symbol `summary` properties for all symbol types.
- Added a container `summary` property.
- Added support for setting GAMS special values with `str` types when setting records with MultiIndex DataFrames.
- Function `setRecords` no longer drops zero valued records when setting records with MultiIndex DataFrames.
- Added new symbol methods to drop (potentially) unwanted records: `dropZeros` (parameters only), `dropDefaults`, `dropNA`, `dropUndef`, `dropMissing`, and `dropEps`.
- Exposed a new public property `default_records` for variables and equations.
- Added support for Pandas 2.1.0.
- Function `toDense` now checks categorical ordering before creating an array (for `relaxed` domain symbols).
- Fixed a bug when reading in an Alias symbol from GMD objects.
- Fixed a bug where a symbol's UEL (categorical) order was not maintained from GDX.

GAMS Transfer R

- New libraries 2.6.
  - Officially removing the beta label.
  - **Breaking**: removed all `Const*` classes. `ConstContainer` is no longer supported. Use `Container` instead.
  - **Breaking**: Symbol field `refContainer` renamed to `container`.
  - **Breaking**: removed `getUniverseSet` method from `Container`. Use `getUELs` instead.
  - Records columns that are not specified by the user in a dataframe are not auto completed to save memory. For example, a set with only the domain columns will now not have the `element_text` columns. A default value is assumed for the missing attributes.
  - New field `defaultValues` for symbols of type `Parameter`, `Variable`, and `Equation`.
  - Reorganized `describe*` `Container` methods for clarity and brevity.
  - Refined field `summary` for `Symbol` objects for clarity.
  - `Container` objects now have a `summary` field.
  - New convenience methods for `Container` objects: `getSets`, `getAliases`, `getParameters`, `getVariables`, and `getEquations`.
  - Enabled registering any UEL using `uelPriority` argument in `Container` method `write`.
  - `Container` method `write` now supports `mapped` write mode with the help of new argument `mode`.
  - Following `Container` methods do not support `list` input for `symbols` argument: `describeSets`, `describeAliases`, `describeParameters`, `describeVariables`, `describeEquations`, `read`, `removeSymbols`, `getSymbols`. Use `vector` inputs instead.
  - Argument `types` in the `Container` methods `listVariables` and `listEquations` does not support the input of type `list`. Use `vector` inputs instead.
  - Argument `uelPriority` in the `Container` method `write` does not support the input of type `list`. Use `vector` inputs instead.
  - Fixed bug in failed `Symbol` constructor call resulting in symbol being added to the `Container`.
  - Fixed bug in registering unused UELs when not all symbols from the container are written to a GDX file.
  - Fixed bug in read for `Variable` and `Equation` classes where the `lower` and `upper` attributes were interchanged.
  - Fixed bug in the Symbol method `equals` where identical domain symbols exist in different containers.
  - Fixed bug in Symbol methods `reorderUELs` and `toDense` for symbols with `relaxed domain`.

Jupyter Notebooks

- The newly introduced back-end class gams.magic.GamsInteractive can be used to translate GAMS Jupyter notebooks into standalone Python scripts.

Matlab

- Added GAMS Engine support:
  - Added classes **GAMSEngineConfiguration**, **GAMSEngineJob**, **GAMSEngineJobBuilder**, and **GAMSEngineRunParameters**.
  - Added method **GAMSJob.runEngine()**.

  - Added example `transport_engine.m` to show how to run a job with GAMS Engine from within the GAMS Matlab API (requires Matlab with at least Java SE 11).

- Added classes **AbstractRunParameters**, **GAMSRunParameters**, **MIIMode**, **Replace**, **SolveOpt**, and **PrintStream** (thin wrapper around a Java print stream).
- Changed method signatures of **GAMSJob.run()** and **GAMSModelInstance.solve()** to use **PrintStream** for output handling.
- Changed handling of Java null pointers: Instead of raising an error, GAMS Matlab now uses `[]` to indicate null.
- Fixed internal handling of Java lists, sets, and maps.

PAL

- Added new functions to query the expiration date for time-limited licenses (`palLicenseGetEvalDate`) and the maintenance end-date for perpetual licenses (`palLicenseGetMaintDate`).

Python

- As announced, dropped support for Python 3.7.
- The `gams.numpy` API has been moved to `gams.transfer.numpy` and is now considered an internal API of `gams.transfer`. The documentation as well as the examples `g2np_example[1|2].py` have been removed and users are encouraged to use `gams.transfer` as a replacement.
- Renamed the `gams` Python wheel to `gamsapi`, this change will not impact import statements, but users will need to use install differently with `pip install gamsapi`.
- New optional parameter `container` for `gams.connect.ConnectDatabase` constructor that allows to use an already existing instance of `gams.transfer.Container`.
- Fixed wrong `model_status/solver_status` after calling `gams.control.GamsModelInstance.solve()` with `debug=True`.

3.4.1.9 Model Libraries

GAMS API Library

- Dropped `Pgams2numpy`.
- Updated **PBuildXPLevelAPI.gms : Test building and installing the GAMS Python API from source distribution**.

GAMS Data Library

- Updated **GMSPythonLib.gms : GMSPYTHONLIB compatibility check**.

GAMS Model Library

- Improved numerics of **fdesign.gms : Linear Phase Lowpass Filter Design**.

GAMS Test Library

- Updated **gams2numpy01.gms : Test gams.core.numpy Python API string mode**.
- Updated **gams2numpy02.gms : Test gams.core.numpy Python API raw mode**.
- Updated **gamsjupyter01.gms : Test GAMS Jupyter Notebooks**.
- Added **knitro02.gms : KNITRO test suite - model setup issue**.
- Added **knitro03.gms : KNITRO test suite - model setup issue**.

3.4.2 45.2.0 Minor release (October 30, 2023)

3.4.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.4.2.2 Solvers

CBC

- New libraries Cbc 2.10.11 and Clp 1.17.9.

COPT

- New libraries 7.0.2.
  - New option SolTimeLimit to set a timelimit (for the whole solve) that is only effective after a feasible solution has been found.

3.4.2.3 APIs

C++

- Added CMake option `USE-GCC` for example subproject to change library selection to prefer GCC over clang.

GAMS Transfer R

- New libraries 2.8.
  - Fixed bug in reading symbols from GDX with unused UELs from domain.
  - Fixed bug in symbol method `getDomainViolations` when the domain symbol has `NULL` records.

Java

- Fixed wrong `ModelStatus/SolveStatus` after calling `GAMSModelInstance.solve()` with `debug` option set to `true`.

.Net

- Fixed wrong `ModelStatus/SolveStatus` after calling `GAMSModelInstance.Solve()` with `debug=true`.

3.4.3 45.3.0 Minor release (November 11, 2023)

3.4.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.4.3.2 GAMS System

GAMS

- Fixed a problem with command line parameter etLim which was ignored in many cases at compile time.

3.4.3.3 Solvers

Ipopt

- New libraries Ipopt 3.14.13.
- New libraries MUMPS 5.6.2.

MOSEK

- New libraries 10.1.16.

SCIP Optimization Suite

- New libraries SCIP 8.0 (6f841064d0).
- New libraries PaPILO 2.1 (ee0677c4).

3.4.3.4 Tools

GAMS Studio

- New version 1.16.2 with bug fixes and minor enhancements:
  - Enhanced GAMS Engine dialog:
    - Compute remaining time depending on instance factor and always show remaining seconds.
    - Added support for `JobTag` for job identification.
    - Fixed alignment.
    - Fixed error message when server not found.
  - Fixed rare crash in search.
  - Fixed search result not clickable after changing search term.

GAMS Tools Library

- Modified tool ExcelTalk to provide better error messages. Moreover, the matching of the workbook name is done on the base name (without the path) of the file.

3.4.3.5 APIs

Python

- Added support for Python 3.12.

Control

- Fixed unwanted side effect when passing `engine_options` dictionary to `gams.control.GamsJob.run_engine()` method.
- `gams.control.GamsJob.run_engine()` now correctly handles the response status code `429 Too Many Requests` from the server.

Transfer

- Fixed a bug that prevented syncing of records (in jupyter environments) when setting records with a tabular dataframe or int/float data type.

3.4.4 45.4.0 Minor release (November 27, 2023)

3.4.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Josef Kallrath.

3.4.4.2 MPSGE

- Fixed issues solving MPSGE-generated problems with multithreading enabled due to incorrect parallel Jacobian evaluation.

3.4.4.3 Solvers

COPT

- New libraries 7.0.3.

MINOS and SNOPT

- Fixed incorrect global optimal model status for non-convex models with linear constraints.

3.4.4.4 Tools

GAMS Studio

- New version 1.16.3 with bug fixes and minor enhancements:
  - Relaxed boundaries of the GDX Viewer splitter to allow for more resizing flexibility.
  - Reduced allowed SSL warnings when the user accepts self-certified GAMS Engine connection.
  - Fixed that command line changes were lost when switching to another project.
  - Fixed that a double click on a `.gsp`-file did not activate the project.
  - Fixed that the position of the search dialog was not saved when closing with close button in titlebar.

GAMS Tools Library

- Fixed a bug in tool ExcelMerge when accessing the number of sheets in a workbook and improved error messages.

3.4.4.5 APIs

GEV

- Disable multi-threaded Jacobian evaluation in `gevEvalJacLegacyX` for model instances with external equations (aka `=X=` rows): it cannot be assumed that the user-provided evaluation function is thread-safe.

Python

- Fixed a Python 3.12 `SyntaxWarning` in the Control API.

3.4.5 45.5.0 Minor release (December 14, 2023)

3.4.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Rob Davies, Gabriel Homsi, and Sherman Robinson.

3.4.5.2 GAMS System

GAMS Connect

- Fixed a bug in the PandasExcelReader that prevented reading columns containing both numerical values and dates.

3.4.5.3 Solvers

MOSEK

- New libraries 10.1.21.
  - Option MSK_DPAR_CHECK_CONVEXITY_REL_TOL is no longer effective.

SCIP

- New libraries 8.1.0.

3.4.5.4 Tools

GAMS Tools Library

- Fixed a bug in tool ExcelTalk when Excel files are located in (sub)directories.
- Added command `open` and named argument `quit=0|1` to tool ExcelTalk.

3.4.5.5 APIs

GMD

- Fixed memory leak related to not freeing a symbol record iterator when updating a symbol inside a model.

Python

- Fixed a potential memory leak in the control API observed when iterating multiple times over the same symbol. This was also affecting `GAMSModelInstance.solve()`.
- Fixed a warning when building the `gamsapi` wheel using the source distribution.

3.4.6 45.6.0 Minor release (January 04, 2024)

3.4.6.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Simon Wesley Bowen, Rob Davies, and Mart Saluri.

3.4.6.2 GAMS System

GAMS

- Changed $loadDCR to not complain anymore when it should be used to clear a set, that is used as domain, if that set had no data so far.
- Fixed a bug which could have caused a wrong dump file with an empty data statement when dumpOptGDX is set.
- Fixed a bug which could have caused a wrong dump file when $loadM is used while dumpOptGDX is set.
- Fixed a potentially wrong result of a sameAs statement, when it is used in a loop construct with a singleton set which is empty when entering the construct and gets a value in it.

GAMS Connect

- Improved exception messages of several agents when handling symbols that do not exist.

3.4.6.3 Solvers

COPT

- New libraries 7.0.4.

SCIP

- New libraries 8.1 (0dff9f8a3e).

3.4.6.4 Tools

GAMS Studio

- New version 1.16.4 with bug fixes:
  - Fixed that check for update crashed when Studio is opened and immediately closed.
  - Fixed check for update redirect policy (`NoLessSafeRedirectPolicy`) and check for update behavior when disabled.
  - Fixed wrong sorting behavior in the export dialog of the GDX Viewer.

3.4.7 45.7.0 Minor release (January 18, 2024)

3.4.7.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.4.7.2 GAMS System

GAMS

- Fixed MIIMode to implicitly set keep=1 as expected.
- Fixed a problem when loading from a GDX file at compile time which could have caused an incomplete load of data, if the data depends on a domain set that was reloaded before from the same file replacing already existing records.
- Fixed a bug which could have caused a broken dump file with certain data statements.

GMSPython

- Packages `Jinja2` and `urllib3` have been updated to version `3.1.3` and `2.1.0`, respectively, which include fixes for known vulnerabilities.

3.4.7.3 Solvers

COPT

- New libraries 7.0.6.

IPOPT

- New libraries 3.14.14.

MOSEK

- Reduce overhead when calling MOSEK for final solve and avoid its output to stdout when it should have been disabled.

3.5 44 Distribution

3.5.1 44.1.0 Major release (July 20, 2023)

3.5.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Wolfgang Britz, Rob Davies, Michael Ferris, Bruce McCarl, and Thomas Rutherford.

3.5.1.2 GAMS System

GAMS

- Added new function gdxLoad to have a flexible way of loading from GDX files at execution time. The load behavior can be modified using the new options filtered and replace. This new function can be used for both, explicit loading of single symbols but also a bulk load of all symbols in the GDX file that match the declaration in the model.
- The requirements for logic equations have been relaxed to make them more useful in future releases. For example, continuous variables and non-boolean functions/operators can now be present in logic equations. This relaxed use of algebra in logic equations prevents some simple preprocessing steps, e.g. `not not x` is only `x` if `x` is either 0 or 1. Since this is not the case anymore, such preprocessing has been disabled. This might impact some (linear) reformulation of pure boolean logic equations done by LOGMip.
- Added new command line parameter solveOpt to initialize the already existing option `solveOpt`.
- Added new command line parameter MIIMode.
- As announced, the command line parameter logOption was changed. `LogOption=1` was marked as deprecated and became a synonym for the default `logOption=3`, which sends the log output to the standard output.
- PreviousWork now writes a workfile compatible with GAMS 43 and newer.
- Fixed a potential bug with $save and put_utility save.

GAMS Connect

- As announced, the `debug` option of the Options agent has been dropped.
- The CSVReader now supports using the symbolic constant `lastCol` without a `header` or `names`. If no `header` or `names` is provided, `lastCol` will be determined by the first line of data.
- The CSVReader now supports reading multi-row headers for parameters.
- Added LabelManipulator agent to Connect.

3.5.1.3 Installer

- Docker images with a pre-installed GAMS distribution for linux/amd64 are now available at Docker Hub.

3.5.1.4 Licensing

- A GAMS demo license is now included in the GAMS distribution. It is valid for approximately 5 months.

3.5.1.5 Documentation

- The HTML documentation now uses a new style based on Doxygen Awesome.

3.5.1.6 Solvers

BARON

- New libraries 23.6.22.
  - Improved continuous and integer presolve and facilities for quadratic programs.
  - New reformulator.
  - Added options AllowCbc, AllowCplex, AllowHsl, AllowXpress to adjust which solvers can be picked by automatic LP/MIP/QP solver selection.
  - Added support for macOS on ARM64 CPUs. Ipopt and Xpress cannot be used as NLP and LP/MIP/QP solver, respectively, by BARON on this platform so far, that is, options AllowIpopt and AllowXpress are 0 by default.

Gurobi

- New libraries 10.0.2.

HiGHS

- New libraries 1.5.3.
  - New option presolve_reduction_limit.
  - New option ipx_dualize_strategy.
  - Renamed option `simplex_dualise_strategy` to simplex_dualize_strategy.

IPOPT

- New libraries MUMPS 5.6.1.

LINDO/LINDOGLOBAL

- New libraries 14.0.279.

Mosek

- New libraries 10.0.46.

Octeract

- We plan to drop Octeract with one of the following major releases.

SCIP Optimization Suite

- New libraries SCIP 8.0 (bf58b8fcd5).
  - Removed non-default values for option propagating/symmetry/recomputerestart, that is, recomputing symmetry information after a restart can no longer be enabled (as this can produce wrong results).
- New libraries PaPILO 2.1 (2ed99c46).

SELKIE

- As announced, the research solver SELKIE has been dropped from the GAMS distribution. It is expected that it will be made available directly from the authors.

3.5.1.7 Tools

GAMS Studio

- New version 1.15.1.
  - New feature GAMS Debugger: This allows to pause the execution at the beginning of execution statements and review the current data in a temporary GDX file.
  - Improvements for the GDX Viewer:
    - Added search facility to the data view.
    - Added settings to specify default numerical formatting options and show/hide attributes.
    - Disable preferences menu for sets and aliases.
  - Improvements for the GAMS Configuration Editor:
    - Move tab selection from bottom to top.
    - Fixed status in definition section when editing a `Key`.
  - Improvements for the GAMS Configuration Editor / Parameter File Edior / Extended Parameter Editor:
    - Add `group` in parameter/option definition.
    - List all available solvers for `Solver` parameter/option definition.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Fixed OpenSSL issue for Manjaro, Ubuntu 22.04 LTS and similar Linux distributions.
    - Fixed a bug where `precision=Full` was not restored properly in the GDX Viewer.
    - Fixed path issue for project files: existing projects with a path starting with "." can be fixed manually using "Move Project File..."

GDX2ACCESS

- Fixed gdx2access for systems where both 32-bit Office and 64-bit Access runtime are installed.

MDB2GMS

- Fixed mdb2gms for systems where both 32-bit Office and 64-bit Access runtime are installed.
- Made table browser in MDB2GMS not crash when field sizes for memo or long binary fields cannot be queried (now showing `???` instead).

3.5.1.8 APIs

C

- File `apifiles/C/api/gcmt.c` does no longer need to compiled to use C or Fortran API files. Files `gcmt.c` and `gcmt.h` are now empty and will be removed in a future version.
- File `apifiles/C/api/gclgms.c` does no longer need to compiled to have the arrays and functions from `gclgms.h` defined (they are inlined now). File `gclgms.c` is now empty and will be removed in a future version.
- File `apifiles/C/api/gcdllinit.h` is now empty and will be removed in a future version.
- The definitions `GAMSVERSION`, `GAMSMAJOR`, `GAMSMINOR`, and `GAMSGOLD` in `gclgms.h` are deprecated and will be removed in a future version.

Delphi

- The Delphi API files in `apifiles/Delphi` will be removed with a future major release.

Fortran

- The Fortran API files in `apifiles/Fortran` will be removed with a future major release.

GAMS Transfer Python

- Breaking: Dropped `ConstContainer` and all `Const*` symbols – users should only use `Container` and accompanying symbols.
- Method `setRecords` (and the `records` argument) now supports setting records with `pandas.Series` and `DataFrames` with `Index` or `MultiIndex` axes (must set `uels_on_axes=True`).
- Method `toDense` now requires domain sets to have self-consistent ordering (i.e., record data order and category order must be equal).
- Method `reorderUELs` now reorders UELs to data order (and append unused categories) if `uels` is `None` (the default).
- Fixed bug when attempting to load libraries from different GAMS versions with the `system_directory` argument.

GAMS Transfer R

- New libraries 2.2.0
  - Fixed bug with library unload upon read or write.
  - Performance improvement in setting records for symbols.
- Note: `ConstContainer` and the corresponding symbols will be dropped with the next major GAMS version. Users are advised to use `Container` and accompanying symbols.

GDX

- The dynamic library file on Linux (.so), macOS (.dylib), and Windows (.DLL) has been changed from `(lib)gdxdclib64` to `(lib)gdxcclib64` after porting the GDX codebase from Delphi to C++. While the GDX API remains compatible, the underlying shared library is very different and cannot be renamed back. Therefore, a copy of the old `(lib)gdxdclib64.{so,dylib,DLL}` is still distributed with GAMS for now. Eventually the Delphi library will be dropped, hence it is sensible to compile existing user applications against the new C++-based GDX library and corresponding API files.
- Modified function `gdxDataReadRawFastEx` to allow the callback function to stop the reading after each record. The callback must now return an integer indicating if reading should be continued (>=1) or stopped (=0).

GMD

- Fixed a problem that resulted in a crash when retrieving the domain list with an alias of symbol (`gmdGetDomain`).

GMO

- As announced, the functions `gmoEvalFuncNLCluster` and `gmoEvalFuncNLCluster_MT` have been removed.

Java

- Added method `runEngine` to `GAMSJob` class to run jobs on GAMS Engine.
- Changed minimum requirement of Java SE to compile and run a Java program using the latest GAMS Java API:
  - All classes in `[Path/To/GAMS]/apifiles/Java/api/GAMSJavaAPI.jar` require Java SE 11 or later to run.
  - `GAMSJavaAPI.jar` has an additional dependency on `JSON.simple`, located in `[Path/To/GAMS]/apifiles/Java`
  - `GAMSJavaAPI.jar` and `json-simple-1.1.1.jar` are required to be in the same directory to run.
- Changed GAMS Java API name for a Java program that still requires Java SE 8 to compile and run:
  - All classes that target Java SE 8 are in `[Path/To/GAMS]/apifiles/Java/api/GAMSJavaAPI-8.jar`.
  - New or updated functionalities may not be made available in this version, only corrective maintenance support will be provided in the future.
  - `GAMSJavaAPI-8.jar` has no additional dependency.

Python

- We plan to drop support for Python 3.7 in a future GAMS release.

3.5.1.9 Model Libraries

GAMS Test Library

- Dropped `SELKIE` test models `selkie01` through `selkie19`.
- Added **load18.gms : Test gdxLoad**.
- Added **calabelm.gms : Test Connect agent LabelManipulator**.
- Added **solveopt01.gms : Test solveopt option and command line parameter**.

3.5.2 44.1.1 Maintenance release (August 03, 2023)

3.5.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Hugo Joudrier-Faure.

3.5.2.2 Solvers

COPT

- New libraries 6.5.7.

HiGHS

- New libraries 1.5.4.

NLPEC

- Fixed that the setting of option NCPBounds was not being honored for doubly-bounded variables.
- Fixed implementation of reformulation type `FB_neg`.
- Fixed implementation of reformulation type `min` for the case of upper-bounded variables and no slack variables.

3.5.2.3 APIs

GAMS Transfer Matlab

- Fixed bug when using more than 255 UELs.

GAMS Transfer R

- New libraries 2.4.0.
  - Fixed read for `Variable` and `Equation` classes where the `lower` and `upper` attributes were interchanged.

3.5.3 44.2.0 Minor release (August 17, 2023)

3.5.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Mogens B. Laursen, Orenzo Porporino, and Hannes Wornig.

3.5.3.2 GAMS System

GAMS

- Fixed errors with $declareAndLoad and $gdxLoadAll which could have caused problems when dealing with aliases.
- Fixed a memory leak with the Multi-Threading Solve Facility (`solveLink=6/7`).

Embedded Python Code Facility

- Fixed a problem when command line parameter `pyMultInst` has been set to 1. Please note that the interrupt signal (e.g., from Ctrl-C) in embedded Python code does not work with `pyMultInst=1`.

GAMS Connect

- Allow the LabelManipulator agent to convert multiple labels to the same target label.

3.5.3.3 Installer

- Fixed a bug of the Windows installer overwriting an existing license file from a previous installation with the demo license.

3.5.3.4 Solvers

SoPlex

- Improved performance for passing the LP to SoPlex.

3.5.3.5 Tools

GAMS Studio

- New version 1.15.3 with some bug fixes and minor enhancements:
  - Fixed missing OpenSSL library on Linux.
  - Fixed missing projects when a project path is missing.
  - Fixed a bug in the GDX Viewer where restoring a symbol state of a partially loaded symbol resulted in a crash.
  - Fixed crash on closing a GDX Viewer instance while symbol data is loading.
  - Fixed GAMS process not terminating when closing Studio.
  - Improved handling of interrupt and stop.

3.5.4 44.3.0 Minor release (September 01, 2023)

3.5.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.5.4.2 Solvers

BARON

- Fixed that setting GAMS option threads to a negative value did not enable parallelization in MIP solver.

CBC

- Fixed that solver did not stop on interrupt signal.

CPLEX

- Fixed model status for CPLEX's termination `CPXMIP_OPTIMAL_POPULATED_TOL` and incorrect infeasibility warning for `CPXMIP_OPTIMAL_POPULATED` and `CPXMIP_OPTIMAL_POPULATED_TOL`.

HiGHS

- Fixed issue when running HiGHS more than once in the same process with multiple threads enabled.

NLPEC

- Fixed an incorrect reformulation (required equations were omitted from the reformulated model) that occured when aggregate was set to `partial none`.
- Fixed case where an invalid option combination (aggregate set to `full` but different reformulation type set for single and double) was allowed: this is now shifted to a valid option combination.

SHOT

- Fixed use of multiple threads with CBC as MIP solver.

3.5.4.3 Tools

GAMS Studio

- New version 1.15.4 with some bug fixes and a minor enhancement:
  - Added tab key support for filter widgets in GDX Viewer.
  - Fixed the GDX Viewer not displaying symbol data with too many records by only showing about the first 107 million entries.
  - Fixed path selection for GAMS license installation.

3.5.4.4 Model Libraries

GAMS Test Library

- Updated **casqlr.gms : Test Connect agent SQLReader**.
- Updated **casqlw.gms : Test Connect agent SQLWriter**.
- Added **nlpec03.gms : NLPEC test suite - loop over option combos**.

3.5.5 44.4.0 Minor release (September 19, 2023)

3.5.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Alan Fox, Erwin Kalvelagen, and Nick Sahinidis.

3.5.5.2 GAMS System

GAMS

- Fixed potential problem with $declareAndLoad when loading symbols with name clash for internal symbols or functions.

3.5.5.3 Solvers

CONOPT 3

- New libraries 3.17O.

CONVERT

- Fixed equation type in `=B=` and `=X=` equations in GAMS format.

3.5.5.4 Tools

GAMS Studio

- New version 1.15.5 with a bug fix and a minor enhancement:
  - Fixed crash in Reference File Viewer when searching for a symbol in `FileUsed` tab.
  - Removed the obsolete studio command line option `--help-all`.

3.5.5.5 APIs

GDX

- Fixed a bug causing large GDX files to be read incorrectly due to storing the number of remaining bytes (in the file) in a variable of wrong (not wide enough) type.

3.6 43 Distribution

3.6.1 43.1.0 Major release (April 27, 2023)

3.6.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Pedro Andres Sanchez-Perez, Mogens Bech Laursen, Bruce McCarl, Scott McDonald, and Thomas Rutherford.

3.6.1.2 Platforms

- The GAMS distribution is now also available as a native build for macOS 13 on ARM64 CPUs (Apple M1/M2). Compared to the macOS system for x86_64 CPUs, these are the differences:
  - Third-party software for which no native builds are available (so far):
    - BARON and hence no GAMS/BARON
    - FICO XPRESS and hence no GAMS/XPRESS
    - Matlab and hence no GAMS Transfer Matlab
  - Effects from `Intel's Math Kernel Library` not being available:
    - Pardiso is not available as linear solver in Ipopt.
    - Intel MKL is not available as blasoption for Knitro.
    - `Apple's Accelerate Framework` is used instead by ANTIGONE, CBC, IPOPT, SCIP, and SHOT.
  - The clang compiler frontend is Apple's preferred way to build C/C++ programs on macOS. A GCC variant of the high-level C++ API library has therefore not been included for this platform. GCC users can build the library from `source`.
  - Components marked as deprecated have not been ported:
    - GDXMRW
    - GDXRRW
  - Support for Python 3.7 and macOS versions 11 and 12 are not included.

3.6.1.3 GAMS System

GAMS

- The command line parameter logOption will change with the next major release. Currently, `logOption=1` sends the log output to the console (i.e. `con:` or `/dev/tty`). This feature is planned to be dropped. `LogOption=1` will become a synonym for the default `logOption=3`, which sends the log output to the standard output.
- Added new command line parameter writeOutput, which allows to suppress the creation of the output file completely.
- Added new keyword executeTool and put_utility 'execTool' to invoke tools from the GAMS tools library (see below) at execution time.
- Added new dollar control options $callTool and $hiddenCallTool to invoke tools from the GAMS tools library (see below) at compile time.
- Added new dollar control options $gdxLoadAll and $declareAndLoad, which allow a convenient import of all (even undeclared) symbols from a GDX file at compile time.
- Added new dollar control options $on/offImplicitAssign, which allow to suppress compilation error 141 ("Symbol declared but no values have been assigned."). This is useful in situations where the compiler is unaware that symbols are loaded implicitly (e.g. `execute_loadpoint "solutionfile.gdx"`).
- Added a new section to the end of the reference file that lists all files included.
- Extended some internal limits to allow generation of huge scalar models.
- Renamed compile time constants `platformCode.DEG` and `platformCode.LEG` to `platformCode.DEX` and `platformCode.LEX`, respectively, to be consistent with the system attribute `platform`.
- Minor adjustment to the return code of the function readyCollect: In the past, it returned `0` only if it waited until a job is ready to be collected. Now, it also returns `0` when there is a job ready to be collected without the need to wait for it (that case returned `1` in the past; now the meaning of `1` has changed to "There is neither an active job to wait for nor a job ready to be collected").
- Fixed function platformCode (was not working properly on macOS and Linux).
- Fixed an issue converting strings of length 255, which could cause problems when creating GDX files.
- Fixed a bug where scalars where not updated properly when implicitly loaded from embedded code inside a loop.

Documentation

- The PDF version of the documentation will be dropped in a future release.

Embedded Code Facility

- React on interrupt signal (e.g., from Ctrl-C) when executing embedded code. If an interrupt signal is received, the execution is interrupted and a compilation or execution error gets issued.
- Setting gams.debug only affects the debug behavior of the `GamsWorkspace` since the exception traceback is always enabled now.
- Fixed exception traceback being written to `stdout` instead of GAMS log.
- Fixed wrong line numbers in exception traceback.

GAMS Connect

- Exception traceback has been enabled for unhandled Python exceptions.
- The `debug` option of the Options agent has been deprecated and will be removed in a future version. Use the Options agent with trace > 0 instead to get the exception traceback of Connect errors .
- Fixed exception traceback being written to `stdout` instead of GAMS log.
- Added RawCSVReader agent to Connect.
- Updated long label renaming logic in RawExcelReader so that the suffix number `~n` gets incremented only when necessary.
- With pandas version 1.5.0, the `mad` aggregation method is deprecated and, therefore, will not be available for the Projection agent in a future release.
- The Concatenate agent now supports concatenating the same symbol more than once.
- The SQLReader and SQLWriter agents (former `PandasSQLReader` and `PandasSQLWriter`) have been revised and now support native SQL connections for faster read/write operations. Both agents now connect to MySQL, Postgres, MS-SQL (SQL-Server), SQLite and PyODBC through their respective python package. `pandas.DataFrame` class' I/O API methods `read_sql` and `to_sql` can be used in combination with `connectionType sqlalchemy` and allows to connect to any other database if the relevant drivers are present on the system.
- The SQLWriter agent supports writeAll. If `True`, all symbols (sets and parameters) in the Connect database will be written to the specified database.

GMSPython

- Added the packages `pymssql` and `pymysql`. For macOS on ARM64 CPUs the additional package `freetds` has been added as a dependency for `pymssql`.

3.6.1.4 Solvers

ANTIGONE, CBC, Ipopt, SCIP, SHOT

- New libraries Intel MKL 2023.1 on Linux and macOS for x86_64.

CBC

- New libraries Cbc 2.10.10, Cgl 0.60.7, Clp 1.17.8, CoinUtils 2.11.8.
  - Extensions to symmetry handling.
  - New values `fastish`, `lightweight`, `moreprinting`, `cuts`, and `cutslight` for option OrbitalBranching.
- New libraries nauty 2.8.6.
- As announced, the CBC alias `COINCBC` has been dropped.

CONOPT

- As announced, the CONOPT3 alias `CONOPTD` has been dropped.

CONVERT

- The AMPL .nl writer can now write equation marginals as well.
- Added options AmplNlInitDual and AmplNlInitPrimal to specify which equation marginal and variable level values to write to AMPL .nl file.
- As announced, the CONVERT alias `CONVERTD` has been dropped.

COPT

- New libraries 6.5.2.
  - Enhanced support for special ordered sets and indicator constraints.
- Added possibility to write solve trace files. New options solvetrace, solvetracenodefreq, and solvetracetimefreq.

CPLEX and OSICPLEX

- GAMS/CPLEX can now be used to solve LPs and MIPs without a GAMS/CPLEX or GAMS/CPLEX Link license, but with a OSICPLEX license. It is thus similar to the GAMS/CPLEX Link license, but restricted to (mixed-integer) linear problems. To use ranging, conflict analysis, feasopt, tuning, column generation, solution pool, lazy constraints, quadratic constraints, indicator constraints, linear user cuts, multi-objective optimization, priorities, benders decomposition, or user callbacks, a GAMS/CPLEX or GAMS/CPLEX Link license is still required.
- GAMS/OSICPLEX is now an alias for GAMS/CPLEX. The alias GAMS/OSICPLEX will be dropped with a future major release. Former GAMS/OSICPLEX option files cannot be processed by GAMS/CPLEX.
- As announced, the CPLEX alias `CPLEXD` has been dropped.

DE

- Introduced an experimental and hidden option `deDict` to produce a text file with dictionary type information of the generated deterministic equivalent.

DECIS

- As announced, the EMP-SP solver DECIS has been dropped. This does not effect the stochastic LP solvers DECISC and DECISM. They remain in the system.

Examiner

- Examiner is now solveLink=5 capable. Some cosmetic output changes were made.

GUROBI and OSIGUROBI

- New libraries 10.0.1.
- GAMS/GUROBI can now be used to solve LPs and MIPs without a GAMS/GUROBI or GAMS/GUROBI Link license if a separate GUROBI license is installed on the machine. It is thus similar to the GAMS/GUROBI Link license, but restricted to (mixed-integer) linear problems. To use quadratic constraints, indicator constraints, general or nonlinear constraints, lazy constraints, multi-objective optimization, multiple MIP starts, partitions, MIP stop expression, solution pool, feasopt, iis, sensitivity analysis, or tuning, a GAMS/GUROBI or GAMS/GUROBI Link license is still required.
- GAMS/OSIGUROBI is now an alias for GAMS/GUROBI. The alias GAMS/OSIGUROBI will be dropped with a future major release.

IPOPT

- As announced, the IPOPT alias `COINIPOPT` has been dropped.
- New libraries 3.14.12.
  - Fixed that for a square problem, the dual solution sometimes did not satisfy optimality conditions even though the problem was claimed to be solved to optimality.

KESTREL

- Removed access to discontinued IBM DOcloud.

LINDO/LINDOGLOBAL

- New libraries 14.0.255.

MILES

- As announced, the MILES alias `MILESE` has been dropped.

MINOS

- As announced, the MINOS aliases `MINOS5` and `MINOS55` have been dropped.

MOSEK and OSIMOSEK

- GAMS/MOSEK can now be used to solve LPs and MIPs without a GAMS/MOSEK or GAMS/MOSEK Link license if a separate MOSEK license is installed on the machine. It is thus similar to the GAMS/MOSEK Link license, but restricted to (mixed-integer) linear problems. To use second-order, semidefinite, power, or exponential cones, a GAMS/MOSEK or GAMS/MOSEK Link license is still required.
- GAMS/OSIMOSEK is now an alias for GAMS/MOSEK. The alias GAMS/OSIMOSEK will be dropped with a future major release.
- GAMS/MOSEK should work equivalently to GAMS/OSIMOSEK in most cases. The main differences are:
  - A MIP solve is now followed by an LP solve with all discrete variables fixed by default. Use option SOLVEFINAL to turn this off.
  - Setting GAMS option integer2 does not enable writing the instance to a file anymore. Set option MSK_SPAR_DATA_FILE_NAME instead.

Octeract

- New libraries 4.7.1.

ODHCPLEX

- New libraries 7.07.
  - New option addcuts: Indicator for adding cuts from CPLEX master solve.
  - New option firstfeaslpitlim: Limit on number of relaxed re-solves in first feasible heuristic.
  - New option firstfeasrelaxcrit: Smallest sum of infeasibilites/row where relaxed solution used.
  - New option ignoresetslvrparams: Flag to control whether solver parameters can be dynamically altered by ODH.
  - New option keypartition: Use of solver partition information.
  - New option keysminimum: Minimum number of keys that the automatic decomposition method attempts to find.
  - New option localsearch: Indicator for local search heuristic.
  - New option loosefeastol: Loose feasibility tolerance.
  - New option objthreshold: Threshold for absolute value of objective coefficients.
  - New option sosfind: Automatic detection of special ordered sets (SOSs).
  - New option sosinkey: Assign each SOS to its own sub-model component (key).
  - New option sosmember: Automatically detect SOSs whose variable member names match this pattern.
  - New option sosovar: Automatically detect SOSs whose output variable name matches this pattern.
  - New option sosselect: Select sub-set of SOS members.
  - New option sosselect16: Select sub-set of SOS members for sets with 16 or fewer members only.
  - New option soswvar: Automatically detect SOSs whose input(weight) variable name matches this pattern.
  - New option strictdeterministic: Terminate ODH deterministically when improvement heuristic finishes.
  - New option subcheckfreq: Frequency with which sub-model LPs are interrupted for mutual communication.
  - New option tightenprebounds: Level of bound tightening in ODH presolved model.
  - New option trialbound: Trial bound heuristic.
  - New option trialboundfile: Trial bound file.
  - New option trialboundsetsize: Size adjustment to automatically generated trial bound sets.
  - New option usehistory: Use of past sub-model selections in current selection.
  - New option varcleanlpmethod: Method used to solve variable cleaning LPs.
  - Changed lower bound of option interdiv to 1.
  - Removed lower bound of option seed. Changed default value to 12345.
  - Changed lower bound of option feastol to 0 and upper bound to 1.
  - Changed lower bound of option subnodelimit to -2.
  - Changed lower bound of option divisor to 2 and default value to 4.
  - Changed upper bound of option decompdensity to 1.
  - Changed upper bound of option firstfeascontinue to 2. Changed option type to integer.
  - Changed default value of option firstfeasshift to 0.
  - Changed default value of option recurseminiterlim to 10.
  - Changed default value of option variableclean to 1.
  - Removed option `newcallback`.
  - Removed option `odhpresolve`.
  - Removed option `subpresolve`.

PATH

- The PATH alias `PATHC` has been dropped.

SCIP

- New libraries bliss 0.77.
- As announced, the SCIP alias `COINSCIP` has been dropped.

SOPLEX

- As announced, the SOPLEX alias `OSISOPLEX` has been dropped.

XPRESS and OSIXPRESS

- New libraries 41.01.03.
- GAMS/XPRESS can now be used to solve LPs and MIPs without a GAMS/XPRESS or GAMS/XPRESS Link license if a separate XPRESS license is installed on the machine. It is thus similar to the GAMS/XPRESS Link license, but restricted to (mixed-integer) linear problems. To use quadratic constraints, nonlinear constraints, indicator constraints, priorities, MIP trace, solution pool, a GAMS/XPRESS or GAMS/XPRESS Link license is still required.
- GAMS/OSIXPRESS is now an alias for GAMS/XPRESS. The alias GAMS/OSIXPRESS will be dropped with a future major release.

3.6.1.5 Tools

$LibInclude files

- The libinclude files `gdxservice`, `linalg` and `win32` are deprecated and will be removed in a future release. Please use the corresponding tools of the more flexible and convenient GAMS tools library instead.

CHK4UPD

- As announced, the command line tool `CHK4UPD` has been dropped. The functionality of that tool is still available through GAMS Studio.

CSDP

- As announced, the tool `csdp` has been dropped. GAMS/MOSEK could be used instead.

GAMS Studio

- New version 1.14.2.
  - Improved command line parameter handling for projects:
    - Added editor for parameter file.
    - Added "Add new GAMS Parameter File" to Project Explorer context menu.
    - Added selection of main and parameter file in Project Settings.
  - Added GAMS Engine authorization by token.
  - Added GDX Viewer setting to control decimal separator used when copying data.
  - Added "File Used" section in reference file viewer.

GAMS Tools Library

- The GAMS tools library is a collection of tools to provide an easy access to a complex task. The traditional tool collection will be replaced over time by GAMS Connect agents and tools in the GAMS tools library. For some time both ways will be supported but the executable tools will go away, so when in doubt what tool to pick, select Connect or a tool from the GAMS tools library.
- The GAMS tools library currently consists of the categories `alg` with Rank, `data` with ExcelDump, `gdxservice` with GDXEncoding and GDXRename, `linalg` with Cholesky, Eigenvalue, Eigenvector, Invert, and OLS (Ordinary Least Squares), and `win32` with ExcelMerge, ExcelTalk, MSAppAvail, and ShellExecute.
- From within a GAMS program, tools from the GAMS tools library can be invoked via $callTool (compile time) and executeTool or put_utility 'execTool' (execution time).
- From a shell/command prompt the script gamstool can be used to run tools from the GAMS tools library.

GDXTROLL

- As announced, the tool `gdxtroll` has been dropped.

MPS2GMS

- MPS2GMS can now be instructed to add up or ignore multiple coefficients for the same term in the objective or a constraint of an LP file. See new option `DUPLICATES` in the MPS2GMS documentation.

3.6.1.6 APIs

GAMS Engine API

- Updated for GAMS Engine version 23.03.31.

GAMS Transfer Matlab

- Breaking: `Symbol.domain_labels` now mirrors the column or field names for domains in `Symbol.records`. Changing `Symbol.domain_labels` will change `Symbol.records` and vice versa. `Symbol.domain_labels` now exists in `struct` and `table` format only. Domain fields in records are those fields that are not one of the following:
  - Variables and equations: `level`, `marginal`, `lower`, `upper`, `scale`.
  - Parameters: `value`.
  - Sets: `text`.

  Furthermore, the default labels changed: If `Symbol.domain_names` is a unique list of domain names, then those names are used as domain labels. Otherwise, the previous label strategy "<name>_<dim>" is used. For example, a symbol with domain {`i, j`}, now has domain labels `i` and `j` in records and with a domain {`i, j, i`} it stays `i_1`, `j_2`, `i_3` (unless the table columns or struct fields are named differently by the user).
- Added possibility to modify `Symbol.domain_labels` to any unique list of domain labels. If `Symbol.domain` is modified, domain labels are reset to default label strategy, described above.
- Changed `Symbol.domain_forwarding` to be a vector of length `Symbol.dimension` to enable/disable domain forwarding for each dimension independently.
- Removed `Symbol.getCardinality`, `Symbol.getUELLabels`, `Symbol.initUELs`, and `Container.getUniverseSet`.
- Fixed possibly incorrect order of UELs of symbols in `dense_matrix` or `sparse_matrix` format.
- Fixed `Symbol.setRecords` for cell input and symbols of dimension >= 3.

GAMS Transfer Python

- Breaking: renamed `generateRecords` argument `densities` to `density`.
- Breaking: removed the `getCardinality` method.
- Breaking: renamed $*$ column for `UniverseAlias` symbols to `uni` to be more consistent with other symbol formats.
- Breaking: new dataframe column naming convention. Defaults to `domain_names` if unique. If not unique, `domain_names` will be tagged with a dimension index. Can be customized with new `domain_labels` setter functionality.
- `Container` and `ConstContainer` have been made iterable.
- Exposed `Const`$*$ symbol classes to the user in order to enable better tab completion behavior.
- New symbol method `toValue` (for scalar symbols) – returns symbol records as `float` (underlying Pandas DataFrame is not modified).
- New symbol method `toList` (for all symbols) – returns symbol records as a python `list`.
- New symbol method `toDict` (for only Parameter, Variable and Equation symbol types) – returns symbol records as a python `dict`.
- Allow a `list` of `bool` to be passed to `domain_forwarding` to selectively forward set elements.
- Following GAMS convention, singleton sets can no longer be used to define a symbol domain.
- Small adjustments to the object string representation (`__repr__`) functions.
- Added an `is_scalar` symbol property to (Const)Variable and (Const)Equation symbols.

- Added support for `len` function to `Container` and `ConstContainer` – returns the number of symbols in the container.
- Added support for `PathLike` objects in `load_from` argument.
- Better handling of `str` type relative paths in `load_from` argument.
- Drop unused categories from columns when using `generateRecords`.
- Fixed bug in `getUELs` when there were unused categories in the domain set and the data were out of order from the category order. Impacted behavior of `toDense` and `toSparseCoo` methods.
- Removed the previously deprecated `getUniverseSet` method, use `<container>.getUELs()` instead.
- Better error message with `whereMin`, `whereMax`, `whereMaxAbs` functions if all symbol values are `NaN`.

GAMS Transfer R

- New libraries 1.16.0.
  - Added checks for singleton and multidimensional checks in `Symbol` method `isValid()`.
  - Changed the default domain labels. User-specified domain labels are preserved if unique.
  - Performance improvement in `Container` method `read`.

GDX

- Added new function `gdxDataReadRawFastEx` that behaves like `gdxDataReadRawFast` but works with a callback function that also has the `DimFrst` and `UserMem` argument.

GMO

- Added new function `gmoGetObjL` to get objective activity level. This is useful when reformulating models.
- Functions `gmoEvalFuncNLCluster` and `gmoEvalFuncNLCluster_MT` are declared deprecated and will be removed with the next major release.

Java

- **GAMSModelInstance** of this version is no longer compatible with GAMS 33 or older.

Matlab

- Added option `implicitAssign` to `GAMSOptions` and enumeration class `ImplicitAssign`.

.Net

- `GAMSModelInstance` of this version is not compatible anymore with GAMS 33 or older.

Python

- Added support for Python 3.11.
- **GamsModelInstance** of this version is not compatible anymore with GAMS 33 or older.
- The Python examples located in <sysdir>/api/python/examples have been updated and revised.
  - The examples xp_example[1|2].py have been renamed to core_example[1|2].py.

3.6.1.7 Model Libraries

GAMS EMP Library

- Updated **farmsp.gms : The Farmer's Problem - Stochastic**.

GAMS Model Library

- Updated **schulz.gms : Termination routine to ensure solvers stay with resource limit**.
- **gqapsdp** and **kqkpsdp**: SDPs are now solved with Mosek.

GAMS Test Library

- Updated **carxr.gms : Test Connect agent RawExcelReader**.
- Added **carcr.gms : Test Connect agent RawCSVReader**.
- Added **output01.gms : Test Output related Command Line Parameters**.
- Added **conopt03.gms : CONOPT test suite - different libraries in one process**.
- Added **interrupt.gms : Check Ctrl-C/Interrupt handling of Embedded Code, MIP solver, and GAMS**.
- Added **load17.gms : Test $declareAndLoad and $gdxLoadAll**.
- Added **implassign01.gms : Test implicitAssign**.
- Renamed capdsqlr to **casqlr.gms : Test Connect agent SQLReader** and updated for revised SQLReader.
- Renamed capdsqlw to **casqlw.gms : Test Connect agent SQLWriter** and updated for revised SQLWriter.

3.6.2 43.2.0 Minor release (May 04, 2023)

3.6.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Ferris and Mehmet Sert.

3.6.2.2 GAMS System

GAMS

- Improved the dollar control options $declareAndLoad to consider domain information and the subtype of a symbol as well (i.e., distinguish between positive and free variables).

3.6.2.3 Solvers

CPLEX, GUROBI, XPRESS

- Fixed that the bare-bone mode to solve LPs or MIPs was not accessible.

GUROBI

- Fixed that models with quadratic equations were rejected when using model type (D/(R)MI)NLP.

3.6.2.4 Tools

GAMS IDE

- Fixed that GAMS did not run anymore.

3.6.2.5 APIs

GAMS Transfer R

- New version 1.18.
  - Added `isScalar` property for the symbols of type `Variable` and `Equation`.
  - Updated symbol method `reorderUELs()`. If the argument `uels` is not passed, UELs are reordered based on the records.
  - Symbol method `isValid` now checks also for scalars with more than one record entries.
  - Breaking: Symbol method `toDense()` now requires domain UELs and domain records to be in the same order and unused UELs in the domain (if any) at the end of the UEL list.
  - Breaking: Container method `read` now preserves the domain type from the source and avoids domain linking by symbol name.
  - Breaking: Symbol method `getCardinality` is removed.
  - Fixed bug in longer symbol `description`.
  - Fixed bug in accessing Container symbols in a case-insensitive manner.
  - Fixed bug in the Container method `describeAliases`.

Jupyter Notebooks

- New optional argument `--system_directory=<path/to/gams>` for `gams_reset` used to explicitly specify a GAMS system directory.

Python

- The pip extras `all` and `connect` now install `psycopg2-binary` instead of `psycopg2` in order to avoid additional dependencies when installing the GAMS Python API.

3.6.2.6 Model Libraries

GAMS Test Library

- Updated **gamsjupyter01.gms : Test GAMS Jupyter Notebooks**.

3.6.3 43.3.0 Minor release (May 18, 2023)

3.6.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.6.3.2 GAMS System

GAMS

- Fixed a wrong default value of 255 for the command line parameter putPW (the default is actually 32767).

3.6.3.3 Solvers

COPT

- New libraries 6.5.3.

HIGHS

- Fixed that solver link crashed when interrupted.

3.6.3.4 Tools

GAMS Studio

- New version 1.14.3 with some bug fixes and minor enhancements, for example:
  - Added `abort` and `abort.noError` to highlighter and completer.
  - Fixed connecting to GAMS Engine via HTTPS on macOS.
  - Fixed GAMS Engine failing when using a parameter file.
  - Fixed false detection of `parmFile` command line parameter.
  - Fixed font not immediately updating after changing it in "Settings > Editor & Log".
  - Fixed crash in Connect Editor when opening a file containing unknown schema name.

3.6.3.5 APIs

Jupyter Notebooks

- Fixed a bug where specifying the `--system_directory` argument of `gams_reset` had no effect.

Python

- Fixed a problem with the debug output of Control API destructors.

3.6.4 43.3.1 Maintenance release (June 01, 2023)

3.6.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Gabriel Homsi.

3.6.4.2 GAMS System

Installer

- Fixed a problem of the Windows installer that prevented successful installation with a system account that misses a user documents directory.

3.6.4.3 Solvers

HiGHS

- Fixed crash when resolving model instance after modification of constraint coefficients.

3.6.5 43.4.0 Minor release (June 15, 2023)

3.6.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Bruce McCarl, Alberto Valsecchi, and Wolfgang Britz.

3.6.5.2 GAMS System

GAMS

- Removed the capability to execute tools via the put_utility 'execTool'.
- Fixed a bug in $declareAndLoad which caused any Alias being loaded as Singleton Set.

3.6.5.3 Solvers

COPT

- New libraries 6.5.4.

3.6.5.4 Tools

GAMS Studio

- New version 1.14.4 with some bug fixes and minor enhancements, for example:
  - Delay license dialog to ensure Studio is already visible.
  - Added information to system log with Studio start arguments.
  - Added warning to system log if setting files could not be created.
  - Fixed issues with parameter file on macOS and Linux.
  - Fixed project setting for parameter file lost or reset on Studio restart.
  - Fixed OpenSSL issue for Manjaro, Ubuntu 22.04 LTS, and similar Linux distributions.

3.6.6 43.4.1 Maintenance release (June 22, 2023)

3.6.6.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Guido M. Bazzani, Hirotaka Isogai and Bruce McCarl.

3.6.6.2 Solvers

CONOPT

- Fixed that when CONOPT reported about variables or equations to the listing file, the wrong variable/equation was refered to (the prior variable/equation was mentioned instead).

CPLEX

- Fixed that a wrong CPLEX algorithm was called for final solve of a MIQP with fixed discrete variables.
- Automatically change the optimality target to look only for a locally optimal solution (value 2) of a fixed MIQP solve.

3.6.6.3 Tools

GAMS Studio

- New version 1.14.5 with some bug fixes:
  - Fixed error link from lst to code not working.
  - Fixed parameters ignored when no pf-file is assigned to the project.
  - Fixed order of parameters: parameter-box can overrule pf-file.
  - Fixed parameters were cleared when project settings were opened.
  - Fixed pf-file set to `-none-` hasn't been stored.
  - Fixed project file name contains suffix like ".gms" when automatically created.

3.7 42 Distribution

3.7.1 42.1.0 Major release (February 01, 2023)

3.7.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Brian Sergi.

3.7.1.2 Platforms

- As announced, dropped support for macOS 10.15 (Catalina).
- As announced, dropped support for Windows 8.
- Added support for macOS 13 (Ventura).

3.7.1.3 GAMS System

- The End User License Agreement (`eula.pdf` in the GAMS system directory) has been updated to version 01/2023.

GAMS

- Change for the profile option: Entry `Solve Alg` was renamed to `Solver`. The value reported with it matches now the value from model attribute etSolver. In previous versions, `Solve Alg` was reported to be zero when running with solveLink=0. This has been fixed.
- Improved speed in GAMS and GDX for models with many labels.
- In case the overall GAMS program uses some extrinsic functions but the particular model instance does not, then the extrinsic functions are not loaded any longer into the solver link.
- Added dollar control option $save[.keepCode] to create a work file during compilation.

Connect

- Added new Filter agent to reduce symbol data by applying filters on labels and numerical values.
- The PandasExcelReader now enforces sufficient ranges. A range must cover the complete dimension of a symbol including its value (parameter) or text (set). Reading set element text is mandatory and can no longer be skipped. Dropping unwanted text can be achieved using the Projection agent.
- The PandasExcelWriter supports `.xlsx` and `.xlsm` files. `.xls` files are not supported. For other file formats, such as `.ods` files, it might be required to install additional Python packages.
- The PandasExcelReader supports `.xlsx` and `.xlsm` files. For other file formats, such as `.xls` or `.ods` files, it might be required to install additional Python packages.
- Improved exception messages for various Connect agents.
- Fixed bug where writer agents would fail if a symbol was read empty by one of the reader agents.
- Fixed a bug in the PythonCode agent that prevented local variables to be accessible in a subsequent enclosing namespace.

Embedded GAMS Code Facility

- Added GAMS to the family of supported embedded code languages.

Embedded Python Code Facility

- Fixed a crash when using `gams.printLog()` with LogOption being set to `0` (no log output).

GMSPython

- The Python version of GMSPython has been updated to `3.8.16`.

3.7.1.4 Solvers

BARON

- New libraries 23.1.5.
  - Significant improvements for quadratic programs, tree management strategies, and integer presolve.

CBC

- The time reported back to GAMS (e.g., resUsd attribute) is now measured by the clock that is specified by the clocktype option.
- We plan to drop the CBC alias `COINCBC` with the next major release.

CONOPT

- We plan to drop the CONOPT3 alias `CONOPTD` with the next major release.

CONVERT

- Added concurrent mode (value 3) to option qextractalg.
- We plan to drop the CONVERT alias `CONVERTD` with the next major release.

COPT

- New libraries 6.0.4.
  - COPT can now solve convex MIQCPs and MISOCPs. Enabled GAMS model type MIQCP for COPT.
  - A parameter tuning tool has been added. New options Tuning, TuneParams, TuneMethod, TuneMode, TuneMeasure, TunePermutes, TuneOutputLevel, TuneTargetRelGap, TuneTargetTime, TuneTimeLimit.
  - Option Crossover is now an integer option with possible values -1, 0, and 1.
  - Added possible value 5 for option LpMethod: automatic choice of LP method
- Changed type of option iis from boolean to integer. Added value 2 to request an IIS computation without a previous solve.

CPLEX

- New libraries 22.1.1.0.
  - Added option cardls: decides how often to apply the cardinality local search heuristic (CLSH).
- Added concurrent mode (value 3) to option qextractalg.
- Changed default of rerun to `nono`. With this change the solver may not be able to distinguish between unbounded and infeasible models anymore and may just report the model to be infeasible. In order to check for unbounded models, set rerun to `yes` to rerun the optimization with presolve turned off.
- We plan to drop the CPLEX alias `CPLEXD` with the next major release.

DE

- Added option empInfoFile to DE.

DECIS

- We plan to drop the EMP-SP solver DECIS with the next major release. This does not effect the stochastic LP solvers DECISC and DECISM. They will remain in the system.

GUROBI

- New libraries 10.0.0.
  - Added option softmemlimit: Soft memory limit.
  - Added option obbt: Controls aggressiveness of optimality-based bound tightening.
  - Added option networkalg: Network simplex algorithm.
  - Added support of nonlinear constraint `r =e= sigmoid(x)` (or `r =e= 1 / (1 + exp(-x))`), see Gurobi: Nonlinear Programming.
- Added concurrent mode (value 3) to option qextractalg.
- Changed default of rerun to -1 (no). With this change the solver may not be able to distinguish between unbounded and infeasible models anymore and may just report the model to be infeasible. In order to check for unbounded models, set rerun to 1 to rerun the optimization with presolve turned off.
- Fixed multimipstart: Initial guess could have been sent to Gurobi in a wrong order and thus be rejected by Gurobi, e.g., as infeasible.
- Removed requirement of being a MIP to use mipstart, multimipstart, or varhint because Gurobi may switch to "MIP mode" (branch-and-bound) during solve (e.g. for nonconvex QCPs).

HiGHS

- New libraries 1.4.1.
  - Added option mipstart: Initial level values can be passed as starting point to a MIP (if no semicontinuous or semiinteger variables are present). If infeasible, then HiGHS attempts to find a feasible assignment of the continuous variables by solving an LP.
  - Improved reliability of interior-point solver if cross-over is not always run.
  - Option run_crossover changed from boolean to string. New possible value "choose", to run crossover only if the result without crossover is imprecise.
  - Added options to enable and adjust "iCrash": icrash, icrash_approx_iter, icrash_breakpoints, icrash_dualize, icrash_exact, icrash_iterations, icrash_starting_weight, icrash_strategy.
  - Option write_solution_style: New value -1 now specifies "oldraw" format (was value 2 before); value 2 and new value 3 now allow to print solution in GMPL format.
  - New options presolve_rule_logging and presolve_rule_off.

IPOPT

- We plan to drop the IPOPT alias `COINIPOPT` with the next major release.

KNITRO

- New libraries 13.2.0.
  - New option presolveop_redundant: Determine whether or not to enable the Knitro presolve operation to detect and remove redundant constraints.
  - New option mip_gomory: Specifies rules for adding Gomory mixed-integer cuts.
  - New value for option presolveop_tighten: 2 and 3.
  - New value for option mip_clique: -1 (new default). Removed value 3.
  - New value for option mip_knapsack: -1 (new default). Removed value 3.
  - New value for option mip_zerohalf: -1 (new default). Removed value 3.
  - New value for option mip_liftproject: -1 (new default). Changed option type to integer.
  - Changed default value of option mip_cutting_plane: 1.
- Added concurrent mode (value 3) to option qextractalg.

LINDO/LINDOGLOBAL

- New libraries 14.0.204.
- Added option empInfoFile to LINDO.

MILES

- We plan to drop the MILES alias `MILESE` with the next major release.

MINOS

- We plan to drop the MINOS aliases `MINOS5` and `MINOS55` with the next major release.

MOSEK

- Made parameters MSK_IPAR_PTF_WRITE_PARAMETERS and MSK_IPAR_PTF_WRITE_SOLUTIONS available.
- Added concurrent mode (value 3) to option QEXTRACTALG.

OCTERACT

- New libraries 4.6.0.
  - Removed the possibility to use Gurobi or Xpress as MIP solver. Removed GUROBI and XPRESS from possible values for options `MILP_SOLVER` and `MIP_SOLVER`.

ODHCPLEX

- Added concurrent mode (value 3) to option qextractalg.
- Changed default of rerun to `nono`. With this change the solver may not be able to distinguish between unbounded and infeasible models anymore and may just report the model to be infeasible. In order to check for unbounded models, set rerun to `yes` to rerun the optimization with presolve turned off.

SCIP

- We plan to drop the SCIP alias `COINSCIP` with the next major release.

SELKIE

- We plan to drop the research solver `SELKIE` with the next major release.

SHOT

- Added concurrent mode (value 3) to option ModelingSystem.GAMS.QExtractAlg.

SOPLEX

- We plan to drop the SOPLEX alias `OSISOPLEX` with the next major release.

XPRESS

- New libraries 41.01.01.
  - Dynamic adjustment of the reliability threshold for pseudo cost updates.
  - Improved branching strategies on MIP models with highly degenerate objective function.
  - Extended the effect of numericalEmphasis to some bound tightening reductions. This can help to avoid wrong answers in case of numerically challenging problems.
  - New option globalBoundingBox: If a nonlinear problem cannot be solved due to appearing unbounded, it can automatically be regularized by the application of a bounding box on the variables.
  - New option timeLimit: Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time.
  - New option solTimeLimit: Maximum time in seconds that the Optimizer will run a MIP solve before it terminates, given that a solution has been found.
  - New option preConfiguration: Determines whether binary rows with only few repeating coefficients should be reformulated.
  - New option primalOps: Allows fine tuning the variable selection in the primal simplex solver.
  - New options cutSelect_gomory and treeCutSelect_gomory: Strong Chvatal-Gomory cuts.
  - New options cutSelect_farkas and treeCutSelect_farkas: Farkas cuts.
  - New option feasibilityJump: Decides if the Feasibility Jump heuristic should be run.
  - New bits in cutSelect, treeCutSelect and barRegularize.
  - New option value (2) for xslp_solver: Use Xpress-Optimizer if possible (convex quadratic problems only).
  - New default for option xslp_iterLimit: 1000.
  - New default for option xslp_mipDefaultAlgorithm: 3.
  - Option xslp_postsolve has been changed from boolean to integer with new default -1: Postsolve if the problem could be solved to optimality/infeasibility.
  - Options maxStallTime and maxCutTime have been changed from integer to double options.
  - Deprecated options `maxTime` (use timeLimit or solTimeLimit instead), `cacheSize`, `l1Cache` and `sleepOnThreadWait`.
  - Removed options `extraPresolve` and `lpThreads`.
- Added concurrent mode (value 3) to option qextractalg.
- New bit options barPresolveOps_standard, barPresolveOps_extra, barPresolveOps_full.

3.7.1.5 Tools

$LibInclude gdxservice

- Added tool GDXEncoding to convert labels in a GDX file from one encoding to another one.

CHK4UPD

- We plan to drop the command line tool `CHK4UPD` with the next major release. The functionality of that tool will still be available through GAMS Studio.

CSDP

- We will remove the tool/solver `csdp` in a future GAMS release. GAMS/MOSEK should be used instead.

GAMS Studio

- New version 1.13.1.
  - New feature: GAMS Connect editor.
  - Project handling / Project Explorer improvements:
    - Projects get now saved to separate files automatically (`GSP` - GAMS Studio Project).
      - Each project is stored in a separate file, the `Project Settings` show a representation of that.
      - File menu and context menu now provide `Open Project`, `New project`, `Move Project File`, and `Copy Project`.
      - `Import project` and `Export project` have been removed.
      - A project name is tied to the name of the project file.
      - Projects in different paths with the same name get a number added. This number is assigned in the "name and path" order, so changing the path of a project may change the assigned number.
    - Fixed that projects were not always saved properly.
  - GDX Viewer improvements:
    - Improved numerical formatting of the GDX Viewer when using `g-format` with `Full` precision.
    - State of GDX files is now persistent even after restarting Studio.
    - Added symbol filter to GDX state and persist it.
    - Added support for label and value filters in GDX Viewer export functionality.
  - Improved Check for Update dialog, including HTML output and text updates.
  - Studio checks now online for a new available GAMS version when started (can be changed in the settings).
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Improved request behavior of GAMS Engine server communication.
    - Adjusted `Replace All` to show search term in clear text instead of internal representation.

GDXCOPY

- Fixed a problem with missing relaxed domain information in the copied GDX file.

GDXTROLL

- We will remove the tool `gdxtroll` in a future GAMS release.

GDX2XLS

- We will remove the tool gdx2xls in a future GAMS release. GAMS Connect agent PandasExcelWriter should be used instead.

MPS2GMS

- New libraries HiGHS 1.4.1 for LP/MPS reading.

XLS2GMS

- We will remove the tool xls2gms in a future GAMS release. GAMS Connect agent PandasExcelReader should be used instead.

XLSDUMP

- We will remove the tool xlsdump in a future GAMS release. GAMS Connect agent RawExcelReader should be used instead.

3.7.1.6 APIs

.Net

- Changed the `TargetFramework` of the GAMS .Net API from 4.0 to 4.5.
- Added method `RunEngine` to `GAMSJob` class to run jobs on GAMS Engine, rather than locally.

Matlab

- Added option SuffixAlgebraVars.
- Added option values RoundedFloatingDec (3) and ForEFloatingDec (4) to option PutNR.

GAMS Transfer Matlab

- Improved performance of `Container.hasSymbols`. Among others, this has a significant effect when adding many symbols.
- Added support of partial write.
- Added parameter `symbols` to `Container.write`, `Container.getDomainViolations`, `Container.resolveDomainVio` and `Container.isValid`.
- Added parameter `allow_merge` to `Container.renameUELs` and `Symbol.renameUELs` in order support merging UELs while renaming (renaming a UEL to an already existing UEL).

GAMS Transfer Python

- New `generateRecords` method to automatically generate records from domain information.
- New `pivot` convenience method to pivot symbol records into various shapes.
- Removed possible `dict` type for `rtol` and `atol` in `equals` method.

GAMS Transfer R

- `removeSymbols` removes symbol links in other symbols.
- Added `symbols` argument to Container methods `renameUELs` and `removeUELs`.
- `findDuplicateRecords` now returns a data frame instead of row indices.
- **Breaking**: `Container` `data` field is now an ordered dictionary from `collections` package instead of named list. Instead of `m$data$<symbolname>`, use `m[<symbolname>]`.
- Performance improvement to `Container` method `hasSymbols`. This results in significant speed-ups when adding multiple symbols to the container.
- Added `symbols` argument to `Container` methods `getDomainViolations`, `hasDomainViolations`, `countDomainViolations`, `dropDomainViolations`, `hasDuplicateRecords`, `countDuplicateRecords`, `dropDuplicateRecords`, `isValid`, and `write` for partial operation.
- `Container` method `getSymbols` now always returns a list.
- Added `equals` method to `Symbols` to check if symbols are equal.
- Bugfix in `SpecialValues$isNA`.
- Bugfix in `getUELs` for scalar symbols.
- Bugfix in `Symbol` method `isValid` for symbols containing only `NA`.
- Bugfix in `Variable` and `Equation` set records for numeric inputs.
- Added `equals` method for `Container` and `ConstContainer`.

Jupyter Notebooks

- Removed methods `gams.pivot` and `gams.pivot2d`. This functionality is now available from GAMS Transfer Python via the pivot method.
- As announced, the package `gams_magic_legacy` has been removed, use `gams.magic` instead.

Python

- The GAMS Python API structure has been revised. Detailed information about the new structure can be found in the Python API documentation:

  Attention

  - Due to the changed structure of the API, `import` statements in existing code might not work anymore - please refer to Migrate import statements for details on how to migrate.
  - Replaced the use of `distutils` by `setuptools`. Installation/uninstallation of the Python API is now done using `pip`.
  - All examples have been moved to `<sysdir>/api/python/examples` and are organized by sub packages.
  - Documentation has been restructured and contains information on the `GAMS numpy API` (previously `gams2numpy`) now.

3.7.1.7 Model Libraries

GAMS Model Library

- Added **binpacking.gms : Bin packing problem with different ways to estimate number of bins**.
- **maxcut.gms : Goemans/Williamson Randomized Approximation Algorithm for Max-Cut** : SDP is now solved with Mosek if called with `--SDPSOLVER=MOSEK`.
- **tablelayout.gms : Configuring text layout in table cells to minimize table height** : Uses now embedded code GAMS.

GAMS Test Library

- Added **scensol10.gms : MCP GUSS Test**.
- Added **cafilter.gms : Test Connect agent Filter**.
- Added **gdxencoding1.gms : Simple gdxencoding test**.
- Added **save3.gms : Test DCO save**.
- Added **embgms01.gms : Test for embedded code facility**.
- Added **embgms02.gms : Test for embedded code facility**.
- Added **embgms03.gms : Test projection operator when loading data from embedded code**.
- Added **embgms04.gms : Test continuation of embedded code blocks**.
- Added **embgms05.gms : Test merge/replace when loading data from embedded code**.
- Added **embgms06.gms : Test domain check/filtered when loading data from embedded code**.
- Added **embgms08.gms : Test filtered load from Embedded Code**.
- Added **embgms09.gms : Test Embedded Code after restart**.
- Added **gdxcopy6.gms : Test gdxcopy with relaxed domain information**.

API Library

- Added **gdxperf.gms : Test various GDX APIs and report run times**.
- Added **generate.gms : Generate some random but structured GDX files**.

3.7.2 42.2.0 Minor release (February 16, 2023)

3.7.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Lorena Reyes-Rubiano.

3.7.2.2 GAMS System

GAMS

- Fixed a potential problem that did not allow to execute an embedded code block as first statement in a repeat loop.
- Improved the way, the Grid Facility is executed to resolve a problem when running a GAMS model with solveLink=3 under GAMS MIRO.

3.7.2.3 Solvers

CONOPT

- New libraries 4.30.
  - Fixes an error (stop without termination message) for models with dummy objective function.

3.7.2.4 Tools

MPS2GMS

- Fixed that parameter `COLUMNINTVARSAREBINARY` could not be set.
- Fixed that objective function was lost if MPS reading falled back to the reader for the fixed MPS format.

3.7.2.5 APIs

GAMS Transfer R

- Significant performance improvement when reading from a GDX file.
- Partial domain forwarding is now allowed by passing a logical vector as the `domainForwarding` argument.
- Added `generateRecords` method for `Symbols` to automatically generate records.

3.7.3 42.3.0 Minor release (March 02, 2023)

3.7.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Yuzar Aryadi, Wolfgang Britz, Geoffroy Duparc-Portier, Scott McDonald, and Tom Rutherford.

3.7.3.2 GAMS System

GAMS

- Fixed a bug which could have caused a crash when option clear/kill was used inside a loop on symbol attributes.
- Fixed a bug which caused a potentially wrong dump file when Singleton Sets are loaded.
- Fixed a bug that could have caused an unwanted error in rare cases when relaxed punctuation was used to declare a list of symbols without separating them by comma.

GAMS Connect

- Fixed a problem with labels containing non-printable characters as well as wrong sheet size calculations in RawExcelReader.
- Fixed a problem in RawExcelReader with workbooks that did not have any cells with numerical data.
- Fixed bug in the CSVReader agent where `indexSubstitutions` in a stacked dimension would lead to `NaN`.
- Fixed bug in the CSVReader agent where `indexSubstitutions` would also substitute in the value column of parameters.
- Fixed bug in the CSVReader agent where index and text columns were read as numeric.
- Fixed bug where the CSVWriter agent converts the text column of a set to numeric.
- Fixed bug where the Concatenate agent converts GAMS `NA` into GAMS `UNDF` for a symbol that solely has GAMS `NA` und `UNDF` records.

3.7.3.3 Solvers

CPLEX

- Fix for the case that solvefinal failed: GAMS/CPLEX will now return the solution from the preceeding full solve.

MOSEK

- Added workaround for crash when GAMS/Mosek link terminates after running Mosek with multiple threads.

3.7.3.4 Tools

GAMS Studio

- New version 1.13.3 with some bug fixes and minor enhancements, for example:
  - Added a special group `-GAMS-System-` on project level to bundle files like `Changelog` and `gamsconfig.yaml`.
  - Added support for macro symbol in Reference File Viewer.
  - Enabled controls for empty symbols in GDX Viewer as well.
  - Fixed crash when reloading an empty GDX symbol in table view mode.
  - Fixed several memory leaks.

3.7.4 42.4.0 Minor release (March 16, 2023)

3.7.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen and Pedro Andres Sanchez-Perez.

3.7.4.2 GAMS System

GAMS

- Fixed duplicate prints of some lines in the output file when $onDollar is set.

GAMS Connect

- Fixed bug where the Projection agent unintentionally alters source symbols in the Connect database.

3.7.4.3 Solvers

BARON

- New libraries 23.3.11.
  - Fixed that a wrong dual bound was reported for a maximization problem when interrupted by the user (`SIGINT`).

CONOPT

- Worked around some library symbol mix-ups when using both CONOPT 3 and CONOPT 4 in the same GAMS process with solvelink 5 or higher on Linux.

COPT

- New libraries 6.0.5.

CPLEX

- Fixed hanging program after fulfilled or ignored mipstopexpr.

HiGHS

- New libraries 1.5.1.
  - New value 4 for option write_solution_style.
  - Changed default for option presolve_rule_logging from 1 to 0.

MOSEK

- New libraries 10.0.38.

SCIP Optimization Suite

- New libraries SCIP 8.0 (1870b6ada8).
- New libraries PaPILO 2.1 (cf0c6277).

SHOT

- New libraries 1.1 (3ba57397).

3.7.4.4 Tools

GAMS Studio

- New version 1.13.4 with some bug fixes and minor enhancements, for example:
  - Added support for Connect filter agent to Studio connect editor.
  - Fixed crash on creating an `.opt` file via context menu in the Project Explorer.
  - Fixed wrong `.opt` file extension which prevented saving.
  - Fixed value edit in GAMS Configuration Editor and allowed to delete `minVersion` and `maxVersion` values.
  - Fixed GdxDiffDialog crash after opening an input file on macOS.

3.7.4.5 APIs

GAMS Transfer Python

- Fixed a bug associated with long symbol descriptions

Python

- Fixed a bug where **GamsWorkspace.add_job_from_file** did not raise an exception in case of a non-existing file.
- Fixed a bug where **GamsModelInstance.copy_modelinstance** did fail if the source instance was instantiated with **GamsModifiers** for parameters.
- Fixed the `==` operator of **_GamsSymbol** and its subclasses that resulted in `True` even for different symbols.
- Fixed **GamsWorkspace.add_database_from_gdx** not raising an exception in case of argument `gdx_file_name` being `None` or the empty string.
- Changed return type of the `==` operator of **_GamsSymbolRecord** and its subclasses from `int` to `bool`.

3.7.5 42.5.0 Minor release (March 30, 2023)

3.7.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jason Hayes and Scott McDonald.

3.7.5.2 GAMS System

GAMS Connect

- Fixed the Projection agent failing on empty symbols.

Installer

- Fixed a problem of the Windows installer that prevented successful installation with a system account (e.g. when using SCCM).

3.7.5.3 Solvers

PATH and PATHNLP

- New libraries 5.0.07.

CONVERT

- Fixed writing `eps` instead of 0 for linear coefficients in GAMS format.

3.7.5.4 Tools

subsubsection g4250_STUDIO GAMS Studio

- New version 1.13.5 with some bug fixes and minor enhancements, for example:
  - Added automatic opening of project editor after creating a new project.
  - Fixed duplicated tab in reference file viewer when reloading a reference file.
  - Fixed crash on macOS when a GAMS related file is opened via double-click in Finder.
  - Fixed broken compilation error link to `.gms` file in `.lst` file.

3.7.5.5 APIs

GAMS Transfer R

- Significant performance improvements when writing a GDX file from a Container.
- Fixed bug in Container read when reading a `Symbol` with unused UELs.
- Fixed bug in `todense` method for `Symbol`.
- Fixed bug in writing empty container.
- Added `Symbol` method `copy` to copy symbol from one `Container` or `ConstContainer` to another `Container`.
- Added `Container` and `ConstContainer` method `copy` to copy symbols to another Container.
- Fixed bug in using ConstContainer Alias methods when the aliased parent set is absent.

3.8 41 Distribution

3.8.1 41.1.0 Major release (October 28, 2022)

3.8.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Sebastian Braun, Wolfgang Britz, Arne Stolbjerg Drud, Michael Ferris, Mitch Phillipson, and Zhang Tao.

3.8.1.2 Platforms

- We plan to drop support for macOS 10.15 with the next major release.
- We plan to drop support for Windows 8.1 with the next major release.

3.8.1.3 GAMS System

Connect

- Symbol names in Connect are now case insensitive. The global attribute `caseSensitiveLookup` has been removed.
- Added new Concatenate agent that allows concatenating multiple symbols into a single symbol.
- The `CSVReader`, `PandasExcelReader`, and `PandasSQLReader` now read relaxed domain information.
- The `PandasSQLReader` now supports pyodbc connections. The connection type can be configured via the new option connectionType.
- Options `readAll` and `writeAll` available in some agents allow and default to value `auto`. So if the `symbols` section is missing, `auto` becomes `True`, otherwise `False`.
- Fixed bug where `PandasExcelWriter` and `PandasSQLWriter` would not properly close the file/database connection in case of an exception.
- Fixed bug where `GAMSWriter` and `GDXWriter` would fail when writing an empty symbol with relaxed domains.
- Fixed bug where `PandasExcelReader` and `CSVReader` would generated `NaN` entries for labels with trailing spaces.

GAMS

- As announced we have removed language elements to access some commercial and licensing information:
  - System suffixes `components`, `clipCodes`, `clipComponentMap`, `componentSolverMap`, `gamsLicenses`, `gamsLicenseTypes`, `lice1`, `lice2`, `licenseDateEvalN`, `licenseDateEvalS`, `licenseDateMaintN`, `licenseDateMaintS`, `licenseDateN`, `licenseDateS`, `licenseDateSysN`, `licenseDateSysS`, `licenseDaysEval`, `licenseDaysMaint`, `licenseDC`, `licenseEval`, `licenseID`, `licenseInstitution`, `licenseLevelText`, `licenseLicensee`, `licenseMudText`, `licensePlatform`, `licensePlatformText`, `licenseStatus`, `licenseStatusText`, `licenseType`, `licenseVendor`, and `vendors`.
  - Predefined sets `componentEDate`, `componentMDate`, and `componentLicenseOptions`.
  - Many of these elements were used in the GAMS Model Library model `licememo`, which we also dropped.
- Added new intrinsic functions lseMax, lseMaxSc, lseMin, and lseMinSc.
- Added new dollar control options $on/offSuffixAlgebraVars and related command line parameter SuffixAlgebraVars to disallow the use of variable suffixes (aka. attributes) in model algebra. This option allows to easily detect unintentional use of variables with suffixes in equation algebra.
- Improved message when exceeding the limit of the GAMS Community License or Demo License.
- Patched up the Windows memory reporting for showOSMemory and procTreeMemMonitor, and added clarifying documentation.

GMSPython

- Added the package `psycopg2`.
- Removed the package `pyyaml-include`.

Embedded Python Code Facility

- On Windows, the directory with the Python DLL is automatically added to `PATH`, so some DLLs are properly found.

3.8.1.4 Solvers

ANTIGONE, CBC, Ipopt, SCIP, SHOT

- Updated MKL to 2022.2.0 on Linux and macOS.

BARON

- New libraries 22.9.30.
  - Better treatment of convex and quadratic problems, including improved relaxations for binary quadratic programs.
  - Improved cutting, range reduction, and branching strategies.
  - Improved continuous and integer presolve algorithms.
  - Improved interfaces to CPLEX, CBC, and IPOPT.

CONOPT

- New libraries 3.17N.
- New libraries 4.29.

CONVERT

- Added option AmplNL: Generates AMPL `.nl` file.
- Added option AmplNLBin: Enables to write `.nl` file in binary format.

COPT

- New libraries 5.0.5.
- Value 1 for option Presolve has been changed to mean "fast presolve". Additional values 2 and 3 have been added to specify normal and aggressive presolving levels.

CPLEX

- Changed iis from boolean to integer option and added option value 2: Conflict analysis without previous solve.
- The time reported in model attribute resUsd now corresponds to the chosen clock type. That is, the CPU time spend by CPLEX is reported if `clocktype` is changed to 1.

DICOPT

- Added option dumpsubprob to activate writing of MIP and NLP subproblems as GAMS files.

GUROBI

- Added support for more nonlinear constraints: 1-norm, 2-norm, and inf-norm specified as nonlinear expressions.
- Deprecated dot-option `.GenConstrType`: Please use nonlinear expressions instead.
- Changed iis from boolean to integer option and added option value 2: Conflict analysis without previous solve.

Ipopt

- New libraries 3.14.10.
- Small performance improvement for problems with i) linear objective function, ii) quadratic objective and linear constraints, iii) only linear equality constraints, or iv) only linear inequality constraints.

Lindo/LindoGlobal

- New libraries 14.0.162:
  - LP Solver Improvements:
    - Improved algorithms for searching alternative optima.
  - MIP Solver Improvements:
    - Improved selection of search parameters when solving difficult instances.
  - Linearization:
    - Recognition of more expressions than previous versions.
    - Advanced linearization of QP and conic models.
  - Nonlinear Solver Improvements:
    - Recognition of fractional linear programs and algorithmic improvements for this class.
  - Global Solver Improvements:
    - Introduce auxiliary variables to optimize in hyperspace for improved performance.
    - Improved warning messages for possible sub-optimal solutions.
    - Improved bound-tightening process.
- Added support for new intrinsic function lseMax.

MOSEK

- New libraries 10.0.25.
  - Improved presolve for conic problems.
  - Improved performance of interior-point optimizer for large-scale LPs and when running on recent AMD CPUs.
  - Improved cutting plane separation and presolve for mixed-integer programs.
    - Default of option MSK_IPAR_MIO_CUT_IMPLIED_BOUND changed from off to on.
    - New option MSK_IPAR_MIO_CUT_LIPRO to enable lift-and-project cuts.
    - New option MSK_IPAR_MIO_PRESOLVE_AGGREGATOR_USE to control use of aggregator.
  - Added symmetry detection and exploitation for mixed-integer programs. New option MSK_IPAR_MIO_SYMMETRY_LEVEL to control level of symmetry detection and handling.
  - Introduced reformulations for MIQCPs, which allows solution of more non-convex MIQCPs that can be reformulated into convex ones. New option MSK_IPAR_MIO_QCQO_REFORMULATION_METHOD to set reformulation method.
  - Added possibilities to enable memory saving and higher numerical emphasis for mixed-integer programs by use of new options MSK_IPAR_MIO_MEMORY_EMPHASIS_LEVEL and MSK_IPAR_MIO_NUMERICAL_EMPHASIS_LEVEL, respectively.
  - Added possibility to solve continuous problem obtained from fixing all integer variables to initial level values by enabling new option MSK_IPAR_MIO_CONSTRUCT_SOL.
  - Additional option changes:
    - New option MSK_DPAR_PRESOLVE_TOL_PRIMAL_INFEAS_PERTURBATION to specify amount by which Mosek can perturb problem in presolve to avoid infeasibility.
    - Removed option `MSK_IPAR_INTPNT_MULTI_THREAD`.
    - Removed moderate and aggressive scaling options from MSK_IPAR_INTPNT_SCALING and MSK_IPAR_SIM_SCALING.
    - New option MSK_IPAR_MIO_DATA_PERMUTATION_METHOD to enable permutation of mixed-integer problems.
    - New option MSK_IPAR_WRITE_JSON_INDENTATION to control whether json files are written with indentation.
    - Removed options `MSK_IPAR_WRITE_LP_QUOTED_NAMES`, `MSK_IPAR_WRITE_LP_STRICT_FORMAT`, `MSK_IPAR_WRITE_LP_TERMS_PER_LINE`, and `MSK_IPAR_WRITE_PRECISION`.

Octeract

- New libraries 4.5.1.

ODHCPLEX

- The time reported in model attribute resUsd now corresponds to the chosen clock type. That is, the CPU time spend by ODHCPLEX is reported if `clocktype` is changed to 1.

SCIP

- New libraries 8.0.2.

XA

- As announced, dropped XA.

XPRESS

- New libraries 40.01.03.

3.8.1.5 Tools

GAMS Studio

- New version 1.12.1.
  - New feature: Navigator (`Ctrl+k`)
    - Please note: this feature is currently in beta and does not have mouse support yet!
    - Filter files by typing a search term, wildcards are also supported (e.g.: `*.gms`).
    - Press `Enter` to jump to a selected file.
    - Type `?` to show help about all available prefixes.
    - The `GoTo`- and `TabBrowser`-dialogs are now obsolete and will be removed in the future.
  - GDX Viewer improvements:
    - New feature: Added first version of an export dialog, currently supporting Excel output only.
    - New feature: Added quick selection to GDX Viewer filters.
    - Improved auto-resizing behavior.
    - Improved symbol table colors especially when the theme has changed.
  - Search and Replace improvements:
    - Added highlighting to matches in `Search Result View`.
    - Added capture group support for regular expressions in `Search Dialog`.
  - Added filter to MIRO deploy dialog and EFI editor.
  - Added function to open directly in Pin-View from Project Explorer by `Ctrl+double-click` (for horizontal pin) or `Ctrl+Shift+double-click` (for vertical pin).
  - Added icons to the main tabs (except for macOS).

- Added editor settings to skip syntax highlighting for long lines (this can improve performance significantly).
- Stability improvements, bug fixes, and minor enhancements, e.g.:
  * Changed GAMS version mismatch error message to a warning message.
  * Fixed GDX Viewer crash when reloading a file with an alias selected.
  * Fixed crash when switching tabs on macOS.
  * Fixed project changes on search over multiple files where a file is linked to more than one project.
  * Fixed unexpected behavior when adding the main file to an EFI file.
  * Fixed wrong context menu for new entry in Project Explorer after using `Save as...`.
  * Fixed that models with names containing spaces failed to be executed on NEOS and Engine.

GDXRRW

- GDXRRW is now deprecated and will be removed in a future release. Please use GAMS Transfer R instead. If you encounter issues with the transition to GAMS Transfer R or if you have any feature requests for GAMS Transfer R or concerns about the transition, do not hesitate to contact GAMS support.

GDXXRW

- When the limit on number of supported of rows or columns is reached when reading from a file, a warning is now given that subsequent entries might have been skipped.

$libInclude win32

- Added `XLSMerge` functionality to <`sysdir`>\`inclib`\`win32.gms` to merge two Excel workbooks.

3.8.1.6 APIs

gams2numpy

- Non-UTF-8 characters do not result in an exception anymore. Instead, such characters are transferred to an alternative representation by using the Python error handler `backslashreplace`. This change affects `gams2numpy` and all its clients – `GAMS Transfer`, `Connect`, and `gams_magic` (Jupyter notebooks).
- The binaries are now build with `numpy 1.21.6` for Python 3.7 and `numpy 1.23.3` for Python 3.8, 3.9, and 3.10.

GAMS Transfer Matlab

- Breaking: Symbol name uniqueness is now checked case insensitively. For example, it is not possible anymore to have three different symbols named `symbol`, `Symbol`, and `SYMBOL`.
- Breaking: Changed `Symbol.addUELs` signature from `addUELs(dim, uels)` to `addUELs(uels, dim)`. `dim` is now allowed to accept a vector of dimensions.
- Breaking: Changed `Symbol.setUELs` signature from `setUELs(dim, uels)` to `setUELs(uels, dim)` and `setUELS(_, "rename", true/false)`. Setting `rename` to `true` triggers the old `Symbol.initUELs`. `dim` is now allowed to accept a vector of dimensions.
- Breaking: Changed `Symbol.removeUELs` signature from `removeUELs(dim, uels)` to `removeUELs()`, `removeUELs(uels)`, and `removeUELs(uels, dim)`. `dim` is now allowed to accept a vector of dimensions.
- Breaking: Changed `Symbol.renameUELs` signature from `renameUELs(dim, olduels, newuels)` to `renameUELs(uels)` and `renameUELs(uels, dim)`. `uels` can now be `cellstr`, `struct`, or `containers.Map`. `dim` is now allowed to accept a vector of dimensions.
- Added method `Container.getSymbolNames` to return the original symbol names for a list of symbol names of any case.
- Added method `Container.hasSymbols` to check if symbol name (case insensitive) exists.
- Added method `Container.getUELs` to get UELs from all symbols.
- Added method `Container.removeUELs` to remove UELs from all symbols.
- Added method `Container.renameUELs` to rename UELs in all symbols.
- Added method `Symbol.reorderUELs` to reorder UELs without changing the meaning of records.
- Added flags `Container.modified` and `Symbol.modified` to indicate if a container and/or symbol has been modified since last reset.
- Added possibility to filter UEL codes in `Symbol.getUELs`.
- Added possibility to pass a vector of dimensions to `Symbol.getUELs`.
- Added possibility to overwrite symbols with `Container.add*` if main symbol definition (e.g. type, domain) is equal.
- Changed `Container.getSymbols`, `Container.removeSymbol`, `Container.renameSymbol`, `Container.describe*`, and others that use `Container.getSymbols` to accept symbol names case insensitively.
- Changed behaviour of default records: Default records do not get written to GDX anymore if the records format is `dense_matrix` and either the container is in indexed mode or if the symbol has a regular domain.
- Changed behaviour of `getDomainViolations`: As in GDX, different character case does not lead to a domain violation.
- Categoricals for record domain labels are now created with `Ordinal` set to `true`, but ordinal categoricals are not enforced, i.e., users may pass categoricals with `Ordinal` set to `false`.
- Changed symbol read order when reading a subset of symbols: Symbol order is defined by source order (e.g., symbol order in GDX file) rather than user supplied order. To establish a custom order after the read, use `reorderSymbols`.
- Deprecated `Symbol.getUELLabels`. Use `Symbol.getUELs` instead.
- Deprecated `Symbol.initUELs`. Use `Symbol.setUELs` instead.
- Deprecated `Container.getUniverseSet`. Use `Container.getUELs` instead.

- Fixed failing symbol constructors when using `domain_forwarding`, but none of the optional arguments.
- Fixed `Symbol.transformRecords` (table-like to matrix-like formats) in case the domain set records and UELs differ.
- Fixed write of sets defined over sets.

GAMS Transfer Python

- The API has been redesigned to more closely mimic GAMS behavior (i.e., GAMS is case preserving, not case sensitive).
- The `.data` dict has been replaced with a custom `dict` that preserves the case of symbol names. This mimics the convention in GAMS. Symbol lookup from this custom `dict` is case insensitive.
- Added new methods to customize dimension, symbol, and container UELs: `getUELs`, `setUELs`, `renameUELs`, `removeUELs`, `addUELs`, and `reorderUELs`
- New Symbol method `equals` can be used to compare symbol objects.
- Deprecated the container method `getUniverseSet`. This method will be removed in a future major release. Use `<Container>.getUELs()` instead.
- Container methods `addSet`, `addAlias`, `addParameter`, `addVariable`, and `addEquation` now allow for symbol overwriting. Previously, an error was raised and the symbol had to be removed before recreation.
- New class `UniverseAlias` and new Container method `addUniverseAlias` to allows creation of a symbol which is an alias to the universe (fixes bug).
- Container no longer link symbol categoricals together when setting records with `setRecords`; data that results in domain violations is not immediately lost and the user has greater flexibility to modify inplace to the `Container`.
- Updated behavior of `removeSymbols`: the domain of dependent symbols is relaxed to "$*$" if a set/alias is removed. If a parent set of an alias is removed, the alias symbol will also be removed automatically.
- Implemented a new class called `DomainViolation` to organize where domain violations occur in data.
- New method `getDomainViolations` to return a list of `DomainViolation` objects, should they exist.
- Methods $*$`DomainViolations` locate domain violations by referencing all appropriate domain sets. `findDomainViolations` now returns a view of the `records` DataFrame that contains all domain violations (previously returned only an `Index` where domain violations occurred).
- Methods $*$`DuplicateRecords` locate duplicate records on a case insensitive basis (consistent with GAMS behavior).
- Removed tests for duplicate records and domain violations from the `<Symbol>.isValid()` method. `<Symbol>.isValid()` validates the structural aspects of the data, not the quality of the data. This improves performance by not looping over all records.
- Created a Symbol `modified` flag that tracks if any changes have been made to a symbol. These flags can be set/reset by setting `<Container>.modified=True/False`.
- Enabled the use of the Python `in` operator to test if a symbol is `in` a container with the syntax `<symbol_object> in <container_object>` or `<symbol_string_name> in <container_object>`, where `<symbol_string_name>` is case insensitive.

- The Container is now subscriptable, i.e., `m[<symbol_name>]` returns the symbol object. Symbol objects are still accessible through the underlying dictionary, i.e., `m.data[<symbol_name>]`.
- `setRecords` now maintains user specified categoricals when passing a DataFrame.
- `setRecords`, `getUELs`, `setUELs`, `renameUELs`, and `addUELs` methods now strip any trailing whitespace from UELs.
- Improved Container behavior if reading from `ConstContainer`/`Container`: lists passed to the symbols argument `read(<source>, symbols)` are no longer considered to be ordered – previously, if an alias was listed before its parent set, an exception would occur.
- Fixed bug when attempting to read in a symbol named `all`, but the Container read in all symbols.
- Exposed (previously hidden) `ConstContainer` methods `getCardinality()` and `getSparsity()`.
- An exception is now raised if attempting to read a symbol that does not exist in the data source. Previously, such symbol names were silently ignored.
- Improved clarity of some exception messages and other error handling.
- Fixed bug that prevented `dict_keys` and `dict_items` (returns from dict methods `.keys()` and `.items()`, respectively) objects from being passed directly into `setRecords`.
- Fixed bug that resulted in a `NameError` when calling `.whereMin()` or `.whereMax()` on variables or equations.
- New tests within `<Container>.isValid()` method to detect broken container references in symbols and inconsistent symbol naming between the `<Container>.data` dict and the symbol objects. These issues can occur when creating new symbols in a container with a copy/deepcopy operation.
- Restructured `ConstContainer` symbol classes to improve read-only behavior.

GAMS Transfer R

- Breaking: Symbol name uniqueness is now checked case insensitively. For example, it is not possible anymore to have three different symbols named `symbol`, `Symbol`, and `SYMBOL`.
- Breaking: Symbol records and symbol names are treated in a case insensitive manner. Symbols domain is not checked automatically.
- Added a new class `ConstContainer` for efficient data transfer.
- Allow read from `Container`/`ConstContainer` into another `Container`.
- Added a method `Container$getSymbolNames` to return the original symbol names for a list of symbol names of any case.
- Added a method `Container$hasSymbols` to check if symbol name (case insensitive) exists.
- Changed `Container$getSymbols`, `Container$removeSymbols`, `Container$renameSymbol`, `Container$describe*`, and others that use `Container$getSymbols` to accept symbol names case insensitively.
- New Symbol methods `hasDuplicateRecords`, `countDuplicateRecords`, `findDuplicateRecords`, and `dropDuplicateRecords` to help debug and resolve errors with duplicate records.
- New Container methods `hasDuplicateRecords`, `countDuplicateRecords`, and `dropDuplicateRecords` to help find symbols that contain duplicate records that cause the Symbol to be invalid.
- New tests within `Container$isValid()` method to detect broken container references in symbols and inconsistent symbol naming between the `<Container>$data` field and the symbol objects.
- Method `isValid` does not check for symbol record domain columns being factors, for duplicates, and for domain violations.

- New Symbol methods `hasDomainViolations`, `countDomainViolations`, `findDomainViolations`, `dropDomainViolations`, and `getDomainViolations`.
- New Container methods `hasDomainViolations`, `countDomainViolations`, and `dropDomainViolations`.
- Allowed symbol overwriting with `addSet/addParameter/addVariable/addEquation/addAlias` methods when everything other than records and description is unchanged.
- Added methods `SpecialValues$isNA`, `SpecialValues$isEps`, `SpecialValues$isUndef`, `SpecialValues$isPosInf`, `SpcialValues$isNegInf` to test for special values.
- The argument for `where*` methods changed from `columns` to `column`.
- Trailing whitespaces is now removed automatically from UELs in `setRecords` and `*UEL` methods.

GMO

- Added a concurrent mode for QP extraction. In this mode, independent extraction methods are run in parallel threads. Extraction terminates when the first method completes. This is done row-wise: the concurrent threads work on each row in turn, using the result of the first thread to finish for that row and moving on together to the next row. Setting the `gmoQExtractAlg` property to 3 selects this method.
- Added new function `gmoGetQMakerStats` to get statistics about QP extraction.
- Added new function `gmoFillMatches` to complete the row/column matching for MCP models.
- Added new function `gmoLoadDataLegacyEx` to API: this function differs from the existing `gmoLoadDataLegacy` function in that the new function includes a flag `fillMatches` to toggle the completion of matching information for MCP models during the load.
- Changed the behavior of `gmoLoadDataLegacy` vis-a-vis matching information for MCP. Previously, `gmoLoadDataLegacy` behaved like `gmoLoadDataLegacyEx(fillMatches=true)`. With this release, it behaves like `gmoLoadDataLegacyEx(fillMatches=false)`. Users of this function that require the old behavior must switch to calling `gmoLoadDataLegacyEx(fillMatches=true)` or call `gmoFillMatches` explicitly.

Jupyter Notebooks

- The data synchronization between Python and GAMS relies now entirely on GAMS Transfer.
- *Environments* allow working with different GAMS instances.
- Instead of `gams_push` and `gams_pull` with various Python data formats, GAMS lines and cells automatically synchronize symbols between GAMS and Python.
- GAMS Symbols can now be declared in the Transfer container in Python rather than in the GAMS cells. Please inspect the Magic (Jupyter Notebooks) Magic "GAMS Jupyter API description" for details.
- The older version of GAMS magic commands is still available under `apifiles/Python/gams/gams_magic_legacy`. This will be removed with one of the next major versions.

Python

- Added example `transport_gt.py` that demonstrates how to combine the GAMS Python high level API with a GAMS Transfer Container, essentially replacing the `GAMSDatabase` class.
- Added method `run_engine` to `GAMSJob` class to run jobs on GAMS Engine, rather than locally.

3.8.1.7 Model Libraries

GAMS Data Library

- Added **connect05.gms : Simple Connect Example for Excel**.

GAMS Model Library

- Dropped `licememo`.

GAMS Test Library

- Added **fnlse.gms : Rough correctness test for LSE max/min intrinsics**.
- Added **fnlsemax.gms : Test correctness of LSEMax intrinsic**.
- Added **fnlsemaxsc.gms : Test correctness of LSEMaxSc intrinsic**.
- Added **fnlsemin.gms : Test correctness of LSEMin intrinsic**.
- Added **fnlseminsc.gms : Test correctness of LSEMinSc intrinsic**.
- Added **fnlseslv.gms : Rough solver correctness test for LSEMax intrinsics**.
- Added **caconcat.gms : Test Connect agent Concatenate**.
- Added **suffix02.gms : Test CLP suffixAlgebraVars**.

FIN Library

- Fixed **ThreeStageSPDA : A three stage stochastic programming model for SPDA**.

PSOPT Library

- Fixed **DED : Dynamic Economic Load Dispatch**.
- Fixed **DED-PB : Price based Dynamic Economic Load Dispatch**.
- Fixed **DED-wind : Dynamic Economic Load Dispatch considering Wind generation**.
- Fixed **DEDESS : Cost based Dynamic Economic Dispatch integrated with Energy Storage**.
- Fixed **DEDESSwind : Cost based Dynamic Economic Dispatch integrated with Energy Storage and Wind**.
- Fixed **ESSDCOPFwind : DC-OPF integrated with Energy Storage and Wind**.
- Fixed **MultiperiodDCOPF24bus : Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding**.
- Fixed **PBUC : Price based Unit commitment**.

3.8.2 41.2.0 Minor release (November 14, 2022)

3.8.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz.

3.8.2.2 GAMS System

GAMS

- Improved the dollar control options $abort[.noError], $error, and $log, so that the text given as an optional argument is not limited to 255 characters anymore.
- Fixed the creation of a potentially wrong dump file with dumpOptGDX.

3.8.2.3 APIs

GAMS Transfer Python

- Enabled writing of partial `Containers` to GDX with `write_symbols` argument.
- Changed `Container.write()` argument `write_symbols` to `symbols` to better harmonize with Matlab and R versions of GAMS Transfer.
- Fixed bug with `equals` symbol method when comparing `UniverseAliases`.

Jupyter Notebooks

- Fixed a bug in `%gams` line magic that prevented code containing dashes preceded by a space from being executed properly.

3.8.3 41.3.0 Minor release (November 28, 2022)

3.8.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Mart Saluri.

3.8.3.2 GAMS System

GAMS

- Improved performance when using the command line parameter GDX for programs with many labels.
- Fixed a potential problem using a platform specific license with the pLicense parameter.

3.8.3.3 Solvers

COPT

- Fixed that option AbsGap was not available.

Lindo/LindoGlobal

- New libraries 14.0.191.

3.8.3.4 Tools

GAMS Studio

- New version 1.12.2 with some bug fixes and minor enhancements, for example:
  - Added support for trailing `:NUMBER` when choosing files in Navigator.
  - Fixed crash when moving line in text file.
  - Fixed crash when reloading an invalid GDX file.

3.8.3.5 APIs

GMO

- Fixed function `gmoNameInput`: in case old control files are read, the result string was uninitialized.

3.8.4 41.4.0 Minor release (December 14, 2022)

3.8.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.8.4.2 Solvers

GUSS

- Fixed a bug that could have caused unwanted skipping of scenarios when the scenario data is sparse.

MOSEK

- New libraries 10.0.31.

SCIP Optimization Suite

- New libraries SCIP 8.0.3.
- New libraries SoPlex 6.0.3.
- New libraries PaPILO 2.1.2.

3.8.4.3 Tools

GAMS Studio

- New version 1.12.3 with some bug fixes and minor enhancements, for example:
  - Added `x` prefix to Navigator to access Quick Actions.
  - Unified Navigator input field with other search fields, adding regex and exact match modifiers.
  - Fixed behavior of `Squeeze Trailing Zeroes` check box in GDX Viewer when using `g-format` or `e-format` with `Full` precision.
  - Fixed help view being empty on some Linux distributions.

3.8.4.4 APIs

GAMS Transfer Python

- Fixed `setRecords` throwing an exception in case of labels that differ in trailing spaces only.
- Fixed a bug when reading data from multiple sources with a single `Container` instance.
- Fixed a bug when writing a GDX file with a symbol list.
- Fixed a bug that prevented writing when the first symbol in the `Container` is a `UniverseAlias`.

Jupyter Notebooks

- Utilize partial GDX writing of GAMS Transfer containers in GAMS magic. Only symbols that are new or modified will be written to GDX. This improves the data exchange performance between Python and GAMS.

3.8.5 41.5.0 Minor release (January 03, 2023)

3.8.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.8.5.2 Solvers

CONVERT

- Fixed error messages to be thrown incorrectly when using external functions (files were written correctly).

GUSS

- Fixed a problem with MCP models and variable fixings as scenario data.

Mosek

- New libraries 10.0.33.

3.8.5.3 APIs

gams2numpy

- Fixed a memory leak in `gdxWriteSymbol[Raw|Str]` and `gmdFillSymbol[Raw|Str]`.
- Fixed a problem with uel and string numbers that do not point to a label or element text.
- Improve performance converting GDX/GMD strings to Python strings.
- Allow to specify an optional encoding string for methods `[gdx|gmd]GetUelList` and `[gdx|gmd]ReadSymbol[Raw|Str]`.

3.9 40 Distribution

3.9.1 40.1.0 Major release (August 01, 2022)

3.9.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Daniel Dias, and Scott McDonald.

3.9.1.2 GAMS System

GAMS

- Added two new indexed operators sAnd and sOr.
- The file containing the collection of legacy default values has been renamed from `gams31config.yaml` to `gamsLegacyConfig.yaml`, as legacy behavior is not entirely identical to GAMS 31.
- Changed default of command line parameter digit to `off`. As a result, extremely large or small constants in the GAMS source will not result in compilation errors but rather in special values (e.g. 1e300 becomes UNDF, 1e-300 becomes EPS). The old default `digit=on` has been added to `gamsLegacyConfig.yaml`.
- Changed default of model attribute tolProj to 0. This means that GAMS no longer by default modifies solution values returned by the solver that are close to variable bounds or equation sides.
- Throw a compilation error consistently, when one tries to load data into an Alias. In the past, this was just ignored in some cases. It appears that when writing to an alias in embedded code an exception is made and GAMS implicitly imports into a set, not an alias. Details about this subtlety can be found in the embedded code chapter.
- Made command line parameter IDCProtect available as runtime option as well (the runtime option gets initialized by the command line parameter).

- Do not allow to load a symbol implicitly from $offEmbeddedCode under $onExternalInput, when it was not declared as `external input` symbol (the same check was so far done for explicit loading only).
- Changed the interaction of external input and $gdxIn to allow the continued use of a `$gdxIn` file over multiple external input sections. So, the following code works now, but threw an error in the past:

```
$onExternalInput
$gdxIn trnsport.gdx
Set i(*) canning plants ;
$load i
$offExternalInput

* Do something but not opening another GDX file

$onExternalInput
Set j(*) markets ;
$load j
$offExternalInput
```

- Changed the behavior when encountering a symbol with unknown dimension with an execution time load or embedded code statement. In the past, this resulted in an error, now the dimension of that symbol is set to 0 (or 1, if it is a set) implicitly. As a result, the following code runs without error now:

```
$call gams trnsport gdx=default
Variable z;
execute_load 'trnsport.gdx', z;
display z.l;
```

- Also changed the behavior when encountering a symbol with unknown dimension with a compile time embedded code statement. In the past, this resulted in an error, now the dimension of that symbol is set to the dimension defined in the embedded code block.
- Make sure that we do not change the loop control index by implicit loading from endEmbeddedCode (the same check was so far done for explicit loading only).
- Added an explicit error check to ensure that the command line parameter restartNamed is used together with the command line parameter restart only.
- Changed the put utility facility to ignore the extra double quotes added when the print control is set to `4`, `5`, or `6`. In the past that lead to an error since the commands were not recognized when they are quoted.
- We plan to remove language elements to access some commercial and licensing information with the next major release:
  - System suffixes: `components`, `clipCodes`, `clipComponentMap`, `componentSolverMap`, `gamsLicenses`, `gamsLicenseTypes`, `lice1`, `lice2`, `licenseDateEvalN`, `licenseDateEvalS`, `licenseDateMaintN`, `licenseDateMaintS`, `licenseDateN`, `licenseDateS`, `licenseDateSysN`, `licenseDateSysS`, `licenseDaysEval`, `licenseDaysMaint`, `licenseDC`, `licenseEval`, `licenseID`, `licenseInstitution`, `licenseLevel`, `licenseLevelText`, `licenseLicensee`, `licenseMudText`, `licensePlatform`, `licensePlatformText`, `licenseStatus`, `licenseStatusText`, `licenseType`, `licenseVendor`, and `vendors`.
  - Predefined sets `componentEDate`, `componentMDate`, and `componentLicenseOptions`.
  - Many of these are used in the GAMS Model Library model `licememo`, which we also plan to remove.
- Fixed that exceeding the internal limit of 2.1 billion instructions did not raise an error.

- Fixed a rare problem which stopped GAMS from terminating if a solver invoked in an asynchronous thread did not return.
- Fixed an error causing missing domain information, when implicit sets are used while creating a dump file.

GMSPython

- Added the packages `sqlalchemy` and `greenlet` to GMSPython. On Windows, also added the packages `sqlalchemy-access`, `pyodbc`, and `pywintypes`.

Connect

- Domain information is copied into the Connect database when using agents GAMSReader and GDXReader. Agent GDXWriter exports the domain information to the GDX file.
- Added attribute `duplicateRecords` to GAMSWriter and GDXWriter to control the way to deal with duplicate records in a Connect container symbol when writing to GAMS or GDX. Note that both agents currently deal with duplicate records in a case sensitive way.
- Added new DomainWriter agent to modify domain information of Connect symbols.
- Added new PandasSQLReader and PandasSQLWriter agents to read from and write to SQL databases.
- Updated Projection agent:
  - Changed boolean attribute `dropText` to a string attribute text.
  - Added boolean attribute asParameter to turn variables into parameters with an extra index to store the suffixes.
  - Allow a list of symbol names for attribute name to combine multiple scalar symbols into a single one-dimensional symbol.
- Symbol names in Connect are now case sensitive by default. So casing in the YAML file is important and needs to match e.g. when reading from GDX or GAMS (which use case in-sensitive symbol name lookup) or across agents. There is now a global attribute caseSensitiveLookup in agent Options to control the case-(in)sensitive symbol lookup.
- Added new attribute `debug` in agent Options to provide traceback information in case of an exception.
- Dropped support for writing variables and equations with CSVWriter and PandasExcelWriter. Variables and equations can be turned into parameters using the Projection agent.
- Added attribute `trace` to GAMSReader, GAMSWriter, GDXReader, and GDXWriter.
- Fixed bug where PandasExcelWriter failed when writing no data.

Embedded Python Code Facility

- Allow to specify source code encoding by providing a comment of format `# coding=<encoding name>` as first line in an embedded Python code section.
- If `gams._debug` is set to an integer greater than 0 a traceback is printed to `stdout` in case of an exception.

Installer

- For Windows, updated the text in the file association dialog to make clear that the GAMS IDE is deprecated.

3.9.1.3 Solvers

BARON

- New libraries 22.7.23.
  - Improved presolve.

Bonmin and BonminH

- As announced, the solvers Bonmin and BonminH have been removed. For the time being, libraries of GAMS/Bonmin are available at the `COIN-OR GAMSlinks project`. Note, that GAMS does not test or offer support for these libraries.

CBC, SCIP, SHOT

- New libraries Cbc 2.10.8, Cgl 0.60.0, Clp 1.17.7, Osi 0.108.7, CoinUtils 2.11.6, nauty 2.7r3.

CONVERT

- Export prettier formulas (`x` for `x**1`, `power(x,1)`, `vcpower(x,1)` or `rpower(x,1)`).

COPT

- New libraries 5.0.2.
  - Added possibility to compute feasible relaxation for infeasible problem. New options FeasRelax and FeasRelaxMode to enable this feature and set relaxation mode, respectively. New dot option .feaspref to specify preferences on relaxation of variable bounds and linear constraint sides.
  - Added options MipStartMode and MipStartNodeLimit to adjust handling of complete and partial MIP starts.
  - Added option ReqFarkasRay.
  - Option crossover has been made available.
- Changed handling of MIP starting point:
  - GAMS/COPT will pass on a partial instead of a full MIP start also if `MipStartMode = 2` is selected.
  - When setting the value for a discrete variable in a partial MIP start (tryint > 0), it will be rounded to an integer value.
- For an unbounded LP, a primal ray is now returned in the variables level values and `UNBND` markers are set in the solution listing.
- For an infeasible LP, a Farkas proof is now returned in the equations marginal values and `INFES` markers are set in the solution listing.

GLOMIQO

- As announced, dropped GLOMIQO. The use of ANTIGONE is equivalent.

GUROBI

- New libraries 9.5.2.
  - Changed aggregate option type from `bool` to `int`. Allowed values are 0 (off), 1 (moderate) and 2 (aggressive).
- Added support of certain nonlinear constraints: `max`, `min`, `smax`, `smin`, `and`, `or`, `sand`, `sor`, `abs`, `exp`, `**`, `log`, `log2`, `log10`, `sin`, `cos`, `tan`, `edist`, `poly`.
  To make these accessible, Gurobi can now be used for model types (D)NLP and (R)MINLP as well, but equations need to follow a special form.
- Added option multimipstart: Use multiple (partial) mipstarts provided via GDX files.

HiGHS

- New LP/MIP solver HiGHS 1.2.2 developed by the Edinburgh Research Group in Optimization. HiGHS is included in the GAMS base system for users with an academic GAMS license. Users with a commercial GAMS license need to contact `sales@gams.com` to enable the use of HiGHS.

Ipopt

- New libraries Ipopt 3.14.9.
  - Added options ma27_print_level, ma57_print_level, and mumps_print_level.
  - Fixed that variable names for variable bounds in detailed log output were wrong for problems with fixed variables.
- New libraries Mumps 5.5.0.

KNITRO

- New libraries 13.1.0.
  - Significant performance improvements when using the BFGS/LBFGS Hessian approximation.
  - New options:
    - findiff_estnoise: Estimate of the noise in the model when using finite-difference.
    - bar_mpec_heuristic: Enable heuristic approach when solving MPEC models with the barrier algorithm.
    - mip_heuristic_misqp: Enable the MIP MISQP heuristic.
    - mip_restart: Enable the MIP restart procedure.
    - conic_numthreads: Number of threads to use for operations in the conic algorithm.

LGO

- As announced, dropped LGO.

MPSGE

- Increased the internal MAXFUN limit (from 10000 to 50000) on the number of components (inputs, outputs, taxes, etc.) in any MPSGE row.
- Print info about the size of the largest MPSGE function (i.e. the one with the most input/output/tax/etc coefficients) to the `sysout` file.

MSNLP

- As announced, dropped MSNLP.

Octeract

- The GAMS/Octeract link has been rewritten.
  - Temporary files are now removed, unless GAMS option keep is enabled.
  - Octeract is now also available for solvelink=5 and solvelink=6.
  - Octeract options are now documented and Octeract option files can be created via the GAMS Studio options editor.
  - The default for `MAX_SOLVER_ITERATIONS` is now set to GAMS iterlim.
  - The default for `MAX_SOLVER_MEMORY` is now set to GAMS workspace.
  - New option `nlbinary`.
- New libraries 4.4.1.

SCIP

- Added support for logical functions `bool_and`, `bool_eqv`, `bool_imp`, `bool_not`, `bool_or`, `bool_xor`. Only constants, binary variable, and logical functions are allowed as arguments for these operators. The GAMS/SCIP link introduces additional variables and constraints of types and, or, and xor to handle these functions.
- New libraries SCIP 8.0 (504f5f2749).
  - Improved and extended cut selection statistics.
  - Added options presolving/milp/maxbadgesizepar and presolving/milp/maxbadgesizeseq.
- New libraries PaPILO 2.1 (79da073).

XPRESS

- New libraries 40.01.01.
  - MIP performance improvements:
    - Improved separation of Mixed Integer Rounding (MIR) cuts in the tree.
    - Improved selection of cutting planes based on orthogonality measures.
    - Some subMIP heuristics at the root node now solve the subMIPs using multiple threads.
    - More advanced MIP presolve operations.
  - Improved crash heuristic for dual simplex.
  - Improved parallel performance of the crossover algorithm.
  - Improved sparse matrix-vector multiplication selection method in dual crossover.
  - New option numericalEmphasis: specify emphasis to place on numerical stability over solving time.
  - Changed default of treeCutSelect to -1.
  - Changed default of treeCutSelect_mirRowAggregation to 1.
- Support mipCleanup also for nonlinear models.

3.9.1.4 Tools

GAMS IDE

- Added a startup message to announce the drop of the classic GAMS IDE.

GAMS Studio

- New version 1.11.1.
  - New feature: Allow to open a directory to add all files in that directory to a project.
  - New feature: Added HTML format when copying text to clipboard.
  - GDX Viewer improvements:
    - Saves/restore state (e.g. filters, sorting, ...) when data has to be reloaded from file.
    - Added invert selection for column filter and for the attribute selection.
    - Fixed that auto resize of columns was not triggered for 1-dimensional symbols when the table view has been selected as default view.
  - Added zoom for editors/viewers with proportional fonts (GDX Viewer and Option Editor).
  - Added editor to edit `efi` files for GAMS Engine.
  - Improved and unified filter line edits for tables and trees to support regular expressions and exact matches.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Moved result files from an GAMS Engine run to the working directory.
    - Added link to MIRO output that opens the directory in the file explorer.
    - Improved trimming behavior of search results.
    - Adjusted wording in search results table header.
    - Fixed focus and auto-fill when re-triggering search dialog while it is already open.
    - Fixed "All Files" filter not showing files without extension on Linux and macOS.
    - Fixed error in restoring selection of MIRO deployment dialog.

GDX2ACCESS

- We will remove the tool gdx2access in a future GAMS release. GAMS Connect agent PandasSQLWriter should be used instead.

GDX2SQLITE

- We will remove the tool gdx2sqlite together with the tool `sqlite3` in a future GAMS release. GAMS Connect agent PandasSQLWriter should be used instead.

GDXVIEWER

- For the interactive mode added a startup message to announce the drop of the GDXVIEWER.

MDB2GMS

- We will remove the tool mdb2gms in a future GAMS release. GAMS Connect agent PandasSQLReader should be used instead.

MPS2GMS

- Fixed that non-continuous variables in cones (`CSECTION`) were missing in `=c=` equations in written GAMS file.
- Polished written GAMS file, in particular eliminate use of `$batinclude`.
- Quadratic cones (`CSECTION`) are now reformulated into quadratic equations. New option `CEQUATIONS` can be used to enable previous behavior of writing `=c=` equations.
- Input files that were compressed with gzip (`.gz`) can now be handled.
- Added support for input in LP format.
- Updated MPS reader to HiGHS 892691737.

SQL2GMS

- We will remove the tool sql2gms in a future GAMS release. GAMS Connect agent PandasSQLReader should be used instead.

3.9.1.5 APIs

GAMS Transfer Python

- Modified behavior of registering UELs: Previously, GAMS Transfer generated UELs from data in record order (i.e., all UELs from the first data row are registered, then all UELs from the next row are registered, etc.). GAMS Transfer now registers UELs columnwise (i.e., all UELs from the first domain column are registered, then all UELs from the next domain column are registered, etc.). This behavior change will impact symbols written over `"*"` or with relaxed domains.
- New `Symbol` methods `hasDuplicateRecords`, `countDuplicateRecords`, `findDuplicateRecords`, and `dropDuplicateRecords` to help debug and resolve errors with duplicate records.
- New `Container` methods `hasDuplicateRecords`, `countDuplicateRecords`, and `dropDuplicateRecords` to help find symbols that contain duplicate records that cause the `Symbol` to be invalid.
- New `Symbol` methods `hasDomainViolations`, `countDomainViolations`, and `dropDomainViolations` to help debug and resolve errors with domain violations.
- New `Container` methods `hasDomainViolations`, `countDomainViolations`, and `dropDomainViolations` to help debug and resolve errors with domain violations.
- Fixed that the column headings of the records `DataFrame` were not updated when a domain set/alias was renamed or the `.domain` attribute of a symbol was updated directly.
- Fixed read of equation with unknown subtype (recast as `=E=`/`eq`).

GAMS Transfer R

- New API GAMS Transfer R to exchange data between GAMS and R.

Python

- As announced, dropped support for Python 3.6.

3.9.1.6 Model Libraries

GAMS Data Library

- Added **connect04.gms : Simple Connect Example for SQL**.

GAMS Test Library

- Added **load15.gms : Test consistent compile time error checking when loading symbols**.
- Added **gurobi07.gms : GUROBI test suite - nonlinear constraints to general constraints**.
- Added **load16.gms : Test implicit dimension setting when loading a symbol**.
- Added **gamsxcppmex.gms : Test calling and validating new C++ compiler against legacy Delphi compiler**.
- Added **gdxdiff2.gms : Test GDXDIFFs fldonly option**.
- Added **capdsqlr.gms : Test Connect agent PandasSqlReader**.
- Added **capdsqlw.gms : Test Connect agents PandasSqlWriter**.
- Added **cadomainw.gms : Test Connect agent DomainWriter**.

3.9.2 40.1.1 Maintenance release (August 16, 2022)

3.9.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.9.2.2 GAMS System

GAMS

- Fixed a bug that cause restart files containing sums that add set elements to execute incorrectly. Restart files created with GAMS 40.1.0 carry this bug and should not be used but recreated.

3.9.2.3 Solvers

COPT

- New libraries 5.0.3.

MOSEK

- New libraries 9.3.21.

OCTERACT

- The options documentation provided on the Octeract webpage was apparently not uptodate when their last releases were made. Therefore, for the GAMS/Octeract link, the available options and their documentation also did not match the solvers libraries. We have updated these now and provide the list of changes to available options here:
  - Changed default for `BOUND_VIOLATION_TOLERANCE` from 1e-8 to 1e-6.
  - Added values `MOST_FRACTIONAL_VARIABLE` and `MODIFIED_MOST_NONCONVEX_VARIABLE` for option `BRANCHING_STRATEGY`.
  - New option `STRONG_BRANCHING_DEPTH`.
  - Removed `CBC_LB_MAX_NODES`. Added option `MILP_LB_MAX_NODES`.

  - Removed CBC_PRESOLVE.
  - Added values GUROBI and XPRESS for MIP_SOLVER (see also docu).
  - New options HEUR_INEQUALITY and HEUR_SUPREME.
  - Changed default for HEUR_NL_FEASIBILITY_PUMP from 0 to 1.
  - Replaced IS_PURGE_CUTS_ENABLED by new option PURGE_CUTS.
  - Added option LOCAL_SEARCH.
  - New option PRESOLVE.
  - New options REDUCE_LINEAR_CONSTRAINTS and STRENGTHEN_LINEAR_CONSTRAINTS.
  - Changed type of option REFORMULATE_INTEGERS_IN_MIQCQP to boolean.
  - New option USE_NONLINEAR_RELAXATION.
  - Changed default for OUTPUT_FREQUENCY from ∞ to 1.
- Fixed default for CONVERGENCE_TOLERANCE: Since Octeract uses this value as both absolute and relative gap tolerance, the default is now min(GAMS optcr, GAMS optca) to avoid too early termination on instances with objective value in (-1,1).
- Added workaround for wrong dual bound reported by Octeract if problem is reformulated into MILP and the MILP solver does not solve to optimality (e.g., stops due to a timelimit). This resulted in wrongly declaring solutions as global optimal.

SCIP

- New libraries 8.0 (0e5ff0a6b5).
  - Added options estimation/showstats, heuristics/alns/shownbstats, misc/showdivingstats to reenable some statistics that are now disabled.

3.9.3 40.2.0 Minor release (September 01, 2022)

3.9.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.9.3.2 GAMS System

GAMS

- Fixed the creation of a potentially wrong dump file with dumpOptGDX.

3.9.3.3 Solvers

COPT

- New libraries 5.0.4.

IPOPT

- New libraries MUMPS 5.5.1.

SCIP

- New libraries 8.0 (f0a1490e3b).
- Added parameter gams/infbound to instruct the GAMS/SCIP link to replace all missing variable bounds by a given value (off by default).

SHOT

- Fixed use of Gurobi for solving relaxations.

3.9.3.4 APIs

Python

- Fixed `setup.py` not copying schema files for Connect agents.

GAMS Transfer Matlab

- New version 0.2.2:
  - Fixed read of equation with unknown subtype (recast as `=e=`).
  - Fixed partial read of symbols in indexed container.
  - Fixed `equals` method in indexed container.
  - Fixed possible segfault when reading a subset of symbols as dense matrix with at least one scalar symbol.

3.9.4 40.3.0 Minor release (September 16, 2022)

3.9.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz.

3.9.4.2 GAMS System

- Fixed an error with command line parameter dumpOpt, that ignored the `SemiInt` modifier for a variable.

3.9.4.3 Solvers

CPLEX

- Fixed reporting of final (fixed) solve objective value instead of MIP solve objective value if final solve is enabled.

3.9.4.4 Tools

MODEL2TEX

- Added support for more (singleton) set attributes.

GAMS Studio

- New version 1.11.2 with some bug fixes, for example:
  - Updated tooltip of a tab after filename changed with "save as...".
  - Removed link to outdated introduction video.
  - Fixed occasional crash when opening search dialog after closing all files.
  - Fixed drag'n'drop creating group with invalid working directory.
  - Fixed GDX Viewer showing wrong data in table view because of a falsely restored symbol which dimension or type has changed.
  - Fixed GDX Viewer crash occurring when a file is reloaded during a drag'n'drop operation in table view mode.
  - Fixed disabled "Create" button in MIRO dialog on missing assembly file.

3.9.5 40.4.0 Minor release (October 03, 2022)

3.9.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.9.5.2 GAMS System

GAMS

- Fixed wrong result for set attributes `.tlen` and `.tval` when used with Singleton Sets.
- Fixed an unexpected compilation error, when an embedded code section starts right after an `else` statement.

3.9.5.3 Solvers

CONVERT

- Fix model statement in GAMS format for MCP models with incomplete matching information.

3.9.5.4 Tools

GAMS Studio

- New version 1.11.3 with some bug fixes and minor enhancements, for example:
  - Added shortcut `Ctrl + G` to also close the `GoTo` dialog.
  - Added `Ctrl + C` shortcut to system log.
  - Added `Clear Log` action to the system log context menu.
  - Added shortcut descriptions for various actions in context menu of editor.
  - Fixed drag'n'drop not working in project explorer on macOS.
  - Fixed wrong dialog title for "New Project".

3.10 39 Distribution

3.10.1 39.1.0 Major release (May 03, 2022)

3.10.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Wolfgang Britz, Rob Davies, Torbjoern Jansson, Bruce McCarl, and Yihe Zhuo.

3.10.1.2 GAMS System

GAMS

- Added basic model statistics (range of absolute non-zero values for the bounds, right hand sides and matrix coefficients) to the output file, and log.
- Added model attributes to access the values of the basic model statistics also programmatically: rngBndMax, rngBndMin, rngMatMax, rngMatMin, rngRhsMax, rngRhsMin.
- Added new command line parameter multi to initialize the state of $on/offMuli and $on/offMultiR.
- Extended the syntax of $(on|off)Echo[S|V], $(on|off)Put[S|V], $(on|off)EmbeddedCode[S|V], and (end|pause)EmbeddedCode[S|V] with an optional suffix to allow nested use. Note that this might trigger an error for code that was OK before. In the following example, the suffix at `$onEcho` was ignored in the past. Now, this will result in an error, since there is no `$offEcho` with matching suffix:

```
$onEcho.abc > x.txt
abc
$offEcho
```

- In embedded code Python, the Python interpreter stays alive even when the embedded code section ends with $offEmbeddedCode and endEmbeddedCode. So one has access to Python objects across embedded Python code sections. Nevertheless, the `gams` object gets newly initialized (with the exception of continueEmbeddedCode). Hence old references to `gams` or derived objects, e.g. `sym = gams.get("sym")` still exist in Python but the connected external resources are no longer available. Accessing these objects results in a crash as demonstrated in the following example:

```
Set s1 / i1*i3 /, s2 / j1*j3 /;
parameter p1(s1, s2);
$onEmbeddedCode Python:
s1 = gams.get('s1')
s2 = gams.get('s2')
$offEmbeddedCode

$onEmbeddedCode Python:
p1 = [(i, j, 3.14) for i,j in zip(s1, s2) ]
gams.set('p1', p1)
$offEmbeddedCode p1
```

In the second embedded Python code section the object references `s1` and `s2` use unavailable external resources, and the code in the section will crash GAMS. There is no need to use `gams` or derived objects from previous embedded code sections, since one can always use the current `gams` object. For legacy code that makes use of this unintended feature, we allow the use of the deprecated (and hidden) command line option `freeEmbeddedPython=0` for some time to get the old behavior. If you find yourself in need to set this option, you need to rework your embedded Python code section to prevent use of previous `gams` and derived objects. The option `freeEmbeddedPython` will (as announced) eventually be removed.

- Added new command line parameter and option ECImplicitLoad, as well as related dollar control options $on/offECImplicitLoad.
- Added new command line parameters ConnectIn and ConnectOut to instruct GAMS to pass the Connect YAML files provided by these option to the Connect framework at the beginning of a GAMS job (`ConnectIn`) and at the end (`ConnectOut`) of the GAMS job.
- Added new put_utility command `ECArguments` to extend the embedded code *arguments* with a dynamic text.
- Added explicit range checking for some Put File Attributes. In the past, unexpected values for some attributes (e.g. `file.nr = 8;`) could have led to unwanted output. Now, unacceptable values get projected to the nearest acceptable value.
- Updated use of decimals (file.nd) value in floating-point put output. Previously, the decimals value was treated as a specification, with putfile error messages resulting if the output contained fewer decimals. We treat the decimals value as a limit now: it's not an error if fewer digits are shown because of the width limit or for other reasons.
- Removed the GDX file `gmspfmap.gdx` that contained some partial mapping of files to components from the system directory.
- There was a hidden option `work`. This cannot be used anymore. The command line parameter or model attribute workSpace should be used instead.
- Allow holdFixed=1 for EMP, but not EMPSP models. The partly reverts the change of holdFixed for EMP models from GAMS 38.
- Fixed a bug where the command line parameters holdFixed, nodLim, workFactor and workSpace took precedence over the related model attributes.
- Fixed an error with constant evaluation in data statements for scalar symbols in a parameter statement.
- Fixed output of very large negative numbers (e.g. `-DBL_MAX`) to trace files.
- Fixed minor rounding and display issues with double-precision numbers. This is relevant to values displayed in the listing file, in put files, and less commonly in the GAMS log. Ties are now resolved using the **round-to-even** rule instead of **round-towards-zero**. This new tie-breaking rule is consistent with the display routines in C++, Python, Julia, and R. For example:
  - with `option decimals=5`, `scalar p / 9999998.4 /` was displayed as `1.000000E+7` – now as `9.999998E+6`

  - with `option dispwidth=9, decimals=5, scalar p / -8.123441235 /` was displayed as `-0.8123E+1` – now as `-8.1234412`
  - very small values (`1e-250` or less) were displayed as 0 but are now displayed using E-format in the usual way
  - displaying 1.5 or 2.5 with zero decimals both now show 2, while previously 1.5 would display as 1
  - similarly, 1.75 with `decimals=1` now displays as 1.8 instead of 1.7 as it did previously

Connect

- We have added the Connect framework to the distribution. *Connect* gives unified and platform independent access to data exchange with different formats (e.g., CSV and Excel). The instructions how to access the various data sources are given in YAML syntax. *Connect* is available as a standalone command line utility (`gamsconnect`), via the GAMS command line parameters ConnectIn and ConnectOut, and via embedded Connect code. The *Connect* framework is currently in beta status.

Embedded Code

- Allow implicit loading of symbols in embedded code. In the past the embedded code had to *"set"* a symbol and the symbol has to be explicitly imported on the `$off/end/pauseEmbeddedCode` line. This is no longer necessary. By default, a symbol that has been "set" by the embedded code will be imported into GAMS. The behavior with respect to this *implicit loading* is controlled by the command line parameter ECImplicitLoad and the dollar control options $on/offECImplicitLoad.

Embedded Connect Code Facility

- We added the new embedded code engine *Connect*. The embedded Connect code gives access to the Connect framework. The YAML formatted *"code"* can be utilized to import and export data with GAMS during compile and execution time.

Embedded Python Code Facility

- The Python version of GMSPython has been updated to `3.8.13`.
- Added the packages `cerberus` and `pyyaml-include` to GMSPython.
- Removed decoration (`---`) from log messages printed using `gams.printLog()` and fixed a bug that prevented long messages from being displayed correctly.

Extrinsic Function libraries

- As announced the extrinsic function library `parcclib` has been dropped.
- The mutex library `mtxcclib`, hidden in the system since 24.6, has now been documented and modified. With this version a mutex first has to be *created* via the function `Create` before it can be used (e.g. *locked*).

Windows Installer

- The installer no longer creates a Desktop icon for the `GAMS IDE` by default.
- Fixed bug that prevented command line parameter `/desktopIcons=no` from having an effect.

3.10.1.3 Solvers

CONOPT

- New libraries 3.17M.
  - Fixed issue with incorrect infeasibility reporting for infeasible CNS models or models with infinite post-triangular variables.
- New libraries 4.27.
  - Improved preprocessor on models with very small coefficients and models with constant nonlinear Jacobian elements.
  - Improved detection of post-triangular parts in CNS models.
  - Improved speed of analyzing the numerical stability and density of definitional constraints.
  - Improved numerical stability of creating and testing the initial basis.
  - Added options:
    - Flg_TraceCNS: Flag for tracing a CNS solution.
    - Trace_MinStep: Minimum step between reinversions when using `TraceCNS`.

COPT

- New libraries 4.0.5.
  - Improved performance for LP and MIP solving.
  - Added support for convex quadratic equations in continuous problems (model types QCP and RMIQCP). Currently, marginals are not provided if quadratic constraints are present.
  - Added option to find an Irreducible Inconsistent Subsystem (IIS) for an infeasible LP or MIP. New options iis to enable the IIS finder and IISMethod to specify IIS finder method.
  - New parameter BarOrder to specify ordering algorithm in Barrier solver.
  - For GAMS/COPT-Link users: If no COPT license is available, COPT can still be used for non-commercial use and LPs with at most 10000 variables and 10000 constraints and for MIPs/QCPs with at most 2000 variables and 2000 constraints.

CPLEX

- New libraries 22.1.0.
  - New options:
    - lowerobjstop: in a minimization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value lower than or equal to the specified value.
    - upperobjstop: in a maximization MILP or MIQP, the solver will abort the optimization process as soon as it finds a solution of value greater than or equal to the specified value.
  - Removed CPLEX Remote Object Server and Distributed MIP.

  - Removed options `computeserver`, `polishtime`, `rampupdettimelimit`, `rampupduration` and `rampuptimelimit`.

- New option exactkappa: Report exact condition number in quality report. Note: Previously, the exact condition number has always been reported. Now, default is to not do it due to possibly high computation times.
- Add previously hidden options:
  - iafile: secondary option file to be read in interactive mode triggered by iatriggerfile.
  - iatriggerfile: file that triggers the reading of a secondary option file in interactive mode.
  - iatriggertime: time interval in seconds the link looks for the trigger file in interactive mode.
  - ltol: basis identification primal tolerance.
  - mtol: basis identification dual tolerance.
  - readparams: read CPLEX parameter file.

DE

- Introduced an experimental and hidden option `pipsStages` to annotate the resulting deterministic equivalent with PIPS-IPM++ conforming block information.

EMPSP

- For EMPSP models feasible empty rows will no longer be sent to the solver.

GLOMIQO

- We plan to drop GLOMIQO with the next major release. The ANTIGONE solver (a superset of GLOMIQO) remains in the system.

GUSS/ScenarioSolver

- GUSS/ScenarioSolver allows now to manually scale model instances via the `.scale` variable and equation suffix together with model attribute scaleOpt=1.

Ipopt

- New libraries 3.14.6.

KNITRO

- Added support for models with more than 2^{31} entries in the coefficients matrix.
- Changed handling of initial levels and marginals, see initvalues0 and initvalues.
- Only scale the model instance if `scaleOpt` is set to 1.
- Added options:
  - initvalues0: enable use of initial guess for levels and marginals (first solve).
  - initvalues: enable use of initial guess for levels and marginals (subsequent solve).

LGO

- We plan to drop LGO with the next major release.

Lindo/LindoGlobal

- New libraries 13.0.340.

MOSEK

- New libraries 9.3.20.
- For GAMS/MOSEK and GAMS/OsiMosek, a separate MOSEK license is now required also for academic GAMS licenses that include a GAMS/MOSEK link license but no full GAMS/MOSEK license.

MSNLP

- We plan to drop MSNLP with the next major release.

Octeract

- New libraries 4.3.1.
  - Fixed that GAMS options were ignored when a solver options file was specified.

ODHCPLEX

- New libraries 6.11.

SCIP Optimization Suite

- New libraries PaPILO 2.0 (60ab076).
- New libraries SoPlex 6.0 (f084e555).
- New libraries SCIP 8.0 (899dc92dda).

XA

- We plan to drop XA with the next major release.

XPRESS

- New libraries 39.01.06.

3.10.1.4 Tools

GAMS Studio

- New version 1.10.1.
  - New feature: Added `pin view`: The main edit area can be split vertically or horizontally to show a second editor.
    - `Ctrl + Left Click` on a tab creates a vertical split.
    - `Ctrl + Shift + Left Click` on a tab creates a horizontal split.
  - Added new search scope: `Folder` (aka `Find in Files`).
    - This allows users to search a directory on disk without having to load the whole directory in Studio first.
  - Some rework of the "Search and Replace" dialog:
    - Added file exclusion pattern input field and functionality.
    - Added info about number of files searched to search dialog.
    - Changed default position of search dialog to top right.
    - Search now respects open file behavior settings when jumping to results in unopened files.
    - Fixed crash in search when current editor has no file associated.
    - Fixed search not being interruptible when searching many small files.
  - Added GDX Viewer tab to the settings dialog.
  - Added new setting to specify the default symbol view of the GDX Viewer.
  - User model libraries have been moved to the first tab of the Model Library Explorer.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    - Configuration editor now displays `gamsconfig.yaml` file only.
    - Added search related group to project explorer when files where found that were unknown to Studio.
    - Added automatic deactivation of search selection when leaving "Selection" search scope.
    - Added feedback for empty search term, invalid regex, and invalid path in search dialog.
    - Added completer handling for `$offEcho`.
    - Changed behavior of completer: Allow all keywords after opening a paired dollar control option (DCO) and showing closing DCOs first.
    - Ensure unique project name and keep log name in sync with project name.
    - Fixed crash in ModelLibrary dialog on `Ctrl-rightClick` on entry.
    - Fixed white table headers in dark mode.
    - Fixed code completer activation issues.
    - Fixed broken syntax in data statements with division.

MPS2GMS

- The tool has been reimplemented and now uses the readers of the `HiGHS solver`.
- If the MPS file appears to be in fixed form (row or character names with spaces and at most 8 characters), then parsing in fixed form is attempted.
- GDX and GMS files are now also written if no GDX and GMS filenames are provided explicitly.
- Dropped support for writing an MPS file.
- Dropped support for `OBJNAME` section.

- Sections SOS and SETS are now assumed to follow the format used by CPLEX, GUROBI, and FICO XPRESS.
- Dropped parameters NAME, N, RHS, RANGES, BOUNDS, MPSOut, Trace.
- Added parameter COLUMNINTVARSAREBINARY to specify how to handle integer variables that appear first in COLUMNS section.
- Quadratic coefficient matrices are no longer written in symmetric form. Zero coefficients (eps) that were written to GDX in certain situations are now omitted.
- See also the MPS2GMS documentation.

3.10.1.5 APIs

GAMS Transfer Matlab

- New version 0.2.0:
  - Improved documentation.
  - Added "equals" method to Container and Symbol classes to compare containers or symbols, respectively.
  - Added "copy" method to Symbol classes to copy symbols to another container.
  - Added support to read symbols directly from Container (not just ConstContainer).

GAMS Transfer Python

- GAMS Transfer will now accept any mixed-case string representations of special values for undef, na, and eps (i.e., Undef or UnDeF are now valid).
- Performance enhancements associated with reading/writing GAMS special values.
- Performance enhancement in .removeSymbols(): isValid check flag is no longer reset for all symbols in the Container if removing a Parameter, Variable or Equation.
- Fixed bug when replacing string special values in a dataframe whose index was not uniformly spaced.
- Fixed bug when testing scalar values with .isUndef.

GMD

- Special value -0.0 for EPS is now properly recognized.
- gmdCopySymbol allows to copy parameter, variable, and equation symbols into a set symbol.
- Added gmdGetUserSpecialValues to access special values GMD currently accepts.

GMO

- Added properties gmoHessNZ64, gmoHessMaxNZ64, and gmoHessLagNZ64 and functions gmoHessStruct64 and gmoHessValue64 to get Hessian element counts as 64-bit integer.
- Added properties gmoQNZ64 and gmoGNLNZ64: all properties returning 32-bit Jacobian nonzero counts now have 64-bit counterparts.
- Fixed a memory leak in the Hessian evaluation: the leak occurred during speculative Hessian evaluations, i.e., evaluations with a tight memory limit intended to see how memory-intensive Hessian evaluation is and if Hessians should be used by the solver.

High-level APIs

- `GamsModelInstance.solve()` falls back to a warm start in case a hot start fails.
- Added read property for `GAMSSet.SetType` (.NET, Python) and `GAMSSet.getSetType` (Java) to distinguish `multi` and `singleton` sets.
- New optional argument `setType=SetType.multi` in `GAMSDatabase.AddSet()` (.NET), `GamsDatabase.add_set()` and `GamsDatabase.add_set_dc()` (Python), and `GAMSDatabase.addSet` (Java) to set type of set.
- Fixed defined enumerated value for options **FDOpt** and **DumpOpt** in Java interface.

3.10.1.6 Model Libraries

GAMS Model Library

- Dropped `deploy`.
- Dropped `dplytst`.
- Updated **cta.gms : Controlled Tabular Adjustments**.
- Updated **dicegrid.gms : MIP Decomposition and Parallel Grid Submission - DICE Example**.
- Updated **herves.gms : Herves (Transposable Element) Activity Calculations**.
- Updated **qmeanvar.gms : Financial Optimization: Risk Management using MIQCP**.
- Updated **sddp.gms : Multi-stage Stochastic Water Reservoir Model solved with SDDP**.
- Updated **seders.gms : ERS Data Manipulations with SED**.
- Updated **tsp5.gms : TSP solution with Miller et al subtour elimination**.
- Added **asyncincbi.gms : Asynchronous processing of incumbents reported by GAMS/CPLEX**.
- Added **springchain.gms : Equilibrium of System with Piecewise Linear Springs**.
- Added **trussm.gms : Truss Toplogy Design with Multiple Loads**.

GAMS Data Library

- Added **gtmvn.gms : Demonstrate the use of numpy.multivariate_normal on stock return data using Transfer**.
- Added **connect01.gms : Complex Connect Example with Spreadsheets**.
- Added **connect02.gms : Complex Connect Example with CSV Files**.
- Added **connect03.gms : Simple Connect Example with CSV Files**.

GAMS Test Library

- Updated **embpy04.gms : Test continuation of embedded code blocks** to remove tests related to freeEmbeddedPython.
- Updated **mtxlib.gms : Test basics of the mutex library** to reflect changes in extrinsic function mutex library.
- Dropped `parlib01` and corresponding library `[lib]parcclib64` and source `parsource.zip`.
- Dropped `pfmaptst`.
- Added **embmihws.gms : ModelInstance hot/warmstart switch**.
- Added **convert17.gms : CONVERT test suite - check stage and scale export in dumpgdx**.
- Added **caproject.gms : Test Connect agent Projection**.
- Added **cagamsrw.gms : Test Connect agent GAMSReader/Writer**.
- Added **cagdxrw.gms : Test Connect agent GDXReader/Writer**.
- Added **capdxlsrw.gms : Test Connect agents PandasExcelReader and PandasExcelWriter**.
- Added **carxr.gms : Test Connect agent RawExcelReader**.
- Added **capcode.gms : Test Connect agent PythonCode**.
- Added **cacsvw.gms : Test Connect agent CSVWriter**.
- Added **embpy12.gms : Test implicit/explicit loading in Embedded Code**.
- Added **cacsvr.gms : Test Connect agent CSVReader**.
- Added **capdxlsr.gms : Test Connect agent PandasExcelReader**.
- Added **embpy13.gms : Test implicit/explicit loading in Embedded Code (execution time)**.
- Added **connectsub.gms : Test substitution for Connect**.
- Added **nestblock01.gms : Test the use of nested blocks**.

FIN Library

- Use Connect instead of Windows-only gdxxrw to allow running the models on all platforms.
- Updated **CreditImmunization : Factor Immunization model for corporate bonds.**.
- Updated **MeanVar : Mean-variance efficient portfolios**.
- Updated **MeanVarShort : Mean-variance model allowing short sales**.
- Updated **PutCall : Put/Call efficient frontier model.**.
- Updated **ReadData : Reads excel files and converts them to gdx format**.
- Updated **SelectiveHedging : Scenario Optimization for selective hedging**.
- Updated **ThreeStageSPDA : A three stage stochastic programming model for SPDA**.

PSOPT Library

- Use Connect instead of Windows-only gdxxrw to allow running the models on all platforms.
- Updated **DED : Dynamic Economic Load Dispatch**.
- Updated **DED-PB : Price based Dynamic Economic Load Dispatch**.
- Updated **DED-wind : Dynamic Economic Load Dispatch considering Wind generation**.
- Updated **DEDESS : Cost based Dynamic Economic Dispatch integrated with Energy Storage**.
- Updated **DEDESSwind : Cost based Dynamic Economic Dispatch integrated with Energy Storage and Wind**.
- Updated **ESSDCOPFwind : DC-OPF integrated with Energy Storage and Wind**.
- Updated **MultiperiodACOPF24bus : Multi-period AC-OPF for IEEE 24-bus network considering wind and load shedding**.
- Updated **MultiperiodDCOPF24bus : Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding**.
- Updated **PBUC : Price based Unit commitment**.
- Updated **RampSenDED : Ramp rate sensitivity analysis for Dynamic Economic Load Dispatch**.

3.10.2 39.1.1 Maintenance release (May 18, 2022)

3.10.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Arne Schulz.

3.10.2.2 Solvers

CPLEX

- Fixed mipkappastats report in case of relaxed or fixed solve after MIP solve (enabled by rerun = no and solvefinal = yes, respectively).

KNITRO

- Fixed incorrect detection as an infeasible model when it actually was feasible (happened if KNITRO terminated due to small relative change in objective).

3.10.2.3 Tools

GAMSCONNECT

- Fixed problem with `gamsconnect` command line tool not working properly when environment variables `PYTHONPATH` or `PYTHONHOME` were set.

GAMS Studio

- New version 1.10.2 with some bug fixes, stability improvements, and minor enhancements, e.g.:
  - Made sure the correct file gets the focus on Studio start-up.
  - Fixed crash on closing a tab when project settings are active.
  - Fixed closing behavior of search dialog on Windows when using `X` button.

GDXDIFF

- Fixed wrong differences of parameters with option `fldOnly`.

MODEL2TEX

- Fixed problem with `model2tex` not working properly when environment variables `PYTHONPATH` or `PYTHONHOME` were set.

3.10.3 39.2.0 Minor release (June 02, 2022)

3.10.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Dominic Lencz.

3.10.3.2 GAMS System

GAMS

- Fixed potential wrong dump file with implicit sets.

Connect

- Fixed a problem in `GAMSWriter` agent that registered unused labels with GAMS.

Embedded Python Code Facility

- Fixed a problem with ignoring `gams.ws.my_eps`.

3.10.3.3 Solvers

CONOPT

- New libraries 4.28.

3.10.3.4 Tools

GAMS Studio

- New version 1.10.4 with some bug fixes, and minor enhancements, namely:
  - Added support for optional suffixes for $(on|off)Echo[S|V], $(on|off)Put[S|V], $(on|off)EmbeddedCode[S|V], and (end|pause)EmbeddedCode[S|V].
  - Fixed GAMS Engine not adding files in subdirectories from `*.efi` file.
  - Fixed problem receiving results from Engine when there is an execution error.

3.10.3.5 APIs

GAMS Transfer Matlab

- New version 0.2.1:
  - Fixed read of variable with unknown subtype (recast as free).
  - Fixed check of variable type on variable creation.
  - Fixed `isEps`, `isNA`, and `isUndef` of `SpecialValues` for sparse matrix input.
  - Fixed default values of external, conic, and boolean equations.

GAMS Transfer Python

- Fixed read of variable with unknown subtype (recast as free).
- Fixed default values of equation subtypes (`eq`, `geq`, `leq`, `cone`, `external`, and `boolean`).

GMD

- Fixed a problem with aliases to the universe.

3.10.4 39.2.1 Maintenance release (June 21, 2022)

3.10.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Erwin Kalvelagen.

3.10.4.2 GAMS System

GAMS

- Report correct number in Solve Summary if iteration count exceeds `maxInt`.
- Added missing entry for empty scalar equations to the tree view of the output file.

Connect

- Fixed a problem with `indexSubstitutions` in `CSVReader` agent where labels in the last index column where not substituted when reading a set without text columns.

3.10.4.3 Solvers

CPLEX

- Fixed crash after singular basis error.
- Fixed overflow in node and iteration counts.

SHOT

- New libraries 1.1 (c9bc78df).

3.10.5 39.3.0 Minor release (July 07, 2022)

3.10.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Bruce McCarl and Tom Rutherford.

3.10.5.2 GAMS System

GAMS

- Fixed a problem that limited the number of characters written to a single line in the log using put files to 255.

3.10.5.3 Solvers

SCIP Optimization Suite

- New libraries SCIP 8.0 (95d63636d5).
- New libraries PaPILO 2.1.0.

SHOT

- New libraries 1.1 (033622c6).

3.10.5.4 Tools

GAMS Studio

- New version 1.10.5 with some bug fixes, and minor enhancements, for example:
  - Fixed Studio ignoring setting to open in current project when opening a file from Explorer.
  - Fixed search not reacting to changes in project file list.
  - Fixed search not always adding new files to correct search group.
  - Fixed potential crash when closing Studio while search dialog is open.
  - Fixed opening of empty editor when using search results to open a deleted file.
  - Added automatic update of results list when still open from last search.

3.10.5.5 APIs

GMO

- Fixed a crash caused by memory corruption in the Hessian evaluation: the crash occurred while cleaning up after speculative Hessian evaluations that exceed a user-specified memory limit.

3.11 38 Distribution

3.11.1 38.1.0 Major release (January 31, 2022)

3.11.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Albert Brouwer, Arne Drud, Daniel Jungen, Scott McDonald, Tom Rutherford, Seyed Amin Sedgh, and Wenjin Zhou.

3.11.1.2 Platforms

- As announced, dropped support for macOS 10.14 (Mojave).
- Added support for macOS 12 (Monterey).

3.11.1.3 GAMS System

GAMS

- Added new command line parameter dumpOptGDX to load the data needed in dumpOpt files from GDX instead of data statements.
- Added new command line parameter ReferenceLineNo to control the line numbers written to a reference file.
- We plan to drop the command line parameter `freeEmbeddedPython` with the next major release.
- Extended the Solve Summary written with asyncSolLst=1 to include information about controlling loop indices during job submission, name of the solver called, source line number of the solve statement, resource and iteration limit.
- Make handling of execution errors during model generation (e.g. division by zero in an equation) more consistent across different settings for the solveLink option. In the past, the error count was set to 0 automatically when returning from a solve with `solveLink=0` only (which is equivalent to setting execError=0 after the solve statement). This is not done anymore.
- Write additional information about execution errors during model generation (e.g. division by zero error) to the lst file, e.g., the equation name and index causing the problem.
- Improve recognition of '/' as path delimiter on Windows.
- Pause automated time dependent log update while executing embedded code sections.
- Check for certain byte order marks (BOMs) in GAMS input files. Files with UTF8 BOM can be processed now, other BOMs generate a compilation error.

- Added support for (mixed-integer) quadratic models whose Q matrices contain more than 2^{31} = 2,147,483,648 nonzeros in their upper triangle. At this time, only the solver links for CPLEX and ODHCPLEX are capable of handling such large model instances.
- Changed system suffix `isAlfaBeta` to `isAlphaBeta`.
- Fixed a problem for EMP models with holdFixed model attribute.
- Fixed a problem where IDCGenerateGDXInput, IDCGenerateGDXOutput, IDCGDXOutput , and IDCGenerateGDX did not write a GDX file if the execution was stopped with abort[.noError].

Extended Mathematical Programming (EMP)

- Stochastic EMP: Changed the `stage` behavior so that it creates an explicit error when a stage gets assigned twice for the symbol. In the past, this caused erratic behavior.

Embedded Python Code Facility

- The Python version of GMSPython has been updated to `3.8.12`.

Extrinsic Function libraries

- With the next distribution we will drop the extrinsic function library `parcclib`.

3.11.1.4 Solvers

BARON

- New libraries 22.1.16.
  - new presolve implementation with novel presolve techniques for linear and nonlinear optimization problems improves performance for many problem classes
  - more classes of SOCPs are now recognized
  - new lift-and-project implementation that extends the previous RLT implementations to generic NLPs and MINLPs and leads to substantial reduction of duality gaps for difficult problems
  - improved tree management, including restarts of branch-and-bound search
  - improved branching routines for the identification of most important branching variables
  - dynamic LP algorithm selection strategy improves robustness for numerically difficult problems by automatically choosing between CPLEX (if licensed) and CLP/CBC and possibly switching during the search, see also option LPSol
  - improved control on the effect of floating point round-off errors
  - faster hashing routines
  - the embedded FilterSD algorithm is now off by default
  - better integration with GAMS NLP subsolvers
  - improvements to CBC and IPOPT interfaces
  - update the Xpress interface to work with FICO XPRESS 39
- Fixed reporting of proven irreducible infeasible sets ("IIS" instead of "(I)IS").

CONOPT

- New libraries 4.25.
  - General improvements in the construction of the initial basis and in the startup of the optimization process, especially for very large models.
  - Many small improvements and corrections of errors found by users.

CONVERT

- The symbol `We` in DumpGDX is now stored sparse.
- Changed option default of GDXHessian and GDXQuadratic to 0.

COPT

- Added new parallel LP and MIP solver COPT 3.0.5 by Cardinal Operations (`https://www.shanshu.ai/copt`).
- For GAMS demo and community licenses, model size limitations as for other solvers apply. For an unlimited GAMS/COPT or GAMS/COPT-Link license, contact `sales@gams.com`.

CPLEX

- Fix appending userjobid to userincbicall, usergdxin, and usergdxnameinc in BCH calls.
- Fixed computing dual multipler at cone top (QCP models).

DICOPT

- Fixed that non-default stage information was setup in sub-MIPs when `prioropt=0`.

KNITRO

- New libraries 13.0.
  - Introduces an updated, parallel, branch-and-bound solver for mixed-integer optimization. This updated solver is able to exploit parallelism and uses improved heuristics to solve mixed-integer problems much faster than before.
  - Offers new initial point strategies for non-convex quadratic programs (QPs) and quadratically constrained quadratic programs (QCQPs). These new initial point strategies improve the likelihood of finding the global solution, and can be used in conjunction with the Knitro multi-start procedure to search for global or better local solutions for non-convex QP and QCQP models.
  - Offers significant robustness and speed improvements on difficult nonlinear optimization problems.
  - Offers improved performance when using the SQP and MISQP algorithms on larger models.
  - Added options:
    - ncvx_qcqp_init: Specifies the initialization strategy used for non-convex QPs and QCQPs.
    - mip_cutoff: This value specifies the objective cutoff value for MIP.

    * mip_heuristic_lns: Specifies whether or not to enable the MIP large neighborhood search (LNS) heuristics.
    * mip_liftproject: Specifies rules for adding lift and project cuts.
    * mip_multistart: Use to enable MIP multi-start at the branch-and-bound level.
    * mip_numthreads: Specify the number of threads to use for MIP branch and bound.
  - Renamed options (old option names still available as synonyms but deprecated):
    * `bar_pencons` to bar_penaltycons.
    * `bar_penrule` to bar_penaltyrule.
    * `mip_integral_gap_abs` to mip_opt_gap_abs.
    * `mip_integral_gap_rel` to mip_opt_gap_rel.
    * `par_msnumthreads` to ms_numthreads.
    * `par_blasnumthreads` to blas_numthreads.
    * `par_lsnumthreads` to linsolver_numthreads.
    * `tuner_maxtimecpu` to tuner_maxtime_cpu.
    * `tuner_maxtimereal` to tuner_maxtime_real.
  - Added option values:
    * blasoption: 3.
    * mip_heuristic_diving: bits 1 - 4.
  - Changed option defaults:
    * restarts: -1 (auto).
    * mip_strong_candlim: 128.

- Fixed possible error of incorrect Jacobian for QCP models.

Lindo/LindoGlobal

- New libraries 13.0.319.

LocalSolver

- As announced, dropped LocalSolver and LocalSolver70.

MOSEK

- New libraries 9.3.11.
- Added support for LPs and MIPs with more than 2^{31} entries in the coefficients matrix.

Octeract

- New libraries 4.1.0.
  - Reduced memory requirement and improved performance.

ODHCPLEX

- New libraries 6.0.8.
- Added support of solution pool export via solnpool and solnpoolmerge.

SCIP Optimization Suite

- New libraries PaPILO 2.0.0.
  - Added dual postsolve functionality for LPs.
  - Immediate application of a presolvers reductions if run sequentially.
  - Improvements in performance and functionality of many presolvers.
  - For more details, see [22] and the `PaPILO CHANGELOG`.
  - Updated TBB to version 2021.5.0.
- New libraries SoPlex 6.0.0.
  - PaPILO can now be enabled as presolver by setting int:simplifier to the new value 2.
  - SoPlex can now be interrupted by Ctrl+C/SIGINT.
  - Changed default for option int:simplifier from 1 to new value 3. The value 1 now means "auto".
  - New option real:simplifier_modifyrowfac.
  - For more details, see [22] and the `SoPlex CHANGELOG`.
- New libraries SCIP 8.0.0.
  - Symmetry handling:
    - New symmetry handling inequalities based on the Schreier Sims table, which are able to handle symmetries of arbitrary kinds of variables.
    - The symmetry code can now heuristically search for orbitopes that do not completely handle a symmetry component and add certain Schreier Sims cuts to such components.
    - In-tree restarts due to tree size estimation have been made compatible with orbital fixing.
    - Improved performance of upgrades to packing/partitioning orbitopes, symresack cover separation, and propagation for orbisack and symresack.
    - Symmetry handling has been extended to detect also symmetries between variables that also appear in nonlinear constraints.
  - Cutting planes:
    - New separator mixing to generate mixing cuts.
    - New separator rlt to compute cuts via the reformulation-linearization technique (RLT).
    - New separator minor to compute cuts from 2x2 minors of a violated semidefiniteness constraint that is implied by the extended formulation for bilinear products.
    - New separator interminor to compute intersection cuts from 2x2 (not only principle) minors of a violated rank-one constraint that is implied by the extended formulation for bilinear products (currently disabled by default).
    - Separator "aggregation" now uses the objective cutoff row as base row and separates lifted cover cuts based on newer lifting function of Letchford and Souli (2019).
    - Separators "strongcg" and "gomory" now share the same computed basis.
  - Primal Heuristics:
    - New construction heuristic DPS which additionally needs a user-provided decomposition and splits the problem into several sub-SCIPs according to this decomposition. The sub-SCIPs are solved and updated repeatedly until a feasible solution of the original problem is found.
    - PADM can now reoptimize found solution with original objective function.
    - The RENS neighborhood in the heuristic ALNS now fixes fractional variables if necessary for reaching its target fixing rate.
    - Revised and improved heuristic subNLP, in particular choice of NLP iteration limit and starting condition and reuse of subSCIP.
  - The handling of algebraic expressions and nonlinear constraints has been rewritten:
    - Support for trigonometric functions sine and cosine and for the entropy function has been added.

  - Improved recognition of common subexpressions, in particular square and bilinear terms.
  - All type of nonlinear constraints, including quadratic and second-order-cones, are now handled by the constraint handler for nonlinear constraints. The specialized constraint handlers have been removed. However, methods that work on a particular nonlinear structure are now implemented via nonlinear handlers (nlhdlr).
  - Added nonlinear handler for quadratic, bilinear, convex, concave, and quotient expressions, second-order cone constraints, and perspective tightening for expressions in semi-continuous variables.
  - As before, an extended formulation for nonlinear constraints is constructed. However, this formulation is now handled implicitly and used to construct the LP relaxation only, while the original formulation is used to check feasibility, propagate variable domains, etc. This difference should drastically improved the likelihood that a solution that satisfies the nonlinear constraints in the presolved problem is also feasible for the original problem.
  - Products in nonlinear constraints are no longer disaggregated for the extended formulation.
  - Improved analysis on which nonlinear variables in nonlinear constraints can be increased or decreased without harming feasibility by taking monotonicity into account.
  - Improved linearization of (sums of) products of binary variables, e.g., clique information is now taken into account.
  - When a variable appears in only one concave less-or-equal constraint, it will be fixed to one of its bounds in more cases now.
  - New branching rule for variables in nonlinear constraints that scores candidates based on constraint violation, variable type, and pseudo-costs simultaneously. Variables that are added for the extended formulation of a nonlinear constraint are no longer branched on by default.
  - New strategies to deal with weak estimators for nonlinear functions and small violations of nonlinear constraints.
  - Improved under/overestimation of multidimensional vertex-polyhedral (e.g., multilinear or concave) functions by use of scaling and keeping the cut-generating LP around.
  - Added tables to print statistics of nonlinear constraint handler, nonlinear handlers, and handlers for all supported functions.
- Revised and improved interfaces to Ipopt and CppAD, e.g.:
  - Optimization of taped expressions and sparse Hessian evaluation of CppAD are used now.
  - Added table to print statistics on NLP solvers.
- The interfaces to Gurobi and Mosek are thread-safe now.
- Parameters removed:
  - `gams/resolvenlp`
  - `constraints/abspower/&lowast;`, `constraints/bivariate/&lowast;`, `constraints/quadratic/&lowa` `constraints/soc/&lowast;`
  - `constraints/nonlinear/cutmaxrange`, `constraints/nonlinear/linfeasshift`, `constraints/nonlinear/reformulate`, `constraints/nonlinear/sepanlpmincont`, `constraints/nonlinear/enfocutsremovable`, `constraints/nonlinear/maxexpansionexponent`, `constraints/nonlinear/upgrade/abspower`, `constraints/nonlinear/upgrade/and`, `constraints/nonlinear/upgrade/bivariate`, `constraints/nonlinear/upgrade/quadratic`
  - `constraints/orbitope/usedynamicprop`
  - `heuristics/multistart/nlpminimpr`
  - `heuristics/subnlp/iteroffset`, `heuristics/subnlp/iterquotient`, `heuristics/subnlp/nlpiterlim` `heuristics/subnlp/nlptimelimit`, `heuristics/subnlp/runalways`, `heuristics/subnlp/minimprove`, `heuristics/subnlp/nlpoptfile`, `heuristics/subnlp/resolvefromscratch`, `heuristics/subnlp/reso`

– Parameters changed:

  - default of constraints/nonlinear/maxproprounds changed from 1 to 10
  - default of display/nexternbranchcands/active changed from 2 to 1 also for nonlinear instances
  - default of display/nfrac/active changed from 2 to 1 also if discrete variables are present
  - default of heuristics/dualval/priority changed from 0 to -10
  - default of heuristics/lpface/priority changed from -1104000 to -1104010
  - default of heuristics/mutation/priority changed from -1103000 to -1103010
  - default of heuristics/nlpdiving/priority changed from -1003000 to -1003010
  - default of heuristics/repair/priority changed from 0 to -20
  - default of heuristics/simplerounding/priority from 0 to -30

    - default of heuristics/subnlp/forbidfixings from 1 to 0
    - default of heuristics/subnlp/itermin changed from 300 to 20
    - default of SCIPheuristics_subnlp_priority heuristics/subnlp/priority changed from -2000000 to -2000010
    - default of heuristics/trivialnegation/priority changed from 40000 to 39990
    - default of heuristics/trustregion/priority changed from -1102000 to -1102010
    - default of heuristics/trysol/priority changed from -3000000 to -3000010
    - default of misc/usesymmetry changed from 3 to 7 and range changed from {0,...,3} to {0,...,7}
    - default of presolving/qpkktref/maxrounds changed from -1 to 0
    - default of propagating/obbt/onlynonconvexvars changed from 0 to 1
    - default of propagating/symmetry/addsymresacks changed from 1 to 0
    - type of propagating/symmetry/recomputerestart changed from boolean to int with range {0,...,2}
    - default of separating/strongcg/maxbounddist changed from 1 to 0
    - default of separating/strongcg/priority changed from -2000 to -100000
    - replaced `separating/minortho` by cutselection/hybrid/minortho, replaced `separating/minorthoroot` by cutselection/hybrid/minorthoroot, replaced `separating/dircutoffdistfac` by cutselection/hybrid/dircutoffdistweight, replaced `separating/efficacyfac` by cutselection/hybrid/efficacyweight, replaced `separating/intsupportfac` by cutselection/hybrid/intsuppo replaced `separating/objparalfac` by cutselection/hybrid/objparalweight
  - For more details, see [22] and the `SCIP release notes`.

- Added support for GAMS functions `sin`, `cos`, and `entropy` for GAMS/SCIP.
- Since SCIP has dropped support for `min` and `max`, the GAMS/SCIP link reformulates GAMS functions `min` and `max` by use of `abs` now.
- Removed the feature that ran Ipopt from a returned solution that is recognized by SCIP to be not feasible in the original (non-presolved) nonlinear problem in order to obtain a feasible solution.

SHOT

- New libraries 1.1 (e225a002).
  - Added parameter Model.Reformulation.Quadratics.EigenValueDecomposition.Tolerance.

XPRESS

- New libraries 39.01.03.
  - Improved MIP performance:
    - The Optimizer now uses an ML module to decide whether to use in-tree cutting. See autoCutting.
    - Improved separation of Mixed Integer Rounding (MIR) cuts.
    - Improved cut activation and deactivation strategies.
    - Improved application of strong branching during the tree search.
    - More information carried through a MIP restart.
    - The 'R' local search heuristic will now be called more frequently in the early phase of a MIP solve.
  - Improved crossover performance after a Barrier solve through automatic objective perturbation. See barObjPerturb.

  - Improved Barrier performance for large problems on CPUs that support AVX2 (requires setting cpuPlatform to -2).
  - New options:
    * autoCutting: Automatically decide whether to generate cutting planes at local nodes in the tree.
    * barObjPerturb: Defines how the barrier perturbs the objective.
    * ioTimeout: Maximum number of seconds to wait for an I/O operation before it is cancelled.
    * maxStallTime: Maximum time in seconds that the Optimizer will continue to search for improving solution after finding a new incumbent.
    * preCliqueStrategy: Determines how much effort to spend on clique covers in presolve.
    * siftPresolveOps: Determines the presolve operations for solving the subproblems during the sifting algorithm.
  - Changed option default of xslp_mipDefaultAlgorithm: 1.
- Added option fixoptfile: name of option file which is read just before solving the fixed problem.
- Changed default value of option mipAddCutoff and mipRelCutoff to 0.
- Fixed unnecessary solve of fixed MIP (see mipCleanup) when solving a linear program as MIP.

3.11.1.5 Tools

BIB2GMS

- As announced, dropped the tool `bib2gms`.

CSV2GDX

- Check for certain byte order marks (BOMs) in input files. Files with UTF8 BOM can be processed now, other BOMs generate an explicit error.

GAMS Studio

- New version 1.9.4.
  - Added Project Options editor.
  - Added possibility to create an empty project.
  - Adjusted loading from a model library to add files to active project working directory if "Open in existing project" is checked.
  - Added selection of user instances on `GAMS Engine SaaS`.
  - Added selection of namespaces on GAMS Engine Server.
  - Stability improvements, bug fixes, and minor enhancements, e.g.:
    * Expanded MIRO installation location on macOS if AppBundle has been selected.
    * Adjusted check if the MIRO data contract is available before the MIRO app is deployed.
    * Changed mouse wheel behavior in tab bars:
      · `Mouse Wheel Up/Down`: moves active tab
      · `Ctrl + Mouse Wheel Up/Down`: changes active tab
    * Added touch pad support for tab bars.
    * Added highlight in `LST` file for current section header of `LXI` viewer.

* Changed behavior of search in selection: the search selection is now only set once until the user resets it.
* Changed "Clear" button to remove search selection on first click when present.
* Fixed non-overridden recurrence of immediate options on command line parameters.
* Fixed jump behavior of search when using "This File" and navigating different files.
* Fixed `Find Next` broken for results across multiple files.
* Fixed crash on showing "Project Options" for a project without a runnable `gms` file.
* Fixed search not updating cache when document has changed.
* Fixed `Clear Selection` button not working as intended, when search scope was set to anything but "Selection".
* Fixed random crash in `Search and Replace` dialog.
* Fixed that checks for file type did not ignore casing (`gms`, `Gms`, `GMS` are all valid).
* Fixed that the default file filter in search dialog expected files to include a '.' character on non-windows platforms.
* Fixed file filter in search dialog not being ignored for scopes "This File" and "Selection".
* Fixed search jump behavior when current file is excluded by file filter.
* Fixed completer and syntax help activation for user defined GAMS source files.

GDXDIFF

- Reduce size of output GDX file in case of input files without differences.
- Added new option ignoreOrder.

GDXMRW

- We mark GDXMRW as deprecated and may remove it in a future release. Please use **GAMS Transfer Matlab** instead. If you encounter issues with the transition to GAMS Transfer Matlab or if you have any feature requests for GAMS Transfer Matlab, do not hesitate to contact us through support.

HEXDUMP

- As announced, dropped the tool `hexdump`.

3.11.1.6 APIs

C++ high-level API

- Removed conversion of mapped network drives to UNC paths.
- Fixed addition of GAMS system directory to `PATH` on Windows.

GAMS Transfer Matlab

- New read-only `ConstContainer` (high reading performance).
- **Container** now supports to read from a `ConstContainer` in addition to a GDX file.
- New argument `types` in **Container::listVariables** and **Container::listEquations** to filter by variable or equation type, respectively.
- **Container::listSets** does not include aliases in the returned list anymore. However, it is still possible to include aliases in **Container::describeSets**.
- New argument `records` in **Container::read** to toggle reading records in addition to symbol meta data.

GAMS Transfer Python

- GAMS Transfer now works with Embedded Python Code.
- New read-only `Container` type called `ConstContainer` (high reading performance).
- New argument `types` for methods `listVariables()` and `listEquations()` to filter by variable or equation type, respectively.
- The method `listSets()` does not include aliases in the returned list anymore.
- The `Container.read()` argument `values` has been renamed to `records`.
- Fixed bug in `SpecialValues.isNegInf()` that did not properly detect scalar `-inf`.
- Fixed error handling when invalid records are set directly with `.records`.

GDX

- Internal adjustment to detection of special values when writing to GDX. The updated GDX behavior will allow better differentiation between distinct double-precision values that the user wants mapped to distinct special values. For example, -0.0 is no longer confused with +0.0, and different IEEE NaN values can map to different GAMS special values.

GMO

- Added routines `gmoGetRowQNZOne64`, `gmoMaxQNZ64`, and `gmoObjQMatNZ64` to get element counts as 64-bit integer.
- Adjust routines `gmoGetRowQNZOne`, `gmoMaxQNZ`, and `gmoObjQMatNZ` to return -1 if the element count is too large for a 32-bit integer.
- Added routines `gmoLNZEx` and `gmoLNZEx64` to get the exact count of linear nonzeros in the Jacobian matrix, and adjusted the description of `gmoLNZ` and `gmoLNZ64` to make clear that these are legacy routines returning an overestimate of this count, especially when gmoUseQ is true.
- Fix gradient intervals for functions involving power(x,i) for i >= 4 and even.

High-level APIs

- The `GAMSDatabase` GDX export method now writes *regular* instead of just *relaxed* domain information if available.

PAL

- Added function `palIsAlpha`. `palIsAlfa` has been deprecated.

Python

- Added support for Python 3.10.
- We plan to drop support for Python 3.6 in a future GAMS release.

3.11.1.7 Model Libraries

GAMS Data Library

New model:

- **GMSPythonLib.gms : GMSPYTHONLIB compatibility check** (142)

GAMS Test Library

New models:

- **dumpopt2.gms : Test dumpOpt with dumpOptGDX**
- **encoding01.gms : Test processing of source files with BOM**

3.11.2 38.2.0 Minor release (February 17, 2022)

3.11.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Gwendal Nivanen.

3.11.2.2 GAMS System

GAMS

- Fixed an incorrect evaluation of intrinsic functions (and their derivatives) having a variable number of arguments (e.g. `edist` or `poly`). This error did not occur in all cases: it depended on a missing or incorrect initialization in the calling environment.
- Fixed a problem in the extrinsic function declaration which required <`FuncName`> to be case sensitive.

3.11.2.3 Solvers

BARON

- New libraries 22.2.3.

CONOPT

- New libraries 4.26.
  - Removed option "Flg_Crash_Basis".
  - Changed default of option Lim_Start_Degen from 10 to 100.

CONVERT

- Fix missing semi-colon at end of comment in lingo output.
- Fix unary minus in lingo output.

COPT

- Added option readparams to instruct COPT to read an additional parameters file.

CPLEX

- Fix solution pool export: Previously the solution pool was only exported if CPLEX terminated successfully with a solution. Now, the solution pool GDX is exported independent of the CPLEX termination status, but may contain no solution. solnpoolpoprepeat and solnpoolpopdel still don't have any effect if CPLEX terminated unsuccessfully.

GAMSCHK

- Add a missing initialization for the case where no subsolver is called. Without this initialization, incorrect output would occur.

Ipopt

- New libraries 3.14.5.
  - Fixed that marginals were always zero if Ipopt stopped due to reaching a timelimit.

XPRESS

- New libraries 39.01.04.

3.11.2.4 APIs

High-level APIs

- Fixed a problem with `GAMSModelInstance.Instantiate` complaining about a missing dictionary file. This happened when a (default) solver for the model type of the instance is active which does not use a dictionary.

GAMS Transfer Python

- Added new property `shape` to `Parameter`, `Variable`, and `Equation` to report the corresponding matrix shape if `toDense` or `toSparseCoo` are called.
- Fixed bug with array generation (1D symbols): `toDense` will now generate a `(n,)` array instead `(1,n)`; harmonized this behavior with `toSparseCoo`.
- Fixed behavior: when `toDense` is called on a scalar symbol an array of shape `()` will be returned instead of a `float`.
- Fixed behavior: when `toSparseCoo` is called on a scalar symbol a sparse `coo_matrix` of shape `(1,1)` will be returned instead of a `float`.
- Better handling of numeric domain information within `setRecords` methods: numeric entries are now converted to `str` and generate categories from the `str` equivalents.

GMO

- The default for the property `gmoHessInclQRows` was accidentally changed to false with GAMS 35.1.0. With this release, it has been changed back to its original setting of `true`. That is, also if `useQ` is set, the Hessian will include information on quadratic equations by default again.

3.11.3 38.2.1 Maintenance release (February 19, 2022)

3.11.3.1 Solvers

CONOPT

- Fixed warning about unknown option name "FLG_CRASH_BASIS" (introduced with GAMS 38.2.0).

Convert

- Fixed error when exporting CNS models with ampl, jump, lingo and pyomo.

Octeract

- Avoid that an ObjEst of ±1.797693134E308 is reported as 1797693134 in GAMS tracefile.

3.11.4 38.3.0 Minor release (April 05, 2022)

3.11.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Daniel Dias, Antti Lehtila, Scott MacDonald, Evangelos Panos, Richard Waltz and Eric Williams.

3.11.4.2 GAMS System

GAMS

- Fixed wrong numbers about infeasibilities (e.g., in the report summary) when bounds with value `EPS` are involved.
- Fixed potential unwanted domain violation error when implicit set definition is used while $onMulti is active to allow a redefinition of symbol data.
- Fixed potential error when loading data filtered from embedded code.

3.11.4.3 Solvers

BARON

- New libraries 22.3.21.

CONVERT

- Fixed export of variable attribute stage for discrete variables when using option DumpGDX.
- Fixed that coefficients in `QCMATRIX` section were wrong. They had only half its value.
- Fixed missing asterisk for bilinear terms in CplexLP format.

COPT

- Fixed that indicators from solver options file were ignored.

CPLEX

- Fixed bug with registering an advanced basis.
- Fixed CPLEX solution status `CPX_STAT_NUM_BEST`. This status is mapped to GAMS model status `feasible`.
- Fixed interactive mode (when no trigger file is set).

GUROBI

- New libraries 9.5.1.

IPOPT

- Fixed that names for vector entries corresponding to inequality equations (as shown with print_level ≥ 8) could be incorrect due to a wrong mapping of indices.

KNITRO

- Fixed unnecessary calls to Knitro evaluation callbacks for linear or quadratic constraints.

Mosek

- New libraries 9.3.18.

Octeract

- New libraries 4.2.0.
  - Improved performance, in particular for problems with quadratic structures.
  - CPLEX is now automatically chosen as subsolver, if licensed.

SCIP Optimization Suite

- New libraries SCIP 8.0 (189beeaf30).
  - Clique lifting for setpartitioning/packing/covering constraints is now only disabled if it has been applied.
- New libraries PaPILO 2.0 (g166dea4).

XPRESS

- New libraries 39.01.05.
- Changed option default of xslp_iterLimit: -1 (auto).

3.11.4.4 Tools

MODEL2TEX

- Fixed a crash that occurred when `SameAs` was used in equations.

MPS2GMS

- Fixed that variables in SOS of type 2 were written as SOS of type 1 to GDX file.
- Fixed that upper bounds of 100 for (semi)integer variables were lost.
- Fixed that `N`-rows that did not specify objective functions were not omitted in parameter `p` (equation right-hand sides).
- Fixed that nonzero coefficients with absolute value at most 1e-20 were lost.
- Fixed that `C`-rows had arbitrary right-hand side value in GDX file (though this value was not accessed from the GAMS model).
- Fixed that an objective constant (nonzero `RHS` for objective row in MPS file) was lost.
- Fixed that off-diagonal elements in `QUADOBJ` and `QSECTION` sections were not handled correctly.

GAMS Studio

- New version 1.9.6 with various bug fixes, stability improvements, and minor enhancements, e.g.:
  - Added `Page-up/-down` keys to extend block edit selection.
  - Added separator line on Windows in horizontal headers of tables and tree views.
  - Remote jobs now can be kept active on Studio exit.
  - Fixed crash in GDX Viewer related to reading a file containing negative UELs.
  - Fixed empty log file when using `logOption=2`.
  - Fixed search not properly counting search results across multiple files.
  - Fixed "Replace All" preview wrongfully including read-only files.
  - Fixed "Search" not always jumping to a result outside current file.
  - Fixed NEOS freezing when the GMS file is not located in the working directory.

3.11.4.5 APIs

GAMS Transfer Python

- Fixed memory leak associated with `gams2numpy`.

3.12 37 Distribution

3.12.1 37.1.0 Major release (November 11, 2021)

3.12.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Boyan Atanasov, Edna Johanna Molina Bacca, Abhijit Bora, Wolfgang Britz, Bruno Charlier, Hancheng Dai, Rob Davies, Ricardo M. Pinto de Lima, Bruce McCarl, Scott McDonald, Guillaume Nimal, Gwendal Nivanen, Zack Pecenak, Tom Rutherford, Nick Sahinidis, Shima Sasanpour, and Denys Yemshanov.

3.12.1.2 Platforms

- We will drop support for macOS 10.14 (Mojave) with the next major release.

3.12.1.3 GAMS System

GAMS

- Added new intrinsic function logit.
- Added new conditional expression `onState` to check the state of certain dollar control options. An example can be seen here.
- Added command line parameter and option EpsToZero as well es dollar control options $onEpsToZero and `$offEpsToZero` to allow writing `EPS` values as zero to GDX.
- Made command line parameters holdFixedAsync, sys15, sys16, sys17, sys18, and sys19 available in option statements as well.
- Avoid warnings if $abort or $call.checkErrorLevel are used within a $ifThen ... $else statement.
- Allow space in limited domain declaration like this: `Model transport / all, x (ij) /;`
- In the past, GAMS threw an execution error, when execute_unload failed because of an invalid file name given. Now, it tries to write to a file with a generic file name first (like it was always done with put files as well).
- Added a new command line parameter and option maxGenericFiles to specify the number of tries to write to a generic file as mentioned above.
- Extended the influence of $offInclude to suppress the include file summary and the creation of an expanded include file as well.
- Added support for (mixed-integer) linear models that generate more than 2^{31} = 2,147,483,648 nonzeros. At this time, only the solver links for CPLEX, GUROBI, and XPRESS are capable of handling such large model instances. The number of rows and columns is still limited to 2^{31}.
- Removed a limitation for the model attribute handle that did not allow to set a value which is anything but a Grid handle (specifically, a multi threading handle was rejected before).
- Throw an explicit execution error, if a solver that comes without executable gets called with the Grid Facility (at the moment, this affects DECIS only).
- Fixed calling a solver with the Grid Facility that is not located in the GAMS system directory.
- Fixed alignment of dmpSym and dmpUserSym output in case of long symbol names.
- Fixed handling of paths with spaces in `gamsconfig.yaml` for items `scriptName` and `executableName` in section `solverConfig`.
- $Call, execute, and it's variants allow now spaces in the path of the script/program to be called if properly quoted.
- Fixed a zero digit `display` bug, where `0` was shown as `0.`.
- Fixed wrong matrix error detections for discrete variables and right hand side of external equations in certain cases.
- Fixed that the GAMS execution system corrupted control or status information in the CPUs SSE registers on Linux when using `$IfE`, `$IfThenE`, and related.

Embedded Python Code Facility

- Print the Python script line number in case an exception is raised.
- Register alias symbols in `gams.db`.
- Provide domain information for symbols via `gams.db[sym].domains` and `gams.db[sym].domains_as_strings`.
- Fix a problem in `pyEmbMI` for double bounded but not fixed variables.
- The Python version of GMSPython has been updated to `3.8.11`.
- Removed package `schema` and its dependency `contextlib2` from GMSPython.

Extended Mathematical Programming (EMP)

- Added new stochastic EMP keyword stageDefault to change the default stage of symbols not assigned to a stage explicitly.
- Changed the `stage` behavior so that it does not count as a terminating error if it is used with a symbol missing in the model.

Windows Installer

- Associate `.gsp` (GAMS Studio project) files with GAMS Studio.

3.12.1.4 Solvers

ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2021.2.0 on Windows.

CONVERT

- Fix default behavior if reading option file fails.

CPLEX

- Fixed duplicate CPLEX output in GUSS cold starts with GUSS `logoption` 2.
- Fixed unwanted consideration of some GAMS command line options in tuning.
- Fixed possible ignorance of an interrupt signal (Ctrl+C).
- Disabling CPLEX solution pool on default (when solnpool and solnpoolmerge are not set).
- Fixed invocation of solution pool export in case of CPLEX termination code 104: solution limit reached.
- Fixed possible crash when using mipstopexpr.

GUROBI

- New libraries 9.5.0.
  - Added norm constraints to general constraint type.
  - New option memlimit: Memory limit.
  - New option worklimit: Work limit.
  - New option lpwarmstart: Warm start usage in simplex.
  - New option nlpheur: Controls the NLP heuristic for non-convex quadratic models.
  - New option presos1encoding: Controls SOS1 reformulation.
  - New option presos2encoding: Controls SOS2 reformulation.
  - New option tunemetric: Metric to aggregate results into a single measure.
  - New option tunetargetmipgap: A target gap to be reached.
  - New option tunetargettime: A target runtime in seconds to be reached.
  - New option liftprojectcuts: Lift-and-project cut generation.
  - Changed default option value of TuneTrials: 0 (auto).
  - Changed default option value of CrossoverBasis: -1 (auto). The option type changed from boolean to integer.

GUSS

- Fixed detection of update requests with symbols that are not present in the generated model.
- Fixed incorrect behavior of option `SolveEmpty` (not only empty but all scenarios were skipped after threshold reached).

KNITRO

- Added support for MCP model type.

Lindo/LindoGlobal

- New libraries 13.0.309.
- Added support for function logit.

LocalSolver

- New libraries 10.5 (20211014).

Mosek

- New libraries 9.3.7.

Octeract

- Added new global MINLP solver Octeract 3.5.0.
- Octeract can be used for model types QCP, RMIQCP, MIQCP, NLP, DNLP, RMINLP, and MINLP and is available for Linux and Windows systems.
- For GAMS demo and community licenses, model size limitations similar to other global solvers apply. For an unlimited GAMS/Octeract license, contact `sales@gams.com`.

SCIP

- New libraries 7.0 (b2afa5403b).

SHOT

- New libraries 1.1.0 (11fda1ec).
  - New option Model.Reformulation.Quadratics.EigenValueDecomposition.Formulation.
  - New option Model.Reformulation.Quadratics.EigenValueDecomposition.Method.
  - Renamed option `Model.Reformulation.Quadratics.UseEigenValueDecomposition` to Model.Reformulation.Quadratics.EigenValueDecomposition.Use.
  - Default value for option Subsolver.Gurobi.NumericFocus changed from 2 to 1.

SOPLEX

- New libraries 5.0 (ad7592b9).

XPRESS

- New libraries 38.01.05.

3.12.1.5 Tools

BIB2GMS

- We will remove the tool `bib2gms` in a future GAMS release.

FINDTHISGAMS

- Support for registry keys for `.gsp` (GAMS Studio project) file association has been added.

GAMS Studio

- New version 1.8.2.
  - New feature: Added tooltips to source code for keywords and Dollar Control Options (can be deactivated in the settings dialog).
  - Rework of the Project Explorer:
    - Changed naming from "group" to "project".
    - Files now appear in folders relative to the working directory of the assigned project.
    - Added import and export of projects.
    - The projects context menu "Project options" allows to change the name and working directory of the project.
    - Added individual working directories for each project.
    - Added dialog to set the base directory on project import.
  - Highlight remotely executed log (NEOS or GAMS Engine).
  - Removed obsolete MIRO Hypercube mode.
  - Replace TAB characters by the proper amount of spaces when pasting text.
  - Set default TAB size to 8.
  - Allow to use GAMS Engine on a HTTP server when the local SSL is not present.
  - Skipped log duplicate in the NEOS log.
  - Added new search scope `Selection` which allows users to search inside a text selection.
  - Added zoom for `lxi` tree view when zooming in lst files.
  - Stability improvements and minor bug fixes, e.g.:
    - Fixed NEOS and GAMS Engine being inactive due to an SSL detection issue.
    - Fixed links to model in NEOS log.
    - Fixed crash when editing long lines ending in an error mark.
    - Fixed highlighting of wrong results in Search Result View.
    - Fixed broken syntax highlighting of `execute_*`.
    - Fixed completer not opening or staying open unwanted.

GDX2HAR/HAR2GDX

- We will remove the tools gdx2har and har2gdx in a future GAMS release. The tools can be accessed from the CoPS web site.

HEXDUMP

- We will remove the tool `hexdump` in a future GAMS release. A similar functionality is available on Unix systems via the `od` utility with parameters `od -A x -t x1z -v`. On Windows `od` is distributed as part of the POSIX utilities.

SCENRED

- We will remove the tool SCENRED in a future GAMS release. The tool SCENRED2 should be used instead.

3.12.1.6 APIs

C++ high-level API

- Fixed `GAMSOption::setOutput` parameter being ignored in `GAMSJob::run()`.

gams2numpy

- The binaries are now build with `numpy 1.20.3` instead of `numpy 1.19.5` for Python 3.7, 3.8, and 3.9.

GAMS Transfer

- New APIs **GAMS Transfer Matlab** and GAMS Transfer for Python to exchange data between GAMS and Matlab and Python, respectively.

GMD

- Allow to add symbols via `gmdAddSymbol` and `gmdAddSymbolX` of type alias (`GMS_DT_ALIAS`).
- Added function `gmdFindSymbolWithAlias` that provides the actual alias symbol rather than the aliased set in case the requested symbol is an alias.
- Added function `gmdGetSymbolByNumber` that provides the symbol based on the GMD_NUMBER which includes the alias symbols.
- Added information key `GMD_NRSYMBOLSWITHALIAS` for function `gmdInfo` to retrieve the number of symbols including alias symbols.

GMO

- Adjusted routine `gmoGetMatrixCol` to fail if called where quadratic structure is explicitly detected/handled (i.e. `useQ` is set). This routine was not intended to be used in this case.
- Added routines `gmoNZ64`, `gmoNLNZ64`, and `gmoLNZ64` to get non-zero counts as 64-bit integer.
- Fixed routine `gmoDirtySetRowFNLInstr`: it was not computing the number of stored NL instructions correctly.

PAL

- Added routines `palLicenseSolverCheckSizes64` and `palLicenseCheck64` for solvers that use 64-bit integers for non-zero counts.

Python high-level API

- Fixed a problem with property `domains` of a symbol in case the domain list consists of a `GamsSet` and string elements.

3.12.1.7 Model Libraries

GAMS Model Library

- MS Access and Excel files have been updated to the MS Office 2007 format, i.e., files with the `xls` extension were changed to `xlsx` or `xlsm` files, files with the `mdb` extension were changed to `accdb` files.
- The structured bibliographic information has been removed. As a consequence, the *Author* column in the table of models (documentation and Studio/IDE) has been removed as well as the *Reference* section for the individual model page (web). The bibliographic references remain part of the model source.

New Models:

- **rcpsp.gms : Resource-Constrained Project Scheduling Problem** (429)

GAMS Test Library

New models:

- **asyncfix02.gms : Test asynchronous solves with holdFixedAsync setting**
- **genfile01.gms : Test generic file names**
- **offinc01.gms : Test dollar control option $offInclude**
- **embpy11.gms : Test proper domain info in Embedded Code**
- **dco01.gms : Test default state and switching state for dollar control options**
- **epstozero1.gms : Test writing eps as zero to GDX**
- **fnlogit.gms : Test correctness of logit intrinsic**
- **empsp01.gms : Test EMPSP keyword stageDefault**
- **gurobi06.gms : GUROBI test suite - general constraints norm**

3.13 36 Distribution

3.13.1 36.1.0 Major release (August 02, 2021)

3.13.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ricardo Manuel Pinto de Lima, Bruce McCarl, Scott McDonald, and Kirk A. Yost.

3.13.1.2 GAMS System

- The End User License Agreement (`eula.pdf` in the GAMS system directory) has been updated to version 08/2021.

GAMS

- Improved performance of model generation for certain equations where the index order of the equations caused an out of order index reference of variables like in this example:

  ```
  ejk(j,k)..  sum(i, x(i,j,k)) =e= 42;
  ```

  Added new command line parameter sys19 to deactivate this performance optimization.
- Added new function platformCode and new compile time constants to be used with it.
- Added information about available CPU sockets, cores, and threads to the log.
- Improve error message for invalid values of the `.scale` attribute.
- Allow to read environment variables and command line parameters at execution time in put context.
- Added Put_Utility commands `setEnv` and `dropEnv` to allow environment variable modification at execution time.
- Added Python function `gams.get_env` to EmbeddedCode Python to access modified environment variables after Python module `os` has been initialized.
- Fixed a problem causing an unexpected error when beginning execution time embedded code as first statement after starting from a restart file.
- Fixed a potential warning using execution time embedded code after starting from a restart file which was created with action=c.

Windows Installer

- Windows installer is now built with `Inno Setup 6`.
- Command line parameter `/allUsers=yes|no` has been deprecated and will be removed in a future GAMS release. Use the new parameter `/installAllUsers=yes|no` instead.
- New command line flags `/allUsers` and `/currentUser` can be used to explicitly control if the installation is performed in administrative or non-administrative installation mode.

GMSPython

- The Python version has been updated to `3.8.10`.

3.13.1.3 Solvers

Bonmin

- We plan to drop Bonmin and BonminH with one of the next major releases.

CONVERT

- Added support for quadratic constraints in formats CplexLP, CplexMPS, and FixedMPS.
- Added option SkipNRows.
- Added option QExtractAlg.
- Fixed writing `eps` for zero marginals of non-basic variables or equations in format Gams.

CPLEX

- Added the following options:
  - multobjoptfiles: List of option files used for individual solves within multi-objective optimization.
  - usercut: User cut activation.
  - usercutpool: Indicator to use user cuts.
  - qextractalg: quadratic extraction algorithm in GAMS interface.
- Fixed handling of special values (incl. missing zero values) in multimipstart.
- Fixed update of Jacobian elements within GUSS scenarios.
- Fixed setting gubcovers via cuts.

GUROBI

- Added option qextractalg: quadratic extraction algorithm in GAMS interface.

GUSS

- Added support of option savepoint for scenario solves.

Ipopt and IpoptH

- New libraries 3.14.1.

  Attention
  - Value `pardiso` of option linear_solver to choose Pardiso from Intel MKL has been **renamed to** `pardisomkl`. Renamed `pardiso_*` options to pardisomkl_*.
  - Added value `pardiso` for option linear_solver to choose to use Pardiso from the `Pardiso Solver Project`. This solver is **not included in the GAMS distribution**. A user needs to provide a Pardiso library. Added option pardisolib to specify name and path of Pardiso library. Added pardiso_* options.
  - Added option hsllib to specify name and path of HSL library to be loaded at runtime (for users of GAMS/Ipopt or users that want to use HSL_MA77).
  - Changed default of honor_original_bounds to `no`. In addition, Ipopt now ensures that, in addition to option bound_relax_factor, variable bounds are relaxed by at most constr_viol_tol. The Ipopt log now shows the violation of variable bounds in the solution.
  - Fixed that marginals for fixed variables were not computed if fixed_variable_treatment is set to `make_parameter` (the default). Added value `make_parameter_nodual` for this option to disable calculation of marginals for fixed variables (which can cost an extra evaluation of the Jacobian).
  - Added options max_wall_time, print_options_mode, print_advanced_options, and timing_statistics.
  - Ipopt should now be threadsafe also when used with MUMPS as linear solver (a mutex ensures that only one thread executes MUMPS at a time).
  - For more information, including bugfixes, see the `Ipopt 3.14.0 release notes`.
- Changed default of constr_viol_tol to 1e-6.
- GAMS ResLim now sets the default for Ipopt option max_wall_time instead of max_cpu_time.

- If GAMS ScaleOpt is set, i.e., the model has been scaled manually, then the default of option nlp_scaling_method is set to `none`.
- The interface has been extended to warmstart Ipopt if a modified model instance is solved, e.g., in the context of GUSS. For the warmstart, previously initialized Ipopt data structures are reused if possible and option warm_start_init_point is enabled, see also Warmstarting IPOPT.
- Enabled solvelink=6 capability for Ipopt and IpoptH.
- Update of HSL routines (IpoptH only):
  - MA57 3.11.0.
  - HSL_MC68 3.3.1.
  - HSL_MA86 1.6.0.
  - HSL_MA97 2.6.0.
- Update of MUMPS to version 5.4.0.
- Changed default of mumps_pivot_order from 5 to 7.

JAMS

- Updated behavior and logging for models with `equ.var` matches in the model statement. If the trivial (aka empty or default) model transformation is specified in the EMP info file, nothing changes: the matches are used as before. In contrast, if a nontrivial or nonempty transformation is specified, the matches are ignored when creating the reformulated model and a message to this effect is sent to the log.

KNITRO

- New libraries 12.4.
  - Improved performance on mixed-integer nonlinear problems (MINLP).
  - Improved performance when using the limited-memory quasi-Newton Hessian approximation.
  - Added option linsolver_maxitref: Indicates the maximum allowable number of iterative refinement steps applied when a linear system is solved inside Knitro.
  - Added option bfgs_scaling: Specify the initial scaling to use for the BFGS or L-BFGS Hessian approximation.
  - Added option bar_linsys_storage: Indicates how to store in memory the linear systems used inside the Interior/Direct algorithm for computing primal-dual steps.
  - Added option mip_cutting_plane: Specifies when to apply the cutting plane procedure.
  - Added option mip_heuristic_diving: Specifies whether or not to enable the MIP diving heuristic.
  - Added option mip_heuristic_feaspump: Specifies whether or not to enable the MIP feasibility pump heuristic.
  - Added option mip_heuristic_mpec: Specifies whether or not to enable the MIP MPEC heuristic.
  - Added option mip_heuristic_strategy: Specifies the level of effort applied for the MIP heuristic search used to try to find an initial integer feasible point.
  - Deprecated option `mip_heuristic`: Use mip_heuristic_strategy instead.
- Added option qextractalg: quadratic extraction algorithm in GAMS interface.

Lindo/LindoGlobal

- New libraries 13.0.291.

LocalSolver

- New libraries 10.5 (20210624).

MOSEK

- Added option QEXTRACTALG.
- New libraries 9.2.47.

ODHCPLEX

- New libraries 6.0.4.

PATH

- New libraries 5.0.04 (maintenance release) include capability to further limit preprocessor output by specifying output_preprocess_level -1.

SCIP

- New libraries 7.0 (d012dac064).
- Updated Ipopt to Ipopt 3.14.1, see also above.

SHOT

- New libraries 1.1 (c898dd84).
  - SHOT can now call itself to solve fixed NLP problems. Activated with new value 2 for option Primal.FixedInteger.Solver. For nonconvex problems it is still recommended to use an external NLP solver.
    Added also options Subsolver.SHOT.ReuseHyperplanes.Fraction, Subsolver.SHOT.ReuseHyperplanes.Use, Subsolver.SHOT.UseFBBT.
  - Partition convex nonseparable quadratic functions as separate constraints using an eigenvalue decomposition-based reformulation. Activated with new option `Model.Reformulation.Quadratics.UseEigenV`
  - Support for performing an initial polyhedral approximation of the nonlinear feasible set before feasibility-based bound tightening. Activated with new option Model.BoundTightening.InitialPOA.Use.
    Added also options Model.BoundTightening.InitialPOA.CutStrategy, Model.BoundTightening.InitialPOA.Itera
    Model.BoundTightening.InitialPOA.StagnationIterationLimit, Model.BoundTightening.InitialPOA.Constraint
    Model.BoundTightening.InitialPOA.ObjectiveConstraintTolerance, Model.BoundTightening.InitialPOA.Objec
    Model.BoundTightening.InitialPOA.ObjectiveGapRelative, Model.BoundTightening.InitialPOA.StagnationCo
    Model.BoundTightening.InitialPOA.TimeLimit.
  - Added support for semi-continuous and semi-integer variables.
  - Added support for special ordered sets.
  - Improved support for generating supporting hyperplanes for the entire nonlinear feasible set instead of the feasible sets for the individual constraint functions. Activated with new option Dual.ESH.Rootsearch.UseMaxFunction.

  - Improved support for passing nonconvex quadratic functions directly to the MIP solver (if supported).
  - Added option ModelingSystem.GAMS.QExtractAlg.
  - Added option Output.GAMS.AlternateSolutionsFile.
  - Added option Dual.HyperplaneCuts.SaveHyperplanePoints.
  - Added option Dual.MIP.InfeasibilityRepair.Use.
  - Added option Dual.ReductionCut.Use.
  - Changed default of option Subsolver.Cbc.Scaling from 0 to 4.
  - Changed default of option Subsolver.Cplex.NumericalEmphasis from 0 to 1.
  - Changed default of option Subsolver.Gurobi.PoolSolution from 1 to 10.
  - Changed default of option Model.BoundTightening.FeasibilityBased.TimeLimit from 5 to 2.
  - Changed default of option Termination.DualStagnation.IterationLimit from 50 to ∞.
  - Changed meaning of values 1 and 2 for option Model.Reformulation.Bilinear.IntegerFormulation.
- Updated Ipopt to Ipopt 3.14.1, see also above.

XPRESS

- New libraries 38.01.03.
  - Xpress Optimizer Release Notes:
    * Improved MIP performance.
    * It is now possible to activate a special heuristic solve mode for MIPs, which emphasizes finding new solutions.
    * Improved sifting algorithm when used with Barrier.
    * Improved numerical stability of the Barrier algorithm.
  - Xpress Nonlinear Release Notes:
    * Significant MINLP performance improvements due to improved nonlinear presolver.
    * Improved performance on instances with very large separable nonlinear expressions due to imroved automatic differentiation.
    * Multistart now uses the nonlinear primal integral for tie breaking.
  - Added options:
    * barPerturb: In numerically challenging cases it is often advantageous to apply perturbations on the KKT system to improve its numerical properties.
    * barRefIter: After terminating the barrier algorithm, further refinement steps can be performed.
    * clamping: Allows for the adjustment of returned solution values such that they are always within bounds.
    * clamping_dual: Adjust primal slack values to always be within constraint bounds.
    * clamping_primal: Adjust primal solution to always be within primal bounds.
    * clamping_rdj: Adjust reduced costs to always be within dual bounds implied by the primal solution.
    * clamping_slacks: Adjust dual solution to always be within the dual bounds implied by the slacks.
    * genConsAbsTransformation: Specifies the reformulation method for absolute value general constraints at the beginning of the search.
    * heurEmphasis: Specifies an emphasis for the search w.r.t. primal heuristics and other procedures that affect the speed of convergence of the primal-dual gap.
    * inputTol: Tolerance on input values elements.

    - mipComponents: Determines whether disconnected components in a MIP should be solved as separate MIPs.
    - mipConcurrentNodes: Sets the node limit for when a winning solve is selected when concurrent MIP solves are enabled.
    - mipConcurrentSolves: Selects the number of concurrent solves to start for a MIP.
    - mipRestartFactor: Fine tune initial conditions to trigger an in-tree restart.
    - mipRestartGapThreshold: Initial gap threshold to delay in-tree restart.
    - netStallLimit: Limit the number of degenerate pivots of the network simplex algorithm, before switching to either primal or dual simplex.
    - nodeProbingEffort: Adjusts the overall level of node probing.
    - outputControls: Toggles the printing of all control settings at the beginning of the search.
    - ppFactor: Partial pricing candidate list sizing parameter.
    - preFolding: Determines if a folding procedure should be used to aggregate continuous columns in an equitable partition.
    - siftPasses: Determines how quickly we allow to grow the worker problems during the sifting algorithm.
    - siftSwitch: Determines which algorithm to use for solving the subproblems during sifting.
    - xslp_presolveOps_noLinear: Avoid performing linear reductions at the NLP level.
    - xslp_presolveOps_noSimplifier: Avoid simplifying nonlinear expressions.
  - Added option values:
    - deterministic: 2.
    - mipRestart: 2.
  - Changed option defaults:
    - mipPresolve: -257 to -1.
    - mipPresolve_symmetryReductions: 0 to 1.
  - Deprecated options:
    - `heurStrategy`. Use heurEmphasis instead.
    - `xslp_matrixTol`. Use matrixTol instead.
  - Removed options:
    - `treePresolve_keepBasis`.
    - `treePresolve`.
    - `treePresolveOps`.
    - `xslp_analyze_autosavePool`.
    - `xslp_analyze_recordLinearization`.
    - `xslp_analyze_recordLinesearch`.
    - `xslp_presolvePassLimit`.
    - `xslp_timePrint`.
- Added option algAfterNetwork: Algorithm to be used for the clean up step after the network simplex solver.
- Added option qextractalg: quadratic extraction algorithm in GAMS interface.
- Removed options that were marked deprecated in GAMS 35.

3.13.1.4 Tools

Cholesky, Eigenvalue, Eigenvector, Invert

- We will remove the tools cholesky, eigenvalue, eigenvector, invert in a future GAMS release. Similar functionality has been added via `$libInclude linalg {cholesky,eigenvalue,eigenvector,invert}`. See the header of the file in `<sysdir>\inclib\linalg.gms` for details.

GAMS Studio

- New version 1.7.2.
  - Dropped support for Ubuntu 16.04 LTS and openSUSE Leap 15.2 because the updated AppImage now requires glibc 2.27. Dropped support for Debian 9.
  - New feature: Allow specifying location of User Model Libraries in Settings dialog.
  - Improved visual distinction between current and other groups in Project Explorer.
  - Added a warning message before printing large files.
  - Added a list of solvers for each model type to be selected in Extended Parameter Editor and Configuration Editor.
  - Added shortcut `Alt+I` (macOS: `Option+I`) to fold blocks of dollar control options.
  - Added setting to automatically collapse dollar control option blocks when opening a file (default: off).
  - Changed shortcuts to show/hide Extended Parameter Editor
    - Windows/Linux: From `Ctrl-Alt-3` to `Shift+Ctrl+3`.
    - macOS: From `Shift-Command-3` to `Control-Option-3`.
  - Improvements for syntax highlighter and code completer, e.g.:
    - Added support for system attributes and compile-time constants.
    - Added support of quoted elements in syntax highlighter.
    - Disabled code completer for certain code blocks like `$onEmbeddedCode` or `$onPut`.
  - Improvements for remote execution support, e.g.:
    - Added support for GAMS Engine server with self-signed certificate (`https`).
    - Added support for GAMS Engine server with `http` protocol.
    - Added option to remember login credentials for GAMS Engine in Settings.
    - Renamed "MIRO" Settings page to "Remote" to better reflect new content.
    - Improved GAMS Engine dialog.
    - Added file type `EFI` to send additional files to a GAMS Engine server.
  - Stability improvements and minor bug fixes, e.g.:
    - Fixed duplicate file entries in the Project Explorer when having two references with different case to a single file
    - Fixed Studio title bar appearing outside of screen in some cases.
    - Fixed wrong content of "File" tab in Reference File Viewer.
    - Fixed missing check of some data locations for GAMS license file.
    - Fixed `ESC` key not behaving like close button in Settings dialog.
    - Fixed crash when reopening a closed log tab.
    - Fixed that MIRO menu entries were not enabled when MIRO was automatically discovered.
    - Fixed that theme could be broken in Settings dialog when using cancel button.

GDXRank, GDXRename

- We will remove the tools gdxrank and gdxrename in a future GAMS release. Similar functionality has been added via `$libInclude gdxservice {gdxrank,gdxservice}`. See the header of the file in <sysdir>\inclib\gdxservice.gms for details.
- The `$libInclude rank` functionality now uses `$libInclude gdxservice gdxrank` to sort a one dimensional parameter instead of the gdxrank tool.

MCFilter

- We will remove the tool mcfilter in a future GAMS release. In case you depend on this tool, this discussion at GAMS World Forum gives an alternative.

MSAppAvail, Shellexecute, XLSTalk

- We will remove the tools msappavail, shellexecute, xlstalk in a future GAMS release. Similar functionality has been added via `$libInclude win32 {msappavail,shellexecute,xlstalk}`. See the header of the file in <sysdir>\inclib\win32.gms for details.

3.13.1.5 APIs

- As announced we removed all Delphi variants but the `dcp` version (i.e. `gdxdcpdef.pas`) and all Fortran variants but the `f9` version (i.e. `gdxf9def.f90`) of the low-level APIs.

CFG

- The function `cfgAlgAllowsModifyProblem` now reports correctly for all solvers if they provide the `xyzModifyProblem` functionality instead of a only for a fixed (and incorrect) list of solvers.

C++ high-level API

- Removed dependency on Qt. Now requiring C++17.
- Added support for Microsoft Visual Studio 2019.
- As announced we dropped support for Microsoft Visual Studio 2015.
- As announced, the Clang compiled version of `libgamscpp.dylib` does not work on macOS 10.14 or older anymore. It has been moved to the subfolder `apifiles/C++/lib/Clang/`.
  The new `libgamscpp.dylib` in `apifiles/C++/lib/` is compiled with GCC.

gams_engine

- Updated for GAMS Engine version 21.06.09 and now using OpenAPI Generator version 5.1.1.

gams2numpy

- New optional parameter `merge` in `gams2numpy.gmdFillSymbolStr` that allows duplicate records in the numpy array as well as writing to non-empty symbols.
- New optional parameter `relaxedType` in `gams2numpy.gmdFillSymbol(Str|Raw)`, and `gams2numpy.gdxWriteSymbol` that allows to automatically convert the columns of the numpy array into the required data types if possible.
- Fixed a bug that prevented error messages from being shown on Linux and further improved error handling.

GAMSX

- As announced, we have dropped the GAMSX API with this release. The example `xp_example2` for various languages has been adjusted to call the GAMS executable instead of the `gamsxRunExecDLL` GAMS API function.

GEV

- The `gmoptr` argument in function `gevGetCurrentSolver` is deprecated and not used anymore. It will be removed from this function in some future release. Moreover, the function should only be used in solver link library functions `xyzReadyAPI` or `xyzCallSolver`.
- Add GEV option `SavePoint` to query the savePoint option.

GMO

- Added option `qExtractAlg` to control the technique used to extract quadratic structure from GAMS models. This structure extraction happens automatically for any QCP model type (e.g. QCP, MIQCP) and the current default choice `ThreePass` (= 1) is almost always the best one. But there some cases where `DoubleForward` (= 2) performs much better.

Solverlink library interface

- The API of a solver link library has changed. This will only effect users that install additional solvers or build and maintain own solver link libraries. The older version of the API is deprecated and will be removed in a future GAMS release. Moreover, COIN-OR project `GAMSlinks` provides a template to work with both new and old APIs.

3.13.1.6 Model Libraries

GAMS API Library

- Updated models **CPPex2**, **CSex2**, **Cex2**, **Fex2**, **Jex1**, **Jex2**, **PBuildXPLevelAPI**, and **VBex2** to adjust for the removal of the GAMSX API.
- Updated model **Pgams_engine** to be compatible with the latest `gams_engine` API.

GAMS Data Library

- Many models have been adjusted to use the library include `win32` to compensate for the future drop of the utilities msappavail and shellexecute.
- Updated models **CHP**, **CHP2**, **Portfolio**, **Samurai**, **SpawnGAMSExcel**, **Sudoku**, and **transxls**. The corresponding Excel files have been changed from format `.xls` to `.xlsm`. Moreover, the VBA code has been adjusted to work without the dropped GAMSX API. The registry key to find the GAMS system directory has been updated.
- Model `Samurai2` has been dropped since it became a duplicate of model **Samurai** after the removal of the GAMSX API.
- Model **LeastSquares** has been updated to use `$libInclude linalg OLS` for solving the linear regression problem. The model also works now with more descriptive data set (diabetes data).

GAMS Test Library

New models:

- **platform01.gms : Test platform function**
- **qcp12.gms : Test different GMO Q extraction algorithms**
- **asyncfix01.gms : Test asynchronous solves with holdFixed**
- **savep2.gms : Test savepoint with async solves**
- **convert16.gms : CONVERT test suite - Basic test of convert output for quadratic model**
- **embpy09.gms : Test Embedded Code after restart**
- **scensol8.gms : Check if solver with modify problem use hotstart in GUSS**
- **gdxrename1.gms : Simple gdxrename test**
- **gdxrename2.gms : Tests some gdxrename stuff**
- **scensol9.gms : Test option savepoint in GUSS**
- **embpy10.gms : Test Embedded Code for Environment Variables**
- **etsuf01.gms : Test Execution Time Suffixes**
- **emp33.gms : JAMS: matches from model statement may be ignored**

Models trilib01, trilib02, trilib03, parlib01, cpplib00:

- Removed jinja2 from associated source archive. It is now required to have the Python package `jinja2` installed to run the `ql.py` script.

3.13.2 36.2.0 Minor release (September 03, 2021)

3.13.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Daniel Dias, Andreas Lundell, Bruce McCarl, and Tom Rutherford.

3.13.2.2 GAMS System

GAMS

- Added new command line parameter holdFixedAsync to allow the use of holdFixed for models solved asynchronously. Activating this option can lead to inconsistent solutions being reported.
- Fixed a potential crash introduced with GAMS 36.1.0 related to the improved performance of model generation.

3.13.2.3 Solvers

CONVERT

- Fixed MCP mapping for DumpGDX.

GAMSCHK

- Fix default solve behavior: if no GCK file is specified, no subsolver should be called as no solution is wanted.

GUSS

- Fixed options `OptfileInit` and `Optfile` being ignored.
- Added fallback to cold start in case of hot start failure.

IPOPT

- New libraries 3.14.3.
- Updated MUMPS to version 5.4.1.

MOSEK

- New libraries 9.3.4.

SHOT

- New libraries 1.1 (9a8893e7).

3.13.2.4 Tools

GAMS Studio

- New version 1.7.3 with various bug fixes, stability improvements, and minor enhancements, e.g.:
  - Allow to duplicate multiple lines at once.
  - Added navigation and selection by word using `ctrl+left/right` in LOG-Viewer.
  - Fixed highlighting issue when a symbol declaration ends with a space.
  - Fixed horizontal scroll in LST viewer when cursor is out of view.
  - Fixed that searching backwards in modified document was not working.
  - Fixed "Replace" ignoring case sensitivity option.

3.14 35 Distribution

3.14.1 35.1.0 Major release (April 29, 2021)

3.14.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Matthew Adams, Jürgen Apfelbeck, Wolfgang Britz, Yacine Gaoua, Carolin Kellenbrink, Masoud Javadi, Bruce McCarl, Scott McDonald, Will Raymond, Tom Rutherford, Sebastian Spieker, and Kirk A. Yost.

3.14.1.2 Platforms

- macOS 11 (on Intel CPUs) has been added to the list of supported macOS versions.

3.14.1.3 GAMS System

GAMS

- Added new dollar control options gdxLoad and gdxUnload to load and unload symbols from and to GDX files in a single instruction at compile time.
- Print an extra log line for echo dollar control options $echo, $echoN, and $onEcho, which write to an external file. When running GAMS from one of the GAMS IDEs, this log line can be clicked to open the file created.
- Extended the report generated by dmpSym and dmpUserSym to include another column reporting a memory estimate for each set, parameter, variable, and equation.
- Removed the columns `DIM-OK`, `ACCESS`, `SPECVAL`, `EXTERN`, `TABLE`, `DOMAIN`, and `LAGLEAD` from the report generated by dmpUserSym. This information is very technical and mostly of internal interest. These columns are still available with dmpSym.
- The status of Multi-Threading for the Grid and Multi-Threading Solve Facility has been changed from beta to released and fully supported.
- Fixed that the stars option was ignored for some messages in the output file.
- Fixed a problem that causes default records in the data statement or when loaded from GDX (see $load) being ignored with implicit set definition. So with

  ```
  Set i;
  Parameter p(i<) / i0 0, i1 1, i2 2 /;
  ```

  only `i1` and `i2` made it into `i`. Now, `i0` is added as well.
- Fixed a problem, where $onDotL and $onDotScale were ignored in put statements.
- Fixed a problem, where $onDelim was applied incorrectly to `display` and `option` statements.
- Fixed a problem, where $onSymXRef and $onUElXRef were ignored when there were too many references.
- Fixed and extended the behavior of $eval: If a GAMS function was hidden by a user defined symbol, `$eval` ignored the latter. This has been changed. Now, the GAMS function needs to be prefixed with `system.` to be accessed in this case. An example for this behavior is given here.
- Fixed a potential problem when doing a filtered load of symbols with domain violations through EmbeddedCode.
- Fixed an unwanted compilation error that happened if $onExternalInput or $onExternalOutput were used on the same line and after $if.
- Fixed a problem where dumpOpt in combination with $onVerbatim skipped a leading substitution character in an $ifThen block.

3.14.1.4 Solvers

AlphaECP

- New version 2.11.01.
  - New options:
    - ECPtoltype: AlphaECP termination criterion.
    - MIPoptcrlimtype: Strategy to increase MIPoptcrlim.
    - MIPoptimaliter: MIP is solved to optimality with this frequency.
    - TOLoptcr: Relative termination tolerance for MINLP.
  - Minor bugfixes.
  - For more information, see the `release paper`.

ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2021.2.0 on Linux and macOS.

BARON

- The NLP solver selected with option extNLPSolver is used in case NLPSol is set to -1 or 6 (and AllowExternal is 1). In the previous releases Conopt was used with NLPSol value -1.

BONMIN

- Fixed an issue where a problem with SOS constraints was rejected due to falsely detected negative variable bounds.

CONOPT

- New libraries for CONOPT3: 3.17K
  - Fixed perturbations of the Jacobian for external equations where 2nd order derivatives are not available.
- Fixed an issue resulting in insufficient CONOPT3 memory.
- Fixed an issue with multi-threading in CONOPT 4.

CPLEX

- New libraries 20.1.0.1.
- Added option usercallparmfile: Command-line parameter include file used in GAMS command-line calls triggered by BCH.
- Fixed incorrect reporting of infeasible solutions of the unrelaxed model in feasopt mode.
- Fixed incorrect variable matching for options objnreltol and objnabstol.
- Fixed parsing of individual objective functions for multiobjective optimization (any ordering of equation definitions is allowed now).

GAMSCHK

- Fix problem with handling of row/column patterns introduced in GAMS 34.3.

GUROBI

- New libraries 9.1.2.
- Added possibility to write a single GDX file with the solution pool (see solnpoolmerge).
- Added the following options:
  - solnpoolmerge: Enable merged solution pool GDX.
  - solnpoolnumsym: Number of variable symbols in merged solution pool GDX.
  - solnpoolprefix: Prefix for variable symbols in merged solution pool GDX.
  - miptrace: Filename of MIP trace file (formerly hidden and undocumented).
  - miptracenode: Node interval when a trace record is written (formerly hidden and undocumented).
  - miptracetime: Time interval when a trace record is written (formerly hidden and undocumented).
- Fixed incorrectly processed (hidden) options `isvname` and `appname`.

GUSS/Scenario Solver

- Measure time internally rather then relying on solvers' reported resUsd to determine the overall running time.

KNITRO

- New GAMS/Knitro link using the KN interface.
- Enabled the possibility to use solvelink = 5 on Linux (other platforms were already enabled).
- Added support of variable and equation scaling.
- Added options:
  - names: Enable to pass variable and equation names to Knitro.
  - blasoptionlib: Specifies a dynamic library name that contains object code for BLAS/LAPACK functions.
  - bndrange: Specifies max limits on the magnitude of constraint and variable bounds.
  - cg_pmem: Specifies the amount of nonzero elements per column of the Hessian of the Lagrangian which are retained when computing the incomplete Cholesky preconditioner.
  - cg_precond: Specifies whether an incomplete Cholesky preconditioner is applied during CG iterations in barrier algorithms.
  - cg_stoptol: Specifies the relative stopping tolerance used for the conjugate gradient (CG) subproblem solves.
  - convex: Declare the problem as convex by setting to 1 or non-convex by setting to 0.
  - cpuplatform: Specify the target instruction set architecture.
  - initpenalty: Specifies the initial penalty parameter used in the Knitro merit functions.

- linesearch: Indicates which linesearch strategy to use for the Interior/Direct or SQP algorithm to search for a new acceptable iterate.
- newpoint: Specifies additional action to take after every iteration in a solve of a continuous problem.
- presolve_level: Set the level of presolve operations to enable through the Knitro presolver.
- presolve_initpt: Control whether the Knitro presolver can shift a user-supplied initial point.
- presolve_passes: Set a maximum limit on the number of passes through the Knitro presolve operations.
- presolveop_tighten: Determine whether or not to enable the Knitro presolve operation to tighten variable bounds.
- restarts: Specifies whether or not to enable automatic restarts in Knitro.
- restarts_maxit: When restarts are enabled, this option can be used to specify a maximum number of iterations before enforcing a restart.
- strat_warm_start: Specifies whether or not to invoke a warm-start strategy.
- findiff_relstepsize: Specifies the relative stepsize used for finite-difference gradients.
- findiff_terminate: Specifies the termination criteria when using finite-difference gradients.
- infeastol_iters: The optimization process will terminate if the relative change in the feasibility error is less than infeastol for infeastol_iters consecutive infeasible iterations.
- xtol_iters: The optimization process will terminate if the relative change in all components of the solution point estimate is less than xtol for xtol_iters.
- bar_conic_enable: Enable special treatments for conic constraints when using the Interior/Direct algorithm (has no affect when using the Interior/CG algorithm).
- bar_initpi_mpec: Specifies the initial value for the MPEC penalty parameter π used when solving problems with complementarity constraints using the barrier algorithms.
- bar_linsys: Indicates which linear system form is used inside the Interior/Direct algorithm for computing primal-dual steps.
- bar_maxcorrectors: Specifies the maximum number of corrector steps allowed for primal-dual steps.
- bar_slackboundpush: Specifies the amount by which the barrier slack variables are initially pushed inside the bounds.
- bar_switchobj: Indicates which objective function to use when the barrier algorithms switch to a pure feasibility phase.
- act_lpfeastol: Specifies the feasibility tolerance used for linear programming subproblems solved when using the Active Set or SQP algorithms.
- act_lppenalty: Indicates whether to use a penalty formulation for linear programming subproblems in the Knitro Active Set or SQP algorithms.
- act_lppresolve: Indicates whether to apply a presolve for linear programming subproblems in the Knitro Active Set or SQP algorithms.
- act_parametric: Indicates whether to use a parametric approach when solving linear programming (LP) subproblems when using the Knitro Active Set or SQP algorithms.
- act_qppenalty: Indicates whether to use a penalty formulation for quadratic programming subproblems in the Knitro SQP algorithm.
- mip_clique: Specifies rules for adding clique cuts.
- mip_cutfactor: This value specifies a limit on the number of cuts added to a node subproblem.
- mip_heuristic_terminate: Specifies the condition for terminating the MIP heuristic.
- mip_intvar_strategy: Specifies how to handle integer variables.
- mip_mir: Specifies rules for adding mixed integer rounding cuts.
- mip_selectdir: Specifies the MIP node selection direction rule (for tiebreakers) for choosing the next node in the branch and bound tree.

  - mip_zerohalf: Specifies rules for adding zero-half cuts.
  - ma_outsub: Enable writing algorithm output to files for the multi-algorithm (algorithm=5) procedure.
  - ms_num_to_save: Specifies the number of distinct feasible points to save in a file named `knitro_mspoints`.
  - ms_outsub: Enable writing algorithm output to files for the parallel multistart procedure.
  - ms_savetol: Specifies the tolerance for deciding if two feasible points are distinct.
  - `par_msnumthreads`: Specify the number of threads to use for multistart (when ms_enable = 1).
  - out_csvinfo: Controls whether or not to generates a file `knitro_solve`.
  - out_csvname: Use to specify a custom csv filename when using out_csvinfo.
  - out_hints: Specifies whether to print diagnostic hints (e.g. about user option settings) after solving.
  - outappend: Specifies whether output should be started in a new file, or appended to existing files.
  - outdir: Specifies a single directory as the location to write all output files.
  - outmode: Specifies where to direct the output from Knitro.
  - outname: Use to specify a custom filename when output is written to a file using outmode.

- Added values to the following options:
  - blasoption: 2 (dynamic)
  - `bar_pencons`: -1 (auto), 3 (equalities)
  - hessopt: 7 (gauss_newton)
  - honorbnds: -1 (auto)
  - ma_terminate: 3
  - mip_knapsack: 3 (all)
  - mip_outlevel: 2 (iterstime), 3 (root)
  - mip_rootalg: 4 (sqp), 5 (multi)
  - scale: 2 (user_none), 3 (internal)

- Updated the following options to KNITRO defaults:
  - fstopval: maxdouble
  - honorbnds: -1 (auto)
  - `par_blasnumthreads`: 0
  - `par_lsnumthreads`: 0
  - xtol: 1e-12
  - `bar_pencons`: -1 (auto)
  - bar_switchrule: -1 (auto)
  - mip_maxnodes: 0
  - mip_maxsolves: 0
  - mip_rounding: -1 (auto)

- Deprecated options:
  - bar_maxbacktrack: Use linesearch_maxtrials instead.
  - maxcgit: Use cg_maxit instead.
  - pivot: Use linsolver_pivottol instead.

- Removed formerly deprecated options:
  - maxcrossit

  - mu
  - feasible
  - feasmodetol
  - barrule
- Removed unused option `reform`.
- Fixed an issue with options not being forwarded to Knitro.

Lindo/LindoGlobal

- New libraries 13.0.262:
  - LP Solver Improvements:
    * With new enhancements made to the simplex solvers, the average performance on large instances where the number of variables is several times larger than the number of constraints has increased by several folds compared to the previous version.
    * Improved performance on LP's when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
  - MIP (Mixed Integer Program) Solver:
    * Improved selection of defaults for cuts and heuristics.
  - Global Solver Improvements:
    * Highly improved ability to recognize convexity of various composite functions, especially involving logarithms and sums, which can gives a performance improvement of one order-of-magnitude in these cases.
    * Performance improvement for convex-concave type functions.
    * Enhanced capabilities for converting nonlinear functions to linear forms.
    * Substantial performance improvement for non-convex quadratic models.

LocalSolver

- New libraries 10.0 (20210330).
- We plan to drop LocalSolver and LocalSolver70 by the end of 2021.

MOSEK

- New libraries 9.2.41.

MPSGE

- Increased the internal MAXFUN limit (from 5000 to 10000) on the number of components (inputs, outputs, taxes, etc.) in any MPSGE row.

ODHCPLEX

- New libraries 5.34.

SBB

- Added option usercallparmfile: Command-line parameter include file used in GAMS command-line calls triggered by BCH.

SCIP

- New libraries 7.0 (c53330372e).

SNOPT

- New libraries 7.7.7 and new GAMS/SNOPT link.
- Changed option value to SNOPT default for the following options:
  - Linesearch Tolerance: 0.9
  - LI Singularity Tolerance: 3.2e-11
- Removed the following parameters:
  - `Start Objective Check`
  - `Start Constraint Check`
  - `Stop Objective Check`
  - `Stop Constraint Check`
  - `Derivative Level`

XPRESS

- Added support for choosing a different algorithm than primal simplex for solving the fixed MIP (see mipCleanup). The algorithm can be chosen with defaultAlg and lpFlags.
- Deprecated the following options:
  - `algorithm`: Use defaultAlg or lpFlags instead.
  - `extraPresolve`
  - `lpThreads`
- Added the following options:
  - algAfterCrossover: Algorithm to be used for the final clean up step after the crossover.
  - autoPerturb: Simplex: Indicates whether automatic perturbation is performed.
  - autoScaling: Whether the Optimizer should automatically select between different scaling algorithms.
  - backtrackTie: Branch and Bound: Specifies how to break ties when selecting the next node to work on when a full backtrack is performed.
  - barCores: If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm.
  - barFailIterLimit: Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm.
  - barFreeScale: Defines how the barrier algorithm scales free variables.
  - barGapTarget: Newton barrier: Target tolerance for the relative duality gap.

- barKernel: Newton barrier: Defines how centrality is weighted in the barrier algorithm.
- barObjScale: Defines how the barrier scales the objective.
- barOrderThreads: If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton barrier method.
- barPresolveOps: Controls the Newton barrier specific presolve operations.
- barRegularize: Determines how the barrier algorithm applies regularization on the KKT system.
- barRhsScale: Defines how the barrier scales the right hand side.
- branchChoice: Once a global entity has been selected for branching, this control determines which of the branches is solved first.
- branchDisj: Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search.
- branchStructural: Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search.
- `cacheSize`: Newton barrier: L2 or L3 (see notes) cache size in kB (kilobytes) of the CPU.
- choleskyAlg: Newton barrier: Type of Cholesky factorization used.
- choleskyTol: Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm.
- conflictCuts: Branch and Bound: Specifies how cautious or aggressive the optimizer should be when searching for and applying conflict cuts.
- coresPerCpu: Used to override the detected value of the number of cores on a CPU.
- cpuTime: How time should be measured when timings are reported in the log and when checking against time limits.
- crossoverAccuracyTol: Newton barrier: Determines how crossover adjusts the default relative pivot tolerance.
- crossoverIterLimit: Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates.
- crossoverOps: Newton barrier: Bit vector for adjusting the behavior of the crossover procedure.
- cutFactor: Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during global search.
- cutSelect: Bit vector providing detailed control of the cuts created for the root node of a global solve.
- dualGradient: Simplex: Dual simplex pricing method.
- dualize: Whether presolve should form the dual of the problem.
- dualizeOps: Bit-vector control for adjusting the behavior when a problem is dualized.
- dualPerturb: Factor by which the problem will be perturbed prior to optimization by dual simplex.
- dualStrategy: Bit-vector control specifies the dual simplex strategy.
- elimFillin: Amount of fill-in allowed when performing an elimination in presolve.
- elimTol: Markowitz tolerance for the elimination phase of the presolve.
- feasibilityPump: Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node.
- feasTolPerturb: Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes.
- feasTolTarget: Target feasibility tolerance for the solution refiner.
- forceParallelDual: Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm.
- genConsDualReductions: Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs.

- heurBeforeLp: Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved.
- heurDiveIterLimit: Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic.
- heurDiveRandomize: Level of randomization to apply in the diving heuristic.
- heurDiveSoftRounding: Enables a more cautious strategy for the diving heuristic.
- heurDiveSpeedUp: Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed.
- heurDiveStrategy: Branch and Bound: Chooses the strategy for the diving heuristic.
- heurForceSpecialObj: Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer.
- heurFreq: Branch and Bound: Frequency at which heuristics are used in the tree search.
- heurSearchEffort: Adjusts the overall level of the local search heuristics.
- heurSearchFreq: Branch and Bound: How often the local search heuristic should be run in the tree.
- heurSearchRootCutFreq: How frequently to run the local search heuristic during root cutting.
- heurSearchRootSelect: Bit vector control for selecting which local search heuristics to apply on the root node of a global solve.
- heurSearchTreeSelect: Bit vector control for selecting which local search heuristics to apply during the tree search of a global solve.
- `heurStrategy`: Branch and Bound: Heuristic strategy.
- historyCosts: Branch and Bound: How to update the pseudo cost for a global entity when a strong branch or a regular branch is applied.
- indLinBigM: Indicator constraints can be internally converted to regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value.
- indPreLinBigM: During presolve, indicator constraints can be internally replaced with regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value.
- `l1Cache`: Newton barrier: L1 cache size in kB (kilo bytes) of the CPU.
- lnpBest: Number of infeasible global entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see gomCuts).
- lnpIterLimit: Number of iterations to perform in improving each lift-and-project cut.
- localChoice: Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree.
- lpFlags: Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem.
- lpFolding: Simplex and barrier: Whether to fold an LP problem before solving it.
- lpLogDelay: Time interval between two LP log lines.
- lpLogStyle: Simplex: Style of the simplex log.
- lpRefineIterLimit: Simplex iteration limit the solution refiner can spend.
- markowitzTol: Markowitz tolerance used for the factorization of the basis matrix.
- maxCutTime: Maximum amount of time allowed for generation of cutting planes and reoptimization.
- maxImpliedBound: Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than maxImpliedBound will be applied to the problem.
- maxLocalBacktrack: Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node.

- maxMemoryHard: Sets the maximum amount of memory in megabytes the optimizer should allocate.
- maxMemorySoft: When resourceStrategy is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate.
- maxMipTasks: Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve.
- maxScaleFactor: Determines the maximum scaling factor that can be applied during scaling.
- `maxTime`: Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time.
- mipDualReductions: Branch and Bound: Limits operations that can reduce the MIP solution space.
- mipFracReduce: Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions.
- mipKappaFreq: Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search.
- mipRampUp: Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search.
- mipRefineIterLimit: Defines an effort limit expressed as simplex iterations for the MIP solution refiner.
- mipRestart: Branch and Bound: Controls strategy for in-tree restarts.
- mipToltarget: Target mipTol value used by the automatic MIP solution refiner as defined by refineOps.
- miqcpAlg: Determines which algorithm is to be used to solve mixed integer quadratically constrained and mixed integer second order cone problems.
- xslp_mipAlgorithm: Bitmap describing the MISLP algorithms to be used.
- xslp_mipFixStepBounds: Bitmap describing the step-bound fixing strategy during MISLP.
- xslp_mipRelaxStepBounds: Bitmap describing the step-bound relaxation strategy during MISLP.
- netCuts: Determines the addition of multi-commodity network cuts to a problem.
- objScaleFactor: Custom global objective scaling factor, expressed as a power of 2.
- optimalityTolTarget: Target optimality tolerance for the solution refiner.
- outputLog: Controls the level of output produced by the Optimizer during optimization.
- outputTol: Zero tolerance on print values.
- preAnalyticCenter: Determines whether analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs.
- preBasisRed: Determines whether a lattice basis reduction algorithm should be attempted as part of presolve.
- preBndRedCone: Determines whether second order cone constraints should be used for inferring bound reductions on variables when solving a MIP.
- preBndRedQuad: Determines whether convex quadratic contraints should be used for inferring bound reductions on variables when solving a MIP.
- preCoefElim: Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem.
- preComponents: Determines whether small independent components should be detected and solved as individual subproblems during root node processing.
- preComponentsEffort: Presolve: Adjusts the overall effort for the independent component presolver.
- preConeDecomp: Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components.

- preConvertSeparable: Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints.
- preDomCol: Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem.
- preDomRow: Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem.
- preDupRow: Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem.
- preElimQuad: Presolve: Allows for elimination of quadratic variables via doubleton rows.
- preImplications: Presolve: Determines whether to use implication structures to remove redundant rows.
- preLinDep: Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem.
- preObjCutDetect: Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed.
- presolveMaxGrow: Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem.
- presolveOps: Specifies the operations which are performed during the presolve.
- presolvePasses: Number of reduction rounds to be performed in presolve.
- primalPerturb: Factor by which the problem will be perturbed prior to optimization by primal simplex.
- primalUnshift: Determines whether primal is allowed to call dual to unshift.
- qcCuts: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratically constrained or mixed integer second order conic problem with outer approximation.
- qcRootAlg: Determines which algorithm is to be used to solve the root of a mixed integer quadratically constrained or mixed integer second order cone problem, when outer approximation is used.
- qSimplexOps: Controls the behavior of the quadratic simplex solvers.
- quadraticUnshift: Determines whether an extra solution purification step is called after a solution found by the quadratic simplex (either primal or dual).
- randomSeed: Sets the initial seed to use for the pseudo-random number generator in the Optimizer.
- refineOps: Specifies when the solution refiner should be executed to reduce solution infeasibilities.
- relaxTreeMemoryLimit: When the memory used by the branch and bound search tree exceeds the target specified by the treeMemoryLimit control, the optimizer will try to reduce this by writing nodes to the global file.
- repairIndefInitEq: Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible.
- resourceStrategy: Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve.
- rootPresolve: Determines if presolving should be performed on the problem after the global search has finished with root cutting and heuristics.
- sbBest: Number of infeasible global entities to initialize pseudo costs on each node.
- sbEffort: Adjusts the overall amount of effort when using strong branching to select an infeasible global entity to branch on.
- sbEstimate: Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible global entity to branch on.

  - sbIterLimit: Number of dual iterations to perform in strong branching for each entity.
  - sifting: Determines whether to enable sifting algorithm with the dual simplex method.
  - xslp_algorithm: Bitmap describing the SLP algorithm(s) to be used.
  - xslp_analyze: Bitmap activating additional options supporting model / solution path analyzis.
  - xslp_augmentation: Bitmap describing the SLP augmentation method(s) to be used.
  - xslp_barStartOps: Controls behaviour when the barrier is used to solve the linearizations.
  - xslp_convergenceOps: Bitmap describing which convergence tests should be carried out.
  - xslp_filter: Bitmap for controlling solution updates.
  - xslp_presolveOps: Bitmap indicating the SLP presolve actions to be taken.
  - xslp_zeroCriterion: Bitmap determining the behavior of the placeholder deletion procedure.
  - sosRefTol: Minimum relative gap between the ordering values of elements in a special ordered set.
  - treeCompression: When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the global file on disk.
  - treeCutSelect: Bit vector providing detailed control of the cuts created during the tree search of a global solve.
  - treeMemoryLimit: Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree.
  - treeMemorySavingTarget: When the memory used by the branch-and-bound search tree exceeds the limit specified by the treeMemoryLimit control, the optimizer will try to save memory by writing lower-rated sections of the tree to the global file.
  - treeQCCuts: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratically constrained or mixed integer second order conic problem with outer approximation.

- Added options to conveniently set bits of XPRESS bitmap options:
  - New bits of refineOps:
    * refineOps_lpOptimal
    * refineOps_mipSolution
    * refineOps_mipNodeLp
    * refineOps_lpPresolve
    * refineOps_iterativeRefiner
    * refineOps_refinerPrecision
    * refineOps_refinerUsePrimal
    * refineOps_refinerUseDual
    * refineOps_mipFixGlobals
    * refineOps_mipFixGlobalsTarget
  - New bits of mipPresolve:
    * mipPresolve_reducedCostFixing
    * mipPresolve_logicPreprocessing
    * mipPresolve_allowChangeBounds
    * mipPresolve_dualReductions
    * mipPresolve_globalCoefTightening
    * mipPresolve_objBasedReductions
    * mipPresolve_allowTreeRestart
    * mipPresolve_symmetryReductions
  - New bits of presolveOps:
    * presolveOps_singletonColRemoval
    * presolveOps_singletonRowRemoval

    * presolveOps_forcingRowRemoval
    * presolveOps_dualReductions
    * presolveOps_redundantRowRemoval
    * presolveOps_duplicateColRemoval
    * presolveOps_duplicateRowRemoval
    * presolveOps_strongDualReductions
    * presolveOps_variableEliminations
    * presolveOps_noIpReductions
    * presolveOps_noGlobalDomainChange
    * presolveOps_noAdvIpReductions
    * presolveOps_linDependRowRemoval
    * presolveOps_noIntVarEliminations
    * presolveOps_noIntVarAndSosDetect
  - New bits of scaling:
    * scaling_rowScaling
    * scaling_colScaling
    * scaling_rowScalingAgain
    * scaling_maximum
    * scaling_curtisReid
    * scaling_byMaxElemNotGeoMean
    * scaling_bigM
    * scaling_simplexObjScaling
    * scaling_ignoreQuadRowPart
    * scaling_beforePresolve
    * scaling_noScalingRowsUp
    * scaling_noScalingColsDown
    * scaling_disableGlobalObjScaling
    * scaling_rhsScaling
    * scaling_noAggressiveQScaling
    * scaling_slackScaling
  - New bits of lpFlags:
    * lpFlags_dual
    * lpFlags_primal
    * lpFlags_barrier
    * lpFlags_network
  - New bits of cutSelect:
    * cutSelect_clique
    * cutSelect_mir
    * cutSelect_cover
    * cutSelect_mirRowAggregation
    * cutSelect_flowpath
    * cutSelect_implication
    * cutSelect_liftAndProject
    * cutSelect_disableCutRows
    * cutSelect_gubCover
    * cutSelect_zeroHalf
    * cutSelect_indicator
  - New bits of treeCutSelect:
    * treeCutSelect_clique
    * treeCutSelect_mir

    * treeCutSelect_cover
    * treeCutSelect_mirRowAggregation
    * treeCutSelect_flowpath
    * treeCutSelect_implication
    * treeCutSelect_liftAndProject
    * treeCutSelect_disableCutRows
    * treeCutSelect_gubCover
    * treeCutSelect_zeroHalf
    * treeCutSelect_indicator

- Renamed the following options to match the original XPRESS options names. Old option names currently serve as alias, but are deprecated and will be removed in an upcoming release:
  - `treePresolveKeepBasis` to `treePresolve_keepBasis`.
  - `slpKnitroOptFile` to knitroOptFile.
  - All XPRESS Nonlinear (SLP) options, e.g., `slpSolver` to xslp_solver.
- Fixed default values of single bit options for XPRESS bitmap options with negative default values.

3.14.1.5 Tools

GAMS Studio

- New version 1.6.1.
  - New feature: Static Code Completion which can be activated by pressing `Ctrl + Space`.
  - New feature: Allow to move multiple lines up and down using `Ctrl + Shift + Arrow`.
  - New feature: Allow to close view tabs using the middle mouse button.
  - Added instant update of tab size in editor when changing corresponding setting.
  - Added word under cursor as default search entry when no text selection is present.
  - Allow to move block selections using the arrow keys.
  - Added `*.inc` as common extension for GAMS files.
  - Added user defined extensions for GAMS files.
  - Added automatic reloading of files that appear in the GAMS log.
  - Added setting for user defined extensions for files to be automatically reloaded.
  - Added auto-reload button to file-changed dialog.
  - Added Studio Documentation entry in Help menu.
  - Added setting to change default open file behavior (new group or current group) and adjusted menu entry for alternative file opening behavior.
  - Hotkey `F1` jumps to the corresponding documentation entry for Project Explorer, Process Logs, GDX Diff Dialog, and Search Widget.
  - Improved GDX Viewer, e.g.:
    * Added facility to access domains and filters in Table View.
    * Show original index position of domains in both list view and table view.
    * Improved automatic column widths.
  - Stability improvements and minor bug fixes, e.g.:
    * Fixed crash when LST file is missing (e.g. because of setting `output=NUL`).
    * Fixed "Reset View" not resetting splitter in the LST/LXI-Viewer.
    * Fixed crash related to comment shortcut in solver option editor when pressing it multiple times.

* Fixed wrong sort order after resetting GDX Viewer.
* Fixed GAMS engine not appending `/api` to the URL on macOS when clicking `OK` directly after editing the URL.
* Fixed `eolCom` not working in some dollar control option lines (like `$include`).
* Fixed jump to next search result if the result is in a different file and the current one has no results.
* Fixed jump to search result occasionally not working.
* Fixed `Find Next/Prev` behavior for `.opt` files.

GDXDUMP

- Added a new line at the end of the file, which was missing if the option noHeader is set.

GDXMERGE

- Added command line option `strict`. When set to `true`, gdxmerge will terminate with an error in case input files cannot be found or the output file already exists.

GDXXRW

- Fixed a potential missing initialization if incRC is set for symbols with either cDim or rDim equal 0.

3.14.1.6 APIs

CFG

- With the next major release the last argument `opt: pointer` of function `cfgAlgReadyAPI` will be dropped.

DCT

- Functions `dctLoadWithHandle`, `dctSymDomIdx`, `dctDomNameCount`, and `dctDomName` have been deprecated and will be removed in the near future.

gams2numpy

- Improved error handling.
- New optional parameter `domains` for `gdxWriteSymbolStr` and `gdxWriteSymbolRaw` that can be used to specify the domains of the symbol. Parameter needs to be a list of strings.

GMO

- Updated to better handle cases where quadratic structure is explicitly detected (i.e. `useQ` is set) and some *but not all* of the nonlinear equations are quadratic. Several new functions have been added. In addition, some existing functions have been renamed - the new names are more descriptive and/or more consistent with new and existing function names. The old names are still available as deprecated synonyms - we expect to remove these synonyms in the near future and potentially without warning.
  - Updated API version to 20 - compatible with some older API versions.
  - New read-only properties:
    - `gmoObjLNZ`: Number of linear nonzeros in objective gradient.
    - `gmoObjNLNZEx`: Number of GMOORDER_NL nonzeros in objective gradient.
    - `gmoObjQNZEx`: Number of GMOORDER_Q nonzeros in objective gradient.
    - `gmoObjCVecNZ`: Number of nonzeros in c vector of objective (-1 if Q information not used).
    - `gmoObjConstEx`: Objective constant - this is independent of `useQ`.
    - `gmoObjQConst`: Constant in solvers quadratic objective.
  - New functions:
    - `gmoGetObjCVec`: Get c vector of quadratic objective.
    - `gmoGetObjSparseEx`: Get information for gradient of objective function (sparse).
    - `gmoGetRowStatEx`: Get Jacobian row nonzero counts: total and by GMOORDER_XX.
    - `gmoGetRowCVecNZOne`: Number of nonzeros in c vector of row si (-1 if Q information not used).
    - `gmoGetRhsOneEx`: Get individual equation RHS - independent of `useQ`.
    - `gmoGetRowSparseEx`: Get info for one row of Jacobian (sparse).
    - `gmoGetRowCVec`: Get c vector of the quadratic form for one row.
    - `gmoGetRowQConst`: Get the constant of the quadratic form for one row.
  - New read-write properties:
    - `gmoHessInclQRows`: if `useQ` is true, this boolean property toggles the inclusion of GMOORDER_Q rows in the Hessian.
      Attention

      The default was originally `true` but has accidentally been changed to `false` with this release (35.1.0). That is, if `useQ` is set, then the Hessian does not include entries from quadratic equations anymore. The default is changed back to true in GAMS 38.2.0.
  - Renamed properties/functions:
    - `gmoObjQNZ` → `gmoObjQMatNZ`: Number of nonzeros in lower triangle of Q matrix of objective (-1 if `useQ` is false).
    - `gmoGetObjQ` → `gmoGetObjQMat`: Get lower triangle of Q matrix of objective.
    - `gmoGetRowQ` → `gmoGetRowQMat`: Get lower triangle of Q matrix of one row.

High-Level APIs

- We might drop support for macOS 10.14 for the C++ API with the next major release.
- Fixed an issue with an updater symbol that tries to update a non-existing symbol in the model instance. This used to make the `solve` method of `GAMSModelInstance` fail, but now just increases the no-match count.
- Fixed `GAMSOptions.Output` (.NET), `GAMSOptions.setOutput` (Java), and `GamsOptions.output` (Python) parameter being ignored in `GAMSJob::Run()`.

Low-Level APIs

- For the next major releases, some clean-up of the distributed APIs is planned. In particular, it is planned to remove all Delphi variants but the `dcp` version (i.e. `gdxdcpdef.pas`) and all Fortran variants but the `f9` version (i.e. `gdxf9def.f90`). Please contact us, if that causes any trouble for your operation.

PAL

- Added functions `palDataDirs` and `palConfigDirs` to retrieve standard locations searched by GAMS.

3.14.1.7 Model Libraries

GAMS Model Library

- **nurses.gms : A Nurse Scheduling Problem** (428)

GAMS Test Library

New models:

- **gdxmerg3.gms : Test strict mode**
- **unload15.gms : Test $gdxUnload**
- **load13.gms : Test $gdxLoad**
- **conopt02.gms : CONOPT test suite - multi-thread test**
- **implset2.gms : Test for Implicit Set Definition with default records**
- **prevwork1.gms : PreviousWork Test**
- **decla3.gms : Test correct loading after multi declaration of domain set**
- **delim5.gms : Limited scope for $onDelim**
- **load14.gms : Test loading of GDX file with bad UELs**
- **eval08.gms : Test $eval with hidden functions**
- **embpy07.gms : Test no_match_limit for model instance**
- **embpy08.gms : Test filtered load from Embedded Code**

3.14.2 35.2.0 Minor release (June 02, 2021)

3.14.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Johannes Hedtrich, Bruce McCarl, Evangelos Panos, Thomas Rutherford, and Kirk A. Yost.

3.14.2.2 GAMS System

GAMS

- Allow to write point files with asynchronous solves as well.
- Moved the log line pointing to a reference file from the end of the compilation phase to the end of the run, to make it easier to recognize.
- Automatically deactivate holdFixed if a model is solved asynchronously, since this could lead to inconsistent solutions otherwise. Note that this can make a square model non-square as in **cns01**. Also note, that this could require some adjustment to models which actually relied on the fact, that models solved like this did not update the solution for fixed variables. Such a change was done for the model **jacobi**.
- Fixed a problem where the file path specified with $gdxIn or $gdxLoad was ignored when inputDir was applied.
- Fixed a potentially broken work file written with previousWork.
- Fixed the default for command line parameter empty. It should be `on` but was `off`.
- Fixed the dollar control options $setComps, $setNames, and $splitOption: They should generate scoped compile-time variable but generated local ones.
- Fixed potentially wrongly reported bounds for models solved with solveLink=6.
- Fixed missing info about objective variable with solveLink = 3 and asyncSolLst = 1.

EMP

- Fixed handling of the empty UEL in the EMP info file

GMSPython

- Removed package `tqdm`.

3.14.2.3 Solvers

AlphaECP

- New library with some minor bug fixes.

CONVERT

- Fixed exporting of variable scale attribute in DumpGDX format.

CPLEX

- Fixed incorrect model status for feasible models after time out in multi-objective optimization.

KNITRO

- Fixed incorrect model status for KNITRO return code "All nodes have been explored. Integer feasible point found." (KN_RC_MIP_EXH_FEAS).

3.14.2.4 Tools

GAMS Studio

- New version 1.6.2. with various bug fixes, stability improvements and minor enhancements, e.g.:
  - Fixed issues with enumerated parameters in extended parameter editor.
  - Fixed issues with "set", "option", and "table" in code-completer.
  - Fixed code-completer opening in non-code files.
  - Fixed "Open in current group" not being used for "User Model Library" and "New file".

3.14.2.5 APIs

Python

- Fixed a bug in the `GDX` expert-level API that required `gdxSymbolGetDomain` to be called in a read context (e.g. after `gdxDataReadStrStart`).
- Fixed a bug in `gams2numpy` functions `gdxReadSymbolStr` and `gdxReadSymbolRaw` that altered the case of the `symName` argument.

DCT

- Fixed broken function `dctSymDomNames` for symbols that have the universe as part of their domain. This caused a crash in sensitivity analysis of CPLEX and Gurobi for models with such variable or equation symbols.

3.14.2.6 Model Libraries

GAMS Model Library

- Changed **jacobi.gms : Asynchronous Jacobi Methods** to work with the changed `holdFixed` behavior with asynchronous solves, mentioned above.

3.15 34 Distribution

3.15.1 34.1.0 Major release (January 29, 2021)

3.15.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Wolfgang Britz, Michael Ferris, Erwin Kalvelagen, Antti Lehtila, Bruce McCarl, Scott McDonald, Cornelius Rüther, Shima Sasanpour, Kaushik Sinha, Elizabeth Wong, and Qi Yuan.

3.15.1.2 Platforms

- The minimal required GLIBC version of the distribution for GNU/Linux is now 2.17.
- macOS 10.13 (High Sierra) is no longer supported.

3.15.1.3 GAMS System

GAMS

- Improved performance of *dense* operations with out-of-order index positions, as in the following code snippet, where the assignment to `d1` was significantly slower than the one to `d2` in the past:

```
d1(j,i) = sum(ij(i,j), exp(pij(i,j)));
d2(j,i) = sum(ij(i,j), abs(pij(i,j)));
```

- Added new debugging option dmpUserSym, to print all symbols defined by the user.
- Added new variants $showFiles, $showMacros, and $showVariables of $show for shorter reports.
- Print an extra log line for compile time GDX operations $gdxIn and $gdxOut. When running GAMS from one of the GAMS IDEs, these log line can be clicked to open the file referenced.
- Add anchors to the log that can be clicked when running GAMS from one of the GAMS IDEs for each mention of an input/include file.
- Added extra info to the log in case of an unmatched $ifThen and its variants, that can be clicked when a GAMS IDE is used to jump to the initial dollar control option.
- Added more details about the problem to the log in case of an error analyzing the solve statement.
- Added new variants for the command line parameter fileCase which allow to use upper or lower case for referenced filenames only and not for the path to the files.
- Fixed a bug where certain checks for errors in the model structure were skipped, if upper and lower bound of a variable are the same. While the selected solver would already have rejected the problem most likely, now GAMS generates an execution error also if lower and upper bounds are the same and
  - the bounds of discrete variables do not have integer values,
  - the lower and upper bounds of binary variables are not equal to 0 or 1, or,
  - the lower bounds of semiCont/semiInt variables are smaller than 0.
- Altered the behavior of execute.checkErrorLevel, put_utility exec.checkErrorLevel, and put_utility shell.checkErrorLevel so the execution would stop right away also within a Flow Control structure, like a `loop`, if an error is encountered. In the past, it would just stop after executing the flow control structure completely.
- Changed the behavior for unloading symbols with $unload. In previous versions the writing of the symbols happened while the compiler processed the `$unload` instructions. With this version forward the writing of the symbols and data to GDX is delayed until the GDX file is about to be closed. This has several advantages, e.g. writing of aliases and full domain information, but it can result in different content of the GDX file in some corner cases. Please check for details in the documentation.
- Avoid export of predefined symbols diag and sameAs to GDX. When all symbols should be exported, these are skipped. When they are tried to be exported explicitly, there will be a compilation error.
- Allow to use Put_Utility `save` to write a save file of the current state of execution inside loops and other flow control structures as well.
- Fixed a wrongly raised compilation error which could happen when an implicit set definition was used with a table statement without data.
- Fixed a problem where dumpOpt in combination with $onVerbatim skipped parts of an $ifThen block.

GMSPython

- Added the packages `pyexcelerate`, `pyyaml`, `xlsxwriter`, and their dependencies.

3.15.1.4 Solvers

AMPL

- As announced, dropped the meta-solver AMPL.

BARON

- New libraries 21.1.13.
  - Improved interface to IPOPT for local search.
  - Changed default for option LPSol to new value -1, which makes BARON use CPLEX for LP or MIP relaxations, if licensed, and CLP/CBC otherwise.
  - Further performance improvements and bugfixes.
- Added option BarName to specify name of file into which to write problem in BARON format.

BDMLP

- As announced, dropped the solver BDMLP.

BENCH

- As announced, dropped the tool BENCH.

CONOPT

- New library 4.22.
  - Some improvements for models with external equations.

CONVERT

- The two solver links CONVERT and CONVERTD were merged under the name CONVERT. Features that were formerly available in only one of the two solver links are now all usable with the new CONVERT link (except for the dropped features, see below). CONVERTD is an alias for CONVERT now.
- JuMP format:
  - Added constraint names.
  - Using `@NLconstraint` and `@NLobjective` instead of `add_NL_constraint` and `set_NL_objective`, respectively.
  - Changed default of option JuMP to `jump.jl`.
- Pyomo format:
  - Fix export of SOS1 and SOS2 variable types.
  - Changed default of option Pyomo to `pyomo.py`.
- DumpGDX format (formerly Hessian or Jacobian):
  - The current behaviour of disabling variable and equation names or UELs when setting the option to "NOVENAMES.gdx" or "NOUELS.gdx" has no special effect anymore. Use GDXNames and GDXUELs instead.
- New options:
  - Width
  - DumpGDX (replaces options Hessian and Jacobian)
  - GDXNames (instead of setting the former options Hessian or Jacobian to "NOVENAMES.gdx")
  - GDXUELs (instead of setting the former options Hessian or Jacobian to "NOUELS.gdx")
  - GDXHessian (enables hessian information for DumpGDX)
  - GDXQuadratic (enables quadratic information for DumpGDX)
- Options PermuteEqus and PermuteVars are now available for all target languages.
- Removed the following formats:
  - AlphaECP
  - AmplNLC
  - Analyze
  - AnalyzeS
  - Baron (GAMS/Baron link provides the option BarName to export this format)
  - Lgo
  - LindoMPI (GAMS/Lindo link provides the option WRITEMPI to export this format)
  - LocalSolver (GAMS/Localsolver link provides the option `writelsp` to export this format)
  - LSPSol
  - Memo
  - Minopt
  - SFS
  - ViennaDag
- Removed the following experimental formats:
  - AmplNLCG
  - CHull

  - CppAD
  - Lago
  - NLP2MCPE
  - PDCO
  - Qmaker (use DumpGDX with GDXQuadratic enabled instead)
  - UnitBC

- The following formats are deprecated and may be removed in an upcoming release:
  - Hessian (use DumpGDX with GDXHessian enabled instead)
  - Jacobian (use DumpGDX instead)

- The following options don't have any effect anymore and will be removed in an upcoming release:
  - ConeReform
  - IntervalEvalDebug
  - Match
  - Terminate

CPLEX

- New libraries 20.1.0.
  - Conflict Analysis (iis) now supports SOS variables and indicator constraints.
  - Added options:
    * prereform: allows to set presolve reformulations
    * conflictalg: algorithm CPLEX uses in the conflict refiner to discover a minimal set of conflicting constraints in an infeasible model
    * nodecuts: allows to decide whether or not cutting planes are separated at the nodes of the branch-and-bound tree
    * sos1reform: automatic logarithmic reformulation of special ordered sets of type 1 (SOS1)
    * sos2reform: automatic logarithmic reformulation of special ordered sets of type 2 (SOS2)
    * Value 5 to mipemphasis: finding high quality feasible solutions as early as possible
  - Deprecated options:
    * `prelinear`: Use prereform instead
  - Deprecated features (will be removed in a future CPLEX release):
    * Remote Object functionality.
    * Distributed parallel optimization of mixed integer programming models (MIP).

- Fixed error messages for CPLEX error 5002 (CPXERR_Q_NOT_POS_DEF).

- Fixed an error that caused a crash for special option file input.

- Fixed an error that wrote additional quotes in GDX files of ranging and column generation information.

- Fixed miptrace timing info.

Gurobi

- New libraries 9.1.1.
- Added the following options:
  - SolFiles: location to store intermediate solution files
  - DualReductions: disables dual reductions in presolve
  - ProjImpliedCuts: projected implied bound cut generation
  - PSDCuts: PSD cut generation
  - FeasRelaxBigM: Big-M value for feasibility relaxations
- Added possible option values for the following options:
  - MinRelNodes: -1 (automatic)
  - NodeMethod: -1 (automatic)
  - PumpPasses: -1 (automatic)
  - StartNodeLimit: -3 (shut off)
  - ZeroObjNodes: -1 (automatic)
  - AggFill: -1 (automatic)
  - PreSparsify: -1 (automatic)
  - TuneResults: -1 (best results)
  - IISMethod: 2 (ignores bound constraints)
  - IISMethod: 3 (IIS the LP relaxation)
  - Method: 5 (both primal and dual simplex)
- Set option value to GUROBI default for the following options:
  - scaleflag: -1
  - Cutoff: maxdouble
  - ImproveStartGap: 0
  - MinRelNodes: -1
  - NodeMethod: -1
  - PartitionPlace: 15
  - PumpPasses: -1
  - ZeroObjNodes: -1
  - AggFill: -1
  - PreSOS2BigM: -1
  - PreSparsify: -1
  - TuneResults: -1
  - TuneTrials: 3
- Removed the following options:
  - `premiqpmethod`
  - `workerport`
- Options for how to access the Gurobi compute server, cluster manager, or Instant Cloud can all be `set through the Gurobi license file`. Therefore, the following link options have been removed:
  - computeserver
  - csgroup
  - cspassword

  - csport
  - cspriority
  - csrouter
  - cstimeoutfrac
  - cstlsinsecure
  - icsecretkey
  - icpool
  - icpriority
  - instantcloud

- Fixed issue of missing logfile output for logoption = 4.
- Fixed an error that wrote additional quotes in GDX files of ranging information.

Ipopt

- Updated MUMPS to version 5.3.5.

KESTREL

- The environment variable `NEOS_EMAIL` can now be used to provide an e-mail address when submitting a job to NEOS.
- Fixed unintentional reading from option file.

KNITRO

- New libraries 12.3.0.
  - Improvements in performance, memory usage, numerical stability, and overall stability.

LINGO

- As announced, dropped the meta-solver LINGO.

LS

As announced, dropped the tool LS.

One possibility to adapt existing GAMS code is to use the Python function `numpy.linalg.lstsq` via the GAMS embedded code facility.

For example, the GAMS code

```
Set i;
Parameter x(i), y(i);
Variables b0, b1, sse;
Equations sumsq, fit(i);
sumsq..   sse =n= 0;
fit(i)..  y(i) =e= b0 + b1*x(i);
option lp = ls;
model leastsq /fit,sumsq/;
solve leastsq using lp minimizing sse;
```

to compute a linear regression for (x,y) can be replaced by

```
Set i;
Parameter x(i), y(i);
Scalars b0, b1, sse;
embeddedCode Python:
  import numpy as np
  x = np.array(gams.get('x', keyFormat=KeyFormat.SKIP))
  y = np.array(gams.get('y', keyFormat=KeyFormat.SKIP))
  A = np.vstack([np.ones(len(x)), x,]).T
  res = np.linalg.lstsq(A, y, rcond=None)
  gams.set('b0', [res[0][0]])
  gams.set('b1', [res[0][1]])
  gams.set('sse', [res[1][0]])
endEmbeddedCode b0 b1 sse
```

For a more detailed example, see the new **LeastSquares.gms** model from the GAMS Data Library.

Mosek

- New libraries 9.2.35.

MPECDUMP

- As announced, dropped the tool MPECDUMP.

NLPEC

- Set the (hidden) GAMS option `relPath` to 1 for the execution of the scalar GAMS model. This fixes a problem when running NLPEC under KESTREL on NEOS.

ODHCPLEX

- New libraries 5.31.
- Fixed missing output of final CPLEX solve for fixed model.
- Fixed possible values of option `odhpresolve` to 1 and 2.

PYOMO

- As announced, dropped the meta-solver PYOMO.

SCIP

- New libraries 7.0 (9a11615b47).

SoPlex

- New libraries 5.0.2.

XPRESS

- Non-convex QCPs don't have to be solved as NLP anymore, but are solved by XPRESS Nonlinear if a XPRESS-NLP or XPRESS-MINLP license is used (XPRESS-MINLP for MIQCPs).
- Fixed an issue that prevented the use of XPRESS Knitro with a XPRESS link license.
- Fixed a bug that prevented to solve (MI)QCP models with an XPRESS-MIP license.

3.15.1.5 Tools

CSV2GDX

- Report the line/field records to the log that lead to `UNDF` conversion for trace level 1 or bigger.

GAMS Studio

- New version 1.5.2.
  - New feature: Allow to edit and store custom color themes in the settings dialog.
  - New feature: Allow to define custom sections in the code, that can be folded using `$onFold` / `$offFold`.
  - Improved MIRO deploy dialog.
  - Added e-mail field for NEOS submissions in NEOS dialog. This can also be initialized from environment variable `NEOS_EMAIL` (which can be set permanently in gamsconfig.yaml).
  - Changed "Autosave on Run" setting to save ALL modified files, not just files of the current group.
  - Changed default light theme comment color to grey for better distinction from declarations.
  - Disabled GAMS syntax highlighting between `$onPut/$offPut` and `$onEcho/$offEcho`.
  - Added "select entry" on clicking timestamp in log.
  - Pressing `Enter` in the LXI tree scrolls to the corresponding position in the LST view.
  - Adjusted list of files in Reference File Viewer to be sorted by order in which they have been used.
  - Stability improvements and minor bug fixes, e.g.:
    - Fixed rare problem with undetected external file changes.

* Fixed broken include file links in combination with end of line comments.
* Fixed missing request for new search cache after switching file.
* Fixed rare crash related to LOG output.
* Fixed endlessly recurring message box for invalid GDX file.
* Fixed missing update of parameter history for a file assigned to more than one group.
* Fixed search results not being highlighted in `.log` files.
* Fixed search performance problem after reset search parameters.
* Fixed behavior of `ESC` key when current widget has a selection.
* Fixed syntax highlighting of `table` statements not detecting row headers.
* Fixed print dialog shortcut not working directly after Studio launch.

GDX2VEDA

- Increase the maximum length of symbol names in the Veda definition file from 31 to 63.

GDXDUMP

- When using the option noData, empty symbols were still written with a data statement. Now empty symbols are also loaded from GDX.

GDXMRW

- Switch from C to C++ as the compiler for these utilities.
- An `unordered_map` container is now used to address a performance issue with `rgdx` and filtered reads.

3.15.1.6 APIs

C++

- We plan to drop support for Microsoft Visual Studio 2015 for the C++ API with the next major release.

Python

- Added support for Python 3.9.
- gams2numpy:
  - New functions `gdxGetUelList` and `gmdGetUelList` allow to retrieve the list of UELs.
  - `gdxReadSymbolRaw` and `gmdReadSymbolRaw` do not return the list of UELs anymore.
  - `gdxReadSymbolStr` and `gmdReadSymbolStr` have a new optional input parameter `uelList`.
  - Fixed a bug that prevented loading of required shared objects in certain cases.

Matlab

- New GAMS Matlab API
  - The API is distributed as package `GAMS` located in `apifiles/Matlab/api`.
  - Examples can be found in `apifiles/Matlab/examples`.

GMO

- Fixed the functions `gmoGetObjSparse`, `gmoGetRowSparse`, `gmoGetColSparse`, `gmoHessLoad`, `gmoHessLagStruct`, and `gmoHessLagVal`: they now work properly when `forceLinear` is set, e.g., when using GUSS.

3.15.1.7 Model Libraries

GAMS API Library

- Changed the following examples to use the MONO compiler `mcs` instead of `dmcs` on Unix:
  - **CSBenders.gms : Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm**
  - **CSCalcInverse.gms : Test expert level C# API to read and write indexed GDX**
  - **CSCutstock.gms : Test object oriented C# API using a cutting stock example**
  - **CSex1.gms : Test expert level C# API to read and write GDX**
  - **CSex2.gms : Test expert level C# API to read and write GDX, set options and execute GAMS**
  - **CSWarehouse.gms : Test object oriented C# API using a warehouse location problem**

GAMS Data Library

New models:

- **LeastSquares.gms : Demonstrate the use of numpy.linalg.lstsq on the diabetes test problem using linalg ols** (141)

GAMS Test Library

New models:

- **show01.gms : Test $show feature**
- **dmpsym01.gms : Test dmpSym and dmpUserSym feature**
- **ide01.gms : Basic test for IDE mode**
- **cplex08.gms : CPLEX test suite - conflict analysis** (841)
- **convert13.gms : CONVERT test suite - apply dict to gams format** (842)

- **convert14.gms : CONVERT test suite - nonlinear expression reformulations** (843)
- **convert15.gms : CONVERT test suite - support of nonlinear functions** (844)
- **unload12.gms : Make sure that sameAs and diag cannot be exported to GDX** (845)
- **unload13.gms : Unload with relaxed and full domain** (846)
- **unload14.gms : Check that unload happens at GDX file closing time** (847)
- **dumpopt1.gms : Test verbatim dumpOpt** (848)

Removed models:

- LS01 (394)
- LS02 (395)
- LS03 (397)
- LS04 (398)

3.15.2 34.2.0 Minor release (February 05, 2021)

3.15.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz and Bruce McCarl.

3.15.2.2 Solvers

CONOPT

- New libraries 4.23.
  - Improvements for models with external equations, models with very large objective terms, and models with variables that only appear in the objective function.
- Fix parallel function evaluation.

CONVERT

- Fix variable coefficients in JuMP format.

CPLEX

- Fixed issue of non-working option userincbicall.

GAMSCHK

- The output formatting for the `BLOCKPIC` and `MATCHIT` procedures was adjusted to better handle very small or large values.

3.15.3 34.3.0 Minor release (February 25, 2021)

3.15.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Luis Alberto Herrero Rozas, Robert Howlett, Erwin Kalvelagen, Antti Lehtila, Bruce McCarl, and Shima Sasanpour.

3.15.3.2 GAMS System

GAMS

- Fixed a problem with embedded Python code and directory names longer than 128 characters.
- Fixed embedded Python code exceptions not handled correctly in case the exception message is empty.
- Fixed a problem where dumpOpt in combination with $onVerbatim produced wrong dollar conditions in an $ifThen block.
- Fixed an abnormal termination issue that occurred on Windows with pathologically-structured large QP models and solvers that use QP structure explicitly.
- Fixed a potentially broken work file written with previousWork. There was a problem introduced with GAMS 34.1 for models written to the work file.
- Fixed wrong behavior of break in certain loops over a set with a single element.

3.15.3.3 Solvers

CONOPT

- New libraries 4.24:
  - The pre-processor has been updated so it will always return a solution.
- Fixed incorrect reference of row / column in error message.

CONVERT

- Fixed possibly incorrect sign of objective function in formats with explicit objective function (e.g., Ampl or JuMP).
- Fixed missing objective constant in formats with explicit objective function (e.g., Ampl or JuMP).
- Fixed possibly missing variable / equation in formats GAMS, DictMap and DumpGDX when converting multiple formats at a time.
- Fixed possibly missing parenthesis when dealing with minus zero.

GAMSCHK

- An error in the POSTOPT procedure that could lead to a segmentation fault or undefined behavior was fixed.
- The output formatting in the BLOCKLIST procedure was improved.

MOSEK

- New libraries 9.2.38.

ODHCPLEX

- Fixed issue of possibly incorrect objective bound reported by GAMS.

OsiMosek

- Fixed reported dual bound (ObjEst) and model status if solved without having closed the optimality gap.

3.15.3.4 Tools

GAMS Studio

- New version 1.5.4. with various bug fixes, stability improvements and minor enhancements, e.g.:
  - Added support for ports in GAMS Engine URL.
  - Improved visibility of current word and parentheses highlighting.
  - Fixed wrong color initialization for dark theme.
  - Fixed unwanted cursor jump when searching listing files without results.
  - Fixed MIRO execution issue if model filenames contain spaces.
  - Fixed GDX file reloading while being rewritten.
  - Fixed file links in log not handling relative paths on Windows.

GDXDUMP

- With option noData the empty symbols are marked with an end of line comment `!!empty`.
- The dollar control options are written in a consistent camel-case style if the output is in GAMS syntax.

GDXXRW

- Fixed a crash which happened when the rng was defined multiple times for a text by accident.

3.15.3.5 APIs

3.15.3.6 Expert Level APIs

- When introducing `gdxStoreDomainSets` with GAMS 33 the default was accidentally set to 0 (don't enable use of one dimensional sets as domain sets). This has been corrected with this version. Setting `gdxStoreDomainSets` to 0 is for *real* experts only, since it can cause inconsistent GDX files when used in combination with `gdxSymbolSetDomain`.

Matlab

- Fixed Java class attribute access to support Matlab versions down to 2017b.

3.16 33 Distribution

3.16.1 33.1.0 Major release (November 01, 2020)

3.16.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Pablo Cachinero, Michael Ferris, and Ben Huebner.

3.16.1.2 Platforms

- We plan to increase the minimal required GLIBC version of the distribution for GNU/Linux to 2.17 with the next major release.
- We plan to drop support for macOS 10.13 (High Sierra) with the next major release.

3.16.1.3 GAMS System

GAMS

- Allow to set the .stage attribute for discrete variables as well. This can be useful for certain solvers like SCIP.
- The status of the Embedded Code Facility has been changed from beta to released and fully supported. The nature of embedded code (especially Python embedded code) prohibits a level of backward compatibility as we guarantee for *intrinsic* GAMS language features: The Python interpreter together with distributed packages are evolving. Moreover, the GAMS/Python communication (e.g. via `gams.get()/set()`) will be subject to necessary modifications.
- Allow multi-line Python strings constructed with triple quotes (`'''` or `"""`) in embedded Python code without getting additional spaces from the internal extra indentation. For multiple lines of Python code that use the line continuation character \, extra indentation is not omitted.
- Added new dollar control options $on/offIDCProtect to control if symbols which are declared as external input can be changed at execution time.
- Quoted text in a display statement adds now an entry to the navigation pane of the LST Viewer in GAMS Studio as well.
- Print an extra log line when execute_load (or one of its variants) is executed. When running GAMS from one of the GAMS IDEs, this log line can be clicked to open the file loaded. Also the log lines generated for execute_unload[idx] were adjusted for better distinction. So adding these lines to a model

```
execute_unload    't.gdx', f;
execute_unloadidx 't.gdx', f;
execute_load      't.gdx', f;
```

  generates this log:

```
--- GDX File (execute_unload) C:\t m p\t.gdx
--- GDX File (execute_unloadidx) C:\t m p\t.gdx
--- GDX File (execute_load) C:\t m p\t.gdx
```

- Fixed a problem using captureModelInstance with solveLink=5/6/7; if `captureModelInstance=1` and `solveLink=6/7`, `solveLink` will be reset to `3/4` automatically.
- Fixed a problem with file names longer than 128 characters for option IDCGenerateJSON.

GMSPython

- Added the packages `urllib3`, `certifi`, and their dependencies.

3.16.1.4 Solvers

AMPL, LINGO, MPECDUMP, PYOMO

- We plan to drop the meta-solvers AMPL, LINGO, MPECDUMP, and PYOMO with the next major release. Convert will continue to produce model instances in these formats with the exception of MPECDUMP.

ANTIGONE, IPOPT, SHOT, SCIP

- Updated Intel MKL to version 2020.2 on Linux and macOS.

BARON

- New libraries 20.10.16.
  - Performance improvements including faster automatic differentiation, improved probing, improved local search, and improvements in BARON's cutting plane routines.
  - Changed default of option WantDual to 1. That is, dual values are now provided by default for nonlinear problems, too.
  - CBC updated to 2.10.5.

BDMLP

- We plan to drop the LP/MIP solver BDMLP with the next major release. Other free alternatives like Cbc outperform BDMLP.

BENCH

- We plan to drop the meta-solver BENCH with the next major release. Scripting tools provide much better facilities to generate benchmarks.

CONOPT

- New library 4.21.
  - Added a warning if the unscaled residuals in a feasible model are large due to very large scale factors.
  - Updated the selection of definitional constraints and improved the numerical behavior.
  - Changed tolerances in the derivative debugger related to very large derivatives.
  - Logic for Definition constraints updated:
    - Infeasibilities are handled with a forward push routine and a backward pull routine.
    - The way dense fill-in is removed is updated and the runtime is improved.
  - Changed a tolerance in the Derivative debugger.
  - Fixed an error in one-dimensional search when there are large 2nd derivatives or discontinuous 1st derivatives. Tried to recover a point that did not exist.
  - Fixed an error with model **hda**: there was a conflict between monotonicity and a tolerance.
  - Fixed some occurrences of system errors 12371, 12372, 88120.
  - Fixed a problem with a very small pivot (non-default tolerance) that created an incorrect penalty constraint.
  - Fixed an error that could appear in models with very long constraints.

Convert and ConvertD

- Added support for semi-integer and semi-continuous variables and complementarity constraints to scalar JuMP output format.
- Added information about discrete variables to the GDX files created by options `Hessian` and `Jacobian` for CONVERTD.
- The `Hessian` and `Jacobian` option for CONVERTD report the `.stage` variable and equation attribute in the variable and equations records only. In the past, the `.prior` and `.scale` attributes were reported.
- Fixed an error with suppressed complementarity constraints in Pyomo output.
- Fixed handling of semicontinuous variables with lower bound equal upper bound when writing MPS files.

Couenne

- As announced, the solver Couenne has been removed from the GAMS system. For the time being, libraries of GAMS/Couenne are available at the `COIN-OR GAMSlinks project`. Note, that GAMS does not test or offer support for these libraries.

CPLEX

- The two solver links CPLEX and CPLEXD were merged under the name CPLEX. Features that were formerly available in only one of the two solver links are now all usable with the new CPLEX link. Those features include:
  - Formerly only CPLEX:
    - SOS1 and SOS2 sets
    - Branching priorities
    - Indicator constraints
    - Conflict refiner
    - Ranging / sensitivity analysis
    - Solution pool for mixed-integer (quadratic) problems
  - Formerly only CPLEXD:
    - Better handling of quadratic constraints (e.g. providing duals)
    - Hot start capability in GUSS
    - Solving multiple instances of `GAMSModelInstance` in parallel using GAMS APIs
    - `Solvelink=solvelink.asyncThreads`
    - Cplex remote object and distributed MIP
    - Benders decomposition
- New features:
  - Partial MIP starts: allow to only include variable levels to the MIP start that are integer (within the tolerance tryint, see mipstart)
  - Multiple MIP starts provided via GDX (see multimipstart)
  - Lower / upper bound ranging / sensitivity analysis (see bndrng)
  - Lazy constraints (see userlazyconcall or .lazy)
  - Added MIP statistics (e.g. number of nodes, solve time, objective lower and upper bounds) to BCH call via GDX files usergdxnameinc and usergdxname.

- Added options:
  - Added option multimipstart for multiple MIP starts
  - Added option conflictdisplay
  - Added option multobjtolmip: the default value changes the behavior of the multi-objective optimization for continuous models
  - Added option bndrng: lower / upper bound ranging / sensitivity analysis
  - Added option indicoptstrict: handle erroneous indicator constraints
  - Added option userlazyconcall: adding lazy constraints using BCH
  - Added dot option .lazy: select linear constraints as lazy constraints
  - Added option mipstopexpr: custom MIP stopping criterion to terminate during branch-and-bound
- Changed options:
  - Changed behaviour of rngrestart: If the specified file extension is GDX, the ranging results will be exported as GDX instead of GMS.
  - Changed behaviour of miptracenode and miptracetime: option has no effect and MIP trace is appended when the solver reports global progress
  - Changed behaviour of quality: added entries regarding indicator constraints and MIP condition numbers
  - Changed default of randomseed from 0 to 201909284
  - Changed default of tuningtilim from 10000 to 1e75
  - Changed default of tuningdettilim from 1e7 to 1e75
  - Changed default of workmem from 128 to 2048
  - Changed name rtlcuts to rltcuts
  - Added documentation for partial MIP starts to mipstart
- Updated documentation for multiobjective optimization about CPLEX's two different strategies for continuous and discrete models (see also multobjtolmip).
- Fixed an error in BCH user heuristics where a false objective function of the incumbent was reported to CPLEX (in former CPLEXD link).

GUROBI

- New libraries 9.1.0.
- New option rngrestart: Export sensitivity information as GAMS readable format (GMS or GDX).
- New option mipstopexpr: Custom MIP stopping criterion to terminate during branch-and-bound.
- New option norelheurwork: controls NoRel heuristic.
- New option norelheurtime: controls NoRel heuristic.
- New option tunecleanup: Enables a tuning cleanup phase.
- New option poolgapabs: Maximum absolute gap for stored solutions.
- New option integralityfocus: Indicator for stricter enforcement of integrality constraints.
- New option value -1 for option .lazy: Treat as a user cut.
- Removed option `norelheuristic`. A finer control of Gurobi's NoRelHeuristic is done through the newly introduced options norelheurwork and norelheurtime.

IPOPT

- Changed default of option acceptable_iter from 15 to 0. This disables a heuristic in Ipopt to stop early with a solution that doesn't satisfy the usual termination tolerances when progress is slow.

Kestrel

- Fixed a bug that prevented job submission on Linux and macOS due to a missing certificate.

Lindo/LindoGlobal

- New libraries 12.0.210.
- Added the facility to detect irreducible infeasible and unbounded sets (IIS and IUS) and some options to control this.
- Added support for functions `div`, `log2`, `round`, and `trunc`.

LocalSolver

- New libraries 9.5 (20200923).

LS

- We plan to drop the least-square solver LS with the next major release. The Python method `numpy.linalg.lstsq` included in the GAMS distribution can be used within an embedded Python code section to efficiently minimize the sum of squared residuals.

MOSEK

- New libraries 9.2.28.

ODHCPLEX

- More features available in the GAMS link:
  - SOS1 and SOS2 sets
  - Branching priorities
  - Indicator constraints
  - Partial MIP starts: allow to only include variable levels to the MIP start that are integer (within the tolerance tryint, see mipstart).
  - Multiple MIP starts provided via GDX (see multimipstart)

SCIP

- New libraries 7.0 (5b13bda).
- The workaround to assign a non-continuous variable to a block for problem decomposition (use suffix `.prior` without `priorOpt=1`) is not necessary anymore (`.stage` is now available for non-continuous variables). If one runs a model that continues to use this workaround with this version of GAMS, all non-continuous variables will end up in block 1 independent of the `.prior` value.

SHOT

- Gurobi is now available as solver for the MIP or MIQCP relaxation on macOS, too.
- Fixed return of final dual bound found by SHOT to GAMS (objEst attribute).

SolveEngine

- Dropped link to Satalia SolveEngine because Satalia retired SolveEngine Beta and a successor is not yet available.

SoPlex

- New libraries 5.0 (2afa64b6).

XPRESS

- New libraries 8.10.1.
  - Removed option `mislpAlgorithmFinalSLP`.
  - Removed option `mislpAlgorithmNoFinalRounding`.
  - Added option `mislpCutStrategy`.
  - Added option mipstopexpr: Custom MIP stopping criterion to terminate during branch-and-bound.

3.16.1.5 Tools

GAMS IDE and GAMS Studio

- Fixed that Bonmin and Ipopt solver option files could not be created or edited via the options editor.

GAMS Studio

- New version 1.4.2.
  - New feature: Remote execution with GAMS Engine.
  - New feature: Allow to open `$[bat|lib]include` files by context menu, `F2` shortcut, or holding `Ctrl` and click on the filename.
  - Renamed `About GAMS` dialog to `GAMS Licensing` dialog to make it more clear, that this allows to install a GAMS license.
  - Improved GAMS license detection during Studio start and in GAMS Licensing dialog; if the content of a license file is in the clipboard when starting Studio, a dialog to install the license is started.
  - Added support for comma separated list as file filter in search dialog.
  - Changed behavior of "Whole Words" search option: `$` is now considered a word boundary.
  - Reworked NEOS integration, e.g.:
    - Allowing to kill submitted active jobs.
    - Moved NEOS control options into dialog.
    - Changed default parameter from `forceWork=1` to `previousWork=1`.
    - Improved handling of network errors.
  - Minor bug fixes and improvements, e.g.:
    - Added dialog for confidentiality and terms of use confirmation before submitting models to NEOS.
    - Added Arrow Up/Down as shortcuts to jump to search results when `Results View` is focused.
    - Added tooltips to options in search dialog.
    - Syntax coloring improvements.
    - Fixed file codec selection for the model assembly dialog.
    - Fixed and enhanced reloading mechanism of the GDX Viewer.
    - Fix to ensure that lowercase directory names are always used for MIRO directories, e.g. `data_mymodel` instead of `data_myModel`.
    - Fixed empty history on welcome page when starting Studio with no tabs open.
    - Fixed potential crash if files are modified in the background while a dialog is open.

MessageReceiverWindow

- Since GAMS does not support any 32bit platform anymore, this tool is compiled for `x64` instead of `Any CPU` now.

MODEL2TEX

- Deprecated command line parameter `-e` has been removed.

3.16.1.6 APIs

.NET

- Since GAMS does not support any 32bit platform anymore, the .Net DLL is compiled for `x64` instead of `Any CPU` now.

C++

- Adjusted compilation of examples to new handling of critical sections in expert level APIs.
- Adjusted some examples since GAMS/CplexD is now a synonym for GAMS/Cplex.

Python

- New experimental API `gams_magic` that enables the use of GAMS in `Jupyter` notebooks has been added. This release of `gams_magic` should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
- New API `gams_engine` that allows the creation of Python clients for `GAMS Engine` has been added.

3.16.1.7 Expert Level APIs

- The new files `gcmt.c` and `gcmt.h` are now required when compiling/linking C expert level API files (e.g. `gdxcc.c/h`) to protect critical sections in the interface for multi-threaded applications. On some platforms, this might also require linking against additional libraries, e.g. `libpthread` on Linux. Adding the define `GC_NO_MUTEX` when compiling the C expert level API files provides the old behavior.
- Added new call `gdxStoreDomainSets` to the GDX API to control the use of one-dimensional sets as domain sets. Disabling the storage of domain information for a one-dimensional set when writing to GDX saves memory but prevents the set from being used for domain checking.

3.16.1.8 Model Libraries

GAMS API Library

New models:

- **Pgams_engine.gms : Test gams_engine API** (60)
- **Pneos.gms : Test submitting GAMS models to NEOS server** (61)

GAMS Test Library

New models:

- **lindgl05.gms : Test new functions added to GAMS/Lindo(Global)** (828)
- **cplex04.gms : CPLEX test suite - free gams model test** (829)
- **cplex05.gms : CPLEX test suite - interactive** (830)
- **cplex06.gms : CPLEX test suite - multiobjective** (831)
- **cplex07.gms : CPLEX test suite - bch incumbent checker** (832)
- **sens01.gms : sensitivity / ranging test** (833)
- **mipstopexpr1.gms : mip stop expression test** (834)
- **attrib01.gms : Test attribute setting and preservation in Convert** (835)
- **gamsjupyter01.gms : Test GAMS Jupyter Notebooks** (836)
- **cmi01.gms : Test captureModelInstance option with all solveLink combinations** (837)

3.16.2 33.2.0 Minor release (December 01, 2020)

3.16.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.16.2.2 GAMS System

GAMS

- Fixed some problems with Implicit set definition:
  - When doing a filtered load from GDX or embeddedCode, the defined set only gets the elements actually loaded but not the ones that were filtered out.
  - Merging to start of existing data (with $onMulti) does not lead to out-of-order data anymore.

3.16.2.3 Solvers

CPLEX

- Fixed issue where option writemst did not produce any output.

KNITRO

- Add workaround to avoid abnormal termination of Knitro 12.2 libraries on AMD processors.

3.16.2.4 Tools

GAMS Studio

- New version 1.4.5 with various bug fixes, stability improvements and minor enhancements, e.g.:
  - Added error output to system log if the given MIRO installation location is invalid.
  - Disabled run actions and MIRO menu when active group has no active executable file.
  - Fixed a problem with GAMS parameters being ignored in rare cases.
  - Fixed a potential crash when reloading a large `gms` file while the syntax highlighter was still processing that file.
  - Improved Search and Replace, e.g.:
    - Improved performance of `Find Next/Previous`.
    - Added possibility to interrupt `Find Next/Previous`.
    - Fixed a problem which did not allow to jump to search results beyond the 50,000th match of the search term.
    - Fixed handling of wrapped lines in search.
  - Improved MIRO and Engine dialogs, e.g.:
    - Removed standalone MIRO assembly file dialog and added it to a new reworked MIRO deploy dialog instead.
    - Fixed version comparison in GAMS Engine dialog.

3.17 32 Distribution

3.17.1 32.1.0 Major release (July 31, 2020)

3.17.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Youngdae Kim, Michaja Pehl, Thomas Rutherford, and Igor Sheleg.

3.17.1.2 Platforms

- Dropped support for Sparc Solaris and AIX systems.

3.17.1.3 GAMS System

GAMS

- New default values for some GAMS options:

	new default	old default
logOption	3	1
empty	on	off
errMsg	1	0
errorLog	2147483647	0
lstTitleLeftAligned	1	0
putPW	32767	255
pageContr	2	3
pageSize	0	58
pageWidth	32767	255
optCR	0.0001	0.1
intVarUp	0	1
resLim	1e10	1000
solveLink	2	0
iterLim	2147483647	2e9

In order to work with the default values active in GAMS 31, copy the file `gams31config.yaml` (part of the GAMS system directory) into the location searched by GAMS for configuration files (e.g. the GAMS system directory) with the name `gamsconfig.yaml`.

- Extended the impact of command line parameter etLim, so that it reduces resLim for models solved automatically if that is greater than `etLim - timeElapsed`.
- Added new option zeroToEps to allow reading zero values as EPS at execution time.
- Added new options procTreeMemMonitor and procTreeMemTicks to enable monitoring of a memory high-water mark for the GAMS process and all its children.
- Adjusted behavior of command line parameters restart, restartNamed, save, saveObfuscate, xsave, and xsaveObfuscate: If a file name is given including a file extension, this extension is kept. In the past it was replaced by a default extension. Also, `?` is not allowed in the file name when writing a save file anymore.
- Extended influence of command line parameter inputDir, so that it also extends the search path for GDX files loaded with $gdxIn.
- Extended the search space for files included via $libInclude, extrinsic function libraries, and external equation libraries: Now, the directories `inclib`, `extrinsic_functions`, and `external_equations`, resp., are checked in all GAMS standard locations before `[GAMS System Directory]/inclib`, `[GAMS System Directory]`, and `[GAMS Working Directory]`, respectively.
- Renamed the command line parameter `execErr` to maxExecError to be in sync with the related function maxExecError. The old name is still available as a synonym.
- Added command line parameter previousWork to instruct GAMS to write a workfile using the format of an older GAMS version. This is useful in particular with submission to the NEOS server.
- Adjusted the function values returned by the power functions (e.g. `x**y`). In some cases where `x` is very small and positive the derivatives may become unbounded but the function values are well-behaved and can still be computed precisely and without overflow.
- Fixed a problem on Linux when the `XGD_CONFIG_DIRS` or `XGD_DATA_DIRS` variables have more than 7 directory entries.

GMSPython

- Added the packages `pandas`, `numpy`, `openpyxl`, `schema`, `tqdm` and their dependencies.

macOS Installer

- New way to install GAMS on macOS using a PKG installer, see the installation notes.

Windows Installer

- Added a checkbox for enabling/disabling the creation of a start menu entry to the `Select Start Menu Folder` Wizard page. The default state of the checkbox is inherited from previous installations.
- Command line argument `/noIcons` can be used in order to check the `Don't create a Start Menu folder` checkbox on the `Select Start Menu Folder` page.
- New command line argument `/desktopIcons=yes|no` (default:`yes`) can be used in order to turn on/off the creation of Desktop icons.
- The installer now writes all registry entries either to `HKEY_CURRENT_USER\Software\Classes` (current user) or `HKEY_LOCAL_MACHINE\Software\Classes` (all users).
- Show warning in case the system `GAMSDIR` environment variable is updated, but a user `GAMSDIR` environment variable exists and not vice versa.
- Always notify the operating system about changed environment variables.
- Changed the default installation location from `C:\GAMS\win64\XX.Y` to `C:\GAMS\XX` (e.g. `C:\GAMS\32`).
- Desktop shortcut names have been changed to `GAMS IDE 32` and `GAMS Studio 32`.
- Start menu entry reads `GAMS XX` (e.g. `GAMS 32`) instead of `GAMS XX.Y (win32/win64)`.
- Fixed a bug that prevented file associations (`.gdx` and `.gms` files) from working properly in certain cases.

3.17.1.4 Solvers

Bonmin, CBC, Couenne, LocalSolver, Osi links, SHOT, SoPlex

- Fixed that a setting of GAMS option iterlim to 2000000000 (the previous default) was not passed on to the solver.

CONOPT

- Added Conopt4 to the thread-safe solvers. It now can be used with solveLink=6.

CONVERT

- New output format: JuMP scalar model.

GUROBI

- Fixed a bug introduced with 31.1.0 and only partly fixed in 31.1.1 where the `GRB_LICENSE_FILE` environment variable was incorrectly dropped.

Ipopt

- Updated Mumps to 5.3.3.

KESTREL

- Kestrel interface source code has been ported from Python 2 to Python 3.
- Also on Windows, the source code of the link is now distributed instead of a binary.
- The GAMS distributed Python intepreter (`GMSPython`) is used for running the Kestrel client.

KNITRO

- New libraries 12.2.2.
  - Knitro 12 adds many improvements to the Knitro mixed-integer (MIP/MINLP) branch-and-cut solver. Several new cuts controlled by Knitro user options have been introduced including mixed-integer rounding cuts, zero-half cuts and clique cuts. In addition, improvements were made to the knapsack cuts implementation.
  - Knitro 12 offers several enhancements to the Knitro presolver. The presolver has been extended to allow multiple passes through the presolve operations. There are new presolve operations for variables in complementarity constraints and to tighten variable bounds.
  - Knitro 12 offers efficiency and storage/memory improvements in the callable library C API - the one used in the GAMS link!
  - Knitro 12.2 enables default parallelism when using multi-start or multi-algorithm features.
  - Knitro 12.2 offers several performance speed-ups:
    - on very large models with the default (i.e. interior-point) algorithm: potentially dramatic
    - when using the limited-memory BFGS Hessian option
    - in the SQP algorithm
  - A number of minor bug fixes and performance improvements are included in this release: rare segmentation fault with knapsack cuts fixed, bug in convexity detection fixed, poor/slow choice of algorithm for LP sub-problems fixed, poor/slow presolve issue on MIP models fixed.

LocalSolver

- New libraries 9.5 (20200701).
- Setting iterlim to the maximal possible value (2147483647) will not change the default iteration limit of LocalSolver anymore, see also the documentation.

Mosek

- New libraries 9.2.14.

ODHCPLEX

- New libraries 5.2.2.
- New options integerTol, subOrder, `subPresolve`, zeroTol, penPerturb, and threadZeroSync have been added. The options `newCallback` and variableClean allow for more option values.
- New handling of solutions that are not quite integer but within the integer feasibility tolerance of CPLEX but become infeasible if one rounds the integer variables. ODHCPLEX used to reject such solutions (while in CPLEX (and other MIP solvers) such solutions are considered acceptable for the user).

SoPlex

- Setting iterlim to the maximal possible value (2147483647) will not change the iteration limit of SoPlex anymore, so that SoPlex will run without a limit.

XPRESS

- New libraries 8.8.5.
- New solver: XPRESS SLP and XPRESS Knitro for nonlinear (mixed-integer) programming.
  - XPRESS SLP is a sequential linear programming (SLP) solver and XPRESS Knitro equals Knitro, but the problem is passed through the XPRESS nonlinear presolve.
  - Both can solve convex MINLP to global optimality and act as a heuristic method for general nonconvex problems.
  - XPRESS SLP offers a multistart to run different configurations in parallel or to start with multiple initial guesses.
  - If both XPRESS SLP and XPRESS Knitro are licensed, XPRESS can choose the nonlinear solver automatically based on instance attributes.
  - For more information about the XPRESS SLP algorithm, see `FICO Xpress Optimization Help (Nonlinear Reference Manual)`.
  - XPRESS SLP and XPRESS Knitro are available on all supported platforms.
  - XPRESS SLP requires a license for continuous nonlinear models or for mixed-integer nonlinear models.
  - XPRESS Knitro requires a GAMS/Knitro license in addition to the XPRESS license for (mixed-integer) nonlinear models.

3.17.1.5 Tools

CHK4UPD

- If the components of the checked license have different expiration dates, the validity of the license always refers to the base component now. In the past, the component with the oldest expiration date was used.

FINDTHISGAMS

- Support for registry key changes of the Windows installer has been added.
- New command line parameters `list`, `delete`, `write`, and `ide`. See the documentation for detailed information.

GAMS Studio

- New version 1.3.3.
  - New feature: Code Folding
    - Shortcut `Alt+L` switches folding state of the current block.
    - Shortcut `Alt+O` folds and `Shift+Alt+O` unfolds all foldable blocks.
    - Code folding is possible for pairs of parentheses that span multiple lines or Dollar Control Options that come in pairs.
  - New feature: Remote execution on NEOS Server for Optimization
    - Models can be executed remotely via the menu `GAMS -> Run NEOS` or the execute button located in the toolbar.
    - Note: Usually it takes some time before the GAMS version at NEOS gets updated. During that time one might get an error because of an incompatible workfile version. This can be avoided by setting the command line parameter previousWork to 1.
  - New feature: Navigation History
    - `Mouse button 4/5` or `Alt+Left/Right` on Windows/Linux and `Ctrl+[/]` on macOS can now be used to jump back to a previous text cursor positions or forward again. This is helpful to quickly navigate between different locations in files that one is currently working with.
  - New feature: Distraction Free Mode
    - Distraction Free Mode quickly turns off everything except for the editor window for better focus on modeling work. This is especially useful for small screens. When leaving Distraction Free Mode all Studio widgets will be put back where they were. To switch to and from Distraction Free Mode go to the Menu > View > Distraction Free Mode, or press `Ctrl+Alt+Enter` on Windows and Linux, or `Cmd+Option+Enter` on macOS.
  - New feature: Print support for text files (`gms`, `txt`, `lst`, `dmp`, ...). This is accessible with the shortcut `Ctrl+P` or in the menu `File -> Print`.
  - Added automatic switch to first non-empty tab when searching the Model Library Explorer. The old tab selection is restored if that tab contains results again.
  - Added header labels to copy actions in GDX Viewer table view. Two additional entries that allow to copy without the labels are available via the context menu.
  - Added `dmp` extension to list of executable file types.
  - Added `Shift+Option+Up/Down` hotkey to start block-edit on macOS.
  - Changed terminal to native macOS Terminal on macOS.
  - Stability improvements and minor bug fixes, e.g.:
    - Fixed syntax highlighter not recognizing "+" and "-" in "Model" statement.
    - Fixed missing `LXI` pane for files containing more than one dot.
    - Fixed group name for `gms` files containing more than one dot in the name.
    - Fixed rare random crash when opening the MIRO Model Assembly File dialog.
    - Fixed some icons not following selected theme.
    - Fixed line wrapping behavior not following settings.
    - Fixed that bookmarks in help view were not being saved permanently.
    - Fixed crash on reading LXI files containing empty lines.
    - Fixed some issues with the license file detection and info in the "About GAMS" dialog.
    - Fixed missing reload if a opened GDX file gets recreated.

MODEL2TEX

- Source code of model2tex has been ported to Python 3 and does not support Python 2 anymore.
- Distribute source code instead of binary on Windows. `model2tex.exe` has been replaced by `model2tex.cmd`.
- The GAMS distributed Python interpreter (`GMSPython`) is used for executing model2tex.
- Command line parameter `-e` has been deprecated and will be removed in the future.

3.17.1.6 APIs

- Automatically finding a GAMS installation from the Windows registry has been changed according to the changes to the Windows installer ([HKEY_CURRENT_USER|HKEY_LOCAL_MACHINE]\Software\Classes\gams.locati
- The performance of the Object-oriented APIs (in particular the class GAMSDatabase) has been improved.

.NET

- Change to GAMSWorkspace.AddCheckpoint: The checkpointName is now determined automatically as well when given as string.Empty, not only when set to null or being omitted.

Python

- As announced, dropped support for Python 2. The Object-oriented API as well as the expert-level APIs can be used with Python 3.6, Python 3.7, and Python 3.8.
- An experimental object oriented data interface called gamstransfer has been added. This interface is built on the expert-level Python APIs and simplifies the work of reading and writing GDX files. The underlying data structure is built on structured numpy arrays; this structure allows data to be easily converted directly to Pandas DataFrames (or other native Python data types). This release of gamstransfer should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.
- New experimental API gams2numpy for communicating data between GAMS and numpy arrays has been added. This release of gams2numpy should be considered a beta product and will be subject to changes in the future that may result in compatibility issues.

3.17.1.7 Model Libraries

GAMS Model Library

New models:

- **scenmerge.gms : Combining scenario results in a directory tree with gdxmerge** (427)

GAMS Test Library

New models:

- **zerotoeps1.gms : Test data loading with $onEps and option zeroToEps** (821)
- **idir01.gms : Test including files from different locations** (822)
- **mrw02.gms : Test MessageReceiverWindow.exe from Python** (823)
- **memmon1.gms : Test procTreeMemMonitor=1 behavior** (824)
- **gams2numpy01.gms : Test gams.core.numpy Python API string mode** (826)
- **gams2numpy02.gms : Test gams.core.numpy Python API raw mode** (827)

GAMS API Library

New models:

- **Pgamstransfer.gms : Test gamstransfer API** (58)
- Pgams2numpy.gms : Test gams.numpy API (59)

3.17.2 32.2.0 Minor release (August 26, 2020)

3.17.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Charles Chan, Ricardo Lima, Sandro Konrad Luh, Ami Reznik, Tom Rutherford, and Berk Uzundere.

3.17.2.2 GAMS System

GAMS

- Introduced new values 3 and 4 for option savePoint that allow to save the point file in the scratch directory.
- Fixed a bug which in rare cases caused GAMS to write files exceeding 80,000 characters per line (and thus the maximum line length GAMS can handle) when the command line parameter dumpopt was set.
- Fixed a bug in restart files that incorrectly stored the location of the GAMS configuration file (`gmscmpXX.txt`).
- Fixed a bug that is related to providing the GAMS configuration file (`gmscmpXX.txt`) explicitly via command line parameter subSys.
- Fixed reporting of compilation errors in encrypted input files.
- Fixed the count of discrete variables in the model statistics in case any discrete variable was fixed.

Windows Installer

- Fixed a bug that prevented registry entries from being removed correctly during uninstallation.

3.17.2.3 Solvers

Gurobi

- New libraries 9.0.3.

Lindo/LindoGlobal

- New libraries 12.0.208.
  - Fixed a rare problem with stochastic problems.

Mosek

- New libraries 9.2.18.

SCIP

- New libraries 7.0 (80549b8905).
- PaPILO updated to 1.0 (d0e5444cd).

SoPlex

- New libraries 5.0 (3623dbc0).

3.17.2.4 Tools

GAMS Studio

- New version 1.3.4.
  - Minor bug fixes, e.g.:
    - Show community license type in the solver matrix.
    - Fixed missing tab browser button when Studio starts in maximized or full-screen mode.
    - Fixed insertion of auto-closing characters in unwanted situations (e.g. beginning of a word).

GDX2VEDA

- Fixed a bug which in rare cases crashed the tool for large data sets on Windows.

3.17.2.5 Model Libraries

GAMS Test Library

Updated models:

- **savep1.gms : execute_loadpoint: save point - clear - loadpoint - reoptimize** (65)

3.18 31 Distribution

3.18.1 31.1.0 Major release (May 01, 2020)

3.18.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Christoph Böhringer, Wolfgang Britz, Andreas Lundell, Scott McDonald, Victor Nechifor, Renger van Nieuwkoop, A. Omidi, Christoph Pahmeyer, Soummya Roy, Thomas Rutherford, Alireza Soroudi, Tim Varelmann, and Elizabeth Wong.

3.18.1.2 Platforms

- As announced, dropped support for 32-bit MS Windows.

3.18.1.3 GAMS System

GAMS

- Extended the syntax of the model statement to allow to restrict the domain of variables used in the model at one spot.
- Added dollar control options $on|offSuffixDLVars and command line parameter SuffixDLVars to control whether it is allowed to use suffixes on variables with limited domains in a model.
- Added new command line parameters to initialize the state of certain dollar control options: Digit, Empty, EolCom, Filtered, InlineCom, Listing.
- Extended the behavior of the command line parameter checkErrorLevel, so that it also initializes the state of the dollar control option $on/offCheckErrorLevel.
- Extended the behavior of the command line parameter strictSingelton, so that it also initializes the state of the dollar control option $on/offStrictSingleton.
- Added new command line parameters to set the default values for certain put file attributes: PutND, PutNR, PutPS, PutPW.
- Removed the limit on the number of significant digits allowed in floating-point values in GAMS source.
  Historically, GAMS has run on widely different platforms where even the floating-point arithmetic varied. To ensure the precision specified in the GAMS input didn't exceed what could be stored and computed with as GAMS ran, we limited the amount of precision (i.e. the number of digits used for numbers in the GAMS source) that could be specified. This limit could be relaxed by using the $offDigit control.
  Modern computers all support IEEE double-precision arithmetic. It's a well-accepted and familiar standard, and the new behavior - to convert the decimal value in the GAMS source into the nearest double-precision value, regardless of the number of digits specified - is what is generally expected. There is a limit (currently 40) on the number of digits treated as significant: digits beyond this point are quietly treated as zero.
  For "nice" values (i.e. those with fewer than 17 digits of precision and exponents of limited size, like 3.14159 or 2.5032e10) there is no difference in the old and new behavior. But for values specified with 17 or more digits of precision or having exponents of large size, the double-precision values can vary slightly between the old and new systems. The new values are the correct ones.
  The new command line parameter sys18 has been added in case any users require the old behavior.
- New options encryptKey and decryptKey to encrypt and decrypt source based on a key rather than a target license. This allows developers to create encrypted input files that can be executed with any GAMS license and the right key.
- GAMS will search standard locations for the license file `gamslice.txt` including the GAMS system directory. The standard locations for your operating system are described in the installation notes. You can also continue to use the license command line parameter to point to a specific license file.
- GAMS can now use a configuration file `gamsconfig.yaml` to specify default values for command line parameters and environment variables: see details in GAMS Configuration in YAML Format. This can be used to implement user-specific default option settings that are shared between different GAMS versions. In the future, we also expect to use this capability to support the setting of options and defaults that support backward compatibility: this will become important as we change GAMS defaults in significant ways to modernize the user experience in the light of current computing environments and user expectations.

- Added system suffixes `%system.licenseFileName%`, `%system.userConfigDir%`, and `%system.userDataDir%`.
- Embedded Python Code Facility:
  - Embedded Python code can be used with Python 3.6, 3.7, and 3.8. `GMSPython` is used for embedded code by default on the core platforms.
  - The GAMS command line parameter `pySetup` has been deprecated. The environment variable `GMSPYTHONLIB` that needs to point to the Python library (e.g. `python38.dll` on Windows) determines the Python installation to be used in embedded Python code.
  - The `gams.set` method to write data back to GAMS has a new argument `mapKeys` that allows to pass a callable to remap the elements of the key.
- Removed GAMS return code 116 ("Could not find GMSPython").
- Fixed the `card` operator for scalar symbols, so that it always returns 1 when the symbol has data. In the past it might have been wrong for symbols that had no data in the declaration, but just from an assignment.
- Fixed issues where GAMS would crash on exceptionally large models (more than 268 million rows or columns) with certain non-default options selected.
- Fixed a problem which allowed multiple declarations of the same equation or variable when $offMulti was active.
- Fixed some 3-argument intrinsic functions whose third argument was optional (e.g. `ncpVUSin`) - these were not taking the default value for the third argument correctly into account when called with two arguments.
- Fixed a bug which caused wrong execution of $onPut and embeddedCode after Programming Flow Controls that were not terminated with a semicolon.
- Fixed a bug which caused variable and equation records fixed at 0 to be dumped incorrectly with dumpOpt.
- Fixed incomplete warning when writing a non-default status of $on/offEmpty to a save file.
- execMode did not prevent the execution of scriptExit. This has been fixed.

GMSPython

- GMSPython has been upgraded from Python 3.6 to Python 3.8 and comes without Python package installer `pip`.
- Added the package `ply`.

Libinclude

- The libinclude file rank.gms got a complete overhaul. The temporary GDX files resides now in the scratch directory, so multiple GAMS models using `rank.gms` can coexist in the same working directory. Moreover, the percentile calculation works with sort values that may include +inf/-inf. Some checks have been added that result in execution errors in case the operation was not successful, e.g. if rank failed to sort.
- Fixed a bug in `pyEmbMI.gms` that prevented string options from being set properly.

Documentation

- Improved the layout. The new layout provides a more responsive view on a smaller screen.

Windows Installer

- Default installation mode has been changed from `All Users` to `Current User`. This can be changed on the `Advanced Options` page or by providing `/allUsers=yes` when running the installer from a command prompt.
- The default application used for associating GAMS (`.gms`) and GDX (`.gdx`) files has been changed from the GAMS IDE to GAMS Studio.
- New command line argument `/allUsers=yes|no` (default:`no`) can be used in order to install for `All Users` instead of `Current User`.
- New command line argument `/noLicense=yes|no` (default:`no`) can be used in order to prevent any GAMS license from being written.
- New `GAMS License` page:
  - Allows to select a GAMS license to be used. The installer tries to find GAMS licenses in different locations and automatically selects a license to be used with the following precedence:
    - Clipboard
    - `C:\Users\username\Documents\GAMS`
    - Previous GAMS installation found from the registry (User)
    - Previous GAMS installation found from the registry (System)
  - A license file is written to `C:\Users\username\Documents\GAMS` when installing for `Current User` (default). Installing for `All Users` or checking `Write License to System Directory` will write the license to the system directory instead.

3.18.1.4 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2020.0 on Windows.

BARON

- New libraries 20.4.14.
  - Improved local search strategies.
  - Increased effectiveness of cut pool manager.
  - Improved relaxations for MIQPs.
  - Added new LP subsolver based on HSL's LA04.

CBC

- GAMS/CBC did not use the default value for all parameters as documented and as used in the CBC standalone program. This has been fixed. To restore some of the previous behavior, the following parameter setting can be used:

```
nodeStrategy      hybrid
preprocess        off
cuts              off
cliqueCuts        off
flowCoverCuts     off
gomoryCuts        off
knapsackCuts      off
mirCuts           off
twoMirCuts        off
probingCuts       off
zeroHalfCuts      off
heuristics        0
feaspump          off
greedyHeuristic   off
roundingHeuristic off
```

CONOPT

- New libraries 3.13L.
  - Added new facilities to print the variables changed by the pre-processor. See options prprec, rtpprec, and rtprel.
- New libraries 4.19.
  - Some errors related to the duals and basic/nonbasic flags for some definitional constraints and forcing constraints have been corrected.
  - The two tolerances `Tol_IFixed` and `Tol_DFixed` for when a variables is fixed have been unified into a single tolerance, Tol_Fixed.
  - The routine for detecting definitional constraints has been simplified and some options from previous versions are no longer used (`Flg_DC_Unique`, `Lim_DFVars`, and `Tol_Def_Ini`) and Tol_Def_Mult has a new default value.

CONVERT

- Added support for option HeaderTimeStamp, which was added for ConvertD before, in Convert.

COUENNE

- We plan to drop Couenne with one of the next major releases.

CPLEX

- Fixed incorrect display of selection of LPMethod when rerunning without presolve for infeasible model.
- Fixed incorrect selection of LPMethod when rerunning without presolve for infeasible model in CplexD.

GUROBI

- New libraries 9.0.2.
- If GAMS/Gurobi is licensed, the setting of the environment variable `GRB_LICENSE_FILE` is ignored. The setting of this environment variable interfered with the GAMS/Gurobi licensing.

IPOPT

- New libraries 3.13.2.
  - MA28 can no longer be loaded at run-time from a user-provided HSL library. Removed option 'ma28_pivtol'.
  - The default of option ma77_order has changed from 'amd' to 'metis'.
  - The default of option ma97_print_level has changed from 0 to -1.
  - The default of option mumps_pivot_order has been changed from 7 to 5 to work around a bug in MUMPS.
- Updated MUMPS to version 5.3.1. MUMPS has been build with OpenMP support enabled.
- Updated METIS (used by HSL codes and MUMPS) to version 5.1.0.

KESTREL

- Fixed a problem with the control file version that prevented Kestrel from being used in GAMS 30.

Lindo/LindoGlobal

- Increased the number of allowed nonlinear nonzeros in the global solver from 30 to 50 when operating under a demo license.

LocalSolver

- New libraries 9.5 (20200409).
  - Performance improvements on mixed-variable models like unit commitment or network design problems.
  - Performance improvements on routing and scheduling problems like CVRPTW or jobshop scheduling problems.
  - Better and faster lower bounds for nonlinear problems as well as for combinatorial problems like TSP.
- New parameter `verbosity`.
- Fixed handling of semi-integer variables.

MOSEK

- New libraries 9.2.4.
- Avoid MOSEK error 1243 on general nonlinear models.

SCIP

- New libraries 7.0.0 (0bc4dc9c65).
  - The symmetry code has been completely restructured and modularity has been increased.
    - It is now possible to use orbitopes (i.e., polyhedral symmetry handling techniques) and orbital fixing on the same instance.
    - Branching decisions can now take symmetry information into account by filtering first variables from orbits (new parameter branching/relpscost/filtercandssym) and transfering pseudo cost information to variables in orbit (new parameter branching/relpscost/transsympscost).
    - Improved performance of orbital fixing and orbitope propagation.
    - Reduced memory usage of symmetry detection.
    - Improved detection of packing/partitioning orbitopes.
    - New possible value 3 for misc/usesymmetry and changed default from 2 to 3.
    - Renamed parameter `propagating/orbitalfixing/enableafterrestart` to propagating/symmetry/recom which decides whether to recompute symmetries after a restart or not.
    - Changed default of constraints/orbitope/propfreq from 5 to 1.
    - Changed default of constraints/orbitope/sepafreq from 5 to -1.
    - Removed parameters `constraints/orbisack/checkalwaysfeas`, `constraints/orbitope/checkalwaysfe` `constraints/symresack/checkalwaysfeas`.

  * Removed parameters `presolving/symmetry/maxgenerators`, `presolving/symmetry/checksymmetries`, and `presolving/symmetry/displaynorbitvars` and added various new parameters in group propagating/symmetry.
  * Removed parameters `presolving/symbreak/conssaddlp`, `presolving/symbreak/addsymresacks`, `presolving/symbreak/computeorbits`, `presolving/symbreak/detectorbitopes`, and `presolving/symbreak/addconsstiming`.
  * Removed parameters `propagating/orbitalfixing/symcomptiming`, `propagating/orbitalfixing/perfo` and `propagating/orbitalfixing/recomputerestart`.
  * New parameter `constraints/orbitope/usedynamicprop` to enable propagation of orbitope constraints by reordering the rows based on the branching strategy.
  * New parameter constraints/symresack/checkmonotonicity to enable upgrade to packing/partitioning symresacks even if the underlying permutation is not monotone.
  * New parameters constraints/orbisack/forceconscopy, constraints/orbitope/forceconscopy, and constraints/symresack/forceconscopy.

- Presolve:
  * The presolve library PaPILO (Parallel Presolve for Integer and Linear Optimization) 1.0 has been integrated as additional presolver for mixed-integer linear programs.
  * Expressions of form $|x|^p x$ in a nonlinear constraint are now sometimes recognized and handled by abspower constraints.
  * Some more quadratic constraints are now recognized as second-order cone constraints.
  * New presolver dualsparsify that tries to combine variables to cancel nonzero coefficients in the constraint matrix of a MIP.
  * Improved performance of tworowbnd presolver. New parameters added. Changed default of presolving/tworowbnd/priority from -500000 to -2000.
  * Extended presolver dualinfer by the ability to perform convex combinations of continuous variables to calculate better bounds for the dual variables. New parameters added.
  * Huge clique tables are now avoided by restriciting the number of nonzero entries relative to the number of nonzeros in the problem. New parameter presolving/clqtablefac.
  * New parameter constraints/linear/extractcliques to turn clique extraction off.
  * Improved presolver "domcol" to not require a complete representation of all constraints in the matrix.
  * Enabling aggressive presolving now activates all available presolving plugins, and decreases parameter presolving/restartfac correctly with respect to default.
  * New parameter constraints/linear/maxdualmultaggrquot and constraints/linear/maxmultaggrquot to limit the maximum coefficient dynamism of an equation on which multiaggregation is performed. Smaller values make multiaggregations numerically more stable.
  * Changed default of `constraints/quadratic/empathy4and` from 0 to 2. This leads to stronger but larger reformulations for products of binary variables.

- Primal heuristics:
  * New Large Neighborhood Search heuristic "Trust region", available as both a standalone heuristic and a neighborhood inside of Adaptive Large Neighborhood Search.
  * New heuristic Adaptive Diving, which registers all publicly available dive sets from other diving heuristics, learns online which divesets reach the best score, and executes them more frequently.
  * New penalty alternating direction heuristic PADM that splits the problem into several sub-SCIPs according to a user-provided decomposition (see below). The sub-SCIPs are solved on an alternating basis until a feasible solution of the original problem is found.
  * The GINS heuristic can make use of a user-provided decomposition (see below) by selecting a block of variables that maximizes the potential, and randomly selecting a start variable for the neighborhood and/or by selecting an interval of consecutive blocks as neighborhood, until fixing rate is reached. In this case, no variable is randomly selected. Several new parameters added for the use of a decomposition in GINS.
  * The LP face heuristic now wastes less time if it decides not to run.
  * Improved performance of Adaptive Large Neighborhood Search heuristic on merely continuous problems.

  - All primal heuristics that use sub-SCIPs are now disabled within the heuristics fast emphasis setting.
  - Replaced parameter `heuristics/localbranching/useuct` by heuristics/useuctsubscip, which affects all LNS heuristics.
  - New parameters heuristics/shiftandpropagate/minfixingratelp and heuristics/locks/minfixingratelp to stop the heuristics after propagating integer fixings if no sufficient fixing of the all variables (including continuous) could be achieved.
  - Changed default value of heuristics/coefdiving/freq from 10 to -1.
  - Changed default value of heuristics/conflictdiving/freq from -1 to 10.
  - Changed default value of heuristics/conflictdiving/lockweight from 1.0 to 0.75.
  - Changed default value of heuristics/rins/nodesquot from 0.1 to 0.3 (due to other code changes, this should not affect default behavior).
  - New value `1` available for heuristics/gins/potential to allow computation based on local LP solution.
  - The display column for memory usage ("mem") now shows the creator name for every new incumbent solution. The heuristic display characters now represents the type of the heuristic (diving, Large Neighborhood Search, propagation, etc.). Changed default of display/width from 139 to 143.

- Branching:
  - New rule vanillafullstrong, mostly for scientific purpose.
  - Improved branching point selection when branching on nonlinear variables. Instead of using exactly the LP solution, a point closer to the middle of the variables domain is chosen. Added parameters branching/midpull and branching/midpullreldomtrig.
  - Many updates to parameters of lookahead branching rule.
  - New parameter branching/relpscost/degeneracyaware to switch degeneracy-aware hybrid branching, which adjusts weights of different scores in relpscost (hybrid) branching rule based on degeneracy information and skips strong branching for very high degeneracy rates.
- Separation:
  - Improvements in cut presolving and cgmip separator.
  - New parameter separating/cgmip/genprimalsols that allows to generate initial primal solutions from Gomory cuts.
  - Changed default of separating/rapidlearning/freq from -1 to 5. Various new parameters for rapidlearning.
  - Changed default of `separating/efficacyfac` from 1.0 to 0.6.
- Approximations on the search tree completion and estimates on the tree size have been added.
  - The approximate search tree completion is shown in a new display column.
  - The tree size estimate is used to trigger a restart if, after a reasonable initialization, the estimated size of the remaining tree is large.
  - New parameter group branching/treemodel to specify the tree model.
- SCIP can now store user decompositions. A GAMS user can specify one decomposition via the `.stage` variable suffix. Statistics regarding the decomposition are printed to the log before presolving (if display/statistics is enabled) and after presolving. New parameter decomposition/maxgraphedge.
- Extended the dual proof analysis for infeasible LPs to consider also locally valid rows (new parameter conflict/uselocalrows).
- If a reference value is given, the primal-reference and reference-dual integrals are calculated automatically and printed within the SCIP statistics.
- Emphasis settings for numerically challenging instances have been added. They increase numerical stability of (mostly) presolving operations such as (multi-)aggregations at the cost of performance.
- Renamed parameters `misc/allowdualreds` and `misc/allowobjprop` to misc/allowstrongdualreds and misc/allowweakdualreds, respectively.

  - Replaced parameter `numerics/lpfeastol` by numerics/lpfeastolfactor to specify which factor should be applied to the SCIP feasibility tolerance to initialize the primal feasibility tolerance of the LP solver.
  - New parameter lp/minmarkowitz to set the Markowitz stability threshold. High values sacrifice performance for stability.
  - Changed default of propagating/redcost/useimplics from TRUE to FALSE.
  - See also the `full release notes` and the `release paper`.
- Symmetry detection and handling is now available on Windows, too.
- Updated Ipopt to 3.13, see above.
- Removed value `soplex2` for option lp/solver. `soplex` is now the default if no CPLEX license is available.

SHOT

- New solver by Andreas Lundell (Åbo Akademi University, Finland) and Jan Kronqvist (Imperial College London, UK).
- SHOT is a deterministic solver for mixed-integer nonlinear programming problems (MINLPs). It can solve convex and some nonconvex MINLP problems to global optimality. For other nonconvex problems, SHOT acts as a heuristic method, i.e., without providing guarantees of global optimality. For more information, see the GAMS/SHOT solver manual, the `SHOT website`, and the publications [126] [122].
- SHOT 1.0.0 (527f1a11) is available for Linux, macOS ($\geq$ 10.13), and Windows. It can be used with a GAMS base system license.

SoPlex

- New libraries 5.0.0 (6535a3c8).
  - Improvements in memory management.
  - The number of violations is now shown in the log.
  - New options bool:forcebasic, int:stattimer, and real:min_markowitz. Replaced option `int:printcondition` by int:printbasismetric.
- GAMS/SoPlex is now available for multithreaded solves.

XPRESS

- New libraries v8.8.3 (aka Optimizer 35.01.04). It has been a longer-than-usual time since the previous library update, so the list of updates and improvements enhancing performance, stability, and correctness is extensive and not reproduced here.

3.18.1.5 Tools

GAMS IDE and GDXVIEWER

- As mentioned above, we switched the default application to be associated with GAMS files on Windows from the GAMS IDE to GAMS Studio with this release. The classic GAMS IDE has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, it does not provide all the features we see in modern development environments.
  Both the GAMS IDE and GDXVIEWER rely on a rather old software stack, which is hard to maintain with current operating systems and will become even harder over time. So we plan to drop the GAMS IDE and GDXVIEWER with an upcoming major release.

GAMS Studio

- New version 1.1.0.
  - Stability improvements.
  - Introduced new settings format.

    Attention

    This required a reset of all settings. They are saved now in JSON format. As a consequence, Studio 1.0.0 cannot use settings that were written by Studio versions prior to 1.0.0 and vice versa.
  - Changed the default file encoding to UTF-8 for all platforms (this mostly affects Windows, there should be no change for other platforms).
  - Added option to change the default text encoding to `Edit -> Encoding -> Select encodings`.
  - Introduced Dark Theme for Windows and Linux as well (can be changed through `Settings -> Editor`).
  - Added editor for GAMS Configuration and menu entry for default GAMS Configuration file.
  - Added option to change display format of numerical values in GDX Viewer.
  - Changed location of default workspace and model library.
  - Changed location where `gamslice.txt` is put when created using the "About GAMS" dialog to the new standard locations searched by GAMS (see installation notes for details).
  - Improved shortcut layout:
    - Reintroduced "Open Terminal" shortcut as `Ctrl+T`.
    - Introduced shortcut for "Run MIRO base mode": `F8`.
    - Introduced shortcut for "Run MIRO hypercube mode": `Shift + F8`.
    - Introduced shortcut for "Run MIRO configuration mode": `Shift + F7`.
    - Changed shortcut for focus "Project Explorer" to `Ctrl + 1`.
    - Changed shortcut for focus "Editor" to `Ctrl + 2`.
    - Changed shortcut for focus "Parameter Editor" to `Ctrl + 3`.
    - Changed shortcut to extend and collapse "Parameter Editor" to `Ctrl + Alt + 3`
    - Changed shortcut for focus "Tab Browser" to `Ctrl + 4`.
    - Changed shortcut for focus "Process Log" to `Ctrl + 5`.
    - Changed shortcut of duplicate line to `Ctrl+D`.
    - Changed shortcut of "Toggle Comment" in "Parameter Editor" to `Ctrl + *`
    - Changed shortcut of action "Go to matching parentheses" to: `Ctrl + B`
    - Changed shortcut of action "Select to matching parentheses" to: `Ctrl + Shift + B`
    - Fixed shortcut on macOS: block edit mode is now `CMD+Shift+Arrow Key`.

GDXMERGE

- Fixed a problem when merging a GDX file with name `.gdx`.

GDXXRW

- Added new option dSetText to control the reading of explanatory text for set elements of domain sets.

3.18.1.6 Object Oriented APIs

- Option `pySetup` has been removed from the class `GAMSOptions`.
- Removed GAMS return code 116 ("Could not find GMSPython") from the enumerate type representing the GAMS return code.
- Fixed a memory leak with `GAMSModelInstance.solve`.

C++

- As announced, dropped support for Microsoft Visual Studio 2013.

Python

- GAMS Python API is now distributed in source code under the MIT open source license.
- To access the GAMS API, the Python interpreter needs to find files in <`GAMS Systemdirectory`>`/apifiles/Python/` and <`GAMS Systemdirectory`>`/apifiles/Python/gams`, where `XY` corresponds to the Python version `X.Y`, e.g. 3.7. The `GMSPython` installation is already set up to find all required files. The Getting Started documentation section gives details on how to connect an external Python system with GAMS.
- There is a different directory structure in <`GAMS Systemdirectory`>`/apifiles/Python`. The content of the `api` directory has been moved to different places:
  - `api_27` for the binary Python 2.7 API files,
  - `src` for the files required to build the expert-level API files from source,
  - `gams` for source files of the GAMS Python API plus a few extra Python source files for working with indexed EMP syntax, e.g. **emppython1**, and
  - `thirdparty` for the Python package `ply` for processing of indexed EMP syntax.

3.18.1.7 Expert Level APIs

- We plan to remove the GAMSX API with one of the next major releases.
- Added `palSetSystemName` to setup a generic auditline in PAL. Increased PAL API version to 3.

3.18.1.8 Model Libraries

GAMS API Library

- All Python examples have been reworked. Tests are performed also with the Python installation in `GMSPython`.
- New model **PBuildXPLevelAPI.gms : Test building and installing the GAMS Python API from source distribution** (57).

GAMS Data Library

New models:

- **rank01.gms : Rank a vector, and display the data in sorted order** (135)
- **rank02.gms : Generate percentiles for a random vector** (136)
- **rank03.gms : Use libinclude rank to report multisectoral Monte Carlo results** (137)
- **rank04.gms : Repeated computation of percentiles within a loop** (138)
- **rank05.gms : Percentile ranking of household expenditure data with heterogenous household size** (139)
- **GMSPythonCheck.gms : Consistency check for GMSPython** (140)

GAMS Model Library

- Updated model **encrypt.gms : Input file encyption demo** (318)
- New model: **waterld.gms : Design of a Water Distribution Network with Limited Domain of Variables** (426)

GAMS Test Library

New models:

- **gdxxrw15.gms : GDXXRW - Testing option dSetText** (810)
- **card03.gms : Test card operator for scalar symbols** (811)
- **limdom01.gms : Test limited domains for variables in model** (812)
- **limdom02.gms : Test performance of limited domains for variables in model** (813)
- **limdom03.gms : Test the syntax of the model statement for limited domains for variables** (814)
- **limdom04.gms : Advanced test for limited domains for variables in model** (815)
- **fnncpf3.gms : Test correctness of ncpf intrinsic** (816)
- **fnncpvupow2.gms : Test correctness of NCPVUpow intrinsic** (817)
- **fnncpvusin2.gms : Test correctness of NCPVUsin intrinsic** (818)
- **loop10.gms : Test relaxed punctuation for control structures** (819)
- **dirs01.gms : Test search and processing of gamslice.txt and gamsconfig.yaml in user space** (820)

PSOPT Model Library

- Updated model **MultiperiodDCOPF24bus : Multi-period DC-OPF for IEEE 24-bus network considering wind and load shedding**

3.18.2 31.1.1 Maintenance release (May 16, 2020)

3.18.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Michael Ferris, Nick Sahinidis, and Karlo Šepetanc.

3.18.2.2 GAMS System

GAMS

- Fixed a bug where loading an empty universe from a GDX file caused an error.
- Fixed a bug in `gamsinst` that is used by the IDE to display available solvers.
- GAMS continues to search directories for the license and configuration file even if the construction of some directory names fails due to the absence of some environment variables, e.g. `HOME`.

GAMS Data Exchange (GDX)

- Fixed a bug where domain violations in higher dimensions might have been undetected when writing symbols to GDX.

3.18.2.3 Solvers

GUROBI

- Fixed a bug introduced with 31.1.0 where the `GRB_LICENSE_FILE` environment variable was incorrectly dropped.

MOSEK

- New libraries 9.2.7.

3.18.2.4 Tools

GAMS Studio

- New version 1.1.1.
  - Added command line parameter editor warnings for missing values.
  - Fixed problem with command line parameters not being updated when changing group.
  - Fixed behavior of `Ctrl - End` shortcut in process log and lst file view.
  - Fixed settings export not working when file already exists.
  - Fixed numpad not working when running Studio from an AppImage on Linux.
  - Fixed `Shift+Arrow Key` not working when running Studio from an AppImage on Linux.

3.18.2.5 Object Oriented APIs

- Fixed a bug in the Python API when exporting options (`GAMSOptions.export()`) that contain `defines`.

3.18.2.6 Model Libraries

GAMS Test Library

- Updated model **dirs01.gms : Test search and processing of gamslice.txt and gamsconfig.yaml in user space** (820)

3.18.3 31.2.0 Minor release (June 19, 2020)

3.18.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Salvador Doménech Martínez, and Kaushik Sinha.

3.18.3.2 GAMS System

GAMS

- The demo/community license limit of indexed external in- and output symbols for the GAMS/MIRO connector has been increased from 5 to 10. There is no limit on *scalar* external in- and output symbols. Starting with this version, one dimensional singleton sets are also not limited.
- Extend the influence of the command line parameter multiPass, so that it also ignores errors about unknown dimension with empty data statements when set to 2.
- Added three new put_utility commands `incMsg`, `incLog`, and `incMsgLog` to include the content of a file into the log or listing file.
- Fixed a crash for CNS models which get solved asynchronously while asyncSolLst is set to `1`.

3.18.3.3 Solvers

Gurobi

- Added option dumpBCSol to write incumbent solutions to GDX point files while Gurobi optimizes.

LocalSolver

- New libraries 9.5 (20200429).

Mosek

- New libraries 9.2.10.

SCIP

- New library 7.0 (01ae80d797).
- Fixed default setting for option misc/usesymmetry on Windows (was still set to 0, but should be 3).

SHOT

- New library 1.0.1.

3.18.3.4 Tools

GAMS Studio

- New version 1.1.2.
  - Performance improvements.
  - Stability improvements and minor bug fixes, e.g.,
    - Fixed crash when reopening a tab of a file that was removed from Project Explorer.
    - Fixed behavior of hotkeys to jump to beginning and end of line and page up/down.
    - Fixed Goto dialog jumping to beginning of file when entering invalid values.
    - Fixed shortcuts to focus Project Explorer and Editor not working when undocked.
    - Fixed that sizes of dock-widgets were not stored in FullScreen or Maximized window.

3.18.3.5 Object Oriented APIs

.NET

- Fixed a problem with reading labels which contain non-ASCII characters trough `GAMSSymbolRecord.Keys`.

3.18.3.6 Expert Level APIs

C#

- Fixed a problem with reading arrays of strings which contain non-ASCII characters through different APIs.

3.19 30 Distribution

3.19.1 30.1.0 Major release (January 10, 2020)

3.19.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Todd Munson, Suguru Otani, Nick Sahinidis, and Dimitri Tomanos.

3.19.1.2 Platforms

- As announced, dropped support for Windows 7. The minimal required Windows version is now 8.1.
- Moved platform 32-bit MS Windows to peripheral platforms. We will completely drop support for 32-bit MS Windows with GAMS 31 (which was originally announced for GAMS 30).

3.19.1.3 Licensing and Demo Limits

- The GAMS demo limits have been increased. GAMS will generate linear (LP, RMIP, MIP) models up to 2000 constraints and 2000 variables and up to 1000 constraints and 1000 variables for all other model types. No other limits apply (e.g. non-zeros or discrete variables). Some solvers (e.g., the global solvers ANTIGONE, BARON, and LindoGlobal) might enforce additional restrictions.
- GAMS provides a free community license for users on request. This community license allows generating even larger models: up to 5000 constraint and variables for linear and 2500 constraints and variables for other model types. These free licenses are for demonstration and evaluation but not for commercial and production work, see the `GAMS End User License Agreement`.
- Starting with this release, GAMS requires a valid license even for the free demo system. Free demo licenses (time-limited for 12 months) can be generated at the `download page`. The free demo and community licenses require also a recent version (not older than 18 months) of GAMS to run. Please check the license documentation for details.
- GAMS Beta versions will stop working 90 days after their release. This is to prevent accidental use of beta software.

3.19.1.4 GAMS System

GAMS

- Added system suffix MACAddress, which contains the MAC address of the first network adapter.
- Allow to declare more than one parameter as table on a single line.
- Added new dollar control options $(on|off)Filtered: These control how GAMS loads data from GDX with $load, $loadR, and $loadM as well as from $offEmbeddedCode.
- Added new dollar control options $loadFiltered, $loadFilteredM, and $loadFilteredR to load data from GDX in filtered mode explicitly.
- Added new dollar control options $(on|off)ExternalInput to load data implicitly from an external source and $(on|off)ExternalOutput to save data implicitly to an external target.
- Added new command line parameters IDCGDXInput, IDCGDXOutput, IDCGenerateGDX, IDCGenerateGDXInput, IDCGenerateGDXOutput, IDCGenerateJSON, and IDCJSON.
- Embedded Python Code:
  - Changed the optional boolean argument `domCheck` to an enumerated option `DomainCheckType` in the gams.set method in embedded code. *This might break existing code.* Even if the `domCheck` argument was not used, the default behavior at execution time changes. In previous versions the content was domain checked, now it is read filtered.
  - The argument `mergeType` was documented incorrectly. With type `MergeType.DEFAULT` (or no argument given) GAMS *merged* the content, in contrast to what the documentation said (here *replace* was mentioned).
- Terminate with a proper error message if lines in the EMP info file exceed the maximum line length of 1020 characters.
- Fixed a problem where the order of a semicolon and certain dollar control options changed the behavior of the compiler.

Installer

- In addition to `.gms` files, the Windows installer also associates `.gdx` files with either the GAMS IDE or GAMS Studio.

3.19.1.5 Solvers

BARON

- New libraries 19.12.7.
  - Performance improvements for large-scale and mixed-integer quadratic problems.
  - Improvements in interface to IPOPT.

CBC

- New libraries.

CONOPT

- New library 4.16 with bug fixes.
  - Improvement in the transition from Phase 0 to Phase 1 and in the one-dimensional search close to optimality.

CPLEX

- New libraries 12.10.0.0.
- New options epLin and heuristicEffort.

GUROBI

- New libraries 9.0.0.
  - Gurobi 9 comes with a new bilinear solver, which allows to solve non-convex quadratic programming problems. The new parameter nonConvex needs to be set.
- New general constraint types have been added to model functions like log, exp, sin, cos, and tan. New options funcPieces, funcPieceError, funcPieceRatio, funcPieceLength, and funcMaxVal have been added to control the piece-wise-linear discretization. The dot options doFuncPieces, doFuncPieceError, doFuncPieceRatio, and doFuncPieceLength allow control on an individual constraint basis.
- New parameters for new cutting planes: BQPCuts, relaxLiftCuts, and RLTCuts.
- Fixed a problem when reporting the primal solution only.
- Report the dual bound for continuous non-convex QP and QCP problems.

JAMS/LogMIP

- New option userPFFile to provide additional GAMS command line parameters for the GAMS run of the reformulated model.

LocalSolver

- New libraries 9.0 (20191219).

MOSEK

- New libraries 9.1.9.

ODHCPLEX

- New libraries 4.3.2 with bug fixes and performance improvements.

PATH

- New library 5.0.01 with bug fixes.
  - Fix seg fault when using the hidden option output_hidden_options.

SCIP

- New libraries 6.0 (90a56e0b).
  - Default for option heuristics/rins/nodesquot changed from 0.1 to 0.3.

3.19.1.6 Tools

GAMS Studio

- New version 0.14.1.
  - Stability improvements.
  - Added GDX Diff dialog to compare two GDX files. It can be opened by choosing `Tools` > `GDX Diff` from the menu or through the context menu off a GDX file in the Project Explorer.
  - Allow to open OS specific terminal in current working directory (`Tools` > `Terminal`) or in working directory of a specific group (using the context menu in the Project Explorer)
    - Note: This feature does not work on all Linux distributions, e.g., Ubuntu, yet.
  - Added basic integration of `GAMS MIRO`.
    - Note: This requires a separate installation of the GAMS MIRO package.
  - Improved GDX Viewer layout to optimize used screen space.
  - Adjusted layout of Reference File Viewer.
  - Added clear button to filter input field in GDX Viewer and Reference File Viewer.

3.19.1.7 Object Oriented APIs

C++

- We plan to drop support for Microsoft Visual Studio 2013 and maybe also 2015 with the next major release.

Python

- Added support for Python 3.8.
- As announced, dropped support for Python 3.4.

3.19.1.8 Expert Level APIs

- Added support for Python 3.8.
- As announced, dropped support for Python 3.4.

3.19.1.9 Model Libraries

GAMS Data Library

New models:

- **pickstock.gms : Stock selection problem with MIRO** (133)
- **transport.gms : Classical transportation problem with MIRO** (134)

GAMS Test Library

New models:

- **embpy05.gms : Test merge/replace when loading data from embedded code** (804)
- **embpy06.gms : Test domain check/filtered when loading data from embedded code** (805)
- **load12.gms : Tests filtered load** (806)
- **idc01.gms : Implicit Data Contract Test** (807)
- **gurobi05.gms : GUROBI test suite - general constraints sin/cos** (808)
- **studio01.gms : Test Studio Startup** (809)

3.19.2 30.2.0 Minor release (February 07, 2020)

3.19.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Iswar Radhakrishnan, Simon Scolan, and Kirk Yost.

3.19.2.2 GAMS System

GAMS

- Fixed a problem when writing implicit data contract in JSON format (IDCGenerateJSON) with symbols that use a set more than once in its domain.
- Fixed a potential wrong domain violation error for symbols declared under $onExternalInput.
- Fixed `gamsinst` and the IDE to give better messages in case a license file is absent.
- GAMS incorrectly removed indexed semi-integer and semi-continuous variables that have been fixed at a level other than zero with holdFixed set to 1. This has been fixed.
- GAMS also removes scalar semi-integer and semi-continuous variables now, when they have been fixed at zero with holdFixed set to 1.
- Fixed an issue where protected symbols could be changed using certain option statements.
- Added new command line parameter IDCProtect to control assignment behavior of external input symbols at execution time: `0` allows assignment, `1` (default) protects external input symbols from being changed.
- Adjusted reading of GAMS command-line arguments on non-Windows platforms to allow for empty arguments and arguments with preceding and trailing blanks. Windows users will not be affected by this change, nor will users who do not use quotes to protect arguments. But these invocations will now work differently on Unix, and will give the same result as on Windows:
  - `gams main.gms --myPrefix "" user1 " four blanks here "`
  - `$call gams subjob.gms --cityA Tokyo --cityB ""`

3.19.2.3 Solvers

CONOPT

- New library 4.17 with bug fixes.
  - Fixed a problem where small infeasibilities were not correctly reported back to GAMS.

DICOPT

- Fixed a possible crash during exit when having used Ipopt as NLP solver.

GUROBI

- New libraries 9.0.1.
- Fixed a problem with tuning of lp/mps files. In contrast to the documention, the tuning suite contained the model generated by GAMS when providing a list of models in lp/mps files to tune.
- Made value 3 available for Gurobi option scaleFlag, available since Gurobi 7.5.

MOSEK

- New libraries 9.1.11.

PATH

- New library 5.0.02.
  - Fix to two preprocessor issues: wrong solutions were being returned.

3.19.2.4 Tools

GAMS Studio

- New version 0.14.3.
  - Stability improvements.
  - New icon design.
  - Added filter facility for value columns in GDX Viewer.

3.19.3 30.3.0 Minor release (March 06, 2020)

3.19.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Andres J. Calderon, Antti Lehtila, Grégoire Pichenot, and Karlo Šepetanc.

3.19.3.2 GAMS System

GAMS

- Allow to create a secure work file on any platform for any target license platform.
- Fixed a bug which could have caused wrong domain violation errors with $offEmbeddedCode.
- Symbols set in embedded Python code via the GAMS Python object oriented API (i.e. `gams.db[sym]`) were imported with `MergeType` "replace" and `DomainCheckType` "filtered". This has been adjusted to both `MergeType` and `DomainCheckType` set to "default".
- Fixed a problem which was introduced with GAMS 30.1: The default for $(on|off)Filtered should always be `$onFiltered`. This was not the case when restarting from an old work file.

3.19.3.3 Solvers

Antigone, Bonmin, Cbc, Couenne, Ipopt, SCIP

- The number of threads as specified by option threads was disregarded. This has been fixed.

CONOPT

- New library 4.18 with bug fixes.
- The degeneracy-breaking logic has been improved for numerically difficult models and the interaction between defined variables and initialized variables has been improved.

JAMS/LogMIP

- The maximum length of the directory name plus file name that GAMS can execute is 255. JAMS and LogMIP stopped working earlier. This has been fixed.

LocalSolver

- Added missing `lskeygen` tool for Linux system.

MOSEK

- New libraries 9.1.13.

3.19.3.4 Tools

GAMS Studio

- New version 0.14.4.
  - Stability improvements.
  - Introduced Dark Mode support for macOS.

3.20 29 Distribution

3.20.1 29.1.0 Major release (November 15, 2019)

3.20.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, David Bernal Neira, Erwin Kalvelagen, and Scolan Simon.

3.20.1.2 Platforms

- As announced, dropped support for macOS 10.12 (Sierra).
- After more than 20 years we plan to drop support for 32-bit MS Windows with the next major release. Some components, e.g., GAMS IDE and gdxxrw, will remain 32-bit executables in the 64-bit MS Windows GAMS distribution.
- We plan to drop support for MS Windows 7 with the next major release.

3.20.1.3 GAMS System

GAMS

- Extended the GAMS log to print out the Double Dash Parameters set in addition to the non-default Command Line Parameters.
- Added dollar control option $setDDList.Cont to allow to define a list of double dash parameters to be checked over multiple lines.
- Added new ways to execute external programs which implicitly check the errorLevel returned and raise a compilation or execution error if it is not zero, namely $call.checkErrorLevel, $hiddencall.checkErrorLevel, execute.checkErrorLevel, put_utility exec.checkErrorLevel and put_utility shell.checkErrorLevel. This behavior can also be triggered without using the `checkErrorLevel` suffix by setting $onCheckErrorlevel and checkErrorLevel, respectively.
- Added command line option captureModelInstance to capture all model instances generated and solved by a solve statement during a GAMS run.
- Allow to declare a parameter as table without entering data.
- Added new Dollar Control Options eval.Set, evalGlobal.Set, and evalLocal.Set to define a compile-time variable based on the content of a GAMS set.
- Removed limit of 10,000 columns in table declaration.
- Changed trace record fields of quadratic model types from historic to today's names (QP --> QCP, QMIP --> MIQCP, RQMIP --> RMIQCP).
- The `gams.exe` and `gamskeep.exe` programs on 64-bit Windows are now native 64-bit executables. Because of some technical requirements related to the Interrupt functionality, the IDE invokes GAMS via the new 32-bit program `gams32.exe`.
- Fixed wrong return string for `%gams.action%`.
- Fixed a problem with interval evaluation for Extrinsic Functions.
- Fixed a problem with GAMS parameter scriptExit when running from the object-oriented APIs, GAMS Studio, or GAMS IDE.
- Fixed a problem with trace record field ETSolve which reported `NA` always.
- Fixed a problem with potentially wrong explanatory text when implicit sets are loaded using $load.

Installer

- The DMG installer for macOS has been reorganized and is now notarized, so that it should work on macOS 10.15.
- The selfextracting archive for macOS is now a 64-bit application.

3.20.1.4 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2019.5 on Linux and macOS.
- Updated Intel MKL libraries to version 2018.4 on Windows 64-bit again.

CBC

- New libraries.

CONOPT

- New library 4.15 with bug fixes.
- Option `DF_Method` has been replaced by the options Tol_Def_Mult and `Tol_Def_Ini`.

Convert

- Fixed a bug that caused a crash with option `nlp2mcp` selected.

DICOPT

- Fixed so called "integer cuts" when both binary and integer variables are present. DICOPT generated two integer cuts in this case, one that excluded the current values of binary variables and another one that excluded the current values of integer values. Now a single combined cut is generated, which allows that the values of the binary variables can repeat if the values of the integer values change and vice versa.
- Setting option weight to a value larger 10^{20} now disables the augmented penaly relaxation, that is, linearizations of nonlinear equations are added as hard constraints to the MIP relaxation instead of soft constraints.
- Enabling option convex now changes the default for option weight to `maxdouble`.

Examiner

- Added option objvarAutoAdjust to adjust objective variable to make objective equation feasible for models that allow objective reformulation.

Lindo/LindoGlobal

- New libraries 12.0.169.
- Added support for function `signPower`.

LocalSolver

- New libraries 9.0 (20191004) for Linux, macOS, and 64-bit Windows.
  - Performance improvements on packing, routing, and scheduling problems as well as on nonlinear continuous problems.

LGO

- Fixed a bug in the computation of the best feasible solution - an uninitialized variable was used.

MOSEK

- New libraries 9.1.1.
- Correct rejection of problems with non-quadratic nonlinear objective function when constraints are linear.

SoPlex

- New libraries 4.0 (083219e0).

SCIP

- New libraries 6.0 (a15f6c41).

3.20.1.5 Tools

GAMS Studio

- New version 0.13.2
  - Stability and performance improvements.
  - Allow to adjust the numerical precision in the GDX Viewer.
  - Added dialog to create/update license file (pops up when a license is in the user's clipboard and "About GAMS" is opened).
  - Added full screen mode (shortcut on Windows and Linux: `ALT+Return`, shortcut on macOS: `META+CMD+F`).
  - Added auto-resizing of columns when opening the Reference File Viewer.
  - Reworked process log to better handle long and fast output.
  - Improved behavior of `F1` (Help) Key: Studio now opens widget specific help if available.
  - Renamed "Output View" to "Process Log".
- Added a tutorial about the usage of GAMS Studio to the documentation.
- As announced, dropped Studio for 32-bit Windows.

3.20.1.6 Object Oriented APIs

Python

- Added support for Python 3.7 on Windows 64-bit, Linux, and macOS.
- We plan to drop support for Python 3.4 with the next major release.
- Support for Python 2.7 officially stops January 1, 2020. We plan to drop support for Python 2.7 with some future release. If you rely heavily on the availability and support of the GAMS API for Python 2.7 please contact support@gams.com to discuss your options.

Java

- Increase the minimum version requirement of the Java Runtime Environment to Java SE 8.
- The remove operation **GAMSDatabaseIterator.remove** is no longer supported. The method now throws an instance of `java.lang.UnsupportedOperationException` and performs no other actions. (To remove all records of the current iterating symbol, use the method **GAMSSymbol.clear** instead.)
- Fixed the behavior of the remove operation **GAMSSymbolIterator.remove**. The method now removes all records of the last GAMSSymbol element returned by an instance of **GAMSSymbol-Iterator** and can be called only once per call to **GAMSSymbolIterator.next**. The behavior of an iterator is unspecified if the underlying collection is modified while iterating.

3.20.1.7 Expert Level APIs

- Added support for Python 3.7 on Windows 64-bit, Linux, and macOS.
- We plan to drop support for Python 3.4 with the next major release.
- We plan to drop support for Python 2.7 with some future release.

3.20.1.8 Model Libraries

GAMS Model Library

- Added **inscribedsquare.gms : Inscribed Square Problem**.

GAMS Test Library

- Extrinsic function test models: Upgraded query-library generation code ql.py to Python 3. The default for property "description" has been changed to be an empty string.

3.21 28 Distribution

3.21.1 28.1.0 Major release (August 02, 2019)

3.21.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Johan Löfberg, Hans Mittelmann, and José Luis Vilar Zanón.

3.21.1.2 Platforms

- We plan to drop support for macOS 10.12 (Sierra) with the next GAMS major release.

3.21.1.3 GAMS System

GAMS

- Added new dollar control option $scratchFileName.
- Fixed a bug which caused a problem when unloading a multi-dimensional Alias at compile-time.

Documentation

- Improved ranking of results in `offline search` by minimizing the effect of the length of a document on the importance of a search term in that document.
- When searching the `index`, only relevant results are shown for subcategories as well.
- The `full-text search` now shows also results for a search in the `index`.

3.21.1.4 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Downgraded Intel MKL libraries to version 2018.3 on Windows 64-bit.

ANTIGONE

- The timelimit is now applied to the wallclock time and wallclock time is reported in the log and back to GAMS.

BARON

- New libraries 19.7.13.
  - New relaxations and branching rules for nonconvex mixed-integer quadratic programs, leading to significant speedups for this class of problems.
  - Increased robustness in various range reduction routines.
  - Increased solvability of large-scale problems by BARON's cut generators.
  - Enhanced convexity recognition routines.
  - Updated to IPOPT 3.12.13 and CBC 2.10.1.
- Fixed passing constant equations to BARON.

CBC

- Revised solver options.
  - Updated the documentation and possible values for many options, bringing them closer to the original Cbc option names and values.
  - The following options changed their type from boolean to string: crossover, cutoffConstraint, combineSolutions, Dins, DivingRandom, DivingCoefficient, DivingFractional, DivingGuided, DivingLineSearch, DivingPseudoCost, DivingVectorLength, feaspump, naiveHeuristics, pivotAndFix, randomizedRounding, Rens, Rins, roundingHeuristic, proximitySearch, presolve
  - For options dualPivot, primalPivot, and scaling value "auto" has been renamed to "automatic".
  - For option costStrategy, values "binaryfirst" and "binarylast" have been renamed to "01first" and "01last", respectively.
  - The following options have been added: factorization, denseThreshold, smallFactorization, sparseFactor, biasLU, psi, substitution, primalWeight, autoScale, bscale, gamma, KKT, expensiveStrong, OrbitalBranching, infeasibilityWeight, fixOnDj, sosPrioritize, cutLength, lagomoryCuts, latwomirCuts, hOptions, combine2Solutions, diveSolves, feaspump_artcost, feaspump_fracbab, feaspump_cutoff, feaspump_increment, dwHeuristic, pivotAndComplement, VndVariableNeighborhoodSearch

CONOPT

- CONOPT3 accepts models with empty rows. The GAMS/CONOPT3 link sets the hidden option `LSAZRW` to true.

Convert

- Replaced the OSiL writer. The new writer supports more GAMS intrinsic functions and produces slightly smaller OSiL files with more compact expression trees.

IPOPT

- Fixed handling of Ipopt's feasible-point-found status.

LocalSolver

- Added option `logfreq`.

MOSEK

- New libraries 9.0.98.
  - Introduced the power and exponential cones, see also Conic Programming.
  - As announced, the optimizer for general convex nonlinear problems has been removed. Thus, solving a NLP, DNLP, MINLP, or RMINLP for which a conic reformulation is not recognized will now result in a missing capability solver status with GAMS/Mosek.
  - Improved presolve for particular conic problems.
  - Tighten the stopping criteria when solving conic optimization problems: Changed default of MSK_DPAR_INTPNT_CO_TOL_INFEAS from 1e-10 to 1e-12, of MSK_DPAR_INTPNT_CO_TOL_REL_GAP from 1e-7 to 1e-8, and of MSK_DPAR_INTPNT_QO_TOL_INFEAS from 1e-10 to 1e-12. However, note that one can let Mosek relax feasibility and optimality tolerances if it cannot make sufficient progress, see MSK_DPAR_INTPNT_CO_TOL_NEAR_REL and MSK_DPAR_INTPNT_QO_TOL_NEAR_REL.
  - Changed scaling of interior-point optimizer so better accuracy is obtained in some cases.
  - Introduced an outer approximation method for solving conic mixed integer optimization problems. This can be enabled with the parameter MSK_IPAR_MIO_CONIC_OUTER_APPROXIMATION.
  - Much improved performance on recent AMD CPUs. For linear algebra, the BLIS library is employed when run on AMD CPUs.
  - Better performance on CPUs that support AVX-512 instructions.
  - Removed parameters: MSK_DPAR_DATA_TOL_AIJ, MSK_DPAR_INTPNT_NL_*, MSK_DPAR_MIO_DISABLE_TERM_TIME, MSK_DPAR_MIO_NEAR_TOL_ABS_GAP, MSK_DPAR_MIO_NEAR_TOL_REL_GAP, MSK_IPAR_MIO_CONSTRUCT_SOL and synonym "mipstart" (GAMS now always passes the starting point of a MIP to Mosek), MSK_IPAR_OPF_MAX_TERMS_PER_LINE, MSK_IPAR_WRITE_DATA_FORMAT
  - Further new parameters: MSK_IPAR_PRESOLVE_MAX_NUM_PASS, MSK_IPAR_PRESOLVE_MAX_NUM_P
    MSK_IPAR_SIM_SEED, MSK_IPAR_INTPNT_ORDER_GP_NUM_SEEDS, MSK_IPAR_MIO_MAX_NUM_RO
    MSK_IPAR_MIO_PROPAGATE_OBJECTIVE_CONSTRAINT, MSK_IPAR_MIO_SEED,
    MSK_IPAR_MIO_FEASPUMP_LEVEL, MSK_IPAR_WRITE_COMPRESSION, MSK_IPAR_OPF_WRITE_LI
    MSK_IPAR_PTF_WRITE_TRANSFORM
  - Changed default of MSK_DPAR_MIO_TOL_ABS_GAP from 0 to value of GAMS option OptCA (was used for MSK_DPAR_MIO_NEAR_TOL_ABS_GAP before) and of MSK_DPAR_MIO_TOL_REL_GAP from 0 to value of GAMS option OptCR (was used for MSK_DPAR_MIO_NEAR_TOL_REL_GAP before).
- Fixed handling of Mosek certificiates for primal and dual infeasibility, see Infeasible/Unbounded Models.

SCIP

- New libraries 6.0 (f79421d).

3.21.1.5 Tools

GAMS Studio

- New version 0.12.3.
  - Stability and performance improvements.
  - Added GAMS Solver Option Editor to view and edit a solver-specific option file.

  - Renamed Option Editor to Parameter Editor to better distinguish solver options and GAMS parameters.
  - Added menu entry `GAMS -> Delete scratch directories` to delete all scratch directories in current working directory. A similar dialog will also be triggered if GAMS returns `110` ("Too many scratch directories").
  - Added file associations and icons for `.gms` and `.gdx` files on macOS.
  - Changed shortcut to focus Main widget from `Ctrl+H` to `CTRL+E` (there was a collision on macOS).
  - Improved keyboard navigation between files and widgets.
- We plan to drop Studio for 32 bit Windows with the next major release.

3.21.1.6 APIs

- As announced, dropped support for Python 2.6.
- We plan to increase the minimum version requirement of the Java Runtime Environment to Java SE 8 with the next major release.

3.21.1.7 Model Libraries

GAMS Model Library

- Changed model sigma in **immun** to minimize standard-deviation instead of variance.
- Added missing nonnegativity requirement on variables in model **wall**.

3.21.2 28.2.0 Minor release (August 19, 2019)

3.21.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Nayeem Chowdhury, Salvador Doménech Martínez, Michael Ferris, Antti Lehtila, Evangelos Panos, Jochen Uhrich, and Alexey Ziuzin.

3.21.2.2 GAMS System

GAMS

- Setting $onMultiR allows the redefinition of macros as well now.
- Fixed a problem finding the Python interpreter, that comes with GAMS, in certain cases.
- Fixed a bug in the model generation, which could have caused a crash or wrong results in some cases.

3.21.2.3 Solvers

CPLEXD

- Corrected reporting of solution for (MI)QCP problems when using feasopt.
- CplexD now reports the objective of the feasible relaxation in the solution summary when using feasopt.

3.21.2.4 Tools

GAMS Studio

- New version 0.12.4
  - Stability and performance improvements.
  - Improved robustness of glb file parser (see User Libraries).
  - Added "What's new" menu entry to show latest changes of Studio.

3.21.2.5 Object Oriented APIs

- Fixed a problem, where `GAMSDatabase.Export` triggered an exception because of domain violations, even if only relaxed domains were used.

Java

- Added new method **GAMSSymbolRecord.dispose** for on-demand release of external resources hold by non-java library.

3.22 27 Distribution

3.22.1 27.1.0 Major release (April 24, 2019)

3.22.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Arne Drud, Jan-Erik Justkowiak, Renger van Nieuwkoop, and Manuel Wetzel.

3.22.1.2 Platforms

- As announced, support for Mac OS X 10.11 (El Capitan) has been dropped.
- As announced, support for Windows Vista has been dropped.

3.22.1.3 GAMS System

GAMS

- Embedded Python Code:
  - Allow Implicit Set Definition (or: Domain Defining Symbol Declarations) now for symbols loaded from embedded code as well.
  - Changed the default behavior of $offEmbeddedCode and endEmbeddedCode: Previously, internal resources got freed and with the next start of an embedded Python code section, the Python environment had to be reinitialized. This is not the case anymore. Also, the interpreter stays "alive" now, which allows to access Python symbols defined in one embedded code block in a following block. The old behavior could still be activated by setting the new command line parameter `freeEmbeddedPython` to 1.
  - Changed the optional boolean argument `merge` to an enumerated option `mergeType` in the `gams.set` method in embedded code. *This might break existing code.* Even if the `merge` argument was not used, the default behavior at compile time changes. In previous versions the content of an already defined symbol was quietly replaced while GAMS now triggers a compilation error `194 Symbol redefined`.
  - Fixed a bug in embedded code when setting `pySetup` to 0. Additional steps are required on Linux and macOS to use an alternative Python installation. Details can be found in section `Porting to a Different Version of Python`.
  - A `GAMSDatabase` created in embedded code via `gams.ws.add_database(source_database = gams.db)` had all the symbols but no data. This has been fixed.
  - `gams.db.export(file_name)` in embedded code resulted in an error for scalar symbols without data. This has been fixed.
  - Fixed a problem with embeddedCode/continueEmbeddedCode after an assignment that was not finished with a `;` like in this example:

    ```
    Set i /1*3/;
    Parameter xl(i);
    xl(i) = uniform(0.5,1)
    embeddedCode Python:
    print(list(gams.get('xl')))
    endEmbeddedCode
    Display xl;
    ```

    This leads to an error now. In the past, the assignment in line 3 was executed **after** the `embeddedCode` block leading to unexpected results.
- Extended the GAMS log to print out the non-default Command Line Parameters.
- Improved performance of execute_unload when option gdxUELs is set to `full`.
- Improve performance of model generation when multi-dimensional variables are used, where the controlling set for dimension `n>1` is big, e.g.:

  ```
  Set tiny /1*2/, huge /1*100000/ ;
  Variable x(i,j); Equation e;
  ...
  e.. sum((tiny,huge), x(tiny,huge)) =e= 42;
  ...
  ```
- Fixed a potential crash when more than 250 million labels are used in one model.
- Fixed a bug with Implicit Set Definition: When used with $onMulti to merge data into a non-empty set, it could have happened that an element was added twice in some cases.
- Fixed a bug causing a broken dump file if $onVerbatim and $ifThen was used with DumpOpt.

Documentation

- Added documentation for the put_utility keyword `assignText` (which has been in the system since 24.6).

GDX library

- Improve the behavior of GDX when handling large data sets (e.g. writing a set with 210 million elements, each having its own lengthy set text). Performance is better - less memory and less time are required. The limits on the amount of data that can be handled have been extended somewhat, and when these limits are reached this is handled more gracefully than previously - with a helpful message instead of a segmentation fault or erroneous results.
- Introduce consistent handling of the empty string vis-a-vis set text for UELs. *This is only relevant for user applications that use the low-level GDX API in an unsupported way.*
  - Previously the proper usage was to avoid adding the empty string to the list of set text strings. Applications that broke this rule would produce a GDX file with an abnormal internal structure. This structure may lead to jumbled set text.
  - With the updated GDX, it is not necessary to avoid adding an empty string to the set text list.
  - Applications holding to previous proper usage (i.e. those that avoid adding the empty string to the list of set text strings) will produce good GDX files regardless of GAMS version, and these files will behave as expected regardless of the GAMS version in which they are used.

3.22.1.4 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2019.3 on Linux and macOS and to 2018.4 on Windows 64-bit.

BARON

- New libraries 19.3.24.
  - Improved automatic differentiator that is up to two orders of magnitude faster for large-scale problems.
  - Improved data structures and cut pool manager to reduce memory footprint and time requirements for large-scale problems.
  - Improvements in various components, including parallel threads and BARON's IPOPT interface for macOS.
  - New tree management algorithms.
  - Improved range reduction and probing algorithms.
  - Using Intel MKL for faster BLAS and LAPACK routines.
  - Ipopt now uses METIS for linear system partitioning.
  - New option FirstLoc to terminate BARON as soon as a local optimum is found.
- New option ClockType to determine whether wall-clock or CPU time should be reported back to GAMS.

BDMLP and SBB

- The definition of SOS1 and SOS2 variables has changed. BDMLP and SBB used to *count* the number of elements in a set that are *off the lower bound*. BDMLP and SBB were the only two solvers in the GAMS solver portfolio with this definition. All other solvers counted elements that are *off zero*. The definition of SOS1 and SOS2 variables in BDMLP and SBB has been changed to the *off zero* definition to make their behavior more consistent with other GAMS solvers.

CBC

- New libraries 2.10.
  - Improved handling of SOS, starting point, and symmetries.
  - Improved performance of primal heuristics regarding the handling of implicit integer variables.
  - Mini-B&B is now disabled when solving with multiple threads.
  - Changed default value for zero half cuts parameter from `off` to `ifmove`.

CONOPT 4

- New library 4.11 with improvements in reliability and efficiency for large and difficult models.
- New option Tol_Opt_LinF: Optimality tolerance when infeasible in Linear Feasibility Model.

CPLEX/CPLEXD

- New libraries 12.9.0.
  - New options: CPLEXfolding, CPLEXwriteprob (CplexD only), CPLEXwarninglimit.
  - New hierarchical multi-objective optimization (CplexD only): CPLEXmultobj, CPLEXmultobjmethod, CPLEXobjnabstol, CPLEXobjnreltol.
  - The symmetry breaking parameter CPLEXsymmetry now applies only to MIP models. Use the new CPLEXfolding parameter for LP models.

GUROBI

- New libraries 8.1.1.

JAMS

- Experimental indexed EMP syntax has been updated: It can now take all the equilibrium related keywords (max, min, vi, qvi, dualvar, visol, and implicit) and shared constraints and variables.

LocalSolver

- New libraries 8.5 (20190130).
  - Strong lower bounds based on nonlinear relaxation techniques coupled with innovative branch-and-bound heuristics.

Mosek

- New libraries 8.1.0.80.

ODHCPLEX

- New libraries 4.23.

OQNLP

- As announced, OQNLP has been dropped.

3.22.1.5 Tools

CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.
- New library 6.2.0 on macOS.

GAMS Studio

- New version 0.11.1.
  - Stability and performance improvements.
  - Introduced a toolbar to replace the "Execution and Option Parameter Editor".
  - Editor
    - Improved the syntax highlighting.
    - Allow to open huge read-only (lst) files without significant memory requirement.
    - Added bookmark support.
    - Added `Ctrl+Up`/`Ctrl+Down` as shortcut for line wise scrolling without moving the text cursor.
    - Added `Ctrl+Home`/`Ctrl+End` as shortcut for page wise scrolling without moving the text cursor.
    - Added warning pop-up when trying to open a >50 Mb file in edit mode.
  - Various
    - Added `Ctrl+Alt+L` to extend/collapse the extended option editor
  - Forced light application theme on macOS to circumvent problems using the Dark Mode of macOS Mojave.

GDXDUMP

- New command line option setText to show the list of set text stored in a GDX file.
- Option symbols now lists the cardinality of a symbol in the column `Records`.

GDXXRW

- Fixed exit behavior if there were some duplicate records found when reading a symbol but less than specified by maxDupeErrors: If there are no other errors the exit code is 0 now (it was 16 in the past)

GMSZIP/GMSUNZIP

- Replaced the 32bit binaries `gmszip` and `gmsunzip` by more recent 64bit versions on macOS.

MPS2GMS

- Turn some errors that can be safely ignored when reading an MPS file into warnings.

3.22.1.6 Object Oriented APIs

Python

- Fixed a bug with default variable levels being `1.0` instead of `0.0`.

3.22.1.7 Model Libraries

GAMS Data Library

- **GDX2ACCESSExample1.gms : Dumping the Contents of trnsport.gdx** (125)
- **GDX2ACCESSExample2.gms : Writing Explanatory Text to Database** (126)
- **GDX2ACCESSExample3.gms : Dumping a large Table to Database** (127)
- **GDX2ACCESSExample4.gms : Special Value Mapping** (128)
- **GDX2ACCESSExample5.gms : Renaming Fields** (129)

GAMS Test Library

- **sosmiqcp01.gms : SOS1 and SOS2 behavior - MIQCP** (794)
- **sosmip01.gms : SOS1 and SOS2 behavior - MIP** (795)
- **sosminlp01.gms : SOS1 and SOS2 behavior - MINLP** (796)

3.22.2 27.2.0 Minor release (May 23, 2019)

3.22.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Michael Burkhardt, and Karlo Šepetanc.

3.22.2.2 GAMS System

GAMS

- Fix problem with missing entries for scalar variables and equations in the index file for the GAMS Output in certain cases.

3.22.2.3 Solvers

CONOPT

- New library 3.17J.
- New library 4.12.

Lindo/LindoGlobal

- New libraries 12.0.157.

LOCALSOLVER

- New libraries 8.5 (20190430).

NLPEC

- Added new option parmFile to allow to point to additional options for the GAMS run of the scalar model produced by NLPEC.

ODHCPLEX

- New libraries 4.26.

OSIXPRESS

- Fixed use of standalone Xpress license.

3.22.2.4 Tools

GAMS Studio

- New version 0.11.2.
  - Stability and performance improvements.
  - GDX Viewer
    - Added Drag and Drop feature in GDX Table View

3.22.2.5 Object Oriented APIs

Python

- Fixed a memory leak in the Python 3 version of the API.
- We plan to drop support for Python 2.6 with the next major release.

3.22.2.6 Expert Level APIs

- Fixed a memory leak in the Python 3 version of the APIs.
- We plan to drop support for Python 2.6 with the next major release.

3.22.3 27.3.0 Minor release (July 04, 2019)

3.22.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Erwin Kalvelagen, Wolfgang Kuehn, Bruce McCarl, and Michael Winkler.

3.22.3.2 GAMS System

- Fixed a bug that resulted in undercounting the number of physical and logical processors on Windows systems with more than 64 logical processors. GAMS/Base and many solvers use this count, e.g. when setting threads to 0 or -1.

GAMS

- Allow domain projection with $load also if the source symbol is a variable or equation.
- Fixed the cause for an unwanted compilation error with `embeddedCode` in certain situations.
- Unified behavior of the profile option: In the past, the `Profile Summary` was always written, when the profiling was activated from the command line, but was sometimes omitted when set as an option. Now, the summary gets always written. It does not matter anymore, where profiling was activated.

Documentation

- Added a Preface that reflects the history of the GAMS documentation. In particular it points out the importance of external contributors, in particular Bruce McCarl.

3.22.3.3 Solvers

BARON

- Fixed load of Xpress library on Linux.

CBC

- New libraries.

CONOPT

- New library 3.17K.
- Bug fix in library 4.12.

GAMSCHK

- Fixed error in postopt report. Previously, the report for the column occurring last in the listing file would be omitted, and all its entries would appear in the report for the preceding column.
- Fixed crash that occurred in some cases.
- The above problems occurred in GAMS 26 and previous. A fix was introduced with GAMS 27, but this fix went too far and introduced new problems. With this version, the fix to 27.1 is reverted and a more moderate fix is used instead.

LocalSolver

- Fixed missing solver log.

Mosek

- New libraries 8.1.0.81.
- Fixed ignoring option solvefinal.

SCIP

- New libraries 6.0.2.

SoPlex

- New libraries 4.0.2.

3.22.3.4 Tools

GAMS Studio

- New version 0.11.5
  - Stability and performance improvements.
  - Added buttons to toolbar to show/hide Project Explorer, Output-, and Help widget.
  - Added shortcut `Ctrl+H` to focus Main widget.
  - Added shortcut `Ctrl+Shift+G` to focus Output widget.
  - Added shortcut `Esc` to close several widgets.
  - GDX Viewer:
    - Columns in the data view are now resized to the minimum width necessary to see all the data automatically.
    - Added shortcut to auto-resize all columns in the data view after the width was changed by hand (`Ctrl+R`).
  - Search:
    - Added shortcut `Ctrl+Enter` for "Search All".
    - Added ability to replace in more than one file at a time.
    - Find Next/Previous now respects all search options and will jump to the next file if there are also matches.

3.22.3.5 Object Oriented APIs

Python

- Fixed a bug in GamsJob.interrupt() that caused an `OverflowError` on 64 bit platforms.

3.23 26 Distribution

3.23.1 26.1.0 Major release (February 02, 2019)

3.23.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Stefano Alva, Adam Christensen, Hanna Donau, Stephen Frank, Anastasis Giannousakis, Jan-Erik Justkowiak, David Laudy, Andreas Lundell, Thomas Maindl, Nils Mattus, Scott McDonald, Noah Rhodes, Tom Rutherford, and Anna Straubinger.

3.23.1.2 Versioning

From this release on, we use a new interpretation on the GAMS version number scheme XX.Y.Z. XX alone now indicates the GAMS distribution number (was XX.Y before). Y is used to distinguish between beta, major, and minor releases of the XX distribution. Z is used to distinguish different maintenance releases. That is, we now use

- XX.0.Z for beta versions,
- XX.1.0 for the major release of distribution XX,
- XX.Y.0, Y $>$ 1, for minor releases,
- XX.Y.Z, Y $\geq$ 1, Z $>$ 0, for maintenance releases.

See Release Types regarding the meaning or what constitutes a major, minor, or maintenance release. As before, we increase the required license date for major releases only.

Further, we changed the default installation directory of the GAMS system from using only the distribution number to also include the minor version number. Thus, as before, GAMS is now installed into directory names which contain the XX.Y part of the GAMS version number.

3.23.1.3 Platforms

- We plan to drop support for Mac OS X 10.11 (El Capitan) with the next major release.
- We plan to drop support for Windows Vista with the next major release.
- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

3.23.1.4 GAMS System

GAMS

- Changed behavior of $compress, $decompress, and $encrypt: `source` and `target` cannot be identical anymore; this could have lead to unreliable behavior in the past.
- Extended the influence of $onMulti: This affects the model statement as well now.
- Added new dollar control option $onMultiR, which is similar to $onMulti but replaces existing data instead of merging into it.
- Added put_utility keyword `solver` to select a solver for a given or all possible model types by name at execution time.
- Extended the syntax to allow Implicit Set Definition (or: Domain Defining Symbol Declarations). Here is a small example showing how this can be used:

```
Set
   i 'canning plants'
   j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;

Display i,j;
```

And this is the result of the `Display` statement:

```
----     10 SET i  canning plants

seattle  ,    san-diego

----     10 SET j  markets

new-york,    chicago ,    topeka
```

- Updated the base module and components as necessary to allow for spaces in names of any files and directory used by GAMS, including the system directory, the working directory, the scratch directory, the process directory, and remove any checks warning about and preventing this. While the Windows system had already allowed spaces in previous versions, this change updates the other platforms to behave similarly.
- Changed the reading of command-line arguments on non-Windows platforms! This should only affect how arguments with spaces in them are passed on to GAMS. Previously, such arguments needed extra quoting or protection on non-Windows platforms. With this update, the extra protection is no longer needed: the same quoting of space-containing arguments can be used on all platforms. For example, with GAMS 25.1 and previous, two pairs of quotes were required on non-Windows platforms to protect spaces in an argument:

  ```
  gams xx.gms --MY_GDX '"outer space"'
  ```

  while now only one pair of quotes is needed on all platforms:

  ```
  gams xx.gms --MY_GDX "outer space"
  ```

- Increased the number of labels, which can be handled by GAMS from 200 million to ∼2.1 billion and let GAMS terminate with the meaningful error message, if that limit is reached.
- Windows only: Fixed a bug which treated a path (e.g. to an input file or used as inputDir) as relative path, if it starts with `/`. Example: When running `cd C:\tmp && gams.exe /data/myModel.gms`, GAMS tried to load the file `C:\tmp\data\myModel.gms` in the past. Now, it loads `C:\data\myModel.gms`.
- Fixed some problems with option asyncSolLst.
- Fixed a bug which could have caused GAMS to accept duplicate entries in a data statement, when they came in unsorted order.
- Fixed the dollar control option $onUpper (it did not do anything before).

GMSPython

- Updated `pip` to work with recent macOS versions.

3.23.1.5 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Fixed an MKL error when running any of these solvers after CPLEX with solvelink=5 in the same GAMS run on Linux.
- Updated Intel MKL libraries to version 2019.0 on Linux and to version 2018.3 on Windows 64-bit.

BARON

- New libraries 18.11.12 for 64-bit platforms.
  - New cutting planes for convex-transformable functions.
  - New cutting planes for polynomial optimization problems.
  - More robust treatment of cutting planes.
  - Improved optimality-based range reduction mechanisms.
  - CBC can now use multiple threads on Windows, too.
- We plan to drop BARON for Windows 32-bit with some future release.
- The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time.

Bonmin, CBC, Couenne, Ipopt

- New libraries.

CONOPT 4

- New library 4.09 with many reliability improvements and a fix for wrong non-opt markers.

CPLEX

- Ctrl-C (or Interrupt) was broken for GAMS/CplexD. This has been fixed.
- Improved performance of retrieving the solution for a QCP with many quadratic rows.

Gurobi

- The solver time reported back to GAMS (resource usage) is now the wall clock time instead of the CPU time on Unix.
- Allow quadratic rows with `=E=` and let Gurobi deal with potential errors. Gurobi can sometimes substitue quadratic terms defined by `=E=` rows. The check of quadratic row to be either `=L=` or `=G=` in the GAMS/Gurobi link prevented this.

KESTREL

- Added support for MPSGE models.

Knitro

- New libraries 11.1.1 (11.0.1 for 32-bit Windows) containing several bug fixes and performance improvements, including:
  - improved performance on convex quadratic models,
  - improved generation of knapsack cuts, resulting in faster performance on some MINLP models,
  - improved performance when using the SQP algorithm,
  - new values for option linsolver to choose parallel factorization routines MA97 and MA86.
- Artelys has announced that Knitro 11.0 was the last Knitro release to support 32-bit Windows. We will be dropping GAMS/Knitro for 32-bit Windows in the near future.

Lindo/LindoGlobal

- New libraries 12.0.90.
  - LP Solver Improvements:
    - With new enhancements made to the simplex solvers, the average performance on large instances has increased by 18% for the primal simplex and 15% for the dual simplex compared to the previous version.
    - Improved performance on LP's when using multiple cores with concurrent execution of Primal, Dual, and Barrier.
  - Quadratic and Nonlinear Solver Improvements:
    - Much faster handling of large quadratic matrices, e.g. 1000 x 1000.
  - Global Solver Improvements:
    - Improved handling of discontinuous functions, e.g., MOD(x,k), ROUND(x).

LocalSolver

- New libraries 8.0 (20181106).
  - Performance improvements on routing & scheduling problems, especially Pickup & Delivery problems.
  - Learning algorithms inside LocalSolver, which allow to automatically and dynamically tune up the search process for each solved instance, were improved. This leads to improved performances, especially for short resolution times (minutes).

Mosek

- New libraries 8.1.0.72.

ODHCPLEX

- New libraries 4.09 for Linux with many reliability improvements.
- New libraries 4.13 for Windows 64-bit with many reliability improvements and addressing dynamic loading in concurrent threads and processes.
- Updated options: DynamicSearch, FirstFeas, and Strategy
- New options: DecompDensity, Divisor, ODHFeasOpt, MaxBacktrack, `NewCallback`, Recurse, RecurseDecomp, RecurseIterLim, RecurseLog, RecurseMinIterLim, RecurseSolIterLim, RelaxSOS2, and ThreadLog.

OQNLP

- We plan to drop OQNLP with the next major release.

PATH

- New libraries 5.0.00.
  - Fixed crash in Lemke's method that could happen for models with extremely poor scaling.
  - New capability to use alternate basis-handling packages via dynamic loading of shared libraries. Two alternate packages are currently supported:
    * BLU-LUSOL: Block LU updating using the LUSOL routines. The shared library required for this is included in the distribution.
    * UMFPACK: Tim Davis' multifrontal LU factorization package. The shared library required for this is **not** included in the GAMS distribution, but can be downloaded from the SuiteSparse site. N.B.: We have verified UMFPACK on Linux, macOS, and Windows using UMFPACK v5.7.7 from SuiteSparse 5.3.0.

SCIP

- New libraries 6.0.1.
  - Primal Heuristics
    * new diving heuristic farkasdiving that dives into the direction of the pseudosolution and tries to construct Farkas-proofs
    * new diving heuristic conflictdiving that considers locks from conflict constraints
    * performance improvements for Adaptive Large Neighborhood Search
      · changed default of parameter heuristics/alns/adjustminimprove from 1 to 0
      · changed default of parameter heuristics/alns/alpha from 0.2 to 0.0016
      · new parameter heuristics/alns/adjusttargetnodes
      · changed default of parameter heuristics/alns/eps from 0.5 to 0.468584
      · changed default of parameter heuristics/alns/gamma from 0.2 to 0.0704146
      · changed default of parameter heuristics/alns/minimprovehigh from 0.1 to 0.01
      · changed default of parameter heuristics/alns/minimprovelow from 0.0001 to 0.01
      · removed parameter heuristics/alns/stallnodefactor
      · changed default of parameter heuristics/alns/startminimprove from 0.05 to 0.01
      · changed default of parameter heuristics/alns/targetnodefactor from 1.5 to 1.05
      · new parameter heuristics/alns/unfixtol
      · changed default of parameter heuristics/alns/crossover/minfixingrate from 0.4 to 0.3
      · changed default of parameter heuristics/alns/dins/maxfixingrate from 0.5 to 0.9
      · changed default of parameter heuristics/alns/dins/minfixingrate from 0.1 to 0.3
      · changed default of parameter heuristics/alns/localbranching/minfixingrate from 0 to 0.3
      · changed default of parameter heuristics/alns/mutation/minfixingrate from 0.4 to 0.3
      · changed default of parameter heuristics/alns/proximity/minfixingrate from 0 to 0.3
      · changed default of parameter heuristics/alns/rens/maxfixingrate from 0.7 to 0.9
      · changed default of parameter heuristics/alns/rins/maxfixingrate from 0.6 to 0.9
      · changed default of parameter heuristics/alns/rins/minfixingrate from 0.2 to 0.3
      · changed default of parameter heuristics/alns/zeroobjective/minfixingrate from 0 to 0.3
  - New branching rule lookahead that evaluates potential child and grandchild nodes to determine a branching decision
  - LP Solver Interface
    * lp/checkstability is now properly implemented for use with SoPlex
    * new parameter lp/alwaysgetduals

    - new parameter lp/checkfarkas
  - Separation (cutting planes)
    - cuts generated from certain quadratic constraints with convex feasible region are now global
    - new parameter `separating/dircutoffdistfac`
    - new parameter `separating/efficacyfac`
    - removed parameter separating/maxincrounds
    - new parameter separating/zerohalf/dircutoffdistweight
    - new parameter separating/zerohalf/efficacyweight
    - changed default of parameter separating/zerohalf/goodscore from 0.9 to 1
    - new parameter separating/zerohalf/goodmaxparall
    - new parameter separating/zerohalf/initseed
    - new parameter separating/zerohalf/maxparall
    - new parameter separating/zerohalf/objparalweight
  - Symmetry Handling
    - restructured timing of symmetry computation to allow to add symmetry handling components within presolving
    - changed default of parameter constraints/symresack/ppsymresack from 0 to 1
    - new parameter `presolving/symbreak/addconsstiming`
    - changed default of parameter `presolving/symbreak/detectorbitopes` from 1 to 0
    - removed parameter "presolving/symmetry/computepresolved"
    - new parameter `propagating/orbitalfixing/enabledafterrestarts`
    - new parameter `propagating/orbitalfixing/performpresolving`
    - changed default of parameter `propagating/orbitalfixing/presolpriority` from 0 to -1000000
    - changed default of parameter `propagating/orbitalfixing/presoltiming` from 28 to 16
    - new parameter `propagating/orbitalfixing/symcomptiming`
  - improved bound tightening for some quadratic equations
  - new parameter display/relevantstats
  - new parameter misc/scaleobj
  - removed `implfree` presolver
  - See also the `full release notes` and the `release paper`.

SELKIE

The `SELKIE` solver - new to GAMS with this release - is an EMP solver that implements decomposition methods for multi-agent equilibrium and related models.

SoPlex

- New libraries 4.0.1.
  - new simplifier step to perform variable aggregation for equations with two variables
  - new parameter bool:ensureray to re-solve the original problem in case of infeasibility/unboundedness to get a valid proof/ray
  - See also the `full release notes` and the `release paper`.

Xpress

- New libraries 33.01.10.
  - local symmetry re-detection in MIP tree search
  - improved branching for highly symmetric MIPs
  - new or improved cuts, degeneracy handling, crossover, preprocessing
  - FICO does not release patches for all platforms with each patch release, so some platforms lag behind the most-used ones.

3.23.1.6 Tools

CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

CSV2GDX

- Extended recognition of special values:
  - `N/A` is recognized as `NA`,
  - `TRUE` is recognized as `1`,
  - `FALSE`, `NONE` and `NULL` are recognized as `0`.
- Added new option text to specify the column to get explanatory text from when reading a set.
- Changed handling of bad UELs: Reading a bad UEL (e.g. a UEL exceeding the maximum length) causes an error now. The old behavior can be enabled again using the new option acceptBadUels.

GAMS Studio

- New version 0.10.3
  - Stability and performance improvements.
  - Added a new section Comparing GAMS Studio and GAMSIDE to the documentation.
  - Added a Reference File Viewer to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS models and is created using the reference parameter when running the model.
  - Added a Tab Browser (Deprecated) to list and search through all open files. It is accessible with a button next to the main tab bar or via the shortcut `Ctrl+K`.
  - GDX Viewer :
    - Added a first, basic version of a Table View : The new button "Table View" switches the view to a table based representation. The button is only enabled for multidimensional symbols and puts the last dimension into the header of the table. Drag and drop of items is not yet supported but will be in the future.
    - Added option to hide specific value columns for variables and equations.
    - Added support for the use of different encodings using the "Edit->Encoding" menu. The default encoding for a GDX file generated in Studio by running a GMS file with automatic GDX creation (`F10`) is the one used by the GMS file.
  - Editor

    - Added smart typing: Automatic insertion of closing character for brackets and quotes.
    - Added ability to select text and press either a opening bracket or quote to surround text with these symbols.
    - Improved backspace behavior, if auto indentation is active.
  - Output Widget
    - Added info, warning, and error messages to GAMS Studio system log.
    - GAMS log files are now written to disk (can be disabled in settings).
    - Added "clear log" context menu entry.
  - Project Explorer
    - Studio automatically adds all files specified through GAMS parameters (.gdx, .ref, .lst) to the Project Explorer.
    - Allow to rename Project Explorer groups.
    - Groups are closed if they are empty.
    - If a group is closed the associated GAMS process will be stopped.
    - Added drag and drop of files between groups.
    - Added shortcut to focus Project Explorer (`Ctrl+J`) and allow to navigate using arrow keys to select a file.
    - Added "Select all", "Expand all" and "Collapse all" to the context menu.
    - Added shortcut to select all files (`Ctrl+A`).
  - Various
    - Added context menu for tabs (offering different close actions).
    - Added animation for groups with running GAMS processes.
    - Studio comes to foreground when double clicking a Studio-associated file.
    - The "About GAMS" dialog contains many important information like used GAMS version, system directory, or license information. It features a "Copy System Information" button which copies all of these information to easily attach them to a support request. The dialog has a second tab which gives an overview about solvers, their license status, and what kinds of capabilities they have.
    - "File -> New..." dialog starts with a default for a new file name.
    - "File -> Open..." (or drag'n'drop) of one file now focuses that file if it is already present in the Project Explorer.
    - New entry "File -> Open... in new group" to force creation of new group (even if the is already present in the Project Explorer).
    - "File -> Open..." (or drag'n'drop) of multiple files puts all files opened at once into a single group instead of individuals.
    - Added shortcut to focus command line parameter edit field (`Ctrl+L`).
    - Added `Ctrl+F` as close shortcut for search dialog.
    - Changed shortcut to open Settings dialog to `F7`.

Note

This version of GAMS Studio does not support the Dark Mode of MacOS Mojave. Please disable this mode to use GAMS Studio.

GDXDUMP

- New options for writing out special values: `NAOut`, `UndfOut`, `PInfOut`, `MInfOut`, and `ZeroOut`.
- Fixed broken generated GAMS code, if `UelTable` option was used, but there were no UELs.
- Lower and upper bounds of equations are dumped always now (even if their values are the default). This fixes a potential problem, that the equation type is unknown for the generated GAMS code.
- When writing CSV files the element text of set elements could not be written. Now with enabled option CSVSetText the element text of a set element is written as the last column in the CSV file.

GDXXRW

- Fixed a bug which could have caused a crash when reading merged cells from Excel using the GDXXXRW options `useRC` and `cMErge=1`.

MODEL2TEX

- The new script `model2tex.sh` sets the required dependencies for the model2tex tool on Linux and macOS. Using this script is the recommended way for using model2tex. Calling the Python script directly is not recommended anymore since the used Python interpreter would need to be configured manually. `model2tex.sh` uses the Python interpreter that comes with the GAMS distribution.

3.23.1.7 Object Oriented APIs

Python

- The `setup.py` script now installs the idx expert-level API.

3.23.1.8 Model Libraries

GAMS Data Library

New models added:

- **csv2gdx2.gms : CSV2GDX Example 2 - Reading CSV Files with CSV2GDX** (111)
- **csv2gdx3.gms : CSV2GDX Example 3 - Reading Semicolon separated Data** (112)
- **csv2gdx4.gms : CSV2GDX Example 4 - Dealing with missing Labels and Duplicates** (113)
- **csv2gdx5.gms : CSV2GDX Example 5 - Reading more than one Parameter from a single Input File** (114)
- **csv2gdx6.gms : CSV2GDX Example 6 - Reading economic Data from the World Bank Data Catalog** (115)
- **csv2gdx7.gms : CSV2GDX Example 7 - Reading special Values with CSV2GDX** (116)
- **csv2gdx8.gms : CSV2GDX Example 8 - Reading an compressed encrypted Input File** (117)
- **csv2gdx9.gms : CSV2GDX Example 9 - Reading Options from an external File** (118)
- **GDXXRWExample17.gms : Reading several Scalars from Spreadsheet** (119)
- **GDXXRWExample18.gms : Reading Sets from Spreadsheet** (120)
- **GDXXRWExample19.gms : Writing Parameter to Spreadsheet including Zero Values** (121)
- **GDXXRWExample20.gms : Reading empty Cells with colMerge and reading merged Excel Ranges with cMerge** (122)
- **GDXXRWExample21.gms : Skipping empty Rows or Columns and Ignoring Rows or Columns** (123)
- **GDXDUMPExample1.gms : GDXDUMP - Adding double Quotes to an user defined Header when writing to CSV** (124)

GAMS EMP Library

New model added:

- **emppython1.gms : Three Simple EMP Models with Indexed EMP Syntax and Python Parser** (104)

GAMS Test Library

New models added:

- **csv2gdx7.gms : CSV2GDX - Checking the Error Messages for incorrect Parameter Input** (752)
- **csv2gdx8.gms : CSV2GDX - Testing the valueDim Option** (753)
- **csv2gdx9.gms : CSV2GDX - Testing the Field Separator Tab** (754)
- **csv2gdx10.gms : CSV2GDX - Testing the Field Separator Semicolon** (755)
- **csv2gdx11.gms : CSV2GDX - Testing the Field Separator Comma** (756)
- selkie01.gms : SELKIE test suite (757)
- selkie02.gms : SELKIE test suite (758)
- selkie03.gms : SELKIE test suite (759)
- selkie04.gms : SELKIE test suite (760)
- selkie05.gms : SELKIE test suite (761)
- selkie06.gms : SELKIE test suite (762)
- selkie07.gms : SELKIE test suite (763)
- selkie08.gms : SELKIE test suite (764)
- selkie09.gms : SELKIE test suite (765)
- selkie10.gms : SELKIE test suite (766)
- selkie11.gms : SELKIE test suite (767)
- selkie12.gms : SELKIE test suite: sub-diagonalization (768)
- selkie13.gms : SELKIE test suite: dualvar (769)
- selkie14.gms : SELKIE test suite: isolated implicit variable (770)
- selkie15.gms : SELKIE test suite: proximal perturbation (771)
- selkie16.gms : SELKIE test suite: obj variable setting (772)
- selkie17.gms : SELKIE test suite: obj variable setting (773)
- selkie18.gms : SELKIE test suite: obj variable not free (774)
- selkie19.gms : SELKIE test suite: equation marginal values (775)
- **put12.gms : Testing put_utility solver** (776)
- **gdxxrw8.gms : GDXXRW - Testing the Option intAsText** (777)

- **gdxxrw9.gms : GDXXRW - Testing the Option checkDate** (778)
- **gdxxrw10.gms : GDXXRW - Testing cMerge when reading Sets with the values Option** (779)
- **gdxxrw11.gms : GDXXRW - Reading and writing special Values** (780)
- **gdxxrw12.gms : GDXXRW - Testing the skipEmpty and cMerge Option** (781)
- **gdxxrw13.gms : GDXXRW - Testing the values Option when reading or writing Set Elements** (782)
- **gdxxrw14.gms : GDXXRW - Testing different Excel Range Specifications** (783)
- **gdxdump2.gms : GDXDUMP - Testing the dumping Functionality on several GDX Files** (784)
- **gdxdump3.gms : GDXDUMP - Dumping special Values of a Parameter from GDX** (785)
- **gdxdump4.gms : GDXDUMP - Dumping special Values of Variable-Subfields from GDX** (786)
- **onmulti8.gms : Test for $onMultiR** (787)
- **implset1.gms : Test for Implicit Set Definition** (788)
- **emppy1.gms : Test an equilibrium model using emp python** (789)
- **emppy2.gms : Formulate the simplevi.gms example using emp python** (790)
- **emppy3.gms : Test a combination of optimization and vi agents using emp python** (791)
- **miqcp04.gms : Test behavior for integer infeasible model** (792)
- **duplic01.gms : Detecting duplicate entries in unsorted data** (793)

3.24 25.1 Distribution

3.24.1 25.1.1 Major release (May 19, 2018)

3.24.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Eden Huang, Katja Buhrkal Jensen, Jan-Erik Justkowiak, Erwin Kalvelagen, Marko Loparic, Bruce McCarl, Scott McDonald, Edmund Moshammer, Andres Ramos, Tom Rutherford, Wilfredo Sifuentes, and Tapio Westerlund.

3.24.1.2 Platforms

- On Windows, some solvers in the GAMS distribution as well as GAMS Studio have dependencies on certain MS Visual C++ runtime libraries. Most of them are included in the GAMS distribution or are present on most Windows systems. However, we are aware that in in rare cases, some libraries are missing. In such situations, we advise to run the appropriate installer for these libraries:
  - On a 32-bit GAMS version, execute `[GAMS system]\apifiles\C++\lib\vs2013\vcredist_x86.exe`, followed by `[GAMS system]\apifiles\C++\lib\vs2015\vcredist_x86.exe`.
  - On a 64-bit GAMS version, execute `[GAMS system]\apifiles\C++\lib\vs2017\vcredist_x64.exe`.

3.24.1.3 GAMS System

GAMS

- New conditional expressions to be used in conditional compilation, namely `gdxDimension`, `gdxEquType`, `gdxParType`, `gdxSetType`, `gdxSymExist`, `gdxVarType`, and `uelExist`. Details about these can be found here.
- New command line option LstTitleLeftAligned: Write title of LST file left aligned.
- New command line option ShowOSMemory: Show the memory usage reported by the operating system (either resident set size or virtual set size) instead of the internal counting.
- GAMS throws now a compilation error if an unexpected suffix at a symbol is encountered in an option statement involving identifiers. In the past such suffixes were ignored, which could have given the impression that they were actually doing something. So, all the `.dim1` suffixes in the following example will create an error now:

```
Set i(*)
    j(*)
    ij(*,*) / i1.j1, i1.j2, i2.j1, i2.j2 /;

Option i <  ij.dim1;
Option i <= ij.dim1;

Set       k     / k1*k6 /;
Parameter ii(*) / i1 4, i2 5, i3 6 /
          iii(k,*);

Option iii > ii.dim1;
Option shuffle = ii.dim1;
```

- The details of the expansion of multi-line macros were changed with this release. In the past, trailing white space in the macro definition was always removed. Now, in multi-line macros, the white space before the continuation character \ is preserved. This example demonstrates the difference:

```
$macro xAndY(x,y) x and \
                  y
scalar x /1/;
if(xAndY(1,x), display 'true');
```

  In the past, this caused a compilation error, since the macro was expanded to `if(1 andy, display 'true');` ("and" and "y" were concatenated to "andy"). Now that the white space after "and" is preserved, this does not cause a problem anymore.

- The statement `Alias (k,k);` for an unknown symbol `k` causes a compilation error now.

- In rare cases, embedded code recognized indented Python code incorrectly. This has been fixed.
- New property gams.debug for controlling debug information of the Object-oriented API in embedded code sections.
- Fixed a problem related to SSL support in `GMSPython` that prevented certain tools (e.g. pip) from working on Linux and macOS.
- Models of type MCP can now be solved with modifiable parameters in the GUSS framework and as OO-API `GAMSModelInstance`.

3.24.1.4 Solvers

BARON

- New libraries 18.5.8.
  - Updated to Ipopt 3.12.8 and CBC 2.9.9.
  - Replaced Ipopt's linear solver MUMPS by MA57 from HSL, a collection of Fortran codes for large-scale scientific computation. Thus, when using IPOPT as NLP solver, BARON may now be more robust and a little faster, especially for problems without integer variables.
  - New bounds reduction strategies based on optimality conditions can reduce the size of the branch-and-bound tree.
  - Rewrote core memory management routines for speed increase and memory reduction.
  - On some problems, BARON currently provides incorrect marginal values. This problem will be fixed in the near future.
- The use of Ipopt in BARON on macOS is no longer disabled by default.
- There will be no future updates of BARON for Windows 32-bit.

Bonmin(H), CBC, Couenne

- Wall-clock time is now always used to apply a timelimit to Branch-and-Bound. The nww option `clocktype` can be used to switch back to CPU time.

CONOPT

- New libraries 4.05 for CONOPT 4.
  - Improvements for multi-threading.
- New libraries for CONOPT 3.
- Fixed problems with redundancy in preprocessor and an issue related to system error 2024.

ConvertD

- Added options PermuteVars and PermuteEqus to permute the declaration of variables and equations, respectively, in scalar GAMS output.
- Tweaked printing of variable bounds and activity levels in scalar GAMS ouput.
- Fixed handling of infinite upper bounds for integer variables in scalar GAMS output: A line that sets GAMS option intvarup to 0 is now added to the output.

Couenne

- New libraries.

DICOPT

- Improvements to Feasibility Pump:
  - Fixed handling of nonlinear objective function when maximizing.
  - Fixed update of cutoff decrement after a solution with objective value very close to zero has been found.
  - Fixed translation of NLP projection problem optimal value to norm of associated projection. Changed default for option fp_projzerotol from 1e-6 to 1e-4.
  - Added creation of cuts derived from solution of NLP projection problem. Use option fp_projcuts to disable.
  - Added option fp_integercuts to disable integer cuts or enable them for mixed-binary problems only. The latter is the new default.
  - Added option fp_mipgap to specify an optimality tolerance (relative gap limit) for the MIP projection problem.
  - The stall limit is now only applied after a first solution has been found. Changed default for option fp_iterlimit to 20.

GUROBI

- New libraries 8.0.
  - As announced for GAMS 24.9, Gurobi 8 is no longer supported for Windows 32-bit. We continue to ship Gurobi 7.5 for this platform.
- New partition heuristic based on user annotation via the new dot option .partition and enabled with new option PartitionPlace.
- Completely new interface to Gurobi's Remote Services (i.e. compute server, distributed algorithm, and instant cloud). For details see Compute Server and the following sections.

JAMS

- Added capability to handle QVI models.
- The options controlling the reformulation strategy for shared variables in multi-agent EMP models have changed: see ImplVarModel for details.

LocalSolver

- New libraries 7.5 (20180405).
- To use LocalSolver 7.5, a machine-specific LocalSolver license is now required on Linux, too. See the solver manual on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

Mosek

- New libraries 8.1.0.53.

ODHCPLEX

- A new solver GAMS/ODHCPLEX from Optimization Direct Inc. has been added to the GAMS solver portfolio.
- The solver implements a set of heuristic methods (named ODHeuristics) for finding feasible solutions to Mixed Integer Programming (MIP and MIQCP) models and uses IBM CPLEX as its underlying solver engine.
- The heuristics decomposition method works in an automatic fashion or can be guided by user specified selections.
- Users will need a GAMS/CPLEX or GAMS/Cplex link license for this solver to work. Commercial users will also need a GAMS/ODHCPLEX license.
- Currently, the solver is available for Windows 64-bit only.

SCIP

- New libraries 5.0 (09c736f).
  - changed default for parameter `constraints/quadratic/gaugecuts` from 1 to 0
  - changed default for parameter heuristics/completesol/freq from 1 to 0
  - changed default for parameter separating/cmir/freq from -1 to 10
  - changed default for parameter separating/cmir/freq from 1 to 0
  - changed default for parameter separating/flowcover/freq from -1 to 10
  - changed default for parameter separating/flowcover/freq from 1 to 0

Xpress

- New libraries 32.01.10 containing several minor bug fixes and performance improvements.

3.24.1.5 Tools

GAMS Studio

- This release contains the first preview version of GAMS Studio - a completely new integrated development environment for GAMS. GAMS Studio is still in a very early stage of development, but we believe it is already mature enough to be a productive tool. GAMS Studio is available for Linux, macOS, and Windows only.
- GAMS Studio combines many (but not all) features of the classic GAMS IDE with some new elements:
  - a code editor to write GAMS models (including basic syntax coloring, block edit mode, etc.),
  - execution of GAMS models,
  - an output panel that presents the progressing GAMS log,

  - a listing viewer (including a tree view to navigate through the file) to inspect the listing file,
  - an interactive option editor to set GAMS parameters,
  - a GDX viewer that shows the table of content and data of GDX files and offers useful details like sorting and filtering of data,
  - a project explorer helps to manage different projects in one session, and
  - an integrated help system to make it easier to find additional information, e.g., by pressing F1 while the cursor is on a GAMS keyword in the code editor.

- We encourage our users to weigh in, help prioritize GAMS Studio's future development directions, or provide any other feedback. If you find problems, miss features, or have comments, please send a note to studio@gams.com.
- It is also possible to contribute directly or build on top of GAMS Studio, since the source code is available on GitHub (https://github.com/GAMS-dev/studio) under the GNU GPL license (see https://github.com/GAMS-dev/studio).
- We plan to provide updates for GAMS Studio frequently in the near future, also separate from new releases of the GAMS distribution. To facilitate the update process, Studio includes an interactive check (requiring an Internet connection) for the availability of newer versions. This "Check for Update" button can be found below the menu "Help".
- A short overview about GAMS Studio can be found in the YouTube channel GAMS Lessons.

Note

-
  - New options to define the association for GAMS files (`.gms`) have been added to the installer for GAMS on Windows. For now, the GAMS IDE is still the default choice, but this may change for future releases.
  - On Linux, Studio is installed in the form of an AppImage as part of the GAMS system directory.
  - On macOS, Studio is part of the DMG installer only. It is installed as an additional application in the `Applications` directory next to the GAMS Terminal application and is available through the Launchpad. GAMS files (`.gms`) are associated with GAMS Studio.

Attention

-
  - In rare cases, GAMS Studio crashes when the `Open` or `Save` dialog gets opened. This is mostly related to third party software, e.g. older versions of "Dell Backup and Recovery". It is recommend to update, switch off or uninstall the software.
  - We are aware of some performance issues at this stage of development. So while things work well, for example, with the models from our model libraries, you might experience some delay when working with huge files, e.g., while searching or when the log is processed for very long output.

XLSDump

- Sometimes, Excel Spreadsheets contain links to pictures, which cannot be found. This situation caused an error in XLSDump in previous versions. Now, such an error is ignored.

3.24.1.6 Object Oriented APIs

- New implementation of `GAMSJob.Interrupt()` on Linux and macOS that removes dependency to the command line tool `pstree`.

C++

- Added support for Microsoft Visual Studio 2015 on Windows 32-bit.

Java

- Changed the naming scheme of a temporary working directory to be created from `yyyyMMdd_HHmmss` to the prefixed `gams_` (defined by `GAMSGlobals.workingDirectoryPrefix`, in case no working directory has been specified.
- Fixed the behavior when a GAMSDatabase is added with a name that already exists. A GAMSException will be raised now (see **GAMSWorkspace.addDatabase(String databaseName)** and **GAMSWorkspace.addDatabaseFromGDX(String gdxFileName, String databaseName)**).
- Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available, because calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommened to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See **GAMSDatabase.dispose**, **GAMSModelInstance.dispose**, and GAMSOptions.dispose.

3.24.1.7 Expert Level APIs

- All Java native interfaces to expert-level APIs are now included in `[Path/To/GAMS]/apifiles/Java/api/GAMSJava/

GMO

- The constant `MAXEVALTHREADS` (i.e. the number of parallel threads supported for function and derivative evaluations in the solver interface library GMO) has been increased from 16 to 64. This effectively increases the same limit in the CONOPT4 solver.

3.24.1.8 Model Libraries

PSOPTLIB - Power System Optimization Modelling in GAMS

- This new library by Alireza Soroudi has been added to the GAMS system. This is a collection of the models based on the book Power System Optimization Modelling in GAMS by Alireza Soroudi. The library contains a selection of 32 models from various areas of power system optimization expressed in GAMS. Book and library describe how the General Algebraic Modeling System (GAMS) can be used to solve various power system operation and planning optimization problems. The book is the first of its kind to provide readers with a comprehensive reference that includes the solution codes for basic/advanced power system optimization problems in GAMS, a computationally efficient tool for analyzing optimization problems in power and energy systems. The book covers theoretical background as well as the application examples and test case studies. It is a suitable reference for dedicated and general audiences including power system professionals as well as researchers and developers from the energy sector and electrical power engineering community and will be helpful to undergraduate and graduate students.
- You can retrieve the individual models through the IDE and Studio model library browser, via the command line utility `psoptlib` or through calls in the Object Oriented APIs.

GAMS EMP Library

- **simpleqvi1.gms : Simple Quasi-Variational Inequality** (101)
- **simpleqvi2.gms : Simple Quasi-Variational Inequality** (102)
- **simpequil3.gms : Simple Generalized Nash Equilibrium Problem** (103)

GAMS Model Library

- **guss2dim.gms : Two dimensional scenario GUSS Example** (423)
- **obstacle.gms : An Obstacle Problem** (424)
- **csched**: Added two more formulations for a related problem. Contributed by Tapio Westerlund.

3.24.2 25.1.2 Minor release (August 01, 2018)

3.24.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Marcel Adenauer, Shaoyan Guo, Eden Huang, David Laudy, Evangelos Panos, Wilfredo Sifuentes and Larissa de Vries.

3.24.2.2 Platforms

- Fixed problem using solvers with Fortran dependencies on a Mac OS X 10.11 system.

3.24.2.3 GAMS System

GAMS

- Fixed a bug which caused an unexpected error when using the `+` operator in a model statement with the following symbol being a model itself, like this:

```
variable x;
equation e1, e2;
e1.. x =L= 5;
e2.. x =G= 3;
model m2 /e2/;
model m /e1+m2/;
solve m min x use lp;
```

3.24.2.4 Solvers

BARON

- Fixed translation of branching priority values when specified in BARON options file and GAMS option PriorOpt not enabled.
- Specifying `maxdouble` as branching priority in a BARON options file now behaves as if specifying `inf` as branching priority in a GAMS model.

BONMIN

- The default for option `number_cpx_threads` is now initialized according to the value of the GAMS option threads.

CONOPT

- New libraries 3.17I for CONOPT 3.
- New libraries 4.06 for CONOPT 4.

GUSS

- Models with variable parameters and model attribute `holdFixed=1` could not be solved with 25.1.1. In this release the holdFixed option is automatically turned off.

Ipopt

- New libraries.
  - Fixed problems in handling of time limit (reslim).

LocalSolver

- New libraries 7.5 (20180601).

ODHCPLEX

- New libraries 3.4.3.
- ODHCPLEX is now available for Linux, too.

SoPlex

- New libraries 3.1 (b0e0048).

SCIP

- New libraries 5.0 (1d9c207).

3.24.2.5 Tools

MODEL2TEX

- Backslashes in the explanatory text of symbols are replaced automatically with `\textbackslash`.

GAMS Studio

- New version 0.9.2
  - Stability improvements
  - Allow only one instance of Studio to run at the same time (when file association for Studio is active, a double click on a gms file will open that file in a running Studio instance and does not open a new Studio)
  - Added startup parameter `--gams-dir` to specify a non-default GAMS system folder to be used
  - Added shortcuts for `Interrupt` and `Stop` (`F12` and `Shift+F12`)
  - Restructured the `File -> Encoding` menu
  - About dialog: added button to copy product information to clipboard
  - GDX Viewer: added facility to search for symbols
  - Option Editor: allow to use F1 to open help
  - Project Explorer:
    - "Add Existing Files" allows to add multiple files at once
    - Added context menu entry to open the log for a group-node

    Note
  - When migrating from an older version of GAMS Studio, one might have an empty project explorer and no recent files listed. This is expected behavior because of a bug fix within the GAMS Studio settings file.

3.24.2.6 Object Oriented APIs

Python

- Fixed a bug that prevented the setup.py file to be called with parameter `-noCheck` for turning off the version check.
- The setup.py script can be used from an arbitrary location. It is not required anymore to switch to the files location before installing.

3.24.3 25.1.3 Minor release (October 30, 2018)

3.24.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.24.3.2 GAMS System

GAMS

- Fixed a bug which caused the sysIdent property not being set correctly after a solve statement.
- Fixed a bug which could have caused a problem with `execute_load` being called after `endEmbeddedCode` in a loop.

3.24.3.3 Solvers

ANTIGONE

- If interrupting ANTIGONE (using Ctrl+C, for example), the final trydual NLP solve does no longer stop immediately in the first iteration.

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.4 on macOS.

CONVERTD

- When using options `Jacobian` or `Hessian`, new symbols `iobj`, `objConst`, and `objJacVal` are written to the GDX file. If the model can be reformulated with a true objection function, the symbol `iobj` contains the label of the objective defining equation, while the symbols `objConst` and `objJacVal` constain the objective constant and the coefficient of the objective variable. If the model cannot be reformulated with a true objective, `iobj` will be empty and `objConst` and `objJacVal` will be 0.

GUROBI

- New libraries 8.1.0.
- Option GUROBIpreqlinearize allows the value of 2 (Force Linearization and get compact relaxation).

JAMS

- Added some experimental indexed EMP syntax. See example model **emppython1.gms : Three Simple EMP Models with Indexed EMP Syntax and Python Parser**.

Lindo/LindoGlobal

- New libraries 11.0.338.

MOSEK

- New libraries 8.1.0.64.

3.24.3.4 Tools

CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

3.24.3.5 Object Oriented APIs

Python

- The `UpdateAction Primal` and `Dual` in a `GamsModifier` were not recognized and triggered an exception. This has been fixed.

3.24.3.6 Model Libraries

GAMS EMP Library

- **emppython1.gms : Three Simple EMP Models with Indexed EMP Syntax and Python Parser** (104)

3.25 25.0 Distribution

3.25.1 25.0.1 Major release (January 17, 2018)

3.25.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Jeff Dischler, Michael Ferris, Dhruv Gupta, Erwin Kalvelagen, Florian Landis, Andre Lemelin, Erfan Mohagheghi, Anthony Paul, and Nathan Sudermann-Merx.

3.25.1.2 Platforms

- Due to the discontinuation of Cplex on Windows 32bit (with Cplex 12.7 in 2016) we are faced with potentially phasing out/dropping solvers depending on Cplex on Windows 32bit with the next major release. The most likely candidate for this is ANTIGONE. These solvers will still be available for 64-bit Windows and other supported platforms. Other solver vendors (e.g. Gurobi and FICO-Xpress) have also announced the discontinuation of their product on the Windows 32bit platform. If you rely heavily on the availability and support of the Windows 32bit platform please contact `support@gams.com` to discuss your options.
- As announced, dropped support for x86-64 Solaris.
- As announced, increased the minimal required MacOS X version to 10.11.
- As announced, increased the minimal required GLIBC version on Linux to 2.12.

3.25.1.3 GAMS System

GAMS

- Extended the `$offEmbeddedCode` facility to allow the use of a "projection operator": `$offEmbeddedCode {symbol[<[=]embSymbol[.dimX]]}`
  More information can be found here.
- Added support for the Object-oriented GAMS Python API in the Embedded Code Facility for Python. The method `gams.set()` accepts instances of type `GamsParameter`, `GamsSet`, etc. as data. Instances of `GamsWorkspace` and `GamsDatabase` can be retrieved using the properties `gams.ws` and `gams.db`. The property `gams.wsWorkingDir` can be used to specify the working directory of the created GamsWorkspace.
- Added `$libinclude pyEmbMI` to conveniently work with Python OO-API `GamsModelInstance` from embedded code. See **embmiex1.gms : Simple Embedded Code ModelInstance example**.
- Fixed a problem in embedded code when reading an empty scalar symbol.
- Fixed a problem when solving a model with solveLink 5, 6, or 7 with communicating scales without scaleOpt active.
- The EPS value in the Embedded Code Facility for Python has been changed to `4.94066E-324`. This is the same value that is used for EPS in the Object-oriented Python API.
- New Put_Utility `save`: Writes a save file of the current state of execution.
- Improvement for the Put_Utility Statement: It is no longer required to define a file and activate it, just to use a `put_utility`.
- New command line option fileStemApFromEnv: Append a string read from an environment variable to the fileStem.
- Change to command line option fileStem: Create an immediate error when the value contains a \ or / character to avoid problems later on.
- Fixed a bug with `execute_unload`, which could have caused a `set` to be exported mistakenly as `alias` to a different `set`, if symbol renaming was used.
- Fixed a bug which prevented to open more than 65,000 put files.
- Solves with scaleOpt=1 using GUSS or instantiations of OO-API GAMSModelInstances resulted in some circumstances in the report of scaled solutions or other erroneous behavior. Hence GAMS will now reset the modelname.scaleOpt attribute to NA before such a solve or GAMSModelInstance generation. As a consequence, models solved via GUSS or as a GAMSModelInstance in the OO-APIs will not be scaled by GAMS.
- Solving MCP models with scaleOpt=1 using the solvers AMPL or PYOMO creates an execution error now. In the past this lead to wrong results potentially.

3.25.1.4 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- Updated Intel MKL libraries to version 2018.0 for Linux and Mac OS X and to version 2018.1 on Windows 64-bit.

CBC

- New libraries.

CONOPT

- New libraries 3.17G (Conopt3).
- New libraries 4.04 (Conopt4).
  - Fixed a system error 65666.

Couenne

- New libraries.
  - Bugfixes and tuning for fixed point bound tightening.
- If Couenne does not find a feasible solution, but the initial point is feasible, then the initial point is now reported back to GAMS.

CONVERT

- If the filename provided for the `Jacobian` or `Hessian` option contains the string `novenames` ConvertD will not export the original equation and variable names as set text to elements of sets i and j. Having the original equation and variable names can make the GDX file significantly larger and slow to write and read.
- Fixed a problem when trying to write scaled MCP models.

CPLEX

- New libraries 12.8.0.
- New parameters
  - SubMIPScale: Parameter to scale the problem matrix when CPLEX solves a subMIP during MIP optimization
  - SubMIPStartAlg: Starting algorithm for subMIP of a MIP
  - SubMIPSubAlg: Algorithm for subproblems of a subMIP of a MIP
  - DynamicRows: Switch for dynamic management of rows
  - Sifting: Switch for sifting from simplex optimization
- In CplexD allow the BendersPartition to be set via the .stage variable suffix together with option BendersPartitionInStage.

Gurobi

- Fixed a problem for model with SOS variables but no constraints.

KESTREL

- New options `neos_username` and `neos_user_password` can be used in the option file in order to submit authenticated jobs using a NEOS user account.

LocalSolver

- New libraries 7.5 (20171117) for Mac OS X and Windows.
  - Preprocessing entirely rewritten: size reduction by a factor up to 10 on some huge instances.
  - Combinatorial models based on booleans and integers: performance improvement and increased ability to prove optimality.
  - Continuous linear and nonlinear models: performance improvement through the integration of state-of-the-art algorithms.
- Note, that to use LocalSolver 7.5, a machine-specific LocalSolver license is now required. See the solver manual on how to obtain such a license. Alternatively, it is still possible to use LocalSolver 7.0 by choosing LOCALSOLVER70 instead of LOCALSOLVER as solver.

Mosek

- New libraries 8.1.0.34.

SBB

- Fixed a bug introduced in 24.8 that prevents the infeasSeq option to work.

SCIP

- New libraries 5.0 (2b35b18).
  - SCIP can now automatically detect and exploit symmetries in MIPs (Linux and Mac OS X only)
    - added parameter misc/usesymmetry to determine which symmetry handling should be used
    - added parameter groups `presolving/symmetry`, `presolving/symbreak`, constraints/symresack, constraints/orbisack, constraints/orbitope
  - Presolving
    - new presolver sparsify that tries to cancel nonzero coefficients in linear constraints by adding multiples of linear equalities
    - disabled reformulation of products of a binary variable with a linear term that does not solely involve binary variables
      - added parameter `constraints/quadratic/binreformbinaryonly` to disable reformulation of products of binary and non-binary variables
    - revised disaggregation of quadratic constraints: the number of created constraints can now be controlled and the disaggregated constraints are scaled in order to increase numerical accuracy
      - replaced `constraints/quadratic/disaggregate` by `constraints/quadratic/maxdisaggrsize` to bound the total number of created constraints when disaggregating a quadratic constraint
      - added parameter `constraints/quadratic/disaggrmergemethod` to change the strategy of how to merge independent blocks of quadratic constraints
  - Primal Heuristics
    - new primal heuristic ALNS that orchestrates eight different LNS heuristics adaptively using algorithms for the multi-armed bandit problem

  * new primal heuristic MPEC that solves a MPEC reformulation of a mixed-binary nonlinear problem by regularized NLP reformulations
  * improved the clique and variable bound pre-root heuristics, which are now often able to fix many more variables
    - removed parameters heuristics/clique/{multiplier,initseed}
    - replaced parameter heuristics/{clique,vbounds}/minfixingrate by heuristics/clique/minintfixingrate, heuristics/vbounds/minintfixingrate, heuristics/clique/minmipfixingrate, and heuristics/vbounds/minmipfixingrate, which check the fixing rate before LP solving and after sub-MIP presolve
    - added parameters heuristics/clique/maxbacktracks and heuristics/vbounds/maxbacktracks to limit the number of backtracks in the fix-and-propagate phase
    - added parameters heuristics/clique/uselockfixings and heuristics/vbounds/uselockfixings to enable fixing of additional variables based on variable locks
    - added parameters heuristics/vbounds/feasvariant and heuristics/vbounds/tightenvariant to specify the fixing variants used by the vbounds heuristic
    - changed default for parameters heuristics/clique/freq and heuristics/vbounds/freq from -1 to 0
    - changed default for parameter heuristics/clique/priority from -1000500 to 5000
    - changed default for parameter heuristics/vbounds/priority from -1100600 to 2501
  * added parameters heuristics/completesol/beforepresol, heuristics/completesol/maxlpiter, and heuristics/completesol/maxcontvars
  * changed default for parameter heuristics/indicator/oneopt from 1 to 0
  * changed default for parameter heuristics/locks/minfixingrate from 0.25 to 0.65
  * changed default for parameter heuristics/locks/priority from 2000 to 3000

- Separation (cutting planes)
  * utilizing linear inequalities (computed in the OBBT propagator) to compute stronger linearizations for bilinear terms
    - added parameters `constraints/quadratic/usebilinineqbranch`, `constraints/quadratic/minscor` and `constraints/quadratic/bilinineqmaxseparounds`
    - added parameter `constraints/quadratic/mincurvcollectbilinterms` to change the minimal curvature of constraints to be considered when returning bilinear terms to other plugins
    - added parameters propagating/obbt/itlimitfactorbilin, propagating/obbt/minnonconvexity, and propagating/obbt/createbilinineqs
  * improved cut post-processing (apply coefficient tightening, enforce maximal dynamism), selection, and management
    - added parameters separating/maxlocalbounddist, separating/maxcoefratio, and `separating/intsupportfac`
    - removed parameter separating/orthofac
    - changed default for parameter separating/cutagelimit from 100 to 80
    - changed default for parameter separating/minefficacy from 0.05 to 0.0001
    - changed default for parameter separating/minefficacyroot from 0.001 to 0.0001
    - changed defaults for parameters `separating/minortho` and `separating/minorthoroot` from 0.5 to 0.9
    - changed default for parameter `separating/objparalfac` from 0.0001 to 0.1
    - changed default for parameter separating/poolfreq from 0 to 10
  * MIP cutting planes are now separated within the tree search, too
    - parameter separating/maxstallrounds only applies to nodes in the tree (not the root node, anymore); use the new parameter separating/maxstallroundsroot for the root node
    - added parameters separating/*/expbackoff to all separators, which increases the frequency exponentially over the depth in the tree
    - added parameter separating/maxincrounds

- changed default for parameter separating/maxstallrounds from 5 to 1
- changed default for parameter separating/maxrounds from 5 to -1
- changed default for parameter separating/maxroundsrootsubrun from 1 to -1
- changed default for parameter separating/gomory/delayedcuts from 1 to 0
- changed default for parameter separating/gomory/freq from 0 to 10
- changed default for parameter separating/gomory/maxbounddist from 0 to 1
- changed default for parameter separating/impliedbounds/freq from 0 to 10
- changed default for parameter separating/impliedbounds/maxbounddist from 0 to 1
- changed default for parameter separating/strongcg/freq from 0 to 10
- changed default for parameter separating/strongcg/maxbounddist from 0 to 1
- changed default for parameter `separating/strongcg/maxsepacuts` from 50 to 20
- changed default for parameter separating/zerohalf/freq from -1 to 4
- changed default for parameter separating/zerohalf/maxbounddist from 0 to 1

* new implementation of zerohalf separator
  - added parameters separating/zerohalf/badscore, separating/zerohalf/densityoffset, separating/zerohalf/goodscore, separating/zerohalf/maxcutcands, separating/zerohalf/maxrowdensity separating/zerohalf/maxslack, separating/zerohalf/maxslackroot, and separating/zerohalf/minviol
  - removed parameters separating/zerohalf/delayedcuts, separating/zerohalf/ignoreprevzhcuts, separating/zerohalf/maxcutsfound, separating/zerohalf/maxcutsfoundroot separating/zerohalf/maxdepth, separating/zerohalf/maxncalls, separating/zerohalf/maxtestdelta, separating/zerohalf/onlyorigrows, separating/zerohalf/relaxcontvars, separating/zerohalf/scalefraccoeffs, separating/zerohalf/trynegscaling, separating/zerohalf/usezhcutpool, separating/zerohalf/preprocessing/∗, and separating/zerohalf/separating/∗
  - changed default for parameter separating/zerohalf/maxroundsroot from 10 to 20
  - changed default for parameter separating/zerohalf/maxsepacuts from 50 to 20
  - changed default for parameter separating/zerohalf/maxsepacutsroot from 500 to 100
* faster implementation of CMIR cut generation heuristic
  - moved many parameters for flowcover and cmir separators to new parameter group separating/aggregation
  - changed default for parameters separating/cmir/freq and separating/flowcover/freq from 0 to -1
  - changed default for parameters separating/cmir/maxbounddist and separating/flowcover/maxbounddist from 0 to 1
  - changed default for parameter separating/cmir/priority from -3000 to -100000
  - changed default for parameter separating/flowcover/priority from -4000 to -100000
* additional parameter changes
  - removed parameter separating/feastolfac
  - removed parameter separating/cgmip/allowlocal
  - removed parameters separating/{gomory,strongcg}/maxweightrange
  - changed default for parameter separating/gomory/makeintegral from 1 to 0
  - changed default for parameter separating/gomory/maxrank from 3 to -1
  - changed default for parameter separating/gomory/sidetypebasis from 0 to 1
  - added parameter constraints/indicator/maxsepanonviolated to stop separation after separation of non violated cuts
  - removed parameters constraints/{abspower,bivariate,quadratic,nonlinear}/mincutefficacysepa, constraints/{abspower,bivariate,quadratic,nonlinear}/mincutefficacyenfofac, and constraints/soc/minefficacy

– Propagation

* use disjoint set to reduce peak memory usage and time to compute clique table connectedness information
* added analysis of the clique table which identifies possible aggregations via the search for strongly connected components and may detect infeasible assignments on the way

            - added parameter propagating/vbounds/minnewcliques to specify the minimum number of new cliques to trigger another clique table analysis
            - added parameters propagating/vbounds/maxcliquesmedium and propagating/vbounds/maxcliquesexha to limit the number of cliques relative to the number of binary variable for performing clique table analysis
            - changed default for parameter propagating/vbounds/presolpriority from 0 to -90000
            - changed default for parameter propagating/vbounds/presoltiming from 28 to 24
        * extended conflict analysis by analyzing dual solutions of boundexceeding LPs and improved dual ray analysis
            - removed parameters conflict/usemir and conflict/prefermir
            - added parameter conflict/sepaaltproofs
            - added parameter conflict/prefinfproof to determine whether to prefer infeasibility proof to boundexceeding proof
            - changed default for parameter conflict/useboundlp to 'b'
            - changed default for parameter conflict/maxvarsfac from 0.1 to 0.15
            - changed default for parameter conflict/maxvarsfac from 30 to 0
    - LP Relaxation
        * use LP solution polishing during probing and diving mode to activate it during many primal heuristics; remains disabled during strong branching and OBBT
            - only effective if using SoPlex as LP solver
            - added value 3 for parameter lp/solutionpolishing to enable LP polishing only during probing and diving mode
        * added parameter lp/refactorinterval to change the refactorization interval of the LP solver
    - removed parameters constraints/{abspower,bivariate,nonlinear,quadratic,soc}/scaling
    - added parameter groups table/* to control statistic output
    - See also the `full release notes`, the `changelog`, and the `release paper`.

- Fixed a problem when solving a model with solveLink 6 or 7 with scaleOpt active.

SolveEngine

- The GAMS time limit (reslim) is now passed to SolveEngine. Added solver option hardtimelimit to specify a time limit that is enforced on the GAMS side.

SoPlex

- New libraries 3.1.0 (876e6e8).
    - New scaling method that combines geometric and equilibrium scaling. Use new value 6 for option int:scaler to activate this.
    - See also the `release paper`.

Xpress

- New libraries 32.01.05.

3.25.1.5 Tools

CDSP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

GDXXRW

- Sometimes, Excel is not ready (e.g. because some data needs to be refreshed, when a worksheet is opened), when a read request is sent by GDXXRW. This could cause an exception. With this release we changed the behavior of GDXXRW to wait a second and resend the request in this case. This basically mimics the behavior of setting RWait to 1000 in case of the mentioned exception.

3.25.1.6 Object Oriented APIs

C++

- Changed the compiler from GCC to Clang on Mac OS X.
- Added support for Microsoft Visual Studio 2015 and Microsoft Visual Studio 2017 on Windows 64-bit.
- API binaries have been moved to `apifiles/C++/lib`. On Windows, there are further subdirectories for different compiler versions.
- Update of Visual Studio solutions for the examples on Windows. Three different solutions reflecting the supported versions of Microsoft Visual Studio are available (e.g. examples-vs2013.sln, examples-vs2015.sln, examples-vs2017.sln).
- The GAMS C++ API tutorial has been reworked. Information about building the C++ API examples via cmake, qmake, and Microsoft Visual Studio has been added.
- New example `TransportGDX` that shows how to import and export GDX files. A description has been added to the tutorial.

.NET

- Changes for `GAMSSymbol` and `GAMSSymbolRecord`: Both classes got the `IEquatable<T>` Interface. As a result the behavior of the `Equals` function as well as the `==` and `!=` operators were modified. For both classes `Equals` and `==` returns now true, if the internal data reference is the same. Here is an example:

```
GAMSVariable x1 = db.GetVariable("x");
GAMSVariable x2 = db.GetVariable("x");
if(x1 == x2)
    Console.WriteLine("x1 == x2");
else
    Console.WriteLine("x1 != x2");
if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

  In previous versions we got this output:

```
x1 != x2
x1 does not equal x2
```

  Now we get:

```
x1 == x2
x1 equals x2
```

- New example `TransportGDX` that shows how to import and export GDX files.

Java

- The minimum version requirement of the Java Runtime Environment for using the GAMS Java API is now Java SE 7.
- New `TransportGDX` example to demonstrate how to import and export GDX files.
- Removed method `GAMSSymbol.compact`, deprecated since 24.8.1 (December 2016).
- Changed equivalence behavior of `GAMSSymbol` and `GAMSSymbolRecord` objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
  - Two symbols are equivalent if and only if they have the same internal reference.
  - Two symbol records are equivalent if and only if they have the same internal reference.

  The behavior of operator `==` remains unchanged. The following exmaple illustrates the new equivalence behavior:

```
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
GAMSVariable x3 = x1;
assertTrue(x1.equals(x2));   // true,  previously false
assertFalse(x1 == x2);       // false, previously false
assertTrue(x1.equals(x3));   // true,  previously true
assertTrue(x1 == x3);        // true,  previously true
```

Python

- Added implementation of `__eq__()` and `__ne__()` to classes `_GamsSymbol` and `_GamsSymbolRecord` and its derived classes. As a result the behavior of the operators `==` and `!=` has changed. `==` now returns `True`, if the internal data reference is the same. The behavior of `is` remains unchanged. The following example illustrates the change:

```
x1 = db["x"]
x2 = db["x"]
print(x1 == x2) # now: True,  before: False
print(x1 is x2) # now: False, before: False
```

- New example `transport_gdx.py` that shows how to import and export GDX files. A description has been added to the tutorial.

3.25.1.7 Expert Level APIs

- As announced, the expert-level C++ API files were removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in the last major release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.
- The expert-level Java API files now ensure the load of jni libraries in the similar order as those employed by the Object Oriented Java API: first load from `java.library.path`, if neither specified nor found then from the directory where the API classes are located.

GDX

- Do not allow empty filename as argument for `gdxOpenAppend`, `gdxOpenRead`, `gdxOpenWrite`, and `gdxOpenWriteEx`. This will create an error right away now.

3.25.1.8 Model Libraries

GAMS Model Library

- **embmiex1.gms : Simple Embedded Code ModelInstance example** (417)
- **spbenders1.gms : Stochastic Benders - Sequential GAMS Loop** (418)
- **spbenders2.gms : Stochastic Benders - Async Subsolve GAMS Loop** (419)
- **spbenders3.gms : Stochastic Benders - Sequential GamsModelInstance** (420)
- **spbenders4.gms : Stochastic Benders - Parallel MPI** (421)
- **spbenders5.gms : Stochastic Benders - Parallel MPI with GAMSModelInstance** (422)
- Most models in the GAMS Model library have been refurbished to reflect a common syntax style and features introduced since the model was added.
- **prime**: Make use of the `break` statement for a little nicer and faster formulation.

GAMS Test Library

- **scensol7.gms : Test GUSS Option ReportLastScen** (737)
- **emp27.gms : Test LOGMIP/EMP on x.fx=0 handling** (738)
- **embpy03.gms : Test projection operator when loading data from embedded code** (739)
- **qcp11.gms : Test dual solution of SOCP** (740)
- **put11.gms : Put_Utility without file handle** (741)

3.25.2 25.0.2 Maintenance release (January 31, 2018)

3.25.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Tom Rutherford.

3.25.2.2 GAMS System

GAMS

- Bugfix: $offEmbeddedCode does not ignore $onUNDF anymore.
- Bugfix: Special values (NA, EPS, INF, ...) are correctly communicated from embedded code back to GAMS.
- Bugfix: Took care about a problem, which caused an unexpected execution error for certain uses of Put_Utility.
- Fixed a bug in GMSPython on Mac OS X which prevented the Python interpreter from working. This problem occurred with the DMG installer only.

3.25.2.3 Solvers

ANTIGONE, Bonmin, Couenne, Ipopt, SCIP

- On Linux, removed the MKL libraries that were optimized to certain x86 instruction sets (AVX, etc.) as this resulted in errors when running ANTIGONE or SCIP, probably due to library conflicts.

CPLEX

- Option Tuning can be repeated in a GAMS/Cplex option file to provide a larger number of model instances for tuning. Before this change the number was restricted by the maxium line length of an option line (256 characters).

LocalSolver

- New libraries 7.5 (20180119) for Mac OS X and Windows.

3.25.2.4 Tools

CSDP

- See ANTIGONE, Bonmin, Couenne, Ipopt, SCIP.

CSV2GDX

- Bugfix: Reading sets (no Value or Values option) with the option AutoRow works again.

3.25.3 25.0.3 Minor release (March 21, 2018)

3.25.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Dominik Bongartz, Wolfgang Britz, Erwin Kalvelagen, Maria Kannavou, Hans Mittelmann, Christoph Pahmeyer, Gilles Scouvart, and Hermann Westerholt.

3.25.3.2 GAMS System

GAMS

- Bugfix for Put_Utility: If a `put_utility` statement was used as the first statement to mark a file as active (so no statement like `put fx;` was used before) and following `put` or `put_utility` statements did not mention this `file` explicitly, then the `file` association got lost.
- Bugfix: Avoid a crash when one of the following attributes was used on an empty Singleton Set: `.len`, `.uel`, `.val` (an execution error is generated instead now)
- Bugfix for command line option fileStemApFromEnv: In the past, if the input file was defined including a file extension, the value of this option was extended to the extension and not to the file stem as intended. This is fixed now.
- Bugfix for $if exist File on Windows: In the past, if a file was specified as <`Drive`>`:/`<`File`>, e.g., `C:/t.txt` (note the forward slash '/' after the colon ':'), this always returned false, even if the file exists. That has been fixed now.

3.25.3.3 Solvers

BARON

- Fixed use of .EquClass option.

BONMIN(H), CBC, Couenne

- Branch-and-bound now checks wallclock-time, if running with multiple threads.

CONOPT4

- New libraries 4.05.
  - Improved the selection of post-triangular variables when there are multiple candidates.

CPLEX

- Bugfix: If the Cplex conflict refiner (triggered by option iis) could not identify a conflict the behavior was erratic. This has been fixed.
- Bugfix: Value 6 for option MIPStart was documented but got rejected. This has been fixed.

DICOPT

- Fixed setup of NLP projection problem in feasibility pump.
- Fixed stopping criterion when using stop on crossover: DICOPT was stopping as soon as the relative gap between the objective value of the best known solution and the bound provided by the MIP relaxation was below 0.001, thus might have declared suboptimal solutions as optimal. With this release, DICOPT will use the value of GAMS option optcr as optimality tolerance. Note, that the default for this option is 0.1 (!).

Ipopt(H)

- New libraries.

MOSEK

- No update, but be aware that `Mosek announced` to drop the convex nonlinear optimizer in their next major release (Mosek 9). Thus, in a future GAMS release, GAMS/Mosek will not accept models with model types NLP or DNLP anymore. Note, that linear or quadratic problems (LP, MIP, (MI)QCP) are not affected.

SCIP

- New libraries 5.0.1 (227c4c7).
  - New option `presolving/symmetry/displaynorbitvars`.

SoPlex

- New libraries 3.1.1 (ab921a5).

3.25.3.4 Tools

MODEL2TEX

- Added support for singleton sets.
- Fixed a dependency bug on Mac OS X which prevented model2tex from working.
- Fixed a bug regarding SOS variables.
- Fixed a bug regarding domain jumps.
- Added support for Python 3 on Linux and Mac OS X.

3.26 24.9 Distribution

3.26.1 24.9.1 Major release (August 30, 2017)

3.26.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jan Abrell, Etienne Ayotte-Sauvé, Wolfgang Britz, Florian Habermacher, Florian Häberlein, Maximilian Held, Ignacio Herrero, Hanspeter Höschle, Erwin Kalvelagen, Toni Lastusilta, John Ross, Tom Rutherford, and Linus Schrage.

3.26.1.2 Platforms

- The set of supported platforms has not changed, but we've divided it into the *core* platforms (Windows 32-bit, Windows 64-bit, Linux, and Mac OS X) and the *peripheral* platforms (AIX, x86-64 Solaris, and Sparc64 Solaris). See Supported Platforms for more details. Please note, however, that we are *not* changing the content or behavior of GAMS based on this division: GAMS models will continue to work in the same cross-platform way for both core and peripheral platforms.
- We will drop support for x86-64 Solaris with GAMS 25.0.
- We may increase the minimal required GLIBC version on Linux to 2.12 with GAMS 25.0.
- We may increase the minimal required MacOS X version to 10.11 with GAMS 25.0.

3.26.1.3 GAMS System

GAMS

- New feature, the Embedded Code Facility: This extends the connectivity of GAMS to other programming languages. It allows the use of Python code during compile and execution time. GAMS symbols are shared with the external code, so no communication via disk is necessary.
  The embedded code feature is available on Linux, MacOS X, and Windows. For these platforms, a Python 3.6 installation is included with the GAMS distribution. If the user wants to work with a different Python 3.6, installed separately, for models with embedded code the new command line option `pySetup` needs to be set to 0.

  Note

  This feature is currently in beta status. Any feedback to `support@gams.com` is appreciated.
- New command line option procDirPath: Specifies the directory where the process directory should be created.
- New compile time constants to set the model attribute `solPrint`:
  - 0 = %`solPrint.off%`
  - 1 = %`solPrint.on%`
  - 2 = %`solPrint.silent%`
- New compile time constants to set the model attribute `solveOpt`:
  - 0 = %`solveOpt.Replace%`
  - 1 = %`solveOpt.Merge%`
  - 2 = %`solveOpt.Clear%`
- Allow new string synonyms to set the integer values of the following command line options:
  - solPrint: `Off` (=0); `On` (=1); `Silent` (=2)
  - sysOut: `Off` (=0); `On` (=1);
- Fixed a bug where the following dollar control options did not get written to the dump file when the command line parameter dumpOpt was used. Sometimes this caused an error in the generated file.
  - $[on|off]DotScale
  - $[on|off]Embedded
  - $[on|off]Expand
  - $[on|off]Local
  - $[on|off]Macro
  - $[on|off]Margin
  - $[on|off]Order
  - $[on|off]StrictSingleton
  - $[on|off]UNDF
- Fixed an error which caused the loss of equation information when using the Grid facility in certain cases. This could have caused problems when a hot start should be performed.
- A parameter error is now created if the key of a 'double dash' GAMS parameter exceeds 63 characters (in the past, the key was truncated silently in this case).
- Fixed a crash which happened if the `.tl` suffix was used on an empty Singleton Set in a put statement.
- Fixed a bug which could have caused a crash if nested loops where used in a particular combination.
- Fixed a bug with `$onPut ... $offPut` in a `for` and `repeat` structure: When `$onPut` was the first statement inside one of these programming flow control features, it was executed just once and not repeatedly.

Special Functions

- Several of the more exotic GAMS intrinsic functions (aka "special functions") were re-implemented to address some bug reports and to pass a more rigorous set of tests. The updated functions include the loggamma, gamma, logbeta, beta, and binomial functions. In general, the updated functions offer improved precision and a more consistent behavior in exceptional cases (e.g. overflows, singularities, and domain violations) compared to the previous versions. In addition, the gamma and beta functions are now classified as smooth (NLP) instead of nonsmooth (DNLP) and the domains of the beta and binomial functions have been changed.

Documentation

- The contents of GAMS User's Guide and the McCarl (Expanded) User's Guide have been merged, revised, and reorganized as User's Guide as well as A GAMS Tutorial by Richard E. Rosenthal. Also other parts of the documentation has been reorganized and are now more closely integrated.
- The McCarl GAMS User Guide (CHM and PDF) can now be found in the `mccarl/` subdirectory in the distribution.
- The PDFs containing the solver manuals and the GAMS User's Guide have been replaced by a single PDF containing large parts of the current documentation. However, the main format for the documentation is HTML.

3.26.1.4 Solvers

BARON

- New libraries 17.8.7.
  - New range reduction techniques and relaxations for quadratic constraints.
  - New heuristics for finding feasible solutions of integer programs.
  - Improvements in interfaces to local NLP solvers, including the use of second-order derivatives.
  - FilterSQP added to the list of local solvers. New option AllowFilterSQP and added new possible value 14 for option NLPSol.
  - Bugfixes.

CBC

- New libraries.
  - Fixed some problems with the handling of SOS type 2 in presolve.
- Added option dumpsolutionsmerged to write all found alternate solutions into a single GDX file.

Conopt

- New libraries 3.17E and 4.03.
  - Fixed a serious error in Conopt4 for exactly threads=8. Moreover, improved multi-threading performance.
  - Major revisions to Conopt4 for reliability and performance.
- The option Rtzern is now user settable for Conopt3.

CONVERT

- The GAMS equation and variable scale values (suffix `.scale`) will be communicated to CONVERT independent of the ScaleOpt model attribute.

CPLEX

- Added option workerAlgorithm to select the method for optimizing Benders subproblems.
- Added option writeAnnotation to create Cplex annotation file.
- The header of MIP/solve trace files contains now the option number and the name of the model.

DECIS

- DecisC, DecisM, and the EMP-SP solver Decis are now available for MacOS X.

GAMSCHK

- The procedures that generate output in the listing file are summarized at the end of the GAMSCHK execution. If you use the IDE, these summary lines are clickable and locate the cursor to the corresponding subsection in the IDE. Moreover, the procedures are also entered in the listing file index after the Solution Report.
- The lower bound for options LevelFilt and MargFilt has been reset from 1 to -5.

GUROBI

- New libraries 7.5.1.
  - Fewer constraint violations in MIQP solutions: Gurobi has tightened the internal tolerances for MIQP models to reduce the number of cases where the solution exhibits small constraint violations.
- New parameter startNodeLimit provides additional control over how much is performed to complete a partial MIP start.
- Gurobi 7.5 will be the last Gurobi release that supports 32-bit Windows. You should plan to migrate your applications to 64-bit Windows in the future.
- The header of MIP/solve trace files contain now the active option number and the name of the model.

GUSS/Scenario Solver

- Fixed a problem when initializing variables bounds to 0 (`updateType=0`) that have scenario update parameters for lower and upper bounds.

Lindo/LindoGlobal

- New libraries 11.0
  - LP Solver Improvements:
    - With new enhancements made to the simplex solvers, the average performance on large instances has increased by 20% for the primal simplex and 15% for the dual simplex compared to the previous version.
  - MIP Solver Improvements:
    - New symmetry detection capabilities to reduce overall branch-bound effort. This may dramatically reduce the time needed to prove optimality on some models with integer variables.
    - Perspective and soft-clique cuts effective on difficult MIQP and models with assignment constraints.
  - Global Solver Improvements:
    - Improved stability and robustness through several enhancements to quadratic recognition and range reduction.
  - Nonlinear Solver Improvements:
    - New major release of the nonlinear solver.
    - Improved preprocessor.
    - Use of interval function and derivative computations.
    - Advanced scaling leading to improved solution quality.

LocalSolver

- New libraries 7.0 (20170728).
  - Reinforcement of mixed-integer linear programming (LP & MIP) techniques for combinatorial optimization.
  - Reinforcement of nonlinear programming techniques (NLP) for numerical optimization.

MINOS/QUADMINOS

- New libraries 5.6 (dated July 2016).
  - Improved handling of singularites and empty cols in pivoting code.
  - Further bug fixes and improvements.
- Fix improper handling of scaled CNS models.
- Fix handling of logging frequency.
- QUADMINOS, the quadruple-precision version of MINOS, has been available in previous releases (since 24.4). This release includes the library model **[DQQ]**, an example of how to use MINOS and QUADMINOS together to compute greatly improved solutions at moderate cost.

MOSEK

- New libraries 8.1.0.23.
  - Performance of the presolve has been improved slightly.
  - Multi-thread performance of the conic optimizer has been improved for certain large models.
  - Changed scaling for quadratic and quadratically constraint optimization problems.
  - Bugfixes.

MPSGE

- The MPSGE $sysInclude `mpsgeset` allows now for an optional argument `-mt=0` or `1` after the model name. The default value for the argument `mt` can be controlled via the double dash option `--MPSGEMT=0` or `1`. If the `mt` option is set to 1 the `MODEL.GEN` file is created in the GAMS scratch directory. Hence the `$include` before the solve needs to read `$include "%gams.scrdir%MODEL.GEN"`. This allows to run multiple MPSGE jobs with the same model in the same working directory. The default of this option is 0. The model **hansmge** demonstrates the use.

SBB

- The header of MIP/solve trace files contains now the option number and the name of the model.

SCIP

- New libraries 4.0 (9d3c1b1).
  - Improved conflict analysis through central conflict pool and dual ray analysis for primal infeasible LPs.
  - New solution polishing to improve integrality of LP solutions when using SoPlex as LP solver.
  - Added adaptive solving behavior of SCIP based on solving phases and heuristic transitions.
  - Revised pseudo random number generation and introduced central random seed for all plugins.
  - Randomized tie-breaking in different parts of the code to reduce performance variability.
  - New primal heuristics GINS, LP face, Complete Sol, Locks, Repair, and Multistart.
  - The 1-opt heuristic is now iterated as long as new incumbents are found.
  - Improved tuning of heuristic timings.
  - Reduced memory usage of primal heuristics that use problem copies.
  - New presolving steps that disaggregate SOC constraints, reformulate QP's by adding KKT conditions, and treat variables appearing only in a single quadratic constraint with proper square coefficients.
  - New separators for gauge cuts, convex projection cuts, and perspective cuts for indicator constraints.
  - Improved knapsack approximation algorithms, greedy knapsack solution for the flow cover separation, clique partitioning, and clique separation.
  - New propagator for OBBT on convex NLP relaxation.
  - Tuned propagation methods of several constraint handlers and propagation timings.
  - Improved and extended stuffing for linear constraints.
  - Changed handling of coupling constraints for indicator constraints.
  - See also the `full release notes`, the `changelog`, and the `release paper`.
  - Changed parameters:
    - `presolving/components/*` moved to `constraints/components/*`
    - `conflict/depthscorefac` renamed to `conflict/graph/depthscorefac`
    - `misc/permutationseed` renamed to `randomization/permutationseed`
    - `misc/permuteconss` renamed to `randomization/permuteconss`
    - `misc/permutevars` renamed to `randomization/permutevars`
    - `branching/random/seed`: default changed from 0 to 41
    - `constraints/indicator/sepacouplingcuts`: default changed from 0 to 1
    - `constraints/SOS1/perfimplanalysis`: default changed from 1 to 0
    - `heuristics/ofins/freq`: default changed from -1 to 0

  - `heuristics/reoptsols/freq`: default changed from -1 to 0
  - `heuristics/trivialnegation/freq`: default changed from -1 to 0
  - `heuristics/clique/initseed`: default changed from 0 to 61
  - `lp/solver`: default changed from soplex to soplex2, if CPLEX is not licensed
  - `presolving/abortfac`: default changed from 0.001 to 0.0008
  - `separating/clique/cliquedensity`: default changed from 0.05 to 0
  - `conflict/usesb`: default changed from 0 to 1

- Added option gams/dumpsolutionsmerged to write all found alternate solutions into a single GDX file.

- Changed default for timing/clocktype to wallclock time.

- Initial variable levels can now be passed as partial solution to SCIP. To control the various possibilities, the type of option gams/mipstart has changed from bool to integer. See also subsection Starting point in the GAMS/SCIP solver manual.

SolveEngine

- New solver SolveEngine to solve LP and MIP problems remotely via the Satalia SolveEngine. The SolveEngine aggregates different solution algorithms for optimization problems and automatically selects an algorithm that seems to suite best for a given model instance.

- GAMS/SolveEngine comes free of charge with any licensed GAMS system. Users must have an API key for the Satalia SolveEngine to submit jobs.

SoPlex

- New libraries 3.0 (c32c55a).
  - Added a new scaling implementation Least squares (Curtis-Reid scaling).
  - Added persistent scaling to keep scaled LP for multiple reoptimizations.
  - Added an experimental version of a decomposition based approach to avoid degeneracy in the dual simplex method. This feature is activated by setting the parameter bool:decompositiondualsimplex to true, which sets the basis representation to 'row' and the algorithm to 'dual'.
  - New parameter bool:computedegen to enable computation of the degeneracy of the basis in each iteration.
  - New parameter `int:printcondition` to enable printing the condition number of the basis during solve.
  - Automatically use the row representation for problems with more than 20% more constraints than variables.
  - Changed default for parameter int:factor_update_max from 200 to new value 0.
  - See also the `full release notes` and the `release paper`.

- Changed default type of timer to wallclock time.

XPRESS

- New libraries: Optimizer 31.01.09 (aka XPRESS 8.3). There are many improvements and additions:
  - The parallel MIP code has been completely rewritten to improve performance and scalability.
    - Reduced overhead for small, easy MIPs.
    - Reduced the memory usage for very large MIPs, especially those that are significantly reduced during the initial preprocessing.
    - Heuristics can now be run in parallel with cutting in deterministic mode. Previously, heuristics would only be run in parallel after cutting.
    - Improved implementation of zero-half cutting.
    - Aggregated Mixed Integer Rounding cuts have been improved for network-type problems.
  - New presolve reductions, strengthenings and reformulations for convex quadratic problems.
  - Improved performance and numerical stability of crossover.
  - Code support for AVX2 in the barrier solver: use option cpuPlatform to select the target instruction set.
  - Crossover after a barrier solve is now multi-threaded: see option crossoverThreads for details.
- The header of MIP/solve trace files contains now the option number and the name of the model.

3.26.1.5 Tools

CSV2GDX

- New option `ValueDim`: Indicate if an extra dimension for values is added even if there is just one value column. This is ignored, if there is no value column.

GDXDUMP

- Fixed a problem with writing a scalar variable or equation in CSV format with all fields.

GDXMERGE

- Improved feedback about problems when processing input files.

3.26.1.6 Object Oriented APIs

- Fixed a bug regarding `SymbolUpdateType.Zero` that prevented records from being updated in `GAMSModelInstance.Solve()`.

C++

- This release contains a beta version of the object-oriented C++ API that can be used to control GAMS from within C++11 and later. It allows the seamless integration of GAMS into C++ applications by providing appropriate classes for the interaction with GAMS. The GAMSDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GAMSJob class and by using the GAMSModelInstance class a sequence of closely related model instances can be solved in an efficient way.
- The API is available in the distributions for Linux, MacOS X, and Windows.
- Futhermore, the C++ API is published under MIT license and is hosted at the GAMS GitHub organization.
- To use this API please check the GAMS API documentation.

.NET

- New functions `GAMSWorkspace.AddJobFromApiLib`, `GAMSWorkspace.AddJobFromNoaLib` to create GAMSJob from models from the GAMS API Library and the Nonlinear Optimization Applications Library.

Python

- New functions `GamsWorkspace.add_job_from_apilib`, `GamsWorkspace.add_job_from_noalib` to create GamsJob from models from the GAMS API Library and the Nonlinear Optimization Applications Library.
- Added a version check for the setup.py scripts to avoid unintentional installation of wrong versions.

3.26.1.7 Expert Level APIs

- With GAMS 25.0, the expert-level C++ API files will be removed from the distribution. Users should switch to the expert-level C API files. The object-oriented C++ API introduced in this release could also be a good alternative for replacement if the user C++ code exchanges data and runs a GAMS model.

GAMS Modeling Object

- Changed the function `gmoGetModelTypeTxt`: Added argument for model type number instead of using the model type of the stored model.

3.26.1.8 Model Libraries

GAMS Data Library

- **embeddedSort.gms : Sorting of numerical data using the embedded code facility** (108)
- **embeddedSplit.gms : Splitting of labels using the embedded code facility** (109)
- embeddedMultiInstance.gms : Handling multiple instances of the embedded code facility at once (110)

GAMS Model Library

- **dqq.gms : Warm-starting quad-precision MINOS** (414)
- **cbenders.gms : Cplex Benders for a Simple Facility Location Problem** (415)
- **robustlp.gms : Robust linear programming as an SOCP** (416)

GAMS Test Library

- **mpsge14.gms : MPSGE sync test: .GEN/integer1/nsolves** (713)
- **fnsincosintrv.gms : Test sin/cos func/grad interval evals** (714)
- **procdir1.gms : Test correct behavior of procDir, scrDir and procDirPath** (715)
- **empbp06.gms : Bilevel model with phantom vars owned by leader** (716)
- **fnslexp.gms : Test correctness of slexp intrinsic** (717)
- **fnslexp2.gms : Test correctness of slexp intrinsic** (718)
- **fnsqexp.gms : Test correctness of sqexp intrinsic** (719)
- **fnsqexp2.gms : Test correctness of sqexp intrinsic** (720)
- **fnsllog10.gms : Test correctness of sllog10 intrinsic** (721)
- **fnsllog102.gms : Test correctness of sllog10 intrinsic** (722)
- **fnsqlog10.gms : Test correctness of sqlog10 intrinsic** (723)
- **fnsqlog102.gms : Test correctness of sqlog10 intrinsic** (724)
- **fnslrec.gms : Test correctness of slrec intrinsic** (725)
- **fnslrec2.gms : Test correctness of slrec intrinsic** (726)
- **fnsqrec.gms : Test correctness of sqrec intrinsic** (727)
- **fnsqrec2.gms : Test correctness of sqrec intrinsic** (728)
- **fnloggamma.gms : Test correctness of loggamma intrinsic** (729)
- **fnbinomial.gms : Test correctness of binomial intrinsic** (730)
- **breakcont2.gms : Advanced test for break and continue statements** (731)
- **fnlogbeta.gms : Test correctness of logbeta intrinsic** (732)
- **fnbeta.gms : Test correctness of beta intrinsic** (733)
- **ssuffix.gms : List of all System Suffixes** (734)

3.26.2 24.9.2 Minor release (November 14, 2017)

3.26.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Paul Buckland, William N. Caballero, Xin Fang, Christophe Gouel, Fabricio Porras-Ortiz, Shigeru Tsubakitani, and Haoshui Yu.

3.26.2.2 GAMS System

GAMS

- Added prefixing of `PYTHONPATH` with the site-packages directory of the GAMS Python 3.6 installation in `GMSPython`.
- Added support for Python sets in the Embedded Python Code method `gams.set()`.
- Speed up detection/extraction of quadratic terms for QCP models.
- Do not allow the use of Embedded Code if execMode is set to 2 or higher.

Installer

- Removed the execution of a Python script during the Windows installation process that patches the path of certain Python programs in `GMSPython\Scripts`.

3.26.2.3 Solvers

BARON

- New libraries 17.10.16.
- Due to a problem with the Ipopt interface in BARON on Mac OS X, the use of Ipopt in BARON is currently disabled on Mac OS X.
- GAMS can now pass a term like `(negativeConstant)**negativeIntegerVariable` to BARON.

  Note

  By default, GAMS correctly rejects such a formulation, though. To work around this, `MaxExecError` needs to be set to a positive number and the option sys12 needs to be set to 1. Here is an example, how this could be used:

```
scalar a /-2/;
integer variable x;
x.lo = -3;
x.up = 3;

variable z;
equation e;

e.. z =e=a**x;

model m /e/;
x.l=1;
MaxExecError = 10;
option sys12 = 1;
solve m min z use minlp;
```

CPLEX

- Removed any limits on the number of Threads in a GAMS/CPLEX option file. Previously, the maximum for option Threads was 128.

CONOPT

- New libraries 3.17F.
  - Fixed an infinite loop when using option LMMXSF.

CONVERT

- Fix for variables with negative lower and infinite upper bound in LINGO output. The LINGO output has been changed to always use the `@Bnd` keyword to write variable bounds.

GUROBI

- New libraries 7.5.2.

GUSS/Scenario Solver

- Added the GUSS option `ReportLastScen`. If this is set to 1 the solution of the last scenario will be reported back to GAMS rather than solution of the base case. This is particularly useful when GUSS is used to implement a homotopy approach where the shock to a parameter is sliced in several small shocks and hence the last scenario represents the solution to the shocked system.

Lindo/LindoGlobal

- New libraries 11.0.300.

LogMIP

- Fixed improper handling of variables fixed at zero that occurred if they were used in nonlinear equations in a disjunction reformulated via the convex hull.

Mosek

- New libraries 8.1.0.31.
- Fixed dual solution for conic quadratic problems.

SCIP

- New libraries 4.0 (#22b4564).

SoPlex

- New libraries 3.0 (#3bfa247).

3.26.2.4 Object Oriented APIs

C++

- Added a try/catch block around the code that uses the classes from the GAMS C++ OO-API in all examples. Without this, the exceptions thrown by the methods of the GAMS classes will not be reported and *harmless* exceptions, like a compilation or execution error in the GAMSJob.run method result in application crashes.

Python

- Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

3.27 24.8 Distribution

3.27.1 24.8.1 Major release (December 21, 2016)

3.27.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Etienne Ayotte-Sauvé, Wolfgang Britz, Göran Bylund, Wietse Dol, Gregory Dourbois, Katja Jensen, Josef Kallrath, Toni Lastusilta, Renger van Nieuwkoop, and Tom Rutherford.

3.27.1.2 Platforms

- On Linux, the minimal required GLIBC version is now 2.7.
- On MacOS X, for some solvers (ANTIGONE, BARON, CPLEX, COIN-OR, SOPLEX, SCIP) the minimal required Mac OS X version is now 10.10. We will drop support for older Mac OS X versions for the complete GAMS system with the next major release.
- A generic license (with platform code GEN) is now limited to the platforms Windows, Linux, and Mac OS X. If you have a generic license and need a license for one of the other platforms (e.g. AIX), please contact sales or support to receive an additional license file for that platform free of charge.

3.27.1.3 GAMS System

GAMS

- The statements `Break` and `Continue` were added to allow more control over the execution of control structures (loop/while/repeat/for):
  - `Break [n];`: Terminate the n inner most control structures (n is optional, if it is omitted, it is set to 1).
  - `Continue;`: Jump to the end of the inner most control structure.

- Extend the report summary of the solution report to print the number of variables and equations where the level was projected to one of the bounds (compare model attribute tolProj), if that number is greater than 0.
- The model attribute tolProj to project levels to bounds is no longer ignored when the GAMS Grid Facility (solveLink = 3 or 4) is used.
- New command line option `fileStem`: Sets the file stem for output files which use the input file name as stem by default, see fileStem for more details.
- New option `MCPRHoldfx` (can be set using the option statement, a command line parameter, or model attribute):
  - Prints list of rows that are perpendicular to variables removed due to the holdfixed setting if set to 1.
- New option `AsyncSolLst` (can be set using the option statement, or a command line parameter):
  - If set to 1, GAMS prints a solution listing to the lst file also when an asynchronous solve (see The Grid and Multi-Threading Solve Facility) is used.
  - The default value is 0.
- New variant for the solveLink option and model attribute: 7 (compile time constant %`solveLink.threadsSimulate%`) - The problem is passed to the solver in core without use of temporary files, GAMS waits for the solver to come back but uses same submission process as 6 (see Multi-threading Submission Testing)
- New function numCores (available at both compile and execution time): Returns the number of logical cores in the system.
- Allow macro expansion in the domain list of a symbol declaration.
- New dollar control splitOption that splits a string representing a option/value pair into option name and option value.
- Fixed a problem with the optional `maxWait` parameter of the function readyCollect.
- Fixed potential error in file created by dumpOpt, if there were symbols loaded from GDX.
- Fixed an error which could lead to wrong results when assigning to a symbol while the symbol's alias was used on the right hand side of the assignment.
- Fixed an error which could lead to a crash if a phantom set element was used to control an assignment inside a loop.
- Fixed a problem with unscaling solutions for MCP models that resulted in incorrect dual values for scaled MCPs. For an example, compare the new test library model **mcp11** when run with 24.8 and with something previous.

Documentation

- The offline documentation now provides `search` and `keyword` indexing functionalities in addition to navigating the documentation.
- The Microsoft Compiled HTML help file `gams.chm` is no longer available.
- The table of contents for browsing the GAMS model libraries is now available offline in HTML format.

3.27.1.4 Solvers

BARON

- New libraries 16.12.7.

CPLEX

- New libraries 12.7.0.0.
- Support for the platfrom MS Windows 32 bit, Solaris i86pc, and Solaris SPARC 64bit has been dropped by IBM for Cplex 12.7. The GAMS system for these platforms contains Cplex 12.6.3.
- Cplex 12.7 implements Benders Algorithm. This is available in CplexD only.
- The IIS option triggers now the conflict refiner. The IIS function in Cplex 12.7 has been replaced by the conflict refiner. The IIS option now also works on infeasible models with model status `Infeasible No Solution` as well as on problems with discrete variables.
- New parameters
  - BendersFeasCutTol: Tolerance for whether a feasibility cut has been violated in Benders decomposition
  - BendersOptCutTol: Tolerance for optimality cuts in Benders decomposition
  - BendersStrategy: Benders decomposition algorithm as a strategy
  - DataCheck: Data consistency checking and modeling assistance
  - RLTCuts: Reformulation Linearization Technique (RLT) cuts
- Modified parameters:
  - MipStart: A value of 6 accepts the (partical) MipStart without any checks

CONOPT

- This distribution includes the first official release of the CONOPT4 solver. The chapter in the solver manual has an interesting subsection on when you should use CONOPT4 for all existing CONOPT users.
- The current solver alias `CONOPT` still points to the CONOPT3 solver. This might change in the next, or next but one major release. We invite you to share your experience with this new version of CONOPT via support (`support@gams.com`) with us.

ConvertD

- Write proper scale and prior information for equations and variables with option `Jacobian`.

DICOPT

- An implementation of a Feasibility Pump primal heuristic (for convex MINLP) has been added to DICOPT. This heuristic can be run before the actual DICOPT algorithm. Outer approximation cuts from the MIP subproblem of the Feasibility Pump are transferred to initialize the MIP outer approximation of the main DICOPT algorithm. Option feaspump can be used to enable the Feasibility Pump and various other options are available to tune the feasibility pump.
- Option convex has been added to indicate the presence of convex MINLP. If this option is set, the defaults for various other options are modified.

GUROBI

- New libraries 7.0.1.
- Explore alternative solutions via the Solution Pool.
- New parameters
  - BestObjStop: Objective value to stop optimization
  - BestBdStop: Objective bound to stop optimization
  - InfProofCuts: Infeasibility proof cut generation
  - StrongCGCuts: Strong-CG cut generation
  - DegenMoves: Degenerate simplex moves
  - TuneCriterion: Tuning criterion
  - SolNPool: Activate export of alternative solution
  - PoolSolutions, PoolSearchMode, and PoolGap to control generation of alternative solutions
- Gurobi 7 supports general constraints. With the help of the dot-option `.GenConstrType` the user can classify a constraint to be of type `Max`, `Min`, `Abs`, `And`, and `Or`.
- Gurobi 7 supports indicator constraints.
- Gurobi 7 supports multi objective hierarchical optimization. Details can be found in the GAMS/Gurobi manual, in subsection Multiple Objectives.

JAMS

- New option ZipDebug=xxx.zip to specify that, in the event of abnormal termination or behavior, a zip file of debugging info be created.
- New reformulation options to handle shared or duplicated equations and variables in equilibrium models.

Knitro

- New libraries 10.2.0.
  - Significant speed and robustness improvements when using BFGS (hessopt=2) or L-BFGS (hessopt=6) Hessian approximations with the default Knitro interior-point method.
  - General performance improvement on mixed-integer models.
  - Minor bug fixes.
  - New mixed-integer SQP (MISQP) algorithm for nonlinear mixed-integer models (mip_method=3). This new algorithm is intended for small, potentially non-convex models with possibly expensive function evaluations. It can be used even when integer variables are not relaxable (i.e. functions can only be evaluated with integer variables at integer points) by setting mip_relaxable=0, and can be used with parallel multistart.
  - New option mip_nodealg to control algorithm used at B&B nodes: overrides the generic algorithm option.
- The Knitro Tuner is now available from the GAMS/Knitro link.

Lindo/LindoGlobal

- New libraries 10.0.131.
  - LP Solver Improvements:
    - With new enhancements made to the simplex solvers, the average performance on large instances has increased by 35% for the primal simplex and by 20% for the dual simplex compared to the previous version.
  - MIP Solver Improvements:
    - New heuristic algorithms help to find significantly better solutions for many models with knapsack constraints and block structures.
    - New MIP preprocessing level devoted to tightening variable bounds for some nonlinear models.
  - Stochastic Solver Improvements:
    - Improved cut management for Nested Benders Decomposition Method leading to speed improvements over 60% for large linear multistage SP instances.
    - Better handling of multistage SP models which do not have full-recourse.
  - Global Solver Improvements:
    - Incorporates bound tightening process to the linearization procedure and improve solvability of linearized model.

LocalSolver

- New libraries 6.5 (20160729).
  - For near-linear (discrete or continuous) problems, new moves have been introduced based on linear programming and mixed-integer linear programming techniques. These moves allow to intensify the search on near-linear models by exploring optimally larger neighborhoods.
- Added possibility for "Hierarchical Optimization of Multiple Objective Functions".
- Removed option `origlog`. GAMS/LocalSolver will now always print the original LocalSolver log.
- Fixed level values of aggregated variables in solution.

Mosek

- New libraries 8.0.0.48 (`Mosek release notes`)
  - Presolve performance has been improved.
  - The eliminator in the presolve has been reimplemented, is usually faster, and requires much less memory.
  - Presolve has been improved on conic quadratic problems.
  - The numerical stability of conic optimizer has been improved significantly, particularly for semidefinite optimization problems.
  - The scaling routine for the conic optimizer is more aggressive.
  - Quadratic and quadratically constrained problems are now internally converted to conic form and are solved using the conic optimizer. Nevertheless full primal and dual information to the original problems is available.
  - A dualizer for conic quadratic problems is now available. By default it dualize the problems before optimizing if deemed worthwhile. The dualization is transparent to the user and can be turned off.

- The conic optimizer linear algebra is now parallelized using Cilk Plus and scales better when the number of threads is increased for large problems. Moreover, for smallish problems using too many threads does not hurt performance.
- The computational efficiency graph partitioning based ordering method in the interior-point optimizer has been improved.
- It is now possible to force the interior-point optimizer to run in the calling thread.
- Only one mixed integer optimizer is available now, which corresponds to the mixed integer conic optimizer that was introduced with version 7.
- The primal network simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.
- The primal-dual simplex optimizer has been removed. It is suggested to use the dual simplex optimizer instead.
- The concurrent optimizer has been removed. It is suggested to use the interior-point optimizer instead.
- The following GAMS/Mosek options have been removed:
  * MSK_IPAR_ANA_SOL_BASIS
  * MSK_IPAR_ANA_SOL_PRINT_VIOLATED
  * MSK_IPAR_CONCURRENT_NUM_OPTIMIZERS
  * MSK_IPAR_CONCURRENT_PRIORITY_DUAL_SIMPLEX
  * MSK_IPAR_CONCURRENT_PRIORITY_FREE_SIMPLEX
  * MSK_IPAR_CONCURRENT_PRIORITY_INTPNT
  * MSK_IPAR_CONCURRENT_PRIORITY_PRIMAL_SIMPLEX
  * MSK_DPAR_FEASREPAIR_TOL
  * MSK_IPAR_FEASREPAIR_OPTIMIZE
  * MSK_IPAR_INTPNT_FACTOR_DEBUG_LVL
  * MSK_IPAR_INTPNT_FACTOR_METHOD
  * MSK_IPAR_LOG_CONCURRENT
  * MSK_IPAR_LOG_NONCONVEX
  * MSK_IPAR_LOG_PARAM
  * MSK_IPAR_LOG_SENSITIVITY
  * MSK_IPAR_LOG_SENSITIVITY_OPT
  * MSK_IPAR_MAX_NUM_WARNINGS
  * MSK_IPAR_MIO_CONT_SOL
  * MSK_IPAR_MIO_CUT_CG
  * MSK_IPAR_MIO_CUT_LEVEL_ROOT
  * MSK_IPAR_MIO_CUT_LEVEL_TREE
  * MSK_IPAR_MIO_FEASPUMP_LEVEL
  * MSK_DPAR_MIO_HEURISTIC_TIME
  * MSK_IPAR_MIO_HOTSTART
  * MSK_IPAR_MIO_KEEP_BASIS
  * MSK_IPAR_MIO_LOCAL_BRANCH_NUMBER
  * MSK_DPAR_MIO_MAX_TIME_APRX_OPT
  * MSK_IPAR_MIO_PRESOLVE_AGGREGATE
  * MSK_IPAR_MIO_PRESOLVE_PROBING
  * MSK_IPAR_MIO_PRESOLVE_USE
  * MSK_DPAR_MIO_REL_ADD_CUT_LIMITED
  * MSK_IPAR_MIO_STRONG_BRANCH
  * MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS
  * MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS
  * MSK_DPAR_MIO_TOL_REL_RELAX_INT

  - MSK_DPAR_MIO_TOL_X
  - MSK_IPAR_MIO_USE_MULTITHREADED_OPTIMIZER
  - MSK_IPAR_NONCONVEX_MAX_ITERATIONS
  - MSK_DPAR_NONCONVEX_TOL_FEAS
  - MSK_DPAR_NONCONVEX_TOL_OPT
  - MSK_IPAR_PRESOLVE_ELIM_FILL (use MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL instead)
  - MSK_IPAR_PRESOLVE_ELIMINATOR_USE
  - MSK_IPAR_PRIMAL_REPAIR_OPTIMIZER
  - MSK_IPAR_QO_SEPARABLE_REFORMULATION
  - MSK_IPAR_WARNING_LEVEL
  - MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_CONIC_ITEMS (use MSK_IPAR_WRITE_IGNORE_INC instead)
  - MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_NL_ITEMS (use MSK_IPAR_WRITE_IGNORE_INCOM instead)
  - MSK_IPAR_WRITE_IGNORE_INCOMPATIBLE_PSD_ITEMS (use MSK_IPAR_WRITE_IGNORE_INCOM instead)

- The following GAMS/Mosek options have been added:
  - MSK_DPAR_DATA_SYM_MAT_TOL: Absolute zero tolerance for elements in in symmetric matrices.
  - MSK_DPAR_DATA_SYM_MAT_TOL_HUGE: An element in a symmetric matrix which is larger than this value in absolute size causes an error.
  - MSK_DPAR_DATA_SYM_MAT_TOL_LARGE: An element in a symmetric matrix which is larger than this value in absolute size causes a warning message to be printed.
  - MSK_DPAR_INTPNT_QO_TOL_DFEAS: Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_DPAR_INTPNT_QO_TOL_INFEAS: Controls when the conic interior-point optimizer declares the model primal or dual infeasible.
  - MSK_DPAR_INTPNT_QO_TOL_MU_RED: Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_DPAR_INTPNT_QO_TOL_NEAR_REL: Termination tolerance multiplier that is used if no accurate solution can be found.
  - MSK_DPAR_INTPNT_QO_TOL_PFEAS: Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
  - MSK_DPAR_INTPNT_QO_TOL_REL_GAP: Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.
  - `MSK_IPAR_INTPNT_MULTI_THREAD`: Controls whether the interior-point optimizers can employ multiple threads if available.
  - MSK_IPAR_MIO_CUT_CLIQUE: Controls whether clique cuts should be generated.
  - MSK_IPAR_MIO_CUT_GMI: Controls whether GMI cuts should be generated.
  - MSK_IPAR_MIO_CUT_IMPLIED_BOUND: Controls whether implied bound cuts should be generated.
  - MSK_IPAR_MIO_CUT_KNAPSACK_COVER: Controls whether knapsack cover cuts should be generated.
  - MSK_IPAR_MIO_CUT_SELECTION_LEVEL: Controls how aggressively generated cuts are selected to be included in the relaxation.
  - MSK_IPAR_MIO_PERSPECTIVE_REFORMULATE: Enables or disables perspective reformulation in presolve.
  - MSK_IPAR_MIO_ROOT_REPEAT_PRESOLVE_LEVEL: Controls whether presolve can be repeated at root node.
  - MSK_IPAR_MIO_VB_DETECTION_LEVEL: Controls how much effort is put into detecting variable bounds.
  - MSK_IPAR_OPF_WRITE_HEADER: Write a text header with date and MOSEK version in an OPF file.

    - MSK_IPAR_OPF_WRITE_HINTS: Write a hint subsection with problem dimensions in the beginning of an OPF file.
    - MSK_IPAR_OPF_WRITE_PROBLEM: Write objective, constraints, bounds etc.
    - MSK_IPAR_OPF_WRITE_SOL_BAS: Whether to include basic solution in OPF files.
    - MSK_IPAR_OPF_WRITE_SOL_ITG: Whether to include integer solution in OPF files.
    - MSK_IPAR_OPF_WRITE_SOL_ITR: Whether to include interior solution in OPF files.
    - MSK_IPAR_OPF_WRITE_SOLUTIONS: Enable inclusion of solutions in the OPF files.
    - MSK_IPAR_PRESOLVE_ELIMINATOR_MAX_FILL: Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of presolve.
    - MSK_DPAR_SEMIDEFINITE_TOL_APPROX: Tolerance to define a matrix to be positive semidefinite.
    - MSK_IPAR_WRITE_DATA_PARAM: If this option is turned on the parameter settings are written to the data file as parameters.
    - MSK_IPAR_WRITE_LP_FULL_OBJ: Write all variables, including the ones with 0-coefficients, in the objective.
    - MSK_IPAR_WRITE_MPS_FORMAT: Controls in which format the MPS is written.
    - MSK_IPAR_WRITE_TASK_INC_SOL: Controls whether the solutions are stored in the task file too.
    - MSK_SPAR_WRITE_LP_GEN_VAR_NAME: Sometimes when an LP file is written additional variables must be inserted.
  - For the following options, the default value has changed:
    - MSK_DPAR_MIO_TOL_FEAS from 1e-7 to 1e-6
    - MSK_IPAR_LOG_MIO_FREQ from 1000 to 10
    - `MSK_IPAR_WRITE_PRECISION` from 8 to 15
- Fixed selection of optimizer for "fixed solve" of a mixed-integer conic problem.

Pyomo

- Fixed compatibility issues with different versions of Pyomo.

SCIP

- New libraries 3.2 (#0d4fc08).
- Changed the default LP solver to SoPlex also for the case where a CPLEX license is available, due to problems when using CPLEX 12.7.0.0 as LP solver in SCIP.

SoPlex

- The GAMS/SoPlex interface has been rewritten and does not use the OsiSpx layer anymore. The solver OSISOPLEX is now an alias for the solver SoPlex.
- SoPlex parameter files can now be used.
- SoPlex can now be warmstarted when only the model instance data changes (e.g., via GUSS).
- New libraries 2.2 (df190de).

3.27.1.5 Tools

CSV2GDX

- Improved error reporting.

GDXDUMP

- New command line option `CSVAllFields` to get all fields (level, marginal, lower, upper, and scale) when writing a variable or equation symbol in CSV format.

MODEL2TEX

- Increased the page width of the txt file generated by the GAMS command line option `docfile` to 32767 (max. value).
- Changed the default encoding to `latin` and added a new command line parameter that allows to change the encoding (`-e=ENCODING`)
- Changed the default format of the symbol tables.
- The JSON style file contains a new property called `columnSetting` that allows to adjust the columns.
- Avoid some unnecessary parentheses in sum and product operators.
- Minor change in the equations subsection that removes several warnings.
- Several minor bug fixes.

GDXXRW

- Fixed a problem when writing a symbol with option merge or clear to a range with `CDim=0` or `RDim=0`.

GMSZIP/GMSUNZIP

- New versions of `Info-ZIP's` tools `zip` (version 3.1c02) and `unzip` (version 6.00). The executable names have been prefixed with "gms" for clear identification.

3.27.1.6 Object Oriented APIs

- New option GAMSOptions.ErrorLog: Maximal number of error message lines written to the log for each error.

.NET

- New examples that demonstrate the use of the API in a graphical environment: TransportGUI, CutstockGUI, FarmGUI.
- Distribute compiled GUI examples in directory <`GAMSDir`>\`apifiles\GUIexamples` on Windows.
- `GAMSWorkspace.AddJobFromFile`: Throw an exception if a given file does not exist.

Python

- The option `GamsOptions._errorlog` has been renamed to `GamsOptions.errorlog` in order to indicate it as public.

3.27.1.7 Model Libraries

GAMS API Library

- **PInterrupt.gms : Test GamsJob interrupt mechanism in object oriented Python API** (54)
- **CSInterrupt.gms : Test GamsJob interrupt mechanism in object oriented .Net API** (55)

GAMS Model Library

- **asyncloop.gms : Transportation Problem with async loop body execution** (411)
- **trnsindic.gms : Fixed Charge Transportation Problem with Indicator Constraints** (412)
- **timesteps.gms : Accessing previous (or next) time steps in an equation fast** (413)
- Modified models:
  - Make use of the new `break` statement to formulate the following models a little nicer: **tsp1**, **tsp4**, **cutstock**, **awktsp**, **sddp**, **sipres**, **allbases**, **qfilter**
  - **tgridmix**: The of logic of submission and collection has been reworked so that the scenario sets do not have to be one dimensional and ordered (contributed by Tom Rutherford).
  - **asyncjobs**: The logic for putting out the log line in time intervals was flawed and has been corrected.

GAMS Test Library

- **emp17.gms : Simple test of one optimizing agent** (693)
- **breakcont1.gms : Test break and continue statements** (694)
- **lindgl04.gms : Test non-convex quadartic program with Lindo(Global)** (695)
- **mcp11.gms : Test marginals for a scaled MCP problem** (696)
- **csv2gdx1.gms : Test csv2gdx on input containing spaces** (697)
- **gdxxrw7.gms : Test merge and clear option for special data layout** (698)
- **scale02.gms : Test that an MCP with scales is rejected when appropriate** (699)
- **emp18.gms : Test JAMS/EMP on implicit variable handling** (700)
- **emp19.gms : Test JAMS/EMP on implicit variable handling** (701)
- **emp20.gms : Test JAMS/EMP on implicit variable handling** (702)
- **emp21.gms : Test JAMS/EMP on implicit variable handling** (703)
- **emp22.gms : Test JAMS/EMP on implicit variable handling** (704)

- **emp23.gms : Test JAMS/EMP on implicit variable handling** (705)
- **emp24.gms : Test JAMS/EMP on implicit variable handling** (706)
- **emp25.gms : Test JAMS/EMP on implicit variable handling** (707)
- **emp26.gms : Test JAMS/EMP on implicit variable handling** (708)
- **gurobi02.gms : GUROBI test suite - general constraints max,min,abs** (709)
- **gurobi03.gms : GUROBI test suite - general constraints and,or** (710)
- **slx01.gms : run tests for different solvelink values** (711)
- **gurobi04.gms : GUROBI test suite - multi objective** (712)

3.27.2 24.8.2 Maintenance release (January 03, 2017)

3.27.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Evangelos Panos.

3.27.2.2 GAMS System

GAMS

- Change for command line parameter MultiPass: If it is set to 2, als errors from `$gdxIn` are ignored now
- Fixed a bug which caused wrong results in some assignments which use symbols that were used out-of-order in previous assignments.

3.27.2.3 Solvers

SCIP

- Added a workaround that allows for using CPLEX 12.7.0.0 as LP solver in SCIP again. For the moment, the default is still to use SoPlex.

3.27.3 24.8.3 Minor release (January 28, 2017)

3.27.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Mohammad R. Hesamzadeh, and Katja Jensen.

3.27.3.2 GAMS System

GAMS

- Fixed potentially wrong values for model attribute `etSolver` for cases where the command line option `solveLink` was set to 1, 2 or 5.

3.27.3.3 Solvers

BARON

- New libraries 17.1.2.
  - More robust links with COIN-OR solvers and a better link with FICO Xpress.
  - Some new RLT cuts are included in relaxations.

DE

- Create a capability error if DE is called to solve a model of type EMP without stochastic information.

DECIS

- Create a capability error if DECIS is called to solve a model of type EMP without stochastic information.

Examiner2

- Fix behavior when the subsolver returns a model status like `19 Infeasible - No Solution`. The model status can be passed unchanged back to GAMS in such a case.

Kestrel

- Adjusted the default URL to https using port 3333.
- Fixed a bug that prevented to specify the protocol in the `neos_server` parameter in an option file. The complete format of the parameter is now `protocol://host:port`.

LINDO

- Create a capability error if LINDO is called to solve a model of type EMP without stochastic information.

MOSEK

- New libraries 8.0.0.53.

SCIP

- Changed the default LP solver back to CPLEX, if available (see also `24.8.1` and `24.8.2` release notes).

3.27.3.4 Tools

GDXDUMP

- Fixed wrong output in case of nested quotes in symbol text.

3.27.3.5 Model Libraries

GAMS Model Library

- **linearne**: Minor fix to model formulation (contributed by Mohammad R. Hesamzadeh).

3.27.4 24.8.4 Minor release (April 10, 2017)

3.27.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Ivan Leung, Tara Rengarajan, and Sajjad Shafiei.

3.27.4.2 GAMS System

GAMS

- Fixed an issue which caused unnecessary memory consumption if many indexed symbols with explicit labels were used.

3.27.4.3 Solvers

BARON

- New libraries 17.4.1.
  - Bug fixes and an enhanced convexity detector.

CPLEX

- New libraries 12.7.1.0.
  - Note that with this update the log generated by Cplex changed in a way that the Cplex options set (either by the user or by GAMS defaults) are displayed. This is intentional and no sign of a problem. So one could see something like this in the log when running GAMS/Cplex:

```
CPXPARAM_Simplex_Limits_Iterations              2000000000
CPXPARAM_TimeLimit                              1000
CPXPARAM_Threads                                1
```

DICOPT

- Fixed serious bug in feasibility pump implementation.

Examiner, Examiner2

- The list of checks to perform for solved models was set incorrectly when the trace option was used.

GUROBI

- New libraries Gurobi 7.0.2.
- Added options MultiObjMethod and MultiObjPre.
- Fixed a problem that lead to wrong error messages when setting the ObjNAbsTol and ObjNRelTol parameters.
- Fixed a problem that reported back the wrong alternative solution.

JAMS

- Fix problem with bilevel models having variables owned by the leader but not appearing in the leader objective or constraints.

Lindo/LindoGlobal

- New libraries 10.0.179.

MOSEK

- New libraries 8.0.0.60.

NLPEC

- Fix problem handling empty constraints (e.g. `f.. eps*x =G= 0`) that appear in MPEC models. Note that such models can easily be produced by JAMS/EMP.

3.27.4.4 Object Oriented APIs

Python

- Added support for Python 3.6.
- Fixed a bug in `GamsJob.run()` that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.

3.27.5 24.8.5 Maintenance release (May 10, 2017)

3.27.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Ana Carolina, Gary Goldstein, Erwin Kalvelagen, Amit Kanudia, Toni Lastusilta, Antti Lehtila, Bruce McCarl, and Hans Kristian Ringkjob.

3.27.5.2 Platforms

- The AIX system is now build on AIX 7.1.

3.27.5.3 GAMS System

GAMS

- Fixed a bug which could cause a crash in particular assignments involving singleton sets or explicit labels. This was introduced with GAMS 24.8.4.
- Fixed problems with the `break` statement:
  - There was a potential crash if break was used in a "sparse loop", e.g., `loop(j$x(j), ...)`.
  - If break was used in a loop with more than one index, e.g., `loop((i,j), ...)`, that loop was treated as multiple loops for the `break` statement, one for each index. Now it is treated as just one loop as intended.
  - Fixed a problem where a loop was not correctly recognized as a loop if it runs over just one fixed element, e.g., `loop(i('i2'), ...)`.

3.27.5.4 Solvers

BARON

- Initialize BARON option Threads with value of GAMS option Threads, if the latter is at least 1.

CBC

- New libraries.
  - Fixed a bug in presolve that caused problems with fixed discrete variables.

GUROBI

- Suboptimal solutions were not reported back to GAMS. This has been fixed.

Lindo/LindoGlobal

- New libraries 10.0.182.

MOSEK

- New libraries 8.0.0.69.

3.28 24.7 Distribution

3.28.1 24.7.1 Major release (March 14, 2016)

3.28.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Alex Dowling, Johannes Hedtrich, Austin Milt, and Salvador Pineda.

3.28.1.2 GAMS System

GAMS

- Be more strict when the syntax `$LOAD par=var.L` is used: This creates an error now, if `par` is not a parameter (if `par` was a variable before, the complete variable `var` was loaded as if the suffix was omitted)
- GAMS Grid Facility (solveLink = 3 or 4)
  - Fixed a bug for the model attribute `objval`: This could have been wrong when the objective variable was scaled.
  - Fixed a bug for the marginals: These could have been wrong when the objective variable was scaled.
- Solving in parallel threads (solveLink = 6)
  - Allow to solve scaled models (model attribute `scaleOpt` is set to 1) as well (this generated an execution error before).

3.28.1.3 Solvers

BARON

- New libraries 16.3.4.
  - Faster LP interfaces.
  - Additional checks on solution reliability of LP and NLP subsolvers.
  - New automatic differentiation routines.
  - Improved handling of memory-intensive problems.
  - Enhanced presolving for continuous and integer programs.
  - New primal heuristic for integer programs.
  - New facilities for solving constraint (non)linear systems (CNS).

CBC

- New libraries.

ConvertD

- The GDX file created with option `Jacobian` contains now a set ANl that indicates the non-linear Jacobian elements.

CPLEX

- For an unbounded model Cplex did not mark the unbounded variables correctly. This has been fixed.

GUROBI

- Gurobi Optimization, Inc. has decided to end the current arrangement that allows us to offer GAMS/Gurobi integrated licenses. GAMS will continue to offer the latest version of Gurobi but users will need to get a Gurobi license from Gurobi Optimization, Inc. plus a GAMS/Gurobi link license from GAMS or use the free OsiGurobi link. This includes evaluation and demo licenses.
  For existing GAMS/Gurobi customers the following transition arrangements have been negotiated. The GAMS/Gurobi integrated license will continue to work as long as the license stays under maintenance. Academic GAMS/Gurobi customers will not be able to renew maintenance on their GAMS/Gurobi integrated license, their license will be changed into a GAMS/Gurobi link license. Academic users can get free Gurobi licenses from www.gurobi.com.
  In the past, academic GAMS/Gurobi link or GAMS/OsiGurobi licenses did not require a Gurobi license installed. This has changed with this release
- New libraries 6.5.1
- The option PreSOS1BigM and PreSOS2BigM were incorrectly classified as integer options. They have been reclassified as real option.

IPOPTH

- Fixed a memory access issue in the linear solver HSL MA86 in case of very large models.

LocalSolver

- New libraries 6.0 (20160308).

MOSEK

- New libraries 7.1.0.49.

SBB

- Fixed a problem with option `UserHeurCall`. This option required that all discrete variables were declared first in the model. This is not necessary anymore.

SCIP

- New libraries 3.2 (#f69c505).
  - The timing mask for parameters `constraints/.../presoltiming`, `presolving/.../timing`, and `propagating/.../presoltiming` changed from 2/4/8 for fast/medium/exhaustive to 4/8/16.
  - Parameter `constraints/SOS1/updateconflpresol` has been renamed to `constraints/SOS1/perfimplanalys`
  - Detailed Changelog.

SOPLEX

- New libraries 2.2 (#12d3858).

3.28.1.4 Tools

GAMS IDE

- Fixed a bug which caused an error when opening the FINLIB (Practical Financial Optimization Models).

MODEL2TEX

- Fixed a bug regarding negative variables.
- Fixed a bug regarding subscripts of symbol names with underscores.
- Fixed a bug that prevented alternative names from being replaced in Ord constructs.
- New parameter -o (–OUTPUT) that allows to specify an alternative output file.
- Use UTF8 encoding.
- The columns of the symbol table have a fixed (equal) width.
- The original name of a symbol that is changed using the JSON style file is displayed in the symbol table.
- The JSON style file is alphabetically sorted by keys.

3.28.1.5 Object Oriented APIs

- Fixed a bug with the property `GAMSOptions.Defines` (.NET), `GAMSOptions.defines` (Java), and `GamsOptions.defines` (Python): When too many entries were added, all of them were ignored.

Python

- Fixed a memory leak in `GamsDatabase`.

3.28.1.6 Model Libraries

GAMS Test Library

- **scale01.gms : Test results of scaled model** (692)

3.28.2 24.7.2 Minor release (July 07, 2016)

3.28.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Peter Alexander, Daniel Balistrieri, Paul Buckland, Denis Hess, Eden Huang, Josef Kallrath, Sherman Robinson, Tom Rutherford, Jhih-Shyang Shih, and Loic Ventre.

3.28.2.2 Platforms

- With the next major release, the minimal glibc version requirement for the GAMS distribution on Linux will be increased to 2.7.

3.28.2.3 GAMS System

GAMS

- Improved the performance for assignments from one large symbol to itself inside a loop, when only one element gets changed, e.g.:

  ```
  loop((j,cty,yrs,sim), ...; par(j,cty,'Total',yrs,sim) = sum(lnd, par(j,cty,lnd,yrs,sim));)
  ```

- Fixed a performance issue which caused very long model generation time for large scalar models.

3.28.2.4 Solvers

BARON

- New libraries 16.5.16.
  - Added option WantDual to indicate whether BARON should make a final call to an NLP solver to try to compute duals if an inexpensive method of calculating them failed.
- CompIIS option did not print IIS into listing file. This has been fixed.

CBC

- New libraries.

CPLEX

- New libraries 12.6.3.0.2.
- A memory leak in Cplex has been fixed that showed up in combination with the OO-API GAMSModelInstance class.
- Fixed a problem with CplexD option FreeGamsModel.
- Fixed a problem with `MipStart` in combination with SemiInt or SemiCont variables with lower bound 0.

GUROBI

- New libraries 6.5.2.

JAMS

- Fix handling of objectives in optimizing agents of equilibrium systems in cases where the objective coefficient was not 1 or -1, and in the equation level returned for the objective row(s).

LocalSolver

- New libraries 6.0 (20160625).

Mosek

- New libraries 7.1.0.52.

OsiMosek

- Fixed handling of gap tolerances and node limit of MIP solves.

SBB

- Fixed a problem with models that have domain violations in the root NLP.
- Clearly identify text written to the listing file as output from the root solver.

SCIP

- New libraries 3.2 (#e99d344).

SoPlex

- New libraries 2.2 (#3c5e86f).

PATH

- Fixed a problem with bogus report of empty rows/cols when benchmarking a model, i.e. solving with iterlim=0.

XPRESS

- Maintenance update of Optimizer libraries for Windows, Linux, and Mac to 28.01.14.
- Several minor bug fixes that affect correctness and performance in some uncommon cases.

3.28.2.5 Tools

- Increase maximum available memory for GDXVIEWER, MDB2GMS, SQL2GMS, XLS2GMS, GDX2HAR, and HAR2GDX to 3GB.

CSV2GDX

- Fixed a problem with labels with trailing blanks. Labels with trailing blanks potentially resulted in a broken GDX file.
- Introduced the symbolic constant `LastCol` for the Values parameter.
- Report duplicate keys.

GDXXRW

- Fixed a problem with unnecessary memory consumption when writing with option clear or merge.
- Symbols and text were not written in sequence as instructed. This has been fixed.
- Added command line parameter ReCalc that by default prevents frequent recalculations in Excel while writing to the spreadsheet.

3.28.2.6 Object Oriented APIs

- Fixed a bug which did not clear a pending Ctrl-C event, so that it might have been applied to a following GAMSModelinstance.Solve by accident.
- Fixed a problem, that caused a crash instead of a GAMSException in some rare cases.

Python

- Fixed a minor bug regarding the names of GamsJob listing files.

3.28.2.7 Model Libraries

- Some URLs in various models have been updated.

3.28.3 24.7.3 Maintenance release (July 11, 2016)

3.28.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Josef Kallrath, and Toni Lastusilta.

3.28.3.2 Tools

CSV2GDX

- Fixed a bug which caused an error when reading sets from a csv file.

MODEL2TEX

- Fixed a bug regarding wrongly generated equations in the generated LaTeX file.

3.28.4 24.7.4 Minor release (September 19, 2016)

3.28.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Manuel Alvarez, Felix Färber, Ricardo Manuel Pinto de Lima, and Tara Rengarajan.

3.28.4.2 GAMS System

GAMS

- Fixed a problem when using extrinsic function libraries using API version 1.
- Extend possible range of `n` in `fact(n)` at compile time. It was limited to 20 in the past. Now it can be up to 166 (as in assignments at execution time).

Installer

- New default group name (`GAMS xx.x (xx bit)`) for the start menu on Windows 10.

3.28.4.3 Solvers

BARON

- New libraries 16.8.24.
  - Small performance improvements and robustification of LP solver interfaces and bugfixes.
  - The starting point is now utilized before invoking projection and other initialization strategies.
  - The option DeltaTerm is now recognized again.

Couenne

- New libraries.

CPLEXD

- The option MipStart accepts now values other than 0 and 1. The value describes the effort level Cplex uses to determine a MipStart from the starting variable levels. The value 2 is interesting because it just checks for feasibility of the MipStart. In this case the level of all variables, not only the discrete ones, are passed on to Cplex.

DE

- DE crashed if multiple joint variables were present in one stage. This has been fixed.

Lindo/LindoGlobal

- New libraries 9.0.293.

Mosek

- New libraries 7.1.0.55.

SCIP

- New libraries 3.1 (#6b9196f).

SoPlex

- New libraries 2.2 (#074950a).

3.28.4.4 Tools

CSV2GDX

- Fixed a bug which lead to a rejection of unquoted labels with spaces. This bug was introduced in 24.7.2.

GDXXRW

- Fixed a bug which caused an error message when reading a sheet with a non-empty range that contained no data.

3.28.4.5 Object Oriented APIs

- `GAMSModelInstance.Instantiate`: Skip creation of GDX file, which was unreachable from within the APIs anyway.

Python

- Added support for Python 3.4 on Mac OS X.
- Fixed a problems with Exceptions in `GamsWorkspace`.

3.29 24.6 Distribution

3.29.1 24.6.1 Major release (January 18, 2016)

3.29.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Etienne Ayotte-Sauvé, Michael Ferris, Per Ivar Helgesen, Erwin Kalvelagen, Martha Loewe, Geoff Moore, and Renger van Nieuwkoop.

3.29.1.2 Platforms

- The minimal supported Mac OS X version has been increased to 10.9 (Mavericks). COIN-OR solvers, Gurobi, SCIP, and SoPlex now require a system with at least Mac OS X 10.9. The GAMS base system, tools, and other solvers are still working on Mac OS X 10.7 and 10.8, but may stop working in a future release without extra announcement.
- The installer for Wine on Linux has been dropped.

3.29.1.3 GAMS System

GAMS

- Increased controlled set nesting limit from 120 to 300.
- New option SHUFFLE.
- New option for command line parameter MultiPass:
  - 0: standard compilation
  - 1: check-out compilation
  - 2: as 1 and in addition skip `$call` and ignore errors because of missing files with `$include` (NEW)
- Allow to load variable and equation attributes into a parameter at compile time, e.g. `$LOAD par=var.L` (par being a parameter and var a variable)

- Solving in parallel threads (beta feature)

  A new variant for the solveLink option and model attribute has been added. If `solveLink` is set to 6 (compile time constant `%solveLink.asyncThreads%`), GAMS does not wait for the solver to return and does not collect the result when a solve statement is executed. Instead, the model is generated and then passed to the solver in a separate thread while GAMS continues the execution. This way, multiple models can be solved in parallel and the results can be collected later.

  This is similar to the Grid Facility (`solveLink = %solveLink.asyncGrid%=3`) with the difference, that the solver does not operate in its own process space but in a separate thread, which allows efficient in-memory communication between GAMS and the solver (like it is done with `solveLink = %solveLink.loadLibrary%=5`). After the solve statement, one can store a handle of the model instance (using the model attribute mymodel.handle) and use the same functions that are used for the Grid Facility to collect the solution and deal with the model instance: `HandleCollect(handle)`, `HandleStatus(handle)`, and `HandleDelete(handle)`.

  The new function `ReadyCollect(handleParameter [, maxWait])` can be used to wait until a model is ready to be collected. It can be used for both `solveLink = %solveLink.asyncThreads%` and `solveLink = %solveLink.asyncGrid%`. The arguments and return codes are:

  - Arguments
    - `handleParameter`: parameter holding handles of model instances to wait for
    - `maxWait`: maximum time to wait (`+INF` if omitted)
  - Return Codes
    - 0: (one of) the requested job(s) is ready
    - 1: no active job to wait for
    - 2: no handle provided
    - 3: invalid handle
    - 4: user specified time-out when using a `solveLink = %solveLink.asyncThreads%` handle
    - 5: user specified time-out when using a `solveLink = %solveLink.asyncGrid%` handle
    - 8: unknown error (should not happen)

  The new option threadsAsync (available on the command line and with the option statement) sets the maximum number of threads that should be used for the asynchronous solves. If a negative number is set, this specifies how many of the available processors on the host machine should not be used. The default setting is -1.

  Currently, the following solvers can be used with `solveLink = %solveLink.asyncThreads%`:

  - CONOPT
  - CPLEXD
  - GUROBI
  - MOSEK
  - OSICPLEX
  - OSIGUROBI
  - SCIP

  If another solver is selected, `solveLink = %solveLink.asyncGrid%` will be used instead (which is noted in the log).

  An example of how this new feature can be used, can be seen in the GAMS Model Library model **tgridmix**.

Stochastic Programming with EMP

- Fixed a bug which caused wrong expected values for parametric distribution using the `RandVar` keyword.

3.29.1.4 Solvers

ANTIGONE

- New libraries.

BARON

- The handling of branching priorities in a GAMS/BARON options file has changed. Priorities should now always be given in the GAMS convention.

Convert

- GAMS branching priorities are now converted to BARON branching priorities when writing a BARON input file.

CPLEX

- New libraries 12.6.3.
- Cplex and CplexD now report the deterministic time spend (in `ticks` not in seconds) in the model attribute `ETAlg`.
- IBM's Cplex cloud offering "DOcloud" can be accessed via the "Kestrel solver".

DICOPT

- New option usexinit instructs DICOPT to start the NLP sub-solves from the user supplied input point.

GUROBI

- New libraries 6.5.
- New option PreMIQCPForm that determines the format of the presolved version of an MIQCP model.
- New option `WorkerPort` specifies a non-default port number for the distributed worker machines.
- New option VarHint. The variable hints communicated through level and tryint will affect the heuristics that Gurobi uses to find feasible solutions, and the branching decisions that Gurobi makes to explore the MIP search tree.
- GAMS/Gurobi supports solving models in the Gurobi Instant Cloud.
- Fixed a problem with option IIS for models with SOS variables.

IPOPT

- MKL Pardiso is now available as linear solver on Mac OS X, too.

KESTREL

- The Kestrel client provides experimental access to "IBM's DOcloud" offering.

PATH

- Minor fix for zero tolerance in the basis reset routine of the Lemke method.

Sulum

- Sulum will be dropped from the distribution with GAMS 24.8.

XPRESS

- Updated Optimizer libraries for Windows and Linux: 28.01.05 → 28.01.10.
- Several minor bug fixes that affect correctness and performance in some corner cases.

3.29.1.5 Tools

ASK

- New feature SelectDirectory.

GAMS IDE

- Sorting by symbol name is no longer case sensitive.
- GDX viewer can now show numbers with full precision.
- The option editor no longer shows the dot options.
- Fixed a bug where the cursor was not shown after double-clicking on a red line.

GDX2SQLITE

- New version 0.7.
  - Added option varchar to export character columns as `VARCHAR(255)` instead of `TEXT`.
  - Better names of columns when option small is used.
  - Adding timing info.

GDXMERGE

- Protect against very large symbols causing memory errors.
- Added option EXCLUDE to exclude symbols from being merged.

GDXXRW

- An empty range is no longer an error.

SQL2GMS

- In the old version double quotes were removed when reading a command file. In this version we keep double quotes to be able to escape SQL names (table names, column names). E.g. we now can handle non-standard names by double quoting them in a query. Depending on the database you can do:

  ```
  q=select "Some COLUMN" from "This Table"
  ```

  Note that some databases (such as SQL Server) use [ ] for this goal.

  In the special case where you write:

  ```
  q="select c from t"
  ```

  the surrounding double quotes are removed before passing the query on to the database.

MODEL2TEX

- If an identifier is changed using the specifications in the JSON style file, underscores are no longer changed from "_" to "_". This makes it possible to use subscripts when replacing an identifier.

3.29.1.6 Object Oriented APIs

Java

- Fixed a bug in `GAMSModelInstance.copyModelInstance` method when duplicating scratch directory.

Python

- New example `transport8a.py`.

3.29.1.7 Model Libraries

GAMS EMP Library

- **nbcontindep**: use sampling for continuous distributions if another solver than Lindo is selected
- **nbcontjoint**: use sampling for continuous distributions if another solver than Lindo is selected
- **nbsimple**: use discrete distribution

GAMS Test Library

- **shuffle1.gms : Test for option shuffle** (690)
- **sl601.gms : Check correct behavior when using solveLink=6** (691)

3.30 24.5 Distribution

3.30.1 24.5.1 Major release (September 23, 2015)

3.30.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Guillaume Erbs, Michael Ferris, Mahbube Habibian, Josef Kallrath, Jean Mercenier, Stan Peter, Ingmar Schlecht, and Mark Thissen.

3.30.1.2 Platforms

- Support for Windows XP has been dropped completely with this release (as announced).

3.30.1.3 GAMS System

GAMS

- New model attributes
  - `maxInfes`: Maximum of infeasibilities
  - `meanInfes`: Arithmetic mean of infeasibilities
- New option solver. This simplifies the selection of the (default) solver for multiple model types.
  - The command line option `solver=abc` initializes the default solver for the model types solver `abc` is capable of to `abc`. This initialization is done before the default solvers of individual model types are set via command line options. So a command line with `lp=conopt solver=bdmlp` will first set BDMLP as the default solver for model types LP, RMIP, and MIP (these are the model types BDMLP can handle) and then reset Conopt as the default solver for LP. The order of these parameters on the command line has no impact (i.e. `lp=conopt solver=bdmlp` behaves identically to `solver=bdmlp lp=conopt`). If multiple occurrences of option `solver` appear, the last one sets the option as it is with other options, including `LP`, `MIP`, ...
  - The solver for multiple model types can be set via the `Option solver=abc;` in the GAMS model source code. This sets the solver for model types `abc` can handle to `abc`. With the `option solver=abc;` the order among other solver setting options is significant. For example, `option lp=conopt, solver=bdmlp;` will first set the solver for LP to Conopt and in the next step to BDMLP because BDMLP is capable of handling model type LP. Setting `solver` twice can also make sense: `option solver=conopt, solver=cbc;` will result into setting the solver for model types CNS, DNLP, NLP, QCP, RMIQCP, and RMINLP to Conopt and the solver for model types LP, RMIP, and MIP to CBC.
- When using $LOADDC the reporting of domain errors has been improved.
- This release features several improvements of the execution system. The following lists some (extreme) examples:
  - Improved performance when indices of accessed symbol are in "wrong" order, e.g.:

```
$if not set size $set size 10000
set v  / v1*v%size% /
e  / e1*e%size% /;
alias(v,w);
set evw(e,v,w) /#e:#v:#w/
    vw(v,w);
vw(v,w) = sum(e, evw(e,v,w));
```

The final assignment can be done in less than 1% of the time required by GAMS 24.4.

– Improved performance when assigning to non-empty symbols when the assignment is driven by their domain, e.g.:

```
$if not set size $set size 5000
set i / i1*i%size% /; alias (i,j);
parameter a(i,j), b(i,j);
a(i,j)$(uniform(0,1)<0.95) = 1;
b(i,j) = not a(i,j);
a(i,j) = b(i,j);
```

The final assignment can be done in just ∼5% of the time required by GAMS 24.4.

– Improved performance when executing certain combinations of mappings, e.g.:

```
$if not set size1 $set size1 8000
$if not set size2 $set size2 24
set hi          / 1*%size1% /
    ti          / 1*%size2% /
    h           / h1*h%size1% /
    t           / t1*t%size2% /
    hmapx(h,hi) / #h:#hi /
    tmapx(t,ti) / #t:#ti /;
parameter xi(hi,ti), x1(h,t);
xi(hi,ti) = uniform(0,1);
x1(h,t) = sum((hmapx(h,hi),tmapx(t,ti)), xi(hi,ti));
```

The final assignment can be done in just ∼2% of the time required by GAMS 24.4.

– Improved performance when "searching" a lot in a large symbol, e.g.:

```
$if not set size1 $set size1 50
$if not set size2 $set size2 200000
$if not set size3 $set size3 150000
set f /f1*f%size1%/
    j /j1*j%size2%/
    l /l1*l%size3%/
    flmap(f,l);
flmap(f,l)=uniform(0,1)<0.25;
parameter jlpar(j,l) /#j:#l 10/
          fjpar(f,j);
fjpar(f,j) = sum(l$flmap(f,l), jlpar(j,l));
```

The final assignment can be done in just ∼1% of the time required by GAMS 24.4.

Documentation

- The complete GAMS technical documentation (release and installation notes, user's guides, solver and tools manuals, API reference manuals) is now available in HTML format with a unified table of contents. The documentation is available in the following forms:
  - The online GAMS documentation provides search and keyword indexing functionalities in addition to navigating the GAMS documentation.
  - The offline documentation allows access without a network connection:
    * The main navigation page can be found at `[GAMS system directory]/docs/index.html` (not linked from the GAMS IDE).
    * For Windows, additionally a Microsoft Compiled HTML Help file is available at `[GAMS system directory]/docs/gams.chm` and linked from the GAMS IDE Menu: `Help -> GAMS Documentation`.
- The following documents are still available in PDF format: GAMS User's guide, McCarl Expanded GAMS User's guide, all solver manuals, and GAMS GDX API.

Installer

- New way to install GAMS on Mac OS X using a DMG file.

3.30.1.4 Solvers

ANTIGONE

- Added option conopt_optfile to set name of options file to be used for CONOPT calls in ANTIGONE.

BARON

- Now also available for Mac OS X.
- New libraries 15.9.22.
- New NLP solver for local search: FilterSD.
- Options:
  - New option Threads: Number of cores used for solution of MIP subproblems.
  - New option IISOrder: Order in which constraints are considered in the search for an IIS.
  - Options `ConTol` and `IntTol` removed. Tolerances are now set by AbsConFeasTol, RelConFeasTol, AbsIntFeasTol, and RelIntFeasTol.
  - Options `MultMSize`, `MultRel`, `NLPDoLin`, `MipGap`, `MipNodes`, `MipRel`, `NoutIterMip`, `BilRel`, `Cvxbt`, `CvxInitOA`, `CvxRel`, `MipCuts`, and `RLTRel`: Algorithmic features that have been parameterized are now handle in an automatic way.
- The time limit is enforced based on CPU time for single-threaded jobs and based on wall-clock time for multi-threaded jobs.
- Simplified the screen output (eliminated some details and simplified time to a real number in seconds).
- Updated CBC to 2.9.5.
- Updated Ipopt to 3.12.3.

CBC

- New libraries 2.9.
  - Introduced specialized branching methods for dealing with "big Ms".
  - Introduction of conflict cuts (off by default, enable with option conflictcuts).
  - Introduced new methods for dealing with symmetry.

Conopt

- New libraries 3.17A.
  - Corrected problem with options Ls2ndi and Lmusdf.
  - Systems errors related to very tight memory (984) and the inversion routine (2027) have been removed.
  - Three new options have been added to allow the modeler to see the order of the pre-triangular and post-triangular part of the model and the definitional equations:
    - PRPRET: Flag for printing the pre-triangular part of the model.
    - PRDEF: Flag for printing the defined variables and their defining constraints.
    - PRPOST: Flag for printing the post-triangular part of the model.

Couenne

- New libraries 0.5 (major update).
- Better handling of function `signpower(x,k)` for positive integer k≤10.
- The default values for the following options have changed:
  - `cont_var_priority` from 2000 to 99.
  - `int_var_priority` from 1000 to 98.
  - `feas_pump_milpmethod` from -1 to 0.
  - `feas_pump_poolcomp` from 0 to 4.
  - `output_level` from 0 to 4.

CPLEX

- New option FreeGamsModel. This option preserves memory by dumping the GAMS model instance representation temporarily to disk. This option is available in CplexD only.

GUROBI

- New libraries 6.0.5 (technical release).
- New option FreeGamsModel. This option preserves memory by dumping the GAMS model instance representation temporarily to disk.

GUSS/ScenarioSolver

- The set of GUSS model attributes (`Set ma "GUSS Model Attributes" / System.GUSSModelAttributes /;`) has changed:
  - The attribute `NumNOpt` has been removed.
  - The attributes `MaxInfes` and `MeanInfes` have been added.

IPOPT

- New libraries 3.12 (minor changes).

JAMS

- SubSolver option fixed: it was sometimes ignored.

Kestrel

- The option file can be omitted. In this case, the Kestrel call is done with default settings.

Lindo/LindoGlobal

- Dropped Lindo/LindoGlobal libraries for Intel Solaris as announced previously.
- New libraries 9.0.225.

LocalSolver

- New libraries 5.5.
  - Improved accuracy and performance on numerical or mixed-variable optimization problems.

MINOS

- Adjusted default upper bound on the superbasics limit from 500 to 5000 and consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 5000 superbasics, limit the Hessian dimension to 5000 even though the superbasic limit is larger.

MOSEK

- New libraries 7.1.0.33.
- The GAMS option iterlim now sets the iteration limit for both simplex and interior point algorithms.
- More MOSEK options are now available in GAMS/Mosek:
  - MSK_IPAR_MIO_CUT_CG: Controls whether CG (Chvatal-Gomory) cuts should be generated.
  - MSK_IPAR_MIO_CUT_CMIR: Controls whether mixed integer rounding cuts should be generated.
  - MSK_IPAR_MIO_PROBING_LEVEL: Controls the amount of probing employed by the mixed-integer optimizer in presolve.
  - MSK_IPAR_MIO_RINS_MAX_NODES: Controls the maximum number of nodes allowed in each call to the RINS heuristic.
  - MSK_DPAR_MIO_TOL_MAX_CUT_FRAC_RHS: Maximum value of fractional part of right hand side to generate CMIR and CG cuts for.
  - MSK_DPAR_MIO_TOL_MIN_CUT_FRAC_RHS: Minimum value of fractional part of right hand side to generate CMIR and CG cuts for.
  - MSK_DPAR_MIO_TOL_REL_DUAL_BOUND_IMPROVEMENT: If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation.

OS

- Now a hidden solver. Will be dropped from the distribution at some time (without further notice).

PATH

- New libraries 4.07.03.
- Adjusted to use wall-clock time on all platforms.
- Time limit checked more frequently, e.g. at each pivot.
- The presolve has been extended to find more reductions.
- Minor bug fixes.

SCIP

- New libraries 3.2 #c9c4375 (major update):
  - New presolvers "tworowbnd", "dualagg", "implfree", "redvub", and "stuffing", and improved presolve for ranged- and equality-type linear constraints.
  - Presolving levels FAST, MEDIUM, and EXHAUSTIVE are now used to better coordinate the various presolvers.
  - Generalized upgrade from (SOC-representable) quadratic constraints to SOC constraints.
  - New primal heuristics "distribution diving", "indicator", and "bound", improved clique and variable bound heuristics, and adjusted diving heuristics to solve fewer LPs.
  - New branching rules "distribution", "multaggr", and a new rule for SOS1 constraints.
  - New reliability notions and improved treatment of nonlinearities in hybrid reliability pseudo cost branching.
  - New separator "eccuts" for generating edge-concave cuts for quadratic constraints and improved separation for convex quadratic constraints.
  - Decreased total memory usage by using more buffer data structures.
  - Improved propagation and separation for SOS of type 1 by using information from a conflict graph.
  - See also the `full release notes`, the `change log`, and the `technical report`.
- The following options were removed or replaced:
  - `constraints/.../delaypresol` and `constraints/.../timingmask` replaced by `constraints/.../presoltim` and `constraints/.../proptiming`.
  - `presolving/domcol/singcolstuffing` replaced by `presolving/stuffing/...`.
  - `presolving/.../delay` replaced by `presolving/.../timing`.
  - `propagating/.../presoldelay` replaced by `propagating/.../presoltiming`.
  - `propagating/obbt/maxlookahead` removed.
- For the following options, the default value changed:
  - constraints/SOS1/sepafreq from 0 to 10.
  - "heuristics/clique/minfixingrate" from 0.5 to 0.25.
  - "heuristics/vbounds/minfixingrate" from 0.5 to 0.25.
  - heuristics/actconsdiving/maxdiveavgquotnosol from 0 to 1.
  - heuristics/actconsdiving/maxdiveubquotnosol from 0.1 to 1.
  - heuristics/dins/nwaitingnodes from 0 to 200.
  - lp/rowrepswitch from -1 to 1.2.
  - presolving/abortfac from 0.0001 to 0.001.
  - presolving/restartfac from 0.05 to 0.025.
  - presolving/immrestartfac from 0.2 to 0.1.
  - presolving/dualinfer/priority from 20010000 to -200.
  - propagating/obbt/itlimitfactor from 5 to 10.

SoPlex

- New libraries 2.2.0 (major update).

SULUM

- New libraries 4.3.892.
  - Several bug fixes in both the MIP solver and the LP solver.
  - Improved numeric stability, degeneracy handling, and perturbation scheme in LP optimizer.
  - Added a new combined pricing scheme to the dual simplex optimizer.
  - Improved presolve and restart in MIP optimizer.

XPRESS

- New libraries for XPRESS v7.9: Optimizer 28.01.05.
  - Significantly improved linear algebra routines for the simplex solvers improving efficiency of a wide range of problems.
  - Improvement heuristics called more often.
  - The MIP log now provides information which heuristic finds a solution.
  - Improved linear dependency checker for large problems.
  - Improved scaling, including scaling of big-M type rows and of the Curtis-Reid scaling option.
  - Improved inference-learning from infeasible subproblem during the MIP search.
  - Improved presolver for quadratic instances.
  - Improved handling of Special Ordered Sets.
  - Improved propagation of conflict cuts.

3.30.1.5 Tools

GAMS IDE

- In the model library browser the IDE may provide hints about the content of the column when hovering over the headers.
- Option to specify file extensions for files that will be reloaded without a confirmation dialog.

GDXDIFF

- When renaming the temporary file to `gdxdiff.gdx` fails, issue a ViewClose command in case the file is open in the GAMSIDE and try to rename again.
- If no difference was found, issue a message in the log indicating this.
- Add a set with two elements with explanatory text of the two files compared.

GDXMERGE

- When a filename cannot be used as a UEL, use a generated name instead.

GDXXRW

- New options `IgnoreRows` and `IgnoreColumns` to ignore a set of rows or columns for a symbol. Rows can be specified as `IgnoreRows=1,4:5` and columns `IgnoreColumns=A,D:F` or `IgnoreColumns=1,4:6`.

MODEL2TEX

- The beta version of this tool allows the automatic generation of LaTeX code that documents a given GAMS model.

MPSGE

- The documentation of MPSGE has moved again. It can now be found in the User's Guide.

3.30.1.6 Object Oriented APIs

- New examples `SpecialValues` and `Clad` (Java: `specialvalues/SpecialValues.java`, `clad/Clad.java`; Python: `special_values.py`, `clad.py`).
- New functions to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library:
  - .NET: `GAMSWorkspace.ApiLib` and `GAMSWorkspace.NoaLib`.
  - Java: `GAMSWorkspace.addJobFromApiLib` and `GAMSWorkspace.addJobFromNoaLib`.
  - Python: `GamsWorkspace.apilib` and `GamsWorkspace.noalib`.

Python

- Added support for Python 3.4 (Windows and Linux only). The examples have been changed to be compatible with all supported Python versions.

3.30.1.7 Model Libraries

NOALIB - Nonlinear Optimization Applications Using the GAMS Technology

- This new library by Neculai Andrei has been added to the GAMS system. This is a collection of the models based on the book Nonlinear Optimization Applications Using the GAMS Technology by Neculai Andrei. The library contains a wide spectrum of nonlinear optimization applications expressed in GAMS. The book and library emphasize the local solutions of the large-scale, complex, continuous nonlinear optimization applications, and the abundant examples in GAMS are highlighted by those involving ODEs, PDEs, and optimal control. The collection of these examples will be useful for software developers and testers.
- You can retrieve the individual models through the IDE model library browser or via the command line utility `noalib`.

GAMS API Library

- **CSSpecialValues.gms : Test handling of Special Values in object oriented C# API** (47)
- **PSpecialValues.gms : Test handling of Special Values in object oriented Python API** (48)
- **JSpecialValues.gms : Test handling of Special Values in object oriented Java API** (49)
- **CSNUnit.gms : Compiles and runs NUnit tests for object oriented C# API** (50)
- **CSClad.gms : Test changing solver options while running using the interrupt method** (51)
- **PClad.gms : Test changing solver options while running using the interrupt method** (52)
- **JClad.gms : Test changing solver options while running using the interrupt method** (53)

GAMS Data Library

- **invert1**: Pass `gams.sysdir%` to R script to make linkage between GAMS and R explicit.
- **gdxmrw_tr3**: Canonical form LP created in Matlab and solved via `gams()` Mex-function.
- **gdxmrw_tr4**: Better example of `gams()` usage.
- **gdxmrw_tr5**: Better example of `gams()` usage.

GAMS EMP Library

- **transecs**: Fix formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.
- **farmnbd.gms : The Farmer's Problem - Stochastic with NBD** (100)

GAMS Model Library

- In the IDE the GAMS Model Library browser has now a `Lic` column indicating the license requirement of a model. The letters **D** and **G** indicate that the model does not require a license. Models with **G** can even be solved by a global solver without a license (the demo limit for global solvers is 10 variables and 10 equations). A letter **L** indicates that a license is required.
  - **tgridmix**: Fix the logic for sleeping. Only do that if no more jobs to be scheduled or all cores are busy.

GAMS Test Library

- **asynntrp**: Make this model work under Unix that have the `pstree` utility available.
- **call6.gms : Call GAMS in a folder containing a %** (674)
- **cmexrc01.gms : Trigger unexpected cmexRC error** (675)
- **rs02.gms : Solving Three-dimensional Noughts and Crosses using Cplex and Gurobi distributed MIP** (676)
- **single04.gms : Check handling of singleton sets assigned and referenced in a loop** (677)
- **model2tex1.gms : Test that model2tex produces a tex file** (678)
- **exmcp6.gms : External Equation - Example MCP 6** (679)
- **scensol6.gms : Test execute_loadhandle for GUSS/GRID** (680)
- **idxperm1.gms : Check correct behavior when permuting indices in model generation** (684)
- **idxperm2.gms : Check correct behavior when permuting indices in loop etc** (685)

3.30.2 24.5.2 Maintenance release (September 29, 2015)

3.30.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Kevin Doran and Renger van Nieuwkoop.

3.30.2.2 GAMS System

GAMS

- Fixed a bug which caused a crash for certain assignments, in particular it had to be an assignment to a symbol that was also referenced on the RHS, with permuted indices and we actually set some of the records to zero which were non-zero before.

3.30.2.3 Object Oriented APIs

.NET

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. (This is for Mono only.)

Python

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property `GamsWorkspace.system_directory` now always returns the canonical path with all symbolic links resolved.

3.30.2.4 Model Libraries

GAMS Test Library

- **idxperm3.gms : Check correct behavior when permuting indices of symbol used on LHS and RHS** (686)

3.30.3 24.5.3 Maintenance release (October 01, 2015)

3.30.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz.

3.30.3.2 GAMS System

GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments

3.30.4 24.5.4 Maintenance release (October 15, 2015)

3.30.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Per Ivar Helgesen and Jan Imhof.

3.30.4.2 GAMS System

GAMS

- Fixed a bug which caused wrong results in some cases of out-of-order assignments, in particular it had to be an assignment using the same controlling set more than once in one symbol, e.g. `p(i,j,i)`.
- Fixed a bug when handling suffixes (e.g. .val) of Singleton Sets in Equations.

3.30.4.3 Object Oriented APIs

.NET

- Fixed a bug with the property `GAMSOptions.IDir`.

3.30.4.4 Model Libraries

GAMS Test Library

- **single05.gms : Check correctness of set attributes for singleton sets** (687)
- **idxperm4.gms : Check correct behavior when permuting indices of symbol using same controlling set multiple times** (688)

3.30.5 24.5.5 Maintenance release (November 25, 2015)

3.30.5.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Albrecht, Stefan Kemnitz, Martha Loewe, Thomas Maindl, Bruce McCarl, and Andres Ramos.

3.30.5.2 GAMS System

GAMS

- GAMS now always reports the upper bound that is sent to the solver in the column listing and solution report. Hence, with IntVarUp=1 GAMS prints the value of 100 for integer and semiint variables that are at default bound value +INF.
- Fixed a bug which could cause a crash when referencing attributes of equations (e.g. marginals) after a model was solved with a non-default solveLink setting and there was no solution returned.

Stochastic Programming with EMP

- Fixed a bug which caused wrong sample sizes if the sample keyword was used more than once and with different sample sizes.

3.30.5.3 Solvers

Cbc

- New libraries.

CplexD

- Fixed a problem with the computeserver option. The value for the computeserver option is limited to 255 characters. In order to specify a longer list of workers, one can now use multiple lines with the computeserver option.

Ipopt

- New libraries.

LocalSolver

- New libraries 5.5 (20151028).

Mosek

- New libraries 7.1.0.41.

SCIP

- New libraries 3.2 (#e9a5ca7).
  - Removed options `constraints/SOS1/bipbranch`, `constraints/SOS1/neighbranch`, and `constraints/SOS1/sos1branch`.

SoPlex

- New libraries 2.2 (#f17b9e7).

3.30.5.4 Tools

put_toexcel, put_tohtml

- Fixed a problem with `put_toexcel` and `put_tohtml`.

3.30.6 24.5.6 Maintenance release (November 27, 2015)

3.30.6.1 Solvers

COUENNE

- New libraries.

IPOPT, BONMIN, SCIP

- Fixed issue that Ipopt and Bonmin always read `ipopt.opt`, despite of the `optfile` setting in GAMS.

3.31 24.4 Distribution

3.31.1 24.4.1 Major release (December 20, 2014)

3.31.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Jeff Linderoth, and Erkka Rinne.

3.31.1.2 GAMS System

GAMS

- Fixed a bug causing a potential crash when solving an EMP model having an open file handle without an external file name at the same time.
- The `execMode` setting is not ignored by `put_utility` anymore.
- Added `gbin/md5sum.exe` to Windows distribution. This utility allows users to verify the file integrity of newly downloaded GAMS installation files.
- The `gbin_new` directory will be removed with the next distribution.

Installer

- Windows installer removes the GAMS entry in the current user hive of the registry, if GAMS is installed for all users. Previously, the hive for the current user remained unchanged in this situation.

Extrinsic Function libraries

- The new extrinsic function library `parcclib` was added to the system. This library demonstrates how to access the GAMS parameter file and use it's information through the GAMS Option Object. Further information can be found in the GAMS User's Guide, Appendix J.
- Allow up to 20 arguments (used to be 10).
- Support for extrinsic function libraries that do not provide gradient and/or Hessian values. GAMS uses finite differences (same method as for `.gradn` and `.hessn`) to approximate the derivatives, even inside a solver. The example function library `trilib` now implements function `Sine` without any derivatives and leaves their calculation to GAMS.
- New GAMS options have been introduced to parameterize the numerical derivative calculations. While these are most important for extrinsic functions, they also apply to the `.gradn`/`.hessn` calculations of intrinsic functions.
  - `FDDelta`: step size in the numeric gradient and Hessian calculation. For single argument functions, GAMS evaluates the function at f(x-d) and f(x+d) for the numerical gradient. If function values are used for the numerical Hessian, GAMS evaluates at f(x-2d), f(x), and f(x+2d). For multi argument functions, the same is done for the components of the input argument vector. The default for `FDDelta` is 1e-5. This option can be set from the command line, in an option statement, and as a model attribute.
  - **Note:** In previous releases it was possible to set the step size for `.gradn`/`.hessn` using the option `Real1`. This does not work anymore.
  - `FDOpt`: The option value packs two option in the different digits: *ij*. The *i* digit indicates if scaling of the step size (`FDDelta`) by the value of the input argument should be turned off. If *i*=0 (scaling on) the following step size is used: `max(1,|x|)*FDDelta`. The *j* digit is mostly for testing, but has one setting that might be relevant when the extrinsic function provides gradient but no Hessian values. The numerical derivatives routine in this case uses the gradient calculation from the extrinsic function to approximate the Hessian. If the gradient is expensive to calculate compared to a function evaluation, it could be beneficial to use multiple function values to approximate the Hessian. In this case set the *j* digit to 1. Here are all possible values for this option:
    - 0: All derivatives analytically if available, for numerical Hessian use gradient values, scale delta

    - 1: All derivatives analytically if available, for numerical Hessian use function values, scale delta
    - 2: Gradient analytically, force Hessian numerically using gradient values, scale delta (testing only)
    - 3: Gradient analytically, force Hessian numerically using function values, scale delta (testing only)
    - 4: Force gradient and Hessian numerically, scale delta (testing only)
    - 10: Same as 0, but no scale of delta
    - 11: Same as 1, but no scale of delta
    - 12: Same as 2, but no scale of delta (testing only)
    - 13: Same as 3, but no scale of delta (testing only)
    - 14: Same as 4, but no scale of delta (testing only)
  - **Note:** In previous releases it was possible to deactivate the scaling for `.gradn`/`.hessn` using the option `Integer1`. This does not work anymore.

- Renamed and better documented the `EXTRFUNC_ERROR` enum to `EXTRFUNC_EVALERROR` in the C header `extrfunc.h`. The old values are deprecated and will be removed in a future release.

Documentation

- The manuals of all solver and several tools are now available in HTML format. A PDF that contains all solver manuals is still available (`docs/solvers/allsolvers.pdf`).

3.31.1.3 Solvers

AlphaECP

- Alpha-ECP v2.10.06.
  - Added support for solver trace file, i.e. new option `solvetrace`.

ANTIGONE, GloMIQO

- Now also available for Mac OS X.

BARON

- New libraries 14.4.0.
  - Added reliability branching for integer variables.
  - Bug fixes in CBC interface and IIS module.
  - Improved performance of problem reading and reformulation.
  - Updated Ipopt to version 3.11.9.

BENCH

- Removed option `cumulative`. This option makes no sense anymore since all solvers are spawned asynchronously and all get the same limits.

CBC

- Fixed a race-condition in log output when using multiple threads.
- New libraries.

Couenne

- New libraries.

CONOPT

- New libraries 3.16D.
  - Tolerance adjustments that make sense if NaN appears in intermediate calculations.

CPLEX

- Don't rerun primal simplex in cases where there is already an infeasibility status.
- New libraries 12.6.1.
- New parameters:
  - `qtolin` controls the linearization of the quadratic terms in the objective function of a QP or MIQP model
  - `localimplied` controls the generation of locally valid implied bound cuts

DICOPT

- Added support for `=N=` rows.

GUROBI

- New libraries 6.0.0.
- Fixed problem in tuning. Previous version did not write out link options in the tuned option file.
- Gurobi 6.0 supports a distributed MIP algorithm (option `DistributedMIPJobs`). This requires the Gurobi Compute Server to be licensed.
- Explicit lazy constraint: Users can use the "dot" option `.lazy` to mark constraints as lazy. Possible values are 0, 1, 2, and 3. See option `.lazy` for details.
- Option `ConcurrentMIPJobs` has been renamed to `ConcurrentJobs`. The distributed concurrent optimizer now also handles LP models.
- Option `ScaleFlag` allows now value 2 which enables aggressive scaling.
- New parameters:
  - `DistributedMIPJobs` controls the number of workers of the distributed MIP algorithm
  - `.lazy` marks constraints as lazy constraints
  - `LazyConstraints` controls the use of lazy constraints

Knitro

- New libraries 9.1.0.
  - Overall speed and robustness improvements on NLP and MINLP models.
  - New algorithm choice introduced: active-set SQP.
  - Optional barrier solution refinement procedure: option `bar_refinement = NO/yes`.
  - Deterministic parallel multi-start: option `ms_deterministic = no/YES`.
- Dropped Knitro for Solaris on Intel CPUs (as announced).

LocalSolver

- Added the hybrid mathematical programming solver `LocalSolver` 5.0 (Beta) from Innovation 24 to the GAMS solvers portfolio.
- LocalSolver can be applied to large-scale, mixed-variable, non-convex optimization problems (GAMS model types MIP, (MI)QCP, (MI/D)NLP). It combines local search techniques, constraint propagation and inference techniques, linear and mixed-integer programming techniques, and nonlinear programming techniques in a unique hybrid neighborhood search approach to find high-quality feasible solutions. Hence, LocalSolver offers an alternative for problems where conventional branch-and-bound and/or outer-approximation based solution methods do not provide satisfactory results.
- It is suggested to set the GAMS options for iteration or timelimit (iterlim, reslim) appropriately to limit the effort that LocalSolver spends on the problem.

Lindo/LindoGlobal

- We will drop Lindo/LindoGlobal libraries for Intel Solaris with the next major release (24.5).
- New libraries 9.0.142 for Linux, Mac OS X, and Windows:
  - Support for semi-continuous variables.
  - Simplex LP algorithm implementation has been improved for speed and robustness. The performance improvements compared to previous version are 90% for primal simplex and 45% for the dual simplex.
  - Knapsack related cuts improvements. Significantly faster solve times on models with certain knapsack-like constraints.
  - Improved default node selection rules improves performance on most MIPs.
  - New branching variable rule options: maximum coefficients and neighborhood branching. Can reduce number of branches on certain MIPs.
  - Perspective reformulation capability gives improved performance on quadratic portfolio models with semi-continuous variables, e.g. min-buy quantities.
  - Improved default settings for NLPs gives 5% average speed improvement.
  - New preprocessing for LP/MIP significantly reduces coefficient density of certain dense matrices.

Mosek

- New libraries 7.1.0.12.
  - Improved performance of the mixed-integer conic optimizer.

MSNLP/OQNLP

- These solvers now use Conopt as their default solver if Conopt is licensed. Otherwise they will use lsgrg as before.

OS

- We plan to drop the OS solver with GAMS 24.5. The capability of convert to write OSiL files will be kept.

SCIP

- New libraries 3.1 #020d055.

SoPlex

- New libraries 2.0 #d67b17b.

Sulum

- New libraries 4.0.665.
  - Improvements in presolve, leading to more reductions.
  - General improvements in obtaining a feasible solution faster, especially with focus on the root node to obtain a good bound. Rewrite and improvements of feasibility pump, objective diving.
  - The simplex algorithm is now exchanging more information with the branch and cut method. Improvement of SINS heuristic (finding a better basis after the node solve).
  - Added a MIP root restart feature based on reductions.
  - Cutting planes generation was both improved and extended.
  - Changed default for option `mipmaxrestarts` from 5 to 1.

XPRESS

- New libraries for XPRESS v7.8: Optimizer 27.01.02.
  - Automatic solution refinement for LP and MIP models.
  - Improved deterministic concurrent LP.

3.31.1.4 Tools

GAMSIDE

- Added option to suppress trailing zeroes in GDX viewer.
- Improved ability to open files from the Windows Shell.
- Cutoff for number of lines to be syntax colored or not.
- When saving a file, the Undo buffer is no longer cleared.

GDXDUMP

- Text quoted with a single quote did not have a separator when writing `SymbolAsSet`.
- Added option `SymbolAsSetDI`.
- Avoid string overflow when quoting text.
- Added more types for sets and equations.

GDXXRW

- Added option `values=All` which is the new default when `CDim=0` or `RDim=0`.

GDXVIEWER

- Added `ACCDB` format as an output option for MSAccess.

GDX2SQLite, Scenred, Scenred2

- These tools are now also available for AIX.
- Moved documentation of Scenred and Scenred2 from docs/solvers to docs/tools.

IDECMDS

- Allow a pattern to be specified to close files.

MPS2GMS

- The `mps2gms` tool now produces proper generic GAMS source for models with quadratic terms.
- Bug fix for MPS files written by Cplex that contain SOS constraints.

MPSGE

- Moved manual to ''docs/tools''.

3.31.1.5 Expert Level APIs

- There are new API files for the "Indexed GDX" (IDX) library in <`GAMS Dir`>\`apifiles`\<`Language`>\`api`:
  - The indexed GDX library can be used to read and write indexed GDX files.
  - Each symbol in such a GDX file must be a parameter.
  - Each parameter must have a domain consisting of a UELs which forms an integer sequence starting at 1.
  - This way the data is provided in a format convenient to store in arrays in the target language.
  - In GAMS such a file can be read using `$LoadIDX` during compilation.
  - In GAMS such a file can be written using `execute_unloadIDX` during execution.
  - The new example <`GAMS Dir`>\`apifiles`\`CSharp`\`xp_CalcInverseIDX` makes use of this API, this example is also used in the APILib model **CSCalcInverse**.

Python

- Fixed a bug regarding lists of strings in Python 3 (e.g. `gdxDataWriteStr()`).

3.31.1.6 Object Oriented APIs

- We changed the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of GAMSSymbols in a GAMSDatabase, the Aliases will be excluded.
  - If we iterate over all GAMSSymbols in a GAMSDatabase, Aliases will be skipped.
  - If we ask explicitly for an Alias in a GAMSDatabase (`GAMSDatabase.GetSet("a")` with `a` being an Alias) we will get a reference to the GAMSSet referenced by the Alias, not the Alias itself.
  - Note: Aliases can appear in a GAMSDatabase only, if it was initialized by a GDX file containing an Alias.
  - The new examples `Alias` demonstrate this new behavior for the different OO API languages.

Python

- Fixed a bug in `GamsDatabase.merge_record` that prevented the function from creating a record if none was found.

3.31.1.7 Model Libraries

GAMS API Library

This is a new collection of GAMS models. It can be accessed in the GAMS IDE at `Model Libraries` -> `GAMS API Library` or through the command line tool `apilib`. The models in this collection can be used as scripts to compile and execute the example applications using the GAMS object oriented APIs as well as the expert level APIs, which can be found in <`GAMS Dir`>`/apifiles`.

- **apiutil.gms : Generates the API Model Library files** (01)
- **testapi.gms : API Quality Assurance Test** (02)
- **Cex1.gms : Test expert level C API to read and write GDX** (03)
- **CSex1.gms : Test expert level C# API to read and write GDX** (04)
- **CPPex1.gms : Test expert level C API to read and write GDX in C++** (05)
- **DCex1.gms : Test expert level Delphi (function) API to read and write GDX** (06)
- **DOex1.gms : Test expert level Delphi (object) API to read and write GDX** (07)
- **DPex1.gms : Test expert level Delphi (pure) API to read and write GDX** (08)
- **Fex1.gms : Test expert level Fortran API to read and write GDX** (09)
- **Jex1.gms : Test expert level Java API to read and write GDX** (10)
- **Pex1.gms : Test Python core API to read and write GDX** (11)
- **VBex1.gms : Test expert level VB.Net API to read and write GDX** (12)

- **Cex2.gms : Test expert level C API to read and write GDX, set options and execute GAMS** (13)
- **CSex2.gms : Test expert level C# API to read and write GDX, set options and execute GAMS** (14)
- **CPPex2.gms : Test expert level C API to read and write GDX, set options, and execute GAMS in C++** (15)
- **DOex2.gms : Test expert level Delphi (object) API to read and write GDX, set options and execute GAMS** (16)
- **Fex2.gms : Test expert level Fortran API to read and write GDX, set options and execute GAMS** (17)
- **Jex2.gms : Test expert level Java API to read and write GDX, set options and execute GAMS** (18)
- **Pex2.gms : Test Python core API to read and write GDX, set options and execute GAMS** (19)
- **VBex2.gms : Test expert level VB.Net API to read and write GDX, set options and execute GAMS** (20)
- **CStrseq.gms : Test object oriented C# API running a sequence of examples based on a transport model** (21)
- **CPPtrseq.gms : Test object oriented C++ API running a sequence of examples based on a transport model** (22)
- **Jtrseq.gms : Test object oriented Java API running a sequence of examples based on a transport model** (23)
- **Ptrseq.gms : Test object oriented Python API running a sequence of examples based on a transport model** (24)
- **VBtrseq.gms : Test object oriented VB.Net API running a sequence of examples based on a transport model** (25)
- **CSBenders.gms : Test object oriented C# API using a (multi-threaded) Benders Decomposition Algorithm** (26)
- **JBenders.gms : Test object oriented Java API using a (multi-threaded) Benders Decomposition Algorithm** (27)
- **PBenders.gms : Test object oriented Python API using a (multi-threaded) Benders Decomposition Algorithm** (28)
- **CSCutstock.gms : Test object oriented C# API using a cutting stock example** (29)
- **JCutstock.gms : Test object oriented Java API using a cutting stock example** (30)
- **PCutstock.gms : Test object oriented Python API using a cutting stock example** (31)
- **CSDomainChecking.gms : Test object oriented C# API for domain checks** (32)
- **JDomainCheck.gms : Test object oriented Java API for domain checks** (33)
- **PDomainChecking.gms : Test object oriented Python API for domain checks** (34)
- **JInterrupt.gms : Test object oriented Java API for interrupting running GAMS jobs** (35)
- **CSTsp.gms : Test object oriented C# API using a Traveling Salesman Problem** (36)
- **JTsp.gms : Test object oriented Java API using a Traveling Salesman Problem** (37)

- **PTsp.gms : Test object oriented Python API using a Traveling Salesman Problem** (38)
- **CSWarehouse.gms : Test object oriented C# API using a warehouse location problem** (39)
- **JWarehouse.gms : Test object oriented Java API using a warehouse location problem** (40)
- **PWarehouse.gms : Test object oriented Python API using a warehouse location problem** (41)
- **CSAlias.gms : Test handling of Aliases in object oriented C# API** (42)
- **JAlias.gms : Test handling of Aliases in object oriented Java API** (43)
- **PAlias.gms : Test handling of Aliases in object oriented Python API** (44)
- **apihtm.gms : Generates HTM apilib library files** (45)
- **CSCalcInverse.gms : Test expert level C# API to read and write indexed GDX** (46)

GAMS Data Library

- Note: Opening an Excel file (.xls) in protected view may work improperly due to Microsoft issue 2745652. Fix: Enable editing of the Excel file and reopen the file.
- **gdxmrw_qp1_starter.gms : Portfolio Analysis with Matlab and GAMS** (91)
- **gdxmrw_qp2_starter.gms : Portfolio Analysis with Matlab and GAMS** (92)
- **gdxmrw_tr1.gms : Transport LP with non-indexed GDX data interface** (93)
- **gdxmrw_tr2.gms : Transport LP with indexed GDX data interface** (94)
- **gdxmrw_qp3.gms : QP solver M-file using GAMS and GDXMRW** (95)
- **gdxxrw_autoopen.gms : Tests that gdxxrw calls the auto_open macro facility** (96)
- **gdxmrw_qp4.gms : Calling GAMS model from Matlab** (97)
- **gdxmrw_intro01_init.gms : Introduction to data transfer between Matlab and GAMS** (98)
- **gdxmrw_intro02_init.gms : Introduction to calling GAMS from Matlab** (99)
- **gdxmrw_irgdx01_init.gms : Reading data from a indexed GDX file with IRGDX** (100)
- **gdxmrw_iwgdx01_init.gms : Writing data into a indexed GDX file with IWGDX** (101)
- **gdxmrw_rgdx01_init.gms : Reading data from a GDX file into a structure with RGDX** (102)
- **gdxmrw_wgdx01_init.gms : Writing structured data into a GDX file with WGDX** (103)
- **gdxmrw_ext01_init.gms : Extended use of GDXMRW** (104)

GAMS Model Library

- Modified models
  - **tsp1** and **tsp4** now use `Singleton Sets`
  - **flowchan** had incorrect boundary conditions
  - `licememo`: give a full solver/model type matrix independent of the actual license
- **partssupply.gms : Parts Supply Problem** (404) (contains ps2_f_s .. ps5_s_mn, which are still available, as submodels)
- **qfilter.gms : Audio filter design using quad-precision MINOS** (405)
- **derivtst.gms : How to test derivatives of functions** (406)
- **carseq.gms : Car Sequencing** (407)
- **pmedian.gms : P-Median problem** (408)
- **sgolfer.gms : Social Golfer Problem** (409)

GAMS Test Library

- Modified Models
  - **trilib01**, **trilib02**, and **trilib03**: Compare numeric gradient and Hessian values in the models. Function `Sine` in the library does not provide derivatives anymore. Lower the tolerances for acceptance due to numerical derivatives of function `Sine`
- **indic04.gms : Test of indicator constraints with explicit labels** (663)
- parlib01.gms : Test extrinsic functions in parcclib (667)
- **convert10.gms : CONVERT test suite - check interval evaluator in Convert** (668)
- **convert11.gms : CONVERT test suite - check interval evaluator in Convert** (669)
- **convert12.gms : CONVERT test suite - check interval evaluator in Convert** (670)
- **lazy01.gms : Test lazy constraints** (671)
- **mps2gms1.gms : Test mps2gms** (672)
- **execmode01.gms : Test execmode behavior** (673)

3.31.2 24.4.2 Minor release (March 15, 2015)

3.31.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Sergey Kuznetsov, Ricardo M. De Lima, and Corey Noone.

3.31.2.2 GAMS System

GAMS

- Fixed potential problem when running on Windows in a workDir containing a `%`.
- Fixed problem with EMP solves with `solvelink=solveLink.asyncGrid%`.
- Fixed problem with GUSS/Grid when using `execute_loadhandle` instead of `handlecollect`.

3.31.2.3 Solvers

ANTIGONE

- New libraries.

CONOPT

- Introduced new boolean option `PreTri2Log` that send message from Conopt's pre-triangular analyzer that go to the listing file also to the GAMS log. The option requires the generation of the model dictionary, so `mymodel.DictFile=1;` has to be added before the `Solve` statement.

CONVERT

- Convert and ConvertD: Fix for writing scalar MCP models that contained fixed variables removed by `holdfixed=1`.
- ConvertD: Add support for external equations in scalar GAMS models.
- ConvertD: Propagate EPS to scalar GAMS models.

Couenne

- New libraries.

Examiner2

- Support added for custom trace files.

GUROBI

- New libraries 6.0.2.

Lindo/LindoGlobal

- New libraries 9.0.157 for Linux, Mac OS X, and Windows.

LocalSolver

- New libraries 5.0 (20150119).

Mosek

- New libraries 7.1.0.24.

SCIP

- New libraries 3.1 #67d713c.
- Fixed overwriting of solvetrace file by final NLP resolving.

SoPlex

- New libraries 2.0 #8381aa4.

3.31.2.4 Tools

GDXMRW

- `gdxInfo`: fix output of domains in symbol declaration
- `gdxInfo`: handle aliases properly

3.31.2.5 Object Oriented APIs

- Fixed overwriting of the default value for the `integer1` option when running with `GAMSModelInstance`, which lead to unexpected solver behavior.
- Fixed potential problem with `GAMSModelInstance` used with BARON.

.NET

- New property `GAMSSymbol.DomainsAsStrings`: Domains of Symbol, each element is a string, if the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set.

Java

- Changed naming scheme of GDX output scratch file to sequence number.

Python

- Fixed a bug in the constructor of all subclasses of `_GamsSymbol` that occurred when the explanatory text was omitted.
- New property `_GamsSymbol.domains_as_strings`: Domains of Symbol, each element is a string. If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.

3.31.2.6 Expert Level APIs

GMO

- Fixes to `gmoGetRowJacInfoOne` and `gmoGetColJacInfoOne`: In case of an empty row/column, now return -1 in colidx/rowidx if index base is 0.

3.31.2.7 Model Libraries

GAMS Model Library

- **dyncge.gms : A Recursive-Dynamic Standard CGE Model** (410)

3.31.3 24.4.3 Maintenance release (April 02, 2015)

3.31.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Guillaume Erbs and Emiliano Traversi.

3.31.3.2 Solvers

Examiner2

- Fixed incapability to continue on a trace file that already has trace records in it.

LocalSolver

- Corrected computation of values for free variables that appeared (linearly) in one equation only.

3.31.3.3 Tools

GDXXRW

- In 24.4.2 we quietly introduced a new way to determine the content of a sheet. This resulted in a bug for empty sheets and sheets that have been saved with an active filter. This has been fixed.

3.31.4 24.4.4 Maintenance release (May 12, 2015)

3.31.4.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Thomas Counsell, Michael Ferris, Jean Mercenier, and Loïc Ventre.

3.31.4.2 Solvers

Gurobi

- New libraries 6.0.4.
- The new libraries do not work on Windows XP anymore. As the library for COIN-OR solvers, SCIP, and SoPlex link to the Gurobi library, these solvers also do not work on Windows XP anymore.

Ipopt

- New libraries for Linux and Mac OS X.
  - Fixed an issue in the MA97 interface that lead to convergence problems.

Minos

- Consider the number of nonlinear constraint variables, not just the nonlinear objective variables, when computing the superbasics limit: memory is plentiful and cheap.
- Fixed case of memory corruption that resulted when using an initial point containing very many superbasic variables. If the initial point contains more than 500 superbasics, limit the Hessian dimension to 500 even though the superbasic limit is larger.

Mosek

- New libraries 7.1.0.30.

Xpress

- New libraries Optimizer 27.01.08 (was 27.01.02 before).

3.31.4.3 Tools

GDXDUMP

- Fixed a problem when writing a scalar or scalar variable/equation in format CSV.

3.31.4.4 Object Oriented APIs

- Fixed a potential problem with `GAMSModelinstance` and certain OS culture settings.

3.31.4.5 Model Libraries

GAMS EMP Library

- **transecs**: Fixed formulation as embedded complementarity system and provide equivalent alternative as single-agent equilibrium system.

3.31.5 24.4.5 Maintenance release (May 26, 2015)

3.31.5.1 Solvers

COIN-OR solvers, SCIP, SoPlex

- On Windows 32bit, OsiGurobi was split off into a separate library, so that other COIN-OR solvers (e.g., Bonmin, Cbc, Couenne, Ipopt) and SCIP and SoPlex do not require the Gurobi 6.0.4 library anymore. Thus, for this release, only Gurobi and OsiGurobi do not run on Windows XP anymore (see 24.4.4 notes on Gurobi).

3.31.6 24.4.6 Minor release (June 26, 2015)

3.31.6.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Erwin Kalvelagen, Rich Roberts, and Jens Schulz.

3.31.6.2 Solvers

CONOPT

- New libraries 3.16F.
- New option `LMUSDF` for handling definitional equations.
- New option `RVFILL` for memory allocation when memory is tight.
- Changed a sorting procedure in the preprocessor. Models with some very dense rows and many pre-triangular variables can experience a significant speedup for the preprocessor.

CPLEX

- New libraries 12.6.2.0.
- Option changes:
  - The popular option value -1 for `BarCrossAlg` to turn off the crossover after a run with barrier has been deprecated. The new way to turn off crossover is to set the new option `SolutionType` to 2.
  - The option `SolutionTarget` has been renamed to `OptimalityTarget`.
  - The option `CutsFactor` has a new default (-1).
- New options:
  - `BQPCuts`: Boolean Quadric Polytope cuts for solving nonconvex QP or MIQP to global optimality.
  - `CPUMask`: Switch and mask to bind threads to processors. Binding threads to processors/cores helps to reduce variability in running time when using multiple threads.
  - `SolutionType`: Type of solution (basic or non basic) for an LP or QP. Set this option to 2 to prevent crossover after barrier.

MOSEK

- New libraries 7.1.0.31.

3.31.6.3 Tools

GAMSIDE

- Added `.ref` for reference file to the files open dialog.
- Left arrow in the first character position now moves to the end of the previous line.

GDXXRW

- Restore the old behavior when reading a set with `Values=Strings`; all elements will be included, not only the ones with a string.
  - Option `Values=String` and `All` are now deprecated and results in a warning; replaced with `Dense`.
  - New options `Values=Dense` or `Sparse`.

XLSTalk

- Allow for up to 9 parameters for macro call.

3.32 24.3 Distribution

3.32.1 24.3.1 Major release (July 31, 2014)

3.32.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Bond, Sebastian Bothor, Jared Erickson, Michael Ferris, Josef Kallrath, Bastian Niebel, Matt Preston, and Tom Rutherford.

3.32.1.2 Platforms

- The Linux 32bit and Solaris 32bit distributions have been dropped (as announced).
- Support for Windows XP may be dropped with some future GAMS version. As several of our solver vendors have already dropped support for Windows XP, some components of a GAMS system may cease to work under Windows XP in the future. If you notice that a 64bit GAMS system is not working on your Windows XP 64bit machine, please let us know.

3.32.1.3 GAMS System

GAMS

- Introduced new keyword `Singleton Set`: A `Singleton Set` in GAMS is a special `Set` that has at most one element (zero elements are allowed as well). `Singleton Sets` can be especially useful in assignment statements since they don't need to be controlled by a controlling index nor an indexed operator, e.g.:

```
Set           s         / s1*s3 /;
Singleton Set single(s) / s2    /;
Parameter p(s);
Scalar    x;

p(s) = ord(s);
x = p(single);
```

  NOTE: Assigning membership to `Singleton Sets` is different than to usual sets. Since `Singleton Sets` can never have more than one element, any assignment to a `Singleton Set` first clears or empties the set, so no explicit clear is necessary. This is illustrated in the following example:

```
Set            i     Static Set            / a, b, c /
               ii(i) Dynamic Set           /    b    /;
Singleton Set  si(i) Dynamic Singleton Set /    b    /;

ii('c') = yes;
si('c') = yes;

Display ii, si;
```

  Here is the output from the `display` statement in the listing file:

```
----      8 SET ii  Dynamic Set
b,    c

----      8 SET si  Dynamic Singleton Set
c
```

  More information can be found in the GAMS Users Guide.

  - The behavior of assignments to `Singleton Sets` can be influenced by the new option `strictSingleton` [0/1]: This option affects the behavior of a membership assignment to a `Singleton Set`. With `strictSingleton = 0` GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With `strictSingleton = 1` (default), such an assignment raises an error. This option be set via an option statement and via a command line option.
  - Similarly, data statements for `Singleton Sets` can be influenced by the new dollar control options `$onStrictSingleton`/`$offStrictSingleton`: With `$offStrictSingleton` GAMS does not complain about a data statement for a `Singleton Set` that has more than one element but takes the first one. With `$onStrictSingleton` (default), such an assignment raises an error.

- Introduced so-called obfuscated save files, which are save files where symbol and UEL names have been obfuscated. The new options `saveobfuscate` (`so`) and `xsaveobfuscate` (`xso`) can be used to generate uncompressed and compressed, respectively, obfuscated save files. Additionally, a new option `restartNamed` (`rn`) has been added which can be used to bring back the original names when restarting from an obfuscated save file. The intended use is the following.

  - Compile (only) a GAMS model into a named and an obfuscated save file:

```
$call gams trnsport a=c s=0named saveobfuscate=0anon
```

– Move the obfuscated save file to a non-secure machine and execute it there:

```
$echo * Empty > empty.gms
$call gams empty r=0anon s=1anon
```

– Bring the new (still obfuscated) save file with the results back to the safe machine and do a continued compilation with reporting and export. The continued compilation restarts from the obfuscated save file with all the results, etc., but gets a second save file with proper names through option `restartNamed`:

```
$echo execute_unload 'supply', supply.m; > unload.gms
$call gams unload r=1anon restartNamed=0named
```

In this execution, everything is taken from the obfuscated restart file, except for the symbol and UEL names and the listing file title and subtitle, which are taken from the file specified via `restartNamed`.

- Allow to load the universe of labels from a GDX file into a set at run-time:

```
execute_load 'someFile', someSet=*;
```

Note, that only labels known to the GAMS program will be loaded.

- Fixed a bug that caused wrong results when evaluating `prod` (or `smin`/`smax`) over an empty set inside `sum` like in the following example:

```
sets r          / 1    /
     s          / 1, 2 /
     rs(r,s)    / 1.1  /
     subrs(r,s) / 1.2  /;
scalar z1;
z1 = sum(rs, prod(subrs(rs), 2));
display z1;
```

- Fixed a bug in calling error logging routine for extrinsic functions from within solvers.

Function libraries

- The extrinsic function library **cppcclib** has been expanded to include functions for the PDF and CDF of the trivariate normal distribution. Additionally, documentation for **cppcclib** has been added to Appendix J of the GAMS User's Guide and the relevant testlib models `cpplib00` thru `cpplib05` have been added or updated.

3.32.1.4 Solvers

ANTIGONE, Bonmin, Cbc, Couenne, SCIP, Sulum

- Solvetrace files now include the GAMS input name (usually GAMS model name with `.gms` extension stripped) in the header line.

BARON

- New libraries 14.0.2
  - Significant advances in the handling of integer programs. In addition to several classes of integer cutting planes, calls to MIP solvers and hybrid LP/MIP/NLP relaxations for MINLPs have been added.
  - Complete rewrite of the interfaces to LP solvers.
  - Improvements in probing routines.
  - More robust checks for the validity of the solution of LP/NLP subsolvers.
  - Introduced interfaces to COIN-OR/OSI and CBC 2.8.9.
  - Increased numerical robustness for numerically challenging problems.
  - New range reduction techniques.
  - Systematic treatment of infeasible problems. With the `CompIIS` option, which by default is 0, the computation of an Irreducible Inconsistent Set (IIS) can be requested. Five different algorithms are available, with corresponding values of `CompIIS` equal to 1, ..., 5. Algorithm 1 is a fast heuristic, while algorithms 2 through 5 are more time consuming exact algorithms. If an IIS is found, it is reported in the GAMS listing file. BARON does not consider bounds on binary variables to be part of the IIS. For general integers, the option `IISint` can be be used to signal that general integers should be considered as potential members of the IIS, i.e, integrality constraints are questioned.
- Fixed handling of BARON termination status when activating `DeltaTerm` option.

BONMIN

- Dropped MIP capability (use CBC instead).

CONOPT

- New libraries 3.16B.
  - The new option `Lsusdf` was added. If turned on (the default) CONOPT's preprocessor will look for definitional constraints which are constraints of the form `x = f(y)` where the bounds on `x` are wider than the range of the function `f`, given the bounds on `y`. CONOPT will search for and select a maximal set of independent definitional constraints. The dependent variable in a definitional constraints will be selected for the initial basis and CONOPT will try to use the definition to initialize `x`. There are two other options associated with this procedure: If `Lsuqdf` is enabled (default), then only unique definitional constraints are selected. If it is disabled, then option `Lfusdf` specifies a limit (default 2) on the number of candidates a definitional constraint can have.
  - The option `Lsflsh` – flush the buffer, has now been implemented and is automatically turned on if there is a systems error.
  - The lower bound on option `Rtipvr` changed from 1.e-3 to 1.e-10.

Convert

- The AMPL writer supports special ordered sets, semicontinuous variables, and semiinteger variables now.
- Row names in `.lp` and `.mps` files now start with 'e' instead of 'c', so they match the names written by the `dict` option.

CPLEX

- New libraries 12.6.0.1.

CPLEX, SCIP, XPRESS

- Fixed handling of indicator constraints when specified with explicit labels.

DE

- New option `VaRBigM` to control the Big M for a Value at Risk reformulation.

EMPSP

- New keywords `VaRUp` (=`VaR`) and `VaRLo`: These keywords can be used to optimize the Value at Risk for a certain confidence level. The syntax is similar to the one from `cVaRUp` (=`cVaR`) and `cVaRLo`:

  ```
  VaR [rv var] scalar
  ```

  More information can be found here.

- Changed the order of the parameters for the triangular distribution from

  ```
  randvar <name> triangular <low> <high> <mid>
  ```

  to

  ```
  randvar <name> triangular <low> <mid> <high>
  ```

Examiner2

- Fixed a bug in processing special ordered sets.

GUSS/Scenario Solver

- GUSS/Scenario solver can now be combined with the GAMS Grid Facility (see example `GUSSGRID` in the GAMS Model Library).
- New option `RestartType` to determines restart point for the scenarios:
  - 0: Restart from last solution (default)
  - 1: Restart from solution of base case
  - 2: Restart from input point
- New option `SolveEmpty` (default 0) to limit the number of empty scenarios (no scenario data) that are being solved. When the limit is reached, further empty scenarios will be skipped. Skipped scenarios will be reported to the log and listing file.

Ipopt

- New libraries.

Knitro

- As Ziena Optimization has dropped support for Knitro on Solaris (x86) a while ago, we plan to drop GAMS/Knitro on Solaris with the next release.

Lindo/LindoGlobal

- New libraries 8.0.550.
- LindoGlobal is no longer available for Sparc Solaris (as announced).

Mosek

- New libraries 7.0.0.121 (Linux, Mac OS X) and 7.0.0.123 (Windows).

OQNLP

- OQNLP is no longer available for Linux (as announced).

OS

- GAMS to OSiL conversion now creates more compact instances, especially for quadratic equations and long sums or products in general nonlinear expressions.

SCIP

- New libraries `3.1 #695c979`.
  - Added new primal heuristics "random rounding", "proximity", and "dual value", new branching rule "cloud branching", and new node selectors "breadthfirst" and "uct".
  - Added support for strong branching with domain propagation in full strong and reliability pseudo cost branching.
  - Improved numerical stability (now taking the rank of cuts into account; more checks on LP solution; disabled scaling in feasibility check of nonlinear constraints).
  - Many improvements in presolving.
  - Strong branching LP solutions are now checked for feasibility.
  - Changed or removed parameters:
    - branching/relpscost/maxlookahead: default changed from 9 to 8.
    - branching/relpscost/maxreliable: default changed from 8 to 5.
    - constraints/bivariate/scaling: default changed from TRUE to 'o' (type changed to character).
    - constraints/quadratic/scaling: default changed from TRUE to 'o' (type changed to character).

* constraints/soc/scaling: default changed from TRUE to 'o' (type changed to character).
* constraints/varbound/maxlpcoef: default changed from 1E6 to 1E9.
* heuristics/crossover/minnodes: default changed from 500 to 50.
* heuristics/dins/minnodes: default changed from 500 to 50.
* heuristics/feaspump/objfactor: default changed from 1 to 0.1.
* heuristics/rens/minnodes: default changed from 500 to 50.
* heuristics/rins/freq: default changed from -1 to 25.
* heuristics/rins/freqofs: default changed from 5 to 0.
* heuristics/rins/minfixingrate: default changed from 0 to 0.3.
* heuristics/rins/minnodes: default changed from 500 to 50.
* heuristics/shiftandpropagate/sortkey: default changed from 'u' to 'v'.
* lp/checkfeas: replaced by new parameters lp/checkdualfeas and lp/checkprimfeas.
* numerics/dualfeastol: default changed from 1E-6 to 1E-7.
* presolving/dualfix/∗: replaced by propagating/dualfix/∗
* propagating/pseudoobj/presoldelay: default changed from TRUE to FALSE.
* propagating/pseudoobj/timingmask: default changed from 5 to 7.
* propagating/redcost/timingmask: default changed from 2 to 6.
* separating/cgmip/objweighsize: renamed to separating/cgmip/objweightsize and default changed from FALSE to TRUE.
* separating/minefficacyroot: default changed from 0.01 to 0.001.
* separating/closecuts/relintnormtype: removed

SoPlex

- New libraries `2.0.0`.

XPRESS

- New libraries 26.01.08.

3.32.1.5 Tools

GDX2SQLITE

- GDX2SQLITE is a new tool to dump the complete contents of a GAMS GDX file into a SQLite database file.

GDXDUMP

- New option `SymbolsAsSet` to write the symbol table for a set as data.

GDXMRW

- New utilities `irgdx` and `iwgdx` for exchanging indexed GDX data with Matlab.

GDXRENAME

- New utility to rename the same unique elements in a GDX file using a mapping given by a second GDX file.

GDXXRW

- New option to allow the use of R1C1 notation to specify a cell or a range.
- Reading a set using the option `Values=string` now skips empty cells.

3.32.1.6 Expert Level APIs

GMO

- Removed previously deprecated function `gmoDirtyExtractDefVar`.
- Added a number of functions to access information from an EMP info file, to compute the optimality gap, to access extrinsic function libraries, and to get the name of the GAMS input file.

3.32.1.7 Object Oriented APIs

- New example `transport14`.
- New method `GAMSSymbolRecord.Key(int index)` (Java: `GAMSSymbolRecord.getKey`, Python: `_GamsSymbolRecord.key(int index)`) to retrieve the key of `GAMSSymbolRecord` (Python: `_GamsSymbolRecord`) for a given positional index.
- `GAMSSymbol.CopySymbol` now works for the universe of a `GAMSDatabase` (`GAMSDatabase.GetSet("*")`). When copying into the Universe, a merge will be performed.
- Real domains are now registered when exporting a `GAMSDatabase` to GDX (so far, only relaxed domains were registered).
- `GAMSJob.Run` (Python: `GamsJob.run`) now creates `OutDB` (Python: `out_db`) also if it raises a `GAMSExceptionExecution`.
- `GamsModelInstance.Solve` (Java/Python: `GamsModelInstance.solve`) now also works for solvers which require a subsolver, e.g., DICOPT.

.NET

- Fixed default value for `systemDirectory` argument in `GAMSWorkspace` constructor when using MONO: If no value is given, first the `PATH` and then the (`DY`)`LD_LIBRARY_PATH` is checked for a valid GAMS system directory.

Java

- It is no longer necessary to specify `-Djava.library.path` when running a program. If `java.library.path` is specified, the shared libraries will be loaded from `java.library.path`. Otherwise, the shared libraries will be loaded from the class path that contains `GAMSJavaAPI.jar`.
- It is no longer necessary to set up environment variables (`PATH`, (`DY`)`LD_LIBRARY_PATH`) before running a program to find the GAMS system directory, as it can now be specified during run time.
- In the `GAMSWorkspace` default constructor, the default setting for finding the GAMS system directory from environment variables in the following order (depends on the target platform) are applied:
  - Windows: first from `PATH` environment variable. If not found, then from the Windows registry `gams.location`,
  - Mac OS X: first from `PATH` environment variable. If not found, then from `DYLD_LIBRARY_PATH`,
  - other Unix: from `PATH` environment variable. If not found, then from `LD_LIBRARY_PATH`.
- In the non-default `GAMSWorkspace` constructor, the following rules are applied:
  - In case a user specifies a system directory, the API will verify the directory and will not search for GAMS system directory from an environment variable, even when the directory is invalid.
  - In case the specified system directory is `null` or a user does not specify a system directory, the API will apply the default setting from above.
- A memory leak in `GAMSDatabaseIterator` has been closed.
- Issues when using a non-standard locale (`LANG` environment variable) have been fixed.
- All deprecated classes and methods since 24.1 have been removed.

Python

- New behavior on determining a system directory automatically when a workspace is created.
  - Linux: If no system directory is specified in the `GamsWorkspace` constructor, check `PATH` first. If no system directory was found, check `LD_LIBRARY_PATH`.
  - Mac OS X: If no system directory is specified in the `GamsWorkspace` constructor, check `PATH` first. If no system directory was found, check `DYLD_LIBRARY_PATH`.
  - Windows: If no system directory is specified in the `GamsWorkspace` constructor, check the Windows registry.

3.32.1.8 Model Libraries

GAMS Data Library

- `MakeQL`: Moved querylibrary generator into `trisource.zip`, which comes with Test Library models **trilib01**, **trilib02**, **trilib03**, and **trilib04**. Removed `MakeQL` model.
- **invert1.gms : Matrix inversion via R** (89)
- **invert2.gms : Matrix inversion via Matlab** (90)

GAMS Model Library

- **clad.gms : Computation of Fairs extramarital affairs model estimates** (397)
- **gussex1.gms : Simple GUSS example** (398)
- **gussrisk.gms : Simple investment example with varying weight for risk using GUSS** (399)
- **gussgrid.gms : Simple GUSS Grid example** (400)
- **circpack.gms : Pack circles in the smallest possible rectangle** (401)
- **tablelayout.gms : Configuring text layout in table cells to minimize table height** (402)
- **asyncjobs.gms : Execute asynchronously several GAMS jobs and collect the fastest** (403)

GAMS Test Library

- **trilib01**: Reworked tricclib.c source code. Rewrote querylibrary generator.
- **single01.gms : Check handling of singleton sets** (639)
- **execerr1.gms : Test for execerr option** (640)
- **single02.gms : Check assignment to singleton sets** (641)
- **scensol4.gms : Basic GUSS Test** (642)
- **gdxmrw06.gms : run a battery of GDXMRW tests** (643)
- **single03.gms : Check singleton sets in put statement** (644)
- **unload11.gms : Check that GAMS does not crash when writing to non-existing folder** (645)
- **refact00.gms : Check that GAMS produces expected workfile with option sys14=1** (646)
- **refact01.gms : Refactor suite test 1** (647)
- **scenempty.gms : Empty scenario GUSS Test** (648)
- **obfusc01.gms : Test use if obfuscated workfile** (649)
- **load11.gms : Load UEL Table** (650)
- **gussskip.gms : Simple GUSS example with skipped scenario** (651)
- **refact02.gms : Refactor suite test 2** (653)
- **cpplib03.gms : Test extrinsic functions in cppcclib** (654)
- **cpplib04.gms : Test extrinsic functions in cppcclib** (655)
- **cpplib05.gms : Test extrinsic functions in cppcclib** (656)
- **cpplib00.gms : Test build of CPP library** (657)
- **syschk2.gms : Test impact of sys10 setting** (658)
- **scensol5.gms : Test handling of scenario dictionary sets with more than 50 entries** (659)
- **call5.gms : Check that gams works with COMSPEC unset** (660)
- **idxoper1.gms : Test indexed operations** (661)
- **gdxsqlite1.gms : Test basic functionality of GDX2SQLITE tool** (662)

3.32.2 24.3.2 Minor release (August 29, 2014)

3.32.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Alvaro Lorca Galvez, Scott McDonald, Tom Rutherford, Nick Sahinidis, and Uwe Schneider.

3.32.2.2 GAMS System

GAMS

- Allow empty scalar data statements:

```
$onempty
scalar xyz / /;
```

Extrinsic Function libraries

- Pass on parameter file name via `LibInit` call.

3.32.2.3 Solvers

BARON

- New libraries 14.0.3.

CBC

- New libraries.

CONOPT

- New libraries 3.16C.
  - Added checks for internal intermediate results being NaN (Not A Number). If this happens, CONOPT will stop and return a message about it. The solver status will return 4 "Terminated by Solver" and model status 6 or 7, "Intermediate Infeasible" or "Intermediate Feasible."

CONVERT

- Fixed bug in interval evaluations for functions and gradients.
- The interval evaluations are now triggered by their own option (e.g. `intervalEval=yes`) instead of being part of every Jacobian or Hessian dump.

Cplex

- Some Cplex tuning parameters had no or the wrong effect. This has been fixed.
- The BCH usercutcall was not called in case of new constrains only for true cuts (see e.g. GAMS Model library model bchtsp). This has been fixed.

Examiner2

- Fixed error in processing options file.
- Fixed error in trace file generation.

Ipopt

- New libraries.

Mosek

- New libraries 7.0.0.126.
  - Fixed an issue with using the Mosek extended license for MIP solving on Mac OS X.

Osi links

- Fixed writing MPS files with row and column names.

SCIP

- New libraries 3.1 #322574a
  - Changed default of option `heuristics/proximity/minimprove` from 0.25 to 0.02.
  - Changed default of option `heuristics/proximity/usefinallp` from TRUE to FALSE.

XPRESS

- New libraries 26.01.14 for Linux and Windows.

3.32.2.4 Tools

GDXDUMP

- When generating `$GDXIN filename`, the filename now includes the full path of the GDX input file.

GDXXRW

- In the previous release, we changed the behavior that when reading with `Values=String`, the empty cells no longer created an entry. Because reading with this option was the default for the cases with `RDim=0` or `CDim=0`, we changed this default to `Values=NoData` in order not to break existing code.

Shellexecute

- Fixed error causing problems during parameter processing.

3.32.2.5 Expert Level APIs

- Delphi: Distinguish between 32 bit and 64 bit compiler.

3.32.2.6 Object Oriented APIs

- Make more GAMS options available through the GAMSOptions class:
  - GAMSOptions.AppendExpand: Expand file append option
  - GAMSOptions.AppendOut: Output file append option
  - GAMSOptions.DumpOpt: Writes preprocessed input to the file input.dmp
  - GAMSOptions.DumpParms: GAMS parameter logging
  - GAMSOptions.ErrMsg: Placing of compilation error messages
  - GAMSOptions.Expand: Expanded (include) input file name
  - GAMSOptions.FErr: Alternative error message file
  - GAMSOptions.JobTrace: Job trace string to be written to the trace file at the end of a Gams job
  - GAMSOptions.LimCol: Maximum number of columns listed in one variable block
  - GAMSOptions.LimRow: Maximum number of rows listed in one equation block
  - GAMSOptions.LogLine: Amount of line tracing to the log file
  - GAMSOptions.On115: Generate errors for unknown unique element in an equation
  - GAMSOptions.Output: Output file
  - GAMSOptions.PageContr: Output file page control option
  - GAMSOptions.PageSize: Output file page size (=0 no paging)
  - GAMSOptions.PageWidth: Output file page width
  - GAMSOptions.Reference: Symbol reference file
  - GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
  - GAMSOptions.Suppress: Compiler listing option
  - GAMSOptions.Symbol: Symbol table file
  - GAMSOptions.TraceLevel: Solvestat threshold used in conjunction with a=GT

3.32.2.7 Model Libraries

GAMS Data Library

- Fixed some errors in some Matlab examples.

3.32.3 24.3.3 Minor release (September 19, 2014)

3.32.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Henrik Dahl.

3.32.3.2 Solvers

ANTIGONE, Bonmin, CBC, Couenne, Ipopt, SCIP

- Fixed issue loading MKL libraries on Linux machines with AVX2 instruction set.

3.32.3.3 Tools

ASK, GDXVIEWER, SQL2GMS, XLS2GMS

- Fixed problem with character set used for error messages.

GDXXRW

- Fixed error when reading special values from Excel.

MDB2GMS, SQL2GMS

- Fixed problem when using comma as decimal separator.

3.32.3.4 Object Oriented APIs

Java

- Fixed a location of listing file when creating a job from (full-path) file without giving a job name.

3.33 24.2 Distribution

3.33.1 24.2.1 Major release (December 09, 2013)

3.33.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Fernando Consigli, Eligius Hendrix, Erwin Kalvelagen, Alexander Lieder, Phani Murukutla, Yaser Tohidi, and Alexander Weber.

3.33.1.2 Platforms

- Sparc Solaris builds are now built on a SunOS 5.10 (Solaris 10) machine.
- We plan to drop support for Linux 32bit and Sparc Solaris 32bit with the next major release (24.3). As a consequence, we plan to also drop OQNLP on Linux 64bit.

3.33.1.3 GAMS System

Installer

- The dialog for choosing a license file to be copied starts from the user's desktop now
- Fixed a bug, when trying to copy license file to itself

3.33.1.4 Function libraries

- A new extrinsic function library **cppcclib** was added to the system. This library is coded in C++ and implements PDFs and CDFs for the univariate and bivariate normal distributions. The use of C++ is crucial here, as an expression class together with operator overloading is used to do all the relevant computation. In this way, we can automatically compute exact derivatives (first and second) for the function values being computed. Further information on extrinsic function libraries can be found in the GAMS User's Guide, Appendix J. The testlib models `cpplib01` and `cpplib02` are also relevant.

3.33.1.5 GAMS

- Fix bug that caused a negative value for model attribute `etSolver`
- `EXECUTE_LOADDC`: Enhanced `execute_load` with domain checking. Any domain violation will be reported and flagged as execution error. In contrast, `execute_load` ignores all domain violations and loads only data that meets the domain restrictions.
- `EXECUTE_UNLOADDI`: This new keyword does not only write the defined symbols to GDX but also the domain sets.
- Loading one dimensional sets from multi-dimensional parameters/sets via `load i&lt;gdxsym`. Details can be found in the *gdxutils* document in the tools section of the documentation tree.
- New (command line) option `gdxUELs` [squeezed/full]: If `gdxUELs` is set to `squeezed` (default) only the UELs that are required by the exported symbols are registered to GDX (compared to all UELs with `gdxUELs=full`, which behaves like the former default).
- New (command line) option `DumpParmsLogPrefix` (synonym `DPLP`) prefixes log lines that are triggered by `DumpParms=2` with a specific string for easy filtering of these lines.
- New (command line) option `intVarUp` as a replacement for the command line option `pf4` (which is still usable as a synonym for `intVarUp`)
- The option `sys10`, which changes rpower to ipower when the exponent is constant and within e-12 of an integer, is also available as command line option now
- New option `DmpOpt`: This writes all options, which can be set using the option statement, and their values to the listing file

- GAMS checks now more frequently if a GAMS program exceeds the preset elapsed time limit `EtLim` (default 1e20 seconds). In the past this was done only before solve and execute statements. Now, GAMS checks this limit at the same time GAMS checks for a pending Ctrl-C event.

- Renamed model status `7 Intermediate Nonoptimal` to `7 Feasible Solution`. The string constant `%modelStat.intermediateNonOptimal%` is still recognized by the GAMS compiler, but it is advised to switch to `%modelStat.feasibleSolution%`. The model status test is e.g. printed in the solve summary in the listing file and can be written to put files with the model attribute `mymodel.tModStat`.

- New model attributes:

  - `myModel.marginals`: Indicates the presence (1) or absence (0) of a dual solution from the solver after the solve statement. In some circumstances, a solver does not provide a dual solution (.m), in such a case GAMS will not print the marginal column in the solution listing and set the marginal field in variables and equations to NA.
  - `myModel.defPoint`: If this attribute determines what point is passed to the solver as an input point. By default, the user supplied point (set via `x.l(j)=...` and `e.m(i)=...`) is passed to the solver. In some circumstances (mostly during debugging) it can be useful to pass a standard default input point, i.e. level set to 0 or lower bound in case 0 is not within the bounds and marginal set to 0. `myModel.defPoint` controls this behavior: Values other than 1 or 2 result in default behavior, value 1 results in passing default levels and marginals, value 2 results in passing the levels set by the user and defaults (0) for the marginals.

- Added `%system.dirsep%` and `system.dirsep` (for use in put files) to get access to the OS specific file/directory separator character. On Windows platforms this is \ and on Unix and Mac this is `/`. This helps writing platform independent GAMS models.

- Added option 6 to `[file].TF` (text fill) fills `.te()` with quoted element names separated by spaces

- Allow the `Alias` statement on multidimensional sets as well:

```
Set i       / i0*i9 /
    j       / j0*j9 /
    ij(i,j) / #i.#j /;
Alias (ij, ji);
```

3.33.1.6 Solvers

ANTIGONE, BARON, Couenne, SCIP

- Now return model status 7 (feasible but not necessarily optimal) instead of 2 (locally optimal) when finding feasible solution for a model without discrete variables and not having proven global optimality (local optimality cannot be guaranteed).

ANTIGONE

- Fixed bug where optimality gaps were reported for convex problems.

BARON

- New libraries 12.7.3
- Performance improvements in local search, branching, integer presolve, and relaxations for problems with bilinear and/or integer variables
- Added facilities for complementarity problems
- Absolute and relative constraint feasibility and integrality feasibility tolerances
- Added flexible termination criteria based on progress
- Improved treatment of unbounded/infeasible problems
- Selection of specific NLP solvers to be included in BARON's dynamic NLP solver selection strategy
- Automatic setting of many options based on problem characteristics and learning algorithms. As a result, many options are now deprecated
- New options:
  - `AbsConFeasTol`: Absolute constraint feasibility tolerance
  - `AbsIntFeasTol`: Absolute integer feasibility tolerance
  - `AllowExternal`: Indicator for use of External NLP solver with automatic NLP solver selection
  - `AllowIpopt`: Indicator for use of IPOPT with automatic NLP solver selection
  - `AllowMinos`: Indicator for use of MINOS with automatic NLP solver selection
  - `AllowSnopt`: Indicator for use of SNOPT with automatic NLP solver selection
  - `DeltaA`: Absolute improvement for insufficient progress termination
  - `DeltaR`: Relative improvement for insufficient progress termination
  - `DeltaT`: Time interval for insufficient progress termination
  - `DeltaTerm`: Indicates whether insufficient progress termination is on or off
  - `RelConFeasTol`: Relative constraint feasibility tolerance
  - `RelIntFeasTol`: Relative integer feasibility tolerance
- Options deprecated: `modbrpt`, `convexratio`, `maxredpass`, `maxnodepass`, `redreltol`, `redabstol`, `postreltol`, `postabstol`, `hreltol`,`habstol`, `maxheur`, `pbin`, `twoways`, `pstart`, `pend`, `pfreq`, `profra`, `pxdo`, `maxpretime`, `basfra`, `baskp`, `prelpdo`, `numbranch` and `numstore`.

Bonmin(H), CBC, Couenne, Ipopt(H), OS, OsiCplex, OsiGurobi, OsiMosek, OsiXpress, SoPlex

- The solver manual coin.pdf has been split into one document for each solver(group) (bonmin.pdf, cbc.pdf, couenne.pdf, ipopt.pdf, os.pdf, osi.pdf).

CPLEX

- New libraries 12.6.0.
- Cplex 12.6 solves non-convex (MI)QP problems to global optimality when parameter `SOLUTIONTARGET` is set to 3.
- Cplex 12.6 also offers the capability to solve a single MIP instance distributed over a number of machines. The feature, knows as *Distributed MIP*, is available with GAMS/CplexD only and requires a special license and additional software.

CONOPT

- New libraries 3.15M.
  - Fixed a problem with the definition and execution of 'implied free' post-triangular variables. The tolerance was too loose compared with other tolerances and a projection was missing. That could result in functions or derivatives being called with variables slightly outside their bounds (by up to 4.e-10).

Convert

- Fixed writing of mod operator in AMPL syntax.

ConvertD

- The converter to OSiL format can now handle SOS1 and SOS2 variables.

EMPSP

For the keyword `cvarup` (which is the same as `cvar`), the meaning of the defined `scalar` was changed:

```
cvarup [rv var] scalar
```

`Scalar` represents now the confidence level for the Conditional Value at Risk. It holds `NewScalar = 1 - OldScalar`.

Gurobi

- New libraries 5.6
- New options:
  - `PreSOS1BigM` and `PreSOS2BigM`: These new parameters provide user control of presolve SOS linearization
  - `Disconnected`: MIP models are sometimes made up of multiple, independent sub-models. This parameter controls the strategy used to exploit this structure
- Distributed MIP algorithms (in connection with Gurobi's Compute Server):
  - distributed tuning (option `TuneJobs`)
  - distributed concurrent MIP (option `ConcurrentMIPJobs`)
  - See also option `ServerPool` and `ServerPassword`

Ipopt/IpoptH, Bonmin/BonminH, Couenne

- On Linux and Windows, MKL PARDISO has been enabled as additional linear solver for Ipopt (experimental). To try it out, set the option `linear_solver pardiso`.
- For users with an IpoptH license, OpenMP support has been enabled for the HSL codes MA86 and MA97.
  The number of threads to use for HSL MA86, HSL MA97, and PARDISO is controlled by the GAMS threads option.

KNITRO

- New libraries 9.0.0.
- MPEC models are now supported.

Lindo/LindoGlobal

- New libraries 8.0.483.

Mosek

- New libraries 7.0.0.96.
- Mosek provides two algorithms for solving problems with discrete variables: 1) mixed-integer optimizer (`MSK_OPTIMIZER_MIXED_INT`) and 2) mixed-integer optimizer for conic and linear problems (`MSK_OPTIMIZER_MIXED_INT_CONIC`). Algorithm 1 has been available since the introduction of MOSEK to GAMS, but requires an additional license code. Algorithm 2 has been introduced with version 7 of MOSEK (GAMS 24.1). Benchmarks have shown that both algorithms perform very similar. While we will support algorithm 1 for existing GAMS/MOSEK customers for some time, it will not be possible to purchase this option for new GAMS/MOSEK users. They will have to use algorithm 2.
- Fixed issues with solution obtained from fixed solve when using Mosek's conic MIP solver.
- An experimental interface to Mosek's semidefinite programming (SDP) solver has been added, see the GAMS/Mosek solver documentation for details. Note, that the interface is likely to change in the future.

OsiCplex

- Fixed report of CPLEX Error 1217 at end of MIP solve.

OsiCplex, OsiGurobi

- Fixed setting of LP algorithm via solver specific options file.

OsiMosek

- The MIP solver choice has been changed to Mosek's conic mixed-integer programming solver.

OS

- New libraries 2.8

SoPlex

- New libraries 1.7.2

SCIP

- New libraries 3.0 #6078424
- SCIP setting files can be setup with the options editor of the GAMS IDE now.

SULUM

- New libraries 2.0.432.
- Branching priorities are now supported.

XPRESS

- New libraries 25.01.05.
- Fixed best bound field of start record in MIP trace file.

3.33.1.7 Tools & APIs

Tools

- New GDX tool MCFilter. This tool removes duplicate and dominated points in a multi-criteria solution set.

Expert Level APIs

VBA

- Use camel case instead of all lower case for public functions

VB.NET

- Use camel case instead of all lower case for public functions
- Use dynamic loading of DLLs

Object Oriented APIs

- Do not throw an Exception if an Alias is read by GetSet
- Fix wrong equation subtype definition when reading equation from GAMSDatabase
- Throw an GAMSException if UEL exceeds the maximum size of 63 characters
- Throw an GAMSException if explanatory text exceeds the maximum size of 255 characters

.NET

- Add MONO implementation of the object oriented GAMS .Net API for Mac OS X and Linux.
- New version of function GAMSWorkspace.AddOptions creating an instance of GAMSOptions initialized by an existing option file
  - If we pass a nullptr to this Function from C++, we need to cast this to GAMSObject^ now because of the overloading
- New properties: GAMSWorkspace.APIVersion, GAMSWorkspace.APIMajorRelNumber, GAMSWorkspace.APIMinorRelNumber and GAMSWorkspace.APIGOLDRelNumber
- New property GAMSWorkspace.MyEPS: Reset value to be stored in and read from GAMSDatabase for Epsilon, default is double.Epsilon
- New function GAMSOptions.Export: Write GAMSOptions into a parameter file
- Switching type of property GAMSOptions.NoNewVarEqu from Integer to Enum (ENoNewVarEqu)
- Renaming of GAMSEnum.ModelStat.NonOptimalIntermed to GAMSEnum.ModelStat.Feasible
- Renaming of GAMSOptions.PoolFree4 to GAMSOptions.IntVarUp
- New C# Example GAMSRemoteObject

Java

- New
  - tutorial: (`GAMS_java_Tutorial.pdf`) under `<Path/To/GAMS>/docs/API`. From the GAMSIDE this document can be accessed at Help -> Docs -> API.
  - method in `GAMSOptions`: `export`, to write GAMSOptions into a parameter file
  - methods in `GAMSWorkspace`: `addOptions` to create a GAMSOptions object from either another object or an option file
  - methods in `GAMSWorkspace`: `getAPIVersion`, `getAPIMajorReleaseNumber`, `getAPIMinorReleaseNumber`, and `getAPIGoldReleaseNumber`, to retrieve API version number
  - method in `GAMSWorkspace`: `setMyEPS` to reset `GAMSGlobals.SpecialValues.EPS`, the value to be stored in and read from GAMSDatabase for Epsilon.
- Changed
  - default value of `GAMSGlobals.SpecialValues`: `NAN`, `PLUS_INF`, `MINUS_INF`, and `EPS`
  - deprecated `GAMSGlobals.ModelStat.NONOPTIMAL_INTERMED`, replaced by `GAMSGlobals.ModelStat.FEASIBLE`
  - deprecated `GAMSOptions.PoolFree4`, replaced by `GAMSOptions.IntVarUp`
  - deprecated the type of `GAMSOptions.NoNewVarEqu`, replaced by enum `GAMSOptions.ENoNewVarEq`
- Fixed
  - a bug when running a job with an input directory IDir added into GAMSOptions object.

Python

- Add tutorial (`GAMS_python_Tutorial.pdf`) to `<Path/To/GAMS>/docs/API`. From the GAMSIDE this document can be accessed at Help -> Docs -> API.
- New parameter opt_file in function GamsWorkspace.add_options allows to create an instance of GamsOptions that is initialized by an existing option file.
- New function GamsOptions.export: Write GamsOptions into a parameter file
- New properties: GamsWorkspace.api_version, GamsWorkspace.api_major_rel_number, GamsWorkspace.api_minor_rel_
  and GamsWorkspace.api_gold_rel_number
- New property GamsWorkspace.my_eps: Reset value to be stored in and read from GamsDatabase for Epsilon.
- New class NoNewVarEqu providing static fields to set option nonewvarequ
- Renaming of GamsOptions.PoolFree4 to GamsOptions.IntVarUp and property poolfree4 to intvarup
- Renaming of ModelStat.NonOptimalIntermed to ModelStat.Feasible
- The following functions throw an exception, when a wrong data type is passed for the keys/slice parameter: delete_record, find_record, add_record, merge_record, first_record, last_record. Valid data types are str, list, tuple and their subclasses
- Fixed a bug in _GamsSymbol.add_record() that occurred when using empty strings as keys
- Fixed a bug in GamsModelInstance.solve() that affected the logging behavior

3.33.1.8 Model Libraries

GAMS Data Library

- **GDXMRWShowJac1 (86)**: Visualize model Jacobian in Matlab
- **SpawnGAMSAccess (87)**: SpawnGAMS: Spawn GAMS from Access
- **triobal (88)**: Tommasino-Rao Input Output Balance Software

GAMS EMP Library

- **vidualvar (96)**: VI with dualvar specified for VI constraint
- **vi_equil (97)**: Identical VI models with and without containing equilibrium
- **vi_mcp (98)**: Identical models specified using MCP and VI syntax
- **equil_bilevel (99)**: Equilibrium model with and without containing bilevel

GAMS Model Library

- **gastrans (217)**: Added a simple straightforward NLP formulation of the problem, which is now solved by default.
- **knp (321)**: Removed redundant model equations, now regarding best bounds reported by solvers, improved readability.
- **tricp (395)**: Triangular Graph Circle Packing
- **allbases (396)**: Enumerate All Basic Solutions of an LP

GAMS Test Library

- **load7 (613)**: Tests execute_loaddc
- **unload10 (614)**: Test unload options new with GAMS 24.2
- **mpec04 (615)**: MPEC model testing free rows
- **mpec05 (616)**: Simple MPEC unique solution lower bounded matches
- **mpec06 (617)**: Simple MPEC unique solution upper bounded matches
- **mpec07 (618)**: Simple MPEC unique solution doubly-bounded matches
- **mpec08 (619)**: Simple MPEC unique solution LB matches integer var
- **mpsge13 (620)**: MPSGE test - model returns invalid income level
- **card02 (621)**: Tests miniparser card() function
- **uldidx01 (622)**: UnloadIdx - basic operation
- **uldidx02 (623)**: UnloadIdx - checking execution restrictions
- **uldidx03 (624)**: UnloadIdx - checking compilation restrictions
- **ldidx01 (625)**: $loadIdx - checking basic operation
- **ldidx02 (626)**: $loadIdx - checking restrictions
- **ldidx03 (627)**: $loadIdx - checking restrictions
- **ldidx04 (628)**: $loadIdx - checking restrictions
- **ldidx05 (629)**: $loadIdx - checking restrictions
- **sdp01 (630)**: Test of correct solving a simple conic program
- **load8 (631)**: Domain projection load tests
- **load9 (632)**: Domain projection load tests
- **lindgl03 (633)**: Check that Lindo(Global) Option NLP_QUADCHK works
- **dbg01 (634)**: Test debugging option on Windows
- **cpplib01 (635)**: Test extrinsic functions in cppcclib
- **cpplib02 (636)**: Test extrinsic functions in cppcclib
- **alias01 (637)**: Check handling of multidimensional aliases
- **load10 (638)**: Domain projection load tests

3.33.1.9 Solver/Platform Availability Matrix

3.33.2 24.2.2 Maintenance release (March 04, 2014)

3.33.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Bond, Michael Ferris, Erwin Kalvelagen, Timo Lohmann, Kourosh Marjani Rasmussen, Javier Salmeron, Bassel Timani, Shigeru Tsubakitani, Tom Walker, and Jürgen Wolpert.

3.33.2.2 Platforms

- Including now the correct Fortran and C++ standard libraries in a Solaris 64bit Intel system.

3.33.2.3 GAMS System

- Fix a bug that could cause a crash when unloading an alias to the universe to GDX.
- Fix a bug when unloading to a GDX file failed.
- Accept a Mac license when using the GAMS Windows Distribution via Wine.

3.33.2.4 Solvers

BARON

- New libraries 12.7.7.
- Missing option `results` added.
- Option `PrLevel` accepts only 0 or 1.

Bonmin

- New libraries.

CBC

- New libraries.
- Add solution report for LPs that have not been solved to optimality (with corresponding infeasibility, non-optimality, unboundedness markers).

CONOPT

- New library 3.15N.

Couenne

- New libraries.

Cplex

- Fix a bug that resulted in Cplex solving an LP as a MIP in case of solvelink=5.

Gurobi

- New libraries 5.6.2.
- This Gurobi version introduces an experimental no relaxation heuristic that attempts to find good quality feasible solutions to MIP models without first solving the root relaxation. This can be useful in situations where the root relaxation is extremely large or difficult.

GUSS/Scenario Solver

- Fix a bug with keyword 'opt' when retrieving model attributes from the scenario solves.

KNITRO

- New libraries 9.0.1.

Lindo/LindoGlobal

- We will drop LindoGlobal libraries for Sparc Solaris with the next major release (24.3).
- Fix potential problem using multiple threads on LP problem.
- New libraries 8.0.498.

Mosek

- New libraries 7.0.0.106.

SCIP

- New libraries 3.0 #70041f0.

XPRESS

- New libraries 25.01.07.

3.33.2.5 Tools & APIs

GDX Tools

- Fixed a problem with `gdxrank` that surfaced with the new default `Squeezed` of option `gdxUELs`.
- CSV formatted output of `gdxdump` no longer includes a `Val` column for sets.
- Tools like `gdxdump`, `gdxdiff` and `gdxrank` will process an input file without a file extension if that file exists. If the file does not exist, the file with the `.gdx` file extension will be used.

Object Oriented APIs

- Fix error when exporting GAMSDatabase with Aliases.
- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the APIs.
- Fix GAMSExitCodes.
- Make sure that GAMSModelInstance.Instantiate() does not solve the model, but only prepares everything required for the following Solve().

Java

- Changed
  - null string is treated as an invalid key for all record operations of `GAMSSymbol`.
- Fixed
  - a bug when creating `GAMSDatabase` from source database.
  - a bug when initializing a variable type in `GAMSVariable`.
  - a bug in `GAMSSymbols`: methods `getVarType()` and `getEquType()`.
  - a bug in `GAMSWorkspaceInfo`: method `getSystemDirectory()`.

Python

- Fixed a bug in GamsSymbol.delete_record().

3.33.3 24.2.3 Maintenance release (May 22, 2014)

3.33.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Bond, Wolfgang Britz, Carla Caldeira, Markus Drouven, Guillaume Erbs, Michael Ferris, Inki Kim, Bruce McCarl, Nazmi Sener.

3.33.3.2 Platforms

- On AIX, GAMS executables could allocate at most 2 GB of memory. This limit has been increased to 200 GB.

3.33.3.3 GAMS System

- Fixed option `sys10`

3.33.3.4 Solvers

CONOPT

- New libraries 3.15P.

CBC

- New libraries.

CPLEX, Gurobi and Xpress

- Fixed issues regarding missing libraries and wrong library dependencies on AIX.

DICOPT

- Fixed option setting `relaxed = 0`.

EMPSP

- Fixed a bug with chance constraints.
- Fixed a bug where a certain order of random variables could cause a crash.

Gurobi

- New libraries 5.6.3.
- The `writeprob` option now writes an additional mipstart file (`.mst.gz`), if a MIP is written and the `mipstart` option has been set.

GUSS/Scenario Solver

- Previously, GUSS only solved scenarios that had some update data. Now, GUSS solves also an empty scenario, i.e., a scenario without any update data. It now depends on the update type which scenario is solved.
- Fixed a bug which caused a crash when the scenario dictionary set has more than 50 entries.

Ipopt

- New library.
  - Fixed a bug that lead to convergence issues on some instances.

Lindo

- Fixed option `NSAMPLE_PER_STAGE`.

Mosek, OsiMosek

- New libraries 7.0.0.114.
- Fixed deadlock on Windows when using Mosek or OsiMosek with a user (i.e., non-GAMS) license.

3.33.3.5 Tools & APIs

- har2gdx implements -H option
- gdxxrw understands RC notation for cells when using option `UseRC`.

Object Oriented APIs

- Fixed memory leak in GAMSDatabase.

Java

- Fixed a bug in GAMSDatabase.getDatabaseDomainViolation.

3.34 24.1 Distribution

3.34.1 24.1.1 Major release (May 30, 2013)

3.34.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Étienne Ayotte-Sauvé, Stephen Frank, Youngdae Kim, Andres Ramos, Steffen Rebennack, and Francisco Trespalacios.

3.34.1.2 GAMS System

Installer

- The GAMS installer for Windows is now digitally signed which allows to verify the authenticity

Documentation

- McCarl guide has been updated

GAMS

- new log output option lo=4 has been added: writes simultaneously to log file and stdout.
- Memory leak for GUSS/ScenarioSolver fixed. This also was a problem for the GAMSModelInstance in the OO-API.
- Command line option `OptFile` does not overwrite `model.optfile` anymore. `OptFile` now behaves as other GAMS options e.g. like `ResLim`. A new command line option `ForceOptFile` overwrites all other methods of setting a solver option.
- New option `NoNewVarEqu` will trigger a compilation error when new equation or variable symbols are introduced. This is useful for testing GAMS run-time environments.
- New option `SymPrefix` that prefixes all user symbols compiled in this run with the string value of this option before saving to a save/restart file. This is useful when merging multiple models together to avoid name clashes.

GAMS IDE

- The text comparison utility menu has been changed and now has a structure similar to the GDXDIFF menu; previous file selections are available in the drop-down fields
- The help menu has a link to the search page on the GAMS website

3.34.1.3 Solvers

"D" Solvers

- The "D" solvers GAMS/ConvertD and GAMS/CplexD started as research and development versions of the production solvers GAMS/Convert and GAMS/Cplex and offer some interesting new features that eventually will migrate into the production version.

ALPHAECP

- Alpha-ECP v2.10.02. New option *ECPmaster* and minor performance improvements.

ANTIGONE

- The new solver ANTIGONE (Algorithms for coNTinuous / Integer Global Optimization of Nonlinear Equations) is a computational framework for deterministic global optimization of nonconvex MINLP. ANTIGONE performs equivalently to GloMIQO when all nonlinearities in MINLP are quadratic.
- ANTIGONE has been developed by Computer-Aided Systems Laboratory at Princeton University; it was completed in collaboration with the Centre for Process Systems Engineering at Imperial College.
- GAMS/ANTIGONE is available for the 32-bit and 64-bit versions of Windows and Linux.
- GAMS/ANTIGONE requires the presence of a GAMS/CPLEX license and either a GAMS/CONOPT or a GAMS/SNOPT license.

Bonmin, Couenne, Osi∗, SCIP

- Marginals are now reported as 'NA', if not available, instead of 0.

Baron

- New libraries 12.3
- New relaxations for certain types of quadratic problems
- Clp 1.14.8
- Farkas infeasibility test to validate LP subsolver claims of infeasibility (Cplex and Clp only)
- Dynamic memory allocation, options workspace and workfactor have been removed
- Improved integer presolve
- Incorporation of convex envelopes for certain low-dimensional functions

CBC

- New libraries Clp 1.15 and Cbc 2.8
- An implementation of zero-half cuts is now available. So far, they may help only on a small subset of problems and may need some tuning, so they are off by default. The new option zerohalfcuts can be used to enable them.
- Alternative implementations of Gomory mixed-integer and reduce and split cuts are now available. By default, these cuts are off. The new options gomorycuts2 and reduceandsplitcuts2 can be used to enable them.
- Added new parameter cut_passes_slow to encourage the use of some of the more exotic/expensive cut generators.
- The random seeds for CLP and CBC can now be set by user via the new options randomseedclp and randomseedcbc.
- Cbc can now solve the root node multiple times, each with its own different seed. This can be enabled via the new option multiplerootpasses.
- New option extravariables that switches on a trivial re-formulation that introduces extra integer variables to group together variables with same cost.
- New option cutoffconstraint to add the objective function as a constraint which right hand side is set to the current cutoff value to the problem.
- New option parallelmode to switch between deterministic and opportunistic parallelization. NOTE: The default is deterministic, while it was opportunistic in the past.

Cplex

- New libraries 12.5.0.1 (fix pack 1)
- New link option `solnpoolmerge` to write all solutions into a single GDX file
- Solutions from the solution pool are written in sorted order from best to worst
- GAMS/CplexD supports the Cplex remote object. See option `ComputeServer`.

CONOPT

- New libraries 3.15K
- Fixed a system error (303) related to inversion of very large matrices.
- Adjusted some test output to handle more than 1 mill rows and columns.
- If the directional 2nd-derivative routines returned an error and should be turned off they were not turned off after all and the result was poor performance and many strange messages. Problem Fixed.
- The final model could be infeasible and still declared feasible if the initial and final scaling factors were very different. Problem Fixed.

DICOPT

- added parameter 'infbnd' to control which value to use for missing bounds in integer cuts (default is 10000)

EMPSP

New experimental keywords making use of the extrinsic function library `lsadclib` to sample random variables with parametric distributions, any feedback will be appreciated:

- `sample <rv1> [rv2 ... rvn] <sampleSize> [varRedGroup]`
  - `sample`: keyword
  - `rv?`: name of random variable
  - `sampleSize`: size of sample
  - `varRed`: variance reduction group, mapped to variance reduction method using solver option file
  - Example:
    - %emp.info%:
      - `sample d 5 group1`
  - lindo.opt
    - `SVR_LS_ANTITHETIC=group1`
- `setSeed <seed>`
  - Sets the seed for `sample`

GloMIQO

- New libraries 2.2
- Fixed bug in detecting when aBB cuts should be generated.

Gurobi

- New libraries 5.5
- New options
  - GAMS/Gurobi support Gurobi's Compute Server. See options `ComputeServer` and options starting with `CS`
  - Parameter Tuning Tool: See option `Tuning` and options starting with `Tune`
  - `ConcurrentMIP`: This new feature launches multiple, independent solves on the same MIP model, using different settings for each. The solve returns when the first one finishes. This approach allows you to exploit multiple cores to explore a diverse set of search strategies
  - `NumericFocus`: This new parameter allows you to indicate that a model is likely to experience numerical trouble, which then causes our internal algorithms to favor numerical robustness over speed

Ipopt, IpoptH

- New libraries 3.11
- default for option ma57_automatic_scaling changed to no
- new options print_frequency_iter and print_frequency_time to adjust amount of iteration summary output
- fixed assignment of INFES markers in listing file (infeasibilities between constraint violation tolerance and acceptable constraint tolerance were not marked)

IpoptH

- Added a new linear system solver HSL_MA97
- Updated linear system solver HSL_MA86
- Both MA57 and HSL_MA97 should be considered as alternative to the default MA27 (see Ipopt option linear_solver)

JAMS

- fixed a bug in substituting variables in a nonlinear equation during a convex-hull reformulation

KNITRO

- new libraries 8.1.1

Lindo, LindoGlobal

- New libraries Lindo 8.0
- Multithreading support
  - The new GAMS/Lindo/LindoGlobal option `num_threads` defines the number of threads to be used, it is initialized by the GAMS option `threads`
  - The new GAMS/Lindo/LindoGlobal option `multithread_mode` defines the threading mode (auto, concurrent or parallel)
- Stochastic Solver Improvements
  - Nested Benders Decomposition implementation has been improved significantly, achieving speed factors up to 6X compared to the previous version
  - The Chance-programming solver adds a Genetic Algorithm to find high-quality feasible solutions to large-scale instances. Models in this class can now also be solved using the Simple Benders Decomposition method
  - Multithreading with Nested Benders Decomposition (NBD) solver leads to speed improvements from 2.5 to 3.5 when using 4 threads
- MIP Solver Improvements
  - The heuristics are improved significantly, simple rounding and feasibility pump now use bound propagation to improve the current path to a new feasible MIP solution
  - Multithreading can lead to speed improvements from 1.5 to 3.0 times on difficult problems using 4 threads rather than 1, for easy MIP problems, e.g., < 600 seconds, multi-threading may give not much speedup
- Multistart Solver Improvements
  - Multistart solver has been improved significantly, achieving speed factors up to 2X compared to the previous version
  - The likelihood of getting the global optimum has improved by 10-15% over a wide range of nonconvex models
  - Multithreading often leads to speed improvements from 2.0 to 3.0 times when using 4 threads, speed improvements tend to improve as the model size and the number of multistarts increase
- Changed meaning of `objwgt` in chance constraints (CC): now it gets multiplied by the violation ratio of the CC before it was added to the objective, in previous versons it was multiplied by (1 - the violation ratio)
- Further new options
  - `find_block`: graph partitioning method to find block structures
  - `gop_linearz`: flag indicating if GOP exploits linearizable model

Mosek

- Mosek 7.0.0.65
- An additional parallelized mixed integer optimizer has been added. This optimizer is chosen for MIP solves if no Mosek/MIP license is available. See also option MSK_IPAR_OPTIMIZER.
- Recognizes some quadratic constraints as cone constraints, so `=c=` equations can be avoided.
- AVX instructions in the latest INTEL CPUs are now exploited.
- Dropped support for Solaris Intel 64bit platform.

- The option writembt is now deprecated. Please consider using the option MSK_SPAR_DATA_FILE_NAME instead.
- The option mipstart is now a synonym for MSK_IPAR_MIO_CONSTRUCT_SOL and thus takes values MSK_ON and MSK_OFF.
- Numeric values for options with symbolic constants (e.g. MSK_IPAR_INTPNT_BASIS) are not supported anymore.

MSNLP, OQNLP

- fixed function evaluation issues in lsgrg when using external equations

OsiMosek

- dropped OsiMosek on Solaris Intel 64bit platform

OSL/OSLSE

- dropped OSL and OSLSE from this and future GAMS distributions

SCIP

- New libraries 3.0 #a4a627b

SULUM

- New libraries 2.0.263 (Beta)
- The new SULUM libraries comes with support for mixed-integer linear programs (MIP). The new MIP optimizer is an advanced implementation of a branch and cut method, with many performance enhancements added. The key features of the MIP optimizer can be highlighted as :
  - Advanced MIP presolve to reduce the problem size and provide a better formulation for the optimizer.
  - Tight integration with the Sulum LP optimizer to efficiently solve LP's in node and during heuristics.
  - Various branching and node selection methods from computational inexpensive to more expensive schemes.
  - Cutting plane generation and filtering if deemed necessary.
  - Heuristics to either find an initial solution or improve the current incumbent, which includes rounding, diving and sub-mipping heuristics types.
  - Improvements to ensure numerical stability.

XPRESS

- New libraries 24.01.04
  - Improved concurrent LP solve
  - Improved performance when using the parallel barrier solver
  - Fix faulty dispatch of SSE3 instructions in QP
- New link option `solnpoolmerge` to write all solutions into a single GDX file

3.34.1.4 Tools & APIs

Object Oriented APIs

- New features were added to the object oriented GAMS APIs including e.g. the capability to specify the domains of symbols, check for domain violations, copying ModelInstances, or setting the debug level using a environment variable. More details about new and modified functions can be found in the following sections about the different languages.

.NET

- Documentation
  - Add tutorial (`GAMS.net4.Tutorial.chm`) to `<Path/To/GAMS>/docs/API`. From the GAMSIDE this document can be accessed at Help → Docs → API.
- GAMSDatabase
  - New function CheckDomains: Check for all symbols if all records are within the specified domain of the symbol
  - New function GetDatabaseDVs: Return all GAMSDatabaseDomainViolations
  - New property SuppressAutoDomainChecking: Controls whether domain checking is called in GAMSDatabase export
  - New variants of the functions AddEquation, AddParameter, AddSet, AddVariable: Allow to specify domain information
  - Function Compact becomes obsolete and will be dropped in future
- GAMSModelinstance
  - New function CopyModelInstance: Copies a ModelInstance to a new ModelInstance which gets constructed at this call
  - New function Interrupt: Sends interrupt signal to running GAMSModelInstance
- GAMSModifier
  - Allow to define SymbolUpdateType for each GAMSModifier separately
- GAMSSymbol (GAMSEquation, GAMSParameter, GAMSSet, GAMSVariable):
  - New function CheckDomains: Check if all records are within the specified domain of the symbol
  - New function CopyToArray: Copies values of a dense symbol into a dense array
  - New function CopyToSqzdArray: Copies values of a sparse symbol into a squeezed array
  - New function CopySparseToDenseArray: Copies values of a sparse symbol into a dense array
  - New function CopyFromDenseArray: Copies values from dense array into a symbol
  - New function CopySliceFromDenseArray: Copies values from slice of dense array into a symbol
  - New function GetSymbolDVs: Return all GAMSSymbolDomainViolations
  - New function MergeRecord: Finds record in GAMSSymbol if it exists, adds it if not
  - New property Domains: Domains of Symbol, each element is either a GAMSSet (real domain) or a string (relaxed domain)
- GAMSWorkspace
  - Change the Debug parameter from a Boolean flag to an enum type called DebugLevel
  - The Debug parameter can be overwritten by the system environment variable "GAMSOOAPIDEBUG" if set to one of the following: Off, KeepFiles, ShowLog, Verbose

  - Improve performance significantly for function AddDatabase(GAMSDatabase)
  - New functions: AddJobFromGamsLib, AddJobFromTestLib, AddJobFromEmpLib, AddJobFromDataLib and AddJobFromFinLib
  - New properties: Version, MajorRelNumber, MinorRelNumber and GOLDRelNumber
  - New optional parameter inModelName for functions AddDatabaseFromGDX/AddDatabase: GAMS string constant that is used to access this database
- Add new sub class of GAMSException: GAMSExceptionExecution. This provides additional info about the reason of the failed execution.
- New examples:
  - C#: DomainChecking, Markowitz, SimpleCutstock, Transport13, TSP, MessageReceiverWindow
  - C++: Transport Sequence
  - VB.NET: Transport Sequence

Java

- Changes in GAMSDatabase:
  - deprecates the compact method, as it has no effect anymore.
- Changes in GAMSGlobals:
  - the default value of working directory has been changed from System.getProperty("user.dir") to System.getProperty("java.io.tmpdir").
- Changes in GAMSModelInstance:
  - deprecates the instantiate(GAMSOptions options), instantiate(GAMSModifier[]), and instantiate(GAMSOptions, GAMSModifier[]) methods and replaced by instantiate(String, GAMSModifier ...) and instantiate(String, GAMSOptions, GAMSModifier ...) methods.
- Changes in GAMSWorkspace and GAMSWorkspaceInfo:
  - deprecates boolean debug flag and replaced by a debug level flag (type of a new class GAMSGlobals.DebugLevel).
  - allows an override of debug level flag from an environment variable "GAMSOOAPIDEBUG"
- Fixed a bug when iterating through the records of a GAMSSymbol.
- New enumeration class GAMSGlobals.DebugLevel:
  - defines values of different GAMS Debug Levels.
- New enumerated value of GAMSModelInstance.SymbolUpdateType:
  - GAMSModelInstance.SymbolUpdateType.INHERIT: to specify SymbolUpdateType separately for each GAMSModifier.
- New methods in GAMSDatabase:
  - addEquation, addParameter, addSet, and addVariable: to add symbols with domain information.
  - checkDomains: to check whether or not all records of all symbols are within the specified domain of the symbols.
  - getDatabaseDomainViolations: to retrieve a domain violation information as a list of GAMSDatabaseDomainViolation objects.

  - isAutoDomainCheckingSuppressed and suppressAutoDomainChecking: to control whether domain checking will be called when exporting a database.

- Changes in GAMSDatabase:
  - the compact method is obsolete and has no effect anymore. It will be removed in the future.
- New class GAMSDatabaseDomainViolation:
  - contains domain violation information of all symbols (if any) in the database.
  - returns call from a new method GAMSDatabase.getDatabaseDomainViolations.
- New methods in GAMSModelInstance:
  - copyModelInstance: to copy a GAMSModelInstance object.
  - interrupt: to send an interrupt signal to a running GAMSModelInstance.
- new methods in GAMSModifier:
  - constructor: to specify SymbolUpdateType for each GAMSModifier object.
  - getUpdateType: to retrieve SymbolUpdateType property of the object.
- New methods in GAMSSymbol:
  - checkDomains: to check whether or not all records of the symbol are within the specified domain.
  - getDomains: to retrieve a list of domains of the symbol, each element is either a GAMSSet (real domain) or a String (relaxed domain).
  - getSymbolDomainViolations: to retrieve a domain violation information as a list of GAMSSymbolDomainViolation objects.
  - mergeRecord: to add a new symbol record in case the record does not exist.
- Fixed a bug when iterating through the records of a GAMSSymbol.
- New class GAMSSymbolDomainViolation:
  - contains domain violation information of the symbol (if any).
  - returns call from a new method GAMSSymbol.getSymbolDomainViolations.
- New methods in GAMSWorkspace:
  - getGAMSVersion: to retrieve information about GAMS Version.
  - getGoldReleaseNumber: to retrieve GAMS GOLD Release Number.
  - getMajorReleaseNumber: to retrieve GAMS Major Release Number.
  - getMinorReleaseNumber: to retrieve GAMS Minor Release Number.
- Changes of location of examples:
  - from <Path/To/GAMS>/apifiles/Java/Benders∗.java to <Path/To/GAMS>/apifiles/Java/benders/Benders∗.ja
  - from <Path/To/GAMS>/apifiles/Java/Custock.java to <Path/To/GAMS>/apifiles/Java/cutstock/Cutstock.ja
  - from <Path/To/GAMS>/apifiles/Java/ConsoleInterrupt.java to <Path/To/GAMS>/apifiles/Java/interrupt/Co
  - from <Path/To/GAMS>/apifiles/Java/Transport∗.java to <Path/To/GAMS>/apifiles/Java/transport/Transpo
  - from <Path/To/GAMS>/apifiles/Java/Warehouse.java to <Path/To/GAMS>/apifiles/Java/warehouse/Wareh
- New examples:
  - <Path/To/GAMS>/apifiles/Java/cutstock/SimpleCutstock.java
  - <Path/To/GAMS>/apifiles/Java/domain/DomainCheck.java
  - <Path/To/GAMS>/apifiles/Java/transport/Transport13.java
  - <Path/To/GAMS>/apifiles/Java/tsp/Tsp.java

Python

- New examples: markowitz.py, tsp.py, transport13.py, simple_cutstock.py, domain_checking.py
- New facility for GamsSymbols with domain information:
  - GamsDatabase:
    - New functions add_parameter_dc, add_variable_dc, add_equation_dc and add_set_dc: Create GamsSymbols with domain information
    - New function check_domains: Check for all symbols if all records are within the specified domain of the symbol
    - New function get_database_dvs: Return all GamsDatabaseDomainViolations
    - New property suppress_auto_domain_checking: Controls whether domain checking is called in GamsDatabase export
  - _GamsSymbol and its derived classes:
    - New function check_domains: Check if all records are within the specified domain of the symbol
    - New function get_symbol_dvs: Return all GamsDatabaseDomainViolations
    - New property domains: Domains of Symbol, each element is either a GamsSet (real domain) or a string (relaxed domain)
  - New classes GamsDatabaseDomainViolation and GamsSymbolDomainViolation that are returned by GamsDatabase.get_database_dvs and _GamsSymbol.get_symbol_dvs
- New functions in GamsModelInstance:
  - copy_modelinstance: Copies a GamsModelInstance to a new GamsModelInstance which gets constructed at this call
  - interrupt: Sends interrupt signal to running GamsModelInstance
- New function in _GamsSymbol and its derived classes: merge_record finds a record if it exists and adds it if not
- New functions in GamsWorkspace: add_job_from_gamslib, add_job_from_testlib, add_job_from_emplib, add_job_from_datalib and add_job_from_finlib
- New properties in GamsWorkspace: version, major_rel_number, minor_rel_number, gold_rel_number
- New optional parameter in_model_name for functions add_database_from_gdx/add_database in GamsWorkspace: GAMS string constant that is used to access this database
- Changed the debug argument passed to the GamsWorkspace constructor. Use members of class DebugLevel: Off, KeepFiles, ShowLog and Verbose instead of True and False
- New sub class of GamsException: GamsExceptionExecution, which provides additional info about the reason of the failed execution
- Allow to define SymbolUpdateType for each GamsModifier seperately
- Significant performance improvement for function GamsWorkspace.add_database when creating from an already existing database
- Changed the unicode settings on Linux from UCS2 to UCS4
- The Debug parameter of GamsWorkspace can be overwritten by the system environment variable "GAMSOOAPIDEBUG" if set to one of the following: Off, KeepFiles, ShowLog, Verbose
- The compact method of GamsDatabase is obsolete and has no effect anymore. It will be removed in the future
- Fixed a bug in GamsModelInstance.solve()
- Fixed a bug in GamsDatabase, where the special value for undefined was set to 0 instead of 1.0E300 (SV_UNDEF)
- Fixed a bug when iterating through the records of a GamsSymbol

GDXXRW

- Some format of range names are now recognized
- More details in error message for a bad range

GDXDUMP

- Option to replace header
- Option EpsOut
- Performance improvement when writing a large CSV file

CSV2GDX

- New utility to convert a CSV file to a GDX file
  - A simple example is in the GAMS data library

MessageReceiverWindow

- New Windows tool that receives messages from GAMS. The GAMS Test Library model **mrw01** demonstrates its usage.

3.34.1.5 Model Libraries

GAMS Data Library

- **SpawnGAMSExcel (84)**: Spawn an arbitrary model from Excel
- **csv2gdx1 (85)**: testing CSV file conversions

GAMS Model Library

- **cpack (387)**: Packing identical size circles in the unit circle
- **trigx (388)**: Another Trigonometric Example
- **stablem (389)**: Stable Marriage Problem
- **srtree (390)**: Simple Scenario Tree Construction Example
- **tgridmix (391)**: Grid Transportation Problem with Single Submit and Collect Loop
- **prisoner (392)**: Prisoners dilemma as EMP and MCP
- **cesam2 (393)**: Cross Entropy SAM Estimation
- **solmpool (394)**: Cplex Solution Pool for a Simple Facility Location Problem with Merged GDX Solution File

GAMS Test Library

- **nlcode7 (586)**: Test for NL code bug from Dist 24.0.1
- **n3707 (587)**: MIP model used by CTRLC test
- **mod011 (588)**: MIP model used by CTRLC test
- **fuzzy (589)**: MINLP model used by CTRLC test
- **nuclear49b (590)**: MINLP model used by CTRLC test
- **enpro56 (591)**: MINLP model used by CTRLC test
- **popdynmMCP25 (592)**: MCP model used by CTRLC test
- **popdynmMCP250 (593)**: MCP model used by CTRLC test
- **popdynmMCP1000 (594)**: MCP model used by CTRLC test
- **gft (595)**: MPSGE model used by CTRLC test
- **pf4mip (596)**: Test unbounded integer variables (MIP)
- **pf4minlp (597)**: Test unbounded integer variables (MINLP)
- **emp12 (598)**: Test of EMP equilibrium models and fixed vars
- **emp13 (599)**: Test of EMP equilibrium models and fixed vars
- **emp14 (600)**: Test of EMP equilibrium model with vi func
- **emp15 (601)**: Test of EMP equilibrium model with vi func
- **emp16 (602)**: Test of NLP -> MCP via JAMS
- **miqcp03 (603)**: Test modsolstat & solution correctness - multiple QCons & binaries
- **mcp10 (604)**: MCP model with negative equ.var
- **convert8 (605)**: Test that eps in nonlinear code is kept by convert
- **gurobi01 (606)**: GUROBI test suite - tuning test
- **lp15 (607)**: LP with many zeros at solution
- **convert9 (608)**: CONVERT test suite - handling of fixed vars for nlp2mcp
- **lsalib01 (609)**: Test extrinsic functions in lsadclib
- **mrw01 (610)**: Test MessageReceiverWindow.exe
- **rs01 (611)**: Solving a Transportation Problem using Cplex and Gurobi remote server
- **xpress06 (612)**: Solution enumerator example with solnPoolMerge

3.34.1.6 Solver/Platform Availability Matrix

3.34.2 24.1.2 Maintenance release (June 16, 2013)

3.34.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Sergio Corvalan, George Mavrotas, Renger van Nieuwkoop, and Andres Ramos.

3.34.2.2 GAMS System

GAMS

- Fixed a problem when restarting from restart files from 24.0 and previous if extrinsic functions were present

3.34.2.3 Solvers

BARON

- New libs 12.3.3
  - SNOPT 7.2-12.1 with fixes
  - New defaults for options `PreLPDo` (0) and `PDo` (-2) which lets BARON decide about probing
- Fixed an issue with reporting the correct solve time back to GAMS

Cplex/CplexD

- new libs 12.5.1
- new parameters `LiftProjCuts` and `CalcQCPDuals`
- Fixed a problem in CplexD where models with all discrete variables relaxed (prior=inf) were still solved as discrete problems

MOSEK

- New libraries 7.0.0.70

SULUM

- New libraries 2.0.284 (Beta)

3.34.2.4 Tools & APIs

GDXXRW

- Fixed a bug where a range like B5:B5 became a single anchor point

3.34.3 24.1.3 Maintenance release (July 26, 2013)

3.34.3.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Sebastian Dilly, Sascha Herrmann, Aida Khajavirad, and Johan Villaume.

3.34.3.2 GAMS System

Installer

- The GAMS installer for Windows now asks if an existing GAMSDIR environment variable from a previous installation should be updated.

GAMS

- Fix crash with huge dictionary files

GAMS IDE

- Fixed formatting of Ipopt, Bonmin, and Couenne options files when written by options editor.
- Using Help | About now uses the project directory for temporary files avoiding issues with a write protected system directory.

3.34.3.3 Solvers

ANTIGONE and GloMIQO

- New libraries ANTIGONE 1.1 and GloMIQO 2.3
  - eliminate constraint on the number of variables (ANTIGONE/GloMIQO was previously limited to 45,000 variables)
  - improve nonlinear term bound inferences
  - improve automatic scaling of problems with many disparate scales
  - track numerically sensitive variables for possible instability associated with optimality-based bounds tightening

COIN-OR / SCIP / SoPlex

- fixed an issue loading coincclib64.dll on some Windows 64bit machines

CONOPT

- New Libraries 3.15L

IPOPTH

- New HSL libraries MA57 3.8, HSL_MC68 3.3, HSL_MA86 1.5, HSL_MA97 2.2
- Changed default of option ma27_meminc_factor from 10 to 2

MOSEK

- New library 7.0.0.75

SCIP

- New library 3.0 #0b46aef

SULUM

- New library 2.0.314

3.34.3.4 Tools & APIs

Object Oriented APIs

Java

Improve data iterator:

- New classes:
  - `GAMSDatabaseIterator` implements `java.util.Iterator`
  - `GAMSSymbolIterator` implements `java.util.Iterator`
- Deprecated class:
  - `GAMSSymbolIterable`
- Changes in `GAMSDatabase`:
  - `GAMSDatabase` implements `GAMSDatabaseIterator` instead of `GAMSSymbolIterable`
  - deprecated the implemented methods of `GAMSSymbolIterable`: `next()`, `hasnext()`, and `remove()`
- Changes in `GAMSSymbol`:
  - `GAMSSymbol` implements `GAMSSymbolIterator` instead of `GAMSSymbolIterable`
  - deprecated the implemented methods of `GAMSSymbolIterable`: `next()`, `hasnext()`, and `remove()`
- new methods in `GAMSSymbolRecord`:
  - `moveNext()`: to iterate to the next record using the current data iterator criterion
  - `movePrevious()`: to iterate to the previous record using the current data iterator criterion

Updated example:

- `<Path/To/GAMS>/apifiles/Java/transport/Transport12.java`

GDXXRW

- Better error reporting for certain range errors
- Issue a warning when writing to an XLSX file by default when there is a file with the same name that has the extension .XLS

3.35 24.0 Distribution

3.35.1 24.0.1 Major release (December 24, 2012)

3.35.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release.

3.35.1.2 Platforms

- Dropped Mac OS X 32bit build
- Mac OS X 64bit build now on Lion (10.7)

3.35.1.3 GAMS System

APIs

Documentation

- Moved existing documentation about the APIs to <Path/To/GAMS>/docs/API. Also added new documentation there. In the GAMSIDE this documentation can be accessed at Help → Docs → API.

.NET

- Add function Interrupt to GAMSJob: Sends interrupt signal to running GAMSJob

Java

This release contains a beta version of the object-oriented Java API that can be used to control GAMS from a Java program. It allows the seamless integration of GAMS into Java by providing appropriate classes for the interaction with GAMS. GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in the more efficient way (GAMSModelInstance).

- A Java program that uses object-oriented Java API requires at least Java SE 5 to compile and run.
- All classes are distributed within one single jar file GAMSJavaAPI.jar with a namespace com.gams.api, located under the <Path/To/GAMS>/apifiles/Java/api/ directory.
- Java program examples are distributed with a namespace com.gams.examples, located under the <Path/To/GAMS>/apifiles/Java/ directory.
- Installation and detailed documents can be found in <Path/To/GAMS>/apifiles/readme.txt and <Path/To/GAMS>/docs/API/GAMS_java.pdf.
- Javadoc for GAMSJavaAPI.jar can be found under the <Path/To/GAMS>/apifiles/java/api/javadoc directory.

Python

- In the API to the option object the signature of the function `optGetStrStr` has changed from: `value = optGetStrStr(optHandle, "GDX", dummyString)` to `value = optGetStrStr(optHandle, "GDX")`
- The compiled Python libraries are built with Python 2.7 now.
- This release contains a beta version of the object-oriented Python API that can be used to control GAMS from within Python 2.7. It allows the seamless integration of GAMS into Python by providing appropriate classes for the interaction with GAMS. The GamsDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GamsJob class and by using the GamsModelInstance class a sequence of closely related model instances can be solved in an efficient way. To use this API one has to perform one of the following steps:

  Installing the API and the required low level APIs:

  ```
  cd <Path/To/GAMS>/apifiles/Python/api && python setup.py install && cd ..
  ```

  Using the API without installing:

  ```
  export PYTHONPATH=<Path/To/GAMS>/apifiles/Python/api  (Unix)
  set PYTHONPATH=<Path\To\GAMS>\apifiles\Python\api  (Windows)
  ```

  Running transport1.py example:

  ```
  export LD_LIBRARY_PATH=<Path/To/GAMS>:$LD_LIBRARY_PATH (DYLD_LIBRARY_PATH on OS X, not require
  python transport1.py
  ```

  Documentation about this API can be found in <Path/To/GAMS>/docs/API/GAMS_python.pdf.

Documentation

- added separate GAMS installation notes for Mac OS X

External Equations

- Added a list of examples to the GAMS Test Library.

GAMS

- If Solvelink is set to a non-default value. The GAMS log prints out the solvelink selection: `--- Executing SOLVER (Solvelink=i): elapsed 0:00:00.000`
- New date in audit line. Each GAMS component writes an audit line to the GAMS log, e.g. GAMS/Cplex write `IBM ILOG CPLEX Jul 14, 2011 23.7.3 WIN 27723.27726 VS8 x86/MS Windows`. The date in this line used to be the license check date, which does not change with maintenance releases (23.9.X). Starting with 24.0.1 the date displayed in the audit line is the build date of the system and changes with every release including maintenance releases.

- When GAMS is run from the command line on Windows systems and a solver is interrupted, the OS issued a message `Terminate batch job (Y/N)?` and the user had to interact. Now the message is still printed, but GAMS does not wait for a user action anymore. This has a rare side effect that solver keyboard interactions (e.g. in GAMS/Cplex with option `Interactive` and GAMS/SCIP with option `GAMS/Interactive`) will not work unless the new GAMS option `InteractiveSolver` is set to 1.
- For compile time commands like `$include`, the `$` had to be in column 1. Leading blanks are now allowed for such commands, but require an additonal `$`: `$$include`. The `$$` can only be used for the first dollar command in a line. For example, `$set a 'aa' $$set b 'bb'` does not work.
- GAMS has added UserName and ComputerName to the recorded fields of the GAMS Trace facility. Besides many uses in quality assurance testing, the trace facility e.g. can be used to audit the GAMS activities in a multi user environment with a shared GAMS installation.
- Report equations with general non-linearity in lst file for QCP models
- New `put_utility` feature `WinMsg` allows to send a Windows message to a window:

```
put_utility fx 'WinMsg' / 'WindowTitle' / 'Message';
```

- Asynchronous calls on Windows can be started with a new console rather than sharing the console of the parent process. `$CALL.ASYNCNC`, `Execute.AsyncNC` and `Put_Utility` keywords `Exec.AsyncNC` and `Shell.AsyncNC` have been added. `NC` and non `NC` calls behave identical on non-Windows platforms.

GAMS IDE

- The IDE has now an integrated Text differ to compare two text files; see File | Diff Textfiles

GDXRRW

- GDXRRW is a suite of utilities to import/export data between GAMS and R and to call GAMS conveniently from R. The software gives R users the ability to use all the optimization capabilities of GAMS, and allows visualization and other operations on GAMS data directly within R.
- GDXRRW is unique among the GDX interface utilities in that it is an R extension made available as an R package. As such, it is run as part of an R session or script, not as part of a GAMS run, and it follows the usual R package conventions.
- Source and binary packages for GDXRRW are part of the GAMS distribution.

3.35.1.4 Solvers

BARON

- New libs 11.8.0
- BARON uses an improved link to Clp
- BARON uses latest SNOPT 7.2-12
- BARON uses latest IPOPT 3.10.3
- Memory requirements have been significantly reduced

Bonmin

- Faster reaction to user interrupt during solve of initial NLP relaxation.
- Changed default setting for parameters variable_selection and milp_strategy to strong-branching and solve_to_optimality, respectively.
- Renamed miptrace options to solvetrace.

CBC

- New library 2.8
  - A new primal heuristic "Proximity Search" (proposed by Fischetti and Monaci, 2012) has been added. The idea is to define a sub-MIP without additional constraints but with a modified objective function intended to attract the search in the proximity of the incumbent. The heuristic is off by default and can be enabled by setting `proximitysearch 1` in a GAMS/Cbc options file.
- Parallel branch-and-bound search (multithreading) is now also possible under Windows by using [POSIX threads for Win32] (http://sourceware.org/pthreads-win32).
- New option dumpsolutions to output alternative solutions to gdx files.
- The miptrace options have been renamed to solvetrace and activating them does not affect the solving process anymore.

ConvertD

- Added option `localsolver` to convert GAMS models into [LocalSolver language] (http://www.localsolver.com). This is still an experimental feature, i.e., it may not always be possible to process the created .lsp files with LocalSolver. A major limitation is the restriction to binary and bounded integer variables in LocalSolver. To allow for continuous variables that can be defined via other variables, ConvertD can read information about *defined variables* from a ConvertD options file. In such an option file, a line `defvar x1 e1` denotes that the continuous variable x1 is defined via equation e1. Equation e1 then needs to be an equality constraint which contains x1 in a linear expression. Analogously, a statement `defvar y(n,i,j) e(n,i,j)` indicates that variable y(n,i,j) is defined via equation e(n,i,j) for all (n,i,j).

Couenne

- Couenne is now linked against the nauty library, which enables symmetry recognition for MINLPs and their utilization for orbital branching.
- The miptrace options have been renamed to solvetrace.

Cplex/CplexD

- New library 12.5
- The number of threads for CPLEX to use can now be set to any positive integer number, even if this number exceeds the number of cores on the machine. The default behavior of GAMS/CPLEX with respect to the number of threads and cores remains unchanged. That is, by default, GAMS/CPLEX continues to run with a single thread. Setting `THREADS` to 0, result in setting the threads to the number of cores.
- New parameters:
  - `ProbeDetTime`: Limits the amount of time (expressed in deterministic ticks) spent probing
  - `PolishAfterDetTime`: Sets the amount of time expressed in deterministic ticks to spend during a normal mixed integer optimization after which CPLEX starts to polish a feasible solution
  - `TuningDetTiLim`: Sets a time limit in deterministic ticks per model and per test set (that is, suite of models) applicable in tuning
  - `RandomSeed`: Sets the random seed differently for diversity of solutions.
- GAMS/Cplex prints the time spend in Cplex optimization calls. The time is printed in elapsed seconds and elapsed deterministic time in ticks.
- GAMS/CplexD returns proper duals for QCP models

CONOPT

- new library 3.15H

GloMIQO

- new library GloMIQO 2.1:
  - improved reformulation strategies
  - better recognition of special mathematical structure allowing for dominant polyhedral cuts
  - additional strategies for deterministically inferring missing variable bounds
- new option cplex_optfile specifies a GAMS/CPLEX options file that will be applied to every LP and MILP subsolve
- new option dumpsolutions to output alternative solutions to gdx files

GUROBI

- New library 5.0.2

IPOPT and IPOPTH, BONMIN and BONMINH

- IPOPT is now available in two variations. The Open Source IPOPT is part of the Base Module. IPOPTH uses higher performance (but not Open Source) linear algebra routines (HSL) and is separately priced.
- Analogously, BONMIN is part of the Base Module and uses IPOPT. BONMINH requires a license for IPOPTH.
- For Couenne and SCIP, IPOPTH is used to solve NLP subproblems if a corresponding license is available, otherwise IPOPT is used.

LogMIP

- Fixed a bug when reformulating disjunctions with terms that are indicated by a negated variable (disjunction not y1 e1 else ...).

MINOS

- Maintenance updates, primarily for memory allocation issues.

MOSEK

- New libs Mosek 6 Rev 148.

Optimization Services

- New library 2.6

OsiXpress

- OsiXpress is now also available on Mac OS X.

SCIP

- New library 3.0.1
  - New presolvers have been added, among them one that recognizes and utilizes block structures in an instance.
  - New primal heuristics NLP diving (for MINLPs) and Zero-Objective ("Hail Mary") have been added.
  - New propagators for optimization-based bound tightening for MINLPs have been added.
  - The variable bounds propagator has been extended to cliques and implications.
  - Memory limits are now better handled, especially for larger problems.
  - The probing algorithm has been revised and should give better performance.
  - The performance for pseudo-boolean optimization problems has been improved.
  - The complete release notes can be found [here] (https://www.scipopt.org/doc/html/RELEASENOTES.shtml) and a list of all changes (including changes to parameters and their default values) can be found [here] (https://www.scipopt.org/doc/html/CHANGELOG.shtml)
- The GAMS workspace option can now be used to set the SCIP memory limit ('limits/memory' in optionfile).
- The `gams/miptrace` options have been renamed to `gams/solvetrace`.
- The `gams/printstatistics` option has been renamed to `display/statistics`.
- The `gams/interactive` option is now a string option that takes commands for the SCIP shell as arguments. If the commands do not end with a 'quit' command, the SCIP shell still open for user interaction. Note, that in order to be able to input commands interactively on Windows, you have to set the GAMS option interactivesolver to 1 (see above).
- The LP solver in SCIP can now be changed by the `lp/solver` option. Supported values are "cplex", "soplex", and "clp". The default LP solver is now CPLEX, if a CPLEX license is available, and SoPlex otherwise.

SNOPT

- New library 7.2-12 (maintenance release)
- Completely revamped linking code
  - The GAMS/SNOPT link is now thread-safe, allowing it to be used in multi-threaded applications built with the high-level GAMS APIs mentioned above.
  - Updated memory allocation scheme to increase the amount of memory that can be allocated and used for problem solution, and to improve reporting when limits are reached.
  - Miscellaneous bug fixes and usability improvements.

SoPlex

- New library 1.7.1
  - Performance improvements in pricing algorithms
  - Many bugfixes and improvements in numerical stability and infeasibility detection
  - Complete release notes [here] (http://soplex.zib.de/notes-170.txt).

Sulum

- GAMS 24.0 introduces the new LP/MIP Solver Sulum from Sulum Optimization ApS.
- While Sulum currently does not compete with the high-end LP/MIP solvers, Sulum offers a good cost-benefit ratio for LP and MIP solution technology.
- GAMS 24.0.1 features Sulum LP only, but as soon as Sulum Optimization releases their library including the MIP optimizer, a maintenance release will feature the full LP/MIP capabilities of Sulum.

Xpress

- New library Xpress Optimizer 23.01.06 (maintenance release).

3.35.1.5 Model Libraries

GAMS Data Library

GAMS EMP Library

- **simplevi4 (93)**: Equilbrium model consisting of two VIs, one of which has a non-trivial constraint set
- **transsp (94)**: A Stochastic Transportation Problem
- **oa (95)**: Outer Approximation for Convex Minimization Problem with Binary Variables

GAMS Model Library

- **powerset (381)**: PowerSetLeft and PowerSetRight examples
- **linearne (382)**: Linearization techniques for extremal-Nash equilibria
- **saras (383)**: South African Regionalized Farm-level Resource Use & Output Supply Response (SARAS) model
- **epscmmip (384)**: Improved version of eps-Constraint Method for Multiobjective Optimization
- **bidpwl (385)**: Bid Evaluation with Piecewise Linear Functions
- **trnspwlx (386)**: A Transportation Problem with Piecewise Linear Functions

GAMS Test Library

- **testexeq (562)**: Test external equations
- **ex1 (563)**: External Function - Example 1
- **ex1x (564)**: External Function - Example 1x
- **ex2 (565)**: External Function - Example 2
- **ex3 (566)**: External Function - Example 3
- **ex4 (567)**: External Function - Example 4
- **ex4x (568)**: External Function - Example 4x
- **ex5 (569)**: External Function - Example 5
- **er1 (570)**: External Function - Error Example 1
- **er2 (571)**: External Function - Error Example 2
- **er3 (572)**: External Function - Error Example 3
- **exmcp1 (573)**: External Function - Example MCP 1
- **exmcp2 (574)**: External Function - Example MCP 2
- **exmcp3 (575)**: External Function - Example MCP 3
- **exmcp4 (576)**: Hansen/Koopmans: External Function - Example MCP 4
- **exmcp5 (577)**: Intermixed External Rows: External Function - Example MCP 5
- **complink (578)**: Compile and link external equation libraries
- **lindgl02 (579)**: Check that Lindo(Global) works with SOS variables
- **qcp10 (580)**: Test for QCP correctness
- **empdisj6 (581)**: Test disjunctions with negated equality equations
- **gdx9 (582)**: Test unloading and loading a GDX file with variable attributes
- **empdisj7 (583)**: Test disjunctions with negated variables
- **traceuc (584)**: Test if we can get the user and computer name in a trace file
- **asynntrp (585)**: Start GAMS job asynchronously and send interrupt signal to it

3.35.1.6 Tools

SCENRED2

- fixed visualization output to work with recent versions of gnuplot

3.35.1.7 Solver/Platform Availability Matrix

3.35.2 24.0.2 Maintenance release (February 14, 2013)

3.35.2.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Arne Drud, Michael Ferris, Erwin Kalvelagen, Aida Khajavirad, Ignacio Perez, Nick Sahinidis, and Dimitri Tomanos.

3.35.2.2 Platforms

- removed dependency on GLIBC 2.7 in Linux systems

3.35.2.3 GAMS System

APIs

Object Oriented APIs

- introduced new function CopySymbol (see individual languages for precise name)
- label and symbol lookup is now case insensitve
- fixed handling of infinite bounds for GAMSModifiers

.NET

- added new function GAMSSymbol.CopySymbol
- added new examples in Visual C++ and VB.NET

Java

- added new function GAMSSymbol.copySymbol

Python

- added new function _GamsSymbol.copy_symbol
- on Windows and Linux, compiled libraries for both Python 2.6 and Python 2.7 are distributed while the Python 2.7 version can be found in <GAMSDir>\apifiles\Python\api as before, the Python 2.6 version is in <GAMSDir>\apifiles\Python\api_26

GDX

- fixed a casing problems with the function `gdxSymbolGet/SetDomainX` for client languages C++, C#, Fortran, Java, Python, VBA, VB.NET

GMO

- increased API version number to 11 (was forgotten in 24.0.1)

GAMS

- the reason for ignoring an option in the GAMS options file reader is now printed
- fix a bug when reading scalars from a compressed GDX file

GAMS IDE

- changed the interface for the Text Differ to look like the GDXDiff interface
- moved menu for Text Diff under Utilities menu

Utilities

GDXXRW

- gdxxrw works now with Excel Binary Workbook files (file extension `.xlsb`)

3.35.2.4 Solvers

BARON

- new library 11.9.1
- fixed handling of workspace and workfactor options

BONMIN, CBC, Couenne, GloMIQO, SCIP

- fixed too small value in 'seconds' column in solvetrace file
- improved resolution of solvetrace file for Cbc and SCIP

CONOPT

- new library 3.15I
- major update of the CONOPT solver manual (pdf file only)
- revised definition of workspace and workfactor options: workfactor is now ignored if workspace is defined
- minimum memory allocation adjusted for some smaller machines
- removed no longer used options GCFORM, GCPTB1, GCPTB2

GloMIQO

- fixed bug in reporting of dual bound when optca tolerance is larger in magnitude than optcr

GUROBI

- new library 5.1
- new options
  - `ImproveStartNodes`: A new option for transitioning from tree exploration to solution improvement in MIP
  - `Seed`: Modifies the random number seed. This acts as a minor perturbation to the solver, which typically leads to a different solution path. This can be useful for experimentation (e.g., for testing the robustness of a particular set of parameter changes)
- Gurobi dropped support for Linux 32bit, so GAMS/Gurobi uses Gurobi library 5.0.2 on Linux 32bit

MOSEK

- write clearer text error message to log and listing file

MPSGE

- fixed memory issues when both workspace and workfactor are set and when estimates are too high

MSNLP / OQNLP

- fixed problems with LSGRG on instances with more than 10000 variables or more than 10000 equations

SCIP

- new SCIP library 3.0 #0134f8c
- fixed bug where the reported objective value did not equal the level value of the objective variable
- improved cleanup of SCIP solutions that are not feasible in the original problem; the model status is now adjusted accordingly

XPRESS

- fixed reporting of resused and iterused attributes for infeasible and unsolved models

3.35.2.5 Tools

ConvertD

- in LocalSolver output, long linear parts of equations are now printed by using the sum() operator
- added solution output option and functionality for LocalSolver (lspsol)
- fixed bug when using objvar option in conversion to GAMS format
- fixed bug with variable indices when writing nonlinear expressions

EXAMINER

- fixed check of complementarity slackness for discrete variables in MIQCPs
- added a consistency check on model attributes (currently only objval)

JAMS

- fixed many problems with objective functions in equilibrium followers, especially those arising when variables were skipped or when the objective var was reformulated out
- fixed problems with VI models and vars getting squeezed out that should not have been

3.36 23.9 Distribution

3.36.1 23.9.1 Major release (July 04, 2012)

3.36.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Steve Gabriel, Oyvind Hoveid and Renger van Nieuwkoop.

3.36.1.2 Platforms

- We added some instructions on how to install the GAMS Windows version (including the IDE) on the Mac using Wine.
- The Unix installer has already been changed with 23.8. When running the installer, a subdirectory is created (e.g. `gams23.9_linux_x86_32_sfx` for the Linux 32bit installer). Previous versions unpacked the GAMS distribution into the current directory.

3.36.1.3 GAMS System

APIs

.NET

This release contains a beta version of the object-oriented GAMS .NET that can be used to control GAMS from within C# and other programming languages of the .NET framework 4. It allows the seamless integration of GAMS into the .NET environment by providing appropriate classes for the interaction with GAMS. The `GAMSDatabase` class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the `GAMSJob` class and by using the `GAMSModelInstance` class a sequence of closely related model instances can be solved in the most efficient way.

To use this one has to reference `GAMS.net.dll` which can be found in the GAMS system directory. Documentation about this can be found in `<GAMSDir>\apifiles\GAMS.net4.chm`.

C#

- Gamsx, gdx and opt implement IDisposable interface
- New example example2.cs using APIs to gamsx, gdx and opt
- Several new examples using the new .NET

GDX

- Added functions to get and set relaxed domain information
- Added function to get memory usage of a gdx object

GAMS

On/OffOrder

- Lag and lead operations require the reference set to be ordered and constant. In some special cases one would want to use lags and leads on dynamic and/or unordered sets. A dollar control option `on/offOrder` has been added to locally relax the default requirements. The use of this option comes at a price: the system will not be able to diagnose odd and incorrect formulations and data sets. A small example in Test Library **lagd1** illustrates the use of `on/offOrder`.

gamsbatch

- The script to run GAMS in the background (`gamsbatch`) has been removed from Unix distributions. This script was a source of confusion when multiple GAMS systems were installed. A GAMS job can be run in the background easily without this script.

Minor enhancements

- GAMS solvers that provide a bound on the optimal solution (e.g. Branch-and-Cut based solvers) can return this bound to the calling GAMS model through the model attribute `objest`. In previous versions of GAMS this model attribute was not set if no solution was found. This has been fixed with this release.
- When GAMS/Base writes a GDX file containing a subset of all symbols present, it will now also write relaxed domain information to the GDX.

Function libraries

- The new extrinsic function library `lsadclib` was added to the system. It allows to use sampling routines from Lindo inside GAMS. A license for GAMS/Lindo is required to use this library. Without a license only a demo version is available which is restricted to the Normal and the Uniform distribution with not more than 10 sample points. Further information can be found in the GAMS User's Guide, Appendix J.

Utilities

GAMSIDE

- The data viewer in the GAMSIDE shows the domain information
- New history combo box for alternate system directory

GDX2Access

- Use relaxed domain information to generate column names

GDXDUMP

- Added option to write CSV formatted file (Format=[normal, gamsbas, csv])
- Added option to use last dimension as a column header for CSV output (CDim=[Y, N])
- Added option to not filter default values (FilterDef=[Y, N])
- Option to show domain information (DomainInfo)

XLSDump

- Truncate long UELs

XLSTalk

- Allow for a relative path in the file specification

Other

3.36.1.4 Solvers

Baron

- BARON 11: This version comes with a wealth of new branching, relaxation, convexity exploitation, local search, and range reduction techniques. You will see improvements in many problems, including convex ones. In addition, BARON 11 offers systematic treatment of missing bounds through safe LP relaxations. Users will see far fewer messages about missing bounds from BARON from now on, while many more problems will be guaranteed global.

Coin-OR

- new libraries Bonmin 1.6 and OS 2.5
- bugfixes in Cbc and Couenne

Conopt

- New libraries 3.15F

Cplex

- new libraries 12.4 fix pack 1

GloMIQO

- New library GloMIQO 2.0
- GloMIQO 2.0 alternatively uses Conopt or Snopt for finding feasible solutions (default Conopt).
- GloMIQO 2.0 fully integrates integer variables, discrete/discrete products, and discrete/continuous products
- GloMIQO 2.0 implements a branch-and-cut framework with cutting planes derived from edge-concave aggregations, alphaBB cuts, and convex terms. Cuts are based on both individual equations and the collection of quadratic and bilinear terms in MIQCQP.
- GloMIQO 2.0 automatically adds bilinear terms to the model formulation to create Reformulation-Linearization Technique (RLT-1) equations.
- The Boost Interval Arithmetic Library improves the reliability of the GloMIQO 2.0 bound tightening schemes.

Gurobi

- New library Gurobi 5.0.1
- Quadratic constraint support: You can now add Second-Order Cone constraints, rotated Second-Order Cone constraints, and general Quadratic Constraints to an optimization model. Continuous models containing these constraints are solved using a new barrier SOCP solver. Mixed-integer models are solved using a branch-and-cut algorithm, employing either QCP node relaxations or an outer-approximation algorithm.
  - The new options are:
    - `BarQCPConvTol`: Convergence tolerance for the barrier algorithm when solving a QCP.
    - `PreQLinearize`: Controls linearization of Q matrices in the quadratic constraints or a quadratic objective.
    - `QCPDual`: Determines whether dual variable values are computed for QCP models. Gurobi has this off by default. In GAMS/Gurobi this is on by default.
    - `MIQCPMethod`: Determines whether outer approximation is used to solve an MIQCP model.
- Feasibility relaxation: Gurobi now provides a feasibility relaxation model for an infeasible model. This related model will find a solution that minimizes the violation of the original constraints. Check option `FeasOpt` for details.
- Simplex warm-starting from a solution: You can now warm-start the simplex method using a primal and dual solution vector. In previous versions, warm-starting was only possible if you had a simplex basis. Check option `UseBasis` for details.
- Barrier homogeneous algorithm: Gurobi now provides a homogeneous algorithm in the barrier solver. This version should be used when you are likely to ask the barrier solver to solve infeasible or unbounded models. Use the new `BarHomogeneous` option to select this.
- Gurobi now provides both exact and approximate condition number estimates for the optimal simplex basis. Use `Kappa` if you want a quick estimate, or `KappaExact` if you want to spend the sometimes substantial time required to compute the exact condition number.

GUSS

- Introduce option `NoHotStart` to suppress hot starts with hot start capable solver.
- Temporary scenario files are located now in the scratch directory, so multiple GUSS runs can take place in the same directory without interference.

MOSEK

- New libraries Mosek 6 rev 137

PATH

- Bug fix in preprocessor

SCIP

- New library SCIP 2.1.2

Xpress

- New libraries: Xpress Optimizer 23.0.05
  - Improved Barrier performance, especially on modern Intel CPUs. The Barrier solver will now take advantage of Intel's Advanced Vector Extensions (AVX) when available.
  - New symmetry detection and orbital branching for MIPs.
  - Improved in-tree cutting strategy.
  - Added some quick heuristics that will be run before the initial root LP is solved.
- New platform supported: Mac OSX 64-bit
- Minor updates to link
  - bugs fixed: handling of QCP models with equality constraints, interrupted solves
  - pass the objective constant on to Xpress Optimizer
  - add new options to control XPRESS symmetry detection

3.36.1.5 Documentation

- Updated Expanded GAMS Guide (McCarl) to reflect release 23.9
- The solver Manual has been split into two parts: *I The Commercial Solvers* and *II The Free Solvers*. Printed versions of the manual will only contain part I. The on-line/ version has both parts available.

3.36.1.6 Model Libraries

GAMS Data Library

- **TrnsxcllStarter (83)**: Excel Spreadsheet in Charge of GAMS

GAMS EMP Library

GAMS Model Library

- Updated:
  - **qp7 (271)** and **emfl (273)**: Both models use second order cone constraints. The constraints are written with the `=c=` syntax if MOSEK is the selected solver and as general quadratic constraints if CplexD or Gurobi are the selected solvers
  - **feasopt1 (314)**: This model has been modified so it can be used by Cplex and Gurobi. Both solvers support the `FeasOpt` option to find minimal relaxations for infeasible models
- New:
  - **ps5_s_mn (377)**: Parts Supply Problem w/ 5 Types w/ Random p(i)
  - **iobalance (378)**: Updating and Projecting Coefficients: The RAS Approach
  - **fdesign (379)**: Linear Phase Lowpass Filter Design
  - **pmeanvar (380)**: Mean-Variance models with variable upper and lower bounds

GAMS Test Library

- Updated:
  - **circlen (551)**: Added an SOCP formulation to the smallest circle problem
- New:
  - **mpsge12 (558)**: MPSGE test - inter-mixed MPSGE and MCP rows in model
  - **gdxcomp2 (559)**: GDX - compressed and MT operation
  - **lagd1 (560)**: Lag and Lead operations on Dynamic Sets
  - **miqcp02 (561)**: Test of correctness of solvestat

3.36.1.7 Solver/Platform Availability Matrix

3.36.2 23.9.2 Maintenance release (August 29, 2012)

3.36.2.1 GAMS System

APIs

.NET

- `GAMSModelInstance.Instantiate` is now thread-safe
- Additional flag `createOutDB` for method `GAMSJob.Solve` which allows to switch off automatic `outDB` creation
- New class `GAMSModelInstanceOpt` to customize method `GAMSModelInstance.Solve`
- Delete some temporary files, add `GAMSWorkspace.ScratchFilePrefix` (default: `_gams_net`) for temporary files
- `GAMSJob` no longer implements `IDisposable`; examples have changed because the `using` statement no longer works with `GAMSJob`

Java

- Now methods that returned `long` in Java but `void` in C also return `void` in Java

GAMS

MaxProcDir

Changed default for GAMS parameter `MaxProcDir` from 26 to 700 which allow to have up to 700 scratch directories (225a, 225b, ...) in the project/current directory

Utilities

GAMSIDE

Double-click to open a file in the IDE works again (also fixes a single click in the McCarl guide)

3.36.2.2 Solvers

AlphaECP

- Fixed objective estimate `modelname.ObjEst`

Baron

- New BARON 11.3.0 library (bugfixes)

Coin-OR

- New Couenne library (bugfixes)
- New Bonmin library (bugfix for B-OA as algorithm choice)

ConvertD

- New option `DictMap` in ConvertD

Cplex

- CplexD: fixed bug when registering an advanced basis

GloMIQO

- New GloMIQO library (bugfixes)

Gurobi

- New Gurobi 5.0.1 library for AIX
- OsiGurobi: fixed mipstart option (now only values for discrete variables are passed to Gurobi)

Jams

- New option `DisjBinRelax` in JAMS to allow continuous (but implicit binary) variables

Knitro

- Work around problems with knapsack cuts for MINLPs

Lindo

- New Lindo 7.0.1.487 library (bugfixes)

SCIP

- Fixed wrong sign of objective when maximizing a nonlinear objective

3.36.3 23.9.3 Maintenance release (September 26, 2012)

3.36.3.1 GAMS System

APIs

.NET

- Constructor of `GAMSWorkspace` now appends conditionally the GAMS system directory to the PATH environment variable. This fixes a problem with applications that create and dispose many `GAMSWorkspace` instances.

GAMS

- Spaces in Project/Current Directory: With 23.9.2 some solvers (e.g. BARON) do not work if the project/current directory name contains a space. This has been fixed.

Utilities

- GDXMRW: Some bugfixes for the GAMS/MATLAB connector.

3.36.3.2 Solvers

Coin-OR

- New Couenne library (bugfixes)

3.36.4 23.9.4 Maintenance release (October 20, 2012)

3.36.4.1 GAMS System

GAMS

- GAMS did not pass models with quadratic constraints containing the objective variable properly to some solvers (CplexD, Gurobi, Mosek and Xpress). Thanks goes to [Erwin Kalvelagen] (http://yetanothermathprogrammingconsultant.blogspot.com/2012/10/gamsgurobi-qcp-problems.html) bringing this to our attention. This has been fixed.
- The GAMSIDE remembers the scope setting for text searches even after the IDE closes.

3.36.4.2 Solvers

Baron

- New libs 11.5.0
- Fixed a bug when using the external NLP solver on models without constraints
- New speed ups in Baron's parser/reformulator for large scale problems
- Improvements in local search that result in higher quality solutions identified earlier in the search
  - New dive-and-round heuristic for MINLPs. The number of rounds is selected dynamically and the search is activated and applied based on problem characteristics
  - For continuous problems, Baron introduces the ability to automatically select and switch back and forth between NLP solvers. Again, this is done in a dynamic strategy that exploits problem characteristics and solver performance for the problem at hand
  - The `nlpsol` option can now take the value of `-1` in addition to the previously allowed values. `-1`, which is the default value, triggers the automatic NLP solver selection and switching strategy. If the user sets `nlpsol` to a solver that is not licensed, Baron sets it automatically to `-1`
  - The `dolocal` option can now take only two values (`0: no local search; 1: BARON's automatic strategy`). Default is `1` and will determine when/how to apply local search
  - Baron uses the most recent Snopt library (7.2-4)
  - Improvement for links to NLP solvers Minos, Snopt, and IpOpt.

Conopt

- New 3.15G library with bug fixes

GloMIQO

- A problem with parsing integer options has been fixed

Minos

- Improved memory estimation calculations and logging

3.36.5 23.9.5 Maintenance release (November 09, 2012)

3.36.5.1 GAMS System

**GDX
**

- When importing a scalar variable or equation from a GDX file, the `.scale` attribute was set incorrectly. This has been fixed. Thanks go to Étienne Ayotte-Sauvé unearthing this problem.
- Under some circumstances GAMS ended up with an inconsistent database when importing unsorted data. This has been fixed. Thanks go to Wolfgang Britz unearthing this problem.

3.36.5.2 Solvers

Baron

- New libs 11.5.2
- Fixed a reporting problem when no duals are available.

CplexD

- GAMS/CplexD produced in some cases incorrect quadratically constraint and SOCP problems for the Cplex engine. This has been fixed.

LindoGlobal

- Lindo's global solver cannot deal with SOS variables. If a model has SOS variables, the link automatically switches to the local solver.

LogMIP

- Fixed bugs in `bigm` and `indic` reformulation of negated equality equations. The convex hull reformulation still has problems and has therefore been disabled for this case for now. Thanks go to Silvia Tomasi for reporting this problem.

3.37 23.8 Distribution

3.37.1 23.8.1 Major release (March 17, 2012)

3.37.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Alessandro Brozzi, Jan Philipp Dietrich, Michael Ferris, Christophe Gouel, Josef Kallrath, Cheng Khor, Brage Knudsen, Jeff Larson, Yanchao Liu, Alexander Mitos, Renger van Nieuwkoop, Stefan Vigerske.

3.37.1.2 Platforms

- Beta GAMS/Wine system (32bit). Comments are highly appreciated (support@gams.com).
- Improved Windows Installer
  - the default location has changed to `C:\GAMS\(win32|win64)\23.8` to avoid problems produced by the permission settings of the *Program Files* location
  - Two different setup modes. A simple default mode and an advanced mode with additional options like automatic *PATH* manipulation
  - Support for detecting and installing a license from the clipboard

3.37.1.3 GAMS System

APIs

- C#
  - Major improvements, lost compatibility to previous versions!
  - Mixed casing of function names
    - old: gdxdatawritestr
    - new: gdxDataWriteStr
  - Object handle (pointer) no longer needed
    - old: int gdxdatawritestr(IntPtr pgdx,string[] keystr,double[] values)
    - new: int gdxDataWriteStr(string[] KeyStr,double[] Values)
  - Create calls replaced by different constructors
    - old: gdx = new gdxcs(); gdx.gdxCreateD(ref PGX, Sysdir, ref Msg);
    - new: gdx = new gdxcs(Sysdir, ref Msg);
  - See examples in <`GAMS Dir`>\`apifiles`\`CSharp` for reference
- Python
  - Add source code to build C extensions (no need to run SWIG anymore)
  - Add compiled C extension on Linux and Windows (both 32 and 64 Bit)
- VBA
  - Support for 64 Bit version (VBA 7)

GAMS

New model definition features

- **Flexible model list**
  Model definitions containing complementary equ.var pairs can now be used with all model types. The matching information is only used with the appropriate model types (e.g. MCP, MPEC, RMPEC).
- **Model list edits**
  In addition to the ',' which enforces uniqueness of equation entries, two additional model list element separators have been introduced. The '+' separator allows replacement of existing entries. The '-' separator deletes model list entries. All three of these operations can be used with single equation names, equ.var pairs and previously defined model names.
- **Example**

```
$eolcom !
equation e1,e2,e3,e4,e5; variable x1,x2;
e5.. x1 =l= 0;
e4.. x1 =l= 0;
model m1 / e1,e2 /
      m2 / e3,e4 /
      m3 / m2,m1,e5 /                ! e3,e4,e1,e2,e5
      m4 / all-m1+e1+e1 /            ! e3,e4,e5,e1
      m5 / all + e5.x1 + e4.x2 -e1/  ! e2,e3,e5.x1,e4.x2
      m6 / m5 -e5, e5.x2 /           ! e2,e3,e4.x2,e5.x2
      m7 / m5 + e5.x2 /              ! same as m6
```

Note that the equation list is ordered left to right. If we have a '+' separator adding an equation already in the list, the equation (possibly modified) will move to the end of the list.

Permutations via the option statement

- Using the '>' sign one can create complete permutations of one- and multi-dimensional sets and parameters:

```
Option PermAllI > I;
```

  Examples of this new feature can be found in the models **perm1**, **ptsp**, **flowshop**, and **pmelody**.

Minor enhancements

- Functions can have up to 10 arguments. This effects the intrinsic functions `edist` and `poly` and extrinsic function libraries.

Stochastic Programming

In this release we made a first cut at supporting stochastic programming in GAMS. With a few changes uncertainty can be added to an existing deterministic model. For this, the EMP framework is used to replace parameters in the model by random variables. This way (stagewise-independent) multi-stage recourse problems and chance constraint models can be formulated. Three solvers can be selected to solve those problems: DE, DECIS and LINDO.

Further information can be found in the document Stochastic Programming (SP) with EMP.

In addition, you can check examples of type `SP` from the **GAMS EMP Library**.

Utilities

- **mps2gms** MPS input file allows LI (lower integer) bound types and treats tabs as spaces.

Other

- By default GAMS does not call an exit script anymore. If this is required, the GAMS parameter `ScriptExit` has to be set explicitly to the script that should be called after GAMS terminates. An empty template of an exit script can be found in the GAMS system directory (`gmsxitnt.cmd` (Windows) or `gmsxitus.run` (Unix)).

3.37.1.4 Solvers

AlphaECP

- New libraries 2.09.01
- Support of =N= rows

Baron

- New libraries Baron 10.1
- Main developments
  - Minos and Snopt are no longer available as LP subsolvers
  - Clp can be used as the LP subsolver (`lpsol = 8`)
  - Ipopt with Mumps and Metis can be used as the NLP subsolver (`nlpsol = 9`)
  - BARON automatically selects Clp and Ipopt if the selected/default subsolver is not licensed
  - Improved interface to Xpress-LP
  - Introduced cutting planes for convexity exploitation for a variety of functions, including products and ratios, perspectives, norms (including absolute functions) and seminorms, and quadratic functions that are automatically recognized and exploited
  - Polyhedral convexification routines have been rewritten and are now more efficient and numerically robust, as well as performing a number of simplifying transformations that reduce relaxation gaps
  - Introduced relaxations based on inferred bilinear relationships (certain types of first-order RLT)

Bench

- calls solvers to benchmark in parallel using GAMS' grid functionality

Coin-OR

- OSIXpress supported on Solaris/Intel
- Dropped support of GLPK (alias OsiGlpk, alias CoinGlpk)
- New libraries:
  - Bonmin 1.5
  - Cbc 2.7
    - improvements in heuristics and cut generation
  - Clp 1.14
  - Couenne 0.4 (for details see the [Couenne release notes] (http://list.coin-or.org/pipermail/couenne/201
    - feasibility pump heuristic for MINLP (can use SCIP as MIP solver)
    - fixed point bound tightening and two-implied bound tightening
    - introduction of semi-auxiliaries for smaller LP relaxations
  - Ipopt 3.10
  - OS 2.4
    - now supports semicontinuous and semiinteger variables
  - Osi 0.105
- Cbc, Bonmin, and Couenne support `miptrace`

Convert

- Convert supports writing [Optimization Services instance Language (OSiL)] (http://www.coin-or.org/OS/OSiL.ht

Conopt

- New libraries 3.15C

Cplex

- new libraries 12.4
- `dettilim`: option to limit 'ticks'

DE

- `GAMS/DE` accepts EMP models that have been annotated with information about uncertainty. The DE 'solver' reformulates the stochastic model into the extensive form equivalent with implicit non-anticipativity constraints. The reformulated model is solved with any of the regular GAMS solvers. All optimization model types (LP, MIP, QCP, MIQCP, NLP, DNLP, and MINLP) are accepted.

DECIS

- `GAMS/DECIS` accepts 2 stage EMP stochastic models. The stochastic information is processed and is passed to the well known `GAMS/DECISC` or `GAMS/DECISM` solver. The need to provide the stochastic information based on the matrix elements is now unnecessary. `DECIS`, as `GAMS/DECISC` and `GAMS/DECISM`, accepts linear recourse models only (although the stochastic effects might be more complex).

DICOPT

- If the model given to DICOPT is linear, DICOPT just passes this model to the MIP solver. Previously, the MIP solver used parameters OptCR, OptCA, and ResLim as specified by GAMS options even if DICOPT used an option file. Now OptCR, OptCA, and ResLim from a DICOPT option file will overwrite the GAMS parameters.

GloMIQO

The new Global Mixed-Integer Quadratic Optimizer, GloMIQO (GLO-me-ko), solves Quadratically Constrained Programs (QCP) and Mixed-Integer Quadratically Constrained Programs (MIQCP) to epsilon-global optimality.

- GloMIQO has been developed by Prof. C. Floudas and R. Misener from Princeton University
- The GloMIQO solver is available for the 32-bit and 64-bit versions of Windows and Linux
- GloMIQO requires the presence of a GAMS/CPLEX and GAMS/SNOPT license

Gurobi

- New library Gurobi 4.6.1
- New sifting option for linear programs: LP models can now be solved with a sifting algorithm. Gurobi will choose sifting automatically when using the dual simplex algorithm for models that are likely to benefit (those with many more columns than rows). If you want to invoke sifting manually, choose dual simplex and set the new `Sifting` parameter to a value greater than 0.
- Branch priorities: You can now specify priorities for branching variables, allowing greater user control of the MIP search process. Priorities can be specified through the .prior variable attribute and the .prioropt model attribute.
- New Zero Objective heuristic: Gurobi 4.6 contains a new Zero Objective heuristic that can be useful for finding solutions to MIP models where other strategies fail to find feasible solutions in a reasonable amount of time. Use the new `ZeroObjNodes` parameter to control this new heuristic.
- New presolve sparsify option: A new presolve sparsify algorithm is available for MIP models. This method attempts to reduce the number of non-zero coefficients in the constraint matrix. Reductions of 3X or more have been observed on some models, often leading to significant performance improvements. Use the new `PreSparsify` parameter to enable this algorithm.

Guss

- Added option `NoMatchLimit` (default 0) that controls the maximum number of accepted unmatched scenario records before terminating the solve.

Ipopt

- The Serial Graph Partitioning and Fill-reducing Matrix Ordering software METIS can now be used by some of Ipopt's linear solvers.
- Starting with 23.8 GAMS offers a commercially supported version of GAMS/IPOPT. This version of GAMS/IPOPT includes the commercial strength linear solvers MA27, MA57, and MA86 from the Harwell Subroutine Library.

Jams

- Support Xpress and SCIP when reformulating disjunctions with indicators

Knitro

- New libraries Knitro 8.0
- Introduction of a presolver to simplify and reduce the size of the model
- Introduction of parallel (multi-threaded) execution
  - Multi-start
  - Multi-algorithm
- Multi-algorithm method
  - New mode to run multiple algorithms, serially or in parallel
  - Uses the first or (optionally) the best solution found
- New feasibility-only mode: improves robustness and efficiency of detecting infeasible models
- Knitro 8.0 discontinues support for 32-bit Darwin systems - only 64-bit systems are supported on the Mac.

Lindo

- New solver Lindo, similar to LindoGlobal, but
  - Without size limitations
  - No requirement for additional Conopt license
  - `GAMS/LINDO` accepts stochastic EMP models and solves either the extensive form equivalent or uses Benders' decomposition to solve the stochastic model. In addition to discrete random variables, Lindo features also continuous distribution functions and various sampling techniques. All optimization model types (LP, MIP, QCP, MIQCP, NLP, DNLP, and MINLP) are accepted.

LindoGlobal

- New libraries Lindo 7.0
- MIP
  - Significant improvements in root node heuristics for quickly finding good integer feasible solutions
  - Improved identification of special structures, as in multi-period models, and the ability to exploit these structures to achieve significant reductions in solve times
- Global Solver
  - Improved heuristics for finding a good feasible solution quickly
  - Improved ability to identify constraints that can reformulated as second order cone (SOC) constraints and thus be solved by the fast SOC solver
  - Improved ability for efficiently handling polynomial terms
  - Improved bounds for non-convex quadratic terms, using SDP and eigenvalue reformulations
  - Improved control over multi-start algorithm

MOSEK

- New libraries Mosek 6 rev 135

SCIP

- New libraries SCIP 2.1.1 (for details see the [SCIP release notes] (https://www.scipopt.org/doc-2.1.1/html/RELE
- Beta-version of supporting (mixed-integer) nonlinear programs (also nonconvex)
- Supports `miptrace`
- Supports indicators for linear constraints through option `gams/indicatorfile`
- Added option `gams/dumpsolutions` to write all solutions found into gdx solution pool

Snopt

- bug fix for log of LP models

SoPlex

- New libraries SoPlex 1.6.0 (for details see the [SoPlex release notes] (http://soplex.zib.de/notes-160.txt))

XA

- New libraries XA 17 on Windows
- Introduction of native 64-bit Windows support

Xpress

- New libraries 22.01.15 (maintenance release)
- MIP solution pool capability - allows a number of feasible solutions to be stored for later processing. By default the global search is not altered, but there is an option to enumerate all or selected integer feasible solutions. The enumeration can be tailored via the option file to execute a number of different strategies, e.g.:
  - all integer feasible solutions
  - N-best solutions
  - as-good-as-X solutions (all solutions with objective at least as good as X)
  - N-first solutions (first N solutions found)
- Solution pool examples are available in testlib: **xpress03** (default global search), **xpress04** (enumeration of all solutions), **xpress05** (various enumeration strategies).
- Support for continuous models with quadratic constraints (previously only quadratic objectives were supported) and for all mixed-integer quadratic (MIQCP) models
- Support for indicator constraints
- New option `isGoodEnough=X` implemented in the link. If set, the global search will stop once an integer feasible point is found with an objective at least this good. Surprisingly, none of the MIP solver vendors implement such an option directly in their libraries.

3.37.1.5 Documentation

Amongst others, the following topics were revised in both, the **GAMS Users Guide** and the **Bruce McCarl's Expanded GAMS Guide**

- Command Line Parameters
- Dollar Control Options
- Model Attributes
- GAMS Intrinsic and Extrinsic Functions

3.37.1.6 Model Libraries

GAMS Data Library

- **GDXMRWPlotting01 (81): Placeholder for the GDXMRW examples that deal with plotting in Matlab**
- `makeql (82)`: Create Querry Library routines for extrinsic functions

GAMS EMP Library

- **two3emp (68)**: EMP Formulation of Simple 2 x 2 x 2 General Equilibrium Model
- **airsp3 (69)**: Aircraft allocation - stochastic optimization
- **apl1psp (70)**: Stochastic Electric Power Expansion Planning Problem
- **apl1pcasp (71)**: Stochastic Electric Power Expansion Planning Problem
- **clearlaksp (72)**: Scenario Reduction: ClearLake exercise
- **farmsp (73)**: The Farmer's Problem - Stochastic
- **kilosafarm (74)**: Kilosa farm problem
- **landssp (75)**: Optimal Investment
- **nbContIndep (76)**: Newsboy problem, continuous and independent distribution
- **nbContJoint (77)**: Newsboy problem, continuous and joint distribution
- **nbDiscIndep (78)**: Newsboy problem, discrete and independent distribution
- **nbDiscJoint (79)**: Newsboy problem, discrete and joint distribution
- **portfolio (80)**: Stochastic portfolio model
- **prodsp3 (81)**: Stochastic Programming Example
- **simpleChance (82)**: Simple chance constraint model
- **sp3x2 (83)**: Simple stochastic model
- **tr20 (84)**: Extended transport model with stochastic demand and costs
- **nbsimple (85)**: Simple newsboy problem, discrete
- **airlift (86)**: Airlift operations schedule
- **stocfor3 (87)**: Long Range Forest Planning
- **circlesp (88)**: Circle Enclosing Points - Stochastic Example
- **batchsp (89)**: Design of batch chemical plants with stochastic demand and price
- **cargonet (90)**: Cargo network scheduling with stochastic transportation demand
- **gen2s (91)**: Two stage stochastic program in the generic form
- **sku1sp (92)**: Multi-product assemble model with discrete and Poisson demand distribution

GAMS Model Library

- **cubesoln (371)**: Three-dimensional Noughts and Crosses Multiple Solutions
- **sipres (372)**: Global optimization of semi-infinite programs via restriction of the right-hand side
- **cclinpts (373)**: Finding Optimal Breakpoints when linearizing a power utility function
- **ptsp (374)**: Traveling Salesman Problem Instance solved with explicit Permutation Enumeration
- **pmelody (375)**: Choose notes for melodic lines and chords with permutations
- **flowshop (376)**: Flow shop scheduling

GAMS Test Library

- **nlcode6 (534)**: Test for NL code bug from Dist 23.6
- **scensol3 (535)**: NoMatchLimit GUSS Test
- **gzip01 (536)**: Test gzipped input files
- **sl4qcp01 (537)**: Test of correctness for levels & marginals of QCP, with solvelink=1,2,4,5
- **sl4qcp02 (538)**: Test modsolstat & solution correctness - multiple QCons, with solvelink=1,2,4,5
- **sl4qcp03 (539)**: Test case for cancellation in quadratic terms, with solvelink=1,2,4,5
- **miqcp01 (540)**: Test of correctness for levels & marginals of MIQCP
- **indic01 (541)**: Test of =g= indicator constraints
- **indic02 (542)**: Test of =e= indicator constraints
- **kestrel1 (543)**: Kestrel test for lp solvers
- **kestrel2 (544)**: Kestrel test for mcp solvers
- **kestrel3 (545)**: Kestrel test for nlp solvers
- **kestrel4 (546)**: Kestrel test for minlp solvers
- **indic03 (547)**: Test of =e= indicator constraints
- **xpress03 (548)**: XPRESS test suite - solution pool example
- **mip05 (549)**: Maximum queens chess problem
- **xpress04 (550)**: XPRESS test suite - solution enumerator example
- **circlen (551)**: Circle Enclosing Points n dimensional
- **trilib04 (552)**: Demonstrates problems with a stateful function library
- **mip06 (553)**: Cuts and solution enumeration
- **xpress05 (554)**: XPRESS test suite - solution enumerator example
- **qcp09 (555)**: Simplest test for QCP correctness
- **perm1 (556)**: Test for various permutations
- `ctrlcmip (557)`: Test interrupt handling *[not available anymore]*

3.37.1.7 Solver/Platform Availability Matrix

3.37.2 23.8.2 Maintenance release (April 05, 2012)

- Bugfix for models with `=X=` rows and MCP (i.e. MPSGE)
- GloMIQO resets `OptCR=0` properly to 1e-9 and accepts now Ctrl-C on Windows
- Knitro handles MINLP failures better
- XPRESS handles `=E=` quadratic constraints better now
- Changed position of Library Form in GAMSIDE (avoid hang in corner to corner screen setup)
- Model `Trnsxcll` added to GAMS Data Library
- Model `ps5_s_mn` added to GAMS Model Library

3.38 23.7 Distribution

3.38.1 23.7.1 Major release (July 14, 2011)

3.38.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Michael Ferris, Josef Kallrath, Andreas Lundell, Renger van Nieuwkoop, Sabine Ritter, Stefan Vigerske, and Kent Zhao.

3.38.1.2 Platforms

- The 32bit and 64bit Linux systems are now built using the [GNU Compiler Collection (GCC)] (http://gcc.gnu.org/) toolset.
- Dropped support of Windows 95, 98, ME, and 2000.

3.38.1.3 GAMS System

GAMS

Asynchronous Execution

For a long time GAMS supports calling executables via the `$call` and `Execute` in a synchronous way. The new release also supports asynchronous job handling. This means you can start a job without waiting for the result. You can continue in your model and collect the return code of the job later. There are three ways to start a job asynchronously:

- `$Call.ASync ...` (compile time)
- `Execute.ASync '...';` (execution time)
- `put_utility fx 'Exec.ASync' / '...'; / put_utility fx 'Shell.ASync' / '...';` (execution time)

After each of those the function `JobHandle` can be used to get the Process ID (pid) of the last job started. With `JobStatus(pid)` one could check for the status of a job. Possible return values are:

- 0: error (input is not a valid PID or access is denied)
- 1: process is still running
- 2: process is finished with return code which could be accessed by errorlevel
- 3: process not running anymore or was never running, no return code available
- With `JobTerminate(pid)` a interrupt signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.
- With `JobKill(pid)` a kill signal can be sent to a running job. If this was successful the return value is one, otherwise it is zero.
- The model **asynexec** from the GAMS Test Library demonstrates the use of this new feature.

Function Libraries

The new GAMS Function Library Facility allows users to import functions from an external library into a GAMS model. Apart from the import syntax, the imported functions can be used in the same way as intrinsic functions. In particular, they can be used in equation definitions. Some function libraries are included with the standard GAMS software distribution but GAMS users can also create their own libraries using an open programming interface. Simple examples in the programming languages C, Delphi and Fortran come with every GAMS system.

Function libraries are made available to a model using the compiler directive:

```
$FuncLibIn <InternalLibName> <ExternalLibName>
```

Similar to sets, parameters, variables, and equations, functions must be declared before they can be used:

```
Function <InternalFuncName> /<InternalLibName>.<FuncName>/;
```

There are a few libraries which come ready to use with the GAMS system:

- fitfclib: packages FITPACK from P. Dierckx in a way that it works with this facility
- pwpcclib: evaluates piecewise polynomial functions
- stodclib: provides random deviates, probability density functions, cumulative density functions and inverse cumulative density functions for certain distributions
- tricclib, tridclib, trifclib: these simple examples can be found compiled and as source code written in C, Delphi and Fortran respectively

Detailed information can be found in the GAMS User's Guide in chapter 6.3.

In addition, the following examples from the GAMS Test Library can be referred to:

- **stolib01**: Uses the stochastic library which comes with the GAMS system
- **trilib01**: Uses trigonometric function from a library written in C, comes with C source code
- **trilib02**: Uses trigonometric function from a library written in Delphi, comes with Delphi source code
- **trilib03**: Uses trigonometric function from a library written in Fortran, comes with Fortran source code
- **pwplib01**: Uses a library for piecewise polynomial functions which comes with the GAMS system
- **fitlib01**: Uses FITPACK from P. Dierckx which was packaged in a way that it works with this facility and comes with the GAMS system

If you need detailed instructions for connecting your library to GAMS please contact support@gams.com.

Other

- Dropped support for EBCDIC. Functions `ordebcdic` and `ordascii` are no longer available. `oldascii` should be replaced by `ord`.

Bug Fix

- We found and corrected a bug related to the internal organization of non-linear code. This bug was introduced with version 23.6 but fortunately only occurs in rare cases.

Utilities

GAMSIDE

- Version 23.6 made it more difficult to find the directory where GAMS is installed. In this release we reintroduce the EXECUTABLE entry in the GAMSINI file to make this easier.
- The PageWidth option was limited to 255
- Increased the maximum number of jobs that can be run at he same time from 5 to 20.

GAMSINST

- The gamsinst program allows to set the default solvers and to install contributed software packages (e.g. Tom Rutherford's [GAMS Programming Tools] (http://www.mpsge.org/inclib/tools.htm)). Previous versions of gamsinst supported the installation of contributed **solver** packages. The new version of gamsinst does not support these types of solver packages anymore. If you need to install a contributed solver, please contact support@gams.com.

GDXXRW

- Fixed a memory leak that could make it difficult to read large spreadsheets.
- Worked around a limitation to read large spreadsheets by reading the data in multiple slices.
- The option NAin allows a string to be specified to recognize the value for NA when reading a spreadsheet; this is in addition to recognizing the string 'NA'.
- Undf is now recognized as a value without generating an error when reading from a spreadsheet so the entry can be processed in the GAMS model using the $ONUNDF dollar option in GAMS.
- Strings that are not recognized as a special value are no longer read as NA but as Undf instead; use the $ONUNDF in GAMS to read these values.

3.38.1.4 Solvers

AlphaECP

- Update to version 2.04.01
- New options
  - `CUTdelcrit` Improved heuristic to reselect cuts.
  - `CUTnrcuts` Option that the algorithm decides was added.
  - `ECPdumpsol` Write encountered solutions in GDX files.
  - `MIPsolstrat` Strategy for multiple MIP solutions
  - `NLPcall` Option that the algorithm decides was added.
  - `solvelink` Determines the way the NLP and MIP solvers are called. By default AlphaEXP now calls the NLP and MIP solver in memory.
- Deprecated options
  - `CUTautogrowth`, `CUTcheckgrowth`, `CUTgrowth`, `CUTgrowtheq`, `CUTgrowthnr`, `CUTmincuts`
  - `ECPcheckviol`
  - `NLPepsilon`, `NLPlimepsilon`

Baron

- New libraries 9.3
- Compared to previous versions, BARON 9.3 comes with improved multilinear relaxations and improved branching
- Support for the LP solvers XA and OSL has been dropped

Conopt

- New libraries 3.14Y

Coin-OR

- Updated Bonmin and Couenne libraries (bugfixes).
- On Linux and Windows, Ipopt now uses a multithreaded linear algebra library. The number of threads can be set via the GAMS option THREADS.
- Added Bonmin option "print_funceval_statistics" to enable statistics on number of function evaluations during a Bonmin run.
- Added Ipopt, Bonmin, and Couenne option "print_eval_error" to enable printing of information about function evaluation errors into the listing file.
- OsiCplex, OsiGurobi, and OsiXpress now support using the variable level values as initial solution for a MIP solve. This is enabled by setting the GAMS option INTEGER4 to 1.

Cplex

- New libraries 12.3
- Cplex 12.3 solves a greater variety of nonconvex quadratic programming models; that is, QP models with a quadratic term in the objective function. These models are also known as indefinite QPs (in contrast to positive or negative semi-definite QPs). In fact, Cplex 12.3 can find solutions that satisfy Karush-Kuhn-Tucker (KKT) conditions for certain indefinite QPs. A new parameter, solution target type (`SolutionTarget`), lets you specify to Cplex whether you will accept a solution that satisfies first-order optimality conditions (in contrast to accepting only globally optimal solutions), and Cplex computes and searches accordingly.
- Log files improved. You may observe slight differences from previous versions in the format of logs produced by Cplex 12.3. For example, the name of the column formerly titled "best node" in logs of MIP optimizations is now titled "best bound" to reflect more accurately the data recorded there.
- Supports in-core communication (`solvelink=5`)

DEA

- The solver DEA was dropped from our distribution.
- Data Envelopment Analysis (DEA) models can now be solved in GAMS via the Gather-Update-Solve-Scatter (GUSS), for more information see GAMS/DEA modeling

Dicopt

- New option
  - `solvelink` Determines the way the NLP and MIP solvers are called. By default Dicopt now calls the NLP and MIP solver in memory.

Gurobi

- New libraries 4.5.1
- Now available on AIX
- New default Method for continuous models: The new version uses a new Automatic setting as the default for solving continuous models. In previous releases, continuous models were solved with the dual simplex method by default. While the exact strategy used by the new Automatic setting may change in future releases, in this release the new approach uses the concurrent optimizer for continuous models with a linear objective (LPs), the barrier optimizer for continuous models with a quadratic objective (QPs), and the dual simplex optimizer for the root node of a MIP model. You should change the Method parameter if you would like to choose a different method.
- New Minimum Relaxation heuristic: The new version contains a new Minimum Relaxation heuristic that can be useful for finding solutions to MIP models where other strategies fail to find feasible solutions in a reasonable amount of time. Use the new MinRelNodes parameter to control this new heuristic.
- New branch direction control: The new version allows more control over how the branch-and-cut tree is explored. Specifically, when a node in the MIP search is completed and two child nodes, corresponding to the down branch and the up branch are created, the new BranchDir parameter allows you to determine whether the MIP solver will explore the down branch first, the up branch first, or whether it will choose the next node based on a heuristic determination of which sub-tree appears more promising.
- Cut pass limit: The new version allows you to limit the of cut passes performed during root cut generation in MIP. Use the new CutPasses parameter.

Gather-Update-Solve-Scatter (GUSS)

- The purpose of this new Gather-Update-Solve-Scatter manager or short GUSS is to provide syntax at the GAMS modeling level that makes an instance of a problem and allows the modeler limited access to treat that instance as an object, and to update portions of it iteratively. Detailed documentation of this facility is part of the Solver Manual (chapter GUSS).
- Solving MCP and CNS models with GUSS is an experimental feature. GAMS checks the consistency of MCP and CNS model, these checks are currently disabled when models of these types are solved in the GUSS framework.

Jams

- Supports `logic equations`
  - Logic equations can contain
    - binary variables
    - expressions that evaluate to constants
    - Boolean operators (`AND`,`OR`,`XOR`,`NOT`,`IMP(&rarr;)`,`EQV(&hArr;)`)

  - Logic equations can be used in conjunction with disjunctions
  - A version of the food model demonstrates the use of this new feature **foodemp (59)**
- Supports coupling and indicators through EMP's disjunction syntax
  - Indicator `disjunction b e` says that constraint e has to hold if b is true
  - Coupling `disjunction b e else not e` says that constraint e can only hold if and only if b is true
  - Indicators and Couplings can be reformulated using BigM, Convex Hull or CPLEX indicator constraints

LindoGlobal

- New libraries Lindo 6.1.1.588
- New Option `checkrange`: Calculates the feasible range for every variable in each equation while all other variables are fixed to their level. If set, the value of this option defines the name of the GDX file where the results are written to.

LogMIP

- The former LogMIP solvers `lmbigm` and `lmchull` are combined in the new solver solver `logmip`.
- LogMIP now uses the EMP syntax and modeltype.
- The LogMIP examples in the GAMS Model Library were revised.

Minos

- Supports in-core communication (`solvelink=5`)

Mosek

- New libraries 6.0 Rev 114

Msnlp/Oqnlp

- New option
  - `solvelink` determines the way the NLP and MIP solvers are called

Oslse

- The solver Oslse was dropped. Oslse is now an alias to osl.

Path

- Supports in-core communication (`solvelink=5`)

SBB

- New option
  - `solvelink` determines the way the NLP solver is called. By default SBB now calls the NLP solver in memory.

Scip/Soplex

- Dropped support for LPs/RMIPs in Gams/SCIP interface.
- Added new solver OsiSoplex for solving LPs with SoPlex (via COIN-OR/OSI interface).

Snopt

- Supports in-core communication (`solvelink=5`)

Xpress

- New libraries 22.01
- Improved performance through dynamic synchronization in the deterministic concurrent solver
- The stability and performance of the barrier code has been improved
- The default performance of the simplex algorithm has been improved on some models
- Improved zero-half cuts and aggregated cuts for MIPs.
- Tuned some of the automatic strategies for cutting and branching in MIP solves.
- Threads during a MIP solve will now busy-wait by default instead of going to sleep when waiting for work. This is to overcome a performance issue with modern speed-stepping CPUs, which might step down to a lower clock frequency when the load is less than 100%. This feature can be toggled using the SLEEPONTHREADWAIT control.

3.38.1.5 Model Libraries

GAMS Data Library

- **datatest (80)**: Driver for datalib tests of all sorts

GAMS EMP Library

- **foodemp (59)**: Food Manufacturing Problem - Blending of oils
- **simenlp (60)**: Simple example of ENLP
- **nlp2mcp (61)**: nlp2mcp: Form the KKT conditions of an NLP as an MCP
- **simplevi3 (62)**: Another simple VI example
- **simpequil2 (63)**: Simple Equilibrium with external constraint
- **hark-monop (64)**: SPE model from Harker - monopolist and competetive versions
- **hark-oligop (65)**: SPE model from Harker - oligopoly version
- **hark-oligop-ind (66)**: SPE model from Harker - oligopoly version
- **hark-stack (67)**: SPE model from Harker - Stackelberg version

GAMS Model Library

- **kqkpsdp (355)**: SDP Convexifications of the Cardinality Constraint Quadratic Knapsack Problem
- **prodplan (356)**: A Production Planning Example
- **sddp (357)**: Multi-stage Stochastic Water Reservoir Model solved with SDDP
- **ps2_f_s (358)**: Parts Supply Problem w/ 2 Types w/o & w/ Asymmetric Information
- **ps2_f (359)**: Parts Supply Problem w/ 2 Types w/o Asymmetric Information
- **ps2_f_eff (360)**: Parts Supply Problem w/ Efficient Type w/o Asymmetric Information
- **ps2_f_inf (361)**: Parts Supply Problem w/ Inefficient Type w/o Asymmetric Information
- **ps2_s (362)**: Parts Supply Problem w/ 2 Types w/ Asymmetric Information
- **ps3_f (363)**: Parts Supply Problem w/ 3 Types w/o Asymmetric Information
- **ps3_s (364)**: Parts Supply Problem w/ 3 Types w/ Asymmetric Information
- **ps3_s_gic (365)**: Parts Supply Problem w/ 3 Types w/ Global Incentive Comp. Const.
- **ps3_s_mn (366)**: Parts Supply Problem w/ 3 Types w/ Monotonicity Constraint
- **ps3_s_scp (367)**: Parts Supply Problem w/ 3 Types w/o & w/ SCP
- **ps10_s (368)**: Parts Supply Problem w/ 10 Types & w/ Asymmetric Information
- **ps10_s_mn (369)**: Parts Supply Problem w/ 10 Types w/ Random p(i)
- **ccoil (370)**: Oil Pipeline Design Problem using concurrent MIP solves

GAMS Test Library

- **interval (506)**: Test for interval evaluation
- **empdisj3 (507)**: Test Disjunctions using not (equivalence)
- **emplog1 (508)**: Test disjunctions and logical conditions
- **maxima (509)**: Test several maxima of Cmex
- **emplog2 (510)**: Test simple logical conditions
- **qcp07 (511)**: Test correctness for QCP with poly function
- **qcp08 (512)**: Test correctness for QCP with power($*$,2) function
- **empdisj4 (513)**: Test disjunctions with negative bounds on variables
- **funcback (514)**: Test function backward compatibility
- **asynexec (515)**: Test asynchronous execution at compile and execution time
- **scen01 (516)**: Compile time test for the scenario facility
- **empdisj5 (517)**: Test disjunctions using not on binary variable and constraint
- **scen02 (518)**: Execution time test for the scenario facility
- **scen03 (519)**: Multi-dimensional scenario solver test
- **stolib01 (520)**: Test extrinsic functions in stodclib
- **trilib01 (521)**: Test extrinsic functions in tricclib

- **trilib02 (522)**: Test extrinsic functions in tridclib
- **trilib03 (523)**: Test extrinsic functions in trifclib
- **lindorg2 (524)**: Test for LindoGlobals CheckRange Option
- **mip04 (525)**: Exercise new XPRESS return code for unbounded MIP
- **load5 (526)**: Tests UNDF with $load
- **pwplib01 (527)**: Test piecewise polynomials in pwpcclib
- **fitlib01 (528)**: Test the use of FITPACK inside GAMS
- **load6 (529)**: Tests dynamic error messages during $loaddc
- **fnspowx (530)**: Test correctness of signpower intrinsic
- **fnspown (531)**: Test correctness of signpower intrinsic
- **nlcode5 (532)**: Test for NL code bug from Dist 23.6
- **scensol2 (533)**: Test handling of unsorted scenario UELs in GUSS

3.38.1.6 Solver/Platform Availability Matrix

3.38.2 23.7.2 Maintenance release (July 22, 2011)

- Alphaecp: Alphaecp v2.04.02
- Conopt3: Fixed a system error 2003
- Dicopt: Fixed a bug for accidentally determined crossovers
- Inclib: `put_reorderit.gms` update from Bruce McCarl
- Cbc: Disabled preprocessing in case of semicont/semiint variables, it seems buggy
- Cplex: Does no longer require finite bounds on semicont variables
- Gamsinst: Fix problem with blanks in sysdir and IDE error when not having a license

3.38.3 23.7.3 Maintenance release (August 23, 2011)

- alphaecp: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- apifiles:
  - get rid of warnings in cc interface,
  - fix problem with compilation of fat binaries on Darwin in cc interface
  - fix error in `gdxSymbolGetDomain` in Python interface
  - fix errors with constant definitions in C# interface
  - add constant definitions and additional constructor (which gets a handle) in Java interfaces
- conopt3: Version 3.15A maintenance release
- cplex:
  - fix for interrupt (Ctrl-C) when running with `solvelink=5`
  - fix memory leak

- dicopt:
  - fix reporting of `objest` in case of a crossover
  - fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- gamscmex: fix bug related to the internal organization of non-linear code, affects two-argument functions in rare cases
- gamside:
  - close chart files too when changing system directory
  - GAMS project file name independent of casing
- gdxdump: suppress on/off empty when writing single symbol
- gdxmrw: was missing on 64bit Linux
- grid: fix potential problem with scaling
- kestrel: added Xpress support
- minos fix: for interrupt (Ctrl-C)
- sbb: fix problem with accumulating solving times of subsolvers which might lead to an earlier stop
- snopt fix: for interrupt (Ctrl-C)
- xpress: update global search to use callbacks called during root node processing and improve scheme to stop XPRESS when gap is achieved or on user interrupt

3.39 23.6 Distribution

3.39.1 23.6.2 Major release (December 13, 2010)

3.39.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Nico Keyaerts, Leon Lasdon, Xiang Li, Timo Lohmann, Sebastian Ritter, Yannick Rombauts, Tom Rutherford, Uwe Schneider, Stefan Vigerske, Achim Wechsung, and Gyeongbeom Yi.

3.39.1.2 GAMS System

GAMS

- Added the function `RandBinomial(n,p)` which generates random numbers from the Binomial distribution where n is the number of trials and p the probability of success for each trial.
- Added the gams date and release functions to $eval and [..] constant evaluations: `jdate`, `jtime`, `gyear`, `gmonth`, `gday`, `gdow`, `gleap`, `ghour`, `gminute`, `gsecond`, `gmillisec`, `jstart`, `jnow`, `gamsversion`, `gamsrelease`.
- Modified operator precedence binding of `IMP` (->), `EQV` (<->), `OR` and `XOR`. These operator used to have the same precedence binding, so with the usual left to right evaluation an expression like `a -> b OR c` used to be equivalent to `(a -> b) OR c`. `IMP` and `EQV` have now a lower precedence binding, so the expression `a -> b OR c` is now equivalent to `a -> (b OR c)`.

- There is no longer a practical limit for the number of non-linear instructions for a single equation.
- New interpretation of value `default` for command line parameters `gdx` and `rf`: `default` is interpreted as the input file name, this means for example, that `gams trnsport gdx=default` will write the file `trnsport.gdx`. Along the same lines, `gams trnsport rf=default` will write the reference file `trnsport.ref`.
- New command line parameter `Threads`: Controls the number of threads to be used by a solver. It can also be set as GAMS option or model attribute. The model attribute has the highest priority, the command line parameter the lowest. Non-positive values are interpreted as the number of cores to leave free so setting threads to 0 uses all available cores while setting threads to -1 leaves one core free for other tasks.

APIs

- Determine platform dependent library name automatically, no requirement for compiler flags anymore
- Delphi files also support Delphi 2010
- Python files comprehensively improved
- More Fortran examples

Utilities

Chk4Upd

- The new tool chk4upd checks if there is a newer version of GAMS available than the one you are running. It checks for the most recent version available as well as for the newest version you can run with your license in case your maintenance and support is expired. By default it reads gamslice.txt located next to it. Alternatively, you can specify another license on the command line. In addition to the command line tool you will find an integration in the GAMS IDE at Help -> Check for GAMS Update.

GamsIDE

- Integration of 'Check for GAMS Update' in the Help Menu
- The 'Find in Files' option now allows for one or more sub-directories to be excluded from the search
- The selection to use a different GAMS system has been changed. We no longer specify the gams.exe executable but define the alternate GAMS system directory instead.

GDXDiff

- The function to test if two values are different when Eps/RelEps has been specified was changed. The documentation describes the new implementation.

GDXMRW

- GDXMRW is a collection of utilities that make it easier and more reliable to share data between GAMS and Matlab and that allow the Matlab user to call GAMS using something similar to a subroutine interface. Formerly contributed software, these utilities were integrated into GAMS Distribution 23.4 and have been updated and improved since then.

XLSDump

- This new program will write all worksheets of an Excel workbook to a gdx file. Unlike GDXXRW, the program does not require that Excel is installed. Windows platforms only.

3.39.1.3 Solvers

Baron

- Option ExtNLPsolver allows to specify an option file for the GAMS NLP solver chosen (e.g. `ExtNLPSolver conopt.1`)

Coin-OR

- New libraries
  - BONMIN 1.4
  - CSDP 6.1.1
  - CSDP now also available on Solaris x64 on Intel
- The old names COINCPLEX, COINGUROBI, COINMOSEK, and COINXPRESS are not available anymore. Please use the new names OSICPLEX, OSIGUROBI, OSIMOSEK, and OSIXPRESS introduced with distribution 23.4.

Conopt

- Supports in-core communication (`solvelink=5`)
- Dropped support of Conopt 2 (old version of Conopt)

Cplex

- New libraries 12.2.0.1

EMP

- The emp information file now supports block-wise definition
  - A flip operator (`-`) was introduced, see model **flipper (50)**

Gurobi

- New libraries 4.0
- Quadratic programming: The Gurobi Optimizer now supports models with quadratic objective functions. The new version includes primal simplex, dual simplex, and parallel barrier optimizers for continuous QP models, and a parallel branch-and-cut solver for Mixed Integer Quadratic Programming (MIQP) models.
- Concurrent optimizer: The Gurobi Optimizer now allows you to run multiple algorithms simultaneously when solving a linear continuous model on a multi-core machine. The optimizer returns when the first algorithm solves the model. We include both a standard concurrent optimizer and a deterministic concurrent optimizer. The latter returns the exact same solution every time you run it, while the former can sometimes return different optimal solutions from one run to the next. The former can sometimes be significantly faster.
- MIP performance: The MIP solver is faster in release 4.0. These improvements do not require any parameter changes.
- LP performance: The simplex and barrier solvers are slightly faster in release 4.0. We have also improved the numerical stability of the primal simplex solver and the barrier crossover algorithm.
- Delayed MIP strategy change: The Gurobi Optimizer now gives you the option to change a few MIP parameters in the middle of the optimization in order to dynamically shift the search strategy. Specifically, two new parameters, ImproveStartGap and ImproveStartTime, allow you to specify when the algorithm should modify the values of a few parameters that control the intensity of the MIP heuristics. By setting one or both of these parameters to non-default values, you can cause the MIP solver to switch from its standard parameter settings, where it tries to strike a balance between finding better solutions and proving that the current solution is optimal, to a set of parameter values that focus entirely on finding better solutions.
- New approach to choosing the LP algorithm: The functions previously controlled by parameters LPMethod and RootMethod are now controlled by parameters Method and NodeMethod. Use Method to choose the algorithm for solving a continuous model, or for solving the root relaxation in a MIP model. Use NodeMethod to choose the algorithm for solving node relaxations in a MIP model.
- Deprecated options: `LPMethod` and `RootMethod`
- New options
  - `Method`: Controls the algorithm used to solve continuous linear and quadratic models. This parameter also selects the algorithm used to solve the root node of a MIP model.
  - `NodeMethod`: Chooses the algorithm used to solve node relaxations in a MIP model.
  - `ModKCuts`: Controls the generation of mod-k cuts.
  - `ImproveStartGap`: Allows you to specify the optimality gap at which the MIP solver resets a few MIP heuristics parameters in order to shift the attention of the MIP solver to finding the best possible feasible solution.
  - `ImproveStartTime`: Allows you to specify the elapsed time at which the MIP solver resets a few MIP heuristics parameters in order to shift the attention of the MIP solver to finding the best possible feasible solution.
  - `PreMIQPMethod`: Chooses the presolve transformation performed on MIQP models.
  - `PSDTol`: Sets a limit on the amount of diagonal perturbation that the optimizer is allowed to do on the Q matrix for a quadratic model. If a larger perturbation is required, the optimizer will terminate with a message that Q is not positive semi-definite.

Knitro

- New libraries 7.0.0
- Supports the MultiStart feature in Knitro
- Supports in-core communication (`solvelink=5`)
- Supported on 64bit Mac and 64bit Solaris on Intel
- Dropped support on Solaris Sparc and Sparc64

Lgo

- supports in-core communication (`solvelink=5`)
- support of external equations

Mosek

- New libraries 6.0.96
- Supports in-core communication (`solvelink=5`)
- Dropped support on Solaris Sparc and Sparc64

Scip

- New libraries 2.0 ([more details] (https://www.scipopt.org/download/files/SCIP-release-notes-2.0))
- The GAMS/SCIP interface now also supports semicontinuous and semiinteger variables
- GAMS/SCIP now uses SoPlex 1.5.0 as LP solver

Xa

- Dropped support on Solaris Sparc and Sparc64

Xpress

- Supports in-core communication (`solvelink=5`)
- New libraries 21.01

3.39.1.4 Model Libraries

GAMS Data Library

- **GDXXRWExample15 (76)**: Write spreadsheet using a filter
- **GDXXRWExample16 (77)**: Write spreadsheet using text and hyperlinks
- **tompivot (78)**: Little GAMS Program from Tom Rutherford that Illustrates Report Generation with Excel
- **readdata (79)**: Read Data from .inc, .xls, .mdb and .csv file

GAMS EMP Library

- **flipper (50)**: Test of flipping equations
- **scarfemp-dem (51)**: Scarf's Activity Analysis Example
- **scarfemp-altdem (52)**: Scarf's Activity Analysis Example - non-closed form demand function
- **scarfemp-primal (53)**: Scarf's Activity Analysis Example
- **scarfemp-dual (54)**: Scarf's Activity Analysis Example
- **scarfexpend (55)**: Scarf's Activity Analysis Example
- **pies (56)**: PIES Energy Equilibrium
- **exc2x2emp (57)**: pure exchange model (ie no production)
- **exc2x2emp-dem (58)**: pure exchange model (ie no production)

GAMS Model Library

- **relief (353)**: Relief Mission
- **spatequ (354)**: Spatial Equilibrium

GAMS Test Library

- **emp09 (492)**: Test initial levels for equilibrium EMP models
- **xerr1 (493)**: External Function Errors: RHS wrong
- **xerr2 (494)**: External Function Errors: Aij wrong
- **cerr1 (495)**: Cone Equation Errors
- **merr1 (496)**: Matrix Errors
- **mip02 (497)**: Check on MIP solution value
- **mip03 (498)**: Test for zero gap when optcr and optca set to zero
- **emp10 (499)**: Test of EMP equilibrium models and flip operator
- **emp11 (500)**: Test EMP formulations of scarfmcp
- **empdisj2 (501)**: Test disjunctions involving the objective
- **gdxxrw6 (502)**: Test for dset reading problem
- **qcp06 (503)**: Nonlinear model cannot be solved as QCP
- **gdxdump1 (504)**: Use GdxDump NoData on Transportation Problem
- **lindorng (505)**: Test for LindoGlobal's CheckRange Option

3.39.1.5 Solver/Platform Availability Matrix

3.39.2 23.6.3 Maintenance release (February 15, 2011)

- Cmex: Fix for variable level projection
- Bonmin: Several fixes for outer-approximation based algorithms
- Cplex: New version 12.2.0.2
- Gurobi: New version 4.0.1
- Knitro: Documentation update
- Scip: New version 2.0.1
- Xpress: Fix for crash on 64 bit Solaris
- McCarl Guide: Updates for 23.6
- Gdxxrw: Includes system error message when we cannot start Excel
- Gdxmrw: Minor bugfixes

3.39.3 23.6.4 Maintenance release (April 01, 2011)

- CMEX: Maximal nested includes were raised to 40
- Mosek: New Version6 Rev 105
- Lindoglobal: New Version 6.1.1.553
- Conopt: New Version 3.14W
- Xpress: Memory leak fix
- Coin: Solver fixes
- JAMS: Updates for disjunctions
- GDXXRW: Fixes
- GDXMRW: Updates
- McCarl and GDXUtils: Documentation updates
- Model Libraries: Updates

3.39.4 23.6.5 Maintenance release (April 08, 2011)

- CMEX: Bug fix related to situations with very large number of labels in connection with a restart with continued compilation

3.40 23.5 Distribution

3.40.1 23.5.1 Major release (July 05, 2010)

3.40.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Farhad Farnam and Alexander Gocht.

3.40.1.2 GAMS System

APIs

- new VB.net example using GDX, Option and GAMS DLL: apifiles\examples\example2.vb
- combine Java api files in package com.gams.api, existing applications need to be adjusted when using the new Java api files, see e.g. apifiles\examples\example1.java:

```
package com.gams.example1;
import com.gams.api.*;
public class example1 {
...
```

3.40.1.3 Solvers

BARON

- New libraries 9.0.6

CONOPT

- New libraries 3.14U

CPLEX

- New libraries 12.2
- MIP kappa describes a new feature extending the computation of kappa to mixed integer programming (MIP). (In linear programming, kappa is also known as the condition number of a solution.) See GAMS/Cplex parameter `mipkappastats` for details.
- Intel processors prior to Pentium 4 are no longer supported.
- The MIP node log interval (GAMS/Cplex parameter `MIPInterval`) now accepts either a positive or negative integer value, making it easier for you to adjust the amount of information logged for your problem.
- The default value of the GAMS/Cplex `ClockType` parameter has changed from 0=automatic (let Cplex choose) to 2 (wallclock time).
- The concurrent optimizer launches distinct optimizers on multiple threads. Cplex now offers concurrent, deterministic optimization of linear programming models (LPs) when more than one thread is given to Cplex (GAMS/Cplex parameter `Threads`). Running concurrent optimizers simultaneously on multiple threads may consume more memory. If the memory reduction parameter (`MemoryEmphasis`) is turned on, then you have instructed CPLEX to conserve memory. In that case, Cplex does not run concurrent, deterministic optimization unless parameter `LPMethod` is explicitly set to 6.
- New parameter `AuxRootThreads`: Partitions the number of threads for Cplex to use for auxiliary tasks while it solves the root node of a problem. On a system that offers N processors or N global threads, if you set this parameter to n, where $N > n > 0$ then Cplex uses at most n threads for auxiliary tasks and at most N-n threads to solve the root node.

GUROBI

- New libraries 3.0.1
- Now also available on Mac X Intel 64bit

LINDOGLOBAL

- New libraries Lindo 6.1.1 for all platforms except for Solaris Sparc 32 bit and 64 bit
- Now also available on Mac X Intel 64bit

3.40.1.4 Model Libraries

GAMS Test Library

- **gen_r1 (483)**: Generate GDX file for test of GDXMRW
- **gen_r2 (484)**: Generate GDX file for test of GDXMRW
- **gen_rbig (485)**: Generate GDX file for test of GDXMRW
- **gdxmrw03 (486)**: test the Matlab utility rgdx
- **gdxmrw04 (487)**: test the Matlab utility wgdx
- **testinst (488)**: test the Matlab mex-file gams
- **gversion (489)**: test the Matlab mex-file gams
- **gdxmrw05 (490)**: test the Matlab mex-file gams
- **onmulti7 (491)**: Test merge with $onmulti and empty data statement

3.40.1.5 Solver/Platform Availability Matrix

3.40.2 23.5.2 Maintenance release (August 18, 2010)

- AlphaECP: Fix for crash running under IDE
- API: Updated Python and Java APIs and examples
- Baron: Fixed issue with output formatting under Linux
- Baron: Memory leak when using BARON with external NLP solver
- Gdxmerge: Do not use path when checking for `merged.gdx`
- Gurobi: Fixed typo for option displayinterval
- McCarl Guide: Updates for 23.5
- Mosek 6 rev 85 libraries
- MPS2GMS: Removed mps2gms debug message
- Snopt: Fix for wrong return code (local,global)
- Xlsdump utility added

3.41 23.4 Distribution

3.41.1 23.4.1 Major release (May 21, 2010)

3.41.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Phil Bishop, Stefan Boeters, Pavel Borisovski, Wolfgang Britz, Michael Ferris, David Grace, Sascha Herrmann, Alexander Mitsos, Sebastian Ritter, and Tom Rutherford. We also thank Marcel Roelofs for helpful and insightful comments and discussions on Hessian computations.

3.41.1.2 Platforms

AIX

- Now built on AIX 5.3
- 64 bit
- New AIX system no longer supports the following products BARON, CONOPT2, DECIS, OSL3, OSLSE, SCENRED, SCENRED2, and XA

Mac PowerPC

- Dropped support of the Macintosh PowerPC GAMS System. Version 23.3 and older are still available for download

3.41.1.3 GAMS System

GAMS

GridScript

- The GAMS parameter `gridscript` allows to point to a customized grid submission script.

TryLinear

- GAMS checks a model for non-linearities at compile time and requires the user to specify `using nlp` in the `solve` statement. At run time these non-linearities might disappear (cancelation, multiplication of non-linear terms with 0, ...), but the `using nlp` prevented the use of a pure LP solver. The new model attribute `<model>.TryLinear = 1` checks at run time whether a nonlinear model has any non-linearities and then calls the default/chosen solver for the resulting model type.
- Depending on the original model type the resulting model type is:
  - QCP/DNLP/NLP -> LP
  - MIQCP/MINLP -> MIP
  - RMIQCP/RMINLP -> RMIP
- An example was added to the Test Library: **trylin01 (482)**

Compile Time String Comparison

- A compile time equivalent of the predefined symbol `sameas` was added. E.g.

```
$eval a sameas(xyz,xYz)
$eval b sameas ( 'xyz' , "xyz" )
$eval c sameas (12-3,12-3)
$eval d sameas (12-3,13-4)
$log %a% %b% %c% %d%
```

will yield:

```
1 1 1 0
```

Compile Time Constants

For various GAMS options compile time constants were added in order to ease the reading code if used.

- **solPrint**:
  0 %solPrint.summary%
  1 %solPrint.report%
  2 %solPrint.quiet%
- **handleStatus**:
  0 %handleStatus.unknown%
  1 %handleStatus.running%
  2 %handleStatus.ready%
  3 %handleStatus.failure%
- **solveLink**:
  0 %solveLink.chainScript%
  1 %solveLink.callScript%
  2 %solveLink.callModule%
  3 %solveLink.asyncGrid%
  4 %solveLink.asyncSimulate%
  5 %solveLink.loadLibrary%
- **solveStat**:
  1 %solveStat.normalCompletion%
  2 %solveStat.iterationInterrupt%
  3 %solveStat.resourceInterrupt%
  4 %solveStat.terminatedBySolver%
  5 %solveStat.evaluationInterrupt%
  6 %solveStat.capabilityProblems%
  7 %solveStat.licensingProblems%
  8 %solveStat.userInterrupt%
  9 %solveStat.setupFailure%
  10 %solveStat.solverFailure%
  11 %solveStat.internalSolverFailure%
  12 %solveStat.solveProcessingSkipped%
  13 %solveStat.systemFailure%
- **modelStat**:
  1 %modelStat.optimal%
  2 %modelStat.locallyOptimal%
  3 %modelStat.unbounded%
  4 %modelStat.infeasible%

```
5 %modelStat.locallyInfeasible%
6 %modelStat.intermediateInfeasible%
7 %modelStat.intermediateNonoptimal%
8 %modelStat.integerSolution%
9 %modelStat.intermediateNonInteger%
10 %modelStat.integerInfeasible%
11 %modelStat.licensingProblem%
12 %modelStat.errorUnknown%
13 %modelStat.errorNoSolution%
14 %modelStat.noSolutionReturned%
15 %modelStat.solvedUnique%
16 %modelStat.solved%
17 %modelStat.solvedSingular%
18 %modelStat.unboundedNoSolution%
19 %modelStat.infeasibleNoSolution%
```

- E.g. the statments following are the same
  `modelname.solveLink=3; modelname.solPrint=0;`
  `modelname.solveLink=%solveLink.asyncGrid%; modelname.solPrint=%solPrint.summary%;`
- The GAMS model libraries were adjusted and now make use of these constants.

APIs

- new C# example using GDX API: apifiles\examples\example1.cs
- added C++, C# and VB.net project files to make it easier to compile the examples in Visual Studio
- added Delphi Option and Project Configuration Files to make it easier to compile the examples in the Delphi IDE and on the command line
- added Java Native Interface libraries
- `apifiles\common`: dropped file gamsglobals.h, use gclgms.h instead

GDXDCLIB API

- New entry points:
- `gdxOpenAppend` To add symbols to an existing GDX container
- `gdxDataReadRawFast` To read data in raw mode using a callback function

Data Utilities

GDX2ACCESS

- `gdx2access` now supports saving the text associated with set entries in the database.
- Added parameter to indicate which version of the database should be created (.mdb or .accdb)

GDXXRW

- `gdxxrw` now supports writing an Excel file with filters. Filtering can be switched on/off for the symbols that follow the filter option:

```
execute 'gdxxrw.exe test.gdx par=A rdim=3 cdim=0 rng=sheet1!a1 filter=1 par=B rdim=3 cdim=0 rng=
```

- Added options to write texts and hyperlinks to a spreadsheet.

MDB2GMS

- `mdb2gms` now supports writing of the text associated with set entries.

SQL2GMS

- `sql2gms` now supports writing of the text associated with set entries.

EMP

- A new model type `EMP` was added in order to provide the flexibility required for the extended mathematical programming framework.
- The former solver EMP was renamed to JAMS to avoid confusion. JAMS is the default solver for EMP models.
- EMP bilevel programming now supports Variational Inequality (VI) followers in addition to maximization/minimization followers. Example: **multmpec (25)**
- EMP now supports equilibrium models. In contrast to bilevel programs these agent-based systems don't require a leader. Example: **transeql (45)**
- Lots of EMP models were added to the GAMS EMP Library.

IDE

- Fixed bug with writing a symbol with many elements to a spreadsheet
- Opening many .lst files is faster

Libinclude

- McCarl's `put_toexcel` and `put_tohtml` were added to inclib subdirectory of the GAMS system directory and therefore can be used using `$libinclude`. These tools allow greater control when writing multi dimensional symbols to Excel or files. More information can be found here

3.41.1.4 Solvers

BARON

- New Libraries 9.0.5
- Native 64bit Baron libraries in 64bit windows and linux system
- New option `ExtNLPsolver` allows to call any GAMS NLP Solver available
- Dropped support of Baron on platform AIX

Coin-OR

- Renaming
  - of solver links as follows
    - COINBONMIN -> BONMIN
    - COINCBC -> CBC
    - COINCOUENNE -> COUENNE
    - COINGLPK -> GLPK
    - COINIPOPT -> IPOPT
    - COINOS -> OS
    - COINSCIP -> SCIP
  - of bare bone solver links as follows
    - COINCPLEX -> OSICPLEX
    - COINGUROBI -> OSIGUROBI
    - COINMOSEK -> OSIMOSEK
    - COINXPRESS -> OSIXPRESS
  - For convenience of our users we keep the old names as aliases to the new names for the next distribution.
  - Note: The temporary names COINBONMIND, COINCBCD, and COINIPOPTD are not available anymore
- New libraries
  - CBC 2.4
  - Bonmin 1.3
  - Couenne 0.3
  - Ipopt 3.8
  - GLPK 4.43
  - Mumps 4.9 (used by Ipopt and Bonmin)
  - OS 2.1
- The new BONMIN version brings various new MINLP heuristics (Feasibility pump, diving based heuristics, RINS, local branching).
- BONMIN can now use CPLEX as solver for sub-MIPs, see option `milp_solver`
- SCIP now supports convex and nonconvex quadratic constraints (model types QCP, RMIQCP, MIQCP).
- BCH has temporarily been disabled for CBC, BONMIN, and SCIP.
- The OS link now supports only remote solvers via an Optimization Services Server.
- Native CSDP executables were added to the 64bit Windows and Linux system.

CPLEX

- Updated threads option allows specification of cores left free for non-CPLEX work

GUROBI

- New libraries GUROBI 3.0
- New parallel barrier solver
- New MIP features include symmetry handling, improved and additional cutting planes, and additional heuristics.
- Alternate MIP solutions: retrieve all of the feasible solutions found during the branch-and-cut search
- New parameters
  - AggFill: provides finer-grain control of presolve aggregation.
  - BarConvTol: barrier convergence tolerance.
  - BarCorrectors: controls central corrections in barrier.
  - BarIterLimit: limits the number of barrier iterations.
  - BarOrder: controls the fill-reducing ordering in barrier.
  - PreDepRow: controls the presolve dependent row reduction.
  - Crossover: controls barrier crossover.
  - CrossoverBasis: controls the generation of the initial crossover basis.
  - MIPFocus: allows you to modify the MIP solution strategy to better suit the needs of different model types.
  - MIPGapAbs: absolute MIP termination tolerance (GAMS OptCA)
  - NetworkCuts: controls the generation of network cutting planes.
  - PreDual: determines whether presolve should form the dual of the input model.
  - PrePasses: controls the number of passes performed by presolve.
  - PumpPasses: controls the feasibility pump heuristic.
  - RINS: controls the RINS heuristic.
  - Symmetry: controls the new MIP symmetry handling.
  - SubMIPCuts: controls the generation of sub-MIP cutting planes.
  - Threads: allows specification of how many cores to use.

LINDOGLOBAL

- New libraries Lindo 6.0.1.406
- Now also available on Solaris on x64
- Significant improved performance with some models when Mosek is licensed as well

MOSEK

- New libraries MOSEK 6 rev 71

XPRESS

- New libraries XPRESS 20.00

In-core communication solver links

- All Coin-OR solvers are now supported as in-core communication solvers.

3.41.1.5 Model Libraries

GAMS Data Library

- **tsvngdx (75)**: Support GDX Files with `TortoiseSVN` diff

GAMS EMP Library

- **jointc1 (22)**: Educational bilevel model
- **jointc2 (23)**: Educational bilevel model
- **ferris43 (24)**: Educational embedded complementarity system model
- **multmpec (25)**: Educational bilevel model with VI followers
- **transbp (26)**: Transportation model with variable demand function using bilevel programming
- **flds911 (27)**: Princeton Bilevel Optimization Example 9.1.1
- **flds912 (28)**: Princeton Bilevel Optimization Example 9.1.2
- **flds913 (29)**: Princeton Bilevel Optimization Example 9.1.3
- **flds914 (30)**: Princeton Bilevel Optimization Example 9.1.4
- **flds915 (31)**: Princeton Bilevel Optimization Example 9.1.5
- **flds916 (32)**: Princeton Bilevel Optimization Example 9.1.6
- **flds917 (33)**: Princeton Bilevel Optimization Example 9.1.7
- **flds918 (34)**: Princeton Bilevel Optimization Example 9.1.8
- **flds919 (35)**: Princeton Bilevel Optimization Example 9.1.9
- **flds921 (36)**: Princeton Bilevel Optimization Example 9.2.1
- **flds922 (37)**: Princeton Bilevel Optimization Example 9.2.2
- **flds923 (38)**: Princeton Bilevel Optimization Example 9.2.3
- **flds924 (39)**: Princeton Bilevel Optimization Example 9.2.4
- **flds925 (40)**: Princeton Bilevel Optimization Example 9.2.5
- **flds926 (41)**: Princeton Bilevel Optimization Example 9.2.6
- **flds927 (42)**: Princeton Bilevel Optimization Example 9.2.7
- **flds928 (43)**: Princeton Bilevel Optimization Example 9.2.8
- **flds929 (44)**: Princeton Bilevel Optimization Example 9.2.9
- **transeql (45)**: Transportation model as equilibrium problem
- **simplevi (46)**: Simple Variational Inequality
- **simplevi2 (47)**: Simple Nonlinear Variational Inequality
- **affinevi (48)**: Affine Variational Inequality
- **simpequil (49)**: Simple Equilibrium

GAMS Model Library

- **trnspwl (351)**: A Transportation Problem with discretized economies of scale
- **food (352)**: Food Manufacturing Problem - Blending of oils

GAMS Test Library

- **examin04 (464)**: EXAMINER test suite - test returnGamsPoint option and QCP
- **empbp04 (465)**: Bilevel model with and without explicitly defined objective equation
- **empbp05 (466)**: Bilevel model with MIN follower vs. VI follower
- **eval05 (467)**: constant expression test for ceil,floor,trunc,frac
- **eval06 (468)**: matching operators in a column
- **emp06 (469)**: Test of EMP based on trnsport model
- **emp07 (470)**: Test of EMP based on trnsport model
- **emp08 (471)**: Test of EMP based on trnsport model
- **pgams01 (472)**: Test procdir deletion in pgams
- **pgams02 (473)**: Test procdir deletion in pgams
- **tabsubst (474)**: Tab and string substitution for long line
- **eval07 (475)**: Test evaluation of real constants - string2Double conversion
- **dumpsol (476)**: Gurobi Alternate Solutions for a Simple Facility Location Problem
- **ifthen5 (477)**: $ifthen false without sameline
- **ifthen6 (478)**: $ifthen/elseif false without sameline
- **utils02 (479)**: test MPS2GMS - it had range problems
- **utils03 (480)**: test MPS2GMS for reading the second range entry on a line
- **mpsge11 (481)**: MPSGE test - multiple fixed income levels
- **trylin01 (482)**: Test model attribute tryLinear

3.41.1.6 Solver/Platform Availability Matrix

3.41.2 23.4.3 Maintenance release (May 24, 2010)

3.42 23.3 Distribution

3.42.1 23.3.1 Major release (November 01, 2009)

3.42.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Wietse Dol, Daniel T. Fokum, Nuri Gokhan, Iiro Harjunkoski, Josef Kallrath, Lloyd R. Kelly, Kristina Konold, and Uwe Schneider.

3.42.1.2 GAMS System

GAMS

- Assigning members to a set using the asterisk is now possible in decreasing order as well. For example, the following are valid set statements in GAMS.

```
Set years /bc2000*bc1,0*2009/;
Set years /"-20"*"-1"/;
```

- The GAMS parameters `ProcDir` and `MaxProcDir` can be used to control the generation of process directories. `ProcDir=abc` will use abc instead of the 225. The user is responsible to create and remove the directories. `gams.procdir%` will now be defined and give you the actual process directory in use. `MaxProcDir=100` will extend the usual 225a to 225z, 225aa, 225ab, etc. The defaults will be 26 for `MaxProcDir` and 225? for `ProcDir` to make everything work as before.
- The GAMS parameter `RunDir` was removed.
- The Dollar Control Options `$hiddencall` does the same as `$call` but makes sure that the statement is neither shown on the log nor the listing file. This is also true in case `$ondollar` or `dp=2` is used. `$hiddencall` is especially useful in case of an encrypted model that e.g. reads/writes from an password-protected Excel file using `gdxxrw` password option.

GDXXRW

- Support of the Excel 2007 file extension xlsm
- The option `password` allows to pass down a password to a protect Excel file

3.42.1.3 Solvers

Baron

- New libraries: version 9.0
- Conopt can be used to solve nonlinear subproblems, but on 32bit platforms only (NLPSol=6)
- More control over common linear subexpressions

Coin-OR

- CoinScip version 1.2
  - The multi-commodity-flow network cut separator is now used by default
  - Improvements in heuristics, presolving, and branching
- CoinGlpk version 4.39
- CoinCouenne version 0.2
  - A separator for disjunctive cuts has been added
- CoinCplex, CoinGurobi, CoinMosek, CoinXpress
  - These new *bare bone* solver links come free of charge with the GAMS Base system. General GAMS options (reslim, optcr, nodlim, iterlim) are supported. In addition an option file in the format required by the solver can be provided.
- CoinOS 2.0
  - The new experimental link to the Optimization Services project allows you to convert instances of GAMS models into the OS instance language (OSiL) format and to let an Optimization Services Server solve your instances remotely.

GUROBI

- New libraries: version 2.0
- Simplex performance: The simplex optimizers are much faster in the release. The improvements are most pronounced in the dual simplex method.
- MIP performance: The MIP solver is significantly faster as well. Part of this is a consequence of the increased speed of the dual simplex optimizer, and part is due to algorithmic improvements in the MIP itself.
- MIP : You can now compute an Irreducible Inconsistent Subsystem ( ) for an infeasible MIP model. The previous release could only compute IISs for continuous models.
- MIP node files: You can now store search tree nodes on disk. This allows you to solve much larger and more difficult MIP models. Use the new NodefileStart parameter to indicate how much memory you would like to devote to nodes before they are written to disk. The performance impact of putting nodes out to disk is typically quite small.

MINOS

- MINOS5 (old version of MINOS) was dropped. MINOS5 now is an alias to MINOS (Version 5.51) in order to protect users that hard-coded the use of MINOS5.

MOSEK

- New libraries: version 6.0
- Improvement of speed and stability of the interior-point optimizer for linear and conic problems
- More effective presolve for simplex optimizer with hot starts

XPRESS

- New libraries: version 20.00
- Updated licensing: multi-threaded runs and 64-bit versions now included in base license
- Updated `threads` option allows specification of cores left free for non-XPRESS work.

In-core communication solver links

- Lindoglobal supports in-core communication

3.42.1.4 Model Libraries

GAMS Data Library

- **transxls (74)**: Solve classical transportation problem in Excel, using vba API (gamsx, opt and gdx)

GAMS EMP Library

- **negishi (21)**: Pure exchange model solved with EMP, SJM, and CGE

GAMS Model Library

- **bchtsp (348)**: Traveling Salesman Problem Instance with BCH
- **bchstock (349)**: Cutting Stock - A Column Generation Approach with BCH
- **tanksize (350)**: Tank Size Design Problem

GAMS Test Library

- **set10 (449)**: first entry in set/param data has wrong dimension
- **set11 (450)**: test for order when using `set.id` or `set#id` or `#id`
- **gdxcopy5 (451)**: Test GDX environment variables with trailing blanks
- **ifthen2 (452)**: Test nested $ifthen and $endif
- **ifthen3 (453)**: Test $ifthen $elseif/else $endif
- **ifthen4 (454)**: Tests $ifthen from old release notes
- **eval01 (455)**: constant evaluation with non-stop arithmetic
- **eval02 (456)**: $eval/ife/... sameas function
- **forceerr (457)**: ForceError and ForceErrorCnt Example
- **gdxxrw5 (458)**: Test for password handling of gdxxrw and $hiddencall
- **lolp (459)**: LP Test for logoption
- **lonlp (460)**: NLP Test for logoption
- **lomcp (461)**: MCP Test for logoption
- **eval03 (462)**: test constant compile time evaluation functions
- **eval04 (463)**: test constant compile time evaluation operators

3.42.1.5 Solver/Platform Availability Matrix

3.42.2 23.3.2 Maintenance release (November 18, 2009)

- Gurobi 2.0.1 library with bug fixes
- MOSEK 6 rev 53 library with bug fixes
- Updated CoinOS library with bug fixes
- Solver optfile bug fix in GAMSCHK
- Synchronized `tolproj` (1e-8) option for `solvelink=3`

3.42.3 23.3.3 Maintenance release (December 17, 2009)

- MOSEK 6 rev 55 library with bug fixes
- 32bit HAR utilities available in 64bit Windows System
- Slow solution reporting in GAMS/Gurobi and other solvers fixed

3.43 23.2 Distribution

3.43.1 23.2.1 Minor release (August 14, 2009)

3.43.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Shiro Takeda.

3.43.1.2 Solvers

Cplex

- New libraries 12.1
- Now also available on 64-Bit Intel Mac

LindoGlobal

- New libraries 6.0.1.299

3.43.1.3 Solver/Platform Availability Matrix

3.44 23.1 Distribution

3.44.1 23.1.1 Major release (July 13, 2009)

3.44.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Anibal Blanco, Wietse Dol, Arne Drud, Josef Kallrath, Erwin Kalvelagen, Niclas Mattsson, Bruce McCarl, Dominique van der Mensbrugghe, Renger van Nieuwkoop, Stefan Vigerske, and Tongxin Zheng.

3.44.1.2 New Platform

- **(64-Bit) Intel Mac**

3.44.1.3 GAMS System

GAMS

Default Upper Bound on Integer Variables

- The default upper bound on integer variables has changed from 100 to +INF. Since some solve steps in a GAMS applications may inadvertently depend on the previous default value of 100, a the compatibility option, the GAMS parameter `PF4=n`, has been introduced to control what values will be passed to the solver. If the GAMS parameter `PF4` is not used (a value of `PF4=1` is assumed) the solve steps will work as in previous releases.
  - `Pf4=0`: The new default upper bound of +INF will be passed to the solver.
  - `Pf4=1`: The value of 100 instead of +INF will be passed to the solver. The solvers will operate as with older GAMS versions. In addition messages will be written to the log and listing to report on the number of integer or semi-integer variables which had the new default bound of +INF reset to 100.
  - `PF4=2`: The new default values of +INF will be used as with `PF4=0`. When a solution is returned to GAMS and the level value of an integer variable exceeds the old bound value of 100, a message will be written to the log and listing.
  - `PF4=3`: The same as `PF4=2` with an additional execution error issued if the solution reports a level value greater than 100 for any integer variable with a default bound of +INF.

  Setting `PF4` values to 2 and 3 is a convenient way to test if the application relies on the previous default bounds of 100. Future releases may use `PF4=0` as the default.

  An historic note: when GAMS was first introduced, some MIP solvers could only handle binary variable and GAMS applied transformations to simulate integers by using a power expansions. In addition, MIP solvers with integer variables imposed different restrictions on the largest upper bound value. Finally, solvers like DICOPT introduced integer cuts during the solution process, needing some finite upper bound on integer variables. What was once a good choice, turned over time into a source of confusion or resulted in unexpected model behavior.

Default Iteration Limit

- The default iteration limit (`IterLim`) has been increased from 10000 to 2e9. Setting `IterLim` to `INF` will not work since it is treated as an integer by GAMS and many solvers. Some solver, e.g. GAMS/Gurobi, recognize 2e9 and set the solver iteration limit to infinity.

Enhanced Profiling Options

- In addition to `PROFILE=n` and `PROFILETOL=r`, a new GAMS parameter `PROFILEFILE=file` has been introduced to write profiling information to a text file with some fixed format which can easily be imported into a spreadsheet for further analysis.

```
    1        -1        0.000 ExecInit
  139        15        0.000 Assignment cnf
  139        13        0.000 Assignment cnf
    .         .         .    .
    .         .         .    .
    .         .         .    .
 3549       432        0.000 Equation   nbal
 3621     39489        0.032 Solve Fini wsisn
 3621        -1        0.062 GAMS Fini
    1        -1        0.000 ExecInit
 3621        -1        0.047 Solve Read wsisn
 3621        -1        0.000 GAMS Fini
```

A summary report of the ten slowest execution steps will be written to the log and listing.

```
--- Profile Summary (184 records processed)
     0.062      3621 GAMS Fini
     0.047      3621 Solve Read wsisn
     0.046      3529 Equation   divcnlsea (86)
     0.032      3621 Solve Fini wsisn (39489)
     0.016      3274 Assignment wnr (2502)
     0.016      3447 Equation   cost (15)
     0.016      3475 Equation   laborc (180)

     0.016      3546 Equation   subirrc (84)
     0.015      3030 Assignment gwtsa (273)
```

The timing on slow data definitions and gdx loads during compilation will be profiled as well.

Macros

- Added a line continuation character (\) for macro definitions. See test model **macro02**.

Other

- Faster reading of data statements that are not sorted
- Reduced memory usage for projections
- GDX handles IEEE special values

GAMS Data Utilities

GDXDIFF

- Added FldOnly and DiffOnly parameters to write different formats
- Protection against overwriting an input file

GDXVIEWER

- Fixed problem with cubed view

GDXXRW

- Added RWAIT parameter to specify a delay to open Excel to avoid not ready problems
- Added CheckDate option to regenerate output only if input is more recent than output file

SCENRED2

- A libinclude file runscenred2 has been added to make the communication with Scenred2 simpler. See example **srpchase**.

GAMS IDE

- Changed the interface for dealing with tabs
- Tabs expanded to spaces will mark the file as modified
- Added command to select text from current position to a text marker
- Added checks to see if IDE is visible on the monitor
- Move and Size are available on TaskBar icon

Documentation

- Updated McCarl GAMS User's Guide

3.44.1.4 Solvers

AlphaECP

- New libraries 1.75.03

Coin-OR

- New solver CoinCouenne
  - CoinCouenne is a global optimization solver for non-convex mixed integer non-linear programs, similar to the commercial solvers BARON and LindoGlobal. The solver is still in an experimental phase and is hidden in the GAMS system.
- New libraries
  - Cbc 2.3
  - Glpk 4.37
  - Ipopt 3.6
  - Scip now uses Clp 1.10

EMP

- Disjunctive programs can be solved via the following alternative automated reformulations without changes to the model
  - Convex Hull
  - BigM
  - CPLEX indicators
  - Examples
    - EMP Library **sequence (20)**: Sequencing on a single machine
    - Model Library **bilinear (346)**: Convexification of bilinear term binary times x

GUROBI

- New libraries 1.1

KNITRO

- New libraries 6.0
  - Introduces MINLP capability: binary and integer variables are supported. Two algorithms are available, a non-linear branch and bound method and an implementation of the hybrid Quesada-Grossman method for convex MINLP. The Knitro MINLP code is designed for convex mixed integer programming and is a heuristic for nonconvex problems.
  - General performance improvements for both the active-set and interior-point/barrier solvers
  - Reorganized options into groups: general, barrier and MINLP.

MOSEK

- New libraries 5.0 rev 127

In-core communication solver links

- Support of COINBONMIND, COINCBCD, COINIPOPTD and LGOD as in-core communication solvers.

  Where a traditional link already exists, the newer in-core link version has a "D" appended to the name (D for DLL). These in-core links are very similar to their traditional predecessors. They may lack some functionality but offer in-core communication between GAMS and the solver, making potentially large model scratch files unnecessary. This can save time if you solve many models in your GAMS program.

3.44.1.5 Model Libraries

GAMS Data Library

- **Portfolio (68)**: Determines an efficient frontier in Excel, using the GDX DLL (vba API) and the GAMS executable
- **Sudoku (69)**: Solve a Sudoku in Excel, using the GDX DLL (vba API) and the GAMS executable
- **Samurai (70)**: Solve a Samurai Sudoku in Excel, using the GDX DLL (vba API) and the GAMS executable
- Samurai2 (71): Solve a Samurai Sudoku in Excel, using the GDX and GAMSX DLL (vba API) *[not available anymore]*
- **CHP (72)**: Optimize combined heat and power generation in Excel, using vba API (gamsx and opt) and GDXXRW
- **CHP2 (73)**: Optimize combined heat and power generation in Excel, using vba API (gamsx, opt and gdx)

GAMS EMP Library

- **zerofunc (18)**: Match unmatched vars with zero functions in VI
- **traffic2 (19)**: Traffic Assignment Model
- **sequence (20)**: Sequencing on a single machine

GAMS Model Library

- **secure (343)**: Secure Work Files - Example 2
- **srpchase (344)**: Scenario Tree Construction Example
- **tsp5 (345)**: Traveling Salesman Problem - Five
- **bilinear (346)**: Convexification of bilinear term binary times x
- **solveopt (347)**: option solveopt explained

GAMS Test Library

- **minos01 (433)**: MINOS test suite - anti-cycling via expand frequency
- **scnred02 (434)**: Scenred2 test - tree reduction and zero values
- **empvi05 (435)**: Test for EMP's treatment of an odd variable
- **nlcode3 (436)**: Wrong NL code generation for odd case
- **set8 (437)**: Test the `set.id` `set#id` `#id` data macros
- **nlcode4 (438)**: More NL testing when code is deleted
- **compile7 (439)**: Test and document some system.XXX macros
- **mcp09 (440)**: Test inequalities with infinite bounds
- **empadj01 (441)**: Test for EMPs AdjustEqu/NYslp option
- **emp05 (442)**: Test for handling of constant equations
- **examin03 (443)**: EXAMINER test suite - test returnInitPoint option
- **compile8 (444)**: Test for a mapping error
- **sl4mip01 (445)**: Test for known XPRESS bug, with solvelink=1,2,4,5
- **macro02 (446)**: Multi-line macro test
- **put10 (447)**: $on/offput inserted outside the loop
- **set9 (448)**: fast shifting of set elements

3.44.1.6 Solver/Platform Availability Matrix

3.44.2 23.1.2 Maintenance release (July 23, 2009)

- MPSGE: MPSGE ignored the `m.workspace` and `m.workfactor` settings
- GAMSCHK: Fixed a problem with the layout of the reports in some models

3.45 23.0 Distribution

3.45.1 23.0.2 Major release (February 14, 2009)

3.45.1.1 Acknowledgments

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Surendu Korgaokar, Tom Rutherford, Stefan Vigerske and Rich Roberts.

3.45.1.2 GAMS System

GAMS Data Utilities

GDXXRW

- Fix to not limit the size of the block read to 65536 lines

Documentation

- Updated McCarl GAMS User's Guide

Other

As announced earlier we dropped the following systems as of this GAMS Distribution.

- GAMSBAS: The newer savepoint/loadpoint facility is easier to use and more robust.
- MPSWRITE: The newer CONVERT utility includes this capability

3.45.1.3 Model Libraries

GAMS Model Library

- **poutil (342)**: Portfolio Optimization for Electric Utilities

GAMS Test Library

- **privat01 (432)**: Test private workfile behavior
- **emp04 (431)**: Compare results of EMP runs using different options for nlp problem
- **local01 (430)**: Test .local in different context $on/offlocal
- **empdisj1 (429)**: Test EMP Disjunction - Minimize the makespan
- **empecs02 (428)**: Test for EMP-Embedded Complemenarity System
- **empecs01 (427)**: Test for EMP-Embedded Complemenarity System
- **empvi04 (426)**: Test for EMP Variational Inequalities
- **empvi03 (425)**: Compares alternative EMP-VI models
- **empvi02 (424)**: Compares manual and EMP-VI models
- **empvi01 (423)**: Simple test for variational inequalities through EMP
- **empbp03 (422)**: Simple bilevel model, both inner and outer problems have constraints
- **empbp02 (421)**: Simple bilevel model, outer problem consist of objective only
- **empbp01 (420)**: Simple bilevel model, inner problem consist of objective only
- **convert7 (419)**: CONVERT test suite - test hessian info correctness
- **lp14 (418)**: Simple test on one equation AFTER reformulation
- **card01 (417)**: Test extended card and ord functions
- **suffix01 (416)**: Test suffix options on controlling sets
- **nlp01 (415)**: Test of correctness for levels & marginals of NLP

3.45.1.4 Solvers

As announced in the 22.9 release notes we dropped the following solvers as of this GAMS Distribution.

- CONOPT1 (old version of CONOPT). The default CONOPT version, CONOPT 3, will not be dropped.
- MILESOLD (old version of MILES). The default MILES version will not be dropped.
- OSL1 and OSL2 (old versions of OSL). The default OSL version will not be dropped.
- PATHOLD (old version of PATH). The default PATH version will not be dropped. Due to user requests, and despite our earlier announcement, we did *not* drop the following components:
- CONOPT 2 (old version of CONOPT).
- DEA

CPLEX

- New libraries 11.2.1

GUROBI

- The new Gurobi solver provides state-of-the-art simplex-based linear programming (LP) and mixed-integer programming (MIP) capability.
- The Gurobi MIP solver includes shared memory parallelism, capable of simultaneously exploiting any number of processors and cores per processor. The implementation will be deterministic: two separate runs on the same model will produce identical solution paths.
- The Gurobi solver is available for the 32-bit and 64-bit versions of Windows and Linux. Please contact us for an evaluation license.

KNITRO

- New libraries 5.2.0

LINDOGLOBAL

- New libraries 5.0.1.345

MOSEK

- New libraries 5.0 rev 112

XPRESS

- New libraries 19.00.04
- The primal algorithm has been improved and is now 40% faster on XPRESS' LP benchmark test set and 20% faster on XPRESS' large LP benchmark test set.
- The dual algorithm has been improved and is now 22% faster on XPRESS' LP benchmark test set and 45% faster on XPRESS' large LP benchmark test set.
- The MIP performance has been improved and is now 40% faster on XPRESS' MIP benchmark test set
- Improvements to the Quadratic Primal algorithm to avoid cycling problems

In-core communication solver links

- Support of GUROBI as an in-core communication solvers.
- Experimental in-core link MINOSD
- Enhancements and bug fixes for the in-core communication solver links BDMLPD, CONOPTD, and CPLEXD Where a traditional link already exists, the newer in-core link version has a ”D” appended to the name (D for DLL). These in-core links are very similar to their traditional predecessors. They may lack some functionality but offer in-core communication between GAMS and the solver, making potentially large model scratch files unecessary. This can save time if you solve many models in your GAMS program.

Solver/Platform Availability Matrix

3.46 22.9 Distribution

3.46.1 22.9.2 Major release (December 01, 2008)

3.46.1.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Stefan Boeters, Wolfgang Britz, Alexander Gocht, Josef Kallrath, Erwin Kalvelagen, Todd Munson, Yiqi Zhu.

3.46.1.2 Future Deprecation

We are planning to drop the following systems from our next GAMS Distribution 23.0. If you object please submit an email to support@gams.com!

- CONOPT1 and CONOPT 2 (old versions of CONOPT)
- DEA (capability will be offered by a more general scenario framework)
- GAMSBAS
- MPSWRITE
- MILESOLD (old version of MILES)
- MINOS5 (old version of MINOS)
- OSL1 and OSL2 (old versions of OSL)
- PATHOLD (old version of PATH)

3.46.1.3 GAMS System

GAMS

- **GAMS scratch file extension**. Starting with distribution 22.9 the default file extension of intermediate files located in the `225?` directories is `.dat`. The scratch extension is a parameter that can be changed with the GAMS option `ScrExt`, e.g `gams trnsport scrext=tmp`. Within GAMS code you get the scratch extension using `%gams.scrext%`.
- GAMS Parameter **ETlim** (Elapsed Time limit). A GAMS job will terminate if the elapsed time in seconds exceeds the value of ETlim. The job elapsed time is checked before the execution of a $call, execute or solve statement. The system will terminate with a compilation or execution error if the limit (default INF) is reached.
- GAMS Parameter **AppendExpand** (short form **AE**). Allows to control the file opening of the expand file. A value of 0 will open with rewrite, a value of 1, the default, will open with append.
- New **solveopt=clear** option. A third option has been added to option `solveopt=xxx`. The related model attribute <`model`>`.solveopt=n` has been adjusted to match the new option values. If the model attribute is set to `NA` (default), the setting of the corresponding option statement will be used to determine the way solutions values are loaded back into the GAMS data space. The possible values are (the numeric value for the model attribute are given in parenthesis):

  - `replace` (0) all equations appearing in the model list will be completely replaced by the new model results. Variables are only replaced if they appear in the final model.
  - `merge` (1) the new model results are merged into the existing structures. This is the default.
  - `clear` (2) similar to the replace option; in addition, variables appearing in the symbolic equations but squeezed out in the final model, are removed.

- New **solPrint=silent** option. A third option has been added to option `solPrint=xxx`. The related model attribute <`model`>`.solPrint=n` and the GAMS parameter `solPrint=n` have been adjusted to match the new option values. If the model attribute is set to `NA` (default), the setting of the corresponding option statement will be used to control the printing of model generation and solution information. Note that the GAMS parameter initializes the corresponding option statement values. The possible values are (the numeric value for the model attribute are given in parenthesis):
  - `off` (0) detailed solution output is suppressed.
  - `on` (1) the most detailed solution output. This is the default.
  - `silent` (2) all solve related output is suppressed.

- New model attributes returning **elapsed time** information of the solution process:
  - `ETsolve` total elapsed time to execute a solve statement
  - `ETsolver` elapsed time that can be attributed to the solver only
  - `ETalg` elapsed time that can be attributed to the core algorithm

- New suffix for **abort.noerror**. When using the suffix `.noerror` with the `$abort` statement, the error count will NOT be increased. When a save file is written, all remaining unexecuted code will be flushed. This allows effective reuse of the save file.

- Added a test and error message to see if a restart file has not been closed yet when we try to use the file.

The GAMS Macro Facility

The GAMS macro facility has been inspired by the GAMS-F preprocessor for function definition developed by Ferris, Rutherford and Starkweather, 1998, 2005. The GAMS macro facility incorporates the major features of the GAMS-F preprocessor into the standard GAMS release. The GAMS macros acts like a standard macro when defined, however, its recognition for expansion is GAMS syntax driven.

Macros are widely used in computer science to define and automate structured text replacements. The GAMS macro processors functions similar to the popular C/C++ macro preprocessor. The definition takes the form

```
$macro name  macro body
$macro name(arg1,arg3,arg2,..) macro body with tokens arg1,..
```

The name of the macro has to be unique, similar to other GAMS data types like sets and parameters. A (following immediately the macro name starts the list of replacement arguments. The macro body is not further analyzed after removing leading and trailing spaces.

The recognition and following expansion is directed by GAMS syntax. The tokens in the macro body to be replaced by the actual macro arguments follow the standard GAMS identifier conventions. For example:

```
$macro diff(y) system.cosh(y) - cosh(y)
$macro cosh(x) (exp(x) + exp(-x))/2
scalar z; z = diff(2/3); display z;
```

will expand into:

```
scalar z; z = system.cosh(2/3) - (exp(2/3) + exp(-2/3))/2; display z;
```

This expansion takes place in two steps, first GAMS recognizes diff as a macro and changes the input text to:

```
scalar z; z = system.cosh(2/3) - cosh(2/3); display z;
```

Gams will continue to process the modified input text. The first occurrence of cosh is not recognized by gams as a macro, only the second reference to `cosh(2/3)` will result in a second and final expansion.

The recognition of macros and expansion of arguments can further be controlled by the use of ampersands (&) in the macro body. A single ampersand (&) is used as a concatenation or separation symbol to recognize tokens to be replaced. Two ampersands (&&) immediately preceding a token will drop the most outer matching single or double quotes of the replacement argument. For example:

```
$macro  f(i)  sum(j, x(i,j))
$macro equ(q)  equation equ_&q; equ_&q.. q =e= 0;
equ(f(i))
```

will expand into:

```
equation equ_f(i); equ_f(i).. sum(j, x(i,j)) =e= 0;
```

The first step of the above expansion is shown below. GAMS will then only recognize the third occurrence of `f(i)` as a macro which will be expanded to give the above result.:

```
equation equ_f(i); equ_f(i).. f(i) =e= 0;
```

The actual calling arguments of macros can contain complex expressions and other macro calls. Multiple arguments are separated by commas. Pairs of parenthesis and quotes can be used freely to protect the separating comma.

```
$macro many(a,b) scalar x; x=a/&&b); display x;
many((3/5),'(mod(3,2)')
```

Note that the second argument has unbalanced parenthesis and therefor needs to be enclosed in quotes to give the result below.

```
scalar x; x=(3/5)/(mod(3,2)); display x;
```

Some macro use can result in an expansion of infinite length. For example:

```
$macro a  b,a
display a;
```

will expand into:

```
display b,b,b,b,b,b,b,b,b,b,b,b,b,b,b,b,b,...
```

GAMS will eventually refuse to do more substitutions and issue a compilation error.

The use of deeply nested macros may require the use of aliased sets in indexed operations like sum and prod. A minor syntax extension allows the implicit use of aliases. The suffix `.local` on a controlling set will use an implicit alias within the scope of the indexed operation. For example:

```
$macro qq(i) sum(i.local, b(i))
c(q) = qq(q);
```

will expand into:

```
c(q) = sum(q.local, b(q));
```

The use of the `.local` modifier is not limited to macros and can be used in any context.

Another feature motivated by the use of macros is the implicit use of the `.l` suffix in data manipulation statements. This allows using the same algebra in model definitions and assignment statements. The following code snippet illustrates this feature:

```
$macro D(s,h) INCOME(h)*alpha[s,h]*sum{s.local, alpha[s,h]*P[s]*
.  .  .
cmkt(s)..    Y(s) =g= sum(h, D(s,h));
. .  .
$onDotL

dl(s,h) = d(s,h); display dl;
```

where `INCOME` is another macro which calls a number of other nested macros. `D(s,h)` is now used to define the equation `cmky` and is also used in an assignment after the model has been solved. The `$ondotl` enables the implicit `.l` suffix for variables. This feature was introduced to make macros more useful and is not limited to be used in macro bodies. Since this a new feature it has to be enabled. The matching `$offdotl` will disable this feature.

Three more switches are relevant to macros. The `$show` will list any GAMS macros defined. The `$onmacro`/`$offmacro` will enable or disable the expansion of macros; the default is `$onmacro`. Finally, the `$on/offexpand` will change the processing of macros appearing in the arguments of a macro call. The default operation is not to expand macros in the arguments. The switch `$onexpand` enables the recognition and expansion of macros in the macro argument list. `$offexpand` will restore the default behavior.

Macro definitions are preserved in a save/restart file and are available again when performing a continued compilation.

Comparison of GAMS-F with GAMS macros

The GAMS-F preprocessor combines aspects of traditional macros with that of functions and objects. The example 7 from the GAMS-F documentation using macros can be found in the GAMS model library under the name **two3mac**. Some of the main differences between GAMS macros and the GAMS-F preprocessor are:

- A macro is a new GAMS data type and shares the name space of GAMS symbols, like sets, parameters, variables,etc.

- Instead of using <id> == <body>; to recognize a macro, we use $macro <id> <body> with the $ in position 1.
- Surrounding parenthesis are not automatically added to the macro body when the macro is expanded.
- A macro is recognized and expanded anywhere a proper GAMS identifier can be used. This can be suppressed by $onmacro/offmacro.
- No automatic definition of new aliased sets and their use in controlled index positions. The .local feature has been added to ensure local use and eliminates the need for new alias definitions.
- No automatic equation definitions for MCP models.
- The body of the macro is only used during expansion. Hence, the macro definitions are not order dependent.
- Variables in macro bodies will have an implicit .L when using in assignment statements. This is not a macro expansion feature, but a new GAMS feature that needs to be activated by $onDotL/$offDotL

GAMSIDE

- The model library open file no longer converts the file name to lowercase
- The ViewClose command for IDECmds now allows closing for any file
- Added option to execute command scripts (.cmd files) from the IDE
- Pressing F3 (search again) after a search/replace will restart the replace dialog
- Output of the put_utility 'title' option will be shown in the process window

GAMS Data Utilities

- CHOLESKY
  - Compute the Cholesky factors of a symmetric positive-definite matrix
- EIGENVALUE
  - Compute the eigenvalues of a symmetric matrix
- EIGENVECTOR
  - Compute the eigenvalues and eigenvectors of a symmetric matrix
- GDXCOPY
  - When we convert a gdx file using the **-Replace** option, and the file is open in the IDE, the IDE will be signaled to close the file and reopen the file after the conversion is complete.
- GDXDUMP
  - Updated documentation.
- GDXVIEWER
  - Allow resizing of the column width
- GDXDCLIB
  - Reading an aliased set could return too many elements
- GDXMERGE
  - Fixed a problem when we specify a list of identifiers

SCENRED2

Scenred2 is an updated and expanded version of the scenred utility for scenario reduction. Scenred2 is intended to be a replacement for the existing scenred, but we have made the newer version available as scenred2 due to some differences in the options used to control scenred's behavior. Having both available also facilitates comparisons between the two.

New features in scenred2 include:

- Tree construction. Scenred could only reduce existing scenario trees, while scenred2 can create trees from collections of independent scenarios (i.e. from scenario "fans").
- Visualization. Scenred2 contains new options to create input files for GNUPLOT.
- Improved metrics. Tree reduction can now be carried out w.r.t. the Fortet-Mourier metric, instead of the upper bounds given by the Monge-Kantorovich metric.

3.46.1.4 Documentation

- Updated McCarl GAMS User's Guide

3.46.1.5 Other

- Semidefinite Programming Solver CSDP available for Windows, Linux and Macintosh on Intel distributions. Some examples are included in the GAMS Model Library:
  - trnssdp (340)
  - **gqapsdp (339)**
  - **maxcut (338)**
- Additional Lahey Fortan version of all API files does not depend on a C compiler

3.46.1.6 Model Libraries

GAMS Model Library

- **two3mac (341)**: Simple 2 x 2 x 2 General Equilibrium Model Using Macros
- trnssdp (340): Solving the Transportation LP Problem using SDP
- **gqapsdp (339)**: SDP Convexifications of the Generalized Quadratic Assignment Problem
- **maxcut (338)**: Goemans/Williamson Randomized Approximation Algorithm for MaxCut

GAMS Test Library

- **load4 (414)**: Tests various file opening options for GDX files
- **eigvec02 (413)**: Test Eigenvector/Eigenvalue utilities
- **choles02 (412)**: Test 2 Cholesky utility
- **choles01 (411)**: Test 1 Cholesky utility
- **eigvec01 (410)**: Test Eigenvector utility
- **eigval01 (409)**: Test Eigenvalue utility
- **scnred01 (408)**: Basic Scenred2 test - tree construction
- **scensol1 (407)**: Basic Scenario Solver Test
- **gdxmerg2 (406)**: Bad acronym merge in gdxmerge
- **gdx8 (405)**: Bad acronym mapping
- **gdx7 (404)**: Bad acronym loading
- **macro01 (403)**: Several macro tests
- **assign2 (402)**: Test for bad assignment with .fx
- **mcp08 (401)**: Test MCP that turfs up PATH preprocessing error
- **convert6 (400)**: CONVERT test suite - hessian.gdx

3.46.1.7 Solvers

Coin-OR

- New libraries
  - Bonmin 0.100
  - Cbc 2.2
  - Glpk 4.32
  - Ipopt 3.5
- Scip 1.1
- Mumps 4.8.3 (used by Ipopt and Bonmin)
- CoinCbc can now use multiple threads (see new option "threads"). This option is available for all platforms other than Windows.
- Scip supports special ordered set of type 1 and 2 (SOS1 and SOS2). Further, a new heuristic and a new cutting plane separator has been added, the preprocessing has been improved, the Clp interface revised, and bugs were fixed.

Cplex

- New libraries 11.2

  CPLEX 11.2 offers finer control for solution polishing. In previous versions, the only stopping criterion for solution polishing was set by the parameter `PolishTime` to limit time spent polishing a solution. General stopping criteria, such as the time limit, absolute MIP gap, relative MIP gap, MIP node limit or MIP integer solution limit did not apply to solution polishing.

  Now, however, CPLEX 11.2 allows the user to control more finely when solution polishing terminates. In other words, the usual tolerances (`EpAGap` and `EpGapinitialized` with GAMS parameters `OptCA` and `OptCr`) and limits (`IntSolLim`, `NodeLim` and `TiLim` initialized with GAMS paramter `NodLim` and `ResLim`) now apply to solution polishing.

  In addition to those existing parameters that now control the termination of solution polishing, there are also new parameters specific to the starting conditions for solution polishing.

  With these new parameters, a user can tell CPLEX when to switch from branch & cut to solution polishing. CPLEX is able to switch after it has found a feasible solution and put into place the MIP structures needed for solution polishing. When these two conditions are met (feasible solution and structures in place), CPLEX stops branch & cut and switches to solution polishing whenever the first of these starting conditions is met:

  - when CPLEX achieves a specified absolute MIP gap (PolishAfterEpAGap)
  - when CPLEX achieves a specified relative MIP gap (PolishAfterEpGap)
  - when CPLEX finds a specified number of integer solutions (PolishAfterIntSol)
  - when CPLEX processes a specified number of nodes (PolishAfterNode)
  - when CPLEX reaches a specified time limit on time spent in optimization (PolishAfterTime)

  The new parameters are incompatible with the deprecated option PolishTime. If you use them together in an option file you will see an error like this:

```
Reading parameter(s) from "C:\tmp\cplex.opt"

>>  polishtime 5
    Warning line 1: deprecated option "polishtime"; Use option polishafter... for finer soluti
>>  polishafterintsol 1
Finished reading from "cplex.opt"
CPLEX Error  1807: Incompatible parameters.
polishafterintsol: current = 2100000000, default = 2100000000, minimum = 1, maximum = 2100000
```

  A few examples with the corresponding GAMS/CPLEX option file:

  - As an example of how to manage time spent polishing a feasible solution, suppose the user wants to solve a problem by spending 100 seconds in branch & cut and an additional 200 seconds in polishing:

```
TiLim 300
PolishAfterTime 100
```

  - Switch to polishing after first feasible solution:

```
PolishAfterIntSol 1
```

  - For example, the following procedure applies branch & cut until it reaches a 10% gap. Then it starts solution polishing until it narrows the gap to 2%.

```
PolishAfterEpGap 0.1
EpGap 0.02
```

Lindoglobal

- New libraries 5.0.1.292 now also for Sun Sparc Solaris

PATH

- New libraries 4.7.01 fix preprocessing bug for both MCP and NLP front ends

BDMLPD, CPLEXD and CONOPTD

- Enhancements and bug fixes for the three experimental in-core communication solver links BDMLPD, CPLEXD and CONOPTD.

3.46.1.8 Solver/Platform Availability Matrix

3.47 22.8 Distribution

3.47.1 22.8.1 Major release (August 01, 2008)

3.47.1.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Andrea Consiglio, Anton Eremeev, Mustafa Esen,Josef Kallrath, Erwin Kalvelagen, Todd Munson, Rich Roberts, and Andres Ramos.

3.47.1.2 GAMS System

GAMS

- GAMS scratch file extension: Starting with distribution **22.9** the default file extension of intermediate files located in the 225? directories will change from `.scr` to `.dat`. **For distribution 22.8 it is still** `.scr`. The scratch extension now is a parameter that can be changed with the GAMS option `ScrExt`, e.g `gams trnsport screxT=tmp`. Within GAMS code you get the scratch extension using `%gams.screxT%`.
- Increased the maximum input line length to 40,000 characters and the maximum number of columns in a table to 10,000.
- Checking for an interrupt is now also done inside a GAMS looping constructs.
- The `$LOAD` directive can read the universe from a gdx file by specifying `$LOAD id=`$*$.
- Certain gdx file read operations are now faster and use less memory.
- GAMS parameters `gdxcompress` and `gdxconvert`
  - Allow new gdx files to be written in an older format of the gdx file.
  - Usage through an environment variables (valid for all gdx related operations): `gdxconvert = <value>` and `gdxcompress = <value>` or via GAMS command line parameters: `gdxconvert = <value>` and `gdxcompress = <value>`.
  - Possible values for gdxcompress
    - `0` (or empty): no compression
    - `1`: compression turned on
  - Possible values for gdxconvert:
    - V7: version 7

    - V6: version 6
    - V5: version 5
  - E. g. to get a compressed v6 gdx file enter: `gams <model_name> gdxconvert=v6 gdxcompress=1 gdx=<gdx_file>`.
  - Note:
    - With GAMS 22.8 the default format for gdx files is V7 uncompressed.
    - Only V6 and V7 support compression.
    - V7 formatted files were introduced with version 22.6 of GAMS; V6 formatted files were introduced with version 22.3 of GAMS. GAMS platforms that were introduced after 22.3/22.6 (e.g. Mac Intel or SunSparc64) do not support V5/V6.
    - The command line options have a higher precedence as the environment variables with the same name.

Utilities

- New
  - `gdx2xls`: Converts an entire gdx data container to a Microsoft Excel spread sheet.
  - `invert`: Calculates the inverse of a matrix provided as a gdx file (for more information see gdxutils documentation).
  - `msappavail`: Checks which Microsoft Office programs are installed.
  - `xlstalk`: Allows some interaction with Excel to open/close/save Excel files.
- Extended/Updated
  - `gdxcopy`: New option to replace existing gdx files.
  - `gdxdiff`: New id option to compare specified ids only.
  - `gdxmerge`: New optional output parameter to specify the name of the output file.
  - `gdxviewer`: Fixed problem with cube view.

GAMSIDE

- Fixed problem when moving a column to the plane in the gdx data viewer.

3.47.1.3 Model Libraries

GAMS Test Library

- **New models**, including tests for
  - invert utility
  - ls solver
  - poly function
  - gdxconvert and gdxcompress parameters

GAMS Data Utilities

- GAMS introduces the new model library 'GAMS Data Utilities' containing models that demonstrate the various utilities to interface GAMS with other applications.

PRACTICAL FINANCIAL OPTIMIZATION Models

- The models of the forthcoming book PRACTICAL FINANCIAL OPTIMIZATION - A Library of GAMS Models by Andrea Coniglio, Soren Nielsen, and Stavros A. Zenios have been included in the GAMS distribution. It is a companion volume to the book `Practical Financial Optimization` by Stavros A. Zenios.

3.47.1.4 Solvers

BARON

- New libraries 8.1.5 for Windows, Linux, and AIX

BDMLPD

- GAMS 22.8 introduces a third experimental solver BDMLPD besides CONOPTD and CPLEXD. They are very similar compared to their professional brothers BDMLP, CONOPT and CPLEX. They lack some functionality (e.g. CPLEXD does not solve QCP models) but offer in-core communication between GAMS and the solver. No large model scratch files need to be written to disk which can save time if you solve many models in your GAMS program. This in-core execution is activated by setting <`modelname`>`.solvelink=5;` before the solve statement.

Coin-OR

- CoinBonmin
  - New libraries 0.99
  - Support of user-defined cut generators and heuristics via BCH (Branch and Cut Heuristic)
- CoinCbc new libraries 2.1
- CoinScip supports user-defined cut generators, heuristics, and incumbent report callbacks via BCH

Convert

- New option `hessian` to dump the Hessian matrix into a GDX file. Similar to the option `jacobian`.

Cplex

- New libraries 11.1.1

Lindoglobal

- New libraries 5.0.1.292. Sun Sparc Solaris 5.0.1.274.

LS

- Linear Least Squares Solver

Mosek

- New libraries 5 Rev 90

XA

- New libraries for Windows

3.47.1.5 Solver/Platform Availability Matrix

3.48 22.7 Distribution

3.48.1 22.7.1 Major release (May 01, 2008)

3.48.1.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Jens Baudach, Michael Ferris, Josef Kallrath, Aldo Vecchietti and Stefan Vigerske.

3.48.1.2 GAMS System

GAMS

- Enhanced Data Statements

  The data statements have been enhanced to allow initial values for equations and variables in addition to set and parameter data. Those new data statements follow the syntax for list and table data statement for parameters by adding an additional dimension to specify the specific data attribute. The variable and equation suffixes can be used in this additional dimension. For example, the solution values for the transport example could be written as:

```
variable x(i,j) / (seattle.(new-york 50, chicago 300)
                   san-diego.(new-york,topeka) 275   ).l
                  seattle.topeka.m     0.36
                  san-diego.chicago.m  0.009 /;
variable z / l 153.6750 /;

equation demand(j) / (new-york 0.2250
                      chicago  0.1530
                      topeka   0.1260).m /;
```

  Only the non default values need to be specified. The following attributes can be used according to the variable type:

```
.l      level
.m      marginal
.lo     lower bound
.up     upper bound
.scale  scale value
.prior  priority for discrete variables
.fx     shorthand for setting .l,.lo and .up to the same value
```

With table style input all index positions have to appear in the row definition. For example we could write the above list oriented statement in table form as:

```
variable table x(i,j) initial values
                    l       m
seattle. new-york   50
seattle. chicago   300
seattle. topeka          0.36
san-diego.new-york 275
san-diego.topeka   275
san-diego.chicago       0.009
```

As with other data statements, `$onmulti`, `$ondelim` and `$onempty` can be used as well.

- The Matching Operator

  Mappings between n-tuples can be clumsy to enter via data statements and are often difficult to compute. Similar to the product operator (.) we introduced a match operator (:). For example, the two set data statements give the same result:

```
Set I / t1*t6:s3*s5 /
Set j / t1.s3,t2.s4,t3.s5 /
```

  In another example we may want to count "tuples" in some fashion:

```
sets h /h1*h24/, d /d1*d365/, dh(d,h) /#d.#h/
sets t /t1*t8760/, tdh(t,d,h) /#t:#dh/
```

  The resulting set tdh will then have the values:

```
t1.d1.h1, t2.d1.h2, t3.d1.h3 ..
```

  Currently there is no general matching operator for assignment statement. To facilitate some otherwise very clumsy and expensive calculations, one can use the following option statement:

```
Set ijk(I,j,k), x(I,j,k,l) ..
Option ijk(i:j,k), x(ijk:l);
```

  This statement will first clear the set ijk, then apply the matching operators to i and j and finally apply a product operation to the matched (i,j) with k which results in:

```
i1.j1.k1, i1.j1.k2, ..
i2.j2.k1, i2.j2.k2, ..
```

  And x will match ijk with the set l resulting in:

```
i1.j1.k1.l1, i1.j1.k2.l2, ..
```

- Limit on Memory Use - HeapLimit

  In some applications it may be desirable to limit the amount of memory a GAMS job can use. HeapLimit (MB) is a new GAMS parameter and function/property that limits memory used to store dynamic data. If the dynamic data storage exceeds this limit, the job will be terminate with return code 10, out of memory. These features are especially useful in a server environment.

  - The GAMS parameter HeapLimit sets the limit of memory use at compile and execution time for a GAMS job
  - The function/property HeapLimit can be used to interrogate the current limit and allows it to be rest
  - The NLP solver CONOPT also has a HeapLimit option which ensures that the solver will not use more dynamic memory

- Other enhancements
  - A symbol can have up to 20 dimensions and identifiers and labels can have up to 63 characters
  - The GAMS executable understands the 'Keep' and 'CurDir' parameters
  - New derived variable/equation attribute `.range` is defined as `x.range=x.up-x.lo`. This provides a convenient way to see if a variable is fixed
  - Additional references in compile time constant expression in `$eval` and `$ife` statement can now reference scalar parameters and the function `card(id)`
  - Added the tuple text if we display with the format x:0:0:1 which puts single items on one line
  - In table statements under `$ondelim`, we can drop the dummy element in the column definition
  - As in execution time GDX loads, we can extract the domain information with a load statement like `$load setid=parameterid`

Gams Data Exchange (GDX)

- A symbol in a GDX file can have up to 20 dimensions and identifiers and labels can have up to 63 characters
- A GDX file can store domain information for a symbol
- A GDX file can save an aliased set

GDX Utilities

- GDXDUMP writes now data for variables and equations (no longer surrounded by `$ontext` / `$offtext`)
- MDB2GMS allows writing of an empty symbol
- GDXXRW
  - No longer interprets a text field as a numeric value (because of international notation issues); the value returned for such a cell is NA
  - Fixed a problem with the default value for a field for a VAR and EQU
- GDXMERGE did not merge an aliased set correctly
- GDXVIEWER can export all symbols to Excel in command-line mode by specifying `ID=*`

GAMSIDE

- Supports an optional file, 'idecfg.ini', to display additional items like:
  - Option to open a html document
  - Multiple model libraries
  - Display of an image in the process window
- Fixed a problem matching parenthesis on an empty line
- Fixed a problem deleting a 225 directory (when this was the last directory used for opening a file)

GAMS Model Library

- **GAMS Model Library** contains six examples from LogMIP User's Manual

GAMS Test Library

- **30 new models**, including
  - Tests for proper handling of domains larger than 10 and UEL names longer than 31 characters
  - Testing of gdxmerge with aliased sets
  - New tests for DECISC and DECISM
  - Several models testing EMP

Documentation

- Updated McCarl GAMS User's Guide

3.48.1.3 Solvers

BARON

- New libraries (version 8.1.4)

CPLEX

- New libraries (version 11.0.1)

COIN-OR

- New MIP solver SCIP from Zuse Institute Berlin
  - use as option mip=coinscip;
  - uses COIN-OR LP solver CLP
  - free for academic users.
- Support of Windows 64-bit platform
- CoinCbc supports user-defined cut generators and heuristics via BCH (Branch and Cut Heuristic)
- CoinIpopt and CoinBonmin support dynamic load of linear solvers MA27, MA57 (HSL), and Pardiso.
- Minor updates in the libraries and interfaces of CoinCbc, CoinGlpk, CoinIpopt, and CoinBonmin.

CONOPT

- new option Heaplimit (see also gams option)

EMP - Extended Mathematical Programming

- (Experimental) Framework for automated mathematical programming reformulations as
  - Bilevel Programs
  - Disjunctive Programs
  - Extended Nonlinear Programs
  - Embedded Optimization Complementarity Programs

  Thereby new upcoming model types are reformulated into established math programming classes in order to use mature solver technology. EMP comes free of charge with any licensed GAMS system but needs a subsolver to solve the generated models.

LOGMIP

- LogMIP 1.0 is a program for solving linear and nonlinear disjunctive programming problems involving binary variables and disjunction definitions for modeling discrete choices. While the modeling and solution of these disjunctive optimization problems has not yet reached the stage of maturity and reliability as LP, MIP and NLP modeling, these problems have a rich area of applications. LogMIP 1.0 has been developed by A. Vecchietti, J.J. Gil and L. Catania at INGAR (Santa Fe-Argentina) and Ignacio E. Grossmann at Carnegie Mellon University (Pittsburgh-USA) and is composed of:
  - a language compiler for the declaration and definition of disjunctions and logic constraints
  - solvers for linear and non-linear disjunctive models (lmbigm, lmchull, lmlboa)

  LogMIP comes free of charge with any licensed Windows GAMS system but needs a subsolver to solve the generated MIP/MINLP models. For more information see
  - LogMIP Website

MOSEK

- New libraries (version 5.0.0.79)

CPLEXD and CONOPTD

- GAMS 22.7 introduces two experimental solvers: CPLEXD and CONOPTD. They are very similar compared to their professional brothers CPLEX and CONOPT. They lack some functionality (e.g. CPLEXD does not solve QCP models) but offer in-core communication between GAMS and the solver. No large model scratch files need to be written to disk which can save time if you solve many models in your GAMS program. This in-core execution is activated by setting `modelname.solvelink=5;` before the solve statement.

3.48.1.4 Solver/Platform Availability Matrix

3.48.2 22.7.2 Maintenance release (May 13, 2008)

- DICOPT/ALPHAECP/LOGMIPLBOA: Fixed Cplex scaling bug
- GAMS/CPLEX: Small cosmetic Cplex bug fix. We got "CPLEX Error 3003: Not a mixed-integer problem." In case we cannot solve the fixed problem. This was due to some query calls about nodes and iteration.
- GAMSIDE: Fixed a bug that could cause an out of memory error when moving a row or column to the plane index in the gdx data viewer
- GAMS/DEA: Avoid writing zeros to GDX files
- GAMS/LGOLIB: Fixed a memory leak
- Minor documentation updates
- Note: AIX and Mac OS X PPC were not updated.

3.49 22.6 Major release (December 24, 2007)

3.49.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Anton Eremeev, Michael Ferris, Christian Gilow, Uwe Schneider, Monique Guignard-Spielberg and Stefan Vigerske.

3.49.2 New Platforms

- Solaris on Sparc64 (64-bit)
- Mac on Intel (32-bit)

3.49.3 GAMS System

3.49.3.1 GAMS

- `Complete detailed GAMS Release Notes`
- Dollar Control Options
  - `$ife`
  - `$ifthen, $elseif, $else and $endif`
  - `$eval, $evallocal and $evalglobal`
  - `Syntax for Constant Evaluation`
- Additional Licensing Information
  - `At Compile Time: LicenseStatus and LicenseStatusText`
  - `At Run Time: LicenseLevel and LicenseStatus`

- Put Writing Facility
  - `.tn attribute`
- Enhanced Functions on controlling Sets
  - `.len, .off, .ord, .pos, .uel, .val`
- Other Enhancements
  - Unlimited input string length for `$call`, `execute` and `put_utility exec/shell`.
  - The listing file can be redirected to the standard error stream by using the gams parameter ao=3
  - The model attribute .numvarproj was added to count bound projections during model generation. Some minor additions to MODEL STATISTICS and an enhanced column listing help identify potential problems (the variable attribute .infeas could also be used to display potential bound projections)

3.49.3.2 GAMS IDE

- GDXviewer supports Excel 2007 format xlsx
- GDXviewer has an integrated symbol search

3.49.3.3 GAMS Model Library

- New models
  - Asynchronous Jacobi Methods (jacobi)
  - Dantzig Wolfe Decomposition and Grid Computing (danwolfe)
  - Portfolio Modeling with Parallel Solutions (qmeanvag)
  - Cplex Solution Pool for a Simple Facility Location Problem (solnpool)
  - Mission Planning for Synthetic Aperture Radar Surveillance (swath)
  - TSP tour plotting with LaTeX xy-pic environment (tsp2ltx)
  - Min Cost Flow with an Instance generated by NETGEN (netgen)

3.49.3.4 GDXXRW

- Supports Excel 2007 format xlsx

3.49.3.5 GDX2HAR/HAR2GDX

- GAMS distributes and supports utilities for converting HAR (header array) files used by GEMPACK: **gdx2har** and **har2gdx**. Details about these utilities can be found at Tom Rutherford's page `here`.

3.49.4 Solvers

3.49.4.1 AlphaECP

- New libraries (version 1.63). AlphaECP can call an NLP solver during the optimization to improve convergence properties for continuous variables.

3.49.4.2 BARON

- New libraries (version 8.1.1). XPRESS is available as a subsolver for LPs (option "lpsol=7"). Identification of common linear subexpressions in nonlinear functions that speeds up BARON's parsing time considerably for certain problems.

3.49.4.3 COIN-OR Solvers

- New solver libraries of CBC/CLP (2.0), GLPK (4.22), IPOPT (3.3), BONMIN (0.9). The GAMS/CoinCBC link has been completely rewritten so that it offers the performance of the CBC standalone version. Many new options have been added. The GAMS/CoinGLPK link uses now the advanced B&B solver of GLPK. Support of Solaris 64bit Intel platform and Mac OS on Intel chips.

3.49.4.4 CPLEX

- New libraries (11.0). There are quite a few changes in Cplex 11 and the GAMS/CPLEX interface. Please check the detailed GAMS/CPLEX 11 `release notes`. The major enhancements are:
  - Improved Mixed Integer Programming (MIP) Performance
  - Enhanced Parallel MIP
  - Multiple MIP Solutions
  - Performance Tuning tool

3.49.4.5 LINDOGLOBAL

- New libraries (version 5.0.1.183). Support of Solaris Sparc64 platform (SOX) and Intel Mac (DII).

3.49.4.6 MOSEK

- New libraries (version 5.0.0.62). Support of Solaris Sparc64 platform (SOX) and Mac OS on Intel chips (DII).

3.49.4.7 XPRESS

- New libraries (version 18.00)

3.49.4.8 Solver/Platform Availability Matrix

3.50 22.5 Major release (June 01, 2007)

3.50.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Christian Gilow and Josef Kallrath.

3.50.2 GAMS System

3.50.2.1 New functions and features

- Added functions `system.gamsrelease` and `gamsrelease`
- Added function `poly(x,a0,a1,a2,a3..) = sum(i=0 to n, ai*x^i)`
- `Appendout (ao)=2` will redirect the listing file to stdout. This feature is not available when running under the IDE.

3.50.2.2 GAMS IDE

- Open in new window creates now a single new window when multiple files have been selected
- Spelling menu entry added to Edit menu
- Gdxviewer can write a single symbol and all symbols to an Excel file

3.50.2.3 GAMS Model Library

- New models
  - eps-Constraint Method for Multiobjective Optimization (**epscm**)
  - Kissing Number Problem using Variable Neighborhood Search (**knp**)
  - Termination routine to ensure solvers stay with resource limit (**schulz**)
  - How to test for a GAMS version (**version1**)

3.50.3 Solvers

3.50.3.1 AlphaECP

- A new solver called GAMS/AlphaECP for mixed integer non-linear problems has been added to the GAMS solver portfolio. AlphaECP is an implementation of the Extended Cutting Plane method by Tapio Westerlund and Toni Lastusilta from Abo Akademi University, Finland. The GAMS/AlphaECP solver requires the presence of a licensed MIP solver only.

3.50.3.2 BARON

- New libraries (version 7.8) with improved local search routines.

3.50.3.3 COIN-OR Solvers

- New libraries for CoinCbc, CoinGlpk, and CoinIpOpt. The experimental MINLP solver CoinBonmin has been introduced for the GAMS Windows and Linux systems. Bonmin (Basic Open-source Nonlinear Mixed INteger programming) provides an implementation of an NLP-based branch-and-bound algorithm, an outer-approximation decomposition algorithm, an implementation of Quesada and Grossmann's branch-and-cut algorithm, and a hybrid outer-approximation based branch-and-cut algorithm.

3.50.3.4 CONOPT

- New libraries (version 3.14r).

3.50.3.5 CONVERT

- Added option 'NLP2MCP' that reformulates a non-integer program as a mixed complementarity problem (MCP)
- Added option 'AmplNLC' that converts a model into C code for evaluating objectives, constraints, and their derivatives.
- Added option 'Jacobian' that creates a GDX file containing the basic model data (matrix, initial point, evaluation of constraints at initial point and bounds)
- Added option 'LindoMPI' that creates an MPI file which is readable by Lindo.

3.50.3.6 CPLEX

- New libraries (version 10.20).

3.50.3.7 LINDOGLOBAL

- The Global Optimization Solver (GAMS solver name is LINDOGLOBAL) from Lindo Systems, Inc. has been added to the GAMS solver portfolio. LINDOGLOBAL finds proven optimal solutions to non-convex mixed integer non-linear problems. The LINDOGLOBAL solver requires a license for GAMS/CONOPT. The size of a model solved by LINDOGLOBAL is limited to 2,000 equations and 3,000 variables.

3.50.3.8 MOSEK

- New libraries (version 4.0.0.60)

3.50.3.9 XPRESS

- New libraries (version 17.10.12)

3.50.3.10 Solver/Platform Availability Matrix

3.51 22.4 Major release (February 12, 2007)

3.51.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Michael Ferris, Gary Goldstein, and Randy Wigle.

3.51.2 GAMS System

3.51.2.1 GAMS

- Compressed and Encrypted Input Files: Facilities to create and use encrypted and compressed input files have been added. The three new commands: `$compress`, `$decompress` and `$encrypt` are the respective utilities. For more details consult the User's Guide.
- `NonNegative Variable`: This new keyword is a synonym for `Positive Variable`.

3.51.2.2 GAMS IDE

- Added spelling checker
- Added search options for gdxviewer

3.51.2.3 Model Library

- **new models** (cefiles, encrypt) demonstrate the new GAMS feature of compressing and encrypting GAMS input files.

3.51.2.4 Testlib Library

- **new models** to test new features

3.51.3 Solvers

3.51.3.1 COIN

- new libraries and solver from the `GAMSlinks` project hosted at COIN-OR.
  - CoinGlpk: New COIN-OR and Glpk 4.9 libraries.
  - CoinCbc: New COIN-OR and Cbc 1.1.0 libraries.
  - CoinIpopt: A new interior point NLP solver from COIN-OR.
  - The GAMSlinks project (announced January 3 by Stefan Vigerske) was created to develop links between GAMS and the COIN-OR solvers.

3.51.3.2 CPLEX

- New libraries (version 10.1.1).

3.51.3.3 KNITRO

- New libraries (version 5.1).

3.51.3.4 MOSEK

- New libraries (version 4.0.0.59)

3.51.3.5 XPRESS

- New libraries (version 17.10.08)

3.52 22.3 Major release (November 27, 2006)

3.52.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz, Michael Ferris, Josef Kallrath, Antti Lehtila, Scott Malcolm, and Renger van Nieuwkoop.

3.52.2 GAMS System

3.52.2.1 GAMS

- GAMS Grid Facility: The GAMS language has been extended to take advantage of systems with multiple CPUs and High Performance Computing Grids. New language features facilitate the management of asynchronous submission and collection of model solution tasks in a platform independent fashion. A simple architecture, relying on existing operating system functionality allows for rapid introduction of new environments and provides for an open research architecture. For details please consult our documentation.
- `$LoadDC`: Enhanced $load with domain checking. Any domain violations will be reported and flagged as compilation errors. In contrast, $Load ignores all domain violations and loads only data that meets the domain restrictions.
- A new GAMS parameter, WorkSpace allows initializing all modelname.workspace attributes.
- New functions:
  - arccos, arcsin, tan
  - arctan2(y,x): 4-quadrant arctan function, like the atan2(y,x) in the C math library or Matlab, or Mathematica's ArcTan[x,y]
  - binomial(x,y): generalized binomial function, like Mathematica's Binomial[x,y]
  - GamsVersion: returns the current gams version, for example 146 for this release
  - HeapFree: free GAMS heap space in Mbytes
  - HandleStatus, HandleDelete, HandleSubmit, HandleCollect: Grid facility functions, see the grid facility document for details
  - Sleep(sec): suspends GAMS execution for sec seconds, where sec has millisecond resolution.
- GAMS solvers and other processes now inherit their priority from GAMS/Base or GAMSIDE: this is useful on heavily loaded machines where you want GAMS to run with below-normal priority.

3.52.2.2 GAMS IDE

- Removed size limit for the capacity of the clipboard for .lst viewer
- Added a shape graph type (rectangle and ellipse) and multi-line parametric graph type
- Added more context menus
- Option to open .lst file in editor
- Switching tabs or switching application will check for files that changed
- When gamside.ini is not found in the 'My Documents\gamsdir' directory, new directories and an initial project will be created. The IDE will start maximized, and the edit window and process window position and size are initialized.
- Added a GUI editor for solver option files. The editor also provides access to the solver specific help file.
- When searching for text in files (Find in Files) the search window remains open to make switching between editor and search results faster.

3.52.2.3 File Compression

- Every program creating a GDX file (e.g. gdxxrw or gams) will look at the environment variable GDXCOMPRESS; if value is not zero, data will be written compressed.
- Compressed workfiles can be created with parameter xsave.
- Decompression of GDX or workfiles is handled automatically.
- GDX and workfiles can exceed 2GB in size.
- The new utility gdxcopy allows conversion between different formats. For example, a compressed GDX file can be converted so it is understood by older GAMS systems. Of course, all file formats (GDX and workfile) can be read by a current GAMS system.

3.52.2.4 GDXMERGE

- Added ability to process named identifiers only (id=id1, id=id2)
- Added ability to process very large symbols separately by specifying a memory threshold to avoid memory issues.

3.52.2.5 GDXXRW

- String explanatory text for sets is now quoted. (Text starting with '=' created problems.)

3.52.2.6 Testlib Library

- **66 new models**, including
  - New solver-specific models/suites: 24 models, 21 suites
  - Tests for new intrinsic functions and utilities

3.52.3 Solvers

- The processing of solver option files has been centralized/standardized. This allows for a uniform way of documenting and working with solver and options. The GAMS IDE provides a utility for visual processing of options.

3.52.3.1 BARON

- New libraries (version 7.7) with improved range reduction for monomial functions.

3.52.3.2 CONOPT

- New libraries (version 3.14q) with some minor bug fixes and performance improvements.

3.52.3.3 CPLEX

- New libraries (version 10.1) with increased performance when solving models with indicator constraints.

3.52.3.4 KNITRO

- New libraries (version 5.0) with improved efficiency and robustness, especially in the active-set algorithm.

3.52.3.5 MOSEK

- New libraries (version 4.0)
  - There is a parallel extension (option MSK_IPAR_INTPNT_NUM_THREADS) for the interior solver. Moreover, it is possible to solve a problem concurrently with several of MOSEK's algorithms. The parallel extension comes free of charge.
  - Warm start capability for the mixed integer optimizer (option MSK_IPAR_MIO_CONSTRUCT_SOL) has been added.
  - A dual simplex optimizer has been added and the overall performance of the Simplex optimizers has been significantly improved. Moreover, an automatic (and transparent) dualizer has been added to the simplex optimizers.
  - The presolve has been improved especially for large stochastic optimization problems.

3.52.3.6 PATH

- New libraries (version 4.6.07) with some minor bug fixes and performance improvements.

3.52.3.7 SNOPT

- New libraries (version 7.2-4) with some minor bug fixes and performance improvements.

3.52.3.8 XA

- New libraries (version 15.07) with improved presolve and new MIP heuristics.

3.52.3.9 XPRESS

- New libraries (version 17.10)
  - GAMS/XPRESS now supports multiple threads for MIP and Barrier runs.
  - New option (loadmipsol) supports passing an integer feasible point to the MIP solver.
  - Improved factorization speed - yields faster primal and dual algorithms.
  - Improved MIP performance (via presolve and heuristics, e.g.)

3.52.3.10 Solver/Platform Availability Matrix

3.53 22.2 Minor release (April 21, 2006)

3.53.1 Acknowledgements

We would like to thank all of our users who have reported problems and made suggestions for improving this release. In particular, we thank Wolfgang Britz (Bonn University), Paritosh Desai (DemandTec), Michael Ferris (UW-Madison), Edgar Ramirez (at hotmail.com), and Rich Roberts (SRS Technologies).

3.53.2 GAMS System

3.53.2.1 GAMS

- The limit on nonlinear instructions in a single block has been raised from 16 million to 64 million instructions.
- Performance improvements for very large and complicated loop structures.
- International characters in file and path names are now handled correctly.

3.53.2.2 GAMS IDE

- GDX data browser is faster and can sort indices by name vs. entry order
- A symbol shown in the GDX data browser can be written to an Excel file

3.53.3 Solvers

3.53.3.1 CONOPT

- New libraries are included which address minor fixes

3.53.3.2 CPLEX

- New libraries (version 10.0.1, a maintenance release)

3.53.3.3 LGO

- New libraries
  - The built-in stochastic searches have been improved.
  - Some internal limits were increased to allow larger models to be solved.

3.54 22.1 Major release (March 15, 2006)

3.54.1 GAMS System

3.54.1.1 Relaxation of discrete variables (.prior=Inf)

- The priority attribute of a discrete variable can be used to relax a specific variable instance. The priority attribute `.prior` establishes in what order variables are to be fixed to integral values while searching for a solution. Variables with a specific `.prior` value will remain relaxed until all variables with a lower `.prior` values have been fixed. Setting the `.prior` value to +inf will relax this variable permanently. This relaxation is done independent of the model attribute `.prioropt`.

  This feature is useful in solving difficult discrete models. The Model Library model "Linear Recursive Sequence Optimization Model" (lrs.gms) illustrates the use of this feature that specifies that only the first n variables of k are binary, whereas the remaining ones are fractional. This is simply expressed as follows:

```
SET t time horizon /1*350/, f(t) first N steps /1*48/;
Binary Variable k(t);
...
k.prior(t) = inf; k.prior(f) = 1;
```

3.54.1.2 Derived Variable and Equation Attributes (.slacklo,.slackup,.slack,.infeas)

- Calculations involving slacks and infeasibilities have been simplified with four new derived attributes. These attributes are defined on equations and variables as follows:

```
x.slacklo = max(x.l-x.lo,0);
x.slackup = max(x.up-x.l,0);
x.slack = min(x.slacklo,x.slackup);
x.infeas = - min(x.l-x.lo,x.lu-x.l,0);
```

  Note that the slacks or infeasibilities will always be zero or positive.

3.54.1.3 Enhanced Model List

- The entries of a model list can now contain previously defined models. For example:

```
Model one / e1,e2,e3 /
two / one, e4 /
three / two, e5 /;
```

  The model two will now contain equations `e1`,`e2`,`e3`,`e4`. The model three will contain all of model two plus equation `e5`.

3.54.1.4 New model type

- `RMPEC`: The model type `MPEC` now allows discrete variables. The Relaxed Mathematical Program with Equilibrium Constraints (RMPEC) model relaxes the discrete variables as with RMIP and MIP models.

3.54.1.5 Enhanced $IF/IFI statement:

- A check for the existence of a directory has been added to the $if statement.

```
$IF DEXIST directory command
$IFI DEXIST directory command
```

3.54.1.6 GDX Utilities

GDXDIFF

- When a key value pair exists in one file and not in the other we use Eps to determine if the difference should be reported.

GDXDUMP

- All unique elements in the output are now quoted to avoid problems with reserved words etc.

GDXMERGE

- New options introduced to merge only specified identifiers, to merge very large data sets, and to read parameters from a file (@filename).

GDXXRW

- Fixed problem with merging when only the top-left corner of the range was specified.

3.54.1.7 GAMS IDE

- Added a viewer for lst files. In contrast to the editor, this viewer does not load the complete file in memory.
- Added a navigation tree for the lst file.
- Added the option to generate charts using a gdx file.
- All viewers, except the process window, are now organized as tabbed windows.
- The gdxviewer remembers that last symbol viewed for a gdx file and will select the symbol when opening the file.
- Expanded format for library file to use other entries in the library.

3.54.1.8 GAMS Model Library

- **new models**
  - IDE charting facility (**chartdat**)
  - Cplex option feasopt (**feasopt1**)

3.54.1.9 Testlib Library

- **new models**
  - Tests for new GAMS intrinsic functions `NCPVu***`
  - Tests for GDXdiff utility

3.54.1.10 McCarl GAMS User's Guide

- Extensive internal changes to allow better distribution formats
- Now distributed as a single .chm file and a single .pdf file with fully linked topics

3.54.2 Solvers

3.54.2.1 BARON

- XA can now be used as an LP solver inside BARON.
- For the LP solvers Cplex and XA the user can specify the LP algorithm (primal/dual simplex, barrier) using the BARON option `lpalg`.
- The user can control BARON's node selection scheme with the option `nodesel`. Available strategies include best bounds, DFS, minimum infeasibilities, and BARON's own mix.

3.54.2.2 CONOPT

- New libraries (version 3.140)
  - The scaling method has been improved to work better with models with small levels and large derivatives (e.g. sqrt(x) for x close to 0).
  - Minor problems with previous versions corrected.

3.54.2.3 CPLEX

- New libraries (version 10.0)
  - Dropped Platforms: ILOG dropped support for CPLEX 10.0 on the SGI platforms. Also support for Linux with glibc2.2 was dropped but will hopefully be available when GAMS 22.1 will be released. GAMS 22.1 for dropped platforms ships older versions of CPLEX.
  - Solution Polishing: Solution Polishing is appropriate for finding the best solutions to complex and difficult MIP models within a specified time. Solution Polishing is used to improve the best solution at the end of the branch-and-cut process if optimality has not been proven.
  - MIP Starts: The advanced restart capabilities of CPLEX have been improved to utilize initial solutions, partial solutions and partially correct solutions. If the user specifies values for only a portion of the discrete variables, CPLEX 10.0 will attempt to fill in the missing values or correct the wrong values in a way that leads to an integer-feasible solution, potentially reducing the time to solve the problem.
  - Infeasibility analysis tool: CPLEX provides an automatic approach to find the best feasible alternative to an infeasible model. This approach is turned on by an option called `FeasOpt` (for *feasible optimization*). With the `FeasOpt` option CPLEX accepts an infeasible model and selectively relaxes the bounds and constraints in a way that minimizes a weighted penalty function. In essence, the feasible relaxation tries to suggest the least change that would achieve feasibility. It returns an infeasible solution to GAMS and marks the relaxations of bounds and constraints with the INFES marker in the solution section.
  - For details check the GAMS/CPLEX 10 Release Notes.

3.54.2.4 DICOPT

- New option infeasder: It allows for linearization of infeasible NLP subproblems.

3.54.2.5 Examiner

- Default behavior changed: if no action is chosen, Examiner prints a warning message and defaults to "examineInitPoint yes"
- Adjusted to handle new RMPEC model type. Currently MPEC models are not allowed.
- Report format for examination of points changed:
  - better labeling of the point being examined - consistent with the naming scheme and options used to choose the examination
  - use GAMS notation (e.g. `x.l(seattle,topeka), f.m(supply)`) to specify rows/columns
  - add option 'showSlacks' to print slacks/differences explicitly when the difference is small compared to the values themselves

3.54.2.6 XPRESS

- New libraries (version 16.10.03)
  - The dual pricing algorithm has been improved. For some difficult LP problems this has resulted in an order of magnitude speed improvement.
  - The speed and stability of the simplex factorization has been improved.
  - The barrier algorithm now requires less memory.
  - The cut generation has been improved.

3.55 22.0 Major release (August 01, 2005)

3.55.1 New platforms supported

- 64 bit Windows (aka Windows 64-Extended, Windows EM64T) version introduced. Windows licensing includes both 32 and 64 bit systems at a single platform cost. Some solvers exist only in 32 bit mode and are included as such on the 64 bit version. See the solver platform matrix.

3.55.2 Updated build for the Linux platform

- Previous 32-bit Linux GAMS Distributions (e.g. 21.X) were built using only an older Linux machine with version 2.2 of the GNU C Library. This distribution is compatible with both older and newer Linux systems. The installer for this software is located in the systems/lnx/lnx2.2 directory of the CD. The build code for this software is LXI (displayed on the solver audit lines, etc). This build is included in the current CD as it was before.

- This distribution includes a new 32-bit Linux build (build code LX3) that parallels the previously-existing LXI build. The LX3 system is built on a newer Linux machine with version 2.3 of the GNU C Library, and is not compatible with older systems using GNU LIBC 2.2. The installer for this software is located in the systems/lnx/lnx2.3 directory of the CD.

- Consider the following when choosing which Linux build to install:

  – Most Linux users will be using a system with GNU LIBC 2.3 and should use the newer build. You can check your LIBC version by running it. On my machine, I do "/lib/libc.so.6" but be aware your version number may vary.

  – These are builds of the same source, using different compilers. The "older" build uses older compilers, not older source. In cases where different vendor libraries are required, the same comment applies.

  – The different builds use a common GAMS license file.

  – While there is no scheduled end-of-life for the older build we expect that our algorithm vendors will stop supporting it at some point. When this happens, we can only ship updated versions of the new build.

  – If you wish to install both versions, install them in separate directories.

3.55.3 GAMS System

3.55.3.1 GDX Utilities

GDXDIFF

- Modified the comparison routine that determines if two numbers are equal wrt. an absolute or relative tolerance.

3.55.3.2 GAMS IDE

- Added option to save a file in Unix format.
- Added option to save and email the current file.
- Added option to launch Windows Explorer showing directory of the current file with the current file selected.
- gamsdir is now a sub-directory of 'My documents'. gamside.ini file now stored in the gamsdir directory.
- Reload file now also works for GDX files and RefFiles (in addition to regular source files).
- When starting the IDE or opening a project, a scan is made for GAMS temporary directories which can be deleted. This option was also added under the Utilities menu.
- Pressing F1 for help was broken.
- `$ONECHO`/`$OFFECHO` work now like `$OFFTEXT`/`$ONTEXT` for syntax coloring.

3.55.4 Solvers

3.55.4.1 CPLEX

- New libraries (version 9.1)
  - Option mipstart: It is no longer necessary to provide a compete integer solution as the starting point.
  - Option fraccuts: Settings of 1 or 2 will cause Gomory cuts to be generated for MIQCP models.
  - New Option lbheur: When set to 1 (default is 0), CPLEX will use a local branching heuristic to try to improve new incumbents.

3.55.4.2 KNITRO

- New libraries are included which address minor fixes.

3.55.4.3 XA

- New libraries are included which address minor fixes.

3.55.4.4 XPRESS

- New libraries are included which address minor fixes.

3.56 21.7 Major release (April 01, 2005)

3.56.1 Acknowledgements

We would like to thank all of the users who have reported bugs or made suggestions in improving this release.

3.56.2 New platforms supported

- 64 bit x86_64 (Linux) version introduced. Linux licensing includes both 32 and 64 bit at a single platform cost. Some solvers exist only in 32 bit mode and are included as 32 bit on the 64 bit version. See the solver platform matrix below.
- Macintosh PowerPC (Darwin) version introduced.

See our sales page for available solvers by platform.

3.56.3 GAMS System

3.56.3.1 Model Library

- Several new models have been added. See the **GAMS Model Library** for details.

3.56.3.2 New Workfile Format

- now a single file (G00 file extension). Files can be read that were created on different platforms. File is packed and only approx 50% of previous file size. Read and write is also substantially quicker.

3.56.3.3 Testlib Library:

- Updates to quality model
  - take advantage of solver updates & fixes
  - added `--QUICK=1` option to skip slow tests
  - test all solvers, using `system.solverNames` and filter list
  - allow skips of models in solver-specific test suites
- New models
  - convert solver test suite
  - new cmex & MIP tests, test new workfile format save/restart

  See the **testlib library** for details.

3.56.4 Solvers

3.56.4.1 BARON

- New libraries (version 7.2.5) which address minor bug fixes and enhancements

3.56.4.2 BENCH

- promoted from beta solver.

3.56.4.3 GAMS/AMPL Link

- a GAMS/AMPL link has been introduced.

3.56.4.4 GAMS/LINGO Link

- a GAMS/LINGO link has been introduced.

3.56.4.5 MOSEK

- New libraries (version 3.2) which address minor bug fixes and enhancements.

3.56.4.6 NLPEC

- Relaxed the test for complementarity of the solution proposed by the reformulated model to work better for poorly-scaled models

3.56.4.7 XA

- update to documentation (nodelimit, log output)
- numerous library updates to fix outstanding issues
- improved handling of solver status 4=TERMINATED BY SOLVER

3.56.4.8 XPRESS

- deal with "recoverable errors" on return from barrier method
- minor improvements and workarounds for library quirks in link

3.56.4.9 Solver/Platform Availability Matrix

3.57 21.6 Minor release (January 26, 2005)

3.57.1 Acknowledgements

We would like to thank all of the users, particularly Josef Kallrath, who have reported bugs or made suggestions in improving this release.

3.57.2 Solvers

3.57.2.1 BARON

- New libraries are included. Several new features which are documented in the BARON solver manual.

3.57.2.2 CONVERT

- New model instance format CoinFML, Coin style XML model file.
- LINGO format updated to include Version 9 features

3.57.2.3 COIN

- CoinGlpk: New COIN and GlpK 4.7 libraries.
- CoinSbb: This is now called CoinCbc (Coin Branch & Cut). The name CoinSbb will remain for this and the next distribution.
- Three new cuts classes: Clique, Flow Cover, Mixed Integer Rounding and all new libraries.

3.57.2.4 KNITRO

- New libraries are included which address minor fixes.

3.57.2.5 XPRESS

- New libraries are included which address minor fixes.

3.57.3 GAMS System

3.57.3.1 Model Library

- licememo: Generate your own license memorandum and solver matrix with this model.
- deploy: Generate a minimal deployment GAMS system with necessary components only.

3.57.3.2 Testlib

- 26 new quality assurance tests have been added to the suite.

3.57.3.3 Minor enhancements

- `$onecho` and `$onput` have new variants to specify verbatim or substitutions. The new names are: `$onechoV`, `$onechoS`, `$onputV`, `$onputS`.
- Manipulation of system environment variables and prefixing of the search path:

```
$SetEnv name value
$DropEnv name
$PrefixPath value

%SysEnv.name%

$if SetEnv name
```

3.57.3.4 fml2gms

- converts a CoinFML style XML file into GAMS (courtesy of Leo Lopes, University of Arizona). An example showing how to convert from GAMS to CoinFML format and back to GAMS is shown below:

```
> gamslib trnsport
> echo coinfml > convert.opt
> gams trnsport optfile=1 lp=convert
> fml2gms coinfml.xml
> gams fml2gms.gms
```

3.57.4 Documentation

3.57.4.1 Bruce McCarl User's Guide

- accessing the guide through the GAMS/IDE, will now launch the PDF file directly instead of through a web browser. This is due to possible incompatibility issues with Windows XP Service Pack 2 (securtiy settings). To launch via the web, users can go to File > Options and check the box "Launch docs using Explorer."

3.58 21.5 Minor release (November 11, 2004)

Distribution 21.5 includes newly available solver libraries and minor enhancements in the GAMS system, as well as introduces the interior-point NLP solver KNITRO from Ziena Optimization.

3.58.1 Acknowledgements

We would like to thank all of the users who have reported bugs or made suggestions in improving this release, especially Richard Roberts for catching an IDE bug.

3.58.2 Solvers

3.58.2.1 CONOPT

- New libraries (14e) are included which address minor fixes.

3.58.2.2 CPLEX

- New libraries (9.0.2) are included which address minor fixes.

3.58.2.3 KNITRO

- New interior-point nonlinear programming solver added to the GAMS NLP solver portfolio.

3.58.2.4 MOSEK

- New libraries (3.1) are included which address minor fixes.

3.58.2.5 XA

- New libraries are included which address minor fixes.

3.58.2.6 XPRESS

- New libraries are included which address minor fixes.

3.58.3 GAMS System

3.58.3.1 Model Library

- A model showing a successive recalibration algorithm for solving general equilibrium models has been added (**decomphh.gms**).
- A model illustrating numerical integration using trapezoidal approximations for Herves (transposable element) activity calculations is included (**herves.gms**).

3.58.3.2 Testlib

- 27 new quality check models have been added. See the **Testlib** page for details.

3.58.3.3 New functions

- sinh, cosh, tanh

3.58.3.4 $ Dollar control options

- `$on/offVerbatim`
  - The `$on/offVerbatim` commands are used in conjunction with the GAMS parameter `DUMPOPT` to suppress the input preprocessing for input lines that are copied to the dmp file. This feature is mainly used to maintain different versions of related models in a central environment.
    The `$on/offVerbatim` commands are only recognized for `DUMPOPT >= 10` and apply only to lines in the file the commands appeared.
    The use of $goto and `$on/offVerbatim` are incompatible and may produce unexpected results.
- `$on/offPut`
  - This option simplifies the writing of put statements that copy text. Previously, to copy text into a put file one may have to write many lines similar to the ones below:

```
put 'text A with a double quote "' "text A with a single quote '" /
put 'text B with a double quote "' "text B with a single quote '" /
put 'text C with a double quote "' "text C with a single quote '" /
```

This may be cumbersome. The use of `$on/offPut` will result in the same text written to the put file without having to specify the 'put' explicitly for each line and allows you to specify mixed quotes in a single statement. Consider the following example:

```
file fx;
put fx 'text with " and ' "' required a split of the text" /
$onput
With the new on/off put we can freely
mix and match ' and " characters.
$offput
;
```

It also works outside of the put statement:

```
$onput
It even works outisde the put statement,
as long as a put file is assigned.
$offput
```

- `$setDDlist`
  - This statement catches misspelled 'double dash' GAMS parameters. For example, in the program below (ein.gms), the only 'double dash' options are 'one', 'two', 'three' and 'four' (note the use of the string macro for `%two%` automatically makes it part of the allowed list of double dash parameters):

```
$if NOT set one $set one default value
display '%two%';
$setddlist three four
```

The following GAMS invocation will cause an error since `--five` is not a valid 'double dash' option.

```
> gams ein.gms --two=twovalue --five=20

1 Display 'twovalue'
**** --five=20

3 $setddlist three four $620
```

3.58.3.5 Other new features

- alias(∗,u1,u2,..)
  - The universe is assumed to be ordered and ordered operators like lag, leads and ORD can be applied.
- Faster execution of GAMS statements using set(s) containing a single element.
- SortedUels(∗,∗)
  - A new predefined tuple to report sets in sorted order. For example, to write in sorted order:

```
alias(*,u);
loop(SortedUels(u,i),
  put / i.tl i.te(i) );
```

3.59 21.4 Major release (September 06, 2004)

3.59.1 Acknowledgements

We would like to thank all of the users who have reported bugs or made suggestions in improving this release.

3.59.2 GAMS System

3.59.2.1 Model Library

- The model library keeps on growing! A model that implements a column generation scheme for the cutting stock problem (cutstock) has been added. There are two examples that demonstrate the multiple solution feature in BARON (mhw4dxx and bchfcnet).
- The model library also has the new category "GAMS Tools". Models in this category show how to use tools designed to help modelers in their daily work. Three models (awkqap, seders, and awktsp) demonstrate the routine process to take a raw file from a web site and manipulate the text file into a format suitable to be read by GAMS using Unix-style tools SED & AWK.
- Five new models (mingamma, quantum, procmean, mlbeta, and mlgamma) have been added to demonstrate the new statistical functions (discussed below).

3.59.2.2 Testlib

- 33 new models were added to the test library.
- Addition of solver-specific test suites. The models in a test suite are run not for all solvers but for the set of solvers associated with that particular suite.
- Most of the new models test features in GAMS/Base.
- A series of new models tests MCP syntax and matching rules.

3.59.2.3 Windows Setup.exe

- A new Windows setup.exe installation program for GAMS is used adding new functionality and a more user friendly interface.
- The McCarl GAMS User Guide is now part of the Windows installation (for UNIX platforms this must still be installed manually).

3.59.2.4 GDX Utilities

- GDXrank, a standalone sorting utility for GDX files, is now part of the distribution (all platforms)
- A wrapper for GDXrank, called rank.gms, written by Tom Rutherford, is included with the distribution and can be called using the $LIBINCLUDE directive.

3.59.2.5 GAMS IDE

- The IDE recognizes https as www string
- The menu Help | About shows current license file
- If there is a GAMS license file on the ClipBoard, selecting Help | About will prompt to write the ClipBoard to a license file.
- Library files can now have multiple files with a numeric extension; previously,it was the first file only.
- A library file can have have an extension of '.ignore' which will be removed so we can protect '.zip' files.
- After running gdxdiff, an empty difference file will not be shown.

3.59.2.6 Additional functions

- gMilliSec(DayTime): milli seconds of a DayTime number
- MaxExecError: a read/write access to the ExecError values
- TimeElapsed: elapsed time in seconds since the start of a GAMS run
- Gamma(a): Gamma function (DNLP)
- LogGamma(a): Log Gamma function
- GammaReg(x,a): Regularized gamma function
- Beta(a,b): Beta function (DNLP)
- LogBeta(a,b): Log Beta function
- BetaReg(x,a,b): Regularized Beta function
  The definitions and notation for incomplete and regularized gamma and beta functions are not consistent, For example, note the differences with the definitions used in Mathematica:

```
GAMS Mathematica

Gamma(a) Gamma[a]
LogGamma(a) LogGamma[a]
GammaReg(x,a) GammaRegularized[a,0,x]
Beta(a,b) Beta[a,b]
LogBeta(a,b) Log[Beta[a,b]]
BetaReg(x,a,b) BetaRegularized[x,a,b]
```

3.59.2.7 Speed-up for expressions containing constant indices or indices that are not in the natural order

- Speed-up for expressions containing constant indices or indices that are not in the natural order
  - The option sys11 controls this new feature. When we use option sys11=1, GAMS will execute without speedup features as in previous versions; using option sys11=0 will cause GAMS to use procedures that execute some statements faster at the cost of increased memory use (This is now the default value). The following GAMS code illustrates some of the speedups.

```
Sets i / i1*i700 /
     j / j1*j700 /
     k / k1*k500 /
     ik(i,k);

Parameters aij(i,j) bji(j,i), cjk(j,k), dij(i,j);

ik(i,k)$(uniform(0,1) < 0.01) = yes;
aij(i,j) = uniform(0,1);

bji(j,i) = aij(i,j);

cjk(j,k) = sum(ik(i,k), aij(i,j));
dij(i,j) $(aij(i,'j700') > 0.5) = bji(j, 'i700')
```

  A comparison of the execution times in seconds:

```
Assignment sys11=1 sys11=0
Bji 2.7 0.36
Cjk 25.0 2.38
Dij 4.7 0.39
```

– Faster execution of lag / lead operators. This improvement is visible for large sets only as illustrated in the following GAMS code:

```
Set i /i1*i2000/,
    j /j1*j20000/;

Parameter Ai(i),Bj(j);
Ai(i - 1) = Ord(i);
Bj(j - 1) = Ord(j);
```

A comparison of execution times in seconds:

```
Assignment previous current
Ai 0.02 0.0
Bj 3.2 0.0
```

3.59.2.8 Embedded set text and parameter values

- The `$on/offembedded` option enables the use of embedded values in parameter and set data statements. For sets, the final text is concatenated with blank separators. For example, the element texts for the set and j will be identical:

```
Set i(k,l) / a.a 'aaaa cccc dddd', b.a 'bbbb cccc dddd' /;
$onembedded
Set j(k,l) / (a aaaa, b bbbb).(a cccc) dddd /;
```

For parameters, the final value will be the product of the embedded values. If no value is specified, a value of 1 is assumed. For example, the values for x and y will be the same:

```
Parameter x(k,l) / a.a 24, b.a 12, c.a 4, c.b 4, d.a 6, d.b 6 /;
$onembedded
Parameter y(k,l) / (a 2, b).(a 3) 4, (c 2,d 3).((a,b) 2) /;
```

3.59.2.9 New suffixes for functions

- New suffixes Grad and Hess have been introduced to get exact point derivatives from any function. These function suffixes are mainly intended for future testing of functions and cannot be used in equations.
- The first argument gives the position of the element of the Hessian or gradient element desired in the form i or i:j, where i is the row element and j the column element.
- The symbol ':' is used to separate the element position specification from the function argument list.
- For example, the following will return the second derivative for the second and fourth argument, where 1,2,3,4,5 are the normal function arguments:

```
h = EDist.hess(2:4:1,2,3,4,5);
```

If the needed element position index is one, we can drop the argument as shown below:

```
g = exp.grad(1:5) or g = exp.grad(5);
h = log.hess(1:1:3) or h = log.hess(3);

hess(i,j) = betareg.hess(ord(i):ord(j):expr1,expr2,expr3);
```

3.59.2.10 Some new minor and exotic features

- New `%system.xxx%` and `system.xxx` for put statements
  - `system.date1`: different date format: Feb 04, 2004
  - `system.tab`: inserst a tab character
- New File attribute
  - `file.silent`: will suppress the logging of put files
- New `$IF` option allows testing for existing solver at compile time
- `$IF SOLVER` command
- `$if NOT solver baron $goto nobaron`
- Underflow Control
- Release 21.0 introduced new math routines that work over a much wider numerical range than the older systems. The pre 21.0 systems rounded small function return values (less than 1e-30) to zero.
- Some older models may use this rounding to zero feature and will now give slightly different results.
- The new GAMS parameter ZeroRes=real allows you to change the threshold value for internal rounding in the GAMS calculation and the GAMS parameter ZeroResRep=1 will cause GAMS to issue warnings whenever such a rounding occurs.

3.59.3 Pricing

3.59.3.1 Global Packages

- Similar to the NLP Packages (NLP-1 and NLP-2), GAMS now offers Global Packages: If you buy at least two of the Global solvers BARON, LGO, and MSNLP, the prices are reduced by 25%. Please check our pricelist or contact sales@gams.com.

3.59.4 Solvers

3.59.4.1 BARON

- New libraries (version 7.2)
- Branch-and-cut implementation (available only when using CPLEX as the LP solver)
- Automatic exploitation of convexity
- Modeling construct permits user to supply convexity information to the solver
- Modeling construct permits user to have relaxation-only constraints
- Improved local search implementation for large-scale models
- GDX dumps can be used to provide output for the K best solutions
- Several algorithmic fixes and improvements

3.59.4.2 COIN

- GAMS has added a link to the Computational Infrastructure Operations Research (COIN-OR). The COIN-OR project is an initiative to spur the development of open-source software for the operations research community.
- The GAMS/COIN-OR link allows GAMS users to connect their customized solution approaches using the COIN-OR Open Solver Interface (OSI) in a seamless manner.
- The GAMS/COIN-OR Link for LP and MIP problems is available in source and free of charge to any licensed GAMS system.
- Potentially all solvers connected to the COIN-OR/OSI can be made available through the GAMS/COIN-OR link. Currently,
  - CoinGlpk: Gnu Linear Programming Kit
  - CoinSbb: simple branch and bound, a branch and cut code
- are included in the latest Windows and Linux distributions. Please visit the GAMS/COIN-OR web page at https://github.com/coin-or/GAMSlinks for details.

3.59.4.3 CONOPT

- New libraries are included which address minor fixes and improvements.

3.59.4.4 MINOS

- New libraries (MINOS 5.51 June 2004)
- Fixed issues with scaled/unscaled infeasibilities/nonoptimal

3.59.4.5 MSNLP

- MSNLP (Multi-Start NLP) is another stochastic search algorithm from Optimal Methods, Inc for global optimization problems. Like it's bigger brother OQNLP, MSNLP uses a point generator to create candidate starting points for a local NLP solver. Algorithm performance depends strongly on the starting point generator. MSNLP implements a generator creating uniformly distributed points and the Smart Random Generator. This generator uses an initial coarse search to define a promising region within which random starting points are concentrated. Two variants of Smart Random are currently implemented, one using univariate normal distributions, the other using triangular distributions. MSNLP also comes with the local NLP solver LSGRG. MSNLP is available in the Global Packages.

3.59.4.6 NLPEC

- NLPEC has been promoted from beta solver status and has a write up in the solver documents.
- The NLPEC solver for MPECs automates the process of model reformulation. NLPEC reformulates the original MPEC as an NLP (using one of 23 different reformulation strategies), solves the resulting NLP, and translates the results back for return as an MPEC solution.

3.59.4.7 PATHNLP

- PATHNLP has been promoted from beta solver status. The PATHNLP solver suitable is for NLP programs. PATHNLP solves an NLP by internally constructing the Karush-Kuhn-Tucker (KKT) system of first-order optimality conditions associated with the NLP and solving this system using the PATH solver for complementarity problems.
- Some improvements from the beta version include:
  - In some cases where PATHNLP fails to find a solution, it can now return a feasible point where before it would return no solution information whatsoever.
  - Information about the Hessian and it's inverse is now available.

3.59.4.8 OQNLP

- OQNLP's merit and distance filters, which are respondible for starting the NLP solver at a small fraction of the candidate starting points, while still finding the global solution to most problems, have been improved. The *dynamic merit filter logic* and the *basin overlap fix* provide mechanisms for decreasing the radii of some attraction basins, focusing on those which reject points most often and those which overlap. These dynamic filters lead to a substantial improvement in OQNLP's ability to obtain a global optimum, with some increase in the number of solver calls. The OptQuest point generator has been supplemented by two new point generators (see MSNLP).

3.59.4.9 XPRESS

- Updated to use XPRESS 2004 libraries - highlights include:
  - MIP heuristics
  - Lift-and-project cuts to give improved bound information
  - Strong branching
  - Extensive benchmarking & resultant performance improvements

3.60 21.3 Major release (January 19, 2004)

3.60.1 GAMS System

3.60.1.1 Model Library

- Models from the "Handbook of Computible General Equilibrium Modeling", University of Tokyo Press, Tokyo (to appear) have been added to the model library.
- Several QCP models have been added
- A series of models that illustrate the BCH (Branch-and-Cut-and-Heuristic) Facility have been added

3.60.1.2 TESTLIB

- New library of models developed for testing and quality control:
  - Solver correctness
  - Base module features
  - Performance
- Designed for use by GAMS staff and our solver providers
- Allows any user to reproduce our tests
- To retrieve models from testlib: > `testlib ...`.

3.60.1.3 GAMS IDE

- The tabs showing the file names in the editor are maintainded in sorted order using the full path name.
- Support for regular expressions in search, search and replace and search in files
- When searching text using Ctrl-F, the word under the cursor will be used as the text to search for.
- Added a viewer for reference files. A reference file is created using the rf option in the gams call. The IDE assumes that the file extension for the reference file is '.ref'
- An option was added to emulate a subset of the Epsilon keyboard mapping.

3.60.1.4 GDX Utilities

- GDXMerge added; a utility to combine multiple gdx files into a single gdx file.
- GDX2Veda added; a utility to export GAMS data into the [VErsatile Data Analyst (VEDA)] (http://www.kanors-emr.org/software).

3.60.1.5 GAMS Branch-and-Cut-and-Heuristic (BCH) facility

- The GAMS Branch-and-Cut-and-Heuristic (BCH) facility allows GAMS users to interact with a running MIP/MINLP solver by supplying specialized GAMS programs to generate *cutting planes* and good *integer feasible solutions*. This allows GAMS users to apply complex solution stragies without having to have intimate knowledge about the inner workings of a specific MIP system. BCH strategies can now be implemented rapidly and reliably within a matter of days rather than weeks. Details and examples can be found here.

3.60.1.6 Quadratically Constrained Program Types QCP, MIQCP and RMIQCP

- New model types for quadratically constrained problems are:
  - QCP: Quadratically Constrained Programs
  - MIQCP: Mixed Integer Quadratically Constrained Programs
  - RMIQCP: Relaxed Mixed Integer Quadratically Constrained Programs
- These model types are like NLP, MINLP and RMINLP with nonlinearities restricted to be quadratic forms. QCP problems can be solved with existing nonlinear solvers and large-scale LP solvers that offer quadratic extensions. For examples, look at the models qalan, qcp1, qdemo7, and qsambal in the model library.

3.60.1.7 Solver Link Options SOLVELINK

- This new option allows you to control the way solver's or subsystems are invoked. This may be helpful when solving a large number of models that are relatively small compared to the size of the overall database.
- The new options values are:
  - 0: Make an automatic save/restart for each solve (default - old behavior)
  - 1: Calls the subsystem using the shell method
  - 2: Call the subsystem using the spawn method
- This option can be specified as a gams parameter (> `gams ... solvelink=n`), as part of an option statement (`option solvelink=n;`) or specified as a model attribute (`mymodel.solvelink=n;`) Some demo limits removed
- The demo version size restriction on the number of symbols and number of unique set elements has been removed. Previously, the demo/student versions were limited to 2000 symbols.

3.60.1.8 Save Point Options SAVEPOINT

- This new option directs GAMS to write solutions to GDX files for later use in the same or other programs. This may be helpful in cases when we want to provide good starting points or process large number of solutions at a later stage. The new option values are:
  - 0: Do not write point files (default)
  - 1: Write the solution the GDX file <`workdir`><`modelname`>`_p.gdx`
  - 2: Write the solution the GDX file <`workdir`><`modelname`>`_p`<`solvenumber`>`.gdx`
- This option can be specified as a gams parameter (> `gams ... savepoint=n`), as part of an option statement (`option savepoint=n;`) or specified as a model attribute (`mymodel.savepoint=n;`). The `execute_loadpoint` allows you to merge solution points into any GAMS database.

3.60.1.9 Relaxed MCP and MPEC syntax

- A variable can now appear in more than one `equ.var` pair in the model list, however, in the final instance of the model, all mappings have to be unique.

3.60.1.10 Enhancements to EXECUTE_LOAD and EXECUTE_UNLOAD

- execute_load
  - `gamspar = gdxvar.xx`: `xx` can be `l m` ...
  - `gamsvar.xx = gdxvar.xx`
- execute_unload:
  - no arguments means dump all
  - allow multiple occurrence of the same symbol `x.l x.up x a a`
  - `x.l=a`: `a` is the complete `x` variable

3.60.1.11 New EXECUTE_LOADPOINT

- This new command `execute_loadpoint` is similar to `EXECUTE_LOAD`, however, the new values are merged with the old values. If no arguments besides the name of the GDX file are given, all variables and equations that match variables and equations of the calling GAMS programs will be merged with the GDX level and marginal values. Bounds, scales and priorities will remain unchanged. This can be very useful in connection with the `SAVEPOINT` facility.

3.60.1.12 Nested GAMS parameter PF=xxx

- The command line include parameter can now handle nested includes

3.60.1.13 New Functions

A number of new functions have been added.

- `TimeStart`: Accumulated restart time
- `TimeComp`: Compilation time in seconds
- `TimeExec`: Execution time in seconds
- `TimeClose`: accumulated save time
- `Frac`: frac(x) is the fractional part of x
- `ErrorLevel`: Returns code of the most recently called external program
- `HeapSize`: Current Heap size in Mbytes
- `Fact`: Factorial
- `UniformInt`: Uniform integer random number between `UniformInt(low,high)`
- `PI`: The famous constant 3.14....
- `NcpF`: `NcpF(x,y,c) = sqrt(sqr(x) + sqr(y) + 2*c) - x - y` Fisher
- `NcpCM`: `NcpCM(x,y,c) = x - c*ln(1+exp((x-y)/c)` Chen-Mangasarian
- `Entropy`: `entropy(x) = -x*log(x)`
- `Sigmoid`: `sigmoid(x) = 1/(1+exp(-x))`
- `Log2`: logarithm base 2
- `IfThen`: `ifthen(condition,true expression,false expression)`
- `Edist`: `Edist(x,y,..) = sqrt(sqr(x)+sqr(y)+..)`
- `CEntropy`: `centropy(x,c) = x*ln(x/c)` Cross Entropy

3.60.1.14 Set Table

- Allows to enter set data in tabular form similar to parameter data. The data entries can be numbers and special values including yes/no. To allow data tables to be interpreted as Parameters or sets, the special values of NO and YES will be interpreted as 0 and 1 respectively.

3.60.1.15 Some new minor and exotic features

- Dynamic reinterpretation of real powers. When using automatic translation it may be helpful to treat a real power as an integer power if the exponent is constant and within `e-12` of an integer value. This can be enabled by setting Option `sys10=1;` and disabled by setting option `sys10=0;` (default).
- File Name Casing. File names as passed to the operating system maintain the original casing. This can be changed with the GAMS parameter `FILECASE=n`, where
  - `n=0` means to retain original casing (default)
  - `n=1` uppercase the filename, and
  - `n=2` will lowercase the filename.
- `$CLEARERROR` clear all compilation errors
- `$TERMINATE` terminates compilation and skips executions
- `$SETNAMES filename filepath filename fileextension` separates the string filename into its three components and stores then as GAMS environment variables. For example, `$setname d:\gams\xxx.txt fp fn fe` creates/updates three string variables `fp`, `fn`, `fe` which will combine into the original filename string by `%fp%%fn%%fe%`.
- `$SETCOMPS s1.s2.s3.. first second third` separates the string `s1.s2...` into its components and stores them in the environment variables `first`, `second`,..
- `$IF WARNINGS` command
- `$REMARK` comment with string substitution
- `$ON/OFFUNDF` allows the use of the special value `UNDF` in data statements and expression.
- `System.xxx` and `%system.xxx%` have been enhanced and unified. The complete list is:

```
DATE, TIME, TITLE, PAGE, SFILE, RTIME, RDATE, RFILE, IFILE, OFILE
,VERSION PLATFORM, LP, NLP, ...all model types, LICE1, LICE2, GSTRING,
SSTRING, PFILE ILINE, OPAGE, VERID, ELAPSED, MEMORY, TSTART, TCLOSE,
TCOMP, TEXEC, INCPARENT INCPARENTL, INCNAME, INCLINE, LINE, LISTLINE,
FILESYS, PRLINE, PRPAGE, FE, FN FP, REDIRLOG, ERRORLEVEL
```

  The `system.xxx` form is used in `PUT` statements, the `%system.xxx%` form is used for string substitutions during compilation.
- Fast Projections and Aggregations The GAMS executions engine performs poorly on certain large data structures. This can be overcome with telling GAMS to 'pipeline' certain operations via an `OPTION` statement.

  ```
  Option left < right, left <= right,..;
  ```

  Where left and right are GAMS identifiers with conforming domain declarations. The dimensionality of the left symbol has to be equal or less than the dimensionality of the right side. If the left dimensionality is less than the right one, the operation performed is an aggregation or projection depending on the data type of the left side. In all cases, indices are permuted according to the domain definitions. If a symbol has identical domain definitions they are permuted right to left (<) or left to right (<=). For example, assume we have

  ```
  Set i, fromto(i,i), tofrom(i,i);
  alias(i,ii);
  parameter in(i), out(i);

  option tofrom < fromto, in < fromto, out <= fromto;
  ```

is equivalent to

```
tofrom(i,ii) = fromto(ii,i);
in(i) = sum(fromto(ii,i),1);
out(i) = sum(fromto(i,ii), 1);
```

3.60.2 Solvers

3.60.2.1 BARON 6.0

- Improved memory management
- Default bounds are new +/- infinity
- CONOPT run not required to get marginals
- Several algorithmic improvements

3.60.2.2 CPLEX 9.0

- GAMS/Cplex is now based on Cplex 9.0. In addition to performance improvements and enhancements of existing features, support is provided for the new GAMS model types QCP and MIQCP. Because of some compatibility issues, we still ship CPLEX 8.1 for Digital Unix. Details can be found here.

3.60.2.3 Large scale QCP Solvers

- MOSEK handles QCP and MIQCP models
- CPLEX handles QCP and MIQCP models.
- XPRESS handles QCP with quadratic term in the objective only.
- SBB handles MIQCP models.
- PATHNLP takes advantage of quadratic forms for QCP models.

3.60.2.4 NLP solvers capable of solving QCPs

- All NLP solvers (CONOPT, MINOS, SNOPT, ...) handle QCP and RMIQCP models.

3.60.2.5 AMPL and Lingo Wrappers are now part of the GAMS distribution

3.60.2.6 MOSEK 3.0

3.60.2.7 MPSGE

- Improved reporting of formulation errors
- There are new rules for choosing proper labels and identifiers in MPSGE models. The MPSGE engine was initially designed around the old 10-character limit for labels and identifiers imposed by GAMS/Base. When GAMS/Base relaxed these limits to 31 characters, a flag was added to check for compatibility with the old rules to avoid breaking MPSGE. We've now removed the check in GAMS/Base - the MPSGE engine makes its own check now. This means we can use long labels and identifiers under the new rules.
- The testlib models `mpsge01` $*$ `mpsge10` document and test the rules for identifiers in MPSGE models. E.g. do

```
testlib mpsge01
gams mpsge01
```

3.61 21.2 Maintenance release (September 03, 2003)

3.62 21.1 Maintenance release (June 02, 2003)

3.63 21.0 Major release (May 15, 2003)

3.63.1 GAMS System

3.63.1.1 GAMS Model Library

- We added quite a few global optimization models to the GAMS model library that demonstrate the power of the new suite of Global Optimizers available in GAMS: BARON, LGO, and OQNLP. In addition, we added a model that calculates the US holiday schedule (HOLIDAY) and a model for the Five Leaper Tour problem (FIVELEAP). The model NASH gives an example of a Mathematical Program with Equilibrium Constraints (MPEC) which can be solved by the beta solver NLPEC.

3.63.1.2 IDE

- GDX data viewer: Symbols can be sorted by various attributes, and the display uses two grids to display the data. The top grid shows the plane index, the bottom grid the current data. The indices can be arranged using drag and drop. The arrangement is preserved in the project file. The data viewer can write a single symbol or all symbols to an html file.
- Removed Setup button from the print dialog screen. Printer setup is now available from the window that follows this dialog. This allows more printer options to be selected, such as duplex printing.
- Added option to update the GAMS system using a ZIP file in the GAMS system directory. (File | Options | Execute | Update)
- Added entries on the help menu for easy access to some documentation files.
- Revised the on-line help and added a number of screen shots.
- Added `file:///` as a recognized hyperlink.

3.63.1.3 GDX Utilities

- New documentation includes GDX facilities in GAMS.
- GDXXRW (Excel interface)
  - Added 'usage' output
  - Removed SSET as a type, and added Values option for a set.
- GDXDIFF
  - Added option to specify a single field for comparison (for variables and equations)
  - Added option to ignore comparison of associated text
  - Added RelEps option for relative comparisons
- GDXDUMP
  - Added UelTable option

3.63.2 Solvers

3.63.2.1 New Global Solvers

- NLP and MINLP problems frequently have multiple local optima. The three new solvers, BARON, LGO and OQNLP aim at finding the best possible local optima, the global optimum solution. The solvers differ in the methods they use, in whether they find globally optimal solution with proven optimality, in the size of models they can handle, and in the functional forms they accept.

3.63.2.2 BARON

- BARON is from The Optimization Firm, LLC and the University of Illinois at Urbana-Champaign. The Branch And Reduce Optimization Navigator derives its name from its combining interval analysis and duality in its reduce arsenal with enhanced branch and bound concepts as it winds its way through the hills and valleys of complex optimization problems in search of global solutions.

3.63.2.3 LGO

- LGO is from Pinter Consulting Services, Inc. This algorithm combines rigorous statistical methods with traditional mathematical programming methods to find solutions within well defined bounds. LGO stand for Lipschitz Global Optimization.

3.63.2.4 OQNLP

- OQNLP from Optimal Methods, Inc and OptTek Systems, Inc. is a solver for global optimization of non-linear problems with discrete and continuous variables. This multi start solver combines robust nonlinear optimization technologies with state-of-the-art meta heuristics like scatter search. In this official release of OQNLP, nonlinear subproblems with different starting points can be solved by any GAMS NLP solver as well as the build-in LSGRG solver.

3.63.2.5 CONOPT

- The CONOPT family of NLP solvers now have three members, CONOPT1, CONOPT2, and CONOPT3. The alias CONOPT which used to point to CONOPT2 will now call CONOPT3. In case you need to run an older version of CONOPT you must specify CONOPT1 or CONOPT2. CONOPT3 is an enhancement of CONOPT2. An additional solver component based on sequential quadratic programming (SQP) principles has been added and it uses the new 2nd order facilities in GAMS. In addition, an improved automatic scaling routines is now used as default.
- CONOPT3 is a true multi-method solver that combines its many solver components (SQP, SLP or sequential linear programming, Quasi-Newton, and Steepest Descend) with dynamic selection of the best component based on performance statistics.
- CONOPT2 is, apart from minor bug fixes, identical to CONOPT2 from the previous release. CONOPT1 has not been changed and it will not be updated any more. We encourage all CONOPT1 user to move on to CONOPT3 or CONOPT2.

3.63.2.6 CPLEX 8.0

- Find detailed release notes here

3.63.2.7 MINOS

- The new GAMS/MINOS, which is based on MINOS 5.51 uses a new LU factorization with Threshold Rook Pivoting. It also has better memory estimation and improved reporting of infeasibilities.

3.63.2.8 MOSEK

- MOSEK from MOSEK ApS, Copenhagen Denmark is a large scale system for solving linear, mixed-integer linear, and convex nonlinear mathematical optimization problems. MOSEK is particularly well suited for solving sparse large-scale problems using an extremely efficient interior point algorithm. This official release of MOSEK using library version 2.5 also solves second order conic programs.

3.63.2.9 OSL

- The OSL optimizer family is now represented by its newest member, OSL3. You can still run OSL2 and OSL1 (where available) by specifying them explicitly, but the default OSL is OSL3.
- Improvements to OSL3 over past OSL versions include:
  - Better performance for the simplex, barrier, and MIP codes
  - Better memory management
  - More robustness, especially in the barrier code

3.63.2.10 PATH

- The PATH presolve has been extended and strengthened.

3.63.2.11 SNOPT

- The new GAMS/SNOPT, which is based on SNOPT 6.2-1 uses a new LU factorization with Threshold Rook Pivoting. Memory estimation, the reporting of infeasibilities, and the handling of LP's has been improved.

3.63.2.12 XPRESS

- GAMS/XPRESS now links to XPRESS 2003, the latest optimizer from DASH. Optimizer improvements include:
  - Completely redesigned and rewritten branch and bound framework
  - New code for the Newton Barrier optimizer
  - Enhanced branching technology, cut strategies and heuristics
  - Better memory management

3.63.3 Documentation

3.63.3.1 McCarl's GAMS User Guide

- The new McCarl's GAMS User Guide will be installed automatically with CD installation. If you download the GAMS system from our web site, you have to install it separately, see *[not available anymore]*.

3.63.3.2 Solver Manuals

- There is a revised version for most of the solver manuals, all of them are in a uniform format. A composite manual, The Solver Manuals, is also available for printing.

3.64 20.7 Maintenance release (June 14, 2002)

3.65 20.6 Major release (May 25, 2002)

3.65.1 GAMS System

3.65.1.1 MODLIB

- We have two new models (clearlak and srkandw) that demonstrate the use of scenred, an interesting MIP model for scheduling TV commercials, and an example that shows the use of some GDX utilities.

3.65.1.2 MPS2GMS

- This utility converts MPS files into a GAMS program making use of the GAMS GDX facility. This replaces the contributed utility mps2gams.

3.65.1.3 POSIX UTILITIES

- Starting with this distribution the GAMS system for Windows includes a collection of Posix utilities which are usually available for the different Unix systems and therefore help to write platform independent scripts. More information here.

3.65.1.4 SCENRED

- ScenRed (a new addition to the GAMS system) allows GAMS users easy access to the scenario reduction algorithms found in [ScenRed] (http://www.mathematik.hu-berlin.de/%7Eromisch/projects/GAMS/scenre
Given the event tree for a stochastic program, ScenRed determines a subset of scenarios and the optimal redistribution of probabilities for the preserved scenarios. This is useful when the stochastic program that results from using the original (complete) event tree is too large to solve. Making use of the new execution-time GAMS data interface (execute_load/execute_unload), GAMS/ScenRed takes the original tree from the modeler, along with parameters controlling the reduction, and returns a reduced tree for use in subsequent solves or data manipulation.

3.65.2 Solvers

3.65.2.1 SBB

- There are two new options (dfsstay and acceptnonopt) in SBB that can help to find good solutions more quickly as well as handle almost optimal subproblems which are ignored by default.

3.65.2.2 XA

- The GAMS/XA link has been modified to work with the new generation (Version 13) of XA libraries. All XA-supported architectures are now using this new version, and so will include a Newton-barrier capability.

3.65.3 Beta Solvers

3.65.3.1 BARON

- Complete primal and dual solutions values are now reported by using CONOPT as a post processor. The preprocessing has been enhanced to allow free (=N=) equations.

3.65.3.2 MOSEK

- MOSEK from MOSEK ApS is a large scale system for solving problems of the following classes:
  - Linear optimization
  - Mixed integer linear optimization
  - Convex quadratic optimization
  - Conic quadratic optimization
- The released version of MOSEK will also solve
  - Quadratically constrained convex optimization
  - Convex optimization
- More information about MOSEK can be found at [www.mosek.com] (http://www.mosek.com).

3.65.3.3 OQNLP

- OQNLP from Optimal Methods, Inc is a solver for global optimization of smooth constrained problems with either all continuous variables or a mixture of discrete and continuous variables. This multi start method combines mathematical programming approaches with meta heuristics like tabu search.

3.65.3.4 NLPEC

- NLPEC is a solver for MPEC models that works by reformulating the MPEC model as an NLP, solving the NLP using one of the GAMS NLP solvers, and then extracting the MPEC solution from the NLP solution. All of this happens automatically, although it is possible to access the intermediate NLP model. Like the CONVERT solver, the reformulated models NLPEC produces are in scalar form. Many different reformulations (currently around 20) are supported by the NLPEC solver. MPEC models are notorious for their difficultly, but the combination of different reformulations and NLP solvers give users a good chance to solve them.

3.65.3.5 PATHNLP

- PATHNLP is now set up to allow the PATHLIB presolver to perform additional model reductions.
- PATHNLP now uses the same libraries as PATH. Previous versions used an experimental version of PATHLIB (ver 5.X). Since the supported PATHLIB is now 4.6, it looks like PATHNLP now uses an older PATHLIB; this is not the case.

3.66 20.5 Maintenance release (January 28, 2002)

3.67 20.4 Maintenance release (January 21, 2002)

3.68 20.3 Major release (December 24, 2001)

3.68.1 GAMS System

3.68.1.1 GAMS

- Restrictions of number of symbols, set elements and execution code size have been completely removed.
- Performance enhancements for very large models with millions of rows and columns.
- Minor language enhancements: $on/offecho copies a block of lines to a file. The text is subject to string macro processing as well as inline and eol comment removal. For example:

```
$onecho > myfile
...
$offecho
```

- To append to a file use ">>".

3.68.1.2 IDE

- Contributed solver installation files (e.g. QPWRAP, DEA, ... see [User Contributed Software and Tools] (https://forum.gamsworld.org/viewforum.php?f=16&sid=60f52f2a7983d94c0202a0834f780778)) can now be installed using the IDE. Place the installation file (file extension ∗.zip or ∗.pck) in the GAMS system directory and click on the "Update" button in File->Options->Execute

3.68.2 Solvers

3.68.2.1 Uniform Solver Naming Conventions

- Since solvers are distributed with past, production, and beta versions (e.g. OSL, CONOPT, ...) a consistent naming convention has been adoped.
- The following simple rules apply:
  1. The base name of the solver does not change (e.g. CPLEX, OSL, CONOPT, ...) and refers to the current production version.
  2. Past and beta versions have names derived from the base name. For example, in this release we distribute CONOPT1 (past), CONOPT2 (production), and CONOPT3 (future). The base name CONOPT refers to CONOPT2.
- If you select the base name of a solver from now on you will get the most recent production version of the solver. For the following solvers the naming convention has changed:

New Name (20.3-)	Old Name (-20.2)
CONOPT or CONOPT2	CONOPT2
CONOPT3	CONOPT3
CONOPT1	CONOPT
OSL or OSL2	OSL2
OSL3	OSL3
OSL1	OSL
MINOS or MINOS55	MINOS
MINOS5	MINOS5
PATH or PATHC	PATHC
PATHOLD	PATH
MILES or MILESE	MILESE
MILESOLD	MILES

3.68.2.2 CONOPT

- The future version CONOPT3 is also available on Linux.

3.68.2.3 CONVERT

- For BARON and AMPL output GAMS/CONVERT eleminates the objective variable and uses a "true" objective function.

3.68.2.4 SBB

- NLP solvers sometimes have difficulties solving particular nodes and using up all the resources in this node. SBB provides options (see *subres*, *subiter*) to overcome these instances, but options have to be set in advance. Now, SBB keeps track of how much time is spend in the nodes, builds an average over time, and automatically controls the time spend in each node. The option *avgresmult* allows the user to customize this new feature.

3.68.2.5 XPRESS

The XPRESS licensing for Windows, Linux, and Solaris is now much simplified; there is no XPRESS-specific licensing procedure for the user to follow. The GAMS/XPRESS solver takes care of licensing the XPRESS DLL, and does this automatically. Of course, as with other solvers, the GAMS/XPRESS must be licensed with your GAMS system.

3.69 20.2 Maintenance release (November 22, 2001)

3.69.1 Solvers

3.69.1.1 CPLEX 7.5

- Find detailed release notes here

3.69.1.2 XPRESS 13.01

- The GAMS/XPRESS link has been updated to use the new 13.01 solver libraries from XPRESS.

3.70 20.1 Major release (October 31, 2001)

3.70.1 GAMS System

3.70.1.1 GAMS

- A new licensed Privacy and Security feature which allows to purge, hide or protect model data and model components from unauthorized use. Models and data that are saved with the privacy feature enabled are locked to a specific license and protected. For more details consult the corresponding appendix of the GAMS Users Guide.
- A new GAMS parameter EXECMODE can be used to reconfigure certain features when operating in an application service environment. $call/execute, $echo/put and $includes can be disabled or restricted to operate only on certain sub trees of the file system.
- Model options can be initialized from the command line or the GAMS parameter window in the IDE (bratio, iterlim, domlim, reslim, optcr, optca, sysout, solprint, optfile and all solvers for model types). For example:

  ```
  gams myfile LP=BDMLP RESLIM=10
  ```

  will override the default solver to be BDMLP and force an interrupted after 10 seconds.
- Other minor language enhancements are:
  - Factorial function FACT
  - Implication operator (-> or `imp`)
  - Equivalence operator (<=> or `eqv`)
  - $ECHON and echo without EOL
  - $IFi which makes case insensitive string comparisons
- A number of restrictions have been relaxed:
  - NLP model can have up to 8 million constants.
  - A GAMS program can have up to 1 million GAMS symbols or unique elements.
  - The internal code space has been increased to 32 million instructions.
  - The model size is limited by hardware addressing space only.
- GAMS environment variables can now be initialized or reset from the command line or parameter window. The prefix `--` signals an environment variable. For example:

  ```
  gams myfile --mypath="d:a b"
  ```

  is equivalent to inserting `$set mypath d:a b` in the GAMS input file. The GAMS parameter SETTYPE (ST) values of 0 (default), 1 and 2 change the implied $set command to $set/setlocal/setglobal respectively. The evaluation of nonlinear expressions inside solvers of the form <`expression`>**<`integer constant=""`> are now interpreted more restrictive for the values of -1,0,1 and 2. The solver will issue domain violations when the value of an expression becomes negative. For example, x**0 will now require that x is always greater or equal to zero. The function power(expression,integer constant) should be used if this is not intended.
- Derivatives for 0**0 are not defined and may cause problems during the solution process. Warnings are issued when this case arises.

IDE

- Alternate license dialog was disabled
- Selecting 'GAMS model library' will no longer add this entry to the recently used list of libraries.
- Find/Replace dialogs no longer default to 'Selected Text' when text was selected in the editor.

3.70.1.2 GAMS Model Library

- The references for existing models have been updated which allows an indexing by author.
- We added a couple of MINLP models:
  - CSCHED Cyclic Scheduling of Continuous Parallel Units
  - GASNET Optimal Design of a Gas Transmission Network
  - WINDFAC Winding Factor of Electrical Machines
  - STOCKCC Minimizing Total Average Cycle Stock
  - NSHARPX Synthesis of General Distillation Sequences
  - MINLPHIX Heat Integrated Distillation Sequences
- The new model CESAM illustrates a cross entropy technique for estimating the cells of a consistent Social Accounting Matrix (SAM) assuming that the initial data are inconsistent and measured with error.
- The COPS models have been added:
  - POLYGON Largest small polygon COPS 2.0 #1
  - ELEC Distribution of electrons on a sphere COPS 2.0 #2
  - CHAIN Hanging Chain COPS 2.0 #3
  - CAMSHAPE Shape optimization of a cam COPS 2.0 #4
  - PINENE Isometrization of alpha-pinene COPS 2.0 #5
  - POPDYNM Marine population dynamics COPS 2.0 #6
  - FLOWCHAN Flow in a channel COPS 2.0 #7. Uses new function fact
  - ROBOT Robot arm COPS 2.0 #8
  - LNTS Particle steering COPS 2.0 #9
  - ROCKET Goddard rocket COPS 2.0 #10
  - GLIDER Hang glider COPS 2.0 #11
  - GASOIL Catalytic cracking of gas oil COPS 2.0 #12
  - METHANOL Methanol to hydrocarbons COPS 2.0 #13
  - CATMIX Catalyst Mixing COPS 2.0 #14
  - TORSION Elastic-plastic torsion COPS 2.0 #15
  - JBEARING Journal bearing COPS 2.0 #16
  - MINSURF Minimal surface with obstacle COPS 2.0 #17

3.70.2 Solvers

3.70.2.1 CONVERT

- This solver converts a GAMS model instance into a format used by other modeling and solutions systems. The transformed models have only scalar equations and variables with all original naming removed. This 'scalar' format hides the original model and data development and allows one to exchange confidential models for solver tuning and research. Currently, CONVERT can translate GAMS models into the following formats:
  - AMPL
  - BARON
  - CplexLP
  - CplexMPS
  - GAMS
  - LGO
  - LINGO
  - MINOPT
- This solver is also available as an e-mail based service from the GAMS World.

3.70.2.2 CPLEX 7.1

- Find detailed release notes here

3.70.2.3 MPSGE/MCP Solver

- There has been a reorganization of the MCP/MPSGE solvers. Central to this is the introduction of a new core library for MPSGE models. There are two MCP solvers compatible with this new scheme: PATHC and MILESE. Both of these solvers implement the same algorithms as their predecessors PATH and MILES: only their internal interface is changed. The old solvers, using the old interface, are still available for the time being. However, the new solvers offer certain advantages; for example, PATHC contains optional preprocessing of the MCP model that was not possible because of the structure of the old interface. The new interface also relies on the GAMS Base module to perform many more consistency checks on the MCP formulation and gives more immediate and extensive diagnostic information when modeling errors occur. Finally, the new interface will allow one to "plug in" an alternate version of the MPSGE core library to experiment with different MPSGE functional forms.
- It's important to note that backward compatibility is maintained, and that all four solvers (PATH, PATHC, MILES ,and MILESE) will accept the same GAMS files as input. The interface changes referred to above are all internal in nature.

3.70.2.4 OSL3

- The GAMS/OSL link has been updated to use the new OSL3 libraries from IBM.

3.70.2.5 PATHNLP

- PATHNLP is the latest NLP solver at GAMS. Essentially, it implements an SQP algorithm by automatically reformulating an NLP problem as a complementarity problem and solving this using the proven, reliable PATH solver. This allows second order information to be used in the solution of the model, which often results in greater solution efficiency. In addition, the marginal values are sometimes more exact than those provided by first-order methods. The advantages of this approach are most apparent on very large, sparse models with many nonlinear variables and degrees of freedom. In these cases, the superbasics limit of other NLP codes limits their effectiveness but is no barrier when using PATHNLP. The new PATHNLP solver allows the solution of certain previously unsolvable models (e.g. maximum entropy models).

3.70.2.6 SBB

- SBB derives an implicit absolute termination tolerance if the model has a discrete objective row. This may speed up the overall time if the user has tight termination tolerances (optca, optcr).
- SBB passes indicies of rows with domain violations back to the LST file. All domain violation from the root node as well as all sub nodes are reported and the user might take advantage of this information to overcome these violations.

3.70.2.7 XPRESS

- The GAMS/XPRESS link has been updated to use the new 12.50 solver libraries from XPRESS. Benefits include an improved pricing algorithm in dual simplex, improved sparse/dense data handling in all simplex codes, and a general 30% reduction in simplex solve time. The barrier solver incorporates row-wise Cholesky factorization, which gives improved performance on many problems, and has more efficient memory usage. The presolve has more efficient memory management, and the eliminator phase has been improved. The branch and bound algorithm has improved cut selection and faster clique cut generation.
- Improvements to the link itself allow for better detection and reporting of unbounded or infeasible models.

3.70.3 Solvers in Beta Version

3.70.3.1 BARON

- BARON is a computational system for solving non convex optimization problems to global optimality. Purely continuous, purely integer, and mixed-integer nonlinear problems can be solved with the software. The Branch And Reduce Optimization Navigator derives its name from its combining interval analysis and duality in its reduce arsenal with enhanced branch and bound concepts as it winds its way through the hills and valleys of complex optimization problems in search of global solutions.
- The demo size for this solver is reduced to 10 variables and 10 equations. The beta version of BARON is available on Windows, Linux and AIX.

3.70.3.2 CONOPT3

A new version of CONOPT is available for beta testing, find release notes here. It is available on Windows only.

Chapter 4

User's Guide

This documentation guides GAMS users through several topics in the GAMS system.

4.1 Installation and Licensing

This part leads step by step through the installation process on three main platforms and describes the GAMS licensing system:

- Supported Platforms
- Installation Notes for macOS
- Installation Notes for Unix
- Installation Notes for Windows
- Standard Locations
- Licensing

4.2 Tutorials and Examples

This part describes step by step through several selected tutorials and a small number of examples.

- A GAMS Tutorial by Richard E. Rosenthal
- Quick Start Tutorial
- Good Coding Practices
- Fixing Compilation Errors
- Finding and Fixing Execution Errors and Performance Problems
- Comparative Analyses with GAMS
- Good NLP Formulations
- Data Exchange with Other Applications

  - Data Exchange with Text Files
  - Data Exchange with Microsoft Excel
  - Data Exchange with Databases
- Executing GAMS from other Environments
- Using GAMS Studio

There are also tutorials and examples of the Application Programming Interfaces

- .NET Tutorial and `Examples`
- C++ Tutorial and `Examples`
- Java Tutorial and `Examples`
- Python Tutorial and `Examples`

4.3 GAMS Language and Environment

This part introduces the components of the GAMS language in an ordered way, interspersed with detailed examples that are often drawn from the model library.

- Introduction - an introduction to the GAMS User's Guide.
- GAMS Programs - The structure of the GAMS language and its components
- Set Definition - The declaration and initialization of sets, subsets, and domain checking.
- Dynamic Sets - The membership assignment, the usage of dollar controls, and set operations.
- Sets as Sequences: Ordered Sets - Special features used to deal with a set as if it were a sequence.
- Data Manipulations with Parameters - The declaration and assignment of GAMS parameters.
- Data Entry: Parameters, Scalars and Tables - Three basic forms of GAMS data types : Parameters, Scalars and Tables.
- Variables - The declaration and attributes of GAMS variables.
- Equations - The definition and declaration of GAMS equations.
- Model and Solve Statements Model - The specificiation of a GAMS model and how to solve it.
- Conditional Expressions, Assignments and Equations - The conditional assignments, expressions and equations in GAMS.
- The Display Statement - The syntax, control, and label order in display.
- Programming Flow Control Features - The GAMS programing flow control features : loop, if-elseif, while, and for statements.
- The Option Statement - The list and detailed description of options.
- System Attributes - The system attributes
- The Grid and Multi-Threading Solve Facility - The basic concepts and Grid Features.
- Special Features for Mathematical Programs - Special features in GAMS that do not translate across solvers, or are specific to certain model types.

The following discusses the execution of GAMS, the use of special features, and other miscellaneous topics.

- GAMS Output - The control of GAMS compilation output, execution output, output produced by a solve statement, and error reporting.
- GAMS Log
- The GAMS Call and Command Line Parameters - The list and detailed description of GAMS command line parameters.
- Dollar Control Options - The list and detailed description of dollar control options.
- The Put Writing Facility - The put writing facility of the GAMS language.
- Solver Usage - Controlling solvers.
- The Save and Restart Feature - The GAMS save and restart feature and the work file.
- Embedded Code Facility - The Embedded Code Facility (e.g. how to embed Python code into GAMS).
- GAMS Connect - The GAMS Connect Framework.
- Extrinsic Functions - The extrinsic function library and comparison with external equations.
- External Equations - A facility for connecting code written in different programming languages to equations and variables in a GAMS model.
- GAMS Return Codes - The structure of error codes, the return codes of the GAMS compiler and execution system, and the driver return codes.
- GAMS Data eXchange (GDX) - GAMS Data eXchange (GDX) facilities and utilities for Binary Data Exchange.
- Extended Mathematical Programming (EMP) - Extended Mathematical Programming (EMP).
- Accessing Model Libraries - Introduction of GAMS Model Library.
- Mathematical Programming System for General Equilibrium analysis (MPSGE) - A mathematical programming system for general equilibrium analysis which operates as a subsystem within GAMS.
  - Introduction to MPSGE
  - MPSGE Models in GAMS
  - Demand Theory and General Equilibrium: An Intermediate Level Introduction to MPSGE
  - Constant Elasticity of Substitution Functions: Some Hints and Useful Formulae
  - `A Library of Small Examples for Self-Study`
  - `Linking Implan Social Accounts to MPSGE`
  - The MPSGE guide is also available as `PDF`

4.4 Glossary

An alphabetical list of GAMS terms is available in the Glossary.

4.5 Supported Platforms

GAMS supports the following platforms:

Platform	Description
x86 64 bit Linux	AMD- or Intel-based 64-bit (x86_64) Linux systems with glibc 2.17 or higher.
arm 64 bit macOS	Apple Silicon (arm64) Macintosh system with macOS 13 (Ventura) or macOS 14 (Sonoma).
x86 64 bit macOS	Intel-based 64-bit (x86_64) Macintosh system with macOS 12 (Monterey), macOS 13 (Ventura), or macOS 14 (Sonoma).
x86 64 bit MS Windows	Windows 10 or newer on AMD- or Intel-based (x86_64) architectures.

Note

Compared to most of the GAMS system, GAMS Studio has some additional system requirements which are detailed here.

While the GAMS execution system itself is available on all supported platforms, for certain solvers, tools, and APIs, different availabilities can apply. For details, see

- Supported Platforms for Solvers
- Supported Platforms for Tools
- Supported Platforms for High-level APIs
- Supported Platforms for Low-level APIs

4.6 Installation Notes for macOS

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Furthermore, we recommend to use the PKG installer for macOS because it includes the GAMS Studio and it integrates GAMS into macOS, e.g. it is possible to open the GAMS Studio via the Launchpad.

Two installation procedures are available for GAMS on macOS:

- Installation using the PKG installer (GAMS46.4.1.pkg)
- Installation using the self-extracting archive (osx_x64_64_sfx.exe or osx_arm64_sfx.exe)

4.6.1 Installation using the PKG installer (GAMS46.4.1.pkg)

1. Obtain the GAMS PKG file for your CPU architecture (`x86_64` or `arm64`), which is available from `http://www.gams.com/download`.
2. Double click the package and follow the instructions. By clicking on `Customise` in the tab `Installation Type` you can decide to add GAMS to the PATH as well as to reject the installation of GAMS Studio. Note that adding GAMS to the PATH is done by modifying your shell profile file (`~/.zprofile`, `~/.bash_profile` etc.). A backup of your old profile is saved (`~/.zprofile.gamsbackup`, `~/.bash_profile.gamsbackup` etc.).
3. In order to test the GAMS installation with `GAMS Studio` open the `Launchpad` and click the `GAMS Studio 46` icon to open the application. Alternatively, go to Applications and open the `GAMS Studio 46` application.

4. Install your license via the corresponding GAMS Studio dialog. The license file is nowadays sent via email, with instructions. You can also request a demo license from http://www.gams.com/download.

   Optionally, you can create the license file 'gamslice.txt' in a directory that GAMS searches to find a license. GAMS searches a couple of system wide and user specific standard locations for a license file.

5. Open the `Model Library Explorer` and open the `TRNSPORT` model (sequence number 001). Run the model and check the contents of the process log, which should be similar to the Terminal output listed in the next bullet point.

6. In order to test the GAMS installation without using `GAMS Studio` open a Terminal window. Execute the following commands to see if everything works as expected:

```
gamslib trnsport
gams trnsport
```

   The output should be similar to this:

```
--- Job trnsport Start 06/26/14 11:24:56 24.3.1 r46409 DEX-DEG Mac x86_64/Darwin

4.6.2 Uninstall PKG installation

To uninstall a GAMS installation that was installed using the PKG installer, run the following command from the terminal: `sudo bash /Library/Frameworks/GAMS.framework/Versions/46/Resources/uninstall.sh`. Additionally, you can remove GAMS from the PATH in your shell profile file (`~/.zprofile`, `~/.bash_profile`) if GAMS was added to the PATH during installation.

4.6.3 Installation using the self-extracting archive (osx_x64_64_sfx.exe or osx_arm64_sfx.exe)

The following instructions are for the macOS system on Intel/AMD CPUs (`x86_64`). For a macOS system on ARM64 CPUs, the same instructions apply, but with `x64_64` replaced by `arm64` in all file names.

1. Obtain the GAMS distribution file, which is available from http://www.gams.com/download, in one large self-extracting zip archive with a `_sfx.exe` file extension, e.g., `osx_x64_64_sfx.exe`. Check that it has the execute permission set. If you are not sure how to do this, just type in the command `chmod 755 osx_x64_64_sfx.exe` .

   Attention

   The common way to install GAMS on a Mac is the PKG installer. When one tries to run the sfx installer (e.g. for unattended installation) under macOS 10.15 (Catalina) or newer, the installer and several related files will be tagged with the `com.apple.quarantine` flag. There are different solutions to this problem:

   - The flag can be removed by the following command:
     `xattr -rd com.apple.quarantine osx_x64_64_sfx.exe`
   - Instead of downloading the sfx installer through the browser, use a command line tool such as curl (note that by downloading the software, you agree to the License Agreement). The download link may need to be adjusted, depending on the distribution that should be downloaded.
     `curl https://d37drm4t2jghv5.cloudfront.net/distributions/29.1.0/macosx/osx_x64_64_sfx.e`

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in `/Applications/GAMS`, the installer will create the GAMS system directory `/Applications/GAMS/gams24.3_osx_x64_64_sfx`. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.

3. Create the directory that should contain the GAMS system directory, for instance `/Applications/GAMS`. Change to this directory (`cd /Applications/GAMS`). Make sure `pwd` returns the name of this directory correctly.

4. Run the distribution file, either from its current location or after transfering it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

   ```
   mkdir /Applications/GAMS
   cd    /Applications/GAMS
   ~/osx_x64_64_sfx.exe
   ```

5. Create the license file `gamslice.txt` in a directory GAMS searches to find a license. The license file is nowadays sent via email, with instructions. You can also request a demo license from http://www.gams.com/download.

Attention

Do not store the `gamslice.txt` in the GAMS system directory. This invalidates the code signature and cause Gatekeeper to reject the bundle!

GAMS searches a couple of system wide and user specific locations for a license file. For macOS these locations include `/Library/Application Support/GAMS` and `/Users/username/Library/Application Support/GAMS`. The locations can vary due to different system configuration. One can get an ordered list of data directories GAMS searches for `gamslice.txt` by running the program `./gamsinst -listdirs` from the GAMS system directory. Even though this list might contain locations in the system directory, e.g. `/Applications/GAMS31.1` we strongly discourage to place `gamslice.txt` here.

6. Change to the GAMS system directory and run the program `./gamsinst`. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:

   a. rerunning `./gamsinst` and resetting the default values

   b. setting a command line default, e.g., `gams trnsport lp=soplex`

   c. an option statement in the GAMS model, e.g: `option lp=soplex;`

7. Add the GAMS system directory to your path (see below).

8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

```
LP:    trnsport (objective value:  153.675)
NLP:   chenery  (objective value:  1058.9)
MIP:   bid      (optimal solution: 15210109.512)
MINLP: procsel  (optimal solution: 1.9231)
MCP:   scarfmcp (no objective function)
MPSGE: scarfmge (no objective function)
```

9. If you move the GAMS system to another directory, remember to rerun `./gamsinst`. It is also good practice to rerun `./gamsinst` when you change your license file if this has changed the set of licensed solvers.

4.6.3.1 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (`csh`) and its variants you can modify your `.cshrc` file by adding the second of the two lines given below:

```
set path = (/your/previous/path/setting )
set path = ( $path /Applications/GAMS/gams24.3_osx_x64_64_sfx ) # new
```

2. Those of you using the Bourne (`sh`) or Korn (`ksh`) shells and their variants can modify their `.profile` file by adding the second of the three lines below:

```
PATH=/your/previous/path/setting
PATH=$PATH:/Applications/GAMS/gams24.3_osx_x64_64_sfx  # new
export PATH
```

   If the `.profile` file does not exist yet, it needs to be created. You should log out and log in again after you have made any changes to your path.

3. You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their `.cshrc` file:

   ```
   alias gams /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
   alias gamslib /Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
   ```

   The correct Bourne or Korn shell syntax (either command line or `.profile`) is:

   ```
   alias gams=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gams
   alias gamslib=/Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib
   ```

   Again, you should log out and log in in order to put the alias settings in `.cshrc` or `.profile` into effect.

4. Casual users can always type the absolute path names of the GAMS programs, e.g.:

   ```
   /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams trnsport
   ```

4.6.3.2 Example

The following shows the log of a session, where a user downloads a GAMS 24.3.1 system and installs it under `Applications/GAMS/gams24.3_osx_x64_64_sfx`. It is assumed that a GAMS license file has been stored as `/Users/doe/gamslice.txt`.

```
doe@mac:/Users/doe$ curl -L -k -O \
  http://d37drm4t2jghv5.cloudfront.net/distributions/24.3.1/macosx/osx_x64_64_sfx.exe
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100  148M  100  148M    0     0  4374k      0  0:00:34  0:00:34 --:--:-- 5906k

doe@mac:/Users/doe$ chmod 755 osx_x64_64_sfx.exe

-------------------------------------------------------
```

```
gamsinst run on Wed Jun 25 19:25:29 2014
GAMS sysdir is "/Applications/GAMS/gams24.3_osx_x64_64_sfx"

LP (Linear Programming) models can be solved by:
   1.           CBC  (demo or student license)
   2.        CONOPT  (demo or student license)
   3.         CPLEX  (demo or student license)
   4.        GUROBI  (demo or student license)
   5.         IPOPT  (demo or student license)
   6.        IPOPTH  (demo or student license)

...

Installed defaults:

         LP: CPLEX
        MIP: CPLEX
       RMIP: CPLEX
        NLP: CONOPT
        MCP: PATH
       MPEC: NLPEC
      RMPEC: NLPEC
        CNS: CONOPT
       DNLP: CONOPT
     RMINLP: CONOPT
      MINLP: DICOPT
        QCP: CONOPT
      MIQCP: SBB
     RMIQCP: CONOPT
        EMP: JAMS

We are now prepared to set read and execute permissions on the
GAMS system files.  If you are not sure which option to choose,
we recommend option 3.
You can set read (and execute) permission for:
 1. user only.
 2. user and group.
 3. user, group, and world.
 Enter your choice now

3

The files "gams", "gamslib", etc., are now executable.
You can run these commands in a number of ways:
  1. Call them using an absolute path (i.e. /Applications/GAMS/gams24.3_osx_x64_64_sfx/gams).
  2. Create your own aliases for them.
  3. Add the GAMS system directory "/Applications/GAMS/gams24.3_osx_x64_64_sfx" to your path.
Method 3. is recommended.

doe@mac:/Applications/GAMS/gams24.3_osx_x64_64_sfx$cd

doe@mac:/Users/doe$/Applications/GAMS/gams24.3_osx_x64_64_sfx/gamslib trnsport

4.7 Installation Notes for Unix

4.7.1 Installation

To install GAMS, please follow the steps below as closely as possible. We advise you to read this entire document before beginning the installation procedure. Additionally, a video on how to install GAMS on Linux is available at https://www.youtube.com/watch?v=Mx_tYI3wyP4.

1. Obtain the GAMS distribution file, which is available from http://www.gams.com/latest, in one large self-extracting zip archive with a `_sfx.exe` file extension, e.g., `linux_x64_64_sfx.exe` on a Linux 64bit system. Check that it has the execute permission set. If you are not sure how to do this, just type in the command, e.g., `chmod 755 linux_x64_64_sfx.exe`.

2. Choose a location where you want to create the GAMS system directory (the GAMS system directory is the directory where the GAMS system files should reside). At this location the GAMS installer will create a subdirectory with a name that indicates the distribution of GAMS you are installing. For example, if you are installing the 24.3 distribution in `/opt/gams`, the installer will create the GAMS system directory `/opt/gams/gams24.3_linux_x64_64_sfx`. If the directory where you want to install GAMS is not below your home directory, you may need to have root privileges on the machine.

3. Create the directory that should contain the GAMS system directory, for instance `/opt/gams`. Change to this directory (`cd /opt/gams`). Make sure `pwd` returns the name of this directory correctly.

4. Run the distribution file, either from its current location or after transferring it to the directory that should contain the GAMS system directory. By executing the distribution file, the GAMS distribution should be extracted. For example, if you downloaded the distribution file into your home directory, you might execute the following commands:

```
mkdir /opt/gams
cd /opt/gams
~/linux_x64_64_sfx.exe
```

5. Create the license file `gamslice.txt` in a directory GAMS searches to find a license or use the corresponding GAMS Studio dialog. The license file is nowadays sent via email, with instructions. You can also request a demo license from http://www.gams.com/download.

   GAMS searches a couple of system wide and user specific standard locations for a license file.

6. Change to the GAMS system directory and run the program `./gamsinst`. It will prompt you for default solvers to be used for each class of models. If possible, choose solvers you have licensed since unlicensed solvers will only run in demonstration mode. These solver defaults can be changed or overridden by:

   a. rerunning `./gamsinst` and resetting the default values

   b. setting a command line default, e.g., `gams trnsport lp=soplex`

   c. an option statement in the GAMS model, e.g: `option lp=soplex;`

7. Add the GAMS system directory to your path (see below).

8. To test the installation, log in as a normal user and run a few models from your home directory, but not the GAMS system directory:

```
LP:    trnsport (objective value:  153.675)
NLP:   chenery  (objective value:  1058.9)
MIP:   bid      (optimal solution: 15210109.512)
MINLP: procsel  (optimal solution: 1.9231)
MCP:   scarfmcp (no objective function)
MPSGE: scarfmge (no objective function)
```

9. If you move the GAMS system to another directory, remember to rerun `./gamsinst`. It is also good practice to rerun `./gamsinst` when you change your license file if this has changed the set of licensed solvers.

4.7.2 Access to GAMS

To run GAMS you must be able to execute the GAMS programs located in the GAMS system directory. There are several ways to do this. Remember that the GAMS system directory in the examples below may not correspond to the directory where you have installed your GAMS system.

1. If you are using the C shell (`csh`) and its variants you can modify your `.cshrc` file by adding the line

```
set path = ( $path /opt/gams/gams24.3_linux_x64_64_sfx )
```

2. Those of you using the Bourne (`sh`) or Korn (`ksh`) shells and their variants can modify their `.profile` or `.bashrc` file by adding the line

   ```
   PATH=$PATH:/opt/gams/gams24.3_linux_x64_64_sfx
   ```

   If neither `.profile` nor `.bashrc` exist yet, `.profile` needs to be created. You should log out and log in again after you have made any changes to your path.

3. You may prefer to use an alias for the names of the programs instead of modifying the path as described above. C shell users can use the following commands on the command line or in their `.cshrc` file:

   ```
   alias gams /opt/gams/gams24.3_linux_x64_64_sfx/gams
   alias gamslib /opt/gams/gams24.3_linux_x64_64_sfx/gamslib
   ```

   The correct Bourne or Korn shell syntax (either command line or `.profile`) is:

   ```
   alias gams=/opt/gams/gams24.3_linux_x64_64_sfx/gams
   alias gamslib=/opt/gams/gams24.3_linux_x64_64_sfx/gamslib
   ```

   Again, you should log out and log in in order to put the alias settings in `.cshrc` or `.profile` into effect.

4. Casual users can always type the absolute path names of the GAMS programs, e.g.:

   ```
   /opt/gams/gams24.3_linux_x64_64_sfx/gams trnsport
   ```

4.8 Installation Notes for Windows

4.8.1 Installation

1. Run `windows_x64_64.exe` (Windows 64bit): This file is available from https://www.gams.com/latest. Please note that the installation may require administrative privileges on your machine.

   You have two options to run the installer: In default or advanced mode. In the default mode, the installer will prompt you for the name of the directory in which to install GAMS. We call this directory the `GAMS directory`. You may accept the default choice or pick another directory. Please remember: if you want to install two different versions of GAMS, they must be in separate directories.

   If you choose to use the advanced mode, the installer will also ask you for a name of a start menu folder, if GAMS should be installed for all users, if the `GAMS directory` should be added to the `PATH` environment variable and which desktop icons should be created.

   The `GAMS License` page allows to select a GAMS license. The installer tries to find GAMS licenses in different locations and automatically selects a license to be used with the following precedence:

   - Clipboard
   - `C:\Users\username\Documents\GAMS`
   - Previous GAMS installation found from the registry (User)
   - Previous GAMS installation found from the registry (System)

In addition it is possible to browse for a license file (`gamslice.txt`) or to skip all license related actions (`No License`) and install one after the installation process. Note that the use of GAMS requires a license. A free demo license can be requested at https://www.gams.com/download. A license file is written to `C:\Users\username\Documents\GAMS` when installing for `Current User` (default). Installing for `All Users` or checking `Write License to System Directory` will write the license to the GAMS system directory instead.

For automating the installation of GAMS, it is possible to provide the command line parameters `/SP- /SILENT`. This will install GAMS in a non-interactive manner using default settings. Note that depending on the security settings, the User Account Control asking for permission might still be active. The following command line parameters are available to further customize the non-interactive installation:

- `/installAllUsers=yes|no` (default:`no`): Can be used in order to install for `All Users` instead of `Current User`.
- `/noLicense=yes|no` (default:`no`): Can be used in order to prevent any GAMS license from being written.
- `/noIcons` can be used in order to check the `Don't create a Start Menu folder` checkbox on the `Select Start Menu Folder` page.
- `/desktopIcons=yes|no` (default:`undef`) can be used in order to turn on/off the creation of Desktop icons. The default (`undef`) is to create a desktop icon for `GAMS Studio` but not for `GAMS IDE`.
- `/allUsers`: Perform installation in administrative install mode.
- `/currentUser`: Perform installation in non administrative install mode. If specified, `/installAllUsers=yes` has no effect.

Attention

Under Windows 10 the Windows Installer package may not update system environment variables. To work around this issue, log off of Windows after the installation, and then log on again.

Note

The installer can be run unattended with the switches `/SILENT` or `/VERYSILENT` and might require some post installation task (like copying the license file to an appropriate location). This unattended mode also skips execution of some code in the installer that can cause failures on exotically configured systems.

2. During the installation of GAMS, the setup process helps in setting up the license to be used with GAMS. In case no license has been selected during this process it is required to set this up manually. The license file is nowadays sent via email, with instructions. You can also request a demo license from https://www.gams.com/download. If you don't have a license file yet, choose `No license` when asked for the GAMS license options. You can install a license later by either manually creating the license file `gamslice.txt` in a directory GAMS searches to find a license or use the corresponding GAMS Studio dialog.

   GAMS searches a couple of system wide and user specific standard locations for a license file.

3. Choose the default solvers: Run GAMS Studio by double clicking `studio.exe` from the GAMS system subdirectory `Studio`. To view or edit the default solvers, open the GAMS Configuration Editor in Studio. You can also skip this and thus accept the existing defaults if you wish, but most users want to select new default solvers for each model type.

4. Run a few models to test the GAMS system: The Model Library Explorer allows you to pick some models from the GAMS model library easily. After selecting one, press `F9` to run it, and view the solution. To test your installation, run the following models from the GAMS model library:

```
LP:    trnsport (objective value:  153.675)
NLP:   chenery  (objective value:  1058.9)
```

```
MIP:   bid      (optimal solution: 15210109.512)
MINLP: procsel  (optimal solution: 1.9231)
MCP:   scarfmcp (no objective function)
MPSGE: scarfmge (no objective function)
```

4.8.2 Visual C++ Redistributable Dependency

- Some solvers in the system as well as GAMS Studio have dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio or when solving a model, please run the installer `vcredist_x64.exe` for these libraries, which can be found in the GAMS installation folder in directory `[GAMS system]\studio`.

4.8.3 Command Line Use of GAMS

Users wishing to use GAMS from the command line (aka the console mode) may want to perform the following steps. These steps are not necessary to run GAMS via Studio.

1. We recommend to add the GAMS directory to your environment path in order to avoid having to type in an absolute path name each time you run GAMS. Run the installer in advanced mode and mark the check-box `Add GAMS directory to PATH environment variable`.

2. Run the program `gamsinst`: `gamsinst` is a command line program used to configure GAMS. It prompts the user for default solvers to be used for each model type. If possible, choose solvers you have licensed, since unlicensed solvers will only run in demonstration mode. The solver defaults can be changed by:

   a. rerunning `gamsinst` and resetting the default values

   b. setting a command line default, e.g. `gams trnsport lp=soplex`

   c. by an option statement in the GAMS model, e.g: `option lp=soplex;`

   The system wide solver defaults are shared by the command line and GAMS Studio, so you can also choose to set these defaults using GAMS Studio.

4.8.4 Warning from Microsoft SmartScreen Filter

The SmartScreen is a feature that is used in several Microsoft products, including the Internet Explorer, Microsoft Edge, as well as in Windows 8 and newer versions of Windows. It is supposed to help to protect your computer against unwanted software. It uses a reputation-based system to rate files downloaded from the internet. That means that a file gets a better reputation when it gets download more often. As a result you might get a warning like this, especially for GAMS distributions that were recently released:

clicking on “More info” will display an option to continue the installation process.

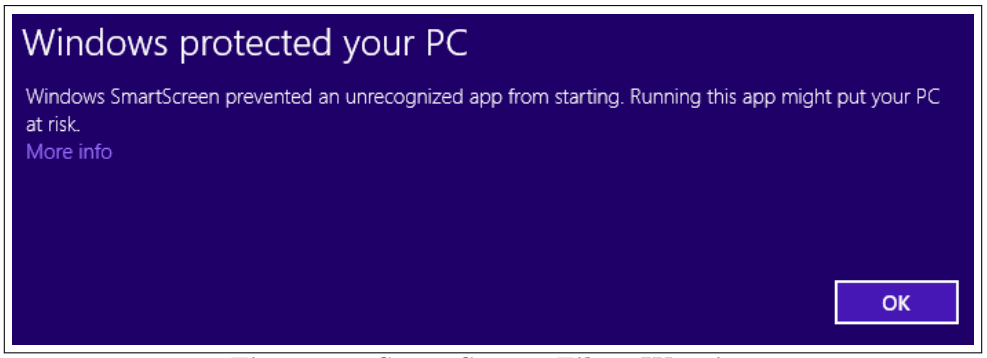

Figure 4.1 SmartScreen Filter Warning

4.9 Standard Locations

GAMS looks for specific files in some system-wide and user-specific locations which are independent of the GAMS installation. This allows the user to store these files in one place without the need to adjust anything when moving from one GAMS version to another. These folders are referred to as *standard locations* and are split into two groups: *configuration directories* and *data directories*. Here are some examples of files, which will be found in the data directories (or subfolders of these):

- The GAMS license file
- LibInclude files
- External Equation libraries
- Extrinsic Function libraries

The GAMS configuration file is expected in one of the configuration directories.

The exact location depends on the operating system used and user specific settings. Running `gamsinst -listdirs` on the command line shows the folders searched explicitly.

4.9.1 Standard Locations on macOS

4.9.1.1 Configuration Directories

These folders get searched on macOS (in the listed order):

- The GAMS system directory
- The subfolder `GAMS` in `$HOME/Library/Preferences` (`$HOME` usually contains the user's home directory)

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
  /Users/JaneDoe/GAMS32
  /Users/JaneDoe/Library/Preferences/GAMS
```

4.9.1.2 Data Directories

These folders get searched on macOS (in the listed order):

- The subfolder `GAMS` in `$HOME/Library/Application Support` (`$HOME` usually contains the user's home directory)
- The subfolder `GAMS` in `/Library/Application Support`
- The subfolder `Resources` next to the GAMS system directory
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
  /Users/JaneDoe/Library/Application Support/GAMS
  /Library/Application Support/GAMS
  /Users/JaneDoe/Resources
  /Users/JaneDoe/GAMS32
```

4.9.2 Standard Locations on Unix

4.9.2.1 Configuration Directories

On Unix the environment variables `XDG_CONFIG_HOME` and `XDG_CONFIG_DIRS` (see XDG Base Directory Specification) influence the search directories. These folders get searched on Unix (in the listed order):

- The GAMS system directory
- The subfolder `GAMS` of folders from `$XDG_CONFIG_DIRS` or the subfolder `GAMS` in `/etc/xdg`
- The folder `$XDG_CONFIG_HOME` or the subfolder `GAMS` in `$HOME/.config` (`$HOME` usually contains the user's home directory)

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
  /home/JohnDoe/GAMS32
  /etc/xdg/GAMS
  /home/JohnDoe/.config/GAMS
```

4.9.2.2 Data Directories

On Unix the environment variables `XDG_DATA_HOME` and `XDG_DATA_DIRS` (see XDG Base Directory Specification) influences the search directories. These folders get searched on Unix (in the listed order):

- The folder `$XDG_DATA_HOME` or the subfolder `GAMS` in `$HOME/.local/share` (`$HOME` usually contains the user's home directory)
- The subfolder `GAMS` of folders from `$XDG_DATA_DIRS` or the subfolder `GAMS` in `/usr/local/share` and the subfolder `GAMS` in `/usr/share`
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
  /home/JohnDoe/.local/share/GAMS
  /usr/local/share/GAMS
  /usr/share/GAMS
  /home/JohnDoe/GAMS32
```

4.9.3 Standard Locations on Windows

4.9.3.1 Configuration Directories

These folders get searched on Windows (in the listed order):

- The GAMS system directory
- The subfolder `GAMS` in `C:\ProgramData`
- The subfolder `GAMS` in `AppData\Local` in the User's directory
- The subfolder `GAMS` in `Documents` in the User's directory

Here is an example output of `gamsinst -listdirs`:

```
Config directories (searched for e.g. gamsconfig.yaml):
  C:\GAMS\32
  C:\ProgramData\GAMS
  C:\Users\JohnDoe\AppData\Local\GAMS
  C:\Users\JohnDoe\Documents\GAMS
```

4.9.3.2 Data Directories

These folders get searched on Windows (in the listed order):

- The subfolder `GAMS` in `Documents` in the User's directory
- The subfolder `GAMS` in `AppData\Roaming` in the User's directory
- The subfolder `GAMS` in `C:\ProgramData`
- The subfolder `data` in the GAMS system directory
- The subfolder `data\GAMS` in the GAMS system directory
- The GAMS system directory

Here is an example output of `gamsinst -listdirs`:

```
Data directories (searched for e.g. gamslice.txt):
  C:\Users\JohnDoe\Documents\GAMS
  C:\Users\JohnDoe\AppData\Roaming\GAMS
  C:\ProgramData\GAMS
  C:\GAMS\32\data
  C:\GAMS\32\data\GAMS
  C:\GAMS\32
```

Note: When running as a service, the "User's directory" mentioned above is not `C:\Users\UserName` but resolves to something like `C:\Windows\system32\config\systemprofile`. So the above output could look like this:

```
Data directories (searched for e.g. gamslice.txt):
  C:\Windows\system32\config\systemprofile\Documents\GAMS
  C:\Windows\system32\config\systemprofile\AppData\Roaming\GAMS
  C:\ProgramData\GAMS
  C:\GAMS\32\data
  C:\GAMS\32\data\GAMS
  C:\GAMS\32
```

4.10 Licensing

4.10.1 General Information

The GAMS system and all connected solvers can be downloaded from the GAMS website at https://www.gams.com/download. The use of the software is governed by the GAMS End User License Agreement, which is available on our website and can also be found in the GAMS System directory (eula.pdf). Without a valid GAMS license the system will not run and produces the following output:

```
*** No license specified and no gamslice.txt found in standard locations.
```

A free demo license time-limited for 5 months is included with the GAMS distribution. The demo license lets you generate and solve small models, see also Additional Limits for the Demo and Community License. On expiration you need to update your GAMS system (that comes with a new demo license) or request a demo license time-limited for 12 months at https://www.gams.com/download. Please note, a valid free demo license requires a recent GAMS version (not older than 18 months). The demo license of MIRO connector allows up to 10 indexed input and output symbols.

GAMS will terminate with an error message, if it hits one of the limits above:

```
*** Status: Terminated due to a licensing error
***         Inspect listing file for more information
```

When the time-limited demo license expires you need to update your GAMS system or request a new demo license at https://www.gams.com/download. Moreover, a valid free demo license requires a recent GAMS version (not older than 18 months).

4.10.2 GAMS Community License

Users can request a free community license from community@gams.com. The community license lets you generate and solve linear models (LP, MIP, and RMIP) that do not exceed 5000 variables and 5000 constraints. For all other model types the model cannot be larger than 2500 variables and 2500 constraints. Restrictions you experience with the demo license, i.e. additional limits enforced by some solvers, time-limitation of 12 months, and a recent GAMS system also apply to the community license. The free demo and community license cannot be combined with a professional license. These free demo and community licenses are for demonstration and evaluation but not for commercial and production work.

4.10.3 GAMS Licenses

GAMS licenses beyond the free demo and community license require a license for the GAMS Base Module and for most of the GAMS/Solvers and the GAMS/Solver-Links:

- The **GAMS Base Module** includes the GAMS Language Compiler, GAMS-APIs, many utilities, some solvers without size restrictions, and most solvers in "demo" mode with a model size limitation. See details below.
- A **GAMS/Solver** connects the GAMS Base module to a particular solver and includes a license for this solver to be used through GAMS. It is not necessary to install additional software. A **GAMS/Solver-Link** connects the GAMS Base Module to a particular solver, but does not include a license for the solver. It may be necessary to install additional software before the solver can be used.

We distinguish between academic and commercial licenses. Academic licenses can only be used for teaching and research at degree granting institutions. Moreover, we distinguish between time-limited and perpetual licenses. For perpetual licenses the first year of maintenance, support and updates is included in the initial purchase of the software. Maintained licenses qualify for free updates, adding components, platform-switching without additional charge, and multi-copy discounts on the same platform. After the first year maintenance can be extended by paying a fee. Licenses are typically limited to a single computer platform type (e.g. Windows or Linux), but there are also licenses available, which will work on all major platform supported by GAMS. Free academic licenses are available for certain solvers. Please visit the GAMS website for further information about the pricing of an appropriate license.

4.10.4 Installing or updating a license file

A GAMS license file is an ASCII file of six lines, which was sent to you via e-mail. Please copy all six lines into a file gamslice.txt and place this into a location searched by GAMS. Details can be found in the installation notes of the specific operating system:

- GAMS Installation Notes for Windows
- GAMS Installation Notes for macOS
- GAMS Installation Notes for Unix

Before installing a new GAMS version, please check whether it will work with your current GAMS license. The "Check for Update" functionality of GAMS Studio can be used to see if a newer GAMS version is available and what the newest version is that can be used with a given license.

Below is a sample output for a license, which is still under maintenance:

```
*** Processing GAMS system directory C:\gams\win64\24.8
*** Reading license file C:\ProgramData\GAMS\gamslice.txt
*** Your system is up to date
```

If your license is no longer under maintenance, you will receive a message like the one below:

```
*** Processing GAMS system directory C:\GAMS\win64\23.9
*** Reading license file C:\ProgramData\GAMS\gamslice.txt
*** Your license is 1276 days too old to run with the most recent system
*** The version of your GAMS system is 23.9.5
*** The last GAMS version you can use is 24.1.3
*** Please request the download of an older version from sales@gams.com
*** For ordering an update to use the most recent version (24.8.5)
*** please contact your distributor
```

4.10.5 License Problems

Errors or warnings triggered by a problem with the GAMS license file (gamslice.txt) are reported both in the log file and in the lst file. Below are some typical error and warning messages and instructions how to overcome them.

4.10.5.1 No License File present

Without a license file GAMS will not work. If you have received a license file (gamslice.txt), follow the instruction from the previous section. Do not try to rename it or to modify the contents of the license file. Without a license GAMS will give you an error message like the one below:

```
*** No license specified and no gamslice.txt found in standard locations.
```

4.10.5.2 License File Invalid or Corrupted

Running GAMS with an invalid license will give you an error message like the one below:

```
*** License File validation failed
```

Do not try to modify your license file, any change will break it. If the original license file is no longer available, please contact sales@gams.com and ask for a copy of your license file. Please attach the license file you are currently using. This error also pops up, if you are using a license file, which was issued for a different platform.

4.10.5.3 License File expired

If are trying to run an old license file with a newer GAMS distribution, you may get an error message stating:

```
*** License file too old for this version of GAMS.
*** Maintenance expired 2840 days ago.
*** More than 60 days since expiration, sorry...
*** Run an older GAMS system or renew the license
```

Replace that GAMS system with the one you got together with your license file (use the "Check for Update" utility mentioned above to find out the latest version you can use with the current license; old systems are available on request from sales@gams.com) or update your license to the current version.

4.10.5.4 No License (for a particular Solver) found

If one of the solvers you are trying to use (or is selected as the default solver) is not included in your license file and the size of the model exceed the limits of the free demo or community version, you will get an error stating:

```
*** No license found
*** To update your license, please contact your distributor.
```

Check whether the default solvers for a particular problem class are included in the license. Please note that some of the solvers call other solvers as a sub-solver, e.g.:

- GAMS/DICOPT requires an NLP and a MIP solver
- GAMS/SBB requires an NLP solver
- MPSGE: If GAMS/PATH is not included in your license, please select GAMS/MILES, which is included in the base system as the default solver for MCP problems.

4.10.6 Warnings

4.10.6.1 License file too old for this version of GAMS

The complete message is:

```
*** License file too old for this version of GAMS.
*** Maintenance expired xx days ago.
```

If GAMS continues working, you can ignore this warning. However, any forthcoming GAMS distribution will most likely not work, but downgrade to the limits of the free demo system.

4.10.6.2 License File has expired xx days ago

This warning (without further error messages) indicates that the time limited license (e.g. an evaluation license) will stop working soon.

4.10.7 The GAMS/BASE Module

The GAMS/BASE module includes:

- **Language Compiler and Execution System**
- GAMS IDE**(Integrated Development Environment) (Windows only)**
  - Project Management
  - Editor, Syntax coloring, Spell checking
  - Launching and monitoring of (multiple) GAMS processes
  - Listing file / Tree view / Syntax-error navigation
  - Solver selection / option selection
  - GDX Viewer: Data cube and export (e.g. to MS Excel), charting facilities
- **GAMS Studio (platform independent, Beta version)**
  - Editor, Syntax coloring
  - Launching and monitoring of (multiple) GAMS processes
  - Listing file / Tree view / Syntax-error navigation
  - GDX Viewer
- **GAMS Free Solvers and Links**
  - Open Source (COIN-OR): CBC, Ipopt, SHOT
  - CONVERT, JAMS and LOGMIP, NLPEC
  - MILES
  - EXAMINER, GAMSCHK
  - Academic licenses only: ODHeuristic (requires a GAMS/CPLEX or GAMS/CPLEX-Link license), SCIP, Soplex
  - GAMS/KESTREL for using the NEOS Server with a local GAMS system

- **Most other solvers in limited versions for demonstration and evaluation, but no commercial use:** 2000 constraints and variables for linear models, and 1000 constraints and variables for other model types. For licensed academic users the size limits are increased: 5000 constraints and variables for linear models, and 2500 constraints and variables for other model types. The solvers might enforce additional limits.
- **EMP (Extended Mathematical Programming Framework)**
- **Posix Utilities**
- Academic licenses only: **MIRO Connector** for using external input and output symbols.
- **GDX (GAMSData eXchange) and related GDX Utilities**
  - Binary data exchange between application, GAMS, and the solver (fast, saves disk space, tailored for large sparse matrices, platform independent, direct GDX interfaces, API support for high-level programming languages)
  - GDX Utilities: GDX Viewer, GDXMERGE, GDXDUMP, GDXCOPY, GDXDIFF, MDB2GMS, GDXMRW, GDXRRW, GDXXRW, GDX2XLS, XLSDump
- **Various other tools**
- GAMS APIs
  - Expert-Level GAMS APIs
    - GAMS
    - GDX
    - Option
    - Supported Languages: C, C++, C#, Delphi, Fortran, Java, Python, VBA, VB.Net
  - Object-Oriented GAMS APIs
    - Supported Languages: C++, C#, Java, Python, VB.Net
- **Documentation**
- **Model Libraries**

4.10.8 Additional Limits for the Demo and Community License

The model size limits enforced by GAMS are:

- 2000 variables and 2000 constraints for linear (LP, RMIP, and MIP) models with a demo license
- 1000 variables and 1000 constraints for all other model types with a demo license
- 5000 variables and 5000 constraints for linear (LP, RMIP, and MIP) models with a community license
- 2500 variables and 2500 constraints for all other model types with a community license

In addition to the GAMS model size limits, the solvers might impose stricter limits when running with a demo or community license. We use m for the number constraints, n for the number variables, nd for the number of discrete variables, nz for the number nonzeros, and $nlnz$ for the number nonlinear nonzeros:

- Antigone, Baron, and LindoGlobal require $m \leq 50$, $n \leq 50$, and $nlnz \leq 50$ with a demo license.
- Antigone, Baron, and LindoGlobal require $m \leq 300$, $n \leq 300$, and $nlnz \leq 100$ with a community license.
- Cplex and ODHCPLEX require $m \leq 2000$ and $n \leq 2000$ with a *pro-bono* community license.
- Decis and Knitro require $m \leq 300$, $n \leq 300$, $nd \leq 50$, $nz \leq 2000$, and $nlnz \leq 1000$ with a demo and community license.
- Xpress requires $m+n \leq 5000$ with a community license.
- In addition Gurobi requires a license file from the vendor to operate.

4.11 A GAMS Tutorial by Richard E. Rosenthal

4.11.1 Introduction

Richard E. Rosenthal of the Naval Postgraduate School in Monterey, California wrote a detailed example of the use of GAMS for formulating, solving, and analyzing a small and simple optimization problem. The example is a quick overview of GAMS and its main features. Many references are made to other parts of the documentation, but they are only to tell you where to look for more details; the material here can be read profitably without reference to the rest of the documentation.

The example is an instance of the transportation problem of linear programming, which has historically served as a *'laboratory animal'* in the development of optimization technology. [See, for example, Dantzig (1963) [1].] It is a good choice for illustrating the power of algebraic modeling languages like GAMS because the transportation problem, no matter how large the instance at hand, possesses a simple, exploitable algebraic structure. You will see that almost all of the statements in the GAMS input file we are about to present would remain unchanged if a much larger transportation problem were considered.

In the familiar transportation problem, we are given the supplies at several plants and the demands at several markets for a single commodity, and we are given the unit costs of shipping the commodity from plants to markets. The economic question is: how much shipment should there be between each plant and each market so as to minimize total transport cost?

The algebraic representation of this problem is usually presented in a format similar to the following.

Indices:

i = plants
j = markets

Given Data:

a_i = supply of commodity of plant i (in cases)
b_j = demand for commodity at market j
c_{ij} = cost per unit shipment between plant i and market j

Decision Variables:

x_{ij} = amount of commodity to ship from plant i to market j
where $x_{ij} \geq 0$, for all i, j

Constraints:

Observe supply limit at plant i: $\sum_j x_{ij} \leq a_i$ for all i (cases)
Satisfy demand at market j: $\sum_i x_{ij} \geq b_j$ for all j (cases)
Objective Function: Minimize $\sum_i \sum_j c_{ij} x_{ij}$ ($K)

[1] Dantzig, George B. (1963). *Linear Programming and Extensions*, Princeton University Press, Princeton N.J.

Note that this simple example reveals some modeling practices that we regard as good habits in general and that are consistent with the design of GAMS. First, all the entities of the model are identified (and grouped) by type. Second, the ordering of entities is chosen so that no symbol is referred to before it is defined. Third, the units of all entities are specified, and, fourth, the units are chosen to a scale such that the numerical values to be encountered by the optimizer have relatively small absolute orders of magnitude. (The symbol $K here means thousands of dollars.)

The names of the types of entities may differ among modelers. For example, economists use the terms *exogenous variable* and *endogenous variable* for *given data* and *decision variable*, respectively. In GAMS, the terminology adopted is as follows: indices are called `sets`, given data are called `parameters`, decision variables are called `variables`, and constraints and the objective function are called `equations`.

The GAMS representation of the transportation problem closely resembles the algebraic representation above. The most important difference, however, is that the GAMS version can be read and processed by a computer.

Table 1: Data for the transportation problem (adapted from Dantzig, 1963) illustrates Shipping Distances from Plants to Markets (1000 miles) as well as Market Demands and Plant Supplies.

Plants ↓	**New York**	**Chicago**	**Topeka**	←***Markets***
Seattle	2.5	1.7	1.8	350
San Diego	2.5	1.8	1.4	600
Demands →	325	300	275	*Supplies* ↑

As an instance of the transportation problem, suppose there are two canning plants and three markets, with the data given in table Table 1. Shipping distances are in thousands of miles, and shipping costs are assumed to be $90.00 per case per thousand miles. The GAMS representation of this problem is as follows:

```
$title a transportation model
Sets
     i   canning plants   / seattle, san-diego /
     j   markets          / new-york, chicago, topeka / ;

Parameters

     a(i)  capacity of plant i in cases
       /    seattle     350
            san-diego   600  /

     b(j)  demand at market j in cases
       /    new-york    325
            chicago     300
            topeka      275  / ;

Table d(i,j)  distance in thousands of miles
                  new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;

Scalar f  freight in dollars per case per thousand miles  /90/ ;

Parameter c(i,j)  transport cost in thousands of dollars per case ;

          c(i,j) = f * d(i,j) / 1000 ;

Variables
```

```
     x(i,j)  shipment quantities in cases
     z       total transportation costs in thousands of dollars ;

Positive Variable x ;

Equations
     cost        define objective function
     supply(i)   observe supply limit at plant i
     demand(j)   satisfy demand at market j ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;

supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;

demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;

Display x.l, x.m ;
```

If you submit a file containing the statements above as input to GAMS , the transportation model will be formulated and solved. Details vary on how to invoke GAMS on different of computers, but the simplest ('*no frills*') way to call GAMS is to enter the word GAMS followed by the input file's name. You will see a number of terse lines describing the progress GAMS is making, including the name of the file onto which the output is being written. When GAMS has finished, examine this file, and if all has gone well the optimal shipments will be displayed at the bottom as follows.

```
             new-york      chicago       topeka
seattle        50.000      300.000
san-diego     275.000                   275.000
```

You will also receive the marginal costs (simplex multipliers) below.

```
              chicago       topeka
seattle                      0.036
san-diego       0.009
```

These results indicate, for example, that it is optimal to send nothing from Seattle to Topeka, but if you insist on sending one case it will add .036 $K (or $36.00) to the optimal cost.

4.11.2 Structure of a GAMS Model

For the remainder of the tutorial, we will discuss the basic components of a GAMS model, with reference to the example above. The basic components are listed in table Table 2.

Table 2: The basic components of a GAMS model

Type	Component
Inputs	Sets Declaration Assignment of members
	Data (`Parameters, Tables, Scalars`) Declaration Assignment of values
	Variables Declaration Assignment of type
	Assignment of Variable Bounds and/or Initial Values (optional)
	Equations Declaration Definition
	Model and Solve Statements
	Display Statements (optional)
Outputs	Echo Prints
	Reference Maps
	Equation Listings
	Status Reports
	Solution Reports

There are optional input components, such as edit checks for bad data and requests for customized reports of results. Other optional advanced features include saving and restoring old models, and creating multiple models in a single run, but this tutorial will discuss only the basic components.

Before treating the individual components, we give a few general remarks.

1. A GAMS model is a collection of statements in the GAMS Language. The only rule governing the ordering of statements is that an entity of the model cannot be referenced before it is declared to exist.
2. GAMS statements may be laid out typographically in almost any style that is appealing to the user. Multiple lines per statement, embedded blank lines, and multiple statements per line are allowed. You will get a good idea of what is allowed from the examples in this tutorial, but precise rules of the road are given in the next Chapter.
3. When you are a beginning GAMS user, you should terminate every statement with a semicolon, as in our examples. The GAMS compiler does not distinguish between upper-and lowercase letters, so you are free to use either.
4. Documentation is crucial to the usefulness of mathematical models. It is more useful (and most likely to be accurate) if it is embedded within the model itself rather than written up separately. There are at least two ways to insert documentation within a GAMS model. First, any line that starts with an asterisk in column 1 is disregarded as a comment line by the GAMS compiler. Second, perhaps more important, documentary text can be inserted within specific GAMS statements.
5. As you can see from the list of input components above, the creation of GAMS entities involves two steps: a declaration and an assignment or definition. *Declaration* means declaring the existence of something and giving it a name. *Assignment* or *definition* means giving something a specific value or form. In the case of equations, you must make the declaration and definition in separate GAMS statements. For all other GAMS entities, however, you have the option of making declarations and assignments in the same statement or separately.
6. The names given to the entities of the model must start with a letter and can be followed by up to 62 more letters or digits.

4.11.3 Sets

Sets are the basic building blocks of a GAMS model, corresponding exactly to the indices in the algebraic representations of models. The Transportation example above contains just one `Set` statement:

```
Sets
     i   canning plants   / seattle, san-diego /
     j   markets          / new-york, chicago, topeka / ;
```

The effect of this statement is probably self-evident. We declared two sets and gave them the names `i` and `j`. We also assigned members to the sets as follows:

i = {Seattle, San Diego}
j = {New York, Chicago, Topeka}.

You should note the typographical differences between the GAMS format and the usual mathematical format for listing the elements of a set. GAMS uses slashes '/' rather than curly braces '{}' to delineate the set. Note also that multiword names like 'New York' have to be quoted ((e.g. 'New York' or "New York") or you must use hyphens instead of blanks (e.g. New-York').

The words after the set names in the `sets` statement above are called *text*. Text is optional. It is there only for internal documentation, serving no formal purpose in the model. The GAMS compiler makes no attempt to interpret the text, but it saves the text and '*parrots*' it back to you at various times for your convenience.

It was not necessary to combine the creation of sets i and j in one statement. We could have put them into separate statements as follows:

```
Set    i   canning plants   / seattle, san-diego / ;
Set    j   markets          / new-york, chicago, topeka / ;
```

The placement of blank spaces and lines (as well as the choice of upper- or lowercase) is up to you. Each GAMS user tends to develop individual stylistic conventions. (The use of the singular `set` is also up to you. Using `set` in a statement that makes a single declaration and `sets` in one that makes several is good English, but GAMS treats the singular and plural synonymously.)

A convenient feature to use when you are assigning members to a set is the asterisk. It applies to cases when the elements follow a sequence. For example, the following are valid `set` statements in GAMS.

```
Set    t   time periods         /1991*2000/;
Set    m   machines             /mach1*mach24/;
```

Here the effect is to assign

t = {1991,1992,1993, ..., 2000}
m = {mach $_1$, mach $_2$,....., mach $_{24}$ }.

Note that set elements are stored as character strings, so the elements of t are not numbers.

Another convenient feature is the alias statement, which is used to give another name to a previously declared set. In the following example:

```
Alias (t,tp);
```

the name `tp` is like a t' in mathematical notation. It is useful in models that are concerned with the interactions of elements within the same set.

The sets `i`, `j`, `t`, and `m` in the statements above are examples of static sets, i.e., they are assigned their members directly by the user and do not change. GAMS has several capabilities for creating dynamic sets, which acquire their members through the execution of set-theoretic and logical operations. Dynamic sets are discussed in chapter Dynamic Sets. Another valuable advanced feature is multidimensional sets, which are discussed in section Multi-Dimensional Sets.

4.11.4 Data

The GAMS model of the transportation problem demonstrates three of the different formats that are allowable for entering data. The three formats are:

- Lists
- Tables
- Direct assignments

The next three subsections will discuss each of these formats in turn.

4.11.4.1 Data Entry by Lists

The first format is illustrated by the first Parameters statement of the example, which is repeated below.

```
Parameters

     a(i)  capacity of plant i in cases
       /    seattle     350
            san-diego   600  /

     b(j)  demand at market j in cases
       /    new-york    325
            chicago     300
            topeka      275  / ;
```

This statement has several effects. Again, they may be self-evident, but it is worthwhile to analyze them in detail. The statement declares the existence of two parameters, gives them the names `a` and `b`, and declares their *domains* to be `i` and `j`, respectively. (A domain is the set, or tuple of sets, over which a parameter, variable, or equation is defined.) The statement also gives documentary text for each parameter and assigns values of `a(i)` and `b(j)` for each element of `i` and `j`. It is perfectly acceptable to break this one statement into two, if you prefer, as follows.

```
Parameters a(i)  capacity of plant i in cases
     / seattle     350
       san-diego   600  / ;

Parameters b(j)  demand at market j in cases
    / new-york    325
      chicago     300
      topeka      275  / ;
```

Here are some points to remember when using the list format.

1. The list of domain elements and their respective parameter values can be laid out in almost any way you like. The only rules are that the entire list must be enclosed in slashes and that the element-value pairs must be separated by commas or entered on separate lines.

2. There is no semicolon separating the element-value list from the name, domain, and text that precede it. This is because the same statement is being used for declaration and assignment when you use the list format. (An element-value list by itself is not interpretable by GAMS and will result in an error message.)

3. The GAMS compiler has an unusual feature called domain checking, which verifies that each domain element in the list is in fact a member of the appropriate set. For example, if you were to spell 'Seattle' correctly in the statement declaring `Set i` but misspell it as 'Seatle' in a subsequent element-value list, the GAMS compiler would give you an error message that the element 'Seatle' does not belong to the set `i`.

4. Zero is the default value for all parameters. Therefore, you only need to include the nonzero entries in the element-value list, and these can be entered in any order.

5. A scalar is regarded as a parameter that has no domain. It can be declared and assigned with a `Scalar` statement containing a *degenerate* list of only one value, as in the following statement from the transportation model.

```
Scalar f freight in dollars per case per thousand miles /90/;
```

If the domain of a parameter has two or more dimensions, it can still have its values entered by the list format. This is very useful for entering arrays that are sparse (having few non-zeros) and super-sparse (having few distinct non-zeros).

4.11.4.2 Data Entry by Tables

Optimization practitioners have noticed for some time that many of the input data for a large model are derived from relatively small tables of numbers. Thus, it is very useful to have the table format for data entry. An example of a two-dimensional table (or matrix) is provided in the transportation model:

```
Table d(i,j)  distance in thousands of miles
                  new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;
```

The effect of this statement is to declare the parameter `d` and to specify its domain as the set of ordered pairs in the Cartesian product of `i` and `j`. The values of `d` are also given in this statement under the appropriate heading. If there are blank entries in the table, they are interpreted as zeroes.

As in the list format, GAMS will perform domain checking to make sure that the row and column names of the table are members of the appropriate sets. Formats for entering tables with more columns than you can fit on one line and for entering tables with more than two dimensions are given in Chapter Data Entry: Parameters, Scalars and Tables.

4.11.4.3 Data Entry by Direct Assignment

The direct assignment method of data entry differs from the list and table methods in that it divides the tasks of parameter declaration and parameter assignment between separate statements. The transportation model contains the following example of this method.

```
Parameter c(i,j)  transport cost in thousands of dollars per case ;
          c(i,j) = f * d(i,j) / 1000 ;
```

It is important to emphasize the presence of the semicolon at the end of the first line. Without it, the GAMS compiler would attempt to interpret both lines as parts of the same statement. (GAMS would fail to discern a valid interpretation, so it would send you an error message.)

The effects of the first statement above are to declare the parameter `c`, to specify the domain `(i,j)`, and to provide some documentary text. The second statement assigns to `c(i,j)` the product of the values of the parameters `f` and `d(i,j)`. Naturally, this is legal in GAMS only if you have already assigned values to `f` and `d(i,j)` in previous statements.

The direct assignment above applies to all `(i,j)` pairs in the domain of `c`. If you wish to make assignments for specific elements in the domain, you enclose the element names in quotes. For example,

```
c('Seattle','New-York')  = 0.40;
```

is a valid GAMS assignment statement.

The same parameter can be assigned a value more than once. Each assignment statement takes effect immediately and overrides any previous values. (In contrast, the same parameter may not be declared more than once. This is a GAMS error check to keep you from accidentally using the same name for two different things.)

The right-hand side of an assignment statement can contain a great variety of mathematical expressions and built-in functions. If you are familiar with a scientific programming language such as C, you will have no trouble in becoming comfortable writing assignment statements in GAMS. (Notice, however, that GAMS has some efficiencies not shared by C. For example, we were able to assign `c(i,j)` values for all `(i,j)` pairs without constructing '*loops*'.)

The GAMS standard operations and supplied functions are given later. Here are some examples of valid assignments. In all cases, assume the left-hand-side parameter has already been declared and the right-hand-side parameters have already been assigned values in previous statements.

```
csquared       = sqr(c);
e              = m*csquared;
w              = 1/lamda;
eoq(i)         = sqrt( 2*demand(i)*ordcost(i)/holdcost(i));
t(i)           = min(p(i), q(i)/r(i), log(s(i)));
euclidean(i,j) = qrt(sqr(xi(i) - xi(j) + sqr(x2(i) - x2(j)));
present(j)     = future(j)*exp(-interest*time(j));
```

The summation and product operators to be introduced later can also be used in direct assignments.

4.11.5 Variables

The decision variables (or endogenous variables) of a GAMS-expressed model must be declared with a `Variables` statement. Each variable is given a name, a domain if appropriate, and (optionally) text. The transportation model contains the following example of a `Variables` statement.

```
Variables
    x(i,j)  shipment quantities in cases
    z       total transportation costs in thousands of dollars ;
```

This statement results in the declaration of a shipment variable for each `(i,j)` pair. (You will see in chapter Equations, how GAMS can handle the typical real-world situation in which only a subset of the `(i,j)` pairs is allowable for shipment.)

The `z` variable is declared without a domain because it is a scalar quantity. Every GAMS optimization model must contain one such variable to serve as the quantity to be minimized or maximized.

Once declared, every variable must be assigned a type. A selection of permissible types are given in table Table 3. For a full list, see section Variable Types.

Table 3 : Permissible variable types

Variable Type	*Allowed Range of Variable*
`free(default)`	$-\infty$ to $+\infty$
`positive`	0 to $+\infty$
`negative`	$-\infty$ to 0
`binary`	0 or 1
`integer`	$0, 1, \ldots, 100$ (default)

The variable that serves as the quantity to be optimized must be a scalar and must be of the `free` type. In our transportation example, `z` is kept free by default, but `x(i,j)` is constrained to non-negativity by the following statement.

```
Positive variable x ;
```

Note that the domain of `x` should not be repeated in the type assignment. All entries in the domain automatically have the same variable type.

Section The .lo, .l, .up, .m Database describes how to assign lower bounds, upper bounds, and initial values to variables

4.11.6 Equations

The power of algebraic modeling languages like GAMS is most apparent in the creation of the equations and inequalities that comprise the model under construction. This is because whenever a group of equations or inequalities has the same algebraic structure, all the members of the group are created simultaneously, not individually.

4.11.6.1 Equation Declaration

Equations must be declared and defined in separate statements. The format of the declaration is the same as for other GAMS entities. First comes the keyword, `Equations` in this case, followed by the name, domain and text of one or more groups of equations or inequalities being declared. Our transportation model contains the following equation declaration:

```
Equations
     cost        define objective function
     supply(i)   observe supply limit at plant i
     demand(j)   satisfy demand at market j ;
```

Keep in mind that the word `Equation` has a broad meaning in GAMS. It encompasses both equality and inequality relationships, and a GAMS equation with a single name can refer to one or several of these relationships. For example, `cost` has no domain so it is a single equation, but `supply` refers to a set of inequalities defined over the domain `i`.

4.11.6.2 GAMS Summation (and Product) Notation

Before going into equation definition we describe the summation notation in GAMS. Remember that GAMS is designed for standard keyboards and line-by-line input readers, so it is not possible (nor would it be convenient for the user) to employ the standard mathematical notation for summations.

The summation notation in GAMS can be used for simple and complex expressions. The format is based on the idea of always thinking of a summation as an operator with two arguments: `Sum(index of summation, summand)` A comma separates the two arguments, and if the first argument requires a comma then it should be in parentheses. The second argument can be any mathematical expression including another summation.

As a simple example, the transportation problem contains the expression

```
Sum(j, x(i,j))
```

that is equivalent to $\sum_j x_{ij}$.

A slightly more complex summation is used in the following example:

```
Sum((i,j), c(i,j)*x(i,j))
```

that is equivalent to $\sum_i \sum_j c_{ij} x_{ij}$.

The last expression could also have been written as a nested summation as follows:

```
Sum(i, Sum(j, c(i,j)*x(i,j)))
```

In section Conditional Indexed Operations, we describe how to use the dollar operator to impose restrictions on the summation operator so that only the elements of `i` and `j` that satisfy specified conditions are included in the summation.

Products are defined in GAMS using exactly the same format as summations, replacing `Sum` by `Prod`. For example,

```
prod(j, x(i, j))
```

is equivalent to: $\Pi_j x_{ij}$.

Summation and product operators may be used in direct assignment statements for parameters. For example,

```
scalar totsupply   total supply over all plants;
totsupply = sum(i, a(i));
```

4.11.6.3 Equation Definition

Equation definitions are the most complex statements in GAMS in terms of their variety. The components of an equation definition are, in order:

1. The name of the equation being defined
2. The domain
3. Domain restriction condition (optional)
4. The symbol '..'
5. Left-hand side expression
6. Relational operator: =l=, =e=, =g= or others. For a complete list, see Table Equation Types.
7. Right-hand side expression

The transportation example contains three of these statements.

```
cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;
```

Here are some points to remember.

- The power to create multiple equations with a single GAMS statement is controlled by the domain. For example, the definition for the demand constraint will result in the creation of one constraint for each element of the domain j, as shown in the following excerpt from the GAMS output.

  ```
  demand(new-york)..x(seattle,new-york) + x(san-diego,new-york)=g=325 ;
  demand(chicago).. x(seattle,chicago) + x(san-diego,chicago)  =g=300 ;
  demand(topeka)..  x(seattle,topeka) + x(san-diego,topeka)    =g=275 ;
  ```

- The key idea here is that the definition of the demand constraints is exactly the same whether we are solving the toy-sized example above or a 20,000-node real-world problem. In either case, the user enters just one generic equation algebraically, and GAMS creates the specific equations that are appropriate for the model instance at hand. (Using some other optimization packages, something like the extract above would be part of the input, not the output.)
- In many real-world problems, some of the members of an equation domain need to be omitted or differentiated from the pattern of the others because of an exception of some kind. GAMS can readily accommodate this loss of structure using a powerful feature known as the *dollar* or '*such-that*' operator, which is not illustrated here. The domain restriction feature can be absolutely essential for keeping the size of a real-world model within the range of solvability.
- The relational operators have the following meanings:

=l=	less than or equal to
=g=	greater than or equal to
=e=	equal to

- It is important to understand the difference between the symbols '=' and '=e='. The '=' symbol is used only in direct assignments, and the '=e=' symbol is used only in equation definitions. These two contexts are very different. A direct assignment gives a desired value to a parameter before the solver is called. An equation definition also describes a desired relationship, but it cannot be satisfied until after the solver is called. It follows that equation definitions must contain variables and direct assignments must not.

- Variables can appear on the left or right-hand side of an equation or both. The same variable can appear in an equation more than once. The GAMS processor will automatically convert the equation to its equivalent standard form (variables on the left, no duplicate appearances) before calling the solver.
- An equation definition may appear anywhere in the GAMS input, provided the equation and all variables and parameters to which it refers were previously declared. (Note that it is permissible for a parameter appearing in the equation to be assigned or reassigned a value after the definition. This is useful when doing multiple model runs with one GAMS input.) The equations need not be defined in the same order in which they were declared.

4.11.7 Objective Function

This is just a reminder that GAMS has no explicit entity called the *objective function*. To specify the function to be optimized, you must create a variable, which is free (unconstrained in sign) and scalar-valued (has no domain) and which appears in an equation definition that equates it to the objective function.

4.11.8 Model and Solve Statements

The word `model` has a very precise meaning in GAMS. It is simply a collection of equations. Like other GAMS entities, it must be given a name in a declaration. The format of the declaration is the keyword `model` followed by the name of the model, followed by a list of equation names enclosed in slashes. If all previously defined equations are to be included, you can enter `/all/` in place of the explicit list. In our example, there is one `model` statement:

```
model transport  /all/  ;
```

This statement may seem superfluous, but it is useful to advanced users who may create several models in one GAMS run. If we were to use the explicit list rather than the shortcut `/all/`, the statement would be written as

```
model transport / cost, supply, demand / ;
```

The domains are omitted from the list since they are not part of the equation name. The list option is used when only a subset of the existing equations comprises a specific model (or sub-model) being generated.

Once a model has been declared and assigned equations, we are ready to call the solver. This is done with a `solve` statement, which in our example is written as

```
solve transport using lp minimizing z ;
```

The format of the solve statement is as follows:

1. The key word `solve`
2. The name of the model to be solved
3. The key word `using`
4. An available solution procedure. A complete list is given below. For further details, see section Classification of Models.

Solution	Description
lp	for linear programming
qcp	for quadratic constraint programming
nlp	for nonlinear programming
dnlp	for nonlinear programming with discontinuous derivatives
mip	for mixed integer programming
rmip	for relaxed mixed integer programming
miqcp	for mixed integer quadratic constraint programming
rmiqcp	for relaxed mixed integer quadratic constraint programming
minlp	for mixed integer nonlinear programming
rminlp	for relaxed mixed integer nonlinear programming
mcp	for mixed complementarity problems
mpec	for mathematical programs with equilibrium constraints
rmpec	for relaxed mathematical program with equilibrium constraints
cns	for constrained nonlinear systems
emp	for extended mathematical programming

5. The keyword '`minimizing`' or '`maximizing`'
6. The name of the variable to be optimized

4.11.9 Display Statements

The `solve` statement will cause several things to happen when executed. The specific instance of interest of the model will be generated, the appropriate data structures for inputting this problem to the solver will be created, the solver will be invoked, and the output from the solver will be printed to a file. To get the optimal values of the primal and/or dual variables, we can look at the solver output, or, if we wish, we can request a display of these results from GAMS. Our example contains the following statement:

```
display x.l, x.m ;
```

that calls for a printout of the final levels, `x.l`, and marginal (or reduced costs), `x.m`, of the shipment variables, `x(i,j)`. GAMS will automatically format this printout in to dimensional tables with appropriate headings.

4.11.10 The .lo, .l, .up, .m Database

GAMS was designed with a small database system in which records are maintained for the variables and equations. The most important fields in each record are:

`.lo` lower bound
`.l` level or primal value
`.up` upper bound
`.m` marginal or dual value

The format for referencing these quantities is the variable or equation's name followed by the field's name, followed (if necessary) by the domain (or an element of the domain).

GAMS allows the user complete read-and write-access to the database. This may not seem remarkable to you now, but it can become a greatly appreciated feature in advanced use. Some examples of use of the database follow.

4.11.10.1 Assignment of Variable Bounds and/or Initial Values

The lower and upper bounds of a variable are set automatically according to the variable's type (`free, positive, negative, binary`, or `integer`), but these bounds can be overwritten by the GAMS user. Some examples follow.

```
x.up(i,j)    =  capacity(i,j)  ;
x.lo(i,j)    =  10.0  ;
x.up('seattle','new-york') = 1.2*capacity('seattle','new-york') ;
```

It is assumed in the first and third examples that `capacity(i,j)` is a parameter that was previously declared and assigned values. These statements must appear after the variable declaration and before the `Solve` statement. All the mathematical expressions available for direct assignments are usable on the right-hand side.

In nonlinear programming it is very important for the modeler to help the solver by specifying as narrow a range as possible between lower and upper bound. It is also very helpful to specify an initial solution from which the solver can start searching for the optimum. For example, in a constrained inventory model, the variables are `quantity(i)`, and it is known that the optimal solution to the unconstrained version of the problem is a parameter called `eoq(i)`. As a guess for the optimum of the constrained problem we enter

```
quantity.l(i)  =  0.5*eoq(i)  ;
```

(The default initial level is zero unless zero is not within the bounded range, in which case it is the bound closest to zero.)

It is important to understand that the `.lo` and `.up` fields are entirely under the control of the GAMS user. The `.l` and `.m` fields, in contrast, can be initialized by the user but are then controlled by the solver.

4.11.10.2 Transformation and Display of Optimal Values

(This section may be skipped on first reading if desired.)

After the optimizer is called via the `solve` statement, the values it computes for the primal and dual variables are placed in the database in the `.l` and `.m` fields. We can then read these results and transform and display them with GAMS statements.

For example, in the transportation problem, suppose we wish to know the percentage of each market's demand that is filled by each plant. After the solve statement, we would enter

```
parameter pctx(i,j)  perc of market j's demand filled by plant i;
pctx(i,j) =  100.0*x.l(i,j)/b(j) ;
display pctx ;
```

Appending these commands to the original transportation problem input results in the following output:

```
pctx    percent of market j's demand filled by plant I
          new-york   chicago   topeka
seattle     15.385   100.000
san-diego   84.615             100.000
```

For an example involving marginal, we briefly consider the *ratio constraints* that commonly appear in blending and refining problems. These linear programming models are concerned with determining the optimal amount of each of several available raw materials to put into each of several desired finished products. Let `y(i,j)` be the variable for the number of tons of raw material i put into finished product `j`. Suppose the *ratio constraint* is that no product can consist of more than 25 percent of one ingredient, that is,

```
y(i,j)/q(j) =l=   .25 ;
```

for all `i`, `j`. To keep the model linear, the constraint is written as

```
ratio(i,j).. y(i,j) - .25*q(j)  =l=  0.0  ;
```

rather than explicitly as a ratio.

The problem here is that `ratio.m(i,j)`, the marginal value associated with the linear form of the constraint, has no intrinsic meaning. At optimality, it tells us by at most how much we can benefit from relaxing the linear constraint to

```
y(i,j) - .25*q(j)  =l=  1.0 ;
```

Unfortunately, this relaxed constraint has no realistic significance. The constraint we are interested in relaxing (or tightening) is the nonlinear form of the ration constraint. For example, we would like to know the marginal benefit arising from changing the ratio constraint to

```
y(i,j)/q(j)  =l=  .26  ;
```

We can in fact obtain the desired marginals by entering the following transformation on the undesired marginals:

```
parameter  amr(i,j)  appropriate marginal for ratio constraint ;
amr(i,j)  =  ratio.m(i,j)*0.01*q.l(j) ;
display amr ;
```

Notice that the assignment statement for `amr` accesses both `.m` and `.l` records from the database. The idea behind the transformation is to notice that

```
y(i,j)/q(j)  =l=  .26  ;
```

is equivalent to

```
y(i,j) - .25*q(j)  =l=  0.01*q(j)  ;
```

4.11.11 GAMS Output

The default output of a GAMS run is extensive and informative. For a complete discussion, see chapter GAMS Output. This tutorial discusses output partially as follows:

- Echo Print
- Reference Maps
- Status Reports
- Error Messages
- Model Statistics
- Solution Reports

A great deal of unnecessary anxiety has been caused by textbooks and users' manuals that give the reader the false impression that flawless use of advanced software should be easy for anyone with a positive pulse rate. GAMS is designed with the understanding that even the most experienced users will make errors. GAMS attempts to catch the errors as soon as possible and to minimize their consequences.

4.11.11.1 Echo Prints

Whether or not errors prevent your optimization problem from being solved, the first section of output from a GAMS run is an echo, or copy, of your input file. For the sake of future reference, GAMS puts line numbers on the left-hand side of the echo. For our transportation example, which luckily contained no errors, the echo print is as follows:

```
 2  Sets
 3       i   canning plants   / seattle, san-diego /
 4       j   markets          / new-york, chicago, topeka / ;
 5
 6  Parameters
 7
 8       a(i)  capacity of plant i in cases
 9         /    seattle     350
10              san-diego   600  /
11
12       b(j)  demand at market j in cases
13         /    new-york    325
14              chicago     300
15              topeka      275  / ;
16
17  Table d(i,j)  distance in thousands of miles
18                     new-york       chicago      topeka
19      seattle           2.5           1.7          1.8
20      san-diego         2.5           1.8          1.4  ;
21
22  Scalar f  freight in dollars per case per thousand miles  /90/ ;
23
24  Parameter c(i,j)  transport cost in thousands of dollars per case ;
25
26            c(i,j) = f * d(i,j) / 1000 ;
27
28  Variables
```

```
29       x(i,j)  shipment quantities in cases
30       z       total transportation costs in thousands of dollars ;
31
32  Positive Variable x ;
33
34  Equations
35       cost        define objective function
36       supply(i)   observe supply limit at plant i
37       demand(j)   satisfy demand at market j ;
38
39  cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
40
41  supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
42
43  demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;
44
45  Model transport /all/ ;
46
47  Solve transport using lp minimizing z ;
48
49  Display x.l, x.m ;
50
```

The reason this echo print starts with line number 2 rather than line number 1 is because the input file contains a *dollar-print-control* statement. This type of instruction controls the output printing, but since it has nothing to do with defining the optimization model, it is omitted from the echo. The dollar print controls must start in column 1.

```
$title a transportation model
```

The `$title` statement causes the subsequent text to be printed at the top of each page of output. Other available instructions are given in chapter Dollar Control Options.

4.11.11.2 Error Messages

When the GAMS compiler encounters an error in the input file, it inserts a coded error message inside the echo print on the line immediately following the scene of the offense. These messages always start with **** and contain a '$' directly below the point at which the compiler thinks the error occurred. The $ is followed by a numerical error code, which is explained after the echo print. Several examples follow.

Example 1 : Entering the statement

```
set  q  quarterly time periods  / spring, sos1, fall, wtr / ;
```

results in the echo

```
      1  set  q  quarterly time periods  / spring, sos1, fall, wtr / ;
****                                                 $160
```

In this case, the GAMS compiler indicates that something is wrong with the set element sum. At the bottom of the echo print, we see the interpretation of error code 160:

```
Error Message
160  Unique element expected....
```

The problem is that `sos1` is a reserved word, which can not be used as identifiers in general. The complete list of reserved words is shown in this chapter. Thus our set element must have a unique name like `'summer'`. This is a common beginner's error.

Example 2 : Another common error is the omission of a semicolon preceding a direct assignment or equation definition. In our transportation example, suppose we omit the semicolon prior to the assignment of `c(i,j)`, as follows.

```
Parameter c(i,j)  transport cost in 1000s of dollars per case
c(i,j)  = f * d(i,j)  /  1000  ;
```

Here is the resulting output.

```
  16   Parameter c(i,j) transport cost in 1000s of dollars per case
  17             c(i,j)  = f * d(i,j)/1000
****                     $97       $195,96,409
Error Message
 96  Blank needed between identifier and text
       (-or- illegal character in identifier)
       (-or- check for missing ';' on previous line)
 97  Explanatory text can not start with '$', '=', or '..'
       (-or- check for missing ';' on previous line)
195  Symbol redefined with a different type
409  Unrecognizable item - skip to find a new statement
       looking for a ';' or a key word to get started again
```

It is not uncommon for one little offense like our missing semicolon to generate five intimidating error messages. The lesson here is: concentrate on fixing the first error and ignore the other! The first error detected (in line 17), code 97, indicate that GAMS thinks the symbols in line 17 are a continuation of the documentary text at the end of line 16 rather than a direct assignment as we intended. The error message also appropriately advises us to check the preceding line for a missing semicolon.

Unfortunately, you cannot always expect error messages to be so accurate in their advice. The compiler cannot read your mind. It will at times fail to comprehend your intentions, so learn to detect the causes of errors by picking up the clues that abound in the GAMS output. For example, the missing semicolon could have been detected by looking up the c entry in the cross-reference list (to be explained in the next section) and noticing that it was never assigned.

```
SYMBOL      TYPE      REFERENCES
c           PARAM     declared     15   ref   17
```

Example 3 : Many errors are caused merely by spelling mistakes and are caught before they can be damaging. For example, with `'Seattle'` spelled in the table differently from the way it was introduced in the set declaration, we get the following error message.

```
   4   sets
   5          i   canning plants  /seattle, san-diego /
   6          j   markets  /new-york, chicago, topeka /  ;
   7
   8   table d(i,j)  distance in thousand of miles
   9            new-york   chicago   topeka
  10      seattle       2.5      1.7        1.8
****         $170
  11      san-diego    2.5      1.8            1.4   ;
Error Message
170  Domain violation for element
```

Example 4 : Similarly, if we mistakenly enter `dem(j)` instead of `b(j)` as the right-hand side of the demand constraint, the result is

```
   45   demand(j)  ..   sum(i,  x(i,j)  )   =g=  dem(j)  ;
****                                          $140
    Error Message
    140  Unknown symbol
```

Example 5 : The next example is a mathematical error, which is sometimes committed by novice modelers and which GAMS is adept at catching. The following is mathematically inconsistent and, hence, is not an interpretable statement.

$$\text{For all } i, \quad \sum_i x_{ij} = 100$$

There are two errors in this equation, both having to do with the co ntrol of indices. Index i is over-controlled and index j is under-controlled.

You should see that index i is getting conflicting orders. By appearing in the quantifier '*for all i*', it is supposed to remain fixed for each instance of the equation. Yet, by appearing as an index of summation, it is supposed to vary. It can't do both. On the other hand, index j is not controlled in any way, so we have no way of knowing which of its possible values to use.

If we enter this meaningless equation into GAMS, both errors are correctly diagnosed.

```
   meaninglss(i)  ..    sum(i, x(i,j))   =e=    100 ;
****                        $125   $149
Error Messages
125  Set is under control already         [This refers to set i.]
149  Uncontrolled set entered as constant [This refers to set j.]
```

More information about error reporting is given in section Error Reporting. Comprehensive error detection and well-designed error messages are a big help in getting models implemented quickly and correctly.

4.11.11.3 Reference Maps

The next section of output, which is the last if errors have been detected, is a pair of *reference maps* that contain summaries and analyses of the input file for the purposes of debugging and documentation.

The first reference map is a *cross-reference map* such as one finds in most modern compilers. It is an alphabetical, cross-referenced list of all the entities (sets, parameters, variables, and equations) of the model. The list shows the type of each entity and a coded reference for each appearance of the entity in the input. The cross-reference map for our transportation example is as follows (we do not display all tables). To turn the *cross-reference map* on, please add the line

```
$onSymXRef
```

at the beginning of your model right after the `$title` statement.

```
SYMBOL      TYPE   REFERENCES

a            PARAM declared        9  defined       10      ref       42
b            PARAM declared       13  defined       14      ref       44
c            PARAM declared       25 assigned       27      ref       40
cost         EQU   declared       36  defined       40 impl-asn       48      ref       46
d            PARAM declared       18  defined       18      ref       27
demand       EQU   declared       38  defined       44 impl-asn       48      ref       46
f            PARAM declared       23  defined       23      ref       27
i            SET   declared        4  defined        4      ref        9       18       25       27
j            SET   declared        5  defined        5      ref       13       18       25       27
supply       EQU   declared       37  defined       42 impl-asn       48      ref       46
transport    MODEL declared       46  defined       46 impl-asn       48      ref       48
x            VAR   declared       30 impl-asn       48      ref       33       40       42       44
z            VAR   declared       31 impl-asn       48      ref       40       48
```

For example, the cross-reference list tells us that the symbol `a` is a parameter that was declared in line 9, defined (assigned value) in line 10, and referenced in line 42. The symbol `i` has a more complicated entry in the cross-reference list. It is shown to be a set that was declared and defined in line 4. It is referenced once in lines 9, 18, 25, 27, 30, 37, 44 and referenced twice in lines 40 and 44. Set `i` is also used as a controlling index in a summation, equation definition or direct parameter assignment in lines 27, 40, 42 and 44.

For the GAMS novice, the detailed analysis of the cross-reference list may not be important. Perhaps the most likely benefit he or she will get from the reference maps will be the discovery of an unwanted entity that mistakenly entered the model owing to a punctuation or syntax error.

The second part of the reference map is a list of model entities grouped by type and listed with their associated documentary text. For example, this list is as follows.

```
SETS

i             canning plants
j             markets

PARAMETERS

a             capacity of plant i in cases
b             demand at market j in cases
c             transport cost in thousands of dollars per case
d             distance in thousands of miles
f             freight in dollars per case per thousand miles

VARIABLES

x             shipment quantities in cases
z             total transportation costs in thousands of dollars

EQUATIONS

cost          define objective function
demand        satisfy demand at market j
supply        observe supply limit at plant i

MODELS

transport
```

4.11.11.4 Equation Listings

Once you succeed in building an input file devoid of compilation errors, GAMS is able to generate a model. The question remains, and only you can answer it, does GAMS generate the model you intended?

The equation listing is probably the best device for studying this extremely important question. A product of the solve command, the equation listing shows the specific instance of the model that is created when the current values of the sets and parameters are plugged into the general algebraic form of the model. For example, the generic demand constraint given in the input file for the transportation model is

```
demand(j)  ..   sum(i, x(i,j))  =g=  b(j)  ;
```

while the equation listing of specific constraints is

```
--------demand   =g=   satisfy demand at market  j
demand(new-york)..  x(seattle, new-york) +x(san-diego, new-york)  =g=  325  ;
demand(chicago)..  x(seattle, chicago) +x(san-diego, chicago )  =g=  300  ;
demand(topeka)..  x(seattle, topeka) +x(san-diego, topeka)  =g=  275 ;
```

The default output is a maximum of three specific equations for each generic equation. To change the default, insert an input statement prior to the solve statement:

```
option limrow  =  r ;
```

where `r` is the desired number.

The default output also contains a section called the column listing, analogous to the equation listing, which shows the coefficients of three specific variables for each generic variable. This listing would be particularly useful for verifying a GAMS model that was previously implemented in MPS format. To change the default number of specific column printouts per generic variable, the above command can be extended:

```
option limrow  =  r,  limcol  = c ;
```

where `c` is the desired number of columns. (Setting `limrow` and `limcol` to 0 is a good way to reduce the size of your lst file after your model has been debugged.) In nonlinear models, the GAMS equation listing shows first-order Taylor approximations of the nonlinear equations. The approximations are taken at the starting values of the variables.

4.11.11.5 Model Statistics

The last section of output that GAMS produces before invoking the solver is a group of statistics about the model's size, as shown below for the transportation example.

```
MODEL STATISTICS

BLOCKS OF EQUATIONS       3     SINGLE EQUATIONS        6
BLOCKS OF VARIABLES       2     SINGLE VARIABLES        7
NON ZERO ELEMENTS        19
```

The `BLOCK` counts refer to the number of generic equations and variables. The `SINGLE` counts refer to individual rows and columns in the specific model instance being generated. For nonlinear models, some other statistics are given to describe the degree of non-linearity in the problem.

4.11.11.6 Status Reports

After the solver executes, GAMS prints out a brief *Solve Summary* whose two most important entries are `SOLVER STATUS` and the `MODEL STATUS`. For our transportation problem the solve summary is as follows:

```
               S O L V E      S U M M A R Y

     MODEL   TRANSPORT           OBJECTIVE  z
     TYPE    LP                  DIRECTION  MINIMIZE
     SOLVER  CPLEX               FROM LINE  49

**** SOLVER STATUS     1 Normal Completion
**** MODEL STATUS      1 Optimal
**** OBJECTIVE VALUE               153.6750

 RESOURCE USAGE, LIMIT          0.031      1000.000
 ITERATION COUNT, LIMIT         4    2000000000
```

The status reports are preceded by the same **** string as an error message, so you should probably develop the habit of searching for all occurrences of this string whenever you look at an output file for the first time. The desired solver status is `1 NORMAL COMPLETION`, but there are other possibilities, documented in section The Solve Summary, which relate to various types of errors and mishaps.

There are eleven possible model statuses, including the usual linear programming termination states (`1 Optimal, 3 Unbounded, 4 Infeasible`), and others relating to nonlinear and integer programming. In nonlinear programming, the status to look for is `2 Locally Optimal`. The most the software can guarantee for nonlinear programming is a local optimum. The user is responsible for analyzing the convexity of the problem to determine whether local optimality is sufficient for global optimality. In integer programming, the status to look for is `8 Integer Solution`. This means that a feasible integer solution has been found. More detail follows as to whether the solution meets the relative and absolute optimality tolerances that the user specifies.

4.11.11.7 Solution Reports

If the solver status and model status are acceptable, then you will be interested in examining the results of the optimization. The results are first presented in as standard mathematical programming output format, with the added feature that rows and columns are grouped and labeled according to names that are appropriate for the specific model just solved. In this format, there is a line of printout for each row and column giving the lower limit, level, upper limit, and marginal. Generic equation block and the column output group the row output by generic variable block. Set element names are embedded in the output for easy reading. In the transportation example, the solver outputs for `supply(i)`, `demand(j)`, and `x(i,j)` are as follows:

```
---- EQU supply      observe supply limit at plant i

             LOWER     LEVEL     UPPER    MARGINAL

seattle       -INF    350.000   350.000      EPS
san-diego     -INF    550.000   600.000      .

---- EQU demand      satisfy demand at market j

             LOWER     LEVEL     UPPER    MARGINAL
```

```
new-york   325.000   325.000     +INF      0.225
chicago    300.000   300.000     +INF      0.153
topeka     275.000   275.000     +INF      0.126

---- VAR x           shipment quantities in cases

                       LOWER     LEVEL     UPPER    MARGINAL

seattle  .new-york       .       50.000     +INF       .
seattle  .chicago        .      300.000     +INF       .
seattle  .topeka         .         .        +INF      0.036
san-diego.new-york       .      275.000     +INF       .
san-diego.chicago        .         .        +INF      0.009
san-diego.topeka         .      275.000     +INF       .
```

The single dots '.' in the output represent zeroes. The entry EPS, which stands for *epsilon*, mean very small but nonzero. In this case, EPS indicates degeneracy. (The slack variable for the Seattle supply constraint is in the basis at zero level. The marginal is marked with EPS rather than zero to facilitate restarting the optimizer from the old basis.)

If the solvers results contain either infeasibilities or marginal costs of the wrong sign, then the offending entries are marked with INFES or NOPT, respectively. If the problem terminates unbounded, then the rows and columns corresponding to extreme rays are marked UNBND.

At the end of the solvers solution report is a very important *report summary*, which gives a tally of the total number of non-optimal, infeasible, and unbounded rows and columns. For our example, the report summary shows all zero tallies as desired.

```
**** REPORT SUMMARY :        0     NONOPT
                             0 INFEASIBLE
                             0  UNBOUNDED
```

After the solver's report is written, control is returned from the solver back to GAMS. All the levels and marginals obtained by the solver are entered into the GAMS database in the .l and .m fields. These values can then be transformed and displayed in any desired report. As noted earlier, the user merely lists the quantities to be displayed, and GAMS automatically formats and labels an appropriate array. For example, the input statement.

```
display x.l, x.m  ;
```

results in the following output.

```
----     50 VARIABLE  x.L           shipment quantities in cases

             new-york     chicago      topeka

seattle        50.000     300.000
san-diego     275.000                 275.000

----     50 VARIABLE  x.M           shipment quantities in cases

              chicago      topeka

seattle                     0.036
san-diego       0.009
```

As seen in reference maps, equation listings, solution reports, and optional displays, GAMS saves the documentary text and '*parrots*' it back throughout the output to help keep the model well documented.

4.11.12 Summary

This tutorial has demonstrated several of the design features of GAMS that enable you to build practical optimization models quickly and effectively. The following discussion summarizes the advantages of using an algebraic modeling language such as GAMS versus a matrix generator or conversational solver.

- By using an algebra-based notation, you can describe an optimization model to a computer nearly as easily as you can describe it to another mathematically trained person.
- Because an algebraic description of a problem has generality, most of the statements in a GAMS model are reusable when new instances of the same or related problems arise. This is especially important in environments where models are constantly changing.
- You save time and reduce generation errors by creating whole sets of closely related constraints in one statement.
- You can save time and reduce input errors by providing formulae for calculating the data rather than entering them explicitly.
- The model is self-documenting. Since the tasks of model development and model documentation can be done simultaneously, the modeler is much more likely to be conscientious about keeping the documentation accurate and up to date.
- The output of GAMS is easy to read and use. The solution report from the solver is automatically reformatted so that related equations and variables are grouped together and appropriately labeled. Also, the `display` command allows you to modify and tabulate results very easily.
- If you are teaching or learning modeling, you can benefit from the insistence of the GAMS compiler that every equation be mathematically consistent. Even if you are an experienced modeler, the hundreds of ways in which errors are detected should greatly reduce development time.
- By using the *dollar* operator and other advanced features not covered in this tutorial, one can efficiently implement large-scale models. Specific applications of the dollar operator include:

  1. It can enforce logical restrictions on the allowable combinations of indices for the variables and equations to be included in the model. You can thereby screen out unnecessary rows and columns and keep the size of the problem within the range of solvability.
  2. It can be used to build complex summations and products, which can then be used in equations or customized reports.
  3. It can be used for issuing warning messages or for terminating prematurely conditioned upon context-specific data edits.

4.12 Quick Start Tutorial

GAMS (the General Algebraic Modeling System) is a high-level modeling system for mathematical programming problems. This tutorial is aimed at modelers who are new to GAMS and are looking for a quick introduction to the core features of GAMS. Note that the text contains many links to the GAMS User's Guide for further exploration. Observe that this tutorial is adapted from the Quick Start Tutorial from Bruce McCarl. Another introductory text is the tutorial A GAMS Tutorial by Richard E. Rosenthal.

4.12.1 Three Basic Models

Most modelers who are interested in GAMS have one (or more) of the following backgrounds:

- They wish to solve constrained optimization problems with objective functions.
- They are looking for a system to solve general equilibrium problems that are arise in various areas of economics.
- They wish to solve nonlinear systems of equations that arise in engineering.

GAMS is well equipped to model and solve all three types of problems. We will start by introducing examples for all three areas and the discussions that will follow will refer to these three basic examples.

4.12.1.1 First Example: Solving a Linear Programming Problem (LP)

The simplest constrained optimization problem is an LP. Assume we wish to solve the following LP that represents a simple farm model where profit is maximized:

$$
\begin{array}{llrcrcrcll}
\max & & 109X_{corn} & + & 90X_{wheat} & + & 115X_{cotton} & & & \\
s.t. & & X_{corn} & + & X_{wheat} & + & X_{cotton} & \leq & 100 & \text{(land)} \\
 & & 6X_{corn} & + & 4X_{wheat} & + & 8X_{cotton} & \leq & 500 & \text{(labor)} \\
 & & & & & & X_{corn} & \geq & 0 & \text{(nonnegativity)} \\
 & & & & & & X_{wheat} & \geq & 0 & \text{(nonnegativity)} \\
 & & & & & & X_{cotton} & \geq & 0 & \text{(nonnegativity)}
\end{array}
$$

Note that there are three decision variables: X_{corn} denotes the land assigned to growing corn, X_{wheat} is the land assigned to growing wheat and X_{cotton} represents the land where cotton is grown. In the first line the total profit is expressed as a function of the land allotted to the three crops, the multipliers represent the expected profit per acre depending of the type of crop. The first inequality imposes a limit on the available land, the second inequality imposes a limit on the available labor and the final three lines restrict the decision variables to nonnegative values.

This problem may be expressed in GAMS as follows:

```
Positive Variables    Xcorn, Xwheat, Xcotton;
Variables             Z;

Equations     obj, land, labor;

obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
land..             Xcorn +      Xwheat +       Xcotton =l= 100;
labor..        6 * Xcorn +  4 * Xwheat +   8 * Xcotton =l= 500;

Model farmproblem / obj, land, labor /;

solve farmproblem using LP maximizing Z;
```

We will analyze this formulation and discuss every part of it after introducing the other two basic examples.

4.12.1.2 Second Example: Solving for an Economic Equilibrium

The simplest general equilibrium model is the single good, single market problem. Assume we wish to solve the following equilibrium problem:

$$\begin{array}{lllll} \text{Demand Price:} & P & \geq & P_d & = & 6 - 0.3Q_d \\ \text{Supply Price:} & P & \leq & P_s & = & 1 + 0.2Q_s \\ \text{Quantity Equilibrium:} & Q_s & \geq & Q_d & & \\ \text{Nonnegativity:} & P & \geq & 0 & & \\ & Q_s & \geq & 0 & & \\ & Q_d & \geq & 0 & & \end{array}$$

Here P is the market clearing price, P_d is the demand curve, Q_d denotes the quantity demanded, P_s the supply curve and Q_s the quantity supplied. Note that this is a problem in 3 equations and 3 variables. The variables are P, Q_d, and Q_s. Note that P_d and P_s are not variables, since they can be computed from the equality relations.

Usually all equality constraints are used for such a set up. However, we will use a more general setup, because it relaxes some assumptions and more accurately depicts a model ready to be implemented in GAMS. In particular, we permit the case where the supply curve price intercept may be above the demand curve price intercept and thus the market may clear with a nonzero price but a zero quantity. In addition, we allow the market price to be above the demand curve price and below the supply curve price. We also impose some additional conditions based on Walras' Law to ensure a proper solution in such cases.

$$\begin{array}{lll} Q_d(P - P_d) = 0 & \text{or} & Q_d(P_d - (6 - 0.3Q_d)) = 0 \\ Q_s(P - P_s) = 0 & \text{or} & Q_s(P_s - (1 + 0.2Q_s)) = 0 \\ P(Q_s - Q_d) = 0 & & \end{array}$$

Here the quantity demanded is nonzero only if the market clearing price equals the demand curve price, the quantity supplied is nonzero only if the market clearing price equals the supply curve price and the market clearing price is only nonzero if $Q_s = Q_d$.

The simplest GAMS formulation is given below. Note that we needed to rearrange the equation `Psupply` in order to achieve a greater than inequality, thus we accomodated the requirements of the solver PATH.

```
Positive Variables  P, Qd , Qs;

Equations     Pdemand, Psupply, Equilibrium;
Pdemand..     P            =g= 6 - 0.3*Qd;
Psupply..    ( 1 + 0.2*Qs) =g= P;
Equilibrium.. Qs           =g= Qd;

Model problem / Pdemand.Qd, Psupply.Qs, Equilibrium.P /;

solve problem using MCP;
```

We will analyze this formulation and discuss every component of it after introducing the third example.

4.12.1.3 Third Example: Solving a Nonlinear Equation System

Engineers often wish to solve a nonlinear system of equations. Examples include chemical equilibria or problems in the context of oil refining. Many other such problems of this type exist. The problem that follows is adapted from the paper Wall, T W, Greening, D, and Woolsey , R E D, "Solving Complex Chemical Equilibria Using a Geometric-Programming Based Technique" Operations Research 34, 3 (1987).

```
ba * so4 = 1

baoh / ba / oh = 4.8

hso4 / so4 / h = 0 .98

h * oh = 1

ba + 1e-7*baoh = so4 + 1e-5*hso4

2 * ba + 1e-7*baoh + 1e-2*h = 2 * so4 + 1e-5*hso4 + 1e-2*oh
```

Note that this is a nonlinear system of equations with the variables `ba`, `so4`, `baoh`, `oh`, `hso4` and `h`. The following formulation in GAMS is from the model [**WALL**] in the GAMS model library.

```
Variables ba, so4, baoh, oh, hso4, h ;

Equations r1, r2, r3, r4, b1, b2 ;

r1..  ba * so4 =e= 1 ;
r2..  baoh / ba / oh =e= 4.8 ;
r3..  hso4 / so4 / h =e= .98 ;
r4..  h * oh =e= 1 ;
b1..  ba + 1e-7*baoh =e= so4 + 1e-5*hso4 ;
b2..  2 * ba + 1e-7*baoh + 1e-2*h =e= 2 * so4 + 1e-5*hso4 + 1e-2*oh ;

Model wall / all / ;

ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;

solve wall using nlp minimizing ba;
```

4.12.2 Components of the Example Models

Now that we have our three basic models in place, we will analyze them and identify and discuss their components, including variables, equations, model definitions, solve statements and starting points.

4.12.2.1 Variables in the Example Models

Variables in GAMS have to be declared as variables with a variable statement. The variable statements in the examples above are repeated below:

- First example:

```
Positive Variables    Xcorn, Xwheat, Xcotton;
Variables             Z;
```

- Second example:

```
Positive Variables     P, Qd , Qs;
```

- Third example:

```
Variables ba, so4, baoh, oh, hso4, h ;
```

Note that `variable(s)` is a keyword in GAMS. `Positive` is another keyword, it serves as a modifier to the keyword `variable` and has the effect that the variables that follow may take only nonnegative values. Variables that are declared with the keyword `variable` without a modifier are unresticted in sign. For more details on variable declarations and variable types, see sections Variable Declarations and Variable Types respectively.

Observe that GAMS is not case sensitive and allows a line feed to be used instead of a comma. Thus, the following three variable declarations are all valid and have the same effect:

```
POSITIVE VARIABLES  Xcorn, Xwheat, Xcotton;
Positive Variables  xcorn,
                    xwheat,
                    xcotton;
positive variables  Xcorn
                    Xwheat , Xcotton;
```

In the GAMS formulation of the first example, we have introduced the variable `Z` in addition to the three variables that featured in the mathematical formulation. Note that GAMS requires the optimization model

```
Maximize cx
```

to have the following form:

```
Maximize z
         z = cx
```

Here `z` is a variable, also called *objective variable*. Observe that it is the objective variable that is maximized, not the function `cx`. The name of the objective variable may be chosen freely by the user, like any other variable name. The objective variable is a free variable, which means that it has no bounds. Hence, it each optimization problem there must always be at least one free variable.

Given the requirement of an objective variable in an optimization problem, we need to declare a new free variable and introduce an equation for it. In our first example we declared `Z` as a free variable, then we declared and specified the equation `obj` setting `Z` equal to the objective function expression and we instructed the solver to maximize `Z`. The relevant lines of code from the first example follow:

```
Variables     Z;

Equation     obj,  land ,  labor;

obj..   Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;

solve farmproblem using LP maximizing Z;
```

Note

> In some optimization problems users do not need to introduce a new variable to serve as an objective variable, but a free variable that already features in the model may be used. For example, in the second example above, `ba` is a free variable that is used as objective variable, since the model type NLP requires an objective variable. We will discuss this further below.

4.12.2.2 Equations in the Example Models

Each equation in a model must first be *declared* with a equation declaration statement and then *defined* with a equation definition statement. We repeat the respective statement from the three examples below:

- First example:

```
Equations     obj, land, labor;

obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
land..             Xcorn +      Xwheat +       Xcotton =l= 100;
labor..        6 * Xcorn +  4 * Xwheat +   8 * Xcotton =l= 500;
```

- Second example:

```
Equations     Pdemand, Psupply, Equilibrium;

Pdemand..     P            =g= 6 - 0.3*Qd;
Psupply..    ( 1 + 0.2*Qs) =g= P;
Equilibrium.. Qs           =g= Qd;
```

- Third example:

```
Equations r1, r2, r3, r4, b1, b2 ;

r1..  ba * so4 =e= 1 ;
r2..  baoh / ba / oh =e= 4.8 ;
r3..  hso4 / so4 / h =e= .98 ;
r4..  h * oh =e= 1 ;
b1..  ba + 1e-7*baoh =e= so4 + 1e-5*hso4 ;
b2..  2 * ba + 1e-7*baoh + 1e-2*h =e= 2 * so4 + 1e-5*hso4 + 1e-2*oh ;
```

Note that the equation declaration statement begins with the keyword `Equation(s)`. Its main purpose is to name the equation(s). For further details on equation declarations, see section Declaring Equations.

The algebraic structure of the equation is specified in the equation definition statement, where the name of the equation is followed by two dots `..` and the algebra. The relation between the left-hand side and right-hand side is specified by special symbols indicating the equation type. The most common symbols are `=e=` for equality, `=l=` for a less than or equal to relation and `=g=` for a greater than or equal to relation. An overview of all GAMS equation types is given in Table Equation Types. For more information on equation definitions, see sections Defining Equations and Conditional Equations.

4.12.2.3 Model Definitions in the Example Models

Once all structural elements of a model have been defined and specified, a model statement is used to define the model that will be solved. The model statement form the three examples follow.

- First example:

```
Model farmproblem / obj, land, labor /;
```

- Second example:

```
Model problem / Pdemand.Qd,  Psupply.Qs, Equilibrium.P /;
```

- Third example:

```
Model wall / all / ;
```

Note that a model statement always starts with the keyword `model`. It is follwed by the name of the model which users may choose freely and a list of the equations that are part of the model. Observe that the list of equations in the first example contains all equations that were declared and defined. However, this need not be the case. It is possible to declare and define an equation and then not use it in a model. For example, users could define several models that contain different subsets of equations. If all equations that were previously declared and defined enter the model, the keyword `all` may be used as a shortcut, like in the third example.

Attention

Only equations that have been declared may be listed in a model statement. All equations in a model must have been defined before the model can be solved.

Note that equilibrium problems like the second example are solved as Mixed Complementarity Problems (MCPs). MCPs require a special variant of the model statement where not only the equations are listed , but also their complementarity relationships. The complementarity relationship between an equation and its associated variable is marked with a dot ".". Hence, in the second example, the equation `Pdemand` is perpendicular to the the variable`Qd`, the equation `Psupply` is perpendicular to the variable `Qs` and the equation `Equilibrium` is perpendicular to the variable `P`.

In the three model statements above the name of the model was immediately followed by the list of the equations included in the model. Observe that an optional explanatory text may be inserted after the name of the model.

4.12.2.4 Solve Statements in the Example Models

After the model has been defined it remains to be solved, i.e. to find a solution for the variables. The solve statement directs GAMS to use a solver to optimize the model or solve the system of equations. The solve statements of the three examples follow:

- First example:

```
solve farmproblem using LP maximizing Z;
```

- Second example:

```
solve problem using MCP;
```

- Third example:

```
solve wall using nlp minimizing ba;
```

Note that a solve statement always begins with the keyword `solve` follwed by the name of the model, as previously specified with a model statement, the keyword `using` and the *type* of the model. We have an LP (linear programming problem) in the first example, an MCP (mixed compementarity problem) in the second example and an NLP (nonlinear programming program) in the third example. A complete list of GAMS model types is given in section Classification of Models. After the model type the direction of the optimization is given: either `maximizing` as in the first example or`minimizing` as in the third example. In the final position is the name of the objective variablethat is to be optimized.

Note

MCPs and systems of equations of the model type Constrained Nonlinear System (CNS) do not have objective variables. Therefore their solve statements end with the model type.

Observe that the system of nonlinear equations in the second example was expressed as an NLP that requires an objective function and a related objective variable. Actually this is an older practice in GAMS as the GAMS model type CNS was added after this example was initially formulated. Hence, we could alternatively use the following solve statement:

```
solve wall using cns;
```

However, note that the model type CNS can only be solved by select solvers and cannot incorporate integer variables. A formulation as an optimization problem relaxes these restrictions, thus allowing the use of the model type MINLP and all NLP solvers. If the model type NLP or one of its variants is chosen, one of the variables must be selected as objective variable to be optimzed. Observe that which variable is chosen may not really have any effect since a feasible solution requires all of the simultaneous equations to be solved. Thus, while in the third example the variable `ba` is maximized, there is no inherent interest in attaining its maximum - it is just convenient.

4.12.2.5 Starting Points

In the third example we have the following line *before* the solve statement:

```
ba.l=1; so4.l=1; baoh.l=1; oh.l=1; hso4.l=1; h.l=1;
```

Note that this line provides starting points for the variables in the model. The suffix `.l` appended to a variable name denotes the level value of that variable. If a level value of a variable is specified before the solve statement, this value will act as a starting point for the search algorithms. The level value of a variable is one example of a *variable attribute*. Other examples include lower and upper bounds which may be set with the suffixes `.lo` and `.up`. For more information on variable attributes, see section Variable Attributes. For guidance on how to choose good starting points, see the tutorial Good NLP Formulations. Specifying starting points may be important for avoiding numerical problems in the model solution. For more on this topic, see the tutorial Finding and Fixing Execution Errors and Performance Problems.

Observe that the statetements above are the first examples of assignment statements in this tutorial. Assignment statements play a crucial role in GAMS, they are introduced in section The Assignment Statement.

4.12.3 Running a GAMS Job

The model formulation of a GAMS model is saved in a text file with the extension `.gms`, say `myfile.gms`. Then the file is submitted to GAMS. GAMS will execute the instructions in the `.gms` file, with the result that calculations are done, solvers are used and an output file with the solution results is created. The output file is also called the *listing file*. By default, the name listing file of the input file `myfile.gms` will be `myfile.lst`.

There are two ways to submit a job to GAMS: via the command line and via the IDE GAMS Studio.

4.12.3.1 Running GAMS on the Command Line

The `myfile.gms` file may be run with GAMS using the following call:

```
> gams myfile
```

Note the extension `.gms` may be omitted. This basic GAMS call may be extended with arguments that are called *command line parameters*. The following example serves as illustration:

```
> gams trnsport pw=80 ps=9999 s=mysave
```

Note that there are three command line parameters: the first will set the page width to 80, the second will set the page length to 9999 and the third will have the effect that a work file named `mysave` is saved. GAMS offers many command line parameters, they are introduced and discussed in detail in chapter The GAMS Call and Command Line Parameters.

4.12.3.2 Running GAMS with GAMS Studio

GAMS Studio is an integrated development environment for Windows, macOS, and Linux that facilitates editing, development, debugging GAMS models and running GAMS jobs.

4.12.4 Examining The Output

The output of a GAMS run is saved in the output or listing file. The listing file may contain many parts. Some parts may be suppressed by the modeler, other parts are suppressed by default and need to be activated. For an introduction and detailed discussion, see chapter GAMS Output.

In this section we will review the output that is generated by running the three example models.

4.12.4.1 The Echo Print

The listing file always begins with the echo print. The echo print is a copy of the input file with added line numbers. For example, the echo print of the first example is given below:

```
 1  Positive Variables    Xcorn, Xwheat, Xcotton;
 2  Variables             Z;
 3
 4  Equations     obj, land, labor;
 5
 6  obj..  Z =e= 109 * Xcorn + 90 * Xwheat + 115 * Xcotton;
 7  land..             Xcorn +      Xwheat +       Xcotton =l= 100;
 8  labor..         6 * Xcorn +  4 * Xwheat +   8 * Xcotton =l= 500;
 9
10  Model farmproblem / obj, land, labor /;
11
12  solve farmproblem using LP maximizing Z;
```

Note that the echo print of the other two examples follows the same principles. Note further, that the echo print serves as an important reference guide since GAMS reports the line numbers of any errors that were detected and of solve and display statements.

Observe that usually the code of even experienced GAMS modelers will contain compilation errors. They are marked in the echo print. For more information on compilation error and how to resolve them, see section Compilation Errors and the tutorial Fixing Compilation Errors.

4.12.4.2 Model Generation Output

Once GAMS has successfully compiled the input file and any numerical computations in assignments have been performed, the solve statements will be executed. The first step is generating a computer readable version of the equations in the problem that will be passed on to an appropriate solver system. During the model generation phase GAMS creates the following output:

- A listing of the equations of the model.
- A listing of the variables of the model.
- A summary of the model structure.
- If errors were detected during model generation they will be reported as well.

The Equation Listing

The equation listing is the first part of the output generated by a solve statement. By default, the first three equations in every block are listed. The equation listing of the first two equations of each of the three examples are given below:

- First example:

```
Equation Listing    SOLVE farmproblem Using LP From line 12

---- obj  =E=

obj..  - 109*Xcorn - 90*Xwheat - 115*Xcotton + Z =E= 0 ; (LHS = 0)

---- land  =L=

land..  Xcorn + Xwheat + Xcotton =L= 100 ; (LHS = 0)
```

- Second example:

```
Equation Listing    SOLVE problem Using MCP From line 10

---- Pdemand  =G=

Pdemand..  P + 0.3*Qd =G= 6 ; (LHS = 0, INFES = 6 ****)

---- Psupply  =G=

Psupply..  - P + 0.2*Qs =G= -1 ; (LHS = 0)
```

- Third example:

```
Equation Listing    SOLVE wall Using NLP From line 16

---- r1  =E=

r1..  (1)*ba + (1)*so4 =E= 1 ; (LHS = 1)

---- r2  =E=

r2..  - (1)*ba + (1)*baoh - (1)*oh =E= 4.8 ; (LHS = 1, INFES = 3.8 ****)
```

Note that the equation listing is a representation of the algebraic structure of the linear terms in the equation and a local representation containing the first derivatives of the nonlinear terms. The nonlinear terms are automatically placed in parentheses to indicate a local approximation. For further details, see section The Equation Listing in chapter GAMS Output.

The Column Listing

The column or variable listing contains a list of the individual coefficients sorted by column rather than by row (like in the equation listing). By default, the first three entries for each variable are shown, along with their lower bound `.lo`, upper bound `.up` and current level values `.l`. The column listing of the first two variables for each of the three examples are given below.

- First example:

```
Column Listing      SOLVE farmproblem Using LP From line 12

---- Xcorn

Xcorn
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
     -109       obj
        1       land
        6       labor

---- Xwheat

Xwheat
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
      -90       obj
        1       land
        4       labor
```

- Second example:

```
Column Listing      SOLVE problem Using MCP From line 10

---- P

P
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
```

```
          1       Pdemand
         -1       Psupply

---- Qd

Qd
                 (.LO, .L, .UP, .M = 0, 0, +INF, 0)
        0.3      Pdemand
       -1        Equilibrium
```

- Third example:

```
Column Listing      SOLVE wall Using NLP From line 16

---- ba

ba
                 (.LO, .L, .UP, .M = -INF, 1, +INF, 0)
       (1)       r1
      (-1)       r2
        1        b1
        2        b2

---- so4

so4
                 (.LO, .L, .UP, .M = -INF, 1, +INF, 0)
       (1)       r1
      (-1)       r3
       -1        b1
       -2        b2
```

Model Statistics

The final information generated while a model is being prepared for solution, is the statistics block. Its most obvious use is to provide details on the size and nonlinearity of the model. The model statistics of the third example follow.

```
MODEL STATISTICS

BLOCKS OF EQUATIONS           6     SINGLE EQUATIONS            6
BLOCKS OF VARIABLES           6     SINGLE VARIABLES            6
NON ZERO ELEMENTS            20     NON LINEAR N-Z             10
DERIVATIVE POOL              20     CONSTANT POOL              16
CODE LENGTH                  22
```

For more information on model statistics, see section The Model Statistics in chapter GAMS Output.

4.12.4.3 The Solution Report

The final major component of the listing file is the solution output. It consists of a summary, some solver-specific output and a report of the solutions for equations and variables.

The Solve Summary

The solve summary is very important since it contains an overview of key information of the solution. The solve summary of the third example is given below.

```
               S O L V E      S U M M A R Y

     MODEL   wall                OBJECTIVE  ba
     TYPE    NLP                 DIRECTION  MINIMIZE
     SOLVER  CONOPT              FROM LINE  16

**** SOLVER STATUS     1 Normal Completion
**** MODEL STATUS      2 Locally Optimal
**** OBJECTIVE VALUE                1.0000

 RESOURCE USAGE, LIMIT          0.034      1000.000
 ITERATION COUNT, LIMIT         7    2000000000
 EVALUATION ERRORS              0             0
```

For details on the solve summary including possible values for `SOLVER STATUS` and `MODEL STATUS`, see section The Solve Summary in chapter GAMS Output.

The Solver Report

The next part of the listing file is the solver report. It contains solver specific output. The respective output of the third example follows:

```
CONOPT 3         24.7.3 r58181 Released Jul 11, 2016 DEG x86 64bit/MacOS X

 ** Optimal solution. There are no superbasic variables.
```

For more on solver reports, see section Solver Report in chapter GAMS Output.

The Solution Listing

The solution listing is a row-by-row then column-by-column listing of the solutions returned to GAMS by the solver program. Each individual equation and variable is listed including their level and marginal values and their lower and upper bounds. The solution listing of the first example follows:

```
                            LOWER          LEVEL          UPPER         MARGINAL

---- EQU obj                  .              .              .             1.0000
---- EQU land               -INF          100.0000       100.0000       52.0000
---- EQU labor              -INF          500.0000       500.0000        9.5000

                            LOWER          LEVEL          UPPER         MARGINAL

---- VAR Xcorn                .             50.0000        +INF            .
---- VAR Xwheat               .             50.0000        +INF            .
---- VAR Xcotton              .                .           +INF         -13.0000
---- VAR Z                  -INF          9950.0000        +INF            .
```

Note that single dots '.' represent zeros. The extended range arithmetic symbols `-INF` and `+INF` denote minus and plus infinity respectively. `EPS` is another extended range arithmetic symbol that often appears in solution listings. In this context, it is used to indicate basis status in the degenerate case. For example, a basic variable is indicated by a zero (single dot) marginal, while a non-basic variable whose marginal is (nearly) zero is indicated by a marginal of EPS. For further details, see section The Solution Listing in chapter GAMS Output.

4.12.5 Exploiting the Algebraic Structure

GAMS was deliberately designed to make it easy to express algebraic relationships. Thus it provides notation for indexed operations like sums. Assume that z is defined as the sum over x_i where $i = \{1, 2, 3\}$:

$$z = \sum_{i=1}^{3} x_i = x_1 + x_2 + x_3$$

This can be expressed in GAMS in the following way:

```
z = sum(i, x(i));
```

Here `i` is a set with three elements, `z` is a scalar or variable and `x(i)` is a parameter or variable defined over the set `i`. Note that the keyword `sum` automatically cycles through all elements of the set `i`.

Indexed operations like `sum` may be used in the algebraic specification of equations or in the context of assignments where the value of identifiers are computed. In the following two sections we will introduce revised versions of the first two examples, where we illustrate how using `sum` simplifies the code and enables more general formulations.

4.12.5.1 Revised First Example

Recall that the first example is the following LP:

$$\begin{array}{lrcrcrcll}
\max & 109X_{corn} & + & 90X_{wheat} & + & 115X_{corn} & & & \\
\text{s.t.} & X_{corn} & + & X_{wheat} & + & X_{cotton} & \leq & 100 & \text{(land)} \\
 & 6X_{corn} & + & 4X_{wheat} & + & 8X_{cotton} & \leq & 500 & \text{(labor)} \\
 & & & & & X_{corn} & \geq & 0 & \text{(nonnegativity)} \\
 & & & & & X_{wheat} & \geq & 0 & \text{(nonnegativity)} \\
 & & & & & X_{cotton} & \geq & 0 & \text{(nonnegativity)}
\end{array}$$

Note that this is a special case of the general resource allocation problem that can be written as follows:

$$\begin{array}{lrcll} \max & \sum_j c_j X_j & & & \\ \text{s.t.} & \sum_j a_{ij} X_j & \leq & b_i & \text{for all } i \\ & X_j & \geq & 0 & \text{for all } j, \end{array}$$

where

- $j = \{\text{corn, wheat, cotton}\}$
- $i = \{\text{land, labor}\}$
- $X_j = \{X_{\text{corn}}, X_{\text{wheat}}, X_{\text{cotton}}\}$
- $c_j = \{109, 90, 115\}$
- $a_{ij} = \begin{pmatrix} 1 & 1 & 1 \\ 6 & 4 & 8 \end{pmatrix}$
- $b_i = \{100, 500\}$.

This model may be formulated in GAMS in the following way:

```
Set       j        / corn, wheat, cotton /
          i        / land, labor /;

Parameter c(j)     / corn 109, wheat 90, cotton 115 /
          b(i)     / land 100 , labor 500 /;

Table     a(i,j)
            corn    wheat    cotton
land          1        1        1
labor         6        4        8      ;

Positive Variables x(j);
Variables          profit;

Equations          objective
                   constraint(i) ;

objective..      profit =e= sum(j, (c(j))*x(j));
constraint(i)..  sum(j, a(i,j) *x(j))  =l=   b(i);

Model resalloc /all/;
solve resalloc using LP maximizing profit;
```

We will discuss the components of this model in section Components of the Revised Example Models below.

4.12.5.2 Revised Second Example

Recall that the second example is an economic equilibrium model with a single commodity:

$$
\begin{array}{lllll}
\text{Demand Price:} & P & \geq & P_d & = & 6 - 0.3Q_d \\
\text{Supply Price:} & P & \leq & P_s & = & 1 + 0.2Q_s \\
\text{Quantity Equilibrium:} & Q_s & \geq & Q_d & & \\
\text{Nonnegativity:} & P & \geq & 0 & & \\
 & Q_s & \geq & 0 & & \\
 & Q_d & \geq & 0 & &
\end{array}
$$

A more general formulation of this model accomodates multiple commodities. Consider the following formulation where c denotes the commodities:

$$
\begin{array}{lllll}
\text{Demand Price for c:} & P_c & \geq & Pd_c & = & Id_c - \sum_{cc} Sd_{c,cc} Qd_{cc} \quad \text{for all } c \\
\text{Supply Price for c:} & P & \leq & Ps_c & = & Is_c + \sum_{cc} Ss_{c,cc} Qs_{cc} \quad \text{for all } c \\
\text{Quantity Equil. for c:} & Qs_c & \geq & Qd_c & & \quad \text{for all } c \\
\text{Nonnegativity:} & P_c & \geq & 0 & & \quad \text{for all } c \\
 & Qs_c & \geq & 0 & & \quad \text{for all } c \\
 & Qd_c & \geq & 0 & & \quad \text{for all } c,
\end{array}
$$

where

- P_c is the price of commodity c,
- Qd_c is the quantity demanded of commodity c,
- Pd_c is the price from the inverse demand curve for commodity c,
- Qs_c is the quantity supplied of commodity c,
- Ps_c is the price from the inverse supply curve for commodity c,
- cc is an alternative notation for the commodities and is equivalent to c,
- Id_c is the inverse demand curve intercept for c,
- $Sd_{c,cc}$ is the slope of the inverse demand curve. It is used to model the effect of buying one unit of commodity cc on the demand price of commodity c. When $c = cc$ it is an own commodity effect and when $c \neq cc$ it is a cross commodity effect.
- Is_c is the inverse supply curve intercept for c,
- Ssc, cc is theslope of the inverse supply curve. It is used to model the effect of supplying one unit of commodity cc on the supply price of commodity c. When $c = cc$ it is an own commodity effect and when $c \neq cc$ it is a cross commodity effect.

This model may be formulated in GAMS in the following way:

```
Set commodities / corn, wheat /;
Set curvetype   / supply, demand/;

Table intercepts(curvetype,commodities)
                  corn   wheat
         demand    4       8
         supply    1       2;
```

```
Table slopes(curvetype,commodities,commodities)
                    corn  wheat
     demand.corn    -.3    -.1
     demand.wheat   -.07   -.4
     supply.corn     .5     .1
     supply.wheat    .1     .3  ;

Positive Variables  P(commodities)
                    Qd(commodities)
                    Qs(commodities);

Equations      PDemand(commodities)
               PSupply(commodities)
               Equilibrium(commodities);

Alias (cc,commodities);

Pdemand(commodities)..
    P(commodities) =g= intercepts("demand",commodities)
                       + sum(cc,slopes("demand",commodities,cc)*Qd(cc));
Psupply(commodities)..
    intercepts("supply",commodities)
    + sum(cc,slopes("supply",commodities,cc)* Qs(cc)) =g= P(commodities);

Equilibrium(commodities)..
     Qs(commodities) =g=  Qd(commodities);

Model problem / Pdemand.Qd, Psupply.Qs,Equilibrium.P /;
solve problem using MCP;
```

4.12.6 Components of the Revised Example Models

The revised example models have several new features including sets, specific data entry, and variables and equations that are defined over sets. In addition, if the models are run, modelers will notice some differences in the output. In this section we will discuss these new language features and the differences in the output they entail.

4.12.6.1 Sets in the Revised Examples

In the revised examples we used the subscripts `i`, `j`, `commodities` and `cc`. In GAMS, subscripts are sets. They have to be defined before they may be used as subscripts. Sets are defind with set statements. Consider the set statement from the first revised example:

```
Set  j   / corn, wheat, cotton /
     i   / land, labor /;
```

Note that the statement begins with the keyword `set` followed by the name of the set and a list of the elements of the set. Note further, that more than one set may be defined with one set statement. In addition, an optional explanatory text may be inserted after the name of the set and also after each set element. For more details on set definitions, see chapter Set Definition.

Observe that the following line appears in the revised second example:

```
Alias (cc,commodities);
```

This is an alias statement that introduces a new alternative name for a set that was defined earlier. In our example, the set `commodities` was defined in the first line of the code and `cc` is the alias, the alternative name for the set `commodities`. Note that more than one alias may be defined in an alias statement. For further information on aliases, see section The Alias Statement: Multiple Names for a Set.

Note that in our example the alias facilitates to consider both the effects of own and cross commodity quantity on the demand and supply price for an item.

4.12.6.2 Data Entry in the Revised Examples

GAMS provides three formats for data entry: scalars, parameters and tables. Usually scalars are defined with a scalar statement, data vectors are defined with a parameter statement and matrices are defined with a table statement.

Note that we used parameter and table statements in the revised examples. In this section we will discuss parameter and table statements. For details on scalar statements, see section Scalars.

Parameters

The parameter format is used to enter items defined over sets. Generally, the parameter format is used for data items that are one-dimensional (vectors), but multi-dimensional data may be entered with a parameter statement as well. Consider the parameter statement from the first revised example:

```
Parameter c(j)     / corn 109, wheat 90, cotton 115 /
          b(i)     / land 100, labor 500 /;
```

Note that the statement begins with the keyword `parameter` followed by the name of the parameter and the set over which the parameter is defined, the *index* or *domain*. Then a list follows where a numerical value is assigned to each member of the index set. Note that the referenced elements must have been defined to be members of the respective set. By default, elements of the domain that are not listed in the parameter statement are assigned the value of zero. Note that more than one parameter may be defined with one parameter statement. For further details on parameter statements, see section Parameters.

Tables

The table format is used to enter data that are dependent on two or more sets. Consider the following two table statements from the revised examples:

```
Table a(i,j) crop data
             corn  wheat cotton
    land      1     1      1
    labor     6     4      8      ;

Table intercepts(curvetype,commodities)
                   corn   wheat
         demand     4       8
         supply     1       2;
```

Note that the statement begins with the keyword `table` followed by the name of the table and the sets over which the table is defined. The next line serves as header for the columns of the table, the elements of the set in the *second* index position are listed here. The elements of the set in the *first* index position are the headers of the rows. Thus the elements of the two index positions span a grid where numerical values may be entered. Like in the parameter format, the referenced set elements must have been defined to be members of the respective set.

Note

Alignment is crucial in table statements. The numerical entries must be placed in one and only one column of the table.

By default, elements of the domain that are not listed in the table statement are assigned the value of zero. Note that only one table may be defined with a table statement. For further details on table statements, see section Tables. Observe that data may also be entered with assignment statements. For more information, see section Data Entry by Assignment.

4.12.6.3 Indexed Variables and Equations in the Revised Examples

When the algebraic structure of a problem is exploited in modeling, variables and equations are often defined over one or more sets, they are *indexed*. For example, in the first revised example we have the following lines:

```
Positive Variable x(j);
Equations         constraint(i);
```

Note that here the variable `x` is defined over the set `j` and the equation `constraint` is indexed over the set `i`. Similarly, in the second revised example we have the following variable and equation statements:

```
Positive Variables P(commodities)
                   Qd(commodities)
                   Qs(commodities) ;
Equations  PDemand(commodities)
           PSupply(commodities)
           Equilibrium(commodities)  ;
```

Observe that here all positive variables and all equations are indexed over the set `commodities`. Such definitions indicate that the variables and equations are potentially defined for every element of the defining set. Thus, for example, a variable `P` could exist for each and every element of the set `commodities`. However, how many of these potential cases are activated is determined by the respective equation definion statement(s) where the variable `P` is used. For further details on indexed variables and equations,see chapter Variables and section Indexed Equations respectively.

Next, we will discuss the equation definition statements. The respectives lines from the first revised example follow:

```
objective..      profit =e= sum(j, (c(j))*x(j));
constraint(i)..  sum(j, a(i,j) *x(j)) =l= b(i);
```

Note that the equation `constraint` is indexed over the set `i` and there are no restrictions specified in the equation definition statement. Thus, GAMS will generate a separate equation for every element of the set `i` in the model generation phase.

The same logic applies to the indexed equations of the second revised example whose definition statements are repeated below:

```
Pdemand(commodities)..
    P(commodities) =g= intercepts("demand",commodities)
                       + sum(cc,slopes("demand",commodities,cc)*Qd(cc));

Psupply(commodities)..
    intercepts("supply",commodities) + sum(cc,slopes("supply",commodities,cc)* Qs(cc))
                     =g= P(commodities);

Equilibrium(commodities)..
    Qs(commodities) =g=  Qd(commodities);
```

Observe that equations may be defined over only a part of their domain. This restriction is usually achieved with dollar conditions. For details see section Conditional Equations.

4.12.6.4 Differences in the Output

If variables and equations are defined over sets, some parts of the listing file will look different. In particular, there are some changes in the equation listing, the variable listing and the solution listing.

Revised Models: The Equation Listing

Note that indexed variables are given with their indices in the equation listing. In addition, the specific equations generated for each element of the domain are listed under the name of an indexed equation. To illustrate, we present the equation listing of the first revised example below:

```
---- objective  =E=

objective..  - 109*x(corn) - 90*x(wheat) - 115*x(cotton) + profit =E= 0 ; (LHS = 0)

---- constraint  =L=

constraint(land)..  x(corn) + x(wheat) + x(cotton) =L= 100 ; (LHS = 0)

constraint(labor)..  6*x(corn) + 4*x(wheat) + 8*x(cotton) =L= 500 ; (LHS = 0)
```

Revised Models: The Column Listing

Similar to indexed equations in the equation listing, each instance of a variable is listed under the name of an indexed variable in the variable listing. The respective output of the first revised model follows.

```
---- x

x(corn)
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
     -109       objective
        1       constraint(land)
        6       constraint(labor)

x(wheat)
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
      -90       objective
        1       constraint(land)
        4       constraint(labor)

x(cotton)
                (.LO, .L, .UP, .M = 0, 0, +INF, 0)
     -115       objective
        1       constraint(land)
        8       constraint(labor)
```

Revised Models: The Solution Listing

In the solution listing of the revised models there is a separate line for each element of the index set. The respective output of the first revised model is given below:

```
---- EQU constraint

             LOWER          LEVEL          UPPER         MARGINAL

land         -INF         100.0000       100.0000        52.0000
labor        -INF         500.0000       500.0000         9.5000

---- VAR x

             LOWER          LEVEL          UPPER         MARGINAL

corn            .           50.0000        +INF             .
wheat           .           50.0000        +INF             .
cotton          .              .           +INF          -13.0000
```

4.12.7 Documenting the GAMS Code

We have now covered the essential GAMS features. However, any good code includes documentation, otherwise it might be useless if it is revisited after a longer time. GAMS offers three ways to document the code: comments, explanatory texts and naming.

Comments

There are several ways to add comments in GAMS. The most common are *single line comments* and *block comments*. Single line comments may be inserted on any line by placing an asterisk $*$ in the first column position. The text that follows the asterisk will be completely ignored by the GAMS compiler and may contain any content including GAMS keywords. Note that several successive lines may be single line comments. Block comments are marked with the dollar control option $ontext at the beginning of the comment block and the dollar control option $offtext at the end of the comment. Block comments usually span several lines, but they may also contain just one line on the one hand and whole sections of the code on the other hand.

In addition, users may freely enter blank lines to set off certain sections of the code and generally enhance readability. For further details on comments, see section Comments.

Explanatory Text

Declarations of sets, parameters, variables and equations may include an optional descriptive text that follows the name of the identifier. In addition, the elements of sets may be accompanied by a text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the respective identifier in the output file. Note that the explanatory textmay be quoted or unquoted and single or double quotes may be used, but they must match. An example is given below. For further details, see section Text.

Naming

Apart from avoiding reserved words, names for identifiers in GAMS may be freely chosen. Some modelers, particularly if they have a background in mathematics, prefer short names like `x(i)`. Other modelers strongly prefer longer descriptive names that makes it easier for them to recall what quantities are denoted. In this case naming is regarded as part of the documentation. GAMS accomodates both styles and modelers may choose which style works best for them. If short names are used, we recommend to generously use descriptive texts and comments for documentation.

To illustrate the virtues of comments, blank lines, explanatory text and long names we will repeat the code of the revised LP from above and then offer an alternative, documented formulation.

```
Set       j        / corn, wheat, cotton /
          i        / land , labor /;

Parameter c(j)     / corn 109, wheat 90, cotton 115 /
          b(i)     / land 100 , labor 500 /;

Table     a(i,j)
            corn    wheat    cotton
land          1        1        1
labor         6        4        8      ;

Positive Variables x(j);
Variables          profit;

Equations          objective
                   constraint(i) ;

objective..      profit =e= sum(j, (c(j))*x(j));
constraint(i)..  sum(j, a(i,j) *x(j))  =l=   b(i);

Model resalloc /all/;
solve resalloc using LP maximizing profit;
```

The documented version with longer names follows:

```
$ontext
  well formatted algebraic version of the first example model
$offtext
Set       products  'Items produced by farm'
              / corn   'in acres'
                wheat  'in acres'
                cotton 'in acres' /
          resources  'Resources limiting farm production'
              / land   'in acres'
                labor  'in hours' /;

Parameter netreturns(products)  'Net returns per unit produced'
              / corn 109 , wheat 90, cotton 115 /
          endowments(resources) 'Amount of each resource available'
              / land 100, labor 500 /;

Table     resourceusage(resources,products) 'Resource usage per unit produced'
                          corn    wheat  cotton
               land          1       1       1
               labor         6       4       8      ;

Positive Variables   production(products) 'Number of units produced';
Variables            profit               'Total sum of net returns';

Equations            profitAcct           'Profit accounting equation'
                     available(resources) 'Resource availability limit';

$ontext
      Specify definition of profit
$offtext

profitAcct..
```

```
      profit
      =e= sum(products, netreturns(products)*production(products));

$ontext
      Limit available resources
      Fix at exogenous levels
$offtext

available(resources)..
      sum(products,
          resourceusage(resources,products) *production(products))
      =l= endowments(resources);

Model resalloc /all/;

solve resalloc using LP maximizing profit;
```

4.12.8 Guidelines on Ordering GAMS Statements and Formatting GAMS Programs

A GAMS program is a collection of GAMS statements. In this section we will offer some general guidelines on ordering GAMS statements and formatting GAMS programs.

- GAMS is case insensitive. This applies to GAMS keywords as well as to user-defined names. For example, the keyword `VARIABLE` is identical to `Variable` and `variable` and the user-defined name `mincost` is identical to `minCost` and `minCOST`. However, note that the spelling in the output file is determined by the spelling in the first occurence of an identifier or label.
- Individual GAMS statements may be formatted in almost any style. Multiple lines may be used for a statement, blank lines may be embedded and any number of spaces or tabs may be inserted. In addition, several statements may be placed on one line. Note that they have to be separated by semicolons `;`.
- We recommend that every GAMS statement is terminated with a semicolon `;`. However, note that semicolons are not manadatory if the next word is a GAMS keyword.
- Identifiers like sets, parameters, scalars, tables, acronyms, variables, equations, models and files must first be *declared* and *defined* before they may be used in the code. An identifier is named in a declaration statement and specific values are assigned to it when it is defined. Often identifiers are defined at the same time they are declared. Note that for equations the declaration and definition statements are always distinct.
- The names for identifiers and labels and the explanatory text must follow certain rules. See chapter GAMS Programs and the tutorial Good Coding Practices for more information.
- Statements must be ordered such that identifiers are declared before they are used. If identifiers are used on the right-hand side of an assignment statement, they must also have been defined. If they are used in an equation and the equation is included in a model, then they must be assigned data before a solve statement for the respective model. Note that compilation errors will be triggered if this order is not followed.

4.12.9 Adding Complexity

There are several GAMS features that are widely used and serve to add subtlety and compexity to models. They include exception handling through conditionals, displaying data in the output file and report writing where the information from the optimal solution is used to create reports that meet the needs of modelers and their clients.

4.12.9.1 Conditionals

Assignments are often valid only for certain cases and sometimes equations should reasonably be restricted to a subset of the domain over which they were defined. It is easy to model such assignments and equations in GAMS with conditionals. Conditional expressions in GAMS are introduced and discussed in detail in chapter Conditional Expressions, Assignments and Equations. In this section we will only give a quick overview to demonstrate the capabilities of conditionals in GAMS.

Note that the dollar condition is at the heart of conditionals in GAMS. The general form of a conditional expression is as follows:

```
term $ logical_condition
```

This translates to: "Do something with 'term' only if the logical condition is true." Observe that `term` may be a number, a set, a parameter, a variable or an equation. The dollar operator `$` is a GAMS speciality and one of the most powerful features of GAMS. The logical condition may take many different forms, see section Logical Conditions for details.

The following examples illustrate how conditionals in GAMS may be used.

Conditional Assignments

Consider the following example:

```
x $ (y > 0) = 10;
```

Note that `x` is assigned the value of ten only if the the scalar `y` is greater than zero, otherwise no assignment is made and `x` keeps its previous value. For more information, see section Conditional Assignments.

Conditional Indexed Operations

Consider the following example:

```
z = sum[i $ (y(i) <> 0), x(i)];
```

Note that the term `x(i)` will only be included in the sum if `y(i)` is nonzero. For further information, see section Conditional Indexed Operations.

Conditionals in the Domain of Definition of Equations

Consider the following equation definition statements:

```
Eq1 $ (qq > 0)..            xvar =e= 3;
Eq2 $ (sum(i, q(i)) > 0)..  yvar =l= 4;
Eq3(i) $ (a(i) > 0)..       ivar(i) =g= -a(i);
```

Note that in each equation the domain of definition is restricted to those cases where the logical condition evaluates to `TRUE`. For further details, see section Dollar Control over the Domain of Definition.

Conditionals in the Algebraic Formulation of Equations

Our last example illustrates how a dollar condition may be used in the body of an equation:

```
Eq4 . .    xvar + yvar $ (qq > 0) =e= 3;
```

Note that the term `yvar` is included in the equation only if `qq` is greater than zero, otherwise `yvar` is treated as if it were zero. For more information, see section Dollar Operators within the Algebra of Equations.

4.12.9.2 Displaying Data

In GAMS, the display statement is a quick way to write data into the output file. For example, assume we add the following statement after the solve statement in the revised and documented version of the farm linear programming model above:

```
display profit.l, production.l;
```

Recall that `profit` and `production` are variables. The suffix `.l` indicates that we wish to display the variable attribute `level`. The following output will be generated in the listing file:

```
----     47 VARIABLE profit.L              =     9950.000  Total sum of net returns

----     47 VARIABLE production.L  Number of units produced

corn  50.000,    wheat 50.000
```

Observe that the name of the variable, the explanatory text and the respective numerical values are given. In addition to data like parameters, sets, variable attributes, equation attributes and model attributes, quoted text may be displayed. Note that numerical entries that equal zero will not be displayed. For a more detailed introduction, see chapter The Display Statement.

4.12.9.3 Report Writing

In many cases modelers wish to summarize the most important results of the solution in a table for a quick overview. GAMS allows post-solution computations where information form the solution may be used to assign values to new parameters that are then displayed. The information from the solution most often used for report writing includes the level values of variables and equations and the marginal values of equations (also called *dual values* or *shadow prices*). Note that variable and equation attributes are accessed as follows:

```
var_name.sfx
eqn_name.sfx
```

Here `var_name` and `eqn_name` is the name of the variable and equation in GAMS respectively. The *attribute* is denoted by `.sfx`, where `sfx` may be `l` for level and `m` for marginal. Note that the suffix `sfx` may take other values as well. For details see sections Variable Attributes and Equation Attributes.

Observe that the numerical values of the levels and marginals of variables and equations are generally undefined until a solve statement is executed. After GAMS has retrieved the solution from the solver, the respective values from the solution are assigned to the attributes. These values remain unchanged until the next solve, where they are replaced with the values from the most recent solution.

In the remainder of this section we will present two examples to illustrate report writing. Assume we add the following report writing sequence after the solve statement to the revised and documented version of the farm linear programming model above:

```
Set item   / Total, "Use by", Marginal /;
Set qitem  / Available, Corn, Wheat, Cotton, Value /;

Parameter Thisreport(resources,item,qitem) 'Report on resources';
Thisreport(resources,"Total","Available") = endowments(resources);
Thisreport(resources,"Use by",qitem) =
   sum(products$sameas(products,qitem),
       resourceusage(resources,products) * production.l(products));
Thisreport(resources,"Marginal","Value") =
        available.m(resources);

option thisreport:2:1:2;
display thisreport;
```

Note that both, equation marginals (`available.m(resources)`) and variable levels (`production.l(products)`) are included in the calculations. The predefined symbol sameas in the logical condition above returns the value `TRUE` if the element of the set `products` is equivalent to the element of the set `qitem` and `FALSE` otherwise. Thus this condition ensures that the third index of the parameter `Thisreport` is identical to the element of the set `products` in the sum. Observe that with the option statement in the penultimate line the appearance of the display is customized. For details see section Local Display Control. The following report will be generated by the display statement:

```
----     61 PARAMETER Thisreport  Report on resources

            Total      Use by      Use by    Marginal
        Available        corn       wheat       Value

land       100.00       50.00       50.00       52.00
labor      500.00      300.00      200.00        9.50
```

Similarly, we could add the following report writing sequence to the revised version of the equilibrium model above:

```
Set         qitem / Demand, Supply, "Market Clearing" /;
Set         item  / Quantity, Price /;

Parameter myreport(qitem,item,commodities);
myreport("Demand","Quantity",commodities) = Qd.l(commodities);
myreport("Supply","Quantity",commodities) = Qs.l(commodities);
myreport("Market Clearing","Price",commodities) = P.l(commodities);

display myreport;
```

Note that in the new parameter the level values for supply and demand as well as the market clearing price are saved. The resulting report follows:

```
----     39 PARAMETER myreport

                              Corn       Wheat
Supply          .Quantity     1.711       8.156
Demand          .Quantity     1.711       8.156
Market Clearing.Price         2.671       4.618
```

For more on report writing, see chapters The Display Statement and The Put Writing Facility.

4.12.10 Advantages of Algebraic Modeling in General

We will conclude this tutorial with a discussion of the advantages of using algebraic modeling in general.

Algebraic modeling languages like GAMS facilitate model formulations in general algebaric terms, that are very concise and readable. Language elements that are essential include sets that may serve as indices, algebraic expressions, indexed operations, powerful sparse index and data handling variables and constraints with user-defined names. Model formulations are largely independent of the data and exact application contexts. Such formulations may be easily transferred to different contexts, data may be added without the need to reformulate the model and the model may be extended to reflect additional complexity.

However, GAMS algebraic requirements and the summation notation are difficult for some users. Some modelers will always prefer the exact problem context, not an abstract general formulation. This may lead to a strategy most modelers use: Start with a small concrete formulations that capture the essence of the problem and support the development of more general GAMS models.

4.12.10.1 One Model - Different Contexts

In the linear programming problem above we modeled profit maximizing in a farm. This model may easily be transferred to another context as follows:

```
Set       products  'Items produced'
            / Chairs, Tables, Dressers /
          resources  'Resources limiting production'
            / RawWood, Labor, WarehouseSpace /;

Parameter Netreturns(products)  'Net returns per unit produced'
            / Chairs 19, Tables 50, Dressers 75 /
          Endowments(resources) 'Amount of each resource available'
            / RawWood 700, Labor 1000,  WarehouseSpace 240 /;

Table     Resourceusage(resources,products) 'Resource usage per unit produced'
                          Chairs   Tables  Dressers
          RawWood            8        20      32
          Labor             12        32      45
          WarehouseSpace     4        12      10   ;

Positive Variables   Production(products) 'Number of units produced';
Variables            Profit               'Total sum of net returns' ;

Equations            ProfitAcct           'Profit accounting equation '
                     Available(resources) 'Resource availability limit';

 ProfitAcct..
      Profit
      =e= sum(products, netreturns(products) * production(products)) ;
 Available(resources)..
      sum(products,
          resourceusage(resources,products) * production(products))
      =l= endowments(resources);

Model resalloc /all/;

solve reasalloc using LP maximizing Profit;
```

Note that in this model we have chairs, tables and dressers instead of corn, wheat and cotton and raw wood, labor and warehouse space instead of land and labor, but the *algebraic structure* of the model is the same. Thus we still have sets for products and resources, parameters for net returns per unit produced and available resources, a table for resource usage per unit produced and exactly the same variables and equations, the same model and solve statement. Hence, if the algebraic structure for a type of problem is built, it may be used in another context of the same problem type with just minor modifications in the data.

4.12.10.2 Adding More Data

It is easy to add more data to a model. For example, we could add two new products and two new resources to the carpenter model above in the following way:

```
Set       products  'Items produced'
              / Chairs, Tables, Dressers, HeadBoards, Cabinets /
          resources  'Resources limiting production'
              / RawWood, Labor, WarehouseSpace, Hardware, ShopTime /;

Parameter Netreturns(products)  'Net returns per unit produced'
            / Chairs 19, Tables 50, Dressers 75, HeadBoards 28, Cabinets 25 /
          Endowments(resources) 'Amount of each resource available'
            / RawWood 700, Labor 1000, WarehouseSpace 240, Hardware 100, Shoptime 600 /;

Table     Resourceusage(resources,products) 'Resource usage per unit produced'
                          Chairs   Tables  Dressers HeadBoards Cabinets
          RawWood            8        20      32         22      15
          Labor             12        32      45         12      18
          WarehouseSpace     4        12      10          3       7
          Hardware           1         1       3          0       2
          Shoptime           6         8      30          5      12;

Positive Variables   Production(products) 'Number of units produced';
Variables            Profit               'Total sum of net returns' ;

Equations            ProfitAcct           'Profit accounting equation'
                     Available(resources) 'Resource availability limit';

 ProfitAcct..
      Pofit
      =e= sum(products, netreturns(products) * production(products)) ;

 Available(resources)..
      sum(products,
          resourceusage(resources,products) * production(products))
      =l= endowments(resources);

Model resalloc /all/;

solve reasalloc using LP maximizing Profit;
```

Observe that the elements `HeadBoards` and `Cabinets` were added to the set `Products` and the elements `Hardware` and `ShopTime` were added to the set `Resources`. In addition, the data in the two parameters and the table was updated to reflect these new labels. However, the model structure remained unchanged. Thus, GAMS models may easily be extended from smaller to larger data sets. Note that this feature may be exploited for model development. Users may develop a model with a small data set and test and debug it. Afterwards, they may move to the full problem data set without having to alter the algebraic structure of the model.For more details on this strategy, see section Small to Large: Aid in Development and Debugging.

4.12.10.3 Extending the Model

Assume we wish to make a model more complex by adding new features. For example, we could extend the carpenter model above to reflect the possibility of renting or hiring additional resources subject to a maximum limit. Consider the following code:

```
Set       products  'Items produced'
              / Chairs, Tables, Dressers /
          resources  'Resources limiting production'
              / RawWood, Labor, WarehouseSpace/
          hireterms  'Resource hiring terms'
              / Cost, Maxavailable /;

Parameter Netreturns(products)  'Net returns per unit produced'
              / Chairs 19, Tables 50, Dressers 75 /
          Endowments(resources) 'Amount of each resource available'
              / RawWood 700, Labor 1000, WarehouseSpace 240 /;

Table     Resourceusage(resources,products) 'Resource usage per unit produced'
                          Chairs   Tables  Dressers
          RawWood            8        20      32
          Labor             12        32      45
          WarehouseSpace     4        12      10   ;

Table     Hiredata(resources,hireterms)  'Resource hiring data'
                          Cost   Maxavailable
          RawWood            3        200
          Labor             12        120
          WarehouseSpace     4        112;

Positive Variables   Production(products)    'Number of units produced'
                     HireResource(resources) 'Resources hired';
Variables            Profit                  'Total sum of net returns' ;

Equations            ProfitAcct              'Profit accounting equation'
                     Available(resources)    'Resource availability limit'
                     Hirelimit(resources)    'Resource hiring limit';

 ProfitAcct..
      Profit
      =e= sum(products, Netreturns(products) * Production(products))
         - sum(resources, Hiredata(resources,"cost") * HireResource(resources))   ;

 Available(resources)..
      sum(products,
          Resourceusage(resources,products) * Production(products))
      =l= Endowments(resources) +  HireResource(resources);

 Hirelimit(resources)..
          HireResource(resources) =l= Hiredata(resources,"Maxavailable");

Model resalloc /all/;

solve reasalloc using LP maximizing Profit;
```

Observe that we introduced the set `hireterms`, the table `Hiredata`, the positive variable `HireResource` and the equation `Hirelimit`. In addition, we included new terms in the equations `Profit` and `Available`

to reflect that through hiring the resources are increased, but hiring comes with a cost diminishing the profit. Thus the algebraic structure of the earlier model could be used as the core for this model that has additional features.

Note that this method may also be exploited for model development. Users may adapt models from other studies customizing them for the problem at hand and thus speeding up the development process. In addition to adapting models from related earlier studies that were done by the modeler or his group, model development may be jumpstarted by adapting models from the extensive GAMS Model Library.

4.13 Good Coding Practices

The GAMS language is quite flexible regarding the syntax and format of the code it accepts, offering users considerable latitude in how they organize and format their GAMS code. Most modelers develop their own style as they gain experience with the GAMS system. This tutorial reflects the coding preferences of Bruce A. McCarl (currently professor of Agricultural Economics at Texas A&M University). Note that Bruce has extensive experience with GAMS, both as a modeler and an educator, and many GAMS users know, use, and benefit from his work. The goal of this tutorial is *not* to present a rigid set of rules to follow arbitrarily, but rather to help users develop their own coding preferences and style. The larger goal is to build self-documenting models that are easy to read and understand, to edit, and to debug: both for the developer working in the present, and for a larger group of colleagues and consultants working with the model over a span of months or years.

We will cover the following topics:

- Using Longer Names and Descriptive Text
- Including Comments
- Choosing Raw Data Instead Of Computed Data
- Avoiding the Universal Set in the Context of Data Input
- Defining Sets and Subsets Wisely
- Structuring and Formatting Files to Improve Readability
- Other Suggestions

4.13.1 Using Longer Names and Descriptive Text

The readability of GAMS code may be significantly improved by using longer self-explanatory names for identifiers (e.g. names of sets, parameters, variables, etc). Consider the following lines of code from the production and inventory model [**ROBERT**]:

```
Sets  p     'products'       / low, medium, high /
      r     'raw materials'  / scrap, new /
      tt    'long horizon'   / 1*4 /
      t(tt) 'short horizon'  / 1*3 /;

Table  a(r,p)  input 'coefficients'

          low  medium  high
 scrap      5     3      1
 new        1     2      3;
```

```
Table  c(p,t)  'expected profits'

           1    2    3
low       25   20   10
medium    50   50   50
high      75   80  100;

Variables  x(p,tt)  'production and sales'
           s(r,tt)  'opening stocks'
           profit;

 Positive variables x, s;

 Equations  cc(t)    'capacity constraint'
            sb(r,tt) 'stock balance'
            pd       'profit definition' ;

 cc(t)..        sum(p, x(p,t)) =l= m;

 sb(r,tt+1)..   s(r,tt+1) =e= s(r,tt) - sum(p, a(r,p)*x(p,tt));

 pd..           profit =e= sum(t, sum(p, c(p,t)*x(p,t))
                          - sum(r, misc("storage-c",r)*s(r,t)))
                          + sum(r, misc("res-value",r)*s(r,"4"));

 s.up(r,"1") = misc("max-stock",r);
```

These lines may be reformatted in the following way (see (good.gms)):

```
Sets process          'available production process'
       / low    'uses a low amount of new materials',
         medium 'uses a medium amount of new materials',
         high   'uses a high amount of new materials' /
     rawmateral        'source of raw materials' / scrap, new /
     Quarters          'long horizon'            / spring, summer, fall, winter /
     quarter(Quarters) 'short horizon'           / spring, summer, fall /

 Table  usage(rawmateral,process)  'input coefficients'
          low  medium  high
 scrap      5     3      1
 new        1     2      3

 Table  expectprof(process,quarters)  'expected profits'
         spring summer fall
 low        25    20    10
 medium     50    50    50
 high       75    80   100;

 Variables  production(process,Quarters)    'production and sales'
            openstock(rawmateral,Quarters)  'opening stocks'
            profit ;

 Positive variables production, openstock;

 Equations  capacity(quarter)               'capacity constarint'
            stockbalan(rawmateral,Quarters) 'stock balance'
            profitacct                      'profit definition' ;
```

```
capacity(quarter)..
       sum(process, production(process,quarter)) =l= mxcapacity;

stockbalan(rawmateral,Quarters+1)..
     openstock(rawmateral,Quarters+1) =e=
     openstock(rawmateral,Quarters)
     - sum(process, usage(rawmateral,process)
                  *production(process,Quarters));

profitacct.. profit =e=
  sum(quarter,
      sum(process, expectprof(process,quarter)
                   *production(process,quarter))
    - sum(rawmateral, miscdata("store-cost",rawmateral)*
                      openstock(rawmateral,quarter)))
    + sum(rawmateral, miscdata("endinv-value",rawmateral)
                     *openstock(rawmateral,"winter"));

openstock.up(rawmateral,"spring") = miscdata("max-stock",rawmateral);
```

Note that the two formulations are equivalent in their effect, but in the second formulation longer, more descriptive names were used for the sets, tables, variables and equations. In addition, longer names were used for the set elements and in the definition of the set `process` the set elements have additional explanatory text. Observe that the second formulation is easier to understand. This will be particularly useful if and when the code is revisited in 5 years' time.

Note

- Recall that GAMS allows long names for identifiers and labels (set elements). Users may exploit this feature to introduce long descriptive names. However, note that names for labels that are longer than 10 characters do not work well in multi-column displays. See the paragraph on customizing display width for details.
- Use explanatory text for identifiers to indicate units, sources, descriptions, etc. It's not that hard to do and it pays dividends later.
- Similarly, use explanatory text for set elements as appropriate.

For example, the descriptive text in the in the second line in the following code snippet is much more informative than the text in the first line:

```
Parameter vehsales(r)   'regional vehicle sales';
Parameter vehsales(r)   'regional vehicle sales ($ millions/yr)';
```

Note that the descriptive text will be displayed whenever the respective identifier is displayed. Hence, including units in the text will save time if results will have to be interpreted later.

4.13.2 Including Comments on Procedures and the Nature and Sources of Data

We recommend that the documentation of the code offers answers to the following questions:

- What are the units of the variables and parameters?

- Where did the data come from?
- What are the characteristics of the data such as units and year of applicability?
- Why was a constraint set up in the way it is implemented?

In addition, it is often helpful to add comments that describe assumptions, the intent of equation terms, data sources, including document name, page number, table number, year of applicability, units, URL etc.

Consider the following example where various forms of comments are illustrated:

```
* this is a one line comment that could describe data
$ontext
My data could be described in this multi-line comment
This is the second line
$offtext

* The following dollar control option activates end-of-line comments
* and redefines the symbol for end-of-line comments
$eolCom #
x = sum(i, z(i)) ; # this is an end-of-line comment

* The following dollar control option activates in-line comments
* and redefines the symbols for in-line comments
$inLineCom (*  *)
x = sum(i, z(i)) ; (* this is an in-line comment *) r = sum(i, z(i)) ;
```

For more information on comments in GAMS, see section Comments.

4.13.3 Choosing Raw Data Instead Of Computed Data

Modelers often have a choice how they enter data: they could either use raw data and transform it to the extent needed inside GAMS or process data externally and enter the final results into GAMS.

The second choice may be attractive if the raw data is available in a spreadsheet where it can be manipulated before it is introduced to GAMS. However, over time spreadsheets and other data manipulation programs change or get lost and often these programs are not documented well. Therefore, we recommend to enter data into GAMS in a form that is as close as possible to the actual collected data and then manipulate the data with GAMS to obtain the desired form. This will make it much easier to update models later or to work out implicit assumptions.

4.13.4 Avoiding the Universal Set in the Context of Data Input

While GAMS permits using the universal set $*$ as an index in a parameter or table statement, in most cases it is *not* advisable to do so. Consider the following example from the production and inventory model [**ROBERT**]:

```
Sets   r          'raw materials'  / scrap, new / ;

Table  misc(*,r)  'other data'
            scrap  new
 max-stock    400  275
 storage-c     .5    2
 res-value     15   25   ;
...

pd.. profit =e= sum(t, sum(p, c(p,t)*x(p,t))
              - sum(r, misc("storage-c",r)*s(r,t)))
              + sum(r, misc("res-value",r)*s(r,"4"));
```

Note that the definition of the table `misc` indicates that any entry in the first index position is allowed. There is no domain checking. Consequently, if the label `res-value` is misspelled as `res-val` in the equation `pd`, GAMS will compile and execute the program without signaling an error, but instead of the expected values (i.e. `misc(r,"res-value")`), the values of `misc(r,"res-val")` will be used in the equation. These zero values will lead to faulty results, and the modeler will not be alerted to this fact. To ensure that the results of a GAMS run are reliable and trustworthy, we strongly recommend to use domain checking by introducing a new set for the labels in the first index position of the table `misc`:

```
Sets   r         'raw materials'
         / scrap, new /
       miscitem  'misc input items'
         / max-stock, storage-c, res-value /;

Table  misc(miscitem,r)  'other data'
            scrap  new
 max-stock    400  275
 storage-c     .5    2
 res-value     15   25   ;
```

Observe that the new set `miscitem` contains exactly the labels that appear in the rows of the table `misc`. Hence the set `miscitem` may be used in the first index position of the definition of `misc` without loss of generality, but with the benefit of domain checking.

4.13.5 Defining Sets and Subsets Wisely

Generally, the elements of a set have a feature in common or they are similar in some way. In this section we will give some guidance on how to partition the labels in the data into sets. In addition, we will discuss in which contexts it is useful to introduce subsets. For an introduction to sets in GAMS, see chapter Set Definition.

For example, suppose we have three grades of oil and three processes to crack it. The question arises whether we should introduce one set with nine elements or two sets with three elements and a two-dimensional set. We recommend the second alternative.

In another example, we consider a budget for farm spending: we have annual (i.e. cumulative yearly) spending for fertilizer and for seed and also monthly spending for labor and for water. There are 26 decisions or items in the budget. We could introduce a set with 26 elements or we could use the following formulation:

```
Sets resources  / fertilizer, seed, labor, water /
     periods    / jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, dec, annual /
     use(resources,periods)
                / (fertilizer,seed).annual
                      (labor,water)    .(jan,feb,mar,apr,may,jun,jul,aug,sep,oct,nov,dec) /;
```

We recommend the formulation above and to err on the side of being more extensive or exact with set definitions.

Occasionally it is necessary to group some labels into one set for a certain purpose and then single out some of them for another purpose. Subsets facilitate modeling such a case. For example, a set of all cities in a model may be needed to enter distances and compute related transportation costs. In addition, a subset can be used to specify the cities that are hubs for some activity, since some equations should be restricted to these hubs.

4.13.6 Structuring and Formatting Files to Improve Readability

In this section we will offer some guidlines on structuring and formatting the GAMS code to make it easy to read.

There are several ways to structure the GAMS code. Two styles are outlined in section Organization of GAMS Programs. The following recommendation to enter the sections of the code in a fixed order is an extended version of the first style:

1. Set definitions for sets that are data related
2. Parameter, scalar and table definitions, possibly intermixed with calculations
3. Variable definitions
4. Equation declarations
5. Equation definitions (algebraic specification of equations)
6. Model and solve statement(s)
7. Definitions of sets and parameters for report writing
8. Calculations for report writing
9. Display statement(s) for reports

Note that the code will be easiest to navigate if each section of the code contains only one type of statements. For example, interspersing set definitions with parameter definitions will make the code unnecessarily difficult to read.

In addition to following a fixed structure, it is also essential to properly format the code. Of course, formatting is in many respects a matter of taste. The following list offers some ideas:

- Align the names of identifiers and descriptive text, as demonstrarted in the examples in this tutorial and in the GAMS User's Guide in general.
- Use spacing and indents.
- Use blank lines to highlight something and to mark sections of the code.
- Ensure that variables and all their index positions are on one line in equation definitions.

- Indent in indexed operations like sums and programming flow control structures like loops and if statements to delineate terms. The structure of a long and complex statement may be revealed through careful indentation and thoughtful placement of closing parentheses.

We will demonstrate the effect of proper formatting with the following two examples. The first example contains valid GAMS code, but is deliberately poorly formatted:

```
Sets  products  'available production process' / low 'uses low new materials'
medium 'uses medium new materials', high 'uses high new materials'/
rawmateral    'source of raw materials'  / scrap, new /
Quarters    'long horizon'   / spring, summer, fall ,winter /
quarter(Quarters) 'short horizon'  / spring, summer, fall / ;
Variables  production(products,Quarters)  'production and sales' ;
openstock(rawmateral,Quarters)  'opening stocks', profit ;
Positive variables production, openstock;
Equations  capacity(quarter)  'capacity constraint',
stockbalan(rawmateral,Quarters) 'stock balance',
profitacct  profit definition ;
profitacct.. profit =e= sum(quarter, sum(products, expectprof(
products,quarter) *production(products,quarter))-sum(
rawmateral,miscdata("store-cost",rawmateral)*openstock(rawmateral
  ,quarter)))+ sum(rawmateral, miscdata("endinv-value",rawmateral)  *openstock(rawmateral,"winter"))
```

The second example contains the same code as the first example, but is carefully formatted:

```
Sets products          'available production process'
       / low    'uses a low amount of new materials',
         medium 'uses a medium amount of new materials',
         high   'uses a high amount of new materials' /
     rawmateral        'source of raw materials' / scrap, new /
     Quarters          'long horizon'            / spring, summer, fall, winter /
     quarter(Quarters) 'short horizon'           / spring, summer, fall / ;

Variables  production(products,Quarters)   'production and sales'
           openstock(rawmateral,Quarters)  'opening stocks'
           profit ;
Positive Variables production, openstock ;

Equations  capacity(quarter)               'capacity constraint'
           stockbalan(rawmateral,Quarters) 'stock balance'
           profitacct                      'profit definition' ;

profitacct..
    profit =e=
    sum(quarter,
       sum(products, expectprof(products,quarter)
                   *production(products,quarter)
           )
      - sum(rawmateral, miscdata("store-cost",rawmateral)*
                        openstock(rawmateral,quarter)
           )
       )
   + sum(rawmateral, miscdata("endinv-value",rawmateral)
                  *openstock(rawmateral,"winter")
       )
  ;
```

Observe that inserting blank lines, aligning the names of identifiers and descriptive text, and indenting and formatting closing parentheses in the sums makes the code much easier to read and understand (both now and in the future) and is well worth adopting as standard practice when writing GAMS code.

4.13.7 Other Suggestions

We will complete this tutorial by offering some other useful suggestions that may help modelers develop their own conventions.

Even though GAMS is case insensitive, it is advisable to establish some convention on the use of upper and lower case letters. For example, Paul N. Leiby (currently at Oak Ridge National Laboratory) uses lower case for texts and comments, and upper case for GAMS reserved words and variable and parameter names. The casing used when an identifier or label is first encountered in a GAMS program is the casing stored by GAMS and used in subsequent outputs like the listing file or a GDX file. Any casing can be used (so `noWhere` is equivalent to `nowHere`) but the casing stored is determined by first use.

A similar situation holds for label quoting: the type of quotes stored (if any) are determined by first use.

Note that the dollar control option $onSymList will cause a list of all identifier names to be displayed in the compilation output of the output file. This list may be used to review the spelling and casing of the identifiers as they will appear in output files. Similarly, the dollar control option $onUELList will cause an ordered list of all labels to be displayed in the compilation output of the output file. This is useful for checking both the case and order of the labels used in the GAMS program. For more on issues related to label ordering, see section Ordered and Unordered Sets.

To keep track of the data types of identifier names, some modelers always start set names with `s_`, names of parameters with `d_` (for "data"), variables names with `v_` and equation names with `e_`.

Some experienced GAMS users always surround explanatory text with quotes: this makes the text stand out, prevents it from being interpreted as a label or identifier, and allows special characters like `$`, `-` and `&` to be used.

If a file is used by several modelers and is updated occasionally, a file modification log at the top of the file will be in order. It should contain the following information: the modification date, version number, modification(s) made and who made the modification. For example, a set called `version` may be used to keep track of the dates the input files were modified:

```
Set version(*,*,*,*);
. . .
version("my_file","May","19","2016") = yes;
version("my_include_file","Sep","30","2016") = yes;
. . .
display version;
```

Note that the display statement will generate a display of all elements of the set `version`, each indicating on which day a component of the model was modified.

4.14 Fixing Compilation Errors

As detailed in chapter GAMS Output, the execution of a GAMS program passes through several stages, where the *compilation* is the first stage. Often when a program is run for the first time, it cannot be solved successfully because of compilation errors. This can be very frustrating, especially for new users. In this tutorial we will explain the causes of the most common compilation errors and offer some advice on how to fix them. For an introduction to compilation errors, see section Compilation Errors. In addition, the tutorial A GAMS Tutorial by Richard E. Rosenthal offers some detailed material on this topic.

Note

> Frequently, many compilation errors in the latter part of the code are actually consequential errors that will disappear as soon as the compilation errors in the beginning have been resolved. Therefore we recommend to start with fixing the first few errors and to run the program again. More often than not, many subsequent compilation errors will have vanished.

4.14.1 Preliminary Remarks

Before we will turn to an overview of the most common errors, examples that illustrate them and advice how to resolve them, we will provide some basic information on compilation errors and error messages.

4.14.1.1 Finding Compilation Errors

Compilation errors are marked with four asterisks (****) in the compilation output of the GAMS listing file (also called output file or lst file, since it has the extension `.lst`), hence it is easy to detect lines where compilation errors occured by inspection.

Note

Compilation error messages also appear in the LOG file. And, if GAMS Studio is used, a click at an error message in the LOG will navigate directly to the problematic code in the source file.

Consider the following simple example:

```
Set c "crops"   / barley, wheat, soy, wheat, rice /;
```

If this set statement appears in a program, the resulting compilation output will contain the following lines:

```
   1  Set c "crops"   / barley, wheat, soy, wheat, rice /;
****                                        $172

...
Error Messages

172  Element is redefined
```

Note that in the echo print of the input file a line starting with **** is inserted and the dollar sign `$` followed by a number appears on this line. This indicates that a compilation error - in this case error `172` - was discovered in the line above. In addition, a list of all errors with explanatory error messages is given at the end of the echo print.

In our example, the error refers to `wheat` and the error message addresses the cause of the error: the respective element is redefined. Thus we check the other elements of the set and quickly realize that `wheat` appears a second time. If we delete the second instance of `wheat` and run the code again, this line will not cause any errors anymore. Note that many compilation errors are as easy to fix as demonstrated here.

4.14.1.2 Repositioning Compilation Error Messages

By default, the error messages are shown directly beneath the line where the respective error is marked. GAMS allows to customize this position with the command line parameter ErrMsg: the value of 0 for `ErrMsg` will list all error messages at the end of the echo print and the value of 2 will suppress the error messages in the lst file completely. Note that the default is 1.

Consider the following simple example.

```
Set       a    / a1 * a7 /;
Set       b(a) / a7 * a9 /;
Parameter p(k) / i3 47 /;
```

The resulting compilation output will contain the following lines:

```
   1  Set       a    / a1 * a7 /;
   2  Set       b(a) / a7 * a9 /;
****                          $170
**** 170  Domain violation for element
   3  Parameter p(k) / i3 47 /;
****              $120
**** 120  Unknown identifier entered as set
```

Observe that the error messages are placed on the line after the error is marked. This can be especially useful if the program contains many lines of code. Next, we run the same code with the following call:

```
  > gams test  ErrMsg=0
```

The resulting compilaton output follows.

```
   1  Set       a    / a1 * a7 /;
   2  Set       b(a) / a7 * a9 /;
****                          $170
   3  Parameter p(k) / i3 47 /;
****              $120
...
Error Messages

120  Unknown identifier entered as set
170  Domain violation for element
```

Now the error messages are displayed at the end of the compiler listing.

Note

Default values for command line parameters and environment variables can be specified using a configuration file gamsconfig.yaml. The GAMS Configuration Editor can be used to view and edit the GAMS configuration file but any other text editor can be used as well. Alternatively, users may change the system level defaults by entering the line `ErrMsg=0` in the file `gmsprmnt.txt` on Windows, or `gmsprmun.txt` on Unix machines as in the following example:

```
************************************************
* GAMS 2.50 Default Parameterfile for Windows NT                *
* Gams Development Corp.                                        *
* Date : 20 Mar, 1998                                           *
************************************************
* entries required by CMEX, put in by gams.exe:
* SYSDIR
* SCRDIR
* SCRIPTNEXT
* INPUT
errmsg=0
```

4.14.2 Resolving Common Compilation Errors

There are hundreds of compilation errors in GAMS, but some of them are particularly frequent. In the table below we present these common errors, with a brief description of the possible cause and a link to a subsection below where examples and more details are given. We recommend that users also read the error messages, since they often contain additional hints.

GAMS Error	Common Cause of Error	Subsections with Examples and More Details
8	Closing parentheses, square brackets or braces are missing.	H
36	The two dots `..` are missing in the equation definition.	I
37	The equation type (eg. `=L=`) is missing in the body of the equation.	I
51-60	There are prohibited nonlinear expressions.	J
66	A data item which has not been given numerical values appears in an equation.	K
71	The equation has been declared, but not defined.	I
96, 97	A statement followed by another statement is not terminated with `;`.	B
120	GAMS cannot find a set with this name. Check for typos in the set name and set elements that are referenced without quotes.	C, L
125	The set is controlled more than once, e.g., by an indexed operation like `sum` and by an equation definition.	F
140	GAMS is looking for a keyword or declared item and cannot find it. Check spelling and declarations.	A, C, K, M

GAMS Error	Common Cause of Error	Subsections with Examples and More Details
141	The parameter without data is used or problems with `solve` and therefore attributes `.l` and `.m` are empty.	K
148	The identifier is referenced with more or less indexed sets than in the declaration.	E
149	The set is not controlled, neither by an indexed operation like `sum`, nor by an equation definition, nor by a loop or similar.	G, L
170	The referenced set element cannot be found in the set defined for this index position. Check for typos, omissions in the set declaration, missing quotes and references to the wrong set.	C, D
171	A domain error. The wrong set is referenced for the respective index position.	E, L
195	The name used here was already used for another identifier.	N
198	Using the operation `ord` or a lag/lead operation with a set that is not ordered.	O
256	Something is wrong with the model specification. This is often a consequential error of another error. Look for other error messages immediately after the solve statement.	I, J
257	The solver is not checked. This may be a consequential error of any GAMS error.	
340	Probably the quotes in a set element reference are missing.	L
408	Surplus closing parentheses, square brackets or braces.	H

4.14.2.1 Error A: Misplaced Semicolons

Maybe the most common error for new users is related to semicolons. Consider the following example adapted from the well-known transportation model [**TRNSPORT**]:

```
Sets  i   "canning plants"   / Seattle, San-Diego / ;
      j   "markets"          / New-York, Chicago, Topeka / ;
```

The resulting compilation output will contain the following lines:

```
   20    Sets i   canning plants   / Seattle, San-Diego / ;
   21         j   markets          / New-York, Chicago, Topeka / ;
****         $140      $36
...
Error Messages

 36  '=' or '..' or ':=' or '$=' operator expected
     rest of statement ignored
140  Unknown symbol
```

What went wrong? GAMS statements like the set statement in our example have to terminate with a semicolon, unless the next line of code begins with a reserved word. Now, set statements may extend over several lines and define several sets. In our example, the set statement extends over two lines and two sets are declared. However, there is a semicolon at the end of the first line, therefore GAMS assumes that the set statement ends there. The symbol `j` at the beginning of the next line has not been declared yet and it is not a GAMS keyword, thus it is marked as `Unknown symbol`. Note that error `36` is a consequential error that will disappear as soon as the first error has been resolved.

How do we fix this? There are two ways: either we could drop the semicolon at the end of the first line and thus indicate that the set statement continues to the second line or we could insert the keyword `Set` at the start of the second line and thus introduce a new set statement. These two alternatives are illustrated below:

```
Sets  i   "canning plants"   / Seattle, San-Diego /
      j   "markets"          / New-York, Chicago, Topeka / ;
```

or

```
Sets  i   "canning plants"   / Seattle, San-Diego / ;
Set   j   "markets"          / New-York, Chicago, Topeka / ;
```

Note

- In general, GAMS statements have to be terminated with a semicolon. The semicolon may be omitted if the next line starts with a GAMS keyword.
- Even if it is not required, it is good practice to always end a statement with a semicolon.

4.14.2.2 Error B: Missing Semicolons

Consider the following example adapted from the well-known transportation model [**TRNSPORT**]:

```
Equations
       cost        "define objective function"
       supply(i)   "observe supply limit at plant i"
       demand(j)   "satisfy demand at market j"

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
```

The resulting compilation output will contain the following lines:

```
   52    Equations
   53         cost        define objective function
   54         supply(i)   observe supply limit at plant i
   55         demand(j)   satisfy demand at market j
   56
   57    cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
****         $97                     $195,96,195,96 $195,96
...
Error Messages

 96  Blank needed between identifier and text
       (-or- illegal character in identifier)
       (-or- check for missing ';' on previous line)
 97  Explanatory text can not start with '$', '=', or '..'
       (-or- check for missing ';' on previous line)
```

What went wrong? GAMS statements like the equation declaration in our example have to terminate with a semicolon, unless the next line of code begins with a GAMS keyword. In our example, we omitted the semicolon at the end of the equation declaration statement and started a new statement after a blank line.

How do we fix this? We simply add a semicolon after the last explanatory text at the end of the equation declaration statement.

Note

A missing semicolon is often associated with error 96 or 97.

4.14.2.3 Error C: Spelling Mistakes

This error occurs if sets, set elements, parameters, etc. are referenced with a different name than the name they were declared with. Note that differences in capitalization are not considered spelling mistakes since GAMS is case insensitive.

Consider the following example adapted from the well-known transportation model [**TRNSPORT**]:

```
Sets i   "canning plants"   / Seattle, San-Diego /
     j   "markets"          / New-York, Chicago, Topeka / ;

Parameters a(i)  "capacity of plant i in cases"
          /   Seatle      350
              san-diego   600  / ;
...
Equations
       cost        "define objective function"
       supply(i)   "observe supply limit at plant i"
       demand(j)   "satisfy demand at market j" ;

cst ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
```

The resulting compilation output will contain the following lines:

```
   20    Sets i   canning plants   / Seattle, San-Diego /
   21         j   markets          / New-York, Chicago, Topeka / ;
   22
   23    Parameters a(i)  capacity of plant i in cases
   24             /   Seatle      350
****                     $170
   25                san-diego   600  / ;
...
   49    Equations
   50         cost        define objective function
   51         supply(i)   observe supply limit at plant i
   52         demand(j)   satisfy demand at market j ;
   53
   54    cst ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
****      $140
...
Error Messages

140  Unknown symbol
...
170  Domain violation for element
```

What went wrong? Note that in line 24 the set element `Seattle` was referenced as `Seatle`. GAMS does not recognize this symbol as an element of the set `i` and thus marks this with error `170`: `Domain violation`. GAMS catches this error since it automatically performs domain checking. The typo in line 54, where the equation `cost` is referenced as `cst`, is marked with error `140` (`Unknown symbol`), since `cst` was *not* declared before.

Note

Set name misspellings are associated with error `120`, set element misspellings with `170` and other misspellings with `140`.

Fixing errors like these is as easy as fixing typos.

4.14.2.4 Error D: Missing Set Elements

Sometimes users forget to include an element in a set statement, but reference it later. Consider the following simple example:

```
Set       c    "crops"                 / barley, wheat, soy /;
Parameter d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
```

The resulting compilation output will contain the following lines:

```
   1  Set            c    "crops"                 / barley, wheat, soy /;
   2  Parameter      d(c) "demand in metric tons" / rice 3, barley 1, wheat 4, soy 2 /;
****                                                $170
...
Error Messages

170  Domain violation for element
```

What went wrong? Note that the symbol `rice` was not defined as an element of the set `c`, thus GAMS does not recognize it and marks it with error `170`: `Domain violation`. GAMS catches this error since it automatically performs domain checking.

Note

If symbols are not defined as set elements, but are referenced as if they belong to the set later, error `170` will occur.

This is easy to fix: we just add the missing element(s) to the elements of the respective set.

4.14.2.5 Error E: Problems with Indices

Recall that variables, sets, parameters and equation may be defined over one or more indices. If the identifiers are referenced later in the program, the indices must appear exactly in the order that was specified in the respective definition statement. Consider the following example adapted from the well-known transportation model [**TRNSPORT**]:

```
Sets i   "canning plants"   / seattle, san-diego /
     j   "markets"          / new-york, chicago, topeka / ;

Table d(i,j)  "distance in thousands of miles"
                    new-york       chicago      topeka
      seattle          2.5           1.7          1.8
      san-diego        2.5           1.8          1.4  ;

Scalar    f       "freight in dollars per case per thousand miles"  /90/ ;
Parameter c(i,j)  "transport cost in thousands of dollars per case" ;
c(i,j,j) = f * d(j,i) / 1000 ;
```

The resulting compilation output will contain the following lines:

```
   40    Parameter c(i,j)  transport cost in thousands of dollars per case ;
   41    c(i,j,j) = f * d(j,i) / 1000 ;
****           $148       $171,171
...
Error Messages

148  Dimension different - The symbol is referenced with more/less
        indices as declared
171  Domain violation for set
```

What went wrong? Note that the parameter `c` was declared over two indices, but in the assignment statement in line 41 it is referenced with three indices. Such a mistake is marked with error `148`. Note further, that the indices of `d` are referenced in the wrong order, which is marked with error `171`.

Note

If an identifier is referenced with more or less indices as declared, then the error `148` will be triggered. If the indices are in the wrong order, the error `171` will be triggered.

This is easy to fix: we just check the declaration or definition statement(s) and adjust the reference.

Observe that the domain error `171` is also triggered if an identifier is referenced with index say `i`, but was defined over say `j`. However, there will be no domain error if `i` is a subset of `j` or `i` and `j` reference the same set since they are aliases.

4.14.2.6 Error F: Summing over Sets that are Already Indexed

Consider the following equation definition that is adapted from the well-known transportation model [**TRNSPORT**]:

```
supply(i) ..   sum((i,j), x(i,j))  =l=  a(i) ;
```

The resulting compilation output will contain the following lines:

```
   59    supply(i) ..   sum((i,j), x(i,j))  =l=  a(i) ;
****                          $125
...
Error Messages

125  Set is under control already
```

What went wrong? Note that the equation is indexed over the set `i`, therefore the indexed operation `sum` in the body of the equation may not be controlled by the index `i` again.

Note

Summing over sets that are already indexed will trigger error `125`.

How do we fix this? We need to carefully check the indexed operation and drop the surplus index. In other cases the controlling index may have to be dropped from the equation name. Note that an error like this is often indicative of a lack of clarity in thinking.

4.14.2.7 Error G: Uncontrolled Sets

Consider the following equation definition that is adapted from the well-known transportation model [**TRNSPORT**]:

```
demand ..   sum(i, x(i,j))  =g=  b(j) ;
```

The resulting compilation output will contain the following lines:

```
   61    demand ..   sum(i, x(i,j))  =g=  b(j) ;
****                             $149        $149
...
Error Messages

149  Uncontrolled set entered as constant
```

What went wrong? Note that the variable `x` is indexed over the sets `i` and `j`, but, while `i` is the index of the indexed operation `sum`, `j` is "free": it does neither appear as index of the equation nor as controlling index in `sum`. Therefore it was entered as if it were a constant. Note further, that `j` is also used as an index on the right-hand side of the equation without being controlled.

Note

Error `149` marks instances when an index is not controlled in the context of an equation or an indexed operation like `sum` or `prod`.

How do we fix this? We have to think what we actually want to model. In this case we need to enter `j` as a controlling index for the equation. But it would also be possible to add it as a controlling index for `sum` (but not both!). In the latter case there would still be the error on the right-hand side which needed to be taken care of with another indexed operation, e.g., `sum` again. Both approaches would remove the compilation error, but one has to think about what actually should be modeled to decide which is the right fix here.

4.14.2.8 Error H: Mismatched Parentheses

Consider the following two equations adapted from the model [**CHENERY**]:

```
mb(i).. x(i) =g= y(i) + sum(j, aio(i,j)*x(j)) + ( e(i) - m(i) ))$t(i) ;
...
dvv(i)$(sig(i) <> 0)..  vv(i) =e= (pi*(1-del(i))/del(i))**(-rho(i)/(1+rho(i)) ;
```

The resulting compilation output will contain the following lines:

```
   137   mb(i).. x(i) =g= y(i) + sum(j, aio(i,j)*x(j)) + ( e(i) - m(i) ))$t(i) ;
****                                                                    $408,409
...
   155   dvv(i)$(sig(i) <> 0)..  vv(i) =e= (pi*(1-del(i))/del(i))**(-rho(i)/(1+rho(i)) ;
****                                                                           $8
...
Error Messages

  8  ')' expected
...
408  Too many ),] or }
409  Unrecognizable item - skip to find a new statement
       looking for a ';' or a key word to get started again
```

What went wrong? Note that in the first equation we have one surplus closing parenthesis, this is marked with error `408`. The error marked with `409` is a consequential error, it will disappear once the first error has been fixed. In the second equation, one closing parenthesis is missing resulting in error `8`.

Attention

Opening and closing parentheses `( )`, square brackets `[ ]` and braces (curly brackets) { } must match.

Note

Surplus closing parentheses, bracketes and braces are marked with error `408` and missing closing parenthesis, brackets and braces are marked with error `8`. *Missing opening* parentheses, brackets and braces may result in GAMS marking *surplus closing* parentheses, brackets and braces; *surplus opening* parentheses, brackets and braces may result in GAMS marking *missing closing* parentheses, brackets and braces.

While fixing errors like these entails carefully counting opening and closing parentheses, there are strategies that help to prevent mismatching parentheses errors. Many text editors (like GAMS Studio) offer a feature that identifies matching parentheses and will issue a warning if there is a mismatch. We recommend to use this feature. Further, we recommend to also use the alternatives to parentheses: square brackets and braces. They are especially useful if there are several opening parentheses since it is easier to determine by inspection if each has a matching closing symbol.

4.14.2.9 Error I: Mistakes Relating to Equations

Recall that each declared equation must be defined if it is to be used in a model statement. If the equation definition is missing, GAMS will mark an error beneath the solve statement that refers to a model which references the respective undefined equation. Consider the following example adapted from the well-known transportation model [**TRNSPORT**]:

```
Equations
       cost        "define objective function"
       supply(i)   "observe supply limit at plant i"
       demand(j)   "satisfy demand at market j" ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;

Model transport /all/ ;
solve transport using lp minimizing z ;
```

The resulting compilation output will contain the following lines:

```
   60    Model transport /all/ ;
   61    solve transport using lp minimizing z ;
****                                          $71,256
**** The following LP errors were detected in model transport:
****  71 demand is an undefined equation
...
Error Messages

 71  The symbol shown has been declared as an equation, but no
       Symbolic equation (..) was found. hint - look for commas in the
       Documentation text for the equations. use quotes around the
       Text or eliminate the commas.
256  Error(s) in analyzing solve statement. More detail appears
     Below the solve statement above
```

What went wrong? Note that the equation `demand` was declared and included in the model `transport`, but it was not defined. GAMS detects that the equation definition is missing when it compiles the solve statement that relates to the model `transport`. Therefore the error `71` appears only there. The error `256` is a consequential error, it will disappear once the missing equation definition has been added (*before* the solve statement).

Note

Error `71` marks a missing equation definition. The message associated with this error is a nice example of an error message that is very descriptive and offers advice on how to fix the error.

Apart from forgetting to define a declared equation and forgetting to terminate the equation definition statement with a semicolon (see above), two other mistakes relating to equations are frequent: omitting the syntax element `..` after the name of the equation and not properly defining the equation type in the equation definition statement. The following simple example adapted from the portfolio analysis model [**ALAN**] illustrates these mistakes:

```
fsum       sum(i, x(i))               =e=  1.0;
dmean..    sum(i, mean(i)*x(i))        =   target;
```

The resulting compilation output will contain the following lines:

```
   45  fsum     sum(i, x(i))                 =e= 1.0;
****             $36
   46  dmean..    sum(i, mean(i)*x(i))        =  target;
****                                        $37
...
Error Messages

36  '=' or '..' or ':=' or '$=' operator expected
     rest of statement ignored
37  '=l=' or '=e=' or '=g=' operator expected
```

What went wrong? Note that in the first equation the two dots `..` are missing, which is marked with error `36`, and in the second equation the equation type is not properly specified, which leads to error `37`.

4.14.2.10 Error J: Issues with Nonlinear Expressions

The compilation error messages `51` to `60` refer to issues with nonlinear expressions involving variables in equations. For example, nonlinear expressions in an LP model will cause errors of this sort. So will discontinuous functions with endogenous arguments in an NLP model. For information on endogenous arguments in functions, see section Functions in Equation Definitions. For an overview of GAMS model types, see section Classification of Models.

Consider the following simple artificial example:

```
Variables x, y, z ;
Equations eq1, eq2 ;

eq1.. x**2 - y =e= z ;
eq2.. min(x,y) =l= 20 ;

Model silly / all / ;
solve silly using lp maximizing z ;
```

The resulting compilation output will contain the following lines:

```
   7  Model silly / all / ;
   8  solve silly using lp maximizing z ;
****                                   $54,51,256
**** The following LP errors were detected in model silly:
****  54 equation eq1.. VAR operands for **
****  51 equation eq2.. the function MIN is called with non-constant arguments

Error Messages

51  Endogenous function argument(s) not allowed in linear models
54  Endogenous operands for ** not allowed in linear models
256  Error(s) in analyzing solve statement. More detail appears
     Below the solve statement above
```

Note that error `54` marks the nonlinear expression x^2 in a linear model and error `51` refers to the discontinuous function `min` that may be used with variables only in models of the type DNLP. The error `256` is a consequence of the two previous errors.

4.14.2.11 Error K: Using Undefined Data

Referencing data items that were not declared with a scalar, parameter or table statement will cause error 140: GAMS will indicate that the respective symbol is unknown. More often data items are declared, but not defined, i.e. they are not initialized with values.

Consider the following example adapted from the well-known transportation model [**TRNSPORT**]. Assume that the scalar f is declared, but has no numerical value. The resulting compilation output will contain the following lines:

```
   40    Scalar f  freight in dollars per case per thousand miles  ;
   41
   42    Parameter c(i,j)  transport cost in thousands of dollars per case ;
   43
   44              c(i,j) = f * d(i,j) / 1000 ;
****                      $141
...
   61    Model transport /all/ ;
   62    solve transport using lp minimizing z ;
****                                          $257
   63
   64    display x.l, x.m ;
****              $141
...
Error Messages

141  Symbol declared but no values have been assigned. Check for missing
        data definition, assignment, data loading or implicit assignment
        via a solve statement.
        A wild shot: You may have spurious commas in the explanatory
        text of a declaration. Check symbol reference list.
257  Solve statement not checked because of previous errors
```

What went wrong? Note that the scalar f was declared, but there was no value assigned to it. Thus, when it is referenced in the calculation in line 44, the "empty" scalar causes error 141. Error 257 is a consequential error and leads to the second error 141. This error occurs in the context of variable attributes in the display statement. Recall that variable attributes are data associated with variables. As the solve statement could not be checked, the level and marginal values of the variable x are not defined and hence error 141 follows.

Note

> Error 141 marks places where data items, that have not been defined, are referenced in computations in the context of assignment statements. It also marks places where undefined variable (or equation) attributes are referenced.

In addition, undefined data items may be referenced in the context of equation definitions. Suppose we declare the parameter c in model [**TRNSPORT**], but forget the corresponding assignment statement. Then the compilation output will contain the following lines:

```
   57    cost ..        z  =e=  sum((i,j), c(i,j)* x(i,j)) ;
 ...
   62    solve transport using lp minimizing z ;
****                                          $66,256
**** The following LP errors were detected in model transport:
```

```
****  66 equation cost.. symbol "c" has no values assigned
...
Error Messages

 66  The symbol shown has not been defined or assigned
        A wild shot: You may have spurious commas in the explanatory
        text of a declaration. Check symbol reference list.
256  Error(s) in analyzing solve statement. More detail appears
     Below the solve statement above
```

Note that the missing data in the body of the equation `cost` is marked with error `66` and the following error is a consequential error which will disappear once `66` has been fixed.

Note

Referencing undefined data items in the body of an equation causes error `66`.

4.14.2.12 Error L: Referencing Set Elements Without Quotes

Recall that if set elements are referenced, they need to appear in single or double quotes. Omitting the quotes may cause different errors depending on the context. The following example is adapted from the well-known transportation model [**TRNSPORT**]. Suppose we start by defining the two sets and the two parameters and then add the following statements:

```
Scalar s;
s = a(seattle);
```

The resulting compilation output will contain the following lines:

```
   37  Scalar s;
   38  s = a(seattle);
****              $120,340,149,171
...
Error Messages

120  Unknown identifier entered as set
149  Uncontrolled set entered as constant
171  Domain violation for set
340  A label/element with the same name exist. You may have forgotten
        to quote a label/element reference. For example,
        set i / a,b,c /; parameter x(i); x('a') = 10;
```

What went wrong? On the right-hand side of the assignment statement we have a reference with missing quotes. Note that this creates four (!) errors:

- `120` - GAMS expects a controlling set and `Seattle` is not recognized and therefore considered an unknown identifier.
- `340` - Then GAMS realizes that actually there is a label called `Seattle` in the program and helpfully offers a hint: `You may have forgotten to quote a label/element reference.`
- `149` - See section Error G: Uncontrolled Sets above.
- `171` - See section Error E: Problems with Indices above.

This is a nice example for one mistake triggering several errors that may look daunting. However, fixing them is as easy as adding single or double quotes.

4.14.2.13 Error M: Missing Declaration Statements

Recall that sets, parameters, variables and equations have to be declared before they may be used in definition or assignment statements. Suppose the equation `demand` in the well-known transportation model [**TRNSPORT**] was defined but not declared. Then the compilation output would contain the following lines:

```
   59    demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;
****         $140
...
Error Messages

140  Unknown symbol
```

Note that as `demand` was not declared, GAMS does not recognize it and therefore marks it with error `140`: `Unknown symbol`.

Note

If error `140` is reported, the respective declaration statement is probably missing. However, the underlying cause may also be a simple typo.

4.14.2.14 Error N: Using the Same Name for Different Identifiers

Recall that each GAMS identifier must have a unique name. If the same name is used more than once, an error will be triggered. Consider the following modification of the transportation model [**TRNSPORT**]:

```
Parameters  capacity(i)  "capacity of plant i in cases"
               / Seattle 350, San-Diego 600 /

            demand(j)    "demand at market j in cases"
               / New-York 325, Chicago 300, Topeka 275 /;
...
Equations
       cost        "define objective function"
       supply(i)   "observe supply limit at plant i"
       demand(j)   "satisfy demand at market j" ;
```

The resulting compilation output will contain the following lines:

```
   47    Equations
   48         cost        define objective function
   49         supply(i)   observe supply limit at plant i
   50         demand(j)   satisfy demand at market j ;
****             $195
...
Error Messages

195  Symbol redefined with a different type
```

What went wrong? Note that `demand` was first declared as a parameter and later as an equation. GAMS will mark this repeated use of the same name with error `195`.

4.14.2.15 Error O: Using ORD with an Unordered Set

Recall that the operation ord is only defined for ordered sets. If `ord` is used with an unordered set, error `198` will be triggered.

Consider the following example:

```
Set    a   "a couple of the elements" / r2, r3 /;
Set    b   "more elements"            / r1*r4 /;
Scalar c   "counter"                  / 0 /;

loop( b $ (ord(b) > 3),
    c = c + 1 );
display c;
```

The resulting compilation output will contain the following lines:

```
   5  loop( b $ (ord(b) > 3),
****                $198
   6      c = c + 1 );
...
Error Messages

198  Set used in 'ord' or lag is not ordered.
        Hint: Some of the elements of the set were used before this
        was initialized and the order was different from the order used
        in this set. Try to initialize the set earlier.
        $offOrder allows lag operations on dynamic sets, reset with
        $onOrder
```

What went wrong? Two elements of the set `b` featured already in set `a` that was defind before set `b`. Therefore the order of the elements in set `b` is as follows:

```
r2 r3 r1 r4
```

Obviously, this set is not orderd and hence GAMS marks error `198` when the operator `ord` is applied to it.

How do we fix this? In this case it is easy: we just define the set `b` before set `a` and `b` will be an ordered set.

Consider one last example:

```
Set    a   "all elements"                / r1*r10 /;
Set    b   "elements in different order" / r3, r1, r4, r7 /;
Scalar c   "counter"                     / 0 /;

loop( b $ (ord(b) > 3),
    c = c +1 );
display c;
```

The resulting compilation output will contain the following lines:

```
   5  loop( b $ (ord(b) > 3),
****                 $198
   6      c = c +1 );
```

What went wrong? Note that even though all elements in set `b` are also elements of set `a`, they are not specified in the same order. Therefore the set `b` is unordered. For more details, see section Ordered and Unordered Sets.

4.15 Finding and Fixing Execution Errors and Performance Problems

This tutorial is structured in four main parts: we will discuss how to find and resolve errors that are detected during execution of a GAMS model, we will give some guidance for model development and debugging and we will present techniques to increase efficiency by reducing GAMS execution time and memory use.

4.15.1 Resolving Execution Errors

Recall that GAMS passes through a program file several times in the process of generating and solving a model. Errors may occur in each phase. In this section we will give some guidance on how to resolve errors that occur during execution, so after compilation. For advice on resolving compilation errors, see the tutorial Fixing Compilation Errors. For more information on the process of generating and solving a model in GAMS, see the introduction to chapter GAMS Output.

At execution, several things could go wrong and cause an error. We will look at these potential error sources separately in this section. First we look at arithmetic errors and exceeded internal limits during data manipulation, we will continue with problems during model generation and model solution. At the end, we will briefly discuss how execution errors may be managed with the function execError.

4.15.1.1 Arithmetic Errors

GAMS execution errors may be caused by illegal arithmetic operations like a negative argument for `log`, division by zero and exponentiation where the base is a negative number. The following simple example serves as illustration:

```
Set       s     / s1*s5 / ;
Parameter p(s)  "data to be exponentiated"
          d(s)  "divisors"
          r(s)  "result";

p(s)    = 1;
p("s2") = -1;
d(s)    = 1;
d("s3") = 0;
r(s)    = p(s)**2.1 / d(s)
display r;
```

The first sign that something in the execution went wrong is the following flag in the log output:

```
*** Status: Execution error(s)
```

The resulting execution output will contain the following lines:

```
E x e c u t i o n

**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)

----     11 PARAMETER r  result

s1 1.000,    s2  UNDF,    s3  UNDF,    s4 1.000,    s5 1.000
```

Observe that the execution output begins with two error messages that can be easily found since they are marked with four asterisks ****. The error messages are very informative: they indicate the line where the errors occurred and provide details about the nature of the errors. Further, the output generated by the display statement shows that the errors occurred when the values for `r("s2")` and `r("s3")` were computed. Inspecting the assignment statement for these two values, we realize that in the first instance the base for the exponentiation is -1, which obviously is a negative number and hence is not allowed in this operation. In the second instance, the problem is that we divide by `d("s3")` which equals zero.

In this example, the errors are easily resolved with data revisions. In general, we recommend to use conditional assignments to prevent errors like these.

Note that in the example above the error messages indicated exactly where the problem was and it was easy to find the cause of the error. However, this is not always the case. In particular, if the problem is within a multi-dimensional item the user will need more patience. Usually it helps to display the results of the problematic operation and look for faulty entries. In addition, displaying the input data to the respective operation will help to investigate the numerical properties of the data that was entered in the computation. Often more displays will be needed to trace faulty input data through the program. Eventually this will lead the user to understand why the data has taken on the specific numerical values it has.

4.15.1.2 Exceeding GAMS Limits

By default, GAMS stops the solve of a model after 1e10 seconds (wall clock time) or 2e9 iterations. These limits may be adjusted with the options reslim and iterlim respectively. Note that both options are also available as command line parameters and model attributes. In addition, the workspace may be limited with the command line parameters WorkFactor and WorkSpace. Note that these options are also available as model attributes. If any of these limits are exceeded, the execution of the solve statement will be interrupted.

For example, we could add the following option statement somewhere *before* the solve statement in the production model [**CHENERY**]:

```
option iterlim = 20;
```

Note that this statement reduces the iteration limit to just 20. The log output will contain the following lines:

```
 ** Feasible solution. Value of objective =    1033.34069261

 ** The iteration limit has been reached.

--- Restarting execution
--- chenery.gms(228) 2 Mb
--- Reading solution for model chenrad
*** Status: Normal completion
--- Job chenery.gms Stop 11/21/16 16:52:43 elapsed 0:00:00.106
```

Also the solve summary in the listing file notes the interrupt:

```
               S O L V E      S U M M A R Y

     MODEL   chenrad             OBJECTIVE  td
     TYPE    NLP                 DIRECTION  MAXIMIZE
     SOLVER  CONOPT              FROM LINE  228

**** SOLVER STATUS     2 Iteration Interrupt
**** MODEL STATUS      7 Feasible Solution
**** OBJECTIVE VALUE             1058.9199

 RESOURCE USAGE, LIMIT          0.078      1000.000
 ITERATION COUNT, LIMIT        20            20
 EVALUATION ERRORS              0             0
```

Observe that the solver status `Iteration Interrupt` indicates that the execution terminated because the iteration limit has been reached resulting in a feasible solution, but not the optimal solution. The line `ITERATION COUNT, LIMIT ...` reports that 20 iterations were performed and that 20 was also the limit for the number of iterations. Setting `iterlim` to a larger value will resolve this issue.

Similarly, allocating too little work space will cause the solver to terminate with no solution. For example, restricting the work space for the nonlinear test model [**MHW4D**] to just 0.1 MB and running it with the solver MINOS will produce the following lines in the log output:

```
 Work space requested by solver --     0.77 Mb
 Work space requested by user   --     0.10 Mb
 Work space allocated           --     0.10 Mb

  Reading Rows...
  Reading Columns...
  Reading Instructions...

 EXIT - Not enough storage to solve the model.
        Request at least    0.19 Mbytes.
```

The solve summary in the listing file will contain the following information:

```
               S O L V E      S U M M A R Y

     MODEL   wright              OBJECTIVE  m
     TYPE    NLP                 DIRECTION  MINIMIZE
     SOLVER  MINOS               FROM LINE  32

**** SOLVER STATUS     9 Setup Failure
**** MODEL STATUS      13 Error No Solution
```

Note that increasing the work space to at least the minimum amount requested by the solver will resolve this issue.

When dealing with large nonlinear expressions defined over a very large domain, one can face the following error.

```
*** Status: Terminated due to limits in NLCodeAdd
***         Cannot handle more than 2147483647 instruction in NL code
***         Inspect listing file for more information
```

The first thing to check in this case is correctness of the model i.e., if you are not generating anything more than necessary. If this is not the case and the model is indeed large, a generic advise is to introduce intermediate variables to get a smaller code size per block of equations. One can also consider partitioning the domains so that one can have more number of smaller blocks.

4.15.1.3 Resolving Model Generation Errors

Further execution errors may be detected when GAMS is generating the model before passing it to the solver. These errors may be arithmetic errors in the *body* of equations or errors in the structure of the model that cause the model to be inherently infeasible.

Consider the following simple example with arithmetic errors in the body of the equations. They are similar to the errors in the assignment in the example in section Arithmetic Errors above.

```
Set       s     / s1*s5 / ;
Parameter p(s)  "data to be exponentiated"
          d(s)  "divisors"
          m(s)  "multipliers";

p(s)    = 1;
p("s2") = -1;
d(s)    = 1;
d("s3") = 0;
m(s)    = 1;
m("s4") = 0;

Positive variable x(s);
Variable          z;

Equations obj  "objective function"
          xlim;

obj..      z =e= sum(s,p(s)**2.2*x(s));
xlim(s)..  m(s) / d(s)*x(s) =e= 1;

Model mymodel / all /;
solve mymodel using lp maximizing z;
```

If we run this model, the log output will contain the followng lines:

```
*** SOLVE aborted
--- Executing CPLEX: elapsed 0:00:00.006
--- test.gms(23) 4 Mb 3 Errors
*** Status: Execution error(s)
--- Job test.gms Stop 11/21/16 19:10:12 elapsed 0:00:00.006
```

Observe that the solve was aborted since there are 3 execution errors. The equation listing in the listing file will contain further details about these execution errors:

```
Equation Listing    SOLVE mymodel Using LP From line 23

**** Exec Error at line 19: rPower: FUNC DOMAIN: x**y, x < 0

---- obj  =E=  objective function

obj..  - x(s1) + UNDF*x(s2) - x(s3) - x(s4) - x(s5) + z =E= UNDF ; (LHS = UNDF)

**** Exec Error at line 20: division by zero (0)
**** Exec Error at line 20: Equation infeasible due to rhs value
```

```
**** INFEASIBLE EQUATIONS ...

---- xlim  =E=

xlim(s4)..  0 =E= 1 ; (LHS = 0, INFES = 1 ****)

REMAINING 4 ENTRIES SKIPPED
```

Note that there is an arithmetic error relating to exponentiation in the first equation and an arithmetic error and an infeasibility in the second equation.

In our example, it was easy to detect the execution errors and their cause. However, an error in a multi-dimensional equation block may be much more difficult to find. Note that by default, only the first three entries in each equation block are shown in the equation listing. We recommend to use the option limrow to get a full listing, as this is the easiest way to inspect execution errors in the body of equations.

4.15.1.4 Resolving Solve Errors

In the solution phase, an external solver program processes the model and creates output with details about the solution process. Solve errors may be either function evaluation errors or presolve errors.

Resolving Function Evaluation Errors

Some solve statements require the evaluation of nonlinear functions and the computation of derivatives. Since these calculations are not carried out by GAMS but by other subsystems not under the direct control of GAMS, errors associated with these calculations are reported in the solution report.

Function evaluation errors are numerical errors like those discussed in section Arithmetic Errors above. Other examples include square roots of negative variables and squaring a negative term, say `x`, using the syntax `x**2`.

Attention

> Squaring a negative term, say `x`, using the syntax `x**2` will cause an error. However, the alternatives `sqr(x)` and `x*x` will work (see here for an explanation).

Note that by default the solver subsystems will interrupt the solution process if arithmetic errors are encountered. Users may wish to permit a certain number of arithmetic errors and have reported *error warnings* instead. The option domlim facilitates this modification. Note that the default value for `domlim` is zero.

The best way to avoid evaluating functions outside their domain of definition is to specify reasonable variable bounds. However, there are cases when bounds are not enough. Consider the following simple example:

```
Set       i  / i1*i5 /;
Variables x(i), z;
Equations r1, r2(i);

r1..     z =e= log(sum(i, x(i)));
r2(i)..  x(i) =l= 10;
x.lo(i) = 0;
x.l(i)  = 5;

Model takelog / all /;
solve takelog using nlp minimizing z;
```

If we try to solve this little program with the solver MINOS, the log output will contain the following line:

```
EXIT - Function evaluation error limit exceeded.
```

The solution report in the listing file will have more detailed information:

```
               S O L V E      S U M M A R Y

     MODEL   takelog             OBJECTIVE  z
     TYPE    NLP                 DIRECTION  MINIMIZE
     SOLVER  MINOS               FROM LINE  12

**** SOLVER STATUS     5 Evaluation Interrupt
**** MODEL STATUS      7 Feasible Solution
**** OBJECTIVE VALUE                0.0000

 RESOURCE USAGE, LIMIT          0.183      1000.000
 ITERATION COUNT, LIMIT         0    2000000000
 EVALUATION ERRORS              2             0

...

 EXIT - Function evaluation error limit exceeded.

**** ERRORS/WARNINGS IN EQUATION r1
     2 error(s): log: FUNC DOMAIN: x < 0 (RETURNED 0)

...

**** REPORT SUMMARY :         1     NONOPT ( NOPT)
                             0 INFEASIBLE
                             0  UNBOUNDED
                             1     ERRORS ( ****)
```

Note that the solver status has a value of 5 (`Evaluation Interrupt`), which means that the solver has been interrupted as more evaluation errors have been encountered than specified with the option domlim. In our case `domlim` equals its default value zero, thus one error is enough to cause the interruption. The equation in which the evaluation error occurred and the type of error is reported a few lines later. In our example, the equation `r1` is problematic, since we take the logarithm of the expression `sum(i, x(i))`, an expression which may become zero.

Note that in models such as this each individual variable `x(i)` should be allowed to become zero, but the sum should not. This may be achieved by introducing an intermediate variable, say `xsum`, adding a lower bound greater than zero for it and using this variable as the argument for the function `log`:

```
Variable xsum;
xsum.lo = 0.0001;

Equations defxsum, r1;

defxsum ..    xsum =e= sum(i, x(i));
r1..          z =e= log(xsum);
```

For more information on intermediate variables, see section Avoiding Expressions in Nonlinear Functions in the tutorial Good NLP Formulations.

Observe that solvers report the type of arithmetic problem encountered and the problematic equation, but do not identify the particular offending variable or the labels in the index of an equation that cause the error. If the cause is not obvious, users will have to investigate the numerical properties of the variables, labels and parameters in the body of the respective equation. This may involve the following:

- Displaying the input data items to the nonlinear terms in the respective equation.
- Searching the solution for equations that are infeasible (`INFES`) and variables that are nonoptimal (`NOPT`) in order to see where problems are present and which variables were being manipulated at the end of the run.
- Investigating variables and equations whose level values are zero, negative or very large at the end of the run.
- Deactivating part of the code to narrow down the problem as discussed in section Isolating Terms in Slow Statements below.

Resolving function evaluation errors will usually entail the following techniques:

- Adding lower bounds to variables to keep them above zero.
- Adding upper bounds to variables to prevent them from getting too large.
- Reformulating the model, for example, introducing intermediate variables.
- Providing better starting points that direct the solver search to a more relevant region. See section Specifying Initial Values in tutorial Good NLP Formulations for details.
- Fixing faulty input data.

Presolve Errors

Some solvers use a pre-processing step where the program is presolved to make the main solution process faster. During this step model errors could already be discovered, as in the following example:

```
Variables         z;
Integer Variables y1,y2;

Equations         r1,r2,r3,r4;

   r1..  z=e=y1+y2;
   r2..  y1=g=0.10;
   r3..  y2=g=0.10;
   r4..  y1+y2=l=1;

Model badpresol /all/;
solve badpresol using mip maximizing z;
```

For this problem, Cplex detects in the presolve already, that there is no feasible integer solution. This is reported in the log:

```
Row 'r4' infeasible, all entries at implied bounds.
Presolve time = 0.00 sec. (0.00 ticks)

...

CPLEX Error  1217: No solution exists.
Problem is integer infeasible.
```

Here, Cplex makes it clear, where we have a problem: Row `r4` is infeasible, because all entries are at their "implied bounds". Lets look at `r2` and `r3` to see what this means: These equations set a lower bound of 0.1 for `y1` and `y2`. Since both variables are defined as `Integer Variables`, they get an implicit lower bound of 1. Given that, equation r4 must be infeasible.

Solver Specific Limits

Many solvers have internal limits that may be exceeded and may cause the listing file to report an execution error. These errors may be resolved by using either GAMS options or solver specific options to increase the respective limits. Usually, the listing file will contain information about which options to use. Note that the solver manuals distributed with GAMS list the options that may be specified for each solver. For example, to relax the MINOS major iteration limit, the user may create a file named `minos.opt` with the following line:

```
Major iterations 1000
```

More about solver option files can be found in section The Solver Options File.

4.15.1.5 Managing Execution Errors with the Function execError

The function execError facilitates implementing procedures that manage execution errors. Consider the following example, which is an extension of the example in section Arithmetic Errors above.

```
Set       s     / s1*s5 / ;
Parameter p(s)  "data to be exponentiated"
          d(s)  "divisors"
          r(s)  "result";

p(s)    = 1;
p("s2") = -1;
d(s)    = 1;
d("s3") = 0;
r(s)    = p(s)**2.1 / d(s)
display r;

*cause z to be undefined
Scalar z;
z = 1/0;

if(execError > 0,
   r(s)$(r(s) = z) = 0;);
display r;
```

Observe that we introduced a new scalar `z` that is deliberately undefined. In the if statement that follows, we use the function `execError` in the logical condition and the undefined scalar in the conditional assignment. The if statement has the effect that undefined entries are removed from the array of the parameter `r`, as illustrated in the following lines of the execution output:

```
E x e c u t i o n

**** Exec Error at line 10: rPower: FUNC DOMAIN: x**y, x < 0
**** Exec Error at line 10: division by zero (0)

----     11 PARAMETER r  result

s1 1.000,    s2  UNDF,    s3  UNDF,    s4 1.000,    s5 1.000

**** Exec Error at line 16: division by zero (0)

----     20 PARAMETER r  result

s1 1.000,    s4 1.000,    s5 1.000
```

In addition, the function execError may be used to reset the count of the number of execution errors. Typically, it is reset to zero so that GAMS will terminate with the status message `Normal completion`. For example, we could add the following line at the end of the code in the example above:

```
execError = 0;
```

Note

Setting `execError = 0;` will not only result in a `normal completion` in the example above. A solve statement will not be executed if there were execution errors before by default. Setting `execError = 0;` before the solve statement, will allow to execute it again.

Setting `execError = 0;` results also in a notification in the log:

```
********************************
*** Errors have been cleared ***
********************************
*** Status: Normal completion
```

4.15.2 Small to Large: Aid in Development and Debugging

Many GAMS users are overly impressed with how easily GAMS handles large models. Modelers often feel such a facility means they should always work on the full model. The result is often a large, sometimes extremely large, model in the early stages of model development. Debugging such large formulations is not easy.

The algebraic modeling style employed in GAMS is inherently expandable. This offers interesting possibilities in terms of the strategy that may be employed for model development and debugging which are discussed herein.

4.15.2.1 An Illustrative Example

The set based algebraic modeling style implemented in GAMS is by its very nature easy to expand. It is easy to use the same model formulation on differently sized data sets. We will illustrate this based on the transportation model [**TRNSPORT**]. Note that we included some post-solution calculations at the end.

```
* Data section
Sets  i   "canning plants"   / Seattle, San-Diego /
      j   "markets"          / New-York, Chicago, Topeka / ;

Parameters  a(i)  "capacity of plant i in cases"
               / Seattle   350, San-Diego  600/

            b(j)  "demand at market j in cases"
               / New-York 325, Chicago 300, Topeka 275 /;

Table       d(i,j)  "distance in thousands of miles"

                          New-York       Chicago      Topeka
           Seattle          2.5            1.7         1.8
           San-Diego        2.5            1.8         1.4  ;

Scalar f  "freight in dollars per case per thousand miles" /90/ ;

Parameter   c(i,j)  "transport cost in thousands of dollars per case" ;
c(i,j) = f * d(i,j) / 1000 ;

* Model Section
Positive Variable  x(i,j)  "shipment quantities in cases";
Variable           z       "total transportation costs in thousands of dollars";

Equations cost        "define objective function"
          supply(i)   "observe supply limit at plant i"
          demand(j)   "satisfy demand at market j";

cost ..        z  =e=  sum((i,j), c(i,j) * x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Parameter   m(*,*)  "commodity movement";
m(i,j) = x.l(i,j);
m("total",j) = sum(i, x.l(i,j));
m(i,"total") = sum(j, x.l(i,j));
m("total","total") = sum(j, m("total",j));
option decimals = 0;
display m;
```

This model may be easily extended by adding more data:

```
* Data section
Sets  i   "canning plants"   / Seattle, San-Diego, Baltimore, Dallas    /
      j   "markets"          / New-York, Chicago, Topeka, Boston, Miami /;
```

```
Parameters  a(i)  "capacity of plant i in cases"
              / Seattle   350, San-Diego  600, Baltimore 450, Dallas  750 /

            b(j)  "demand at market j in cases"
              / New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;

Table       d(i,j)  "distance in thousands of miles"

                          New-York    Chicago   Topeka   Boston   Miami
           Seattle          2.5          1.7      1.8     3.1      3.3
           San-Diego        2.5          1.8      1.4     3.0      2.7
           Baltimore        0.2          0.7      1.8     0.4      1.1
           Dallas           1.5          0.9      0.5     1.8      1.3 ;

Scalar f  "freight in dollars per case per thousand miles" /90/ ;

Parameter   c(i,j)  "transport cost in thousands of dollars per case" ;
c(i,j) = f * d(i,j) / 1000 ;

* Model Section
Positive Variable  x(i,j)  "shipment quantities in cases";
Variable           z       "total transportation costs in thousands of dollars";

Equations cost        "define objective function"
          supply(i)   "observe supply limit at plant i"
          demand(j)   "satisfy demand at market j";

cost ..        z  =e=  sum((i,j), c(i,j) * x(i,j)) ;
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;
solve transport using lp minimizing z ;

Parameter   m(*,*)  "commodity movement";
m(i,j) = x.l(i,j);
m("total",j) = sum(i, x.l(i,j));
m(i,"total") = sum(j, x.l(i,j));
m("total","total")=sum(j, m("total",j));
option decimals = 0;
display m;
```

Observe that the two sets (`i` and `j`) were enlarged, the capacity (`a`) and demand (`b`) data were expanded to cover the new plant and market entries and the distance table (`d`) was adjusted accordingly. However, the data calculation, equations, model definition, model solution and report writing sections are identical in the two models.

4.15.2.2 Motivation and Step by Step Guide

As we have demonstrated in the example above, GAMS allows the model structure, calculations and report writing to be developed and implemented using a small data set, that may be easily expanded to larger data sets. Thus, we strongly recommend to start with a representative purposefully small data set and enlarge it to its full size once the work of model development, testing and debugging has been done. In short: work from small to large.

The larger the model the longer it takes to compile it, generate the model, execute and solve it. Generally, time expands exponentially. Working with a large model from the start will often lead to frustration even when the user is trying to find some relatively small data problems.

If a model that has already been completed needs some modification, it will be tempting to use the large data set instead of developing the modifications on a small data set. We strongly advise to use a small data set in this case, as experience shows that this way a considerable amount of time may be saved.

We recommend to follow these steps in model development:

1. Set up a small data set representing the full model with all structural features, set names, parameters etc.
2. Implement all data calculations, model features and report writing calculations.
3. Test the results of step 2 thoroughly.
4. Save the small model. Then implement a larger version with the full data set. Create separate files for data, calculation, model definition and report writing to maintain size independence. Use include files or the save and restart feature.
5. Test the larger model. Use the modeling techniques discussed below to facilitate your work.
6. Keep the small model current. As additional structural features are added to the large model, use it to test them. See section Introducing Strategical Subsets below for an easy way to maintain a small model.

4.15.2.3 Modeling Techniques

If users follow the steps for model development outlined in section Motivation and Step by Step Guide above, they will notice that it will not always be possible to model every needed feature with the small model. It is important to carefully choose the small data set so that it has all features of the larger data set. However, occasionally the peculiarities and interrelationships of the full data set cannot be reproduced in the small data set. In this section we will introduce some modeling techniques for finding problems that arise *only* when the full data set is used. They include saving and restarting to isolate the problem area, strategically introducing subsets and data reduction.

Isolating Problem Areas through Saving and Restarting

Suppose we have a model with a large data set that takes several hours to run and we wish to add some lines of code in a relatively small segment. The best way to do this is by isolating the relevant part. Isolating the part we wish to modify makes it possible to do tests and repairs without having to input data, do initial calculations and solve the whole model with each run. We recommend to use save and restart files.

For example, in chapter The Save and Restart Feature we demonstrate how to split the transportation model [**TRNSPORT**] in three parts: the file `tranmodel.gms` contains the data and the model, the file `transolve.gms` contains the solve statement and the file `tranreport.gms` contains a display statement. To run the whole model we use the following sequence, saving and restarting from the saved file:

```
> gams tranmodel s=s1
> gams transolve  r=s1  s=s2
> gams tranreport r=s2
```

Assume we want a more elaborate report than just the display of some level values. As the file `tranreport.gms` contains the code relevant for reporting, we will modify only this file. Then we will test the result by running only this file, restarting from `s2`, without having to solve the whole model repeatedly.

Introducing Strategical Subsets

When full data sets are used in debugging or development, it is often helpful to narrow the focus on a few items in a set by introducing subsets. The following example is a modified version of the extended transportation model from section An Illustrative Example above.

```
* Data section
Sets  i   "canning plants"   / Seattle, San-Diego, Baltimore, Dallas /
      j   "markets"          / New-York, Chicago, Topeka, Boston, Miami / ;

Sets  plants(i)   "a reduced set of canning plants"
                            / Seattle, San-Diego /
      markets(j)  "a reduced set of demand markets"
                            / New-York, Chicago, Topeka / ;

*plants(i) = yes; markets(j) = yes;

Parameters  a(i)  "capacity of plant i in cases"
               / Seattle   350, San-Diego  600, Baltimore 450, Dallas  750 /

            b(j)  "demand at market j in cases"
               / New-York 325, Chicago 300, Topeka 275, Boston 330, Miami 290 /;

Table       d(i,j)  "distance in thousands of miles"

                            New-York    Chicago   Topeka   Boston   Miami
           Seattle            2.5          1.7      1.8      3.1      3.3
           San-Diego          2.5          1.8      1.4      3.0      2.7
           Baltimore          0.2          0.7      1.8      0.4      1.1
           Dallas             1.5          0.9      0.5      1.8      1.3;

Scalar f  "freight in dollars per case per thousand miles" /90/ ;

Parameter   c(i,j)  "transport cost in thousands of dollars per case" ;
c(plants,markets) = f * d(plants,markets) / 1000 ;

* Model section
Positive Variable  x(i,j)  "shipment quantities in cases";
Variable           z       "total transportation costs in thousands of dollars";

Equations cost        "define objective function"
          supply(i)   "observe supply limit at plant i"
          demand(j)   "satisfy demand at market j";

cost ..              z  =e=  sum((plants,markets), c(plants,markets) * x(plants,markets)) ;
supply(plants) ..    sum(markets, x(plants,markets))  =l=  a(plants) ;
demand(markets) ..   sum(plants, x(plants,markets))   =g=  b(markets) ;

Model transport /all/ ;
solve transport using lp minimizing z ;
```

Observe that we introduced the subsets `plants` and `markets` that contain only some of the elements of their supersets `i` and `j`. Note that all tables, parameters and variables are defined with the supersets, the equations are *declared* over the supersets, but *defined* over the subsets and the calculation of the parameter `c` is also restricted to the subsets. Hence the model is restricted to the elements of the subsets. However, it is easy to change the restricted model back to the full model by removing the asterisks indicating a comment line:

```
plants(i) = yes; markets(j) = yes;
```

Observe that the sets `plants` and `markets` are now dynamic sets. Note that this assignment could be inserted anywhere in the code. Thus, introducing strategic subsets may be combined with isolating problem areas, as detailed in section Isolating Problem Areas through Saving and Restarting above.

Introducing strategic subsets has proven to be an effective way of maintaining a small data set with little effort. Users only have to choose elements that are representative for model development and debugging from the full sets.

Reducing Data

Recall that GAMS skips cases where data items equal zero. Thus a large model may be reduced by temporarily removing data from data sets by simply setting items to zero. Consider the following example:

```
Sets      o         'origin'                          / o1*o100 /
          d         'destination'                     / d1*d100 /;
Parameter dist(o,d) 'distance';
dist(o,d) = 120 + 50*ord(d) - 0.5*ord(o);

Sets      so(o)     'small set of origins for testing' / o4, o47, o91 /
          sd(d)     'small set of destinations'        / d3, d44, d99 /;

dist(o,d) $ (not (so(o) and sd(d))) = 0;

Parameter cost(o,d) 'transportation cost';
cost(o,d) $ dist(o,d) = 3 + 2*dist(o,d);
display cost, dist;
```

Note that we introduced strategic subsets and used them in the logical condition of a conditional assignment to set almost all entries of the parameter `dist` to zero. Note further, that the assignment for the parameter `cost` is conditioned on nonzero entries for the distance. Now, if the model were conditioned on nonzero transportation costs, the size of the whole model would be greatly reduced.

4.15.3 Increasing Efficiency: Reducing GAMS Execution Time

GAMS can take a long time for computations and model generation. There are some signs which indicate that it may be possible to reduce the execution time, e.g., an execution time that is unexpectedly long in general or a long execution of a single line, which could be seen, if the log shows the same line number for a long time.

In this section we will discuss how to find the causes for slow program execution and how to eliminate the main causes for slow execution.

4.15.3.1 Finding the Causes for Slow Program Execution

The best strategy for discovering the causes for slow execution is a combination of the techniques discussed in section Small to Large: Aid in Development and Debugging above and the techniques that we will introduce in this section, including generating an execution profile and isolating terms in slow statements. We will also touch briefly on observing the log file and we will point out why this is not the first choice.

Generating an Execution Profile

The quickest way to find GAMS statements that take particularly long to execute, is generating an execution profile in the output file. The execution profile contains the individual and cumulative time required to execute the sections of the GAMS model as well as information on memory use. An execution profile is generated when the option profile is assigned a value larger than zero (zero is the default). This can be done either by setting a command line parameter or by using the option statement. We will show an example of an execution profile below. For more information on execution profiles, further examples and details on the values the option `profile` may take, see the detailed description here.

Consider the following example:

```
option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets    a / 1*22 /, b / 1*22 /, c / 1*20 /,
        d / 1*20 /, e / 1*22 /;

Parameters x(e,d,c,b,a), y, z(a,b,c,d,e);
x(e,d,c,b,a) = 10;
z(a,b,c,d,e) = x(e,d,c,b,a);
y            = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a));

Variable obj;
Positive Variable var(e,b,a);

Equations objeq, r(b,c,d), q(a,b,c);

objeq..      obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a) * var(e,b,a));
r(b,c,d)..   sum((a,e), var(e,b,a)) =l= sum((a,e), x(e,d,c,b,a)*z(a,b,c,d,e));
q(a,b,c)..   sum((d,e), var(e,b,a)/x(e,d,c,b,a)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(e,d,c,b,a)*var.l(e,b,a));
display sumofvar;
```

The listing file will contain an execution profile like this (spread over the file):

```
----      9 Assignment x              0.374     0.374 SECS    109 MB  4259200
----     10 Assignment z              2.231     2.605 SECS    286 MB  4259200
----     11 Assignment y              2.324     4.929 SECS    286 MB        0
----     23 Solve Init slow           0.000     4.961 SECS    286 MB
----     18 Equation   objeq          3.510     8.471 SECS    287 MB        1

----     23 GAMS Fini                 0.359     0.359 SECS    470 MB
----      1 InitE                     0.032     0.032 SECS    213 MB
----      1 ExecInit                  0.000     0.032 SECS    213 MB
----     23 Solve Alg  slow           0.000     0.032 SECS    213 MB
----     23 Solve Read slow           0.000     0.032 SECS    215 MB
----     26 Assignment sumofvar       2.620     2.652 SECS    287 MB        0
----     27 Display                   0.032     2.684 SECS    287 MB
----     27 GAMS Fini                 0.000     0.000 SECS    287 MB
```

The first column shows the line number in the input file of the GAMS statement that is executed. The second column reports the type of statement. For an overview of all GAMS statements, see section Classification of GAMS Statements. The next two columns give the individual time needed to execute the respective statement and the cumulative time spent so far. The memory use follows and finally, the number of assignments generated in the respective line is shown.

In addition, there is a `Profile Summary` at the end of the lst file showing the most expensive statements:

```
---- Profile Summary (19 records processed)
     5.741   0.470GB        20 Equation   q (9680)
     3.510   0.287GB        18 Equation   objeq (1)
     3.088   0.464GB        19 Equation   r (8800)
     2.620   0.287GB        26 Assignment sumofvar (0)
     2.324   0.286GB        11 Assignment y (0)
     2.231   0.286GB        10 Assignment z (4259200)
     0.780   0.470GB        23 Solve Fini slow (4482809)
     0.374   0.109GB         9 Assignment x (4259200)
     0.359   0.470GB        23 GAMS Fini
     0.032   0.213GB         1 InitE
```

This shows that the execution of the statements in line numbers 20, 18, 19, 26, 11 and 10 are the most expensive ones (in this order). One reason is an inconsistent order when sets are referenced; we will discuss this topic in section Ordering Indices Consistently below.

Note that the execution profile may contain many lines that are not informative since the execution times reported are negligible. These lines may be suppressed by using the the option profileTol to specify the minimum execution time (in seconds) that is to be included. Observe that the option `profileTol` is available as command line parameter and option statement.

Note further, that the command line parameter profileFile facilitates writing the profiling information to a separate file (instead of the listing file).

Isolating Terms in Slow Statements

In some cases the execution profile shows that the cause for a long execution time is connected with a very long statement. For example, the objective function in some models and some report calculations may take hundreds of lines of code and can contain many terms that are added. If such a long statement is problematic in terms of execution time, it will be necessary to deactivate parts of the code and run the program repeatedly to find the precise lines that are at the root of the problem. This can be done by using comments.

Observing the Log File

Some modelers choose to examine the log file or watch the screen during execution to find the causes for slow program execution. However, we advise against this approach for the following reasons:

- Statements that are executed slowly are easily missed and often statements are misidentified. In addition, screen watchers may be distracted and will have to repeat the process.
- GAMS line reporting can be misleading if flow control statements like if statements and loop statements are executed. For example, individual calculations in a loop are not reported to the screen. A user watching the screen would notice that the loop takes a lot of time, but there is no indication which statement within the loop is problematic. This applies to all GAMS control structures.

Therefore we recommend to use the option `profile` as the main tool for finding the causes for slow program execution. For details, see section Generating an Execution Profile above. In addition, see the techniques outlined in section Advice for Repairing Puzzling Nonworking Code below.

4.15.3.2 Eliminating the Main Causes for Slow Program Execution

The main reasons for a slow program execution include an inconsistent index order when sets are referenced and taking irrelevant cases into consideration. In this section we will give some guidance on how to eliminate these causes, and also point to problems due to the scaling of a model which could cause a unnecessarily long execution time for the solver.

Ordering Indices Consistently

GAMS employs a sparse matrix data storage scheme. For example, consider the parameter `p(a,b,c)`. Assume that the set `a` has k elements, the set `b` has n elements and `c` has m elements. Then the entries for `p` are stored in the following order:

```
a1 b1 c1
a1 b1 c2
...
a1 b1 cm
a1 b2 c1
...
a1 b2 cm
...
a1 bn cm
a2 b1 c1
...
ak bn cm
```

Note that it is a systematic order where the last entry varies the fastest and the first the slowest. Observe that GAMS will withdraw entries from memory fastest if they are referenced in an order consistent with the storage order. Thus, in the following example, the first assignment statement will be processed faster than the second assignment statement.

```
x(a,b,c) = p(a,b,c);
y(b,c,a) = p(a,b,c);
```

Note

> GAMS will execute a program fastest if the sets are always referenced in the same order in definitions, assignments and equations.

The example that follows illustrates this principle. First we will solve a program where the indices appear in an arbitrary order and we will record the output generated by setting the option profile to 1. Then we will reformulate the program so that the indices will always appear in an alphabetical order and solve it again, recording the `profile` output. In the final step, we will compare the execution times of the two runs. We will use the example introduced above.

Note that the indices in the parameters and equations appear in a random order. Here is the profile from the six most expensive statements again:

```
----     10 Assignment z              2.231     2.605 SECS    286 MB  4259200
----     11 Assignment y              2.324     4.929 SECS    286 MB        0
----     18 Equation   objeq          3.510     8.471 SECS    287 MB        1
----     19 Equation   r              3.088    11.559 SECS    464 MB     8800
----     20 Equation   q              5.741    17.300 SECS    470 MB     9680
----     26 Assignment sumofvar       2.620     2.652 SECS    287 MB        0
```

In the next step we reformulate the program such that the indices always appear in the same order. For example, we define the parameter `x` as `x(a,b,c,d,e)` instead of `x(e,d,c,b,a)`. Here is the complete rewritten model:

```
option profile = 1;
option limrow = 0; option limcol = 0;
option solprint = off;

Sets    a / 1*22 /, b / 1*22 /, c / 1*20 /,
        d / 1*20 /, e / 1*22 /;

Parameters x(a,b,c,d,e), y, z(a,b,c,d,e);
x(a,b,c,d,e) = 10;
z(a,b,c,d,e) = x(a,b,c,d,e);
y            = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e));

Variable obj;
Positive Variable var(a,b,e);

Equations objeq, r(b,c,d), q(a,b,c);

objeq..      obj =e= sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e) * var(a,b,e));
r(b,c,d)..   sum((a,e), var(a,b,e)) =l= sum((a,e), x(a,b,c,d,e)*z(a,b,c,d,e));
q(a,b,c)..   sum((d,e), var(a,b,e)/x(a,b,c,d,e)*z(a,b,c,d,e)) =l= 20;

Model slow /all/;
solve slow maximizing obj using lp;

Parameter sumofvar;
sumofvar = sum((a,b,c,d,e), z(a,b,c,d,e)*x(a,b,c,d,e)*var.l(a,b,e));
display sumofvar;
```

After running the modified program, the profile for expensive statements looks like this:

```
----     10 Assignment z             0.593     0.983 SECS    215 MB  4259200
----     11 Assignment y             0.671     1.654 SECS    215 MB        0
----     18 Equation   objeq         1.778     3.432 SECS    215 MB        1
----     19 Equation   r             2.215     5.647 SECS    392 MB     8800
----     20 Equation   q             1.763     7.410 SECS    398 MB     9680
----     26 Assignment sumofvar      0.952     0.983 SECS    216 MB        0
```

Observe that executing for example the assignment to `z` took just 0.593 seconds compared to 2.231 seconds in the first run. Substantial percentage reductions were achieved in all time consuming cases by consistently referencing the sets in the same order.

Replace loops with assignments

The following statement assigns a constant value to a parameter.

```
loop((i,j,k),p(i,j,k)=2;)
```

The following assignment is preferred instead.

```
p(i,j,k)=2;
```

Restricting Assignments and Equations to Relevant Cases

Assignments

Assume that we have a set of cities with different production capacities and demands for various products. We want to know the maximum transportation cost (which depends on the distance, the amount shipped and a fixed factor) from each city to all others. This cost can be calculated in the following way:

```
Sets c "cities"   / c1*c800 /
     p "products" / p1*p10  /;
Alias (c,cc);

Parameter capacity(c,p)  "Production capacity for product p in city c"
          demand(c,p)    "Demand for product p in city c"
          distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(150,250);
demand(c,p)$(uniform(0,1)<0.025)  = uniformInt(50,150);
distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";

maxCost(c,cc) = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);
```

The performance profile will tell us something like this:

```
----     16 Assignment maxCost       0.265     0.436 SECS     19 MB   8756
```

Since we know, that the parameter `maxCost` will be zero for a pair of cities if there is no product with production capacity in the first city and demand in the second one, we could reduce the execution time for the last assignment:

```
Sets c "cities"   / c1*c800 /
     p "products" / p1*p10 / ;
Alias (c,cc);

Parameter capacity(c,p)  "Production capacity for product p in city c"
          demand(c,p)    "Demand for product p in city c"
          distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(50,150);
demand(c,p)$(uniform(0,1)<0.025)  = uniformInt(50,150);
distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter maxCost(c,cc) "Maximum transportation costs between two cities";

maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
  = sum(p, min(capacity(c,p), demand(cc,p))*distance(c,cc)*90);
```

So we did not do the calculation of `maxCost` if we knew before, that it must be zero anyway. This results in a reduced runtime:

```
----     17 Assignment maxCost       0.031     0.187 SECS     19 MB   8756
```

Note

To restrict computations in assignment to the relevant cases, we recommend using dollar conditions and filtering sets. These concepts are introduced and discussed in detail in chapter Conditional Expressions, Assignments and Equations.

For more examples, see sections Conditional Assignments and Conditional Indexed Operations.

Variables and Equations

Like assignments, variables and equations need to be restricted to relevant cases to avoid unnecessary inefficiencies. Dollar conditions and filtering sets may be used over the domain of definition as well as in the body of an equation.

Lets extend the assignment example from the previous paragraph and use the generated data in a transportation model:

```
Sets c "cities"   / c1*c800 /
     p "products" / p1*p10 / ;
Alias (c,cc);

Parameter capacity(c,p)  "Production capacity for product p in city c"
          demand(c,p)    "Demand for product p in city c"
          distance(c,cc) "Distance between two cities";

*Generate some sparse, random data
capacity(c,p)$(uniform(0,1)<0.05) = uniformInt(150,250);
demand(c,p)$(uniform(0,1)<0.025)  = uniformInt(50,150);
distance(c,cc)$(not sameas(c,cc)) = uniformInt(10,800);

Parameter shipCost(c,cc) "Transportatin costs between two cities per case"
          maxCost(c,cc)  "Maximum transportatin costs between two cities";

shipCost(c,cc) = distance(c,cc)*90;
maxCost(c,cc)$sum(p, capacity(c,p)*demand(cc,p))
  = sum(p, min(capacity(c,p), demand(cc,p))*shipCost(c,cc));

Variables
     x(c,cc,p)  "shipment quantities in cases"
     z          "total transportation costs in thousands of dollars" ;

Positive Variable x ;

Equations
     cost         "define objective function"
     supply(c,p)  "observe supply limit at plant i"
     dem(cc,p)    "satisfy demand at market j" ;

cost..         z  =e=  sum((c,cc,p), shipCost(c,cc)*x(c,cc,p)) ;
supply(c,p)..  sum(cc, x(c,cc,p)) =l=  capacity(c,p) ;
dem(cc,p)..    sum(c,  x(c,cc,p)) =g=  demand(cc,p) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;
```

The `Profile Summary` tells us, that the equations are rather expensive to generate and also the reading of the solution takes some time because of the size of the model:

```
---- Profile Summary (18 records processed)
    98.780   1.070GB        34 Equation   dem (8000)
    26.864   0.515GB        38 Solve Read transport
    25.303   0.454GB        32 Equation   cost (1)
     6.599   0.813GB        33 Equation   supply (8000)
```

However, as in the previous example, we know, that a product `p` won't be shipped from city `c` to city `cc` if there is either no production capacity in the first city or no demand in the second one. So we could reduce the size of our model by not generating variables and equations from which we know, that they are irrelevant for the solution. Here is a improved formulations of the equations:

```
cost..                      z  =e=  sum((c,cc,p)$(capacity(c,p)*demand(cc,p)), shipCost(c,cc)*x(c,c
supply(c,p)$capacity(c,p).. sum(cc$demand(cc,p), x(c,cc,p))  =l=  capacity(c,p) ;
dem(cc,p)$demand(cc,p)..    sum(c$capacity(c,p),  x(c,cc,p)) =g=  demand(cc,p) ;
```

This decreases the size of the model and thus the execution time to generate the model and load the solution significantly:

```
---- Profile Summary (18 records processed)
     0.031   0.035GB        33 Equation   cost (1)
     0.031   0.034GB        39 Solve Read transport
     0.016   0.035GB        34 Equation   supply (380)
```

Note that the equation `dem` does not even show up in the summary anymore since its generation was done to quickly.

For more details on conditions in equations, see section Conditional Equations.

Keep the model well scaled

Model solutions within GAMS frequently require manipulation of large matrices and many computations. The heart of most solvers includes many numerical procedures such as a sparse matrix inverter and sets of convergence and infeasibility tolerances. Numerical problems often arise within such procedures. Poorly scaled models can cause excessive time to be taken in solving or can cause the solver to fail. GAMS can assist the user to formulate a well scaled model. Details about this can be found in the sections Model Scaling - The Scale Option and Scaling Variables and Equations.

4.15.3.3 Other Approaches

In addition to the techniques discussed in section Eliminating the Main Causes for Slow Program Execution above, the following approaches may help to reduce the time needed for program execution:

- Trying another appropriate solver.
- Reformulating the model. This may yield particularly good results, if the model is reformulated in such a way that another model type is used, that is easier to solve or for which more advanced solver technology is available.

- Using starting points for NLP models, as discussed in section Specifying Initial Values.
- Trading memory for time.

We conclude the discussion of this topic with an example that demonstrates how memory may be traded for time. If an extensive calculation is repeated many times in a model, it may be possible to restructure the code so that the calculation is performed only once, then the result is saved and accessed later. Consider the following equation:

```
obj..   z =e= sum[(i,j,k,l), a(i,j,k,l)*sum(m, u(m,i))];
```

The execution time may be substantially reduced by defining a new parameter, say `p`, for the second sum and using this parameter in the equation:

```
Parameter p(i);
p(i) = sum(m, u(m,i));
...
obj..   z =e= sum[(i,j,k,l), a(i,j,k,l)*p(i)];
```

There is only one caveat: Users need to carefully consider whether the input data, here `u(m,i)`, is modified between the assignment for the new parameter `p` and the equation where `p` is used. If `u` is updated, then the assignment statement needs to be repeated, otherwise the data that enters the equation will not be current.

4.15.4 Increasing Efficiency: Reducing Memory Use

Besides slow program execution, excessive memory use may be of concern for modelers. In this section we will present some approaches on how to find the causes for extraordinary memory use and give some advice on eliminating the main causes for it.

4.15.4.1 Finding the Causes for Excessive Memory Use

The main techniques for finding the causes for excessive memory use are the same as those for finding the causes for slow program execution. We discussed these techniques in section Finding the Causes for Slow Program Execution above.

In addition, the option dmpUserSym is useful in this context. GAMS will report the number of records stored for each symbol at the point in the program where the option `dmpUserSym` is inserted together with some rough memory estimate.

Consider the following example:

```
Sets i /1*5 /,  j /1*5 /,  k /1*5 /,  l /1*5 /,
     m /1*5 /,  n /1*5 /,  o /1*5 /;
Parameters y(i,j,k,l,m,n,o)
           q(i,j,k);
Variables  x(i,j,k,l,m,n,o)
           f(i,j,k)
           obj;
y(i,j,k,l,m,n,o)       = 10;
q(i,j,k)               = 10;
```

```
x.up(i,j,k,l,m,n,o)    = 10;
x.scale(i,j,k,l,m,n,o) = 1000;

Equations  z(i,j,k,l,m,n,o)
           res(i,j,k)
           ob;

ob..                obj  =e= sum((i,j,k,l,m,n,o), x(i,j,k,l,m,n,o));
z(i,j,k,l,m,n,o)..  x(i,j,k,l,m,n,o) =l= 8;
res(i,j,k)..        f(i,j,k) =l= 7;

Model memory /all/;
option dmpUserSym;
solve memory maximizing obj using lp;
```

Note that an option statement with `dmpUserSym` was added before the solve statement. It generates the following *memory dump* that is included in the execution output of the listing file:

```
SYMBOL TABLE DUMP (USER SYMBOLS ONLY), NR ENTRIES = 16
ENTRY                              ID   TYPE DIM  LENGTH MEMORYEST DEFINED ASSIGNED DATAKNOWN
  135                               i    SET   1       5       0 MB    TRUE    FALSE      TRUE
  136                               j    SET   1       5       0 MB    TRUE    FALSE      TRUE
  137                               k    SET   1       5       0 MB    TRUE    FALSE      TRUE
  138                               l    SET   1       5       0 MB    TRUE    FALSE      TRUE
  139                               m    SET   1       5       0 MB    TRUE    FALSE      TRUE
  140                               n    SET   1       5       0 MB    TRUE    FALSE      TRUE
  141                               o    SET   1       5       0 MB    TRUE    FALSE      TRUE
  142                               y  PARAM   7   78125       3 MB   FALSE     TRUE     FALSE
  143                               q  PARAM   3     125       0 MB   FALSE     TRUE     FALSE
  144                               x    VAR   7   78125       5 MB   FALSE     TRUE     FALSE
  145                               f    VAR   3       0       0 MB   FALSE     TRUE     FALSE
  146                             obj    VAR   0       0       0 MB   FALSE     TRUE     FALSE
  147                               z    EQU   7       0       0 MB   FALSE     TRUE     FALSE
  148                             res    EQU   3       0       0 MB   FALSE     TRUE     FALSE
  149                              ob    EQU   0       0       0 MB   FALSE     TRUE     FALSE
  150                          memory  MODEL   0       3               TRUE     TRUE      TRUE
END OF SYMBOL TABLE DUMP
```

The column `ID` contains the names of the symbols, the column `TYPE` gives the data type of the respective entry, the column `DIM` reports the number of indices and the column `LENGTH` gives the number of records that is related to memory use, which is estimated in the column `MEMORYEST`. Note that the other columns are not relevant for this discussion.

Observe that the rows with high counts in column `LENGTH` indicate symbols within the GAMS program which have large numbers of internal records that must be stored. This is associated with corresponding memory requirements. Note also that not all length counts are of equal significance. In particular, variables and equations use more memory per element than parameters, since they have bounds, levels, marginals and scales that are associated with them. Parameters use more memory per element than sets, since sets may need just one indicator for `yes` or `no`. However, the explanatory text for set elements might increase the memory requirements for set elements.

Nevertheless, users may use this report to identify items with many records and verify that all of them are actually needed. For more details, see section Eliminating the Main Causes for Excessive Memory Use below.

4.15.4.2 Eliminating the Main Causes for Excessive Memory Use

As detailed in section Eliminating the Main Causes for Slow Program Execution above, the main causes for a slow program execution include an inconsistent index order when sets are referenced and taking irrelevant cases into consideration. These programming habits also tend to cause excessive memory use. In this section we will give some advice on avoiding memory traps and show how the memory may be cleared of data that is no longer needed.

Avoiding Memory Traps

Users may inadvertently use a lot of memory if they import data from a database with long explanatory text for sets or set elements. In addition, setting variable attributes for scaling or bounds may be problematic. Consider the following example:

```
x.scale(i,j,k,l,m) = 100;
x.lo(i,j,k,l,m) = 10;
x.up(i,j,k,l,m) = 77;
```

These assignments will probably set many more values than are relevant for a particular problem. Therefore we recommend to carefully consider which label combinations are actually necessary and to restrict the assignments to these cases by the use of dollar conditions or filtering sets. For more information, see section Conditional Assignments.

Clearing Memory of Unneeded Data

Sometimes a lot of memory space is used for data that is needed at some point, but not later. Consider the following simple example:

```
set i /1*1000/
    j /1*1000/;
parameter distance(i,j)
          cost(i,j);
distance(i,j) = 100+ord(i)+ord(j);
cost(i,j)     = 4+8*dist(i,j);
```

Assume that the parameter `distance` is used only here, but nowhere else in the program. Therefore users may wish to free the memory space occupied by the data connected with `distance`. The option clear may be used to achieve this:

```
option clear = distance;
```

This will reset all entries in the matrix associated with `distance` to zero.

Alternatively, an identifier that is no longer needed could be reset to its default value(s) with an assignment statement. In the example above, we could write:

```
distance(i,j) = 0;
```

This statement will have the same effect as the option statement. The advantage of the option statements is that they offer a more compact alternative that is particularly useful if equations or variables are to be cleared and multiple equation attributes or variable attributes are affected.

Note that the dollar control options $clear and $kill may also be used to free memory. These are compile time directives, which have a similar effect on the memory consumption but have different side effects: while `$clear` will reset the values to their defaults, `$kill` will completely remove the identifier from the program. Hence an identifier that was "killed" may be used later in another declaration and definition statement. For example, the following code snippet is legal:

```
Set i /1, 2 ,3/;
$kill i
Set i /a, b, c/;
```

With `$clear` instead of `$kill` this would cause a compilation error.

4.15.4.3 Setting Memory Limits with HEAPLIMIT

In a server environment and in other cases (e.g. to avoid the use of virtual memory) the amount of memory a GAMS run is allowed to use may have to be limited. The command line parameter heapLimit serves this purpose: the amount of memory for GAMS compilation and execution is limited to a specified number (in MB). If the data storage exceeds this limit, the job will be terminated with return code 10, `out of memory`. In addition, the function heapLimit may be used to interrogate the current limit and to reset it.

Note that limiting memory use for *solver execution* is not possible from within the GAMS program. However, some solvers like the NLP solver CONOPT have their own heapLimit option which ensures that the solver will not use more dynamic memory than specified.

4.15.4.4 Advice for Repairing Puzzling Nonworking Code

Assume a GAMS run was terminated and we cannot get a profile output (e.g. because GAMS ran out of memory and crashes). A memory overrun error causes the operating system buffer handling procedures to generally lose the last few lines of profile information when the job malfunctioned. How do we find the problem in this case?

We recommend to use the techniques outlined in section Modeling Techniques above. In addition, successively deactivating code in search for the last GAMS statement that worked will help in most cases. This can be done by using comments. If at some point the run terminates properly, the user will slowly activate parts of the last statements that were deactivated until the code performance will get worse again. By iteratively activating and deactivating terms, the precise problematic terms may be found. The save and restart feature could also be used to save the results until a certain statement and then to execute only the statements that are suspected to be problematic.

4.16 Comparative Analyses with GAMS

Once a model is completed, it is almost always used to investigate alternative scenarios where the analyst compares the results of various scenario assumptions. In this tutorial we will show how such *comaparative analyses* (also called *sensitivity analyses*) are done with GAMS. We will first demonstrate an easy approach, where we will manually change input parameters, use repeated solves and generate reports. In a second step, we will introduce another approach, where a loop structure will be used to automatically cycle through the scenarios. We recommend to read the sections on the manual approach first, since the sections on the automated approach build on code blocks developed in the early sections.

4.16.1 Manual Approach

Suppose we wish to do a comparative analysis by altering some input data in a model. We will use as an example the farm profit-maximizing model farmcomp.gms. The following vector of prices for primary commodities is a part of the input data:

```
Parameter price(primary)  'prices for products in USD'
         / corn  2.20, soybeans   5.00, beef   0.50 /;
```

We will use these data as a base case and compare it with two alternative scenarios: in the first scenario we will change the price of beef to $0.70 and in the second scenario we will change the price of corn to $2.70.

The GAMS file farmrep.gms is related to our example model. It contains only calculations for report writing and may be included with the dollar control option $include. It will generate a report based on the solution of the last solve that was executed in the GAMS program `farmcomp.gms`. The report consists of several tables. We will focus on the table `Farm Summary` that is associated with the parameter `summary`. The relevant code is given below:

```
Set  alli 'allitems'
        / corn, soybeans, beef, cattle,
          water, cropland, pastureland,
          fertilizer, seed, othercost, veterinary, supplement,
          "April labor", "May labor", "summer labor", "Sept labor", "Oct labor",
          cattlefeed, total / ;

Set  measures 'output measures'
        / "Net Income",  "Land Use", "Dry Cropping", "Irr Cropping",
          "Livestock", "Resource Value", "Product Value" /

Parameter summary(alli,measures)   'Farm Summary';
```

Note that the table for the parameter `summary` will contain rows for the commodities which are elements of the set `alli` and columns for all elements of the set `measures`.

We will use a third GAMS file, mancomp.gms,for our comparative analysis. The code of this third GAMS file follows:

```
$include farmcomp.gms
display price;
$include farmrep.gms

price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms

price("corn") = 2.70;
solve farm using LP maximizing netincome;
display price;
$include farmrep.gms
```

Note that this code first solves the original model that also contains the set definitions for the report, displays the initial prices and generates a report. In a second step the price for `beef` is changed to \$0.70, the modified model is solved, the prices for the first alternative scenario are displayed and a report is generated. In a third step the price for `corn` is changed to \$2.70, the model is solved again, the prices for the second alternative scenario are displayed and a third report is generated. Note that in the second alternative scenario (the third solve) the beef price is \$0.70, since it was not reset to base levels after the second run.

There will be three tables associated with the parameter `summary` in the listing file, one for each solve. The first table reports the results associated with the base case:

```
----    279 PARAMETER summary  Farm Summary

             Net Income    Land use  Dry Cropp~  Irr Cropp~   Livestock  Resource ~  Product V~

Corn                                     20.00      200.00                             2.20
Soybeans                                480.00                                         5.00
Beef                                                                                   0.50
cattle                                                             615.79
Water                                                                           16.83
Cropland                    700.00                                             128.49
Pastureland                 130.00                                              84.26
April Labor                                                                     32.34
May Labor                                                                       27.01
Oct Labor                                                                       11.50
Cattlefeed                                                                             4.71
Total         162685.05                 500.00      200.00
```

The second table reports the results from the first alternative scenario where the price for beef was changed to \$0.70:

```
----    351 PARAMETER summary  Farm Summary

             Net Income    Land use  Dry Cropp~  Irr Cropp~   Livestock  Resource ~  Product V~

Corn                                     22.84      160.85                             2.34
Soybeans                                489.86                                         5.00
Beef                                                                                   0.70
cattle                                                             866.67
Cropland                    673.55
Pastureland                 130.00                                            1456.90
April Labor                                                                     82.29
May Labor                                                                       80.53
Sept Labor                                                                      53.57
Oct Labor                                                                       46.21
Cattlefeed                                                                             4.89
Total         373686.10                 512.70      160.85
```

And the third table reports the results from the second alternative scenario where the price for corn was changed to \$2.70 and the price for beef stayed at \$0.70:

```
----    423 PARAMETER summary  Farm Summary

             Net Income    Land use  Dry Cropp~  Irr Cropp~   Livestock  Resource ~  Product V~
```

```
Corn                                  31.98      200.00                              2.70
Soybeans                             410.24                                          5.00
Beef                                                                                 0.70
cattle                                                        866.67
Water                                                                    15.99
Cropland                  642.22
Pastureland               130.00                                       1316.09
April Labor                                                              61.39
May Labor                                                                61.72
Sept Labor                                                               84.92
Oct Labor                                                                87.21
Cattlefeed                                                                           5.36
Total        375839.30                442.22      200.00
```

This quick way to do a comparative analysis has the following drawbacks:

- The relevant output is spread over more than 140 lines.
- There is no cross-scenario report.
- The price of beef in the second alternative scenario is problematic, since it was not automatically reset to the original base price.
- The handling of solves and report writing is repetitive.

The first two issues will be addressed in section Writing Cross-Scenario Reports,a solution for the third issue will be given in section Resetting Data to Base Levels and an alternative approach that will resolve the last issue is presented in section An Automated Approach - Avoiding Repeated Work.

4.16.1.1 Writing Cross-Scenario Reports

We will generate a cross-scenario report by introducing two new sets and a new parameter in a revised version of the third GAMS file, mancompb.gms:

```
Set scenarios / base, beefp, beefcorn /;
Set ordr      / "Scenario Setup", "Scenario Results"/;

Parameter savsumm(ordr,*,alli,scenarios)  'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);
```

Note that the set `scenarios` contains the base case and the two alternative scenarios and the set `ordr` introduces places to save the assumptions and results of the different runs. The new parameter `savsumm` is similar to the parameter `summary` introduced above, but it has two additional dimensions. Observe that the first assignment copies the current setup of the price vector and the second assignment copies the results that are stored in the parameter `summary`.

The full code follows:

```
$include farmcomp.gms
$include farmrep.gms
Set ordr / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios)  'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

price("beef") = 0.70;
solve farm using LP maximizing netincome;
display price ;
$include farmrep.gms
savsumm("Scenario Setup","price",primary,"beefp") = price(primary);
savsumm("Scenario Results",measures,alli,"beefp") = summary(alli,measures);

price("corn") = 2.70;
display price ;
solve farm using LP maximizing netincome;
$include Farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn") = price(primary);
savsumm("Scenario Results",measures,alli,"beefcorn") = summary(alli,measures);

option savsumm:2:3:1;
display savsumm;
```

Observe that the last index in the assignments for `savsumm` is `"base"` after the first solve, `"beefp"` after the second solve and `"beefcorn"` after the third solve. Note that option statement in the penultimate line of the code customizes the output generated by the display statement that follows. For details see section Local Display Control. The listing file will contain the following output:

```
----    436 PARAMETER savsumm  Comparative Farm Summary

                                                    base       beefp    beefcorn

Scenario Setup  .price         .Corn                2.20        2.20        2.70
Scenario Setup  .price         .Soybeans            5.00        5.00        5.00
Scenario Setup  .price         .Beef                0.50        0.70        0.70
Scenario Results.Net Income    .Total          162685.05   373686.10   375839.30
Scenario Results.Land use      .Cropland          700.00      673.55      642.22
Scenario Results.Land use      .Pastureland       130.00      130.00      130.00
Scenario Results.Dry Cropping  .Corn              20.00       22.84       31.98
Scenario Results.Dry Cropping  .Soybeans          480.00      489.86      410.24
Scenario Results.Dry Cropping  .Total             500.00      512.70      442.22
Scenario Results.Irr Cropping  .Corn              200.00      160.85      200.00
Scenario Results.Irr Cropping  .Total             200.00      160.85      200.00
Scenario Results.Livestock     .cattle            615.79      866.67      866.67
Scenario Results.Resource Value.Water             16.83                   15.99
Scenario Results.Resource Value.Cropland          128.49
Scenario Results.Resource Value.Pastureland        84.26     1456.90     1316.09
Scenario Results.Resource Value.April Labor        32.34       82.29       61.39
Scenario Results.Resource Value.May Labor          27.01       80.53       61.72
Scenario Results.Resource Value.Sept Labor                     53.57       84.92
Scenario Results.Resource Value.Oct Labor          11.50       46.21       87.21
Scenario Results.Product Value .Corn                2.20        2.34        2.70
Scenario Results.Product Value .Soybeans            5.00        5.00        5.00
Scenario Results.Product Value .Beef                0.50        0.70        0.70
Scenario Results.Product Value .Cattlefeed          4.71        4.89        5.36
```

In this cross-scenario report all output is in one table and it is easy to compare the base case with the two alternative scenarios.

We could also add percentage change calculations by introducing a further parameter, savsummp:

```
Parameter savsummp(ordr,*,alli,scenarios) 'Comparative Farm Summary (percent chg)';

savsummp(ordr,measures,alli,scenarios)$savsumm(ordr,measures,alli,"base") =
   round{ [savsumm(ordr,measures,alli,scenarios) - savsumm(ordr,measures,alli,"base")]*100
   / savsumm(ordr,measures,alli,"base"),1 };

savsummp(ordr,measures,alli,scenarios)
   $[(savsumm(ordr,measures,alli,"base") = 0) and (savsumm(ordr,measures,alli,scenarios) <> 0)]
   = na;

option savsummp:1:3:1;
display savsummp;
```

Note that both assignment statements are conditional assignments. The first assignment computes percentage changes rounded to one decimal place and the second assignment sets the percentage change to NA if the value in the base case is zero. The output generated by the display statement follows:

```
----    450 PARAMETER savsummp  Comparative Farm Summary (percent chg)

                                                  beefp    beefcorn

Scenario Results.Irr Cropping  .Corn              -19.6
Scenario Results.Irr Cropping  .Total             -19.6
Scenario Results.Livestock     .cattle             40.7        40.7
Scenario Results.Resource Value.Water            -100.0        -5.0
Scenario Results.Resource Value.Cropland         -100.0      -100.0
Scenario Results.Resource Value.Pastureland      1629.0      1461.9
Scenario Results.Resource Value.April Labor       154.4        89.8
Scenario Results.Resource Value.May Labor         198.1       128.5
Scenario Results.Resource Value.Sept Labor           NA          NA
Scenario Results.Resource Value.Oct Labor         301.8       658.4
Scenario Results.Product Value .Corn                6.4        22.7
Scenario Results.Product Value .Beef               40.0        40.0
Scenario Results.Product Value .Cattlefeed          3.9        13.8
```

4.16.1.2 Resetting Data to Base Levels

In the example above the price for beef was changed to $0.70 for the first alternative scenario and it stayed at $0.70 in the second alternative scenario, since we did not reset it manually to the base level. However, in most cases users find it preferable to reset all data to base levels before a new scenario is run. This may be done by saving the base level data in a new parameter, say saveprice, and then resetting the data to base levels before each scenario. In the following final version of the third GAMS file, mancompc.gms, the levels of the commodity prices are reset before each new run:

```
$include farmcomp.gms
$include farmrep.gms

Parameter saveprice(alli) 'saved prices';
saveprice(alli) = price(alli);
```

```
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios)  'Comparative Farm Summary';
savsumm("Scenario Setup","price",primary,"base") = price(primary);
savsumm("Scenario Results",measures,alli,"base") = summary(alli,measures);

price(alli) = saveprice(alli);
price("beef" ) = 0.70;
solve farm using LP maximizing netincome;
display price ;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefp") = price(primary);
savsumm("Scenario Results",measures,alli,"beefp") = summary(alli,measures);

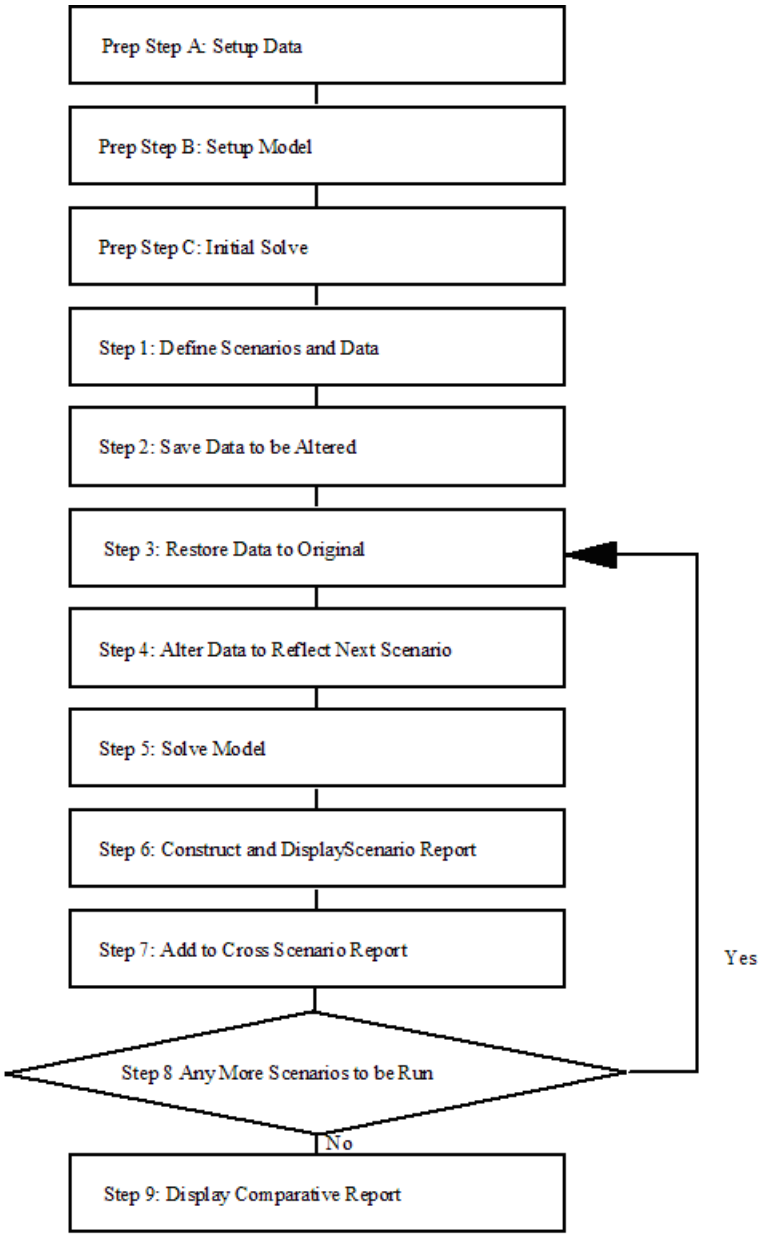
price(alli) = saveprice(alli);
price("corn") = 2.70;
display price ;
solve farm using LP maximizing netincome;
$include farmrep.gms
savsumm("Scenario setup","price",primary,"beefcorn" ) = price(primary);
savsumm("Scenario Results",measures,alli,"beefcorn") = summary(alli,measures);

option savsumm:2:3:1;
display savsumm;
```

In this section we demonstrated how to do a comparitive analysis manually, including a cross-scenario report and resetting the data before each new scenario is run. However, there is still a lot of repetition in how the solves and reports are handled. This issue will be addressed in the next section.

4.16.2 An Automated Approach - Avoiding Repeated Work

The basic structure of a comparative analysis that avoids repetitive instructions for solves and report writing is outlined in the Figure below. Note that the first three boxes represent preparatory steps that are the usual parts of a GAMS program: the initial data is set up, the model is defined and solved. The comparative model analysis begins with the box labeled "Step 1". In Step 1 names for the scenarios are introduced and the scenario data is defined. In Step 2 the base data that will be changed during the scenario runs are saved in a new parameter. We will use this parameter later to restore the data to their base levels before each new scenario run. Starting with Step 3 we enter a loop, where the looping set is the set of scenarios introduced in Step 1. As usual, the statements in the loop are executed for each scenario to be analyzed. The first statement restores the data to their base levels (Step 3). Thus we will always start with the same data. In Step 4 the data and the model is updated for the current scenario and in Step 5 the model solved. In Step 6 a report for the individual scenarios is generated. In Step 7 parameters for cross-scenario comparative reports are saved. In Step 8 we check if more scenarios are to be solved and if this is the case, we return to repeat Steps 3-8 until all scenarios are completed. Finally, we display a comparative report that presents the information saved across scenarios.



This flow chart is implemented in the file `compare.gms` that is given below. Note that it is based on the farm profit-maximizing example discussed in section Manual Approach above. All sets and parameters were introduced in the sections above, only the table `scenprice` in the implementationof Step 1 is new.

```
*Step 1 - Setup scenarios
Set ordr      / "Scenario Setup", "Scenario Results" /;
Set scenarios / base, beefp, beefcorn /;
Parameter savsumm(ordr,*,alli,scenarios) 'Comparative Farm Summary';
Table     scenprice(primary,scenarios)   'price changes by scenario'
                base    beefp   beefcorn
corn                                2.70
soybeans
beef                    0.70            ;

*Step 2 - Save data
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);
```

```
*Step 3 - Reset data to base level
loop(scenarios,
    price(primary) = savprice(primary);

*Step 4 - Change data to levels needed in scenario
    price(primary)$scenprice(primary,scenarios) = scenprice(primary,scenarios);
    display price;

*Step 5 - Solve model
   solve farm using LP maximizing netincome;

*Step 6 - Single scenario report writing
   $include farmrep.gms

*Step 7 - Cross-scenario report writing
    savsumm("Scenario Setup","price",primary,scenarios) = price(primary);
    savsumm("Scenario Results",measures,alli,scenarios) = summary(alli,measures);

*Step 8 - End of loop
    );

*Step 9 - Compute and display final results
option savsumm:2:3:1;
display savsumm;
```

Note that the main feature that facilitates this automatic approach is a loop statement. Loop statements are introduced and discussed in section The Loop Statement. Note further, that in Step 4 we used a conditional assignment to restrict the change of data to those primary commodities that have nonzero entries for the respective scenario in parameter `scenprice`. For details on conditional assignments, see section Conditional Assignments.

4.16.2.1 Adding A Scenario

Given the implementation of an automated comparative analysis above, it is easy to add a new scenario. Only two small modifications are needed: a name for the new scenario has to be added to the set `scenarios` and the respective data has to be added to the table `scenprice`. Both changes are in Step 1. The lines of the respective code are given below:

```
Set scenarios / base, beefp, beefcorn, new/;
Table scenprice(primary,scenarios)  'price alterations by scenario'
                base    beefp   beefcorn  new
corn                                2.70
soybeans                                    4.32
beef                     0.70                   ;
```

Note that we added a third alternative scenario called `new`, where the price of soybeans is changed to \$4.32.Note further, that the remainder of the code is not changed. Once the new scenario is added to the set `scenarios` and the respective data is specified in the table, it will enter the loop and thus all the statements in the loop will be executed for the new scenario.

Observe that the new scenario above was similar to the other scenarios: the price for a primary commodity was modified. However, in some cases new scenarios require that other data, like resources, are changed. For example, assume that in a new scenario the landtype `"cropland"` is increased by 30%. Note that the available resources were defined in the parameter `available(alli)`, where `available("cropland")` equals 700. To accomodate this new scenario we will add the following lines of code to Steps 1 to 4:

```
*Step 1 - Setup scenarios
Set scenarios / base, beefp, beefcorn, new /;
Table scenavailable(alli,scenarios)  'resource alterations by scenario'
                base    beefp   beefcorn  new
cropland                                  1.3;

*Step 2 - Save data
Parameter saveavailable (alli) 'save available resources';
saveavailable (alli) = available (alli);

*Step 3 - Reset data to base level
loop(scenarios,
    available (alli) = saveavailable (alli);

*Step 4 - Change data to levels needed in scenario
    available(alli)$scenavailable(alli,scenarios) =
       available(alli)*scenavailable(alli,scenarios);
    display price, available;
```

Note that in Step 1 we added a new table, `scenavailable`, to specify the resource alternations by scenario. Observe that the values of `scenavailable` will be used as multipliers in Step 4. In Step 2 we introduced the parameter `saveavailable`, that will play a similar role for the available resources like the parameter `savprice` does for the prices of the primary commodities: the base levels are saved in this parameter and we will use it to restore the values of `available` to their base levels before each new scenario run. This is implemented with the new assignment in Step 3. In Step 4 the data levels of the parameter `available` are modified as required for the current scenario using a conditional assignment. Note the similarities to the assignment for updating the values of `price` in Step 4 above. Steps 5 to 9 remain unchanged. Thus we achieved an automated comparative analysis with an additional scenario where another parameter is modified by adding just a few lines of code. The full code is given in the GAMS file `compareother.gms`.

4.16.2.2 Changing the Structure of a Model

Many studies require modifications of the *structure* of a model. In GAMS, context-sensitive model structures may be implemented with dollar conditions. Dollar conditions may be used to control equations as well as specific terms.

To illustrate, we will extend the profi-maximizing farm model from the previous sections to include a conditional constraint that limits the number of cattle. This constraint will be only active if a scalar that varies with the scenarios is nonzero. Consider the lines of code that follow. Note that the set `animals` is a subset of the set `alli`, the elements of the set `livemanage` denote various ways of managing crops and animals, and `liveprod` is a positive variable for livestock production.

```
$include farmcomp.gms
$include farmrep.gms

Scalar   cowlim   'activates cowlimit constraint' /1/;
Equation cowlimit 'conditional equation on cow limits;
cowlimit$cowlim..   sum((animals,livemanage), liveprod(animals,livemanage)) =l= 100;
Model farmcowlim /all/;

Set ordr      / "Scenario setup", "Scenario Results" /;
Set scenarios / base, cowlim /;
Parameter savprice(primary) 'save primary commodity prices';
savprice(primary) = price(primary);
Parameter cowlims(scenarios) 'cowlimit by scenario'
```

```
          / base 0, cowlim 1/;

loop(scenarios,
    cowlim = cowlims(scenarios);
    solve farmcowlim using LP maximizing netincome;
);
```

Note that in the loop the value of the scalar `cowlim` is updated before each scenario is run. Note further, that this value determines whether the new equation `cowlimit` will be active or not. The complete code is given in the GAMS file `comparemod.gms`.

4.16.3 Ranging analysis

Some users are interested in getting ranging output in the form of LP cost and right hand side ranging results. Unfortunately, the base version of GAMS does not yield such information. The user wishing such information has two alternatives. First, one may cause the model to be repeatedly solved under a set of values for the key parameter using the procedures discussed above, but this is cumbersome if a lot of parameters are involved. Second, one can use solver dependent features of GAMS that can be retrieved into a GAMS parameter. Please refer to the solver manuals (e.g. for GAMS/CPLEX: Sensitivity Analysis) for further information how to use them.

4.17 Good NLP Formulations

In this tutorial we offer some advice and guidance on how to set up or formulate an NLP model so that a solver will be able compute a good solution and do so quickly, reliably, and predictably. Much of this applies to other model classes allowing nonlinear functions, but for ease and simplicity of exposition we focus on the NLP case here.

A good formulation for an NLP model typically involves several things, including specifying sensible initial values, setting variable bounds, and scaling variables and equations. Other factors to consider are techniques for blocking degenerate cycling and the potential benefits of avoiding expressions in nonlinear functions. Finally we look at reformulations and approximations for discontinuous functions like `abs`, `max` and `min` in section Reformulating DNLP Models.

4.17.1 Specifying Initial Values

The variable levels and equation marginals in GAMS are typically passed to a solver to be used as the initial point. The initial values specified are especially important for NLP models for several reasons:

- Non-convex models may have multiple local solutions. Local NLP solvers search for a local solution and return it when it is found. An initial point in the neighborhood of a desired solution is more likely to return that solution.
- Initial values that (almost) satisfy many of the constraints reduce the work involved in finding a first feasible solution.
- Initial values that are close to a local optimum reduce the work required to find that local optimum, therefore reducing solution time.
- The progress of the optimization algorithm is based on good directional information, i.e on good derivatives. The derivatives in a nonlinear model depend on the current point, so an improved initial point can improve solver performance.

Variable levels and equation marginals are specified by setting the variable attribute `.L` and the equation attribute `.m` before solution. This is often done with assignments that occur *before* the solve statement, e.g.:

```
domPrice.L(i,region,t) = domPrice0(i,region,t);
flowLim.m(arcs) = 1;
```

Note

The default value for the variable levels and equation marginals is 0.

The variable *bounds* also play a role in determining the initial point passed to the NLP solver. When a solve occurs, the levels for all variables *in the model* are first projected onto the set defined by the variable bounds. Thus, setting a variable's lower bound to a positive value ensures that the initial value of this variable will never be zero. This is very useful, since in many cases zero is an unsuitable initial value for nonlinear variables. For example, based on the product term $x \cdot y$, an initial value of zero for x will lead to an initial derivative value of zero wrt y, so it will appear as if the function does not depend on y. Variables at zero can also cause numerical difficulties with logarithms, real powers, or divisions. These difficulties occur not just at zero but also for very small values (i.e. values very close to zero) as well.

We recommend to specify as many sensible initial values for the nonlinear variables as possible. It may be desirable to initialize all variables to 1 or to the scale factor if the GAMS scaling option is used. A better alternative is to first select reasonable values for some variables that are known from context or experience to be important and then to use some of the equations of the model to compute the values for other variables. For example, consider the following equation, where `pm`, `pwm` and `er` are variables and `tm` is a parameter:

```
pmDef(i)..   pm(i) =e= pwm(i)*er*(1+tm(i));
```

The following assignment statements use the equation to derive consistent initial values for the variable `pm` from sensible initial values for the variables `pwm` and `er`:

```
pwm.L(i) = 1;
er.L = 1;
pm.L(i) = pwm.L(i)*er.L*(1+tm(i));
```

It would be a mistake to assign only to `pwm` and `er` and assume that the solver will choose to adjust the variable `pm` to make the equation feasible: it could choose to adjust `pwm` or `er` instead. With all the assignments above made, we can be assured that the equation `pmDef` will be satisfied at the initial point.

Setting the initial point by loading a prior solution that has been saved via the savepoint mechanism is also an effective strategy that is very easy to implement.

4.17.2 Setting Variable Bounds

Lower and upper bounds on variables are set by assigning values to the variable attributes `.lo` and `.up` in the following way:

```
price.lo(i,region,t) = 1e-4;
flow.up(arcs) = arcCap(arcs);
```

Lower and upper bounds on variables in nonlinear models serve multiple purposes. Some bounds represent constraints based on the reality that is being modeled. For example, a certain production level must be non-negative or an arc in a network has a flow capacity of at most ten. These bounds are called *model bounds*. Other bounds help the algorithm by preventing it from moving far away from any optimal solution and/or into regions with singularities in the nonlinear functions or unreasonably large function or derivative values. These bounds are called *algorithmic bounds*. Solver performance can be improved and execution errors (see domLim and domUsd) avoided when algorithmic bounds on variables are introduced.

Model bounds are determined by the reality being modeled and do not cause any problems. However, algorithmic bounds must be carefully chosen by the modeler. We recommend to pay particular attention if a variable is the argument in log(x), log10(x) or exp(x) and if a variable occurs in the denominator of a division. If log(x) or log10(x) appears in a model, where `x` is a variable, we recommend a lower bound of `1.e-3` for `x` since `log(x)` gets very small as `x` approaches zero and is undefined for negative values of `x`. In addition, the first derivative gets very large as `x` approaches zero. If exp(x) features in a model, where `x` is a variable, we recommend an upper bound between 20 and 25 for `x`. If a variable `x` appears in the denominator, we recommend a lower bound of `1.e-2` for `x`, since `1/x` is extremely nonlinear for small arguments. Small values for variables used with negative exponents are also not desirable. Solver performance can be improved and execution errors avoided when one introduces algorithmic bounds on variables.

Note that lower and upper bounds facilitate finding a feasible solution as most solvers will honor bounds at all times, but inequalities are not necessarily satisfied at intermediate points. A further advantage of variable bounds compared to inequalities is improved presolve performance: NLP solver preprocessors will typically incur little or no computational overhead due to variable bounds.

4.17.3 Avoiding Expressions in Nonlinear Functions

It is often useful to avoid nonlinear functions of expressions (e.g. a division by the sum of many variables). Instead, an *intermediate* variable can be used for the expression. This applies in particular if the expressions depend on many variables. Consider the following example:

```
variable x(i), y;
equation ydef;
ydef..   y =e= 1 / sum(i, x(i));
```

This example could be reformulated via the intermediate variable `xsum` and its defining equation `xsumdef` in the following way:

```
variable x(i), y, xsum;
equation xsumdef, ydef;
xsumdef..   xsum =e= sum(i, x(i));
ydef    ..   y =e= 1/xsum;
xsum.lo = 1.e-2;
```

In the equation `ydef`, the intermediate variable `xsum` appears in the denominator instead of the original summation. This allows us to impose a lower bound on the variable `xsum` to avoid dividing by zero. Of course, the model will contain more rows and columns if intermediate variables are introduced, but this increase in size is offset by a decrease in complexity and, in many cases, by an increase in sparsity as well.

4.17.4 Scaling Variables and Equations

Recall that nonlinear programming algorithms use the derivatives of the objective function and the constraints to find good search directions and they use function values to determine if constraints are satisfied or not. The *relative size* of the derivatives and the function values is influenced by the units of measurement that are used for the variables and constraints, and will have an effect on the performance of the solver and the result computed. Therefore, a proper, consistent scaling of the model is important to the success of the solution algorithm and the quality of the answer returned.

For example, assume that two goods are equally costly: both cost $1 per kg. However, the first is specified in grams and the second in metric tons, so that their coefficients in the cost function will be vastly different: $1000 per gram and $0.001 per ton respectively. If cost is measured in $1000 units, then the coefficients will be 1 and 1.e-6 respectively. This discrepency in size may cause the algorithm to ignore the variable with the smaller coefficient, since the coefficient is comparable to some of the zero tolerances. To avoid such problems, the units of measurements need to be carefully chosen, that is, variables and constraints need to be properly scaled.

We recommend scaling with the following goals in mind:

- Solution level values of variables should fall into a range around 1, e.g. from 0.01 to 100.
- The magnitude of the nonzero constraint marginals at solution should fall into a range around 1, e.g. from 0.01 to 100.
- The magnitude of the derivatives of the nonlinear terms (i.e. the Jacobian elements) should fall into a range around 1, e.g. from 0.01 to 100, both at the initial point and at the solution.
- The constants in the equations should have absolute values around 1, e.g. from 0.01 to 100.

Well-scaled variables are measured in appropriate units. In most cases users should select the unit of measurement for the variables such that their expected value is around unity. Of course, there will always be some variation. For example, if `x(i)` is the production at location `i`, one could select the same unit of measurement for all components of `x`, say, a value around the average capacity.

In well-scaled equations the individual terms are measured in appropriate units. After choosing units for the variables users should choose the unit of measurement for the equations such that the expected values of the individual terms are around 1. For example, if these rules are followed, material balance equations will usually have coefficients of 1 and -1.

Usually well-scaled variables and equations result in well-scaled derivatives. To check whether the derivatives are well-scaled, we recommend running the model with a positive value for the option limrow and inspecting the coefficients in the equation listing of the GAMS list file.

For more about scaling in GAMS, see section Model Scaling - The Scale Option. Note that while many solvers have internal scaling procedures, a better result can generally be achieved by a judicious choice of units by the model developer.

4.17.5 Blocking Degenerate Cycling

Most commercial linear programming solvers use a perturbation technique to avoid degenerate cycling during the solution process: they temporarily add small numbers to the right-hand sides of equations. In general, NLP solvers do not have such an internal feature. Sometimes the success and performance of an NLP solver can be enhanced by a manual perturbation formulation.

In particular, if users observe that the NLP solution process has a large number of iterations where the solver does not make significant progress in altering the objective function value, we recommend to modify

the equations in the model by replacing the value of zero on the right-hand side with a small number. This may accelerate the solution process. Assume that we have the following equation:

$$f(x) \leq 0$$

This could be reformulated as:

$$f(x) \leq \delta * 0.001$$

Here we set δ to 1 if we wish to keep the addition and to zero otherwise. The value of 0.001 is just an example and needs to be adjusted based on the model context. The number should be chosen such that it does not introduce significant distortions into the problem solution. Such an addition quite frequently reduces solution time by helping the solver avoid degenerate cycling. If it is done correctly, the resulting model solution is not qualitatively different from the original model solution. Users may also first solve the model with $\delta = 1$ and subsequently with $\delta = 0$ to get rid of the effects of the small numbers.

We recommend that user avoid using the same number but instead use some systematically varying number or a random number. The technique of adding a small number on the right-hand side may also be used in problems where many equations have the same nonzero value on the right-hand side.

4.17.6 Reformulating DNLP Models

Nonlinear models in GAMS belong to one of the following two classes: *smooth* and *discontinuous*. Typically, all functions with endogenous arguments contained in the model are smooth functions (i.e. functions with continuous derivatives) like `sin`, `exp` and `log`. These models can be solved using NLP. If any of the endogenous functions in the model are not smooth (i.e. are discontinuous), the model cannot be solved as an NLP: the DNLP model type must be used instead. Examples of non-smooth functions include `ceil` and `sign`, where the function itself is not continuous, and `max`, `min`, and `abs`, where the derivatives are not continuous. Typically, NLP solvers are designed to work with continuous derivatives, and much of the convergence theory behind them assumes this continuity. Discontinuous functions or derivatives may cause numerical problems, poor performance, spurious (i.e. wrong) solutions, and other issues, so they should be used with special care and only if necessary.

N.B.: to avoid a proliferation of model types, nonlinear programming is the only model type split into smooth (NLP) and nonsmooth (DNLP) variants. All other model types allowing nonlinear functions (e.g. MINLP, MCP, CNS) include both smooth and nonsmooth functions. This is `not` because nonsmooth functions are less problematic in these contexts. It simply became too unwieldy to maintain this distinction across all types of nonlinear models.

A powerful and effective way to model discontinuous functions is with binary variables, which results in a model of type MINLP. The model **[ABSMIP]** demonstrates this formulation technique for the functions `abs`, `min`, `max` and `sign`. Alternatively, reformulations or approximations may be used to model discontinuous functions such that the resulting model is of type NLP. Here we offer some guidance on how to reformulate or approximate the discontinuous functions `abs`, `max` and `min` using only smooth functions and continuous variables and thus transform a DNLP model into an NLP. This transformation is generally more reliable than solving the original as a DNLP.

Note that some of the *reformulations* suggested below enlarge the feasible space. They rely on the objective function to choose a solution that is contained in the original feasible space, i.e. where the relationship defined by the nonsmooth function holds. If the objective cannot be relied on to do this, it is also possible to use one of the *smooth approximations* for the nonsmooth functions defined below.

4.17.6.1 Reformulating and Approximating the Function ABS

The function `abs(x)` returns the absolute value of the argument `x`. If we are minimizing an absolute value, then we can split this value into its positive and negative parts (both represented by positive variables) and minimize the sum of these variables. This formulation enlarges the feasible region but the optimal solution will be the one where the sum of the positive and negative parts is equal to the absolute value.

```
variables x, y, z;
equations
  obj  '1-norm'
  f ;
obj.. abs(x) + abs(y) =E= z;
f  .. sqr(x-3) + sqr(y+5) =L= 1;

model nonsmooth  / obj, f /;
solve nonsmooth using dnlp min z;

positive variables xPlus, xMinus, yPlus, yMinus;
equations
  obj2 'smooth version of 1-norm'
  xDef
  yDef
  ;
obj2.. xPlus + xMinus + yPlus + yMinus =E= z;
xDef.. x =E= xPlus - xMinus;
yDef.. y =E= yPlus - yMinus;

model smooth / obj2, xDef, yDef, f /;
solve smooth using nlp min z;
```

Note that the discontinuity in the derivative of the function `abs` has been converted into lower bounds on the new variables `xPlus`, `xMinus`, etc: these bounds are handled routinely by any NLP solver. Note too that the feasible space is larger than before. For example, many pairs `xPlus` and `xMinus` satisfy our equation `x =E= xPlus - xMinus;`. However, our objective ensures that one of `xPlus` and `xMinus` will be zero at the solution so that the sum of `xPlus` and `xMinus` wil be the absolute value of `x`.

In case the objective function does not contain a term that tries to minimize the absolute value, a smooth approximation can be used instead of the reformulation described above. This approximation should be close to the absolute value and also have smooth derivatives. Such an approximation for `abs(f(x))` is:

```
sqrt(sqr(f(x)) + sqr(delta))
```

Here `delta` is a small scalar. The value of `delta` controls the accuracy of the approximation and the curvature around `f(x)=0`. The approximation error is largest when `f(x)=0` and decreases as `f(x)` gets farther from zero. A value for `delta` ranging between 1.e-3 and 1.e-4 should be appropriate in most cases. Users could also use a larger value in an initial optimization, reduce it and solve the model again. If `delta` is reduced below 1.e-4, then large second order terms might lead to slow convergence or even prevent convergence. An example of this approximation used for the previous example is below:

```
$macro MYABS(t,d) [sqrt(sqr(t)+sqr(d))]
equation obj3;
obj3.. MYABS(x,1e-4) + MYABS(y,1e-4) =E= z;

model approx / obj3, f /;
solve approx using nlp min z;
```

Note the use of the macro facility to encapsulate the smooth reformulation. As mentioned above, this approximation has its largest error where `f(x)=0`. If it is important to get accurate values at this point, then we recommend the following alternative approximation:

```
sqrt(sqr(f(x)) + sqr(delta)) - delta
```

Note that the only difference is the subtraction of the constant term `delta`. In this case, the error will equal zero at `f(x)=0` and it will increase to `-delta` as `f(x)` moves away from zero.

4.17.6.2 Reformulating and Approximating the Function MAX

The function `max(x1,x2,x3,...)` returns the maximum value of the arguments, where the number of the arguments may vary. Typically, the equation

```
t >= max(f(x),g(y))
```

is replaced by two inequalities:

```
t >= f(x)
t >= g(y)
```

Here `x`, `y` and `t` are variables and `f(x)` and `g(y)` are some functions depending `x` and `y` respectively. Provided the objective function has some term that tries to minimize `t`, one of the constraints will become binding at solution and `t` will equal the maximum of the two terms. The extension to more than two arguments in the function `max` should be obvious. A simple example follows:

```
variables
  x  / LO 0, L 0.2, UP [pi/2] /
  mx 'max[sin(x),cos(x)]'
  z  'objective var'
  ;
equation oDef;
oDef.. x / 100 + max[sin(x),cos(x)] =E= z;

model nonsmooth  / oDef /;
solve nonsmooth using dnlp min z;

equations oDef2, sinBnd, cosBnd;
oDef2.. x / 100 + mx =E= z;
sinBnd.. mx =G= sin(x);
cosBnd.. mx =G= cos(x);

model smooth / oDef2, sinBnd, cosBnd /;
solve smooth using nlp min z;
```

In case the objective function does not force the max-term to be minimized, a smooth approximation for `max(f(x),g(y))` can be used, as in the following example code:

```
[f(x) + g(y) + sqrt(sqr(f(x)-g(y)) + sqr(delta))] /2
```

```
$macro MYMAX(t1,t2,d) [0.5 * [t1 + t2 + sqrt(sqr(t1-t2) + sqr(d))] ]
equation oDef3;
oDef3.. x / 100 + MYMAX(sin(x),cos(x),1e-4) =E= z;

model approx / oDef3 /;
solve approx using nlp min z;
```

Here `delta` is a small scalar, preferably ranging from 1.e-2 to 1.e-4. The approximation error takes its maximum of `delta/2` when `f(x)=g(y)` and decreases as one moves away from this point. To shift the error away from the point of discontinuity, the following approximation can be used:

```
[f(x) + g(y) + sqrt(sqr(f(x)-g(y)) + sqr(delta)) - delta] /2
```

4.17.6.3 Reformulating and Approximating the Function MIN

The reformulation of and approximation to the `min` function is similar to the max case above and will not be repeated in full here. Briefly,

```
t =e= min(f(x),g(y))
```

is replaced by:

```
t =l= f(x)
t =l= g(y)
```

and is effective as long as the objective maximizes `t`. If not, this smooth approximation for `min(f(x),g(y))` can be used:

```
[f(x) + g(y) - sqrt(sqr(f(x)-g(y)) + sqr(delta))] /2
```

4.18 Data Exchange with Other Applications

  - Data Exchange with Sybase

4.18.1 Data Exchange with Text Files

This tutorial describes some ways on how to exchange data between GAMS and text files (usually in ASCII format).

4.18.1.1 Reading Text Files During Compilation

GAMS can read arbitrary text files during compile time by inserting them into the compiler input stream. The file content is then assumed to be GAMS code. Thus, including a text file within a data statement (see also Data Entry: Parameters, Scalars and Tables) allows for an easy way to include data from a text file, as long as the syntax in the text file can be understood by the GAMS compiler. This way, model specification and data input can be separated into different files.

The $include compile-time command is used to instruct the GAMS compiler to include the context of a different file at the current position of the input stream. As a result, the GAMS code behaves as if the `$include` statement has been replaced by the content of the file to be included. This can be very handy when including data from a separate text file. For instance, when data for a table is actually coming from another environment, one could replace the TABLE statement by an include statement. A GAMS table is in fact very well suited for a human being to be read or written, but it is rather awkward for programs to generate (e.g., the numbers have to be approximately below the corresponding headers). Therefore, often parameters are used and long series of assignment statements are generated. For instance, consider the following fragment from model [**TRNSPORT**]:

```
Table d(i,j)  'distance in thousands of miles'
                  new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;
```

When the data for this table is coming from a program it is more convenient to say in the main program:

```
Parameter d(i,j) 'distance in thousands of miles';
$include data.inc
display d;
```

and to have the include file `data.inc` contain the machine generated statements:

```
d("seattle","new-york") = 2.5;
d("san-diego","new-york") = 2.5;
d("seattle","chicago") = 1.7;
d("san-diego","chicago") = 1.8;
d("seattle","topeka") = 1.8;
d("san-diego","topeka") = 1.4;
```

In fact, GAMS can deal quite comfortably with a large number of such assignment statements.

Note, that since the included file is considered as part of the GAMS input stream, it is also echoed in the listing file. When including large text files with data statements, echoing these files in the listing file can be undesired. To suppress echoing to the listing file, the `$include` statement can be surrounded by $offlisting and $onlisting instructions:

```
parameter d(i,j) 'distance in thousands of miles';
$offlisting
$include data.inc
$onlisting
display d;
```

In the listing file, line numbers are skipped where the $offlisting is in effect.

In some cases it may be more convenient to use the initialization syntax of parameters. That is, the main GAMS file could contain the fragment:

```
parameter d(i,j) 'distance in thousands of miles' /
$include data2.inc
/;
display d;
```

and the data file contains the following records:

```
seattle  .new-york  2.5
san-diego.new-york  2.5
seattle  .chicago   1.7
san-diego.chicago   1.8
seattle  .topeka    1.8
san-diego.topeka    1.4
```

This approach is preferable for large data sets as it is more efficient for GAMS.

Note

Tables and parameters are handled exactly the same way by GAMS internally. The only difference is in the specification of data.

When using a table statement, data can also be specified in CSV (Comma-separated values) format if the $ondelim command has been issued. This format can, for instance, be generated by spreadsheet programs.

As example, consider again the following fragment from model [**TRNSPORT**]:

```
Table d(i,j)  'distance in thousands of miles'
                 new-york       chicago      topeka
    seattle         2.5           1.7          1.8
    san-diego       2.5           1.8          1.4  ;
```

A file `data.csv` that specifies the data of this table in CSV format would have the content

```
,new-york,chicago,topeka
seattle,2.5,1.7,1.8
san-diego,2.5,1.8,1.4
```

Notice the empty first element in the first line, which corresponds to the top-left blank in the above table.

This file can now be included directly into GAMS by using the $ondelim and $offdelim commands:

```
Table d(i,j) 'distance in thousands of miles'
$ondelim
$include data.csv
$offdelim
;
```

Attention

The $ondelim command only enables the use of *commas* as a separation symbol. The use of a different separation character is not supported by GAMS. This can become an issue if, for example, a CSV file has been generated with a language setting where commas are used as decimal point and semicolons are used for separating entries in the CSV file. In such a situation, `data.csv` would have the content

```
,new-york;chicago;topeka
seattle;2,5;1,7;1,8
san-diego;2,5;1,8;1,4
```

Therefore, such text files need to be preprocessed before read into GAMS. The following code uses the POSIX tool `tr` to (simultaneously) replace commas by dots and semicolons by commas:

```
$call "tr ,; ., < data.csv > data2.csv"
Table d(i,j) 'distance in thousands of miles' ;
$ondelim
$include data2.csv
$offdelim
```

CSV files can also be used to input higher dimensional data into GAMS. For instance, consider the 3 dimensional table `yieldtl` from model [**TURKEY**]:

```
Table yieldtl(l,cl,ty)  'livestock yield time series (kg per head)'

                      1974      1975      1976      1977      1978      1979

 sheep.meat           10.60     11.42     10.60      9.38      8.97      6.93
 sheep.milk           23.7      24.1      24.2      24.2      24.0      23.9
 sheep.wool            1.3       1.3       1.3       1.3       1.3       1.3
 sheep.hide            0.5       0.6       0.6       0.5       0.6       0.4
 goat.meat             6.39      7.31      8.68      7.31      6.39      6.85
 goat.milk            37.7      38.1      38.2      38.2      38.3      37.8
 goat.wool             0.6       0.6       0.6       0.6       0.6       0.6
 goat.hide             0.2       0.3       0.3       0.3       0.2       0.3
 angora.meat           1.77      1.77      2.66      2.21      1.77      1.77
 angora.milk          14.9      15.2      14.8      15.2      14.8      15.0
 angora.wool           1.6       1.6       1.6       1.6       1.6       1.4
 angora.hide           0.1       0.1       0.1       0.1       0.1       0.1
 cattle.meat          24.59     25.12     21.42     23.00     18.25     25.12
 cattle.milk         210.0     208.1     219.8     213.8     214.8     217.5
 cattle.hide           3.3       3.4       2.9       3.0       2.6       3.3
 buffalo.meat         43.73     45.42     40.61     37.21     32.20     32.68
 buffalo.milk        267.1     269.2     263.8     219.6     275.5     285.1
 buffalo.hide          4.1       3.4       3.0       2.4       2.5       2.6
 poultry.meat          2.24      2.24      2.24      2.24      2.24      2.24
 poultry.egg          62.4      62.2      64.2      78.3      76.4      73.3
;
```

When the data for this parameter is prepared by another application (such as a relational database), it may be more convenient to write it out in a comma-separated value form, e.g., a file `data.csv` could have the content

```
"sheep","meat","1974",10.60
"sheep","meat","1975",11.42
"sheep","meat","1976",10.60
```

```
"sheep","meat","1977",9.38
"sheep","meat","1978",8.97
"sheep","meat","1979",6.93
"sheep","milk","1974",23.70
"sheep","milk","1975",24.10
"sheep","milk","1976",24.20
"sheep","milk","1977",24.20
...
```

Including such formatted data into a GAMS model is possible by using $ondelim for Parameter Data for Higher Dimensions. Thus, the GAMS code would be

```
Parameter yieldtl(l,cl,ty)  'livestock yield time series (kg per head)'
/
$ondelim
$include data.csv
$offdelim
/;
```

4.18.1.2 Writing Text During Compilation

The commands $echo, $onecho, and $offecho send text to named files during compilation. $echo sends one line and is invoked using the syntax:

```
$echo 'text to be sent' > externalfile
```

or

```
$echo 'text to be sent' >> externalfile
```

The use of ">" generates a new file, while ">>" appends to an existing file.

For multi-line messages, the commands $onecho and $offecho can be used, e.g.,

```
$onecho  > externalfile
line 1 of text to be sent
line 2 of text to be sent
...
last line of text to be sent
$offecho
```

A typical example for the usage of these commands is the generation of a solver options file.

Additionally, the $log command can be used to send messages to the log file during compilation.

4.18.1.3 Writing Text Files During Execution

The put writing facility allows customized text output. This is a fairly complex but powerful and flexible report writing facility.

Assume that the following GAMS code is added to the end of model [**TRNSPORT**]. It instructs GAMS to write the model and the solve status together with levels of the decision variables to a file `results.txt`:

```
File results / results.txt /;
put results;
put "Model status",  transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
  put i.tl, j.tl, x.l(i,j) /
);
putclose;
```

First, a file object `results` is declared by using the File statement. The data of the file statement specifies the name of the file (`results.txt`). Next, line `put results;` instructs GAMS that for the following put statements, the file `results` should be used. In the following, the model status and the solve status are written, together with some descriptive text. These model attributes are set by a solve statement. The character '/' instructs GAMS to add a linebreak (newline character) to the results file. The next thing to write out are some variable values. Here, first the level value of variable `z` is written, followed by a loop that writes for each element of sets `i` and `j` the name of the elements (accessed via the .tl attribute) and the level value of `x(i,j)`. Finally, the `putclose;` statement instructs GAMS to close the current file. This will ensure that possibly cached data is flushed to the file.

The output will look like:

```
Model status        1.00
Solver status        1.00
Objective      153.67
Shipments
seattle     new-york           50.00
seattle     chicago           300.00
seattle     topeka              0.00
san-diego   new-york          275.00
san-diego   chicago             0.00
san-diego   topeka            275.00
```

This form can be hard to read by other applications, e.g., because some space characters are to be considered as separators, while others are really part of a string (e.g. "Model status"). However, by using the print control option `.pc` of the put writing facility, comma-separated value files can be written. That is, by adding the line `results.pc = 5;`, i.e.,

```
File results / results.txt /;
results.pc = 5;
put results;
put "Model status",  transport.modelstat /;
put "Solver status", transport.solvestat /;
put "Objective", z.l /;
put "Shipments" /;
loop((i,j),
  put i.tl, j.tl, x.l(i,j) /
);
putclose;
```

one obtains the following output:

```
"Model status",1.00
"Solver status",1.00
"Objective",153.67
"Shipments"
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

If several parameters of the same dimension should be written to a file in a customized format, the put statements can become rather repetitive. For example, the level and marginal values of variable `x` and the parameters `c` and `d` from model [**TRNSPORT**] should be written. This can be coded easily as:

```
file results / results.txt /;
results.pc = 5;
put results;
loop((i,j), put "distance",  i.tl, j.tl, d(i,j)   / );
loop((i,j), put "cost",      i.tl, j.tl, c(i,j)   / );
loop((i,j), put "levels",    i.tl, j.tl, x.l(i,j) / );
loop((i,j), put "marginals", i.tl, j.tl, x.m(i,j) / );
putclose;
```

A separation of the code that writes the data (loop and put statements) from the data that is written (descriptive text, set names, etc.) can be achieved by using $batinclude. This command works similar to the $include statement (see also Section Reading Text Files During Compilation above), but allows for additional arguments (separated by blanks). While including the file, markers `%1`, `%2`, etc., are replaced by the value of the 1st, 2nd, etc., argument.

By using $batinclude, the above example could be simplified to

```
file results / results.txt /;
results.pc = 5;
put results;
$batinclude put.inc distance i j d
$batinclude put.inc cost     i j c
$batinclude put.inc level    i j x.l
$batinclude put.inc marginal i j x.m
putclose;
```

where the file `put.inc` contain the actual loop and put statements:

```
loop((%2,%3), put "%1", %2.tl, %3.tl, %4(%2,%3) / );
```

Finally, the The Put_Utility Statement is referred, which is loosely connected to the put statement and allows the dynamic generation of file names, etc.

4.18.2 Data Exchange with Microsoft Excel

This tutorial gives an overview on how to exchange data between GAMS and Microsoft Excel.

GAMS can communicate with Microsoft Excel via GDX (GAMS Data Exchange) files. In order to write data from GAMS and to Excel, selected GAMS data can be written into a GDX file and then to an Excel file: GAMS -> GDX -> Excel. Similarly selected Excel data can be written to a GDX file and then read into GAMS: Excel -> GDX -> GAMS.

Some of GAMS/Excel data exchange tools that provide functionality to exchange data between GAMS and Excel are also discussed in the section Data Exchange Tools. The data exchange between GAMS and a CSV (Comma-separated values) file format and GAMS is covered in Data Exchange with Text Files.

4.18.2.1 From GAMS to Excel

Consider the following modication of the [**TRNSPORT**] model from the gams model library.

```
Sets
     i   'canning plants'   / seattle, san-diego /
     j   'markets'          / new-york, chicago, topeka / ;

Parameters

     a(i)  'capacity of plant i in cases'
       /    seattle     350
            san-diego   600  /

     b(j)  'demand at market j in cases'
       /    new-york    325
            chicago     300
            topeka      275  / ;

Table d(i,j)  'distance in thousands of miles'
                 new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;

Scalar f  'freight in dollars per case per thousand miles'  /90/ ;

Parameter c(i,j)  'transport cost in thousands of dollars per case' ;

          c(i,j) = f * d(i,j) / 1000 ;

Variables
     x(i,j)  'shipment quantities in cases'
     z       'total transportation costs in thousands of dollars' ;

Positive Variable x ;

Equations
     cost        'define objective function'
     supply(i)   'observe supply limit at plant i'
     demand(j)   'satisfy demand at market j' ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;
```

```
supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;

demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;

Solve transport using lp minimizing z ;

Display x.l, x.m ;

*=== Export to Excel using GDX utilities

*=== First unload to GDX file (occurs during execution phase)
execute_unload "results.gdx" x.L x.M

*=== Now write to variable levels to Excel file from GDX
*=== Since we do not specify a sheet, data is placed in first sheet
execute 'gdxxrw.exe results.gdx o=results.xlsx var=x.L'

*=== Write marginals to a different sheet with a specific range
execute 'gdxxrw.exe  results.gdx o=results.xlsx var=x.M rng=NewSheet!f1:i4'
```

After the solve statement, the data (`x.L` and `x.M`) from variable `x` can be written into a GDX file during the execution time using the command execute_unload:

```
execute_unload "results.gdx" x.L x.M
```

The execute_unload command above is executed during the actual execution phase to create a GDX file called `results.gdx`. The solution `x` and the marginals of `x` in the GDX file can be written to the Excel file `results.xlsx` using GDXXRW tool:

```
execute 'gdxxrw.exe results.gdx var=x.L'
execute 'gdxxrw.exe results.gdx var=x.M rng=NewSheet!f1:i4'
```

For the first call for `x.L`, there is no range specified and the data is written in cell `A1` and beyond in the first available sheet. For the second call for marginals `x.M`, data will be written to cells `F1:I4` in the sheet named `NewSheet`.

Note that GAMS can also write data into a GDX file during compile time. It is also possible to convert data stored in a GDX file into an Excel file spreadsheets using GDX2XLS tool and to write GAMS data to standard output formatted as a GAMS program with data statements using GDXDUMP tool.

4.18.2.2 From Excel to GAMS

Consider the following modifciation of the [**TRNSPORT**] model from the gams model library and the file `results.xlsx` file created from the previous example.

```
Sets
     i   'canning plants'   / seattle, san-diego /
     j   'markets'          / new-york, chicago, topeka / ;

Parameters
```

```
     a(i)  'capacity of plant i in cases'
       /    seattle     350
            san-diego   600  /

     b(j)  'demand at market j in cases'
       /    new-york    325
            chicago     300
            topeka      275  / ;

Table d(i,j)  'distance in thousands of miles'
                  new-york       chicago      topeka
    seattle          2.5           1.7          1.8
    san-diego        2.5           1.8          1.4  ;

Scalar f  'freight in dollars per case per thousand miles'  /90/ ;

Parameter c(i,j)  'transport cost in thousands of dollars per case' ;

          c(i,j) = f * d(i,j) / 1000 ;

Variables
     x(i,j)  'shipment quantities in cases'
     z       'total transportation costs in thousands of dollars' ;

Positive Variable x ;

Equations
     cost        'define objective function'
     supply(i)   'observe supply limit at plant i'
     demand(j)   'satisfy demand at market j' ;

cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;

supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;

demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

Model transport /all/ ;

*=== Import from Excel using GDX utilities

*=== First unload to GDX file (occurs during compilation phase)
$call gdxxrw.exe results.xlsx par=Level rng=sheet1!A1:D3

*=== Now import data from GDX
Parameter Level(i,j);
$gdxin results.gdx
$load Level
$gdxin

*=== Fix variables to values from Excel file
x.FX(i,j) = Level(i,j);
display Level, x.L;

Solve transport using lp minimizing z ;
```

```
Display x.l, x.m ;
```

The data in the Excel file can be loaded into a GDX file using the $call command and GDXXRW tool:

```
$call gdxxrw.exe results.xlsx par=Level rng=A1:D3
```

The command $call above executes a program called GDXXRW during compile time. The GDXXRW reads data from the range `A1:D3` in `results.xlsx` into a GAMS parameter called `Level` in the GDX file `results.gdx`. As an output GDX file is not specified when calling GDXXRW, the output file will be derived from the input file by changing the file extension of the input file and removing any path information.

To import data from a GDX file into a parameter, the parameter must be defined over appropriate sets before read. The data from a GDX file can be read during the compile time using the commands $gdxin and $load:

```
Parameter Level(i,j);
$gdxin results.gdx
$load Level
$gdxin
```

The first command $gdxin specifies the name of the GDX file `results.gdx` to be read. The command $load reads parameter `Level` from the GDX file. The second command $gdxin closed the GDX file.

GAMS can read from a GDX file either during compile time or during execution time. See Example 4 - Reading a GDX File when reading data with domain information and Example 5 - Reading a GDX File when reading from a GDX file during execution time.

Note that it is also possible to write all worksheets of an Excel workbook into a GDX file using XLSDUMP tool.

4.18.2.3 Data Exchange Tools

There are a number of tools that provide functionality to exchange data between GAMS and an Excel file. This section discusses some of the data exchange tools with some examples. The complete list of the tools can be found at GAMS/Excel Data Exchange tools.

GDXXRW

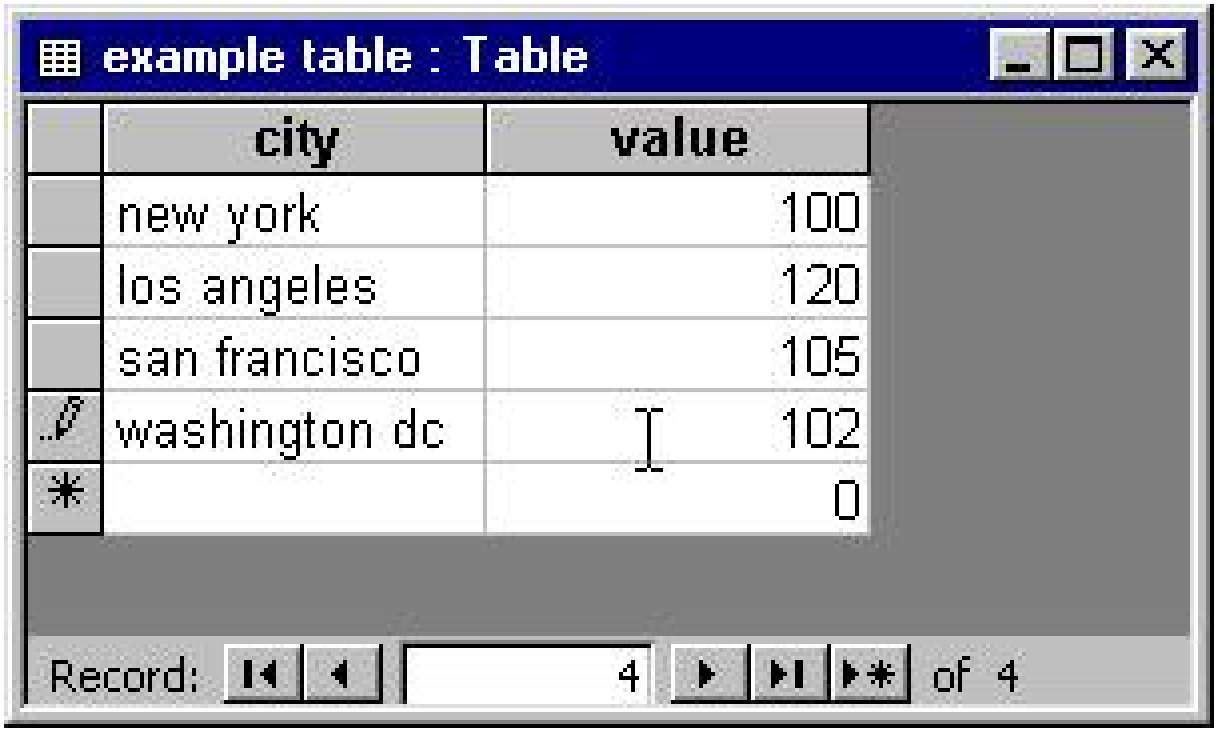
GDXXRW is a tool to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a 'GDX' file, or read from a 'GDX' file, and write the data to different ranges in a spreadsheet.

How to use GDXXRW to exchange data between GAMS and Excel is covered in the section From GAMS to Excel and the section From Excel to GAMS. More details on usage and examples of GDXXRW tool is covered in GDXXRW.

XLS2GMS

XLS2GMS is a simple utility that allows you to extract data from an Excel spreadsheet and convert it into a GAMS include file. XLS2GMS can be run interactively or in batch mode.

Consider the Excel data from the following spreadsheet:



The data can be imported from the Excel file into a GAMS include file by calling XLS2GMS tool and inserted an include file as parameter data elements using the command $include:

```
set ssi /
  'new york', 'washington dc', 'los angeles', 'san francisco'
/;
parameter ssdata(ssi) /
$call =d:\util\xls2gms I="c:\my documents\test2.xlsx" B O=d:\tmp\x.inc
$include d:\tmp\x.inc
/;
display ssdata;
```

Notice the B parameter, which is needed as there are embedded blanks in the labels.

Sometimes a translation between the labels used in the model and the ones used in the is needed. One way to do this is to use a mapping set in GAMS. Suppose the rest of the model is defined in terms of the set I which is defined as:

```
set i / ny, dc, la, sf/;
```

To map a parameter data defined over this set, the following simple GAMS fragment can be used:

```
set map(i,ssi) mapping set /
   ny.'new york'
   dc.'washington dc'
   la.'los angeles'
   sf.'san francisco'
/;
display map;

parameter data(i);
data(i) = sum(map(i,ssi), ssdata(ssi));
display data;
```

SQL2GMS

In some cases it is convenient to consider tabular data in an Excel spreadsheet as a database table and to import it via GDX file using the SQL2GMS tool.

Consider the following spreadsheet:

	A	B	C	D	E
1	year	loc	prod	sales	profit
2	1997	la	hardware	80	5
3	1997	la	software	60	10
4	1997	nyc	hardware	100	15
5	1997	nyc	software	130	25
6	1997	sfo	hardware	50	9
7	1997	sfo	software	60	6
8	1997	was	hardware	80	7
9	1997	was	software	90	8
10	1998	la	hardware	88	5,25
11	1998	la	software	66	10,5
12	1998	nyc	hardware	110	15,75
13	1998	nyc	software	143	26,25
14	1998	sfo	hardware	55	9,45
15	1998	sfo	software	66	6,3
16	1998	was	hardware	88	7,35
17	1998	was	software	99	8,4
18					

This table can be read using an SQL query:

```
SELECT year,loc,prod,'sales',sales FROM [profitdata$] \
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]
```

The table name is equal to the sheet name(profitdata). We can pass the query to the Excel ODBC driver using the tool SQL2GMS tool as follows:

```
set y 'years'   /1997,1998/;
set c 'city'    /la,nyc,sfo,was/;
set p 'product' /hardware,software/;
set k 'key'     /sales,profit/;

$onecho > excelcmd.txt
c=DRIVER=Microsoft Excel Driver (*.xls, *.xlsx, *.xlsm, *.xlsb);dbq=%system.fp%profit.xlsx;
q=SELECT year,loc,prod,'sales',sales FROM [profitdata$] \
  UNION SELECT year,loc,prod,'profit',profit FROM [profitdata$]
x=fromexcel.gdx
$offecho
$call =sql2gms @excelcmd.txt
parameter d(y,c,p,k) ;
$gdxin excel.gdx
$load d=p
display d;
```

and the DISPLAY results will be:

```
---     21 PARAMETER d  FROM SQL2GMS

INDEX 1 = 1997

                   sales      profit

la .hardware      80.000       5.000
la .software      60.000      10.000
nyc.hardware     100.000      15.000
nyc.software     130.000      25.000
sfo.hardware      50.000       9.000
sfo.software      60.000       6.000
was.hardware      80.000       7.000
was.software      90.000       8.000

INDEX 1 = 1998

                   sales      profit

la .hardware      88.000       5.250
la .software      66.000      10.500
nyc.hardware     110.000      15.750
nyc.software     143.000      26.250
sfo.hardware      55.000       9.450
sfo.software      66.000       6.300
was.hardware      88.000       7.350
was.software      99.000       8.400
```

GDXVIEWER

GDXVIEWER is a tool to view and convert data contained in GDX files. It can also export to csv, xlsx, xml-files and pivot tables. The usage and examples are covered in GDXVIEWER.

GDX2XLS

GDX2XLS tool to convert the contents of a GDX file into an Excel file or an xml-file. The usage and examples are covered in GDX2XLS.

4.18.3 Data Exchange with Databases

This tutorial provides a guidance on how to exchange data between GAMS and various Database Management System.

4.18.3.1 Data Exchange with DB2

DB2 is one of IBM's relational database management systems.

Import from DB2

DB2 has an `EXPORT` command that can be used to generate comma delimited files. An example of a DB2 session illustrating this is shown below:

```
------------------------------------ Command Entered -------------------------------------
describe table db2admin.dist
 ;
-----------------------------------------------------------------------------------------

Column                         Type      Type
name                           schema    name               Length   Scale Nulls
------------------------------ --------- ------------------ -------- ----- -----
LOCA                           SYSIBM    VARCHAR                 10     0 No
LOCB                           SYSIBM    VARCHAR                 10     0 No
DISTANCE                       SYSIBM    DOUBLE                   8     0 Yes

  3 record(s) selected.

---------------------------------- Command Entered ---------------------------------------
select * from dist ;
-----------------------------------------------------------------------------------------

LOCA       LOCB       DISTANCE
---------- ---------- ------------------------
seattle    new-york     +2.50000000000000E+000
seattle    chicago      +1.70000000000000E+000
seattle    topeka       +1.80000000000000E+000
san-diego  new-york     +2.50000000000000E+000
san-diego  chicago      +1.80000000000000E+000
san-diego  topeka       +1.40000000000000E+000

  6 record(s) selected.
```

```
---------------------------------- Command Entered ----------------------------------
export to c:\tmp\export.txt of del select * from dist ;
-------------------------------------------------------------------------------------
SQL3104N  The Export utility is beginning to export data to file
"c:\tmp\export.txt".

SQL3105N  The Export utility has finished exporting "6" rows.

Number of rows exported: 6
```

The resulting data file **export.txt** will look like:

```
"seattle","new-york",+2.50000000000000E+000
"seattle","chicago",+1.70000000000000E+000
"seattle","topeka",+1.80000000000000E+000
"san-diego","new-york",+2.50000000000000E+000
"san-diego","chicago",+1.80000000000000E+000
"san-diego","topeka",+1.40000000000000E+000
```

This file can be read into GAMS using $include :

```
parameter d(i,j) 'distance in thousands of miles' /
  $ondelim
  $include export.txt
  $offdelim
/;
display d;
```

Export to DB2

DB2 has an `IMPORT` command that can read delimited files. As an example consider the file generated by GAMS PUT statements:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

A transcript of a DB2 session to read this file, is given below:

```
---------------------------------- Command Entered ----------------------------------
create table results(loca varchar(10) not null,
                     locb varchar(10) not null,
                     shipment double not null)  ;
-------------------------------------------------------------------------------------
DB20000I  The SQL command completed successfully.

---------------------------------- Command Entered ----------------------------------
import from c:\tmp\import.txt of del insert into results ;
```

```
-----------------------------------------------------------------------------------------
SQL3109N  The utility is beginning to load data from file "c:\tmp\import.txt".

SQL3110N  The utility has completed processing.  "6" rows were read from the
input file.

SQL3221W  ...Begin COMMIT WORK. Input Record Count = "6".

SQL3222W  ...COMMIT of any database changes was successful.

SQL3149N  "6" rows were processed from the input file.  "6" rows were
successfully inserted into the table.  "0" rows were rejected.

Number of rows read         = 6
Number of rows skipped      = 0
Number of rows inserted     = 6
Number of rows updated      = 0
Number of rows rejected     = 0
Number of rows committed    = 6
```

For very large data sets it is advised to use the `LOAD` command:

```
------------------------------------ Command Entered ------------------------------------
load from c:\tmp\import.txt of del insert into results ;
-----------------------------------------------------------------------------------------
SQL3501W  The table space(s) in which the table resides will not be placed in
backup pending state since forward recovery is disabled for the database.

SQL3109N  The utility is beginning to load data from file "c:\tmp\import.txt".

SQL3500W  The utility is beginning the "LOAD" phase at time "03-20-2000
18:11:50.213782".

SQL3519W  Begin Load Consistency Point. Input record count = "0".

SQL3520W  Load Consistency Point was successful.

SQL3110N  The utility has completed processing.  "6" rows were read from the
input file.

SQL3519W  Begin Load Consistency Point. Input record count = "6".

SQL3520W  Load Consistency Point was successful.

SQL3515W  The utility has finished the "LOAD" phase at time "03-20-2000
18:11:50.337092".

Number of rows read         = 6
Number of rows skipped      = 0
Number of rows loaded       = 6
Number of rows rejected     = 0
Number of rows deleted      = 0
Number of rows committed    = 6
```

For smaller data sets one can also generate a series of INSERT statements using the PUT facility.

4.18.3.2 Data Exchange with MS Access

Microsoft Office Access, previously known as Microsoft Access, is a relational database management system from Microsoft. It is a member of the Microsoft Office system.

Import from MS Access

MDB2GMS

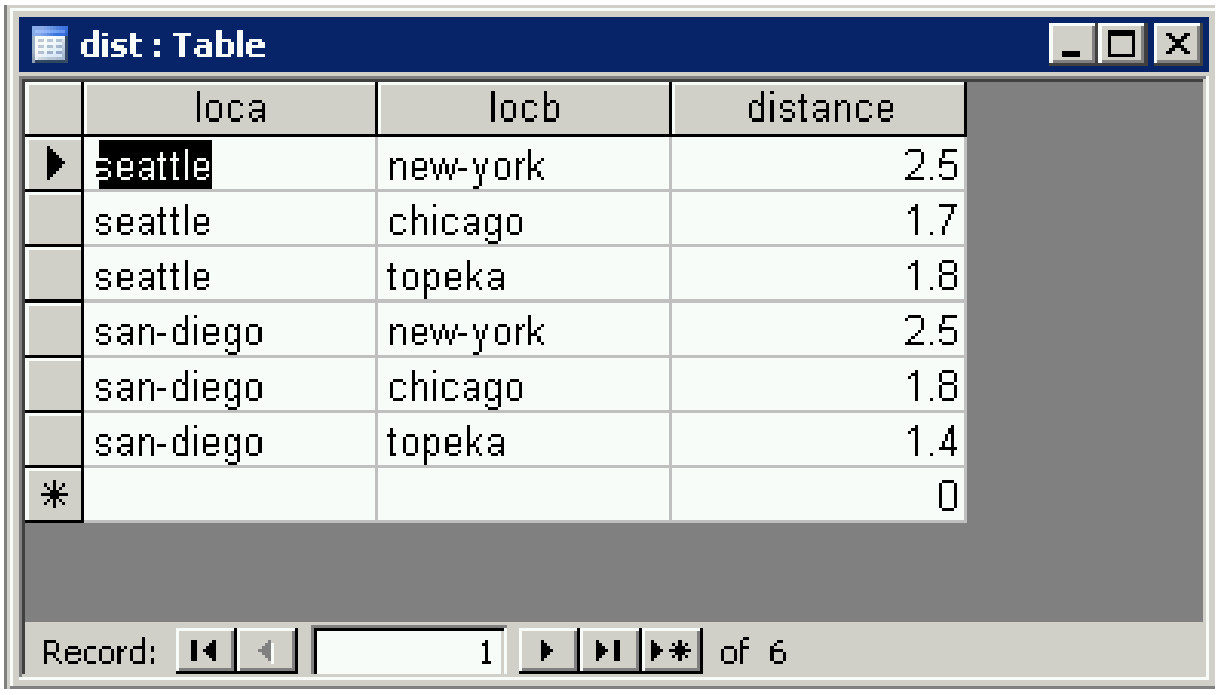
MDB2GMS is a tool to convert data from an Microsoft Access database into GAMS readable format. The source is an MS Access database file (∗.mdb or ∗.accdb) and the target is a GAMS Include File or a GAMS GDX File. MDB2GMS is part of the GAMS Data eXchange Tools, see documentation for more information.

SQL2GMS

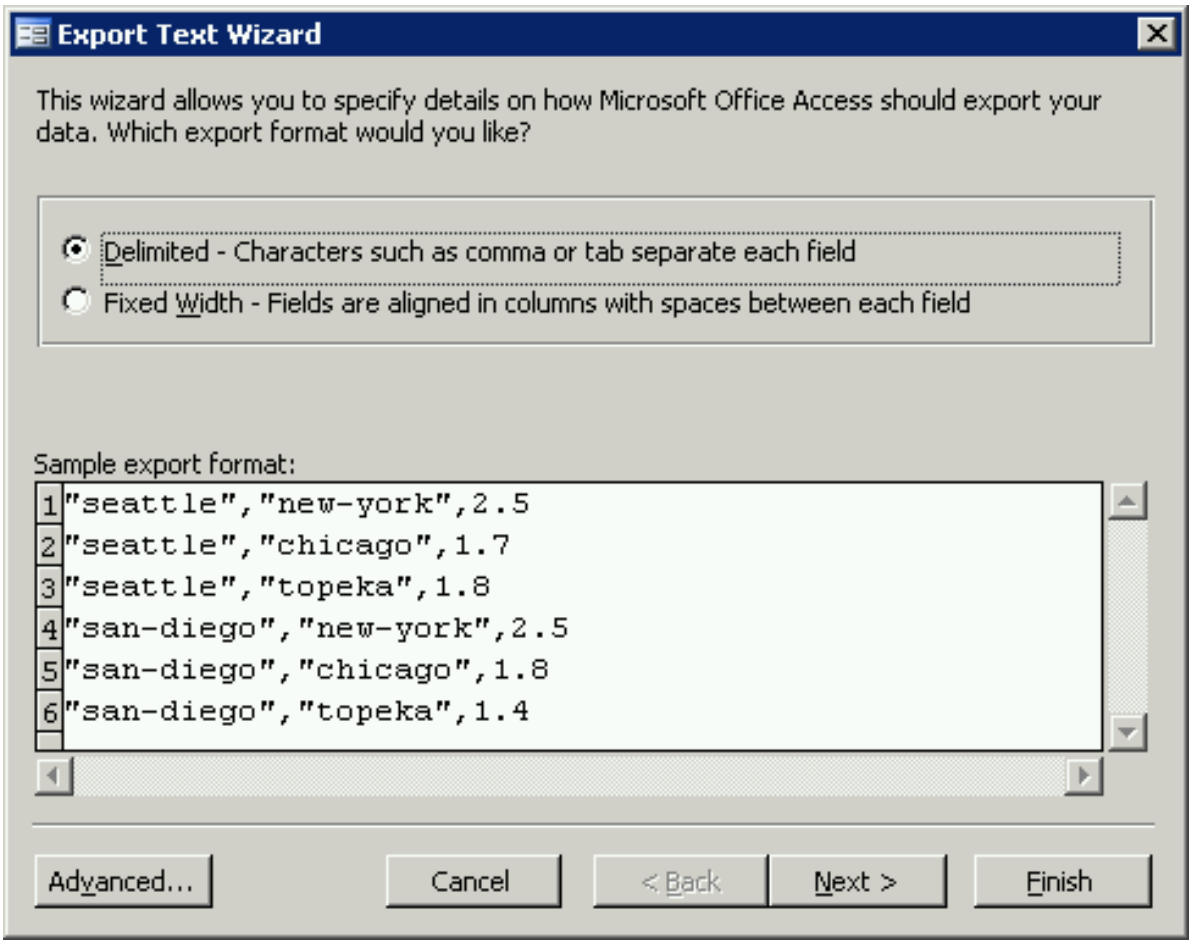
SQL2GMS is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File or a GAMS GDX File. SQL2GMS is part of the GAMS Data eXchange Tools, see documentation for more information.

CSV Files

Microsoft Access can export tables into comma delimited text files using its **Save As/Export** menu. Suppose we have the following table:



After choosing **Save As/Export** and selecting **Text Files** we get the following window:



Just using the default settings, we get the following file:

```
"seattle","new-york",2.50
"seattle","chicago",1.70
"seattle","topeka",1.80
"san-diego","new-york",2.50
"san-diego","chicago",1.80
"san-diego","topeka",1.40
```

which can be handled in GAMS by $ondelim/$offdelim and $include:

```
parameter d(i,j) 'distance in thousands of miles' /
    $ondelim
    $include dist.txt
    $offdelim
/;
display d;
```

Import Dates from Access

GAMS dates are one day off when importing from MS Access. Suppose we have an MS Access table with one single date column:

```
datefield
----------
3/12/2007
3/13/2007 10:00:00 AM
3/14/2007 8:30:00 PM
```

The date data above can be imported into GAMS using $call and MDB2GMS tool as follows:

```
$call =mdb2gms I="%system.fp%Sample.accdb" Q="select datefield,Cdbl(datefield) from datetable" O=x.i
parameter p(*) /
    $include x.inc
/;
display p;
alias(*,i);
parameter q(*,*);
loop(i$p(i),
    q(i,'year') = gyear(p(i));
    q(i,'month') = gmonth(p(i));
    q(i,'day') = gday(p(i));
    q(i,'hour') = ghour(p(i));
    q(i,'minute') = gminute(p(i));
);
display q;
```

Note that the `Cdbl()` function converts the date to a floating point number (double precision). The generated include file looks like:

```
* ------------------------------------------------------
* MDB2GMS Version 2.8, January 2007
* Erwin Kalvelagen, GAMS Development Corp
* ------------------------------------------------------
* DAO version: 3.6
* Jet version: 4.0
* Database:    D:\mdb2gms\examples\Sample.accdb
* Query:       select datefield,Cdbl(datefield) from datetable
* ------------------------------------------------------
'3/12/2007' 39153
'3/13/2007 10:00:00 AM' 39154.4166666667
'3/14/2007 8:30:00 PM' 39155.8541666667
* ------------------------------------------------------
```

which looks o.k. However, when we look at the GAMS results in the listing file we see:

```
----     28 PARAMETER p
3/12/2007             39153.000,    3/13/2007 10:00:00 AM 39154.417,    3/14/2007 8:30:00 PM  39155.8

----     39 PARAMETER q

                            year       month         day        hour      minute

3/12/2007                2007.000       3.000      13.000
3/13/2007 10:00:00 AM    2007.000       3.000      14.000      10.000
3/14/2007 8:30:00 PM     2007.000       3.000      15.000      20.000      30.000
```

Clearly the dates are off by one day: see the column `day`. We can fix this problem in different places, e.g. in the query or in the GAMS model by subtracting 1.0 from an imported date. This problem occurs not only in MS Access but also with other software packages.

Export to MS Access

GDX2ACCESS

GDX2ACCESS is a tool to dump the whole contents of a GDX file to a **new** MS Access file (.mdb or .accdb file). GDX2ACCESS is part of the GAMS Data eXchange Tools, see documentation for more information.

GDXVIEWER

Access tables in MS Access files can be directly generated by the GDXVIEWER tool. The GDXVIEWER tool uses OLE automation to export data to an MS Access database. This means that MS Access needs to be installed for the Access Export facility to work. GDXVIEWER is part of the GAMS Data eXchange Tools, see documentation for more information.

VBScript

VBScript is a scripting tool that can be used to talk to COM objects. In this case we use it to tell Access to import a CSV file.

```
$ontext
    Import a table into MS Access using VBscript
$offtext
$if exist new.accdb $call del new.accdb
set i /i1*i10/;
alias (i,j);
parameter p(i,j);
p(i,j) = uniform(-100,100);
display p;
file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
     put i.tl, j.tl, p(i,j):12:8/
);
putclose;

execute "=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0"
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=%system.fp%;FMT=Delimited].[data#csv]"
Wscript.Echo "Query : " & strSQL
Set oJet = CreateObject("DAO.DBEngine.36")
Wscript.Echo "Jet version : " & oJet.version
Set oDB = oJet.createDatabase("new.accdb",dbLangGeneral)
Wscript.Echo "Created : " & oDB.name
oDB.Execute strSQL
Set TableDef = oDB.TableDefs("mytable")
Wscript.Echo "Rows inserted in mytable : " & TableDef.RecordCount
oDB.Close
Wscript.Echo "Done"
$offecho
```

The CSV file contains a header row with the names of the fields:

```
"i","j","p"
"i1","i1",-65.65057360
"i1","i2",68.65334160
"i1","i3",10.07507120
"i1","i4",-39.77241920
"i1","i5",-41.55757660
....
```

The text driver specification `HDR=Yes` makes sure the first row in the CSV file is treated specially. The log will look like:

```
U:\temp>gams vbaccess.gms
--- Job vbaccess.gms Start 01/28/08 16:57:37
GAMS Rev 149  Copyright (C) 1987-2007 GAMS Development. All rights reserved
...
--- Starting compilation
--- vbaccess.gms(4) 2 Mb
--- call del new.accdb
--- vbaccess.gms(38) 3 Mb
--- Starting execution: elapsed 0:00:00.109
--- vbaccess.gms(18) 4 Mb
Microsoft (R) Windows Script Host Version 5.6
Copyright (C) Microsoft Corporation 1996-2001. All rights reserved.

Running script: access.vbs
Query : SELECT * INTO mytable FROM [Text;HDR=Yes;Database=U:\temp\;FMT=Delimited
].[data#csv]
Jet version : 3.6
Created : U:\temp\new.accdb
Rows inserted in mytable : 100
Done
--- Putfile f U:\temp\data.csv
*** Status: Normal completion
--- Job vbaccess.gms Stop 01/28/08 16:57:38 elapsed 0:00:00.609
U:\temp>
```

Please note that although the $onecho/$offecho is at the bottom of the GAMS file, the file `access.vbs` is created at compile time. I.e. before the executable statements like `PUT`, `EXECUTE` are executed.

JScript

The same script using `JScript` is similar to the one with VScript. We only price the script itself.

```
$ontext
    Import a table into MS Access using JScript
$offtext
$if exist new.accdb $call del new.accdb

set i /i1*i10/;
alias (i,j);
parameter p(i,j);
```

```
p(i,j) = uniform(-100,100);
display p;

file f /data.csv/;
f.pc=5;
put f,'i','j','p'/;
loop((i,j),
     put i.tl, j.tl, p(i,j):12:8/
);
putclose;

execute "=cscript access.js";

$onecho > access.js
// this is a JScript script
WScript.Echo("Running script: access.js");

dbLangGeneral = ";LANGID=0x0409;CP=1252;COUNTRY=0";
strSQL = "SELECT * INTO mytable FROM [Text;HDR=Yes;Database=.;FMT=Delimited].[data#csv]";
WScript.Echo("Query : ",strSQL);

oJet = new ActiveXObject("DAO.DBEngine.36");
WScript.Echo("Jet version : ",oJet.version);

oDB = oJet.createDatabase("new.accdb",dbLangGeneral);
WScript.Echo("Created : ",oDB.name);

oDB.Execute(strSQL);
TableDef = oDB.TableDefs("mytable");
WScript.Echo("Rows inserted in mytable : ",TableDef.RecordCount);

oDB.Close();

WScript.Echo("Done");
$offecho
```

Combining GDX2ACCESS and VBscript

Data in a GDX file do not contain domain information. I.e. a parameter `c(i,j)` is really stored as `c(*,*)`. As a result GDX2ACCESS will invent field names like `dim1`, `dim2`, `Value`. In some cases this may not be convenient, e.g. when more descriptive field names are required. We will show how a small script in VBscript can handle this task. The script will rename the fields `dim1`, `dim2`, `Value` in table `c` to `i`, `j`, and `transportcost`.

```
$call "gamslib 1"
$include trnsport.gms
*
* export to gdx file.
* The domains i,j are lost: gdx only stores c(*,*)
execute_unload "c.gdx",c;
*
* move to access database
* column names are dim1,dim2
*
execute "=gdx2access c.gdx";
*
```

```
* rename columns
*
execute "=cscript access.vbs";

$onecho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"

' Office 2000 DAO version
' Change to local situation.
Set oDAO = CreateObject("DAO.DBEngine.36")
script.Echo "DAO version : " & oDAO.version

Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name

Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name

' rename fields
oTable.Fields.Item("dim1").name = "i"
oTable.Fields.Item("dim2").name = "j"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"

oDB.Close
Wscript.Echo "Done"
$offecho
```

The above VBscript fragment needs to be adapted according to the DAO `Data Access Objects` version available on the client machine. This can be implemented in a more robust fashion by letting MS Access find the DAO engine:

```
'this is a VBscript script
WScript.Echo "Running script: access.vbs"

set oa = CreateObject("Access.Application")
set oDAO = oa.DBEngine
Wscript.Echo "DAO Version: " & oDAO.version

Set oDB = oDAO.openDatabase("%system.fp%c.accdb")
Wscript.Echo "Opened : " & oDB.name

Set oTable = oDB.TableDefs.Item("c")
Wscript.Echo "Table : " & oTable.name

' rename fields
oTable.Fields.Item("dim1").name = "i"
oTable.Fields.Item("dim2").name = "j"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"

oDB.Close

Wscript.Echo "Done"
```

Please note that the macro `%system.fp%` is replaced by GAMS by the working directory (this is the project directory when running GAMS from the IDE).

4.18.3.3 Data Exchange with MySQL

MySQL is a multi-threaded, multi-user SQL database management system.

Import from MySQL

MySQL can write the results of a SELECT statement to a file as follows:

```
mysql> select * from dist;
+-----------+----------+----------+
| loca      | locb     | distance |
+-----------+----------+----------+
| seattle   | new-york |       50 |
| seattle   | chicago  |      300 |
| seattle   | topeka   |        0 |
| san-diego | new-york |      275 |
| san-diego | chicago  |        0 |
| san-diego | topeka   |      275 |
+-----------+----------+----------+
6 rows in set (0.01 sec)

mysql> select * from dist into outfile '/tmp/data.csv'
    -> fields terminated by ','
    -> optionally enclosed by '"'
    -> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)
```

The resulting CSV file looks like:

```
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275
```

which can be read by GAMS directly. This approach can be automated as follows:

```
[erwin@localhost erwin]$ cat myscript
use test
select * from dist into outfile '/tmp/data.csv'
     fields terminated by ','
     optionally enclosed by '"'
     lines terminated by '\n';
[erwin@localhost erwin]$ cat x.gms
set i /seattle, san-diego/;
set j /new-york, chicago, topeka/;

$call 'mysql -u root < myscript'
parameter dist(i,j) /
$ondelim
$include /tmp/data.csv
$offdelim
```

```
/;
display dist;
[erwin@localhost erwin]$ gams x
GAMS Rev 132  Copyright (C) 1987-2002 GAMS Development. All rights reserved
Licensee: GAMS Development Corporation, Washington, DC   G871201:0000XX-XXX
          Free Demo,  202-342-0180,  sales@gams.com,  www.gams.com   DC9999
--- Starting compilation
--- x.gms(5) 1 Mb
--- call mysql -u root < myscript
--- .data.csv(6) 1 Mb
--- x.gms(15) 1 Mb
--- Starting execution
--- x.gms(18) 1 Mb
*** Status: Normal completion
[erwin@localhost erwin]$
```

The listing file shows that the table is read correctly:

```
   1
   2  set i /seattle, san-diego/;
   3  set j /new-york, chicago, topeka/;
   4
   6  parameter dist(i,j) /
INCLUDE    /tmp/data.csv
   9  "seattle","new-york",50
  10  "seattle","chicago",300
  11  "seattle","topeka",0
  12  "san-diego","new-york",275
  13  "san-diego","chicago",0
  14  "san-diego","topeka",275
  16  /;
  17
  18  display dist;
  19
  20
  21

   SEQ   GLOBAL TYPE      PARENT   LOCAL  FILENAME

     1        1 INPUT          0       0  /home/erwin/x.gms
     2        5 CALL           1       5  mysql -u root < myscript
     3        8 INCLUDE        1       8  ./tmp/data.csv

----     18 PARAMETER dist

             new-york     chicago      topeka

seattle        50.000     300.000
san-diego     275.000                 275.000
```

Instead of maintaining the MySQL script in a separate file, it can also be written by GAMS using $onecho/$offecho and a statement like:

```
$onecho > myscript
```

```
use test
select * from dist into outfile '/tmp/data.csv'
     fields terminated by ','
     optionally enclosed by '"'
     lines terminated by '\n';
$offecho
```

This will write the script at compile time.

Export to MySQL

GAMS can export data to MySQL by creating a script containing a series of SQL `INSERT` statements, as shown in section Oracle CSV Import .

It is noted that MySQL does have a REPLACE statement which is a useful blend of an `INSERT` and `UPDATE` statement: update a row if it already exists, otherwise insert it. This is not standard SQL however, so it can cause problems when moving to another database.

For larger result sets it may be better to use the `LOAD DATA INFILE` command. This command can read directly ASCII text files such as comma delimited CSV files.

Consider again the data file created by the PUT statement:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

The following transcript shows how to import this into MySQL:

```
myql> create table dist(loca varchar(10), locb varchar(10), distance double precision);
Query OK, 0 rows affected (0.00 sec)

mysql> show tables;
+----------------+
| Tables_in_test |
+----------------+
| dist           |
+----------------+
1 row in set (0.00 sec)

mysql> describe dist;
+----------+-------------+------+-----+---------+-------+
| Field    | Type        | Null | Key | Default | Extra |
+----------+-------------+------+-----+---------+-------+
| loca     | varchar(10) | YES  |     | NULL    |       |
| locb     | varchar(10) | YES  |     | NULL    |       |
| distance | double      | YES  |     | NULL    |       |
+----------+-------------+------+-----+---------+-------+
3 rows in set (0.00 sec)

mysql> load data infile '/tmp/data.txt' into table dist
    -> fields terminated by ','
```

```
    -> optionally enclosed by '"'
    -> lines terminated by '\n';
Query OK, 6 rows affected (0.00 sec)
Records: 6  Deleted: 0  Skipped: 0  Warnings: 0

mysql> select * from dist;
+-----------+----------+----------+
| loca      | locb     | distance |
+-----------+----------+----------+
| seattle   | new-york |       50 |
| seattle   | chicago  |      300 |
| seattle   | topeka   |        0 |
| san-diego | new-york |      275 |
| san-diego | chicago  |        0 |
| san-diego | topeka   |      275 |
+-----------+----------+----------+
6 rows in set (0.00 sec)
```

Note that we used no keys in our table definition. In practice it is of course highly recommended to define proper keys.

4.18.3.4 Data Exchange with Oracle

The Oracle Database (commonly referred to as Oracle RDBMS or simply as Oracle) is a relational database management system (RDBMS) software product released by Oracle Corporation.

Import from Oracle

SQL∗Plus

To export an Oracle table a simple solution is to write an SQL∗Plus script. E.g. if our table looks like:

```
SQL> describe dist;
 Name                              Null?    Type
 --------------------------------- -------- ------------------------
 LOCA                              NOT NULL VARCHAR2(10)
 LOCB                              NOT NULL VARCHAR2(10)
 DISTANCE                                   NUMBER

SQL> select * from dist;

LOCA       LOCB        DISTANCE
---------- ---------- ---------
seattle    new-york         2.5
seattle    chicago          1.7
seattle    topeka           1.8
san-diego  new-york         2.5
san-diego  chicago          1.8
san-diego  topeka           1.4

6 rows selected.

SQL>
```

then the following script will export this table:

```
set pagesize 0
set pause off
set heading off
spool data
select loca||',',||locb||',',||distance from dist;
spool off
```

The resulting data file "data.lst" will look like:

```
seattle,new-york,2.5
seattle,chicago,1.7
seattle,topeka,1.8
san-diego,new-york,2.5
san-diego,chicago,1.8
san-diego,topeka,1.4
```

This almost looks like our data initialization syntax for parameters:

```
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
```

The only differences are in the delimiters that are being used. These differences are easily digested by GAMS once it is in ondelim mode. I.e. the following syntax can be used to read the *data.lst* file:

```
parameter d(i,j) 'distance in thousands of miles' /
$ondelim
$include data.lst
$offdelim
/;
display d;
```

SQL2GMS

An alternative way to import data from Oracle is to use the tool SQL2GMS which can talk to any database with an ADO or ODBC interface.

Import dates from Oracle databases and converting them to GAMS dates

For most softwares it is easy to generate dates that GAMS can import and understand. The most common issue is that GAMS is one day off compared to Excel, Delphi, Access, ODBC etc. Oracle is somewhat more involved. First it is useful to have the date/time exported as a Julian date. This can be done with the following stored procedure:

```
-- julian representation of a date/time
-- Erwin Kalvelagen, feb 2007
create or replace function to_julian(d IN TIMESTAMP)
return number
is
begin
return to_number(to_char(d,'J')) + to_number(to_char(d,'SSSSS'))/86400;
end;
```

This function can be used to export dates as simple floating point numbers. In GAMS we need just a simple adjustment by adding a constant `''datediff''` defined by:

```
scalar
   refdategams   "march 16, 2006, 00:00"
   refdateoracle "march 16, 2006, 00:00"  /2453811/
   datediff      "difference between GAMS and Oracle date"
;
refdategams = jdate(2006,3,16);
datediff = refdategams-refdateoracle;
```

This trick has been applied in a complex scheduling application where dates are important data types that must be exchanged between the application logic and database tier and the optimization engine.

Export to Oracle

Oracle CSV Import

A familiar way of moving data into Oracle is to generate standard SQL `INSERT` statements. The PUT facility is flexible enough to handle this. For instance the following code:

```
file results /results.sql/;
results.lw=0;
results.nw=0;
put results;
loop((i,j),
     put "insert into result (loca, locb, shipment) ";
     put "values ('",i.tl,"','",j.tl,"',",x.l(i,j),");"/
);
putclose;
```

will generate these SQL statements:

```
insert into result (loca, locb, shipment) values ('seattle','new-york',50.00);
insert into result (loca, locb, shipment) values ('seattle','chicago',300.00);
insert into result (loca, locb, shipment) values ('seattle','topeka',0.00);
insert into result (loca, locb, shipment) values ('san-diego','new-york',275.00);
insert into result (loca, locb, shipment) values ('san-diego','chicago',0.00);
insert into result (loca, locb, shipment) values ('san-diego','topeka',275.00);
```

The `.lw` and `.nw` attributes for the put file indicate that no extra spaces around the labels and the numeric values are needed. These field width attributes have a default value of 12 which would cause the values to look like:

```
'seattle     ','new-york    ',       50.00
```

If the amount of data is large the utility SQL∗Loader can be used to import comma delimited input. I.e. the GAMS code:

```
file results /results.txt/;
results.pc=5;
put results;
loop((i,j),
     put i.tl, j.tl, x.l(i,j)/
);
putclose;
```

produces a file results.txt:

```
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00
```

The following SQL∗Loader control file will read this file:

```
LOAD DATA
INFILE results.txt
INTO TABLE result
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
(loca,locb,shipment)
```

GDX to Oracle

Database tables in an SQL RDBMS can be directly generated by the GDXVIEWER tool. The GDXVIEWER can use three methods to export to Oracle and other RDBMS:

1. The direct ADO/ODBC link can create a new table and populate it.
2. The SQL INSERT script generator can create a script with a number of `INSERT` statements.
3. The SQL `UPDATE` script generator can create a script with a number of UPDATE statements.

4.18.3.5 Data Exchange with SQL Server

Import from SQL Server

Microsoft SQL Server is Microsoft's flagship database. It comes in different flavors, including SQL Server, MSDE and SQL Server Express.

Using SQL2GMS

A good way to import SQL server data into GAMS is using the SQL2GMS tool. Below is an example of its use:

```
$set commandfile commands.txt
$onecho > %commandfile%
C=provider=sqloledb;data source=athlon\SQLExpress;Initial catalog=test;user id=sa;password=password
O=C:\WINNT\gamsdir\xx.inc
Q=SELECT * FROM x
$offecho
$call =sql2gms @%commandfile%
parameter p(i,j) /
$include "C:\WINNT\gamsdir\xx.inc"
/;
display p;
```

Using the BCP utilty and CSV files

To export SQL Server data to CSV files we can use the BCP utility.

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..results out x.csv \
  -S athlon\sqlexpress -c -U sa -P password -t,

Starting copy...

6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total     : 10     Average : (600.00 rows per sec.)

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type x.csv
seattle,new-york,50.0
seattle,chicago,300.0
seattle,topeka,0.0
san-diego,new-york,275.0
san-diego,chicago,0.0
san-diego,topeka,275.0
```

It is somewhat more difficult to create a proper CSV file. A format specification file can help here. For an example see the next section on Data Exchange with Sybase . Other tools to export files include DTS (Data Transformation Services) and linked ODBC data sources.

A direct interface between SQL server tables and GAMS GDX files

Finally we can program directly an interface between SQL server tables and GAMS GDX files. A small example in C# can look like:

```
gdxio = new csharpclient();
//
// read a set
//
gdxio.gdxdatawritestrstart(ap, "location", "from db", 1, csharpclient.dt_set, 0);
String q = "select distinct(location) from exporttable";
SqlCommand cmd = new SqlCommand(q, conn);
SqlDataReader myReader = cmd.ExecuteReader();
String[] astrelements = new String[10];
for (int i = 0; i < 10; ++i)
    astrelements[i] = "";
double[] avals = new double[5];
while (myReader.Read())
{
    astrelements[0] = myReader.GetString(0);
    avals[0] = 0.0;
    Boolean ok = gdxio.gdxdatawritestr(ap,astrelements,avals);
}
gdxio.gdxdatawritedone(ap);
myReader.Close();
//
// read a data table
//
gdxio.gdxdatawritestrstart(ap, "data", "from db", 2, csharpclient.dt_par, 0);
q = "select location, capacity, cost exporttable";
cmd = new SqlCommand(q, conn);
myReader = cmd.ExecuteReader();
while (myReader.Read())
{
    astrelements[0] = myReader.GetString(0);
    astrelements[1] = "capacity";
    avals[0] = myReader.GetInt32(1);
    Boolean ok = gdxio.gdxdatawritestr(ap, astrelements, avals);
    if (!myReader.IsDBNull(2)) {
        astrelements[1] = "cost";
        avals[0] = myReader.GetDouble(2);
        ok = gdxio.gdxdatawritestr(ap, astrelements, avals);
    }
}
gdxio.gdxdatawritedone(ap);
myReader.Close();
gdxio.gdxclose(ref ap);
```

Export to SQL Server

SQL Server has two basic facilities to import CSV files: the `BCP` tool and the `BULK INSERT` statement. Advanced SQL Server users may also be able to use DTS (Data Transformation Services) or linked ODBC data sources. Of course for small data sets we can create standard SQL INSERT statements. In addition the tool GDXVIEWER can be used to get GAMS data into SQL Server.

Export using the BCP tool

A transcript showing the use of BCP is shown below:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test;
2> create table x(loca varchar(10), locb varchar(10), shipment float);
3> go
Changed database context to 'test'.
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
seattle,new-york,50.00
seattle,chicago,300.00
```

```
seattle,topeka,0.00
san-diego,new-york,275.00
san-diego,chicago,0.00
san-diego,topeka,275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>bcp test..x in c:\winnt\gamsdir\results.csv \
  -S athlon\sqlexpress -c -U sa -P password -t,

Starting copy...

6 rows copied.
Network packet size (bytes): 4096
Clock Time (ms.) Total     : 10     Average : (600.00 rows per sec.)

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> select * from x;
3> go
Changed database context to 'test'.
loca       locb       shipment
---------- ---------- ------------------------
seattle    new-york                       50
seattle    chicago                       300
seattle    topeka                          0
san-diego  new-york                       275
san-diego  chicago                          0
san-diego  topeka                         275

(6 rows affected)
1> quit
```

Unfortunately, dealing with quoted strings is not straightforward with this tool (an example using a format file is shown in the next section on Data Exchange with Sybase). The same thing holds for `BULK INSERT`, which can read:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
seattle,new-york,50.00
seattle,chicago,300.00
seattle,topeka,0.00
san-diego,new-york,275.00
san-diego,chicago,0.00
san-diego,topeka,275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> create table x(loca varchar(10), locb varchar(10), shipment float)
3> go
Changed database context to 'test'.
1> bulk insert x from 'c:\winnt\gamsdir\results.csv' with (fieldterminator=',')
2> go

(6 rows affected)
1> select * from x
2> go
loca       locb       shipment
---------- ---------- ------------------------
seattle    new-york                       50
```

```
seattle    chicago                       300
seattle    topeka                          0
san-diego  new-york                      275
san-diego  chicago                         0
san-diego  topeka                        275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

Export using the ODBC Text Driver

A slower but flexible way to load CSV files is to use a linked server through the ODBC Text Driver. First create an ODBC DSN using the Text Driver. This can be done through the ODBC Data Source Administrator Data Sources (ODBC) Then we can use the system procedure SP_AddLinkedServer.

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>type c:\winnt\gamsdir\results.csv
"seattle","new-york",50.00
"seattle","chicago",300.00
"seattle","topeka",0.00
"san-diego","new-york",275.00
"san-diego","chicago",0.00
"san-diego","topeka",275.00

C:\Program Files\Microsoft SQL Server\90\Tools\binn>type trnsport.sql
--
--  test database
--
use test

--
-- create table in SQL server
--
create table results(loca varchar(10), locb varchar(10), ship float)
GO

--
-- Create a linked server
--
EXEC sp_addlinkedserver txtsrv,'Jet 4.0','Microsoft.Jet.OLEDB.4.0','c:\winnt\gamsdir',NULL,'Text'
GO

--
-- copy data from text file c:\winnt\gamsdir\results.csv
--
insert into results(loca,locb,ship)
select * from txtsrv...results#csv
go

--
-- check if all arrived
--
select * from results
go
```

```
--
-- release linked server
--
EXEC sp_dropserver txtsrv
GO

--
-- clean up
--
drop table results
go

C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> :r trnsport.sql
Changed database context to 'test'.

(6 rows affected)
loca       locb       ship
---------- ---------- -------------------------
seattle    new-york                       50
seattle    chicago                       300
seattle    topeka                          0
san-diego  new-york                       275
san-diego  chicago                          0
san-diego  topeka                         275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

A slightly different approach is the following:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\sqlexpress
1> create table t(loca varchar(10), locb varchar(10), ship float)
2> go
1> insert into t
2> select * from
3> OpenRowSet('Microsoft.Jet.OLEDB.4.0',
4> 'Text;Database=c:\winnt\gamsdir\;HDR=NO',
5> 'select * from results.csv')
6> go

(6 rows affected)
1> select * from t
2> go
loca       locb       ship
---------- ---------- -------------------------
seattle    new-york                       50
seattle    chicago                       300
seattle    topeka                          0
san-diego  new-york                       275
san-diego  chicago                          0
san-diego  topeka                         275

(6 rows affected)
1> drop table t
```

```
2> go
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

This can be automated from GAMS as follows:

```
file results /results.csv/;
results.pc=5;
put results;
loop((i,j),
     put i.tl, j.tl, x.l(i,j)/
);
putclose;

file sqlinsert /insert.sql/;
put sqlinsert;
put "use test"/;
put "insert into t select * from OpenRowSet('Microsoft.Jet.OLEDB.4.0',"
    "'Text;Database=c:\winnt\gamsdir\;HDR=NO','select * from results.csv')"/;
putclose;

execute '="C:\Progra~1\Microsoft SQL Server\90\Tools\binn\sqlcmd" -S athlon\SQLExpress -i insert.sql
```

Export using the GDXVIEWER

When using GDXVIEWER to export data to MS SQL server it is noted that MSSQL Server does not accept the default SQL type double for double precision numbers. You will need to set this setting to float or double precision.

When we export variable `x` from the trnsport model, we see:

```
C:\Program Files\Microsoft SQL Server\90\Tools\binn>sqlcmd -S athlon\SQLExpress
1> use test
2> go
Changed database context to 'test'.
1> select * from x
2> go
dim1                           dim2                           level
------------------------------ ------------------------------ -----------------------
seattle                        new-york                                            50
seattle                        chicago                                            300
seattle                        topeka                                               0
san-diego                      new-york                                           275
san-diego                      chicago                                              0
san-diego                      topeka                                             275

(6 rows affected)
1> quit

C:\Program Files\Microsoft SQL Server\90\Tools\binn>
```

4.18.3.6 Data Exchange with SQLite

See GDX2SQLITE for more information.

4.18.3.7 Data Exchange with Sybase

Import from Sybase

Import using the bcp utility

Sybase is largely the same as SQL Server. For exporting ASCII files from a Sybase table, the utility (Using the BCP utilty and CSV files) can be used.

An example of use of this utility is shown below:

```
[erwin@fedora sybase]$ isql -U sa -S LOCALHOST -D testdb -P sybase -J iso_1
1> select * from results
2> go
 loca       locb       shipment
 ---------- ---------- --------------------
 seattle    new-york             50.000000
 seattle    chicago             300.000000
 seattle    topeka                0.000000
 san-diego  new-york             275.000000
 san-diego  chicago                0.000000
 san-diego  topeka               275.000000

(6 rows affected)
1> quit
[erwin@fedora sybase]$ cat bcp.fmt
10.0
4
1       SYBCHAR 0       0       "\""    1       loca
2       SYBCHAR 0       10      "\",\"" 1       loca
3       SYBCHAR 0       10      "\","   2       locb
4       SYBCHAR 0       17      "\n"    3       shipment
[erwin@fedora sybase]$ bcp testdb..results out res.txt -S LOCALHOST  -U sa -P sybase \
  -J iso_1 -f bcp.fmt

Starting copy...

6 rows copied.
Clock Time (ms.): total = 1  Avg = 0 (6000.00 rows per sec.)
[erwin@fedora sybase]$ cat res.txt
"seattle","new-york",50.0
"seattle","chicago",300.0
"seattle","topeka",0.0
"san-diego","new-york",275.0
"san-diego","chicago",0.0
"san-diego","topeka",275.0
[erwin@fedora sybase]$
```

Note: the first column in the format file is a dummy (it has length 0). This is in order to write the leading quote, as bcp only allows for termination symbols.

This can be automated using the following GAMS code:

```
sets
  i   'canning plants'   / seattle, san-diego /
  j   'markets'          / new-york, chicago, topeka / ;

$onecho > bcp.fmt
10.0
4
1       SYBCHAR 0       0       "\""    1       loca
2       SYBCHAR 0       10      "\",\"" 1       loca
3       SYBCHAR 0       10      "\","   2       locb
4       SYBCHAR 0       17      "\n"    3       shipment
$offecho
$call "bcp testdb..results out res.txt -S LOCALHOST  -U sa -P sybase -J iso_1 -f bcp.fmt"
parameter d(i,j)  'distance in thousands of miles'
/
$ondelim
$include res.txt
$offdelim
/;
display d;
```

Import using the SQL2GMS utility

The SQL2GMS tool uses ADO or ActiveX Data Objects to extract data from relational databases. It can connect to almost any database from any vendor as it supports standards like ODBC. See documentation for more information.

Import using a 'SQL2GMS' VBS script

The following GAMS code will generate and execute a script written in VBScript. It mimics the behavior of SQL2GMS.EXE and can be used for debugging or the script can be passed on to the IT support people in case there are problems with accessing the database.

```
$ontext
   This script mimics SQL2GMS.
   Erwin Kalvelagen
   November 2006

4.19 Executing GAMS from other Environments

4.19.1 Some General Comments

Nowadays the objected-oriented APIs are the most efficient and elegant way to interact with the GAMS system. They allow the effective communication of data, and do parameterized runs of GAMS. This whole chapter describes a much more basic interaction of GAMS through calling the GAMS executable from different environments. This still can be useful, e.g. if no object-oriented API is available for the particular target language (e.g. VBA).

While the principle of calling the GAMS executable holds for all operating systems, this chapter often focuses on the Windows platform.

One of the interesting problems one faces when spawning GAMS.EXE in a Windows environment is multi-threading. If one does not take precautions, a call to Shell (VB function) or CreateProcess (Win32 API function) causes GAMS to run asynchronously: the function will return while GAMS is still running. In order to read the results one would need to wait until the GAMS job has finished. The machinery for this requires some Windows trickery, and for Visual Basic version 6 and Delphi version 4 we have implemented some small examples that illustrate how this can be done.

Another issue that needs to be addressed is that GAMS needs a place to put its scratch files. By default this is the current directory, a concept that is not always clear in a windowing environment. A good way of dealing with his is to set both the current drive and the current directory before running the GAMS job. It should be noted that GAMS needs write permission there. In the examples we use the Windows TEMP directory for this, but in a real application you may want to use a designated directory. The Windows TEMP directory is found by calling the API function GetTempPath.

4.19.1.1 The GAMS architecture

GAMS itself is a console mode application. In fact it is not a single program, but a driver program (GAMS.EXE on Windows, otherwise GAMS) that executes in turn the GAMS language compiler (GAMSCMEX) or one of the solvers. For a model with a single solve statement, GAMS.EXE will first call GAMSCMEX to compile the GAMS model. Then GAMSCMEX will start executing the internal code that was generated by the compiler. As soon as it hits the instructions belonging to a SOLVE statement it will generate model instance, and GAMSCMEX will exit. Then GAMS.EXE will spawn a solver capable of solving the model. As soon as the solver is finished, GAMS.EXE will execute GAMSCMEX again so it can read the solution and can continue with executing instructions.

4.19.2 Spawning GAMS from VBA

Visual Basic for Applications (VBA) is a programming language that is built into most Microsoft Office applications, e.g. Excel and Access. A VBA program may include modules, which can be imported from files, i.e. in the VBA editor you can choose menu "File"→"Import File". The GAMS distribution includes some VBA modules, which can be found from:

```
<GAMS System Directory>\apifiles\VBA\api, e.g. "C:\GAMS\win64\24.5\apifiles\VBA\api"
```

Attention

- In order to avoid issues, it's recommended to use the latest version of the modules , i.e. the modules found in the latest GAMS release.

For example, the following modules can be found:

- gamsglobals.bas: Global constants that are used in other modules
- gdxvba.bas: GAMS Data Exchange Object
- idxvba.bas: GAMS IDX Object
- optvba.bas: GAMS Option Object

  For more information, see Expert-Level APIs. VBA programs that use the API can be found from:

  ```
  <GAMS System Directory>\apifiles\VBA, e.g. "C:\GAMS\win64\24.5\apifiles\VBA"
  ```

  The models can also be retrieved via GAMS Studio -> GAMS --> Model Library Explorer -> GAMS Data Utilities Models.

4.19.2.1 Spawning GAMS from Excel

Calling GAMS out of Excel requires some more work than just Data Exchange with Microsoft Excel. The application calling GAMS out of Excel has to:

1. Locate the GAMS system directory and adjust the system path accordingly.
2. Copy the GAMS model into a temporary directory (by default the temporary directory of Windows)
3. Extract the model data from the spreadsheet into a GAMS readable format (gdx)
4. Execute GAMS (solve the model, write the slution back to gdx file)
5. Import the model results back from the gdx files into the spread sheet
6. Update the spreadsheet (graphics, tables)

Using VisualBasic for Applications (VBA) this can be implemented with a few lines of code:

```
Sub solve()
   Dim WorkDir As String
   WorkDir = TempDir()
   Call ClearSolution
   If (Not AddGAMSPath()) Then ' needed to find gdxcclib64.dll and gams.exe
      Exit Sub
   End If
   Call ExportGDXFile(WorkDir)
   Call WriteGAMSModel(WorkDir & "portfolio.gms")
   Call RunGAMS(WorkDir & "portfolio.gms", WorkDir)
   Call ReadListing(WorkDir & "portfolio.lst")
   Call ImportGDXFile(WorkDir)
End Sub
```

For further details, please inspecte the VBA part of the examples below.

4.19.2.2 A Simple Example

This very simple example shows how GAMS can be invoked from an Excel spreadsheet. The "example spreadsheet" has a button, which will cause GAMS to run the trnsport.gms model stored in c:/tmp. There is no data exchange.

A more complete application will write an include file for a GAMS model, and will import a comma delimited file with results when the run is finished. An example of such a complete application is described in http://www.gams.com/mccarl/excelgams.pdf.

4.19.2.3 Sudoku Example

This spreadsheet is a complete example that uses GDX files to exchange information solves a 25x25 Sudoku problem using CPLEX. It comes with the GAMS distribution in *apifiles/VBA/sudoku.xlsm*. You will need a GAMS/CPLEX license to be able to run the spreadsheet. The MIP model solves very easily: the solution is found in the presolve phase.

Note: This spreadsheet requires distribution 22.6 or younger to work properly.

Problem

Solution

4.19.2.4 Efficient frontier example

This example solves a series of NLPs to create an efficient frontier of a portfolio optimization problem. It comes with the GAMS distribution in *apifiles/VBA/portfolio.xlsm*.

Note: This spreadsheet requires distribution 22.6 or younger to work properly.

4.19.3 Spawning GAMS from C

The example below shows an absolute minimal version of calling GAMS from a C program:

```
#include <stdio.h>

int main(int argc, char** argv)
{
   system("gams trnsport lo=2");
   return 0;
}
```

As can be seen the GAMS executable gams.exe is called via a simple invocation of system(). The extra command line parameter `lo=2` indicates that the log file is not written to the screen (this is the default) but to a file `model.log`.

If we want to generate some data from the application program (e.g. parameter `DEMAND`), we can use an include file which is written by the application. Of the way back results can be read from a PUT file. The GAMS file can now look like:

```
Sets
       i   canning plants   / seattle, san-diego /
       j   markets          / new-york, chicago, topeka / ;

  Parameters

       a(i)  capacity of plant i in cases
         /    seattle     350
              san-diego   600  /

       b(j)  demand at market j in cases
         /
$include demand.inc
         / ;

  Table d(i,j)  distance in thousands of miles
                    new-york       chicago      topeka
      seattle          2.5           1.7          1.8
      san-diego        2.5           1.8          1.4  ;

  Scalar f  freight in dollars per case per thousand miles  /90/ ;

  Parameter c(i,j)  transport cost in thousands of dollars per case ;

            c(i,j) = f * d(i,j) / 1000 ;

  Variables
       x(i,j)  shipment quantities in cases
       z       total transportation costs in thousands of dollars ;

  Positive Variable x ;

  Equations
       cost        define objective function
       supply(i)   observe supply limit at plant i
       demand(j)   satisfy demand at market j ;

  cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;

  supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;
```

```
  demand(j) ..   sum(i, x(i,j))  =g=  b(j) ;

  Model transport /all/ ;

  Solve transport using lp minimizing z ;

  Display x.l, x.m ;

file fout /results.txt/;
put fout;
loop((i,j),
   put x.l(i,j):17:5/;
);
putclose;
```

The corresponding C program could look like:

```
//
// example of running a GAMS model
//
#include <stdio.h>
// number of supply and demand locations
#define M 2
#define N 3
char*  dist[M] = {"seattle", "san-diego" };
char*  city[N] = {"new-york","chicago", "topeka" };
double demand[N] = { 325.0, 300.0, 275.0 };
double ship[M][N];
int main(int argc, char** argv)
{
   FILE *f;
   int i,j;
   //
   // write include file
   //
   f = fopen("demand.inc","wt");
   if (f == NULL) {
      perror("fopen");
      exit(1);
   }
   for (i=0; i<N; ++i)
       fprintf(f,"%s %g\n",city[i],demand[i]);
   fclose(f);
   //
   // call GAMS
   //
   system("gams trnsport lo=2");
   //
   // read solution
   //
   f = fopen("results.txt","rt");
   if (f == NULL) {
      perror("fopen");
      exit(1);
   }
   for (i=0; i<M; ++i)
      for (j=0; j<N; ++j)
          fscanf(f,"%lg",&(ship[i][j]));
   fclose(f);
   //
   // display results
   //
   for (i=0; i<M; ++i)
      for (j=0; j<N; ++j)
          printf("%s->%s %g\n",dist[i],city[j],ship[i][j]);
   return 0;
}
```

4.19.4 Spawning GAMS from Visual Basic

This example shows how GAMS can be invoked from a VB program.

When executed a simple window appears where a GAMS model can be specified and possible other command line options. The [GAMS] button will execute the model.

When the Normal display is used, a console window will be opened. This console window will be closed automatically at the end of the run if the Close process window on completion check box is checked.

Minimized does not show a window, but in the taskbar an icon will appear. If the job takes a long time, the user can click on this icon to make the console window visible. The Hidden option prevents any GAMS associated window or icon to appear.

Note: it is required for this program to work, that the GAMS system directory is in the path. If this is not the case, an error code of -1 is returned.

The main program is attached below.

```
Attribute VB_Name = "vbGAMS"
Option Explicit
' ------------------------------
' Module Name: VBGams
' File:  gams.bas
' Version: 1.1
'
'
' Functions:
'   VB_Gams32   - sets up process directory, parameter file, and console, and manages
'                 looping of gams compiler and solver.
'
' --------
' Function VB_Gams32
'   Sets up process directory, parameter file, and console, and manages
'   looping of gams compiler and solver.
'
' Parameters
'   sParams       String      Command line arguments
'   nDisplayMode  Integer     GAMS_NORMAL, GAMS_MIN, or GAMS_HIDDEN
'   bCloseWin     Boolean     Close the console on completion of gams job
'
' Returns
'   1000 missing input string
'   2000 16 bit spawn failed
'   -or-
'   nCmexRC + 100 * nVB_GamsRC
'
'   nCmexRC : return code from last run of GAMS compile/execute module
'             (for DOS/Win XX)
'         0 : normal return

begin
   FreeConsole();
   CloseConsoleButton.Enabled := false;
end;
end.
```

4.19.6 Spawning GAMS from Visual C++

In "this example" we call GAMS from a simple Visual C++ application.

The additional concern is here that we want to intercept the GAMS screen output so it can be written to a multi-line edit control. For more information about the used technique see the Microsoft publication: [HOWTO: Spawn Console Processes with Redirected Standard Handles (Q190351)] (https://support.microsoft.com/en-us/kb/190351) in the Microsoft Knowledge Base.

4.19.7 Spawning GAMS from C#

Below is a simple example:

```
using System.Diagnostics;
void RunGamsModel()
{
    Process p = new Process();
    p.StartInfo.FileName = gamsexe;
    p.StartInfo.WorkingDirectory = tempdir;
    p.StartInfo.Arguments = "\"" + modelname + "\" LO=0 --runid="+runid;
    p.Start();
    p.WaitForExit();
}
```

The command line formed here is `gams modelname LO=0 --runid=xxx`. The option `LO` (logoption) will disable writing a log, and the option `--runid` passes a parameter to the GAMS model (inside the model you can access this through `%runid%`).

4.19.8 Spawning GAMS from Java

Java has a class *Runtime* that implements spawning of processes using the Exec() method. This is quite trivial to use in applications, but in applets the default security settings don't allow this operation (in general). The problem can be solved by loading the applet from a local drive or by using a signed applet. Similarly if the Java classes are loaded from inside a database, this operation may require additional privileges. For an example see the previous section, where GAMS is called from Oracle using a Java Stored Procedure. The relevant code may look like:

```
import java.io.File;
class RunGAMS {
        public static void main(String[] args) {
                System.out.println("Start");
```

```
                String[] cmdArray = new String[5];
                cmdArray[0] = "<PATH/TO/GAMS>" + File.separator + "gams";
                cmdArray[1] = "<PATH>" + File.separator + "trnsport.gms";
                cmdArray[2] = "WDIR=<PATH>" + File.separator + "TMP";
                cmdArray[3] = "SCRDIR=<PATH>" + File.separator + "TMP";
                cmdArray[4] = "LO=2";
                try {
                        Process p = Runtime.getRuntime().exec(cmdArray);
                        p.waitFor();
                }
                catch (java.io.IOException e )
                {
                        System.err.println(">>>>" + e.getMessage() );
                        e.printStackTrace();
                }
                catch (InterruptedException e )
                {
                        System.err.println(">>>>" + e.getMessage() );
                        e.printStackTrace();
                }
                System.out.println("Done");
        }
}
```

Below another example, which avoids problems, if the model has a long screen log (the buffer gets filled and locks the execution), which could happen if GAMS does not write the log to the file like above. This example is based on suggestion made by Edson Valle.

```
import java.io.File;
import java.io.BufferedReader;
import java.io.InputStreamReader;
class RunGAMS {
      public static void main(String[] args) {
              System.out.println("Start");
              String[] cmdArray = new String[5];
              cmdArray[0] = "<PATH/TO/GAMS>" + File.separator + "gams.exe";
              cmdArray[1] = "<PATH>" + File.separator + "trnsport.gms";
              cmdArray[2] = "<PATH>" + File.separator + "tmp";
              cmdArray[3] = "LO=3";
              try {
                      Process p = Runtime.getRuntime().exec(cmdArray);
                      BufferedReader stdInput = new BufferedReader(new InputStreamReader(p.getInputStream()));
                      String s = null;
                      while((s=stdInput.readLine()) !=null){
                         System.out.println(s);
                      }
                      p.waitFor();
              }
              catch (java.io.IOException e )
              {
                      System.err.println(">>>>" + e.getMessage() );
                      e.printStackTrace();
              }
              catch (InterruptedException e )
              {
                      System.err.println(">>>>" + e.getMessage() );
                      e.printStackTrace();
              }
              System.out.println("Done");
      }
}
```

For an example of GAMS usage from a Java based server environment see Alexander Sokolov, Information environment and architecture of decision support system for nutrient reduction in the Baltic Sea, Department of Systems Ecology, Stockholm University.

4.19.9 Spawning GAMS from a Web Server

Running GAMS remotely using a Web based thin-client architecture requires that GAMS is executed directly or indirectly from the Web server or HTTP server. A simple way of doing this is via a CGI process. Common Gateway Interface (CGI) programs can be written in many languages such as C, Perl or Delphi. CGI is relatively slow, as for each interaction, even the most simple one, a process needs to be started. Alternatives exist in the form of CGI extensions such as FastCGI or using DLLs or shared libraries. A basic algorithm for a CGI script could be:

- Create a unique directory, and CD to that directory.

- Get information from user forms and save it as GAMS readable files.
- Run GAMS making sure it does not write the log to the screen (i.e. use the option LO=2 (log to a file) or LO=3 (log to stdout)).
- Let the model write solution info to text files using the PUT statement.
- Read solution, and create formatted HTML to send back to the user.
- Remove temp files and directory.

Complications arise when there is a need to show graphics (files need to be stored somewhere and discarded after a while), when jobs take a long time to finish (you will need to add a facility where the user can pick up results at a later moment) or when the server resources can be exhausted (e.g. because of a large number of simultaneous users or because of large models).

An important complicating issue in the above list are jobs that take more time to finish: web servers like to respond to the user within a short time, and time out errors will occur if a job takes a long time. The solution is to use a queue based approach. An actual implementation available is the NEOS Server - there is also a GAMS interface to NEOS: KESTREL - Remote Solver Execution on NEOS Servers.

4.19.10 Spawning GAMS from PHP

A minimal example

index.html

```
<html>
  <body>
    <form action="calling_gams.php" method="post">
      Solve transport with f = <select name="f">
          <option>70</option>
          <option>80</option>
          <option>90</option>
          <option>100</option>
        </select>
      <input type="submit" value="call GAMS"/>
    </form>
  </body>
</html>
```

calling_gams.php

```
<?php
$f = $_POST['f'];
//some model data
$modelfile = 'trnsport_php.gms';
$city   = array('new-york','chicago', 'topeka');
$demand = array(325.0, 300.0, 275.0);
//write demand.inc
$fh = fopen('./demand.inc', 'w+');
for($i=0; $i<count($city); $i++){
  fwrite($fh, $city[$i]." ".$demand[$i]."\n");
}
fclose($fh);
//write f.inc
$fh = fopen('./f.inc', 'w+');
fwrite($fh, $f);
fclose($fh);
//call gams
system('</path/to/gams>/gams '.$modelfile.' lo=2');
//read solutions
$fh = fopen('./results.txt', 'r');
echo '<p><b>result of '.$modelfile.' (f='.$f.') :</b></p>';
while (!feof($fh)){
   $line = fgets($fh);
   echo '<p>'.$line.'</p>';
}
fclose($fh);
?>
```

trnsport_php.gms

```
Sets
       i   canning plants   / seattle, san-diego /
       j   markets          / new-york, chicago, topeka / ;

  Parameters

       a(i)  capacity of plant i in cases
         /    seattle     350
              san-diego   600  /

       b(j)  demand at market j in cases
         /
$include demand.inc
         / ;

  Table d(i,j)  distance in thousands of miles
                    new-york       chicago      topeka
      seattle          2.5           1.7          1.8
      san-diego        2.5           1.8          1.4  ;

  Scalar f  freight in dollars per case per thousand miles  /
$include f.inc
         / ;

  Parameter c(i,j)  transport cost in thousands of dollars per case ;

            c(i,j) = f * d(i,j) / 1000 ;

  Variables
       x(i,j)  shipment quantities in cases
       z       total transportation costs in thousands of dollars ;

  Positive Variable x ;

  Equations
       cost        define objective function
       supply(i)   observe supply limit at plant i
       demand(j)   satisfy demand at market j ;

  cost ..        z  =e=  sum((i,j), c(i,j)*x(i,j)) ;

  supply(i) ..   sum(j, x(i,j))  =l=  a(i) ;

    put i.tl:0 '->' j.tl:0 ':  ' x.l(i,j)/;
  );
  put 'cost: 'z.l/;
```

```
putclose;
```

4.20 Using GAMS Studio

This tutorial on using GAMS Studio was written initially by and is distributed by courtesy of Bruce A. McCarl [2] . Bruce has extensive experience with GAMS, both as a modeler and an educator, and many GAMS users know, use, and benefit from his work. This tutorial presents a guided tour to the usage of GAMS Studio and on some items it reflects Bruce's personal view and preferences.

4.20.1 What Is It?

A multi platform (not only PCs with Windows) graphical interface to run GAMS

GAMS uses two phases.

1. Text edit

   First, one uses a **text editor** and creates a file which contains GAMS instructions.

2. File submission

   Second, one **submits that file** to GAMS which executes those instructions causing calculations to be done, solvers to be used and a solution file of the execution results to be created.

Approaches to use GAMS.

1. More batch oriented traditional method use a text editor set up the model then use **DOS (or UNIX)** command line instructions to find errors in and run the model.

2. GAMS STUDIO or GAMS IDE alternatives. Graphical interfaces to create, debug, text edit and run GAMS files.

[2] Specialist in Applied Optimization, Distinguished Professor of Agricultural Economics, Texas A&M University, Principal, McCarl and Associates, mccarl[at]tamu.edu, brucemccarl[at]gmail.com, http://agecon2.tamu.edu/people/faculty/mccarl-bruce/

Summary of steps to using

1. Install GAMS and STUDIO on your computer

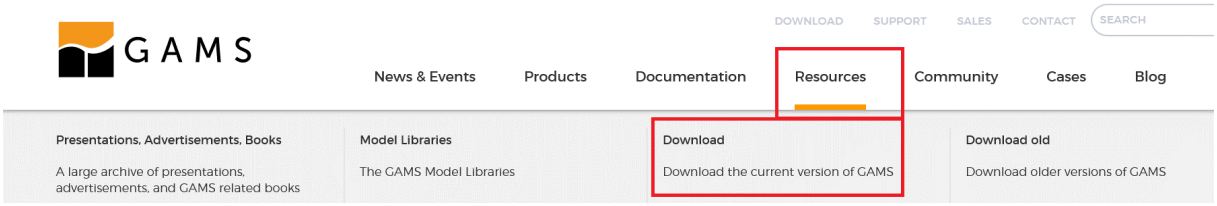
2. Open STUDIO through the icon
3. Open or create a file by going to the file selection in the upper left corner.
4. Prepare the file so you think it is ready for execution
5. Run the file with GAMS by clicking the run button or pressing F9
6. Open and navigate around the output

4.20.2 Installation

Install GAMS and STUDIO

GAMS STUDIO is **automatically installed** when GAMS is installed and you get the **choice of whether to use STUDIO or the IDE as primary editor**. To install do the following steps

1. Download the GAMS installation file from `www.gams.com` under `Resources and Download`

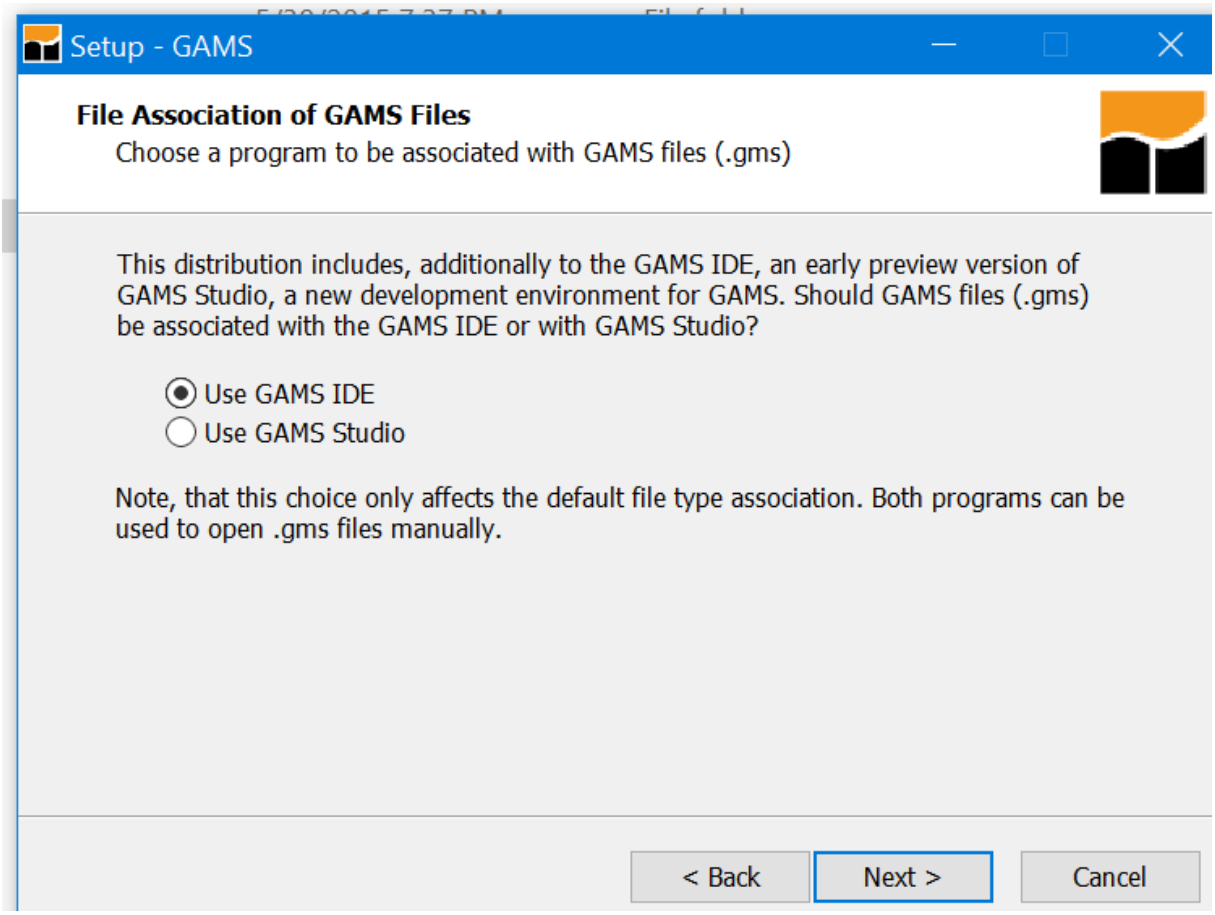


2. Start the installation

Installer should place an icon on the desktop yielding

4.20.3 Using STUDIO after Installation

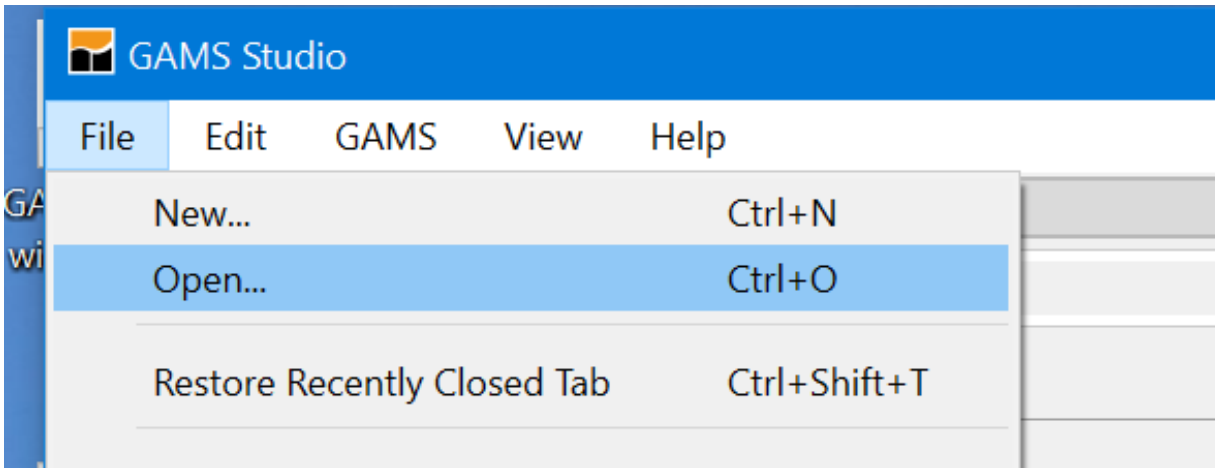
During the install you will find



Which allows you to choose which graphical interface to use as the default. For now choose STUDIO.

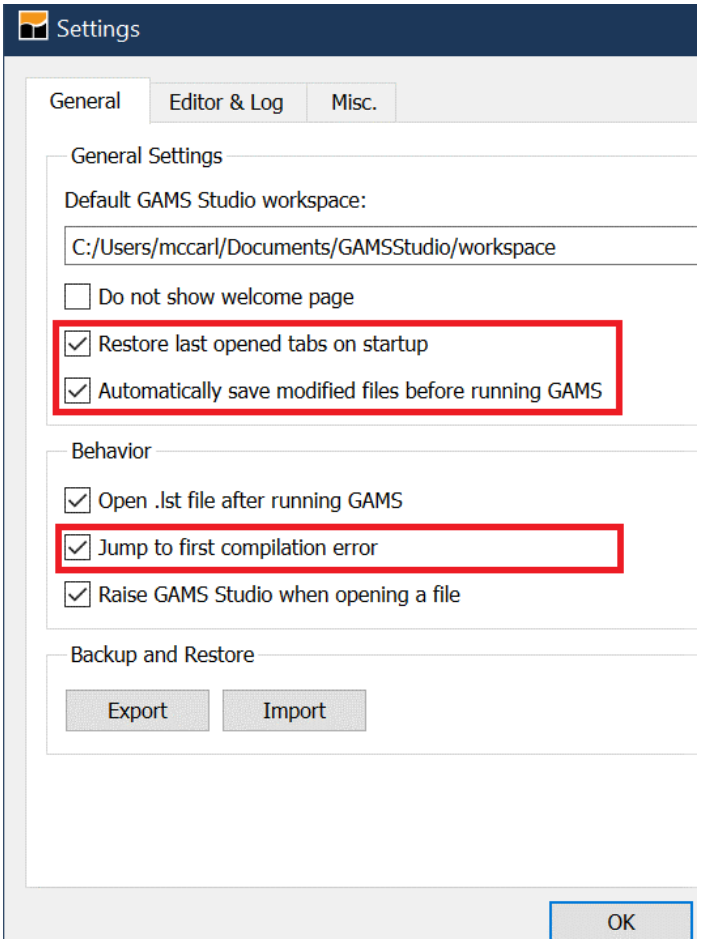
Open STUDIO through the icon

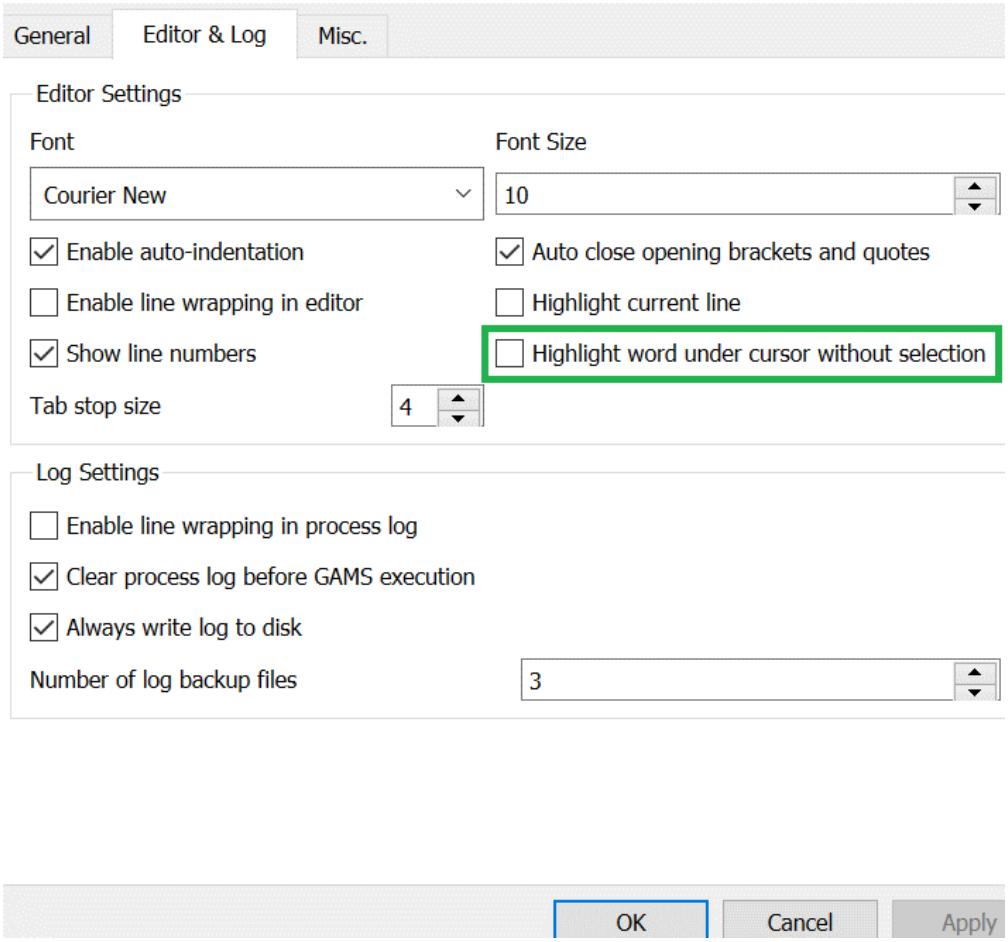
Open the File menu choice. Select a file.



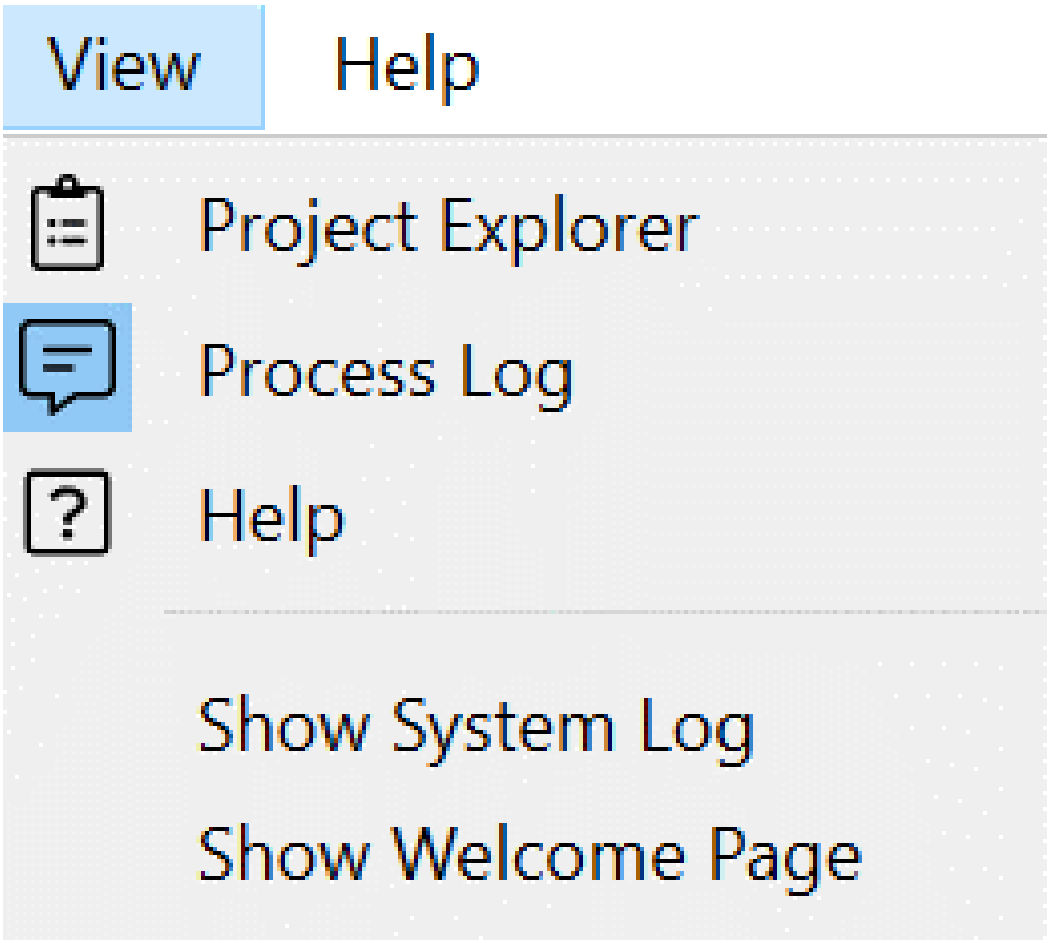
Note, the file location determines where all generated files are placed (to place files elsewhere use the save as dialogue) and where GAMS looks for files when executing. *I recommend that you make sure your file is in a place where you want it also making sure that place contains all associated files ie this is the file storage directory for this endeavor.*

Fix defaults and suppress cursor driven object highlighting. When first opening Studio go to settings and I would make sure check marks are as follows especially the checked ones in the red boxes and the unchecked green one





Here selecting the **Process Log** and possibly the **Explorer** are of interest.



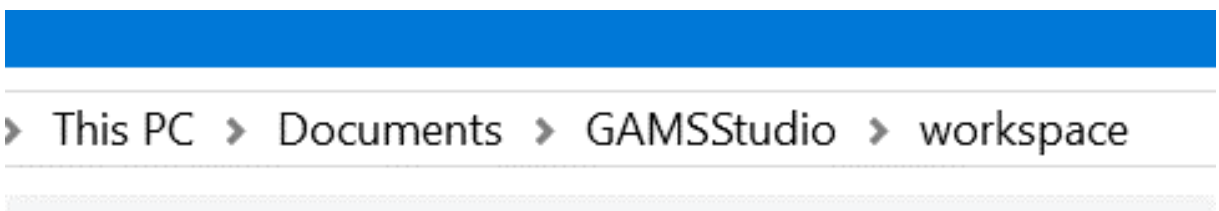
The Explorer will open automatically when a file is opened and the **Process Log** will open when a solve is done. I usually hide the Explorer and sometimes want to get rid of the Process window.

4.20.3.1 Getting Started

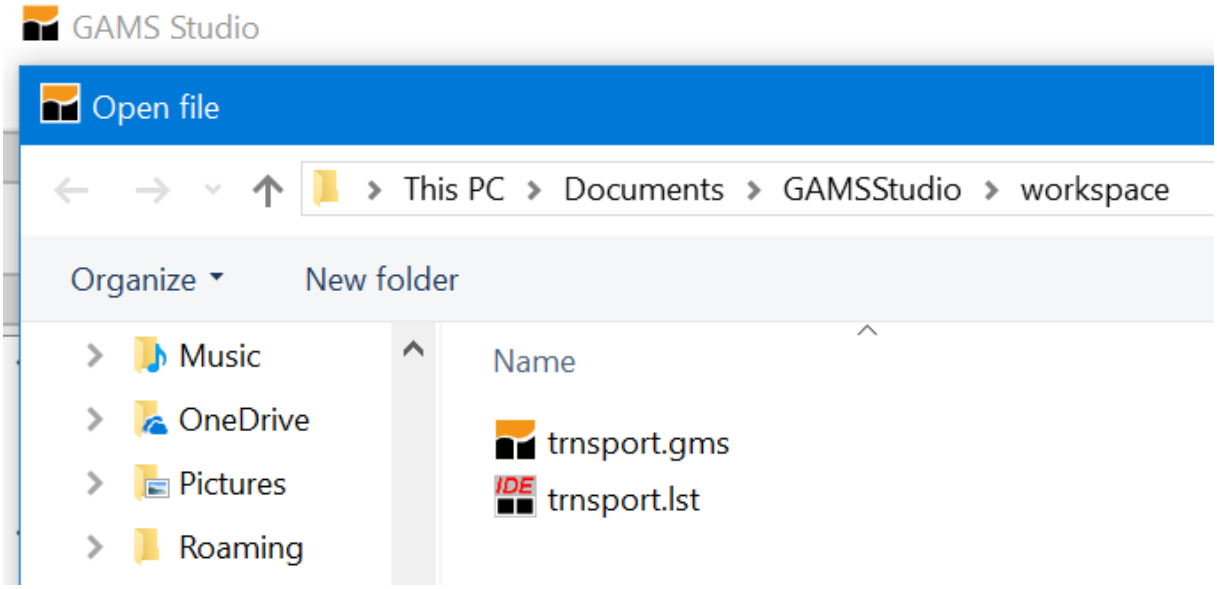
Create or open an existing GMS file

Several cases are possible

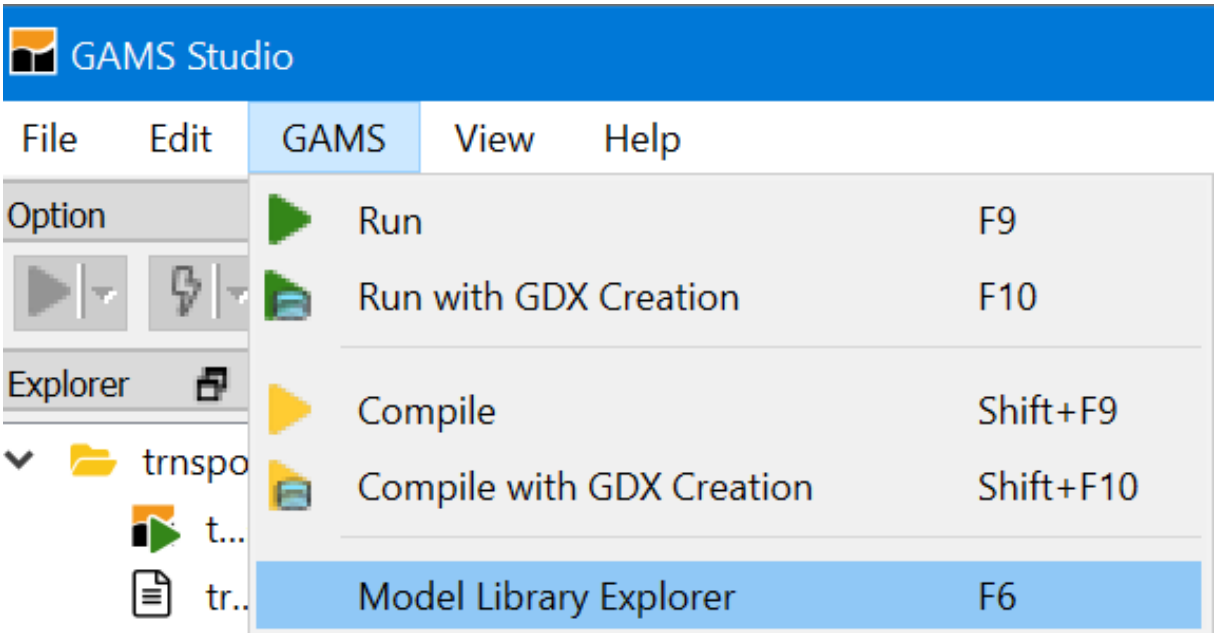
1. Create a new file (covered later)
2. Open an existing file – at first this will be in



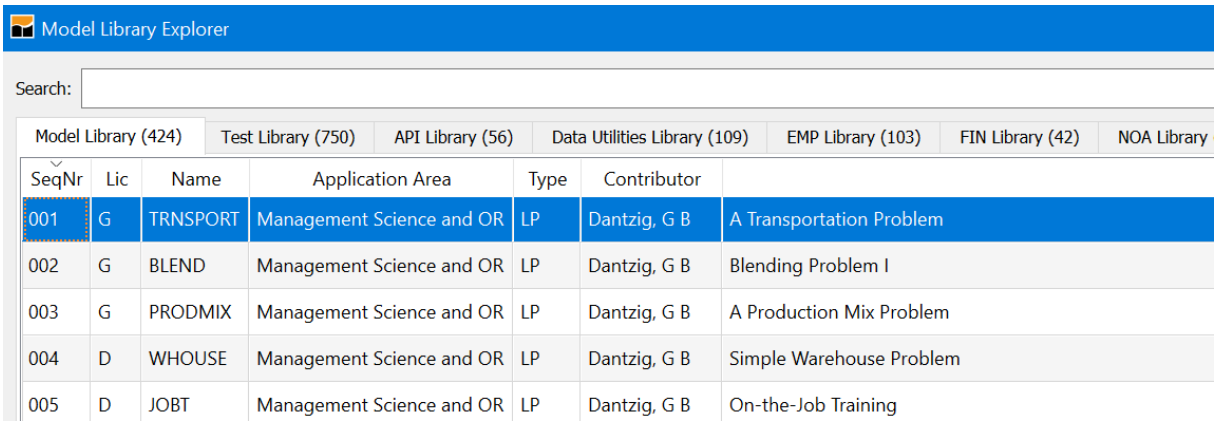
then you see something like



3. Open the GAMS model library explorer under the GAMS tab or press F6 (this is the simplest for first time users and the one we will use)



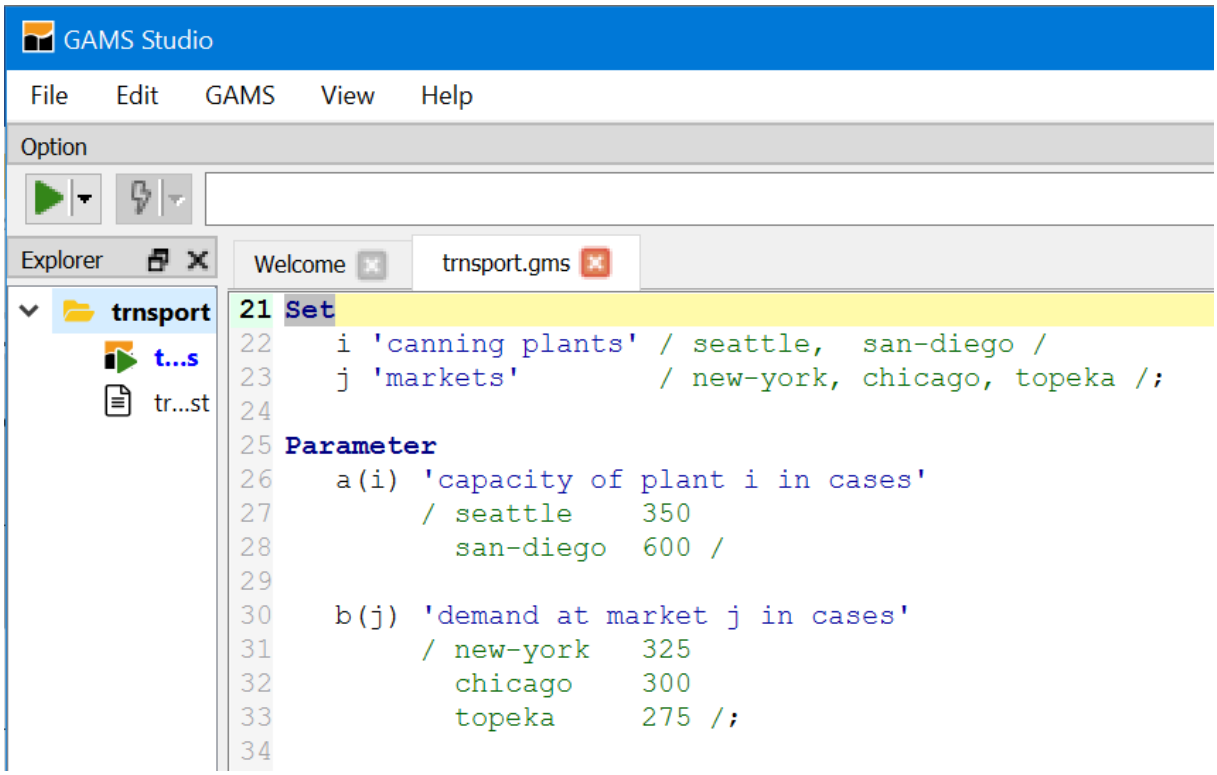
Select a model like *trnsport.gms*



It will be automatically saved in the last directory you used or in the STUDIO default Workspace directory.

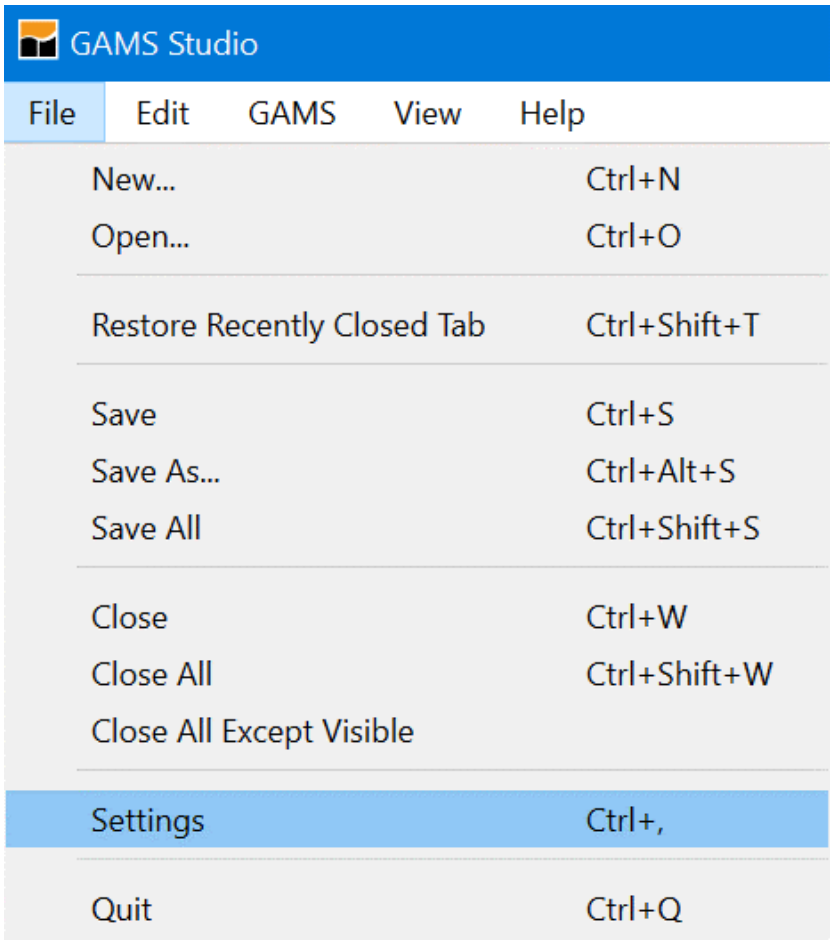
Prepare file for execution

When using model library *trnsport.gms* should now appear as part of your STUDIO screen.



The STUDIO contains a full-featured editor. Go through the file and change what you want.

You can also customize the appearance somewhat through the settings choice under the File menu.

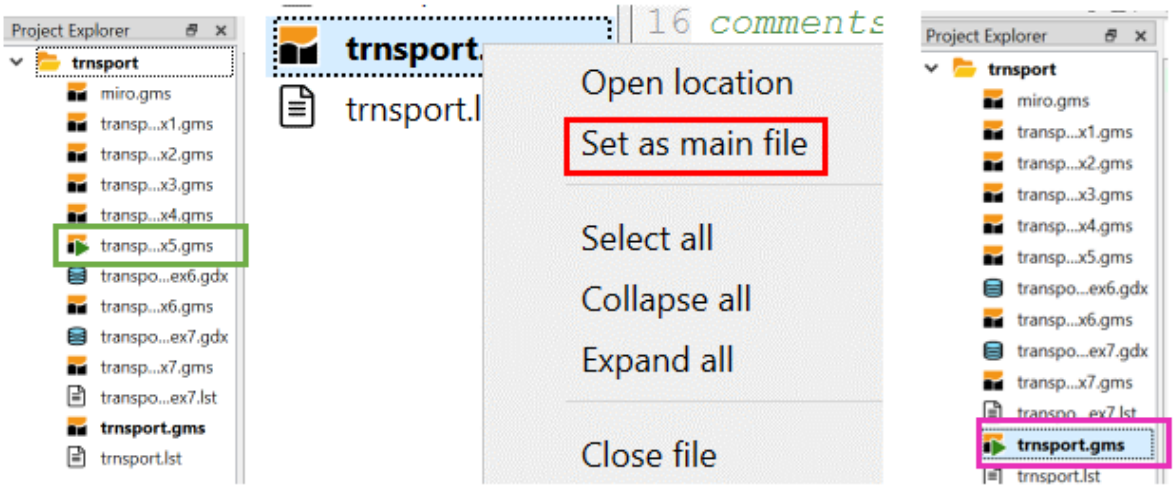


There you can change font size (under editor), tabs, default file location (called workspace) and some other features on how GAMS runs. For now leave it alone.

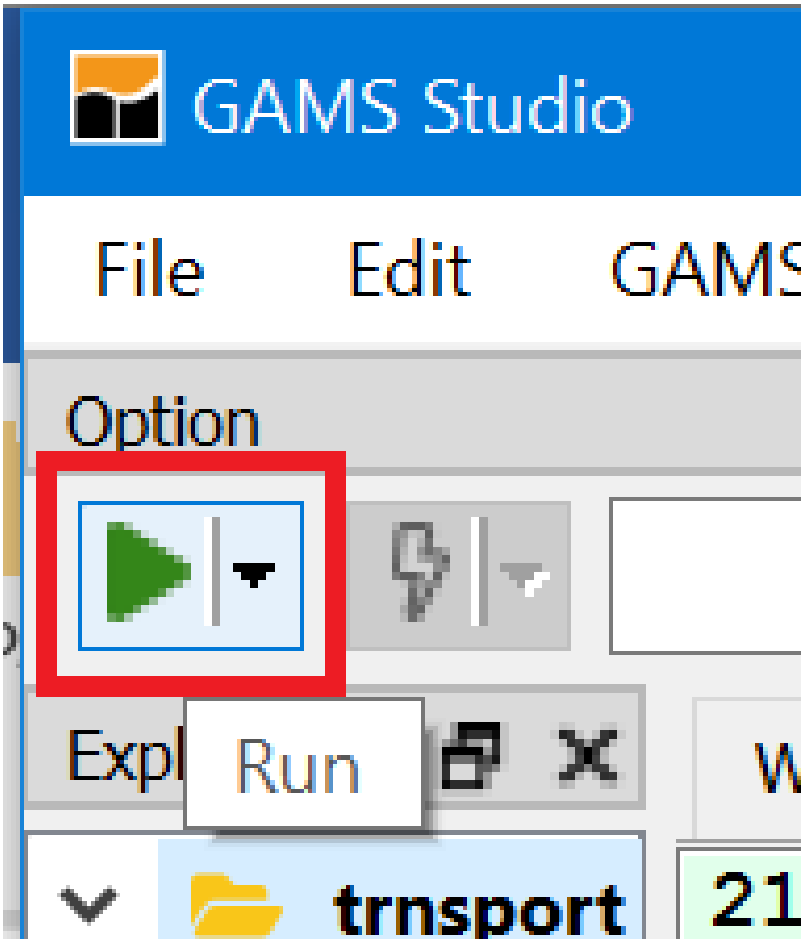
Make sure right file is executed

Unlike a lot of other programs, STUDIO does not necessarily execute the file you have been working on rather executing what it calls the "main" file.

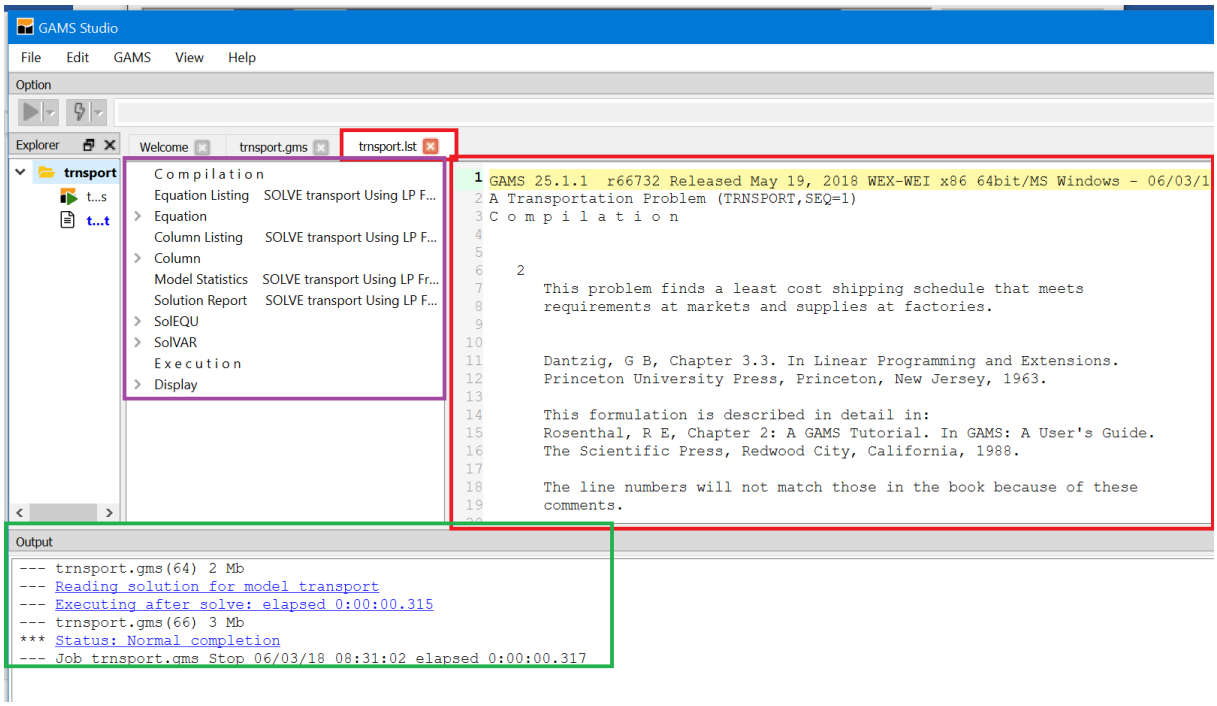
In particular, if you activate the explorer view then the main file is the one marked with a **green triangle** as below. If the triangle is not marking the file to be run you need to right click on that file and then choose **Set as main file**. In turn the triangle will move.



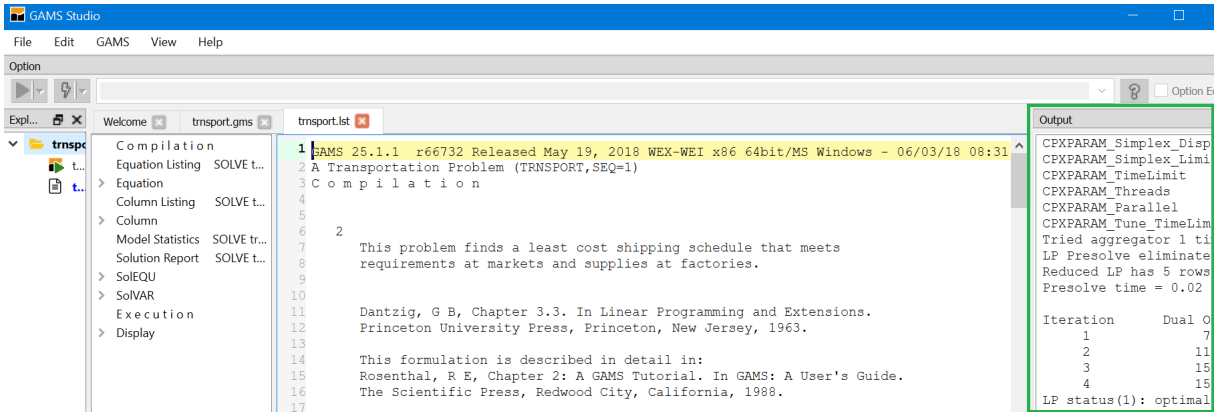
Run GAMS by clicking the run button



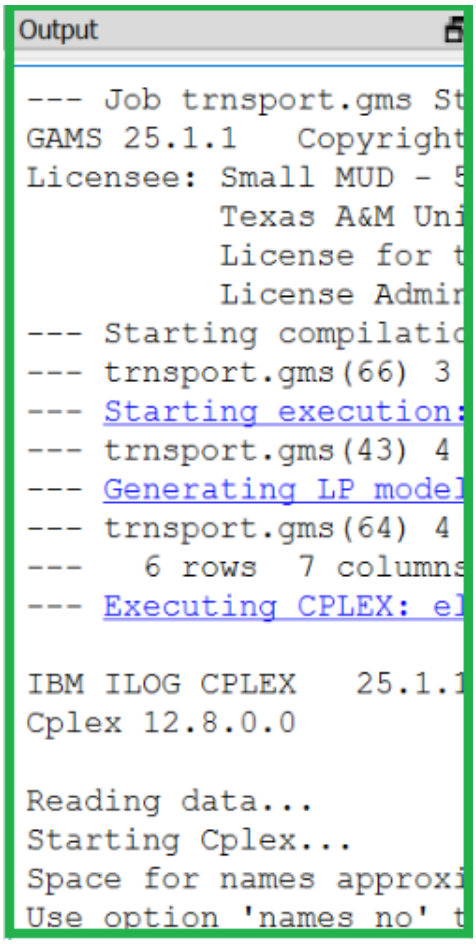
The **Process Log** window (green) will then appear which logs the steps executed in running the model. The **LST file** (red) and the **navigation window** (magenta) also appear. Note to save space I would close the Explorer window and drag the **Process Log** window (green) to the bottom or the right hand side. The process window on the bottom is illustrated here and it is on the right side on the following picture.



Here it is after reconfiguring by dragging the *Process Log* up and to the right then resizing and repositioning.



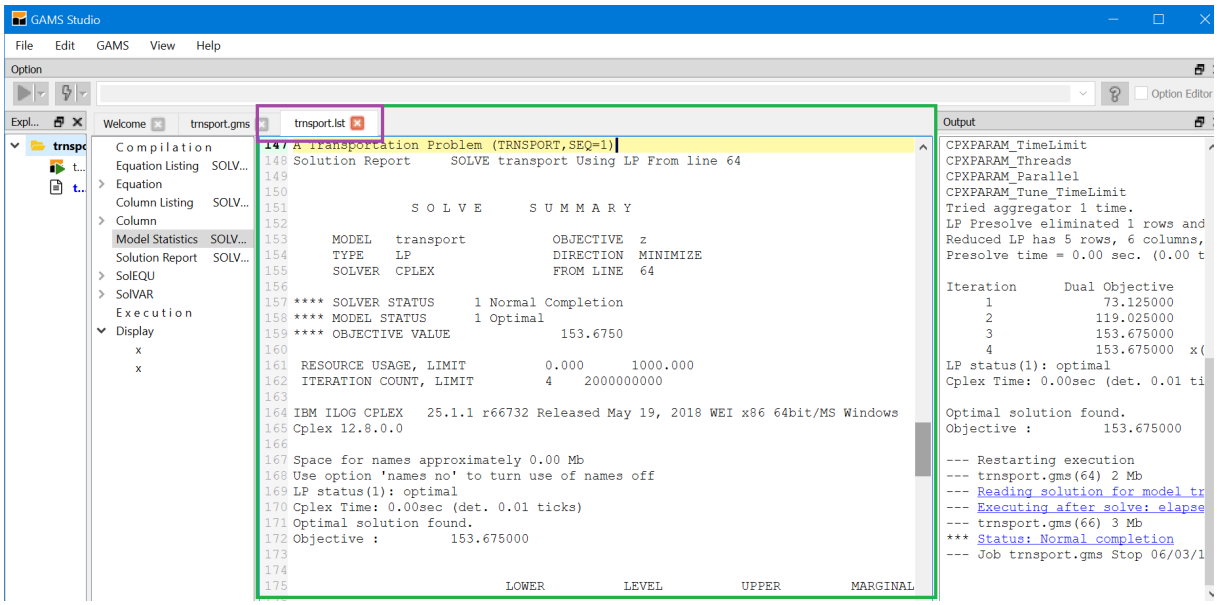
Now use the *process window* (green) to navigate the LST file or open created files. By double clicking on lines in that window you access the LST file at particular locations or open created files. What and where you access is determined by the color of the line you click on.



Color of Line	Function and Destination When Double Clicked
Blue line	Opens LST file and jumps to corresponding place.
Non-bolded black line	Control click on this takes you to LST file. Double click on error message takes you to spot in LST file.
Red line	Marks errors encountered. Cursor is positioned at first red line. When clicked on cursor jumps to Source (GMS) file location of error. Control click takes you to error location in LST file. Error description text is in execution process log and in LST file. You can use a little red icon in source to jump to error message in LST file or a green arrow in the LST to go to error location in source.
Green line	Causes studio to open a file that was created during the run like a GDX, PUT or REF file

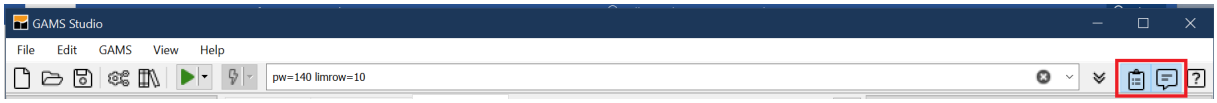
Navigate with process window

After double-clicking on any non-red line, or if we used the automatically open list file option our main editing window is augmented by the **LST file** (green) (see the magenta tabs)



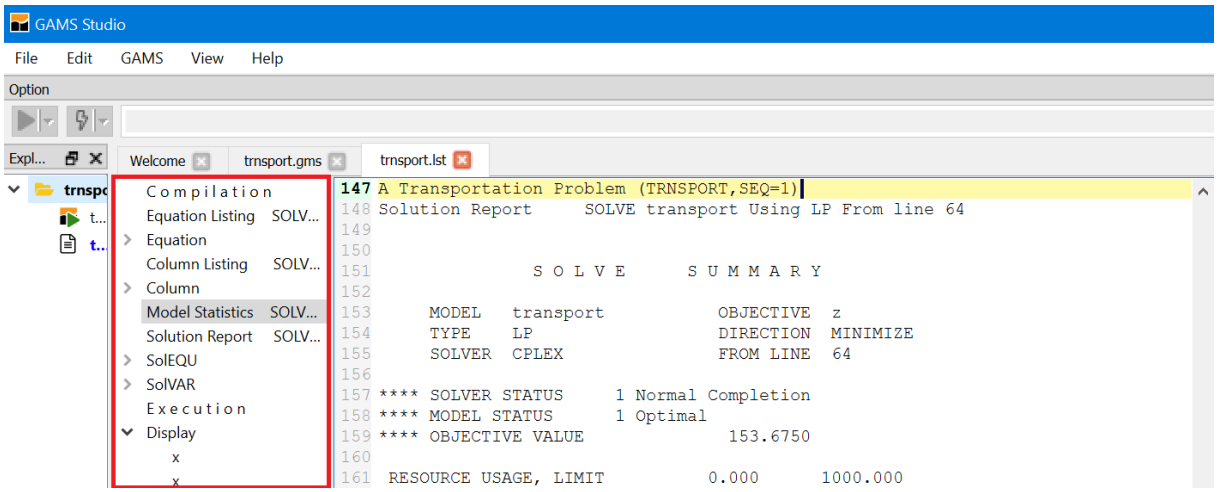
We can navigate as we would with an editor or word processor, as we are automatically in STUDIO text editor.

Sometimes I want to get the process window and explorer out of the way. I can do this through the view window and also through the **icons** (red) on the right side of the top bar



Clicking on these opens and closes the explorer and the process window.

Navigate with LXI window



Navig. Line	Function and Destination When Clicked.
Compilation	Jumps to top of echo print in LST file
Error Mess.	Jumps to list of error messages when errors present

Navig. Line	Function and Destination When Clicked.
Equat. listing	Jumps to list of equation contents
Equation	Expandable allowing jump list of equation contents
Variab. listing	Jumps to list of variable
Variable	Expandable allowing jump to list of variable contents
Model stat.	Jumps to model statistics part of LST file
Solut.Report	Jumps to model summary solution report
SolEQU	Expandable allowing jump solution for each equation
SolVAR	Expandable allowing jump to solution for variable
Execution	Jumps to beginning of post solve execution
Display	Jump to displays of specific parameters and other items

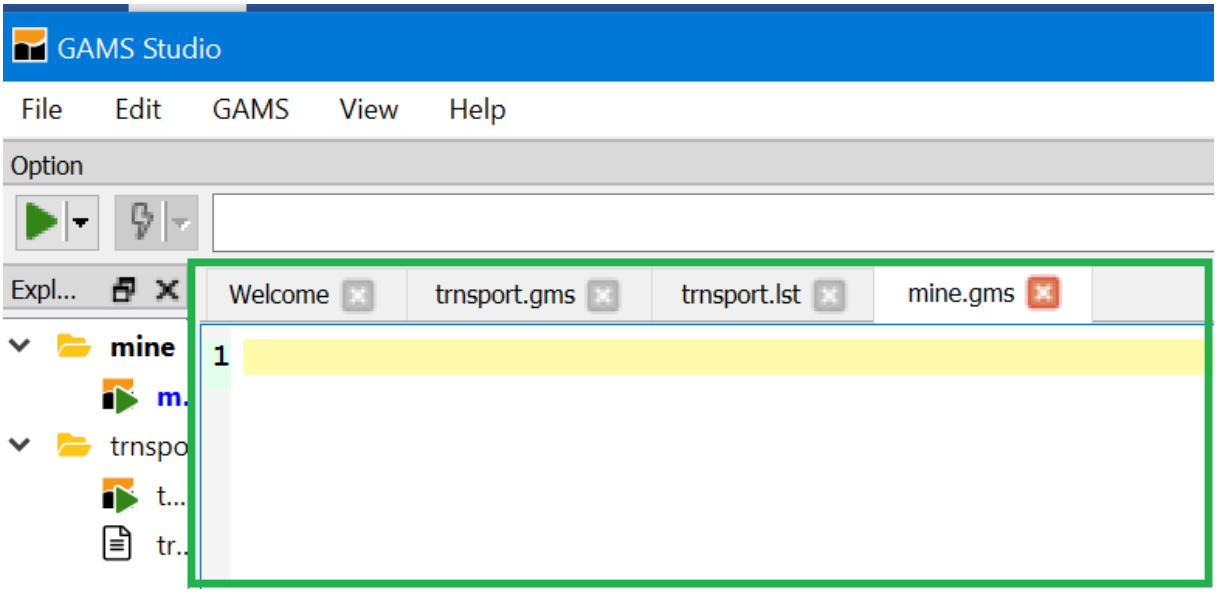
4.20.3.2 Working with your own files

Now you are ready to work with your own files. You may already have a file or you may need to create one.

Creating a new file - Two principal ways

1. Open an existing file through the library or from a location on your hard disk. Then use the **save as** dialogue from the **file** menu to change its name. Now modify contents to what you want. You may cut and paste as in other Windows programs.

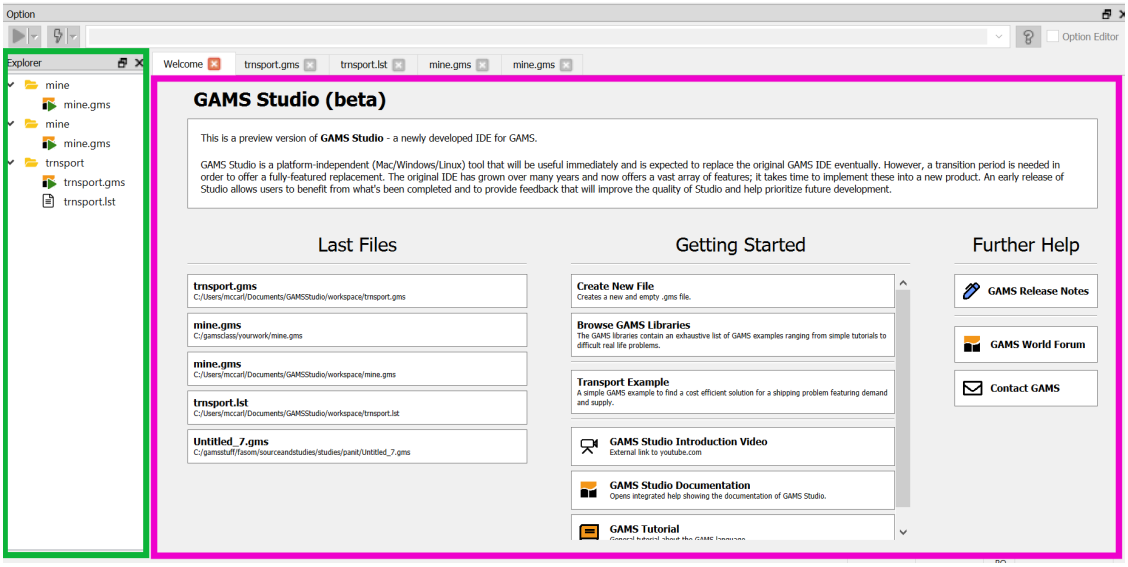
2. Open the **file** menu and use the **new** option. You will then be prompted for a name (I called it mine) with the extension .gms and then have a *blank screen* (green) into which you may type GAMS instructions



Save that file wherever you want and reopen it that will become the new default directory (**this only occurs upon an open not a save as**) and any subsequent non library opens, simple includes or saves will go there. Imports from the library go to the default workspace.

4.20.4 The Welcome and Explorer Windows

As you have worked with STUDIO you will find it shows a **Welcome** (magenta) window (*unless you told it not to in settings*), that remembers previous files plus gives access to documentation.



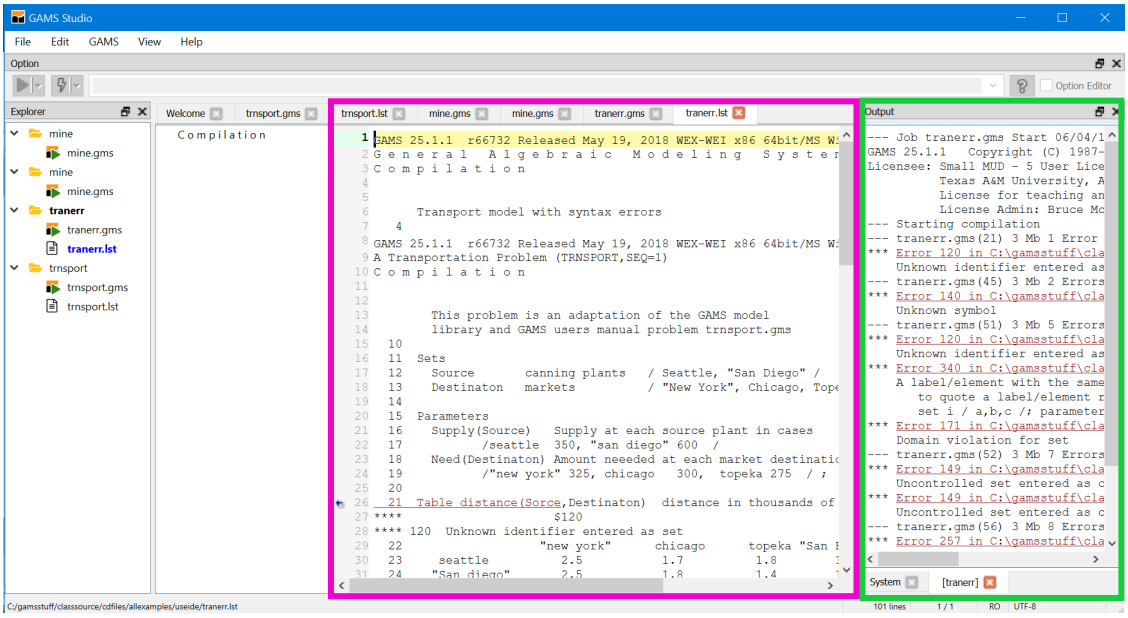
There as of now you get links to files recently used, and links to some documentation.

Also on the left hand side is an **Explorer** (green) window that shows recent files and allows you to open by double clicking. This remains whether you are in the welcome page or editing files unless it is not checked in the View dialogue.

4.20.5 Fixing Compilation Errors

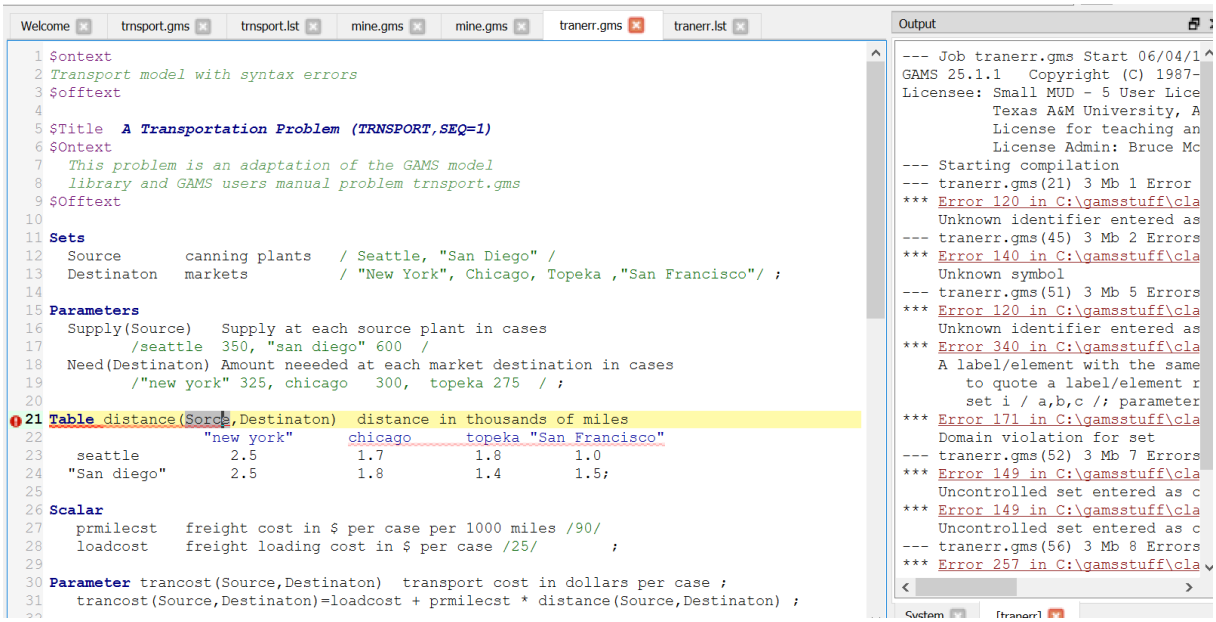
No one is perfect, errors always occur. The STUDIO can help you in finding and fixing those errors.

Let's look at an example with a small typo to illustrate (note: `source` vs. `sorce`). A run yields the windows below where the right part is the **process window** (green) positioned to show the first error and the center is the **lst file** (magenta) positioned to show the first error.



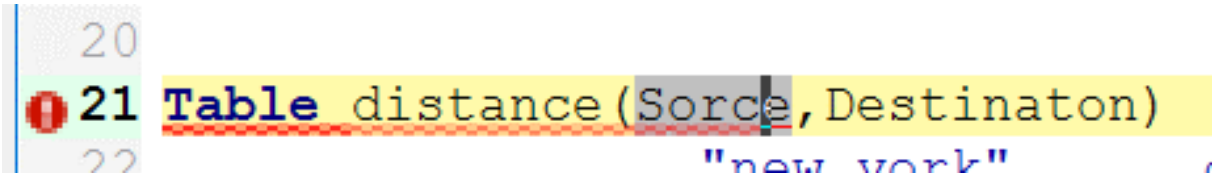
The red lines in the process window mark errors with error messages just below. To see where the errors occurred click on the very first red line which opens the source file or look at the LST file where the marking $ appears

A click on the red line **takes you to the place in the source where the error was made**. The tip here is **always start at the top of the process file when doing this**.

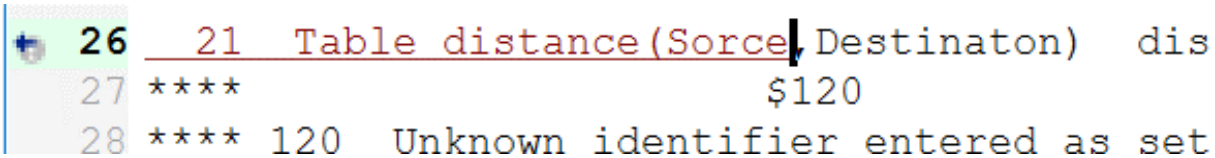


A double click on a black line takes you to the error location in the LST file.

Also in the source file window note the small red circle that appears on the line with the error



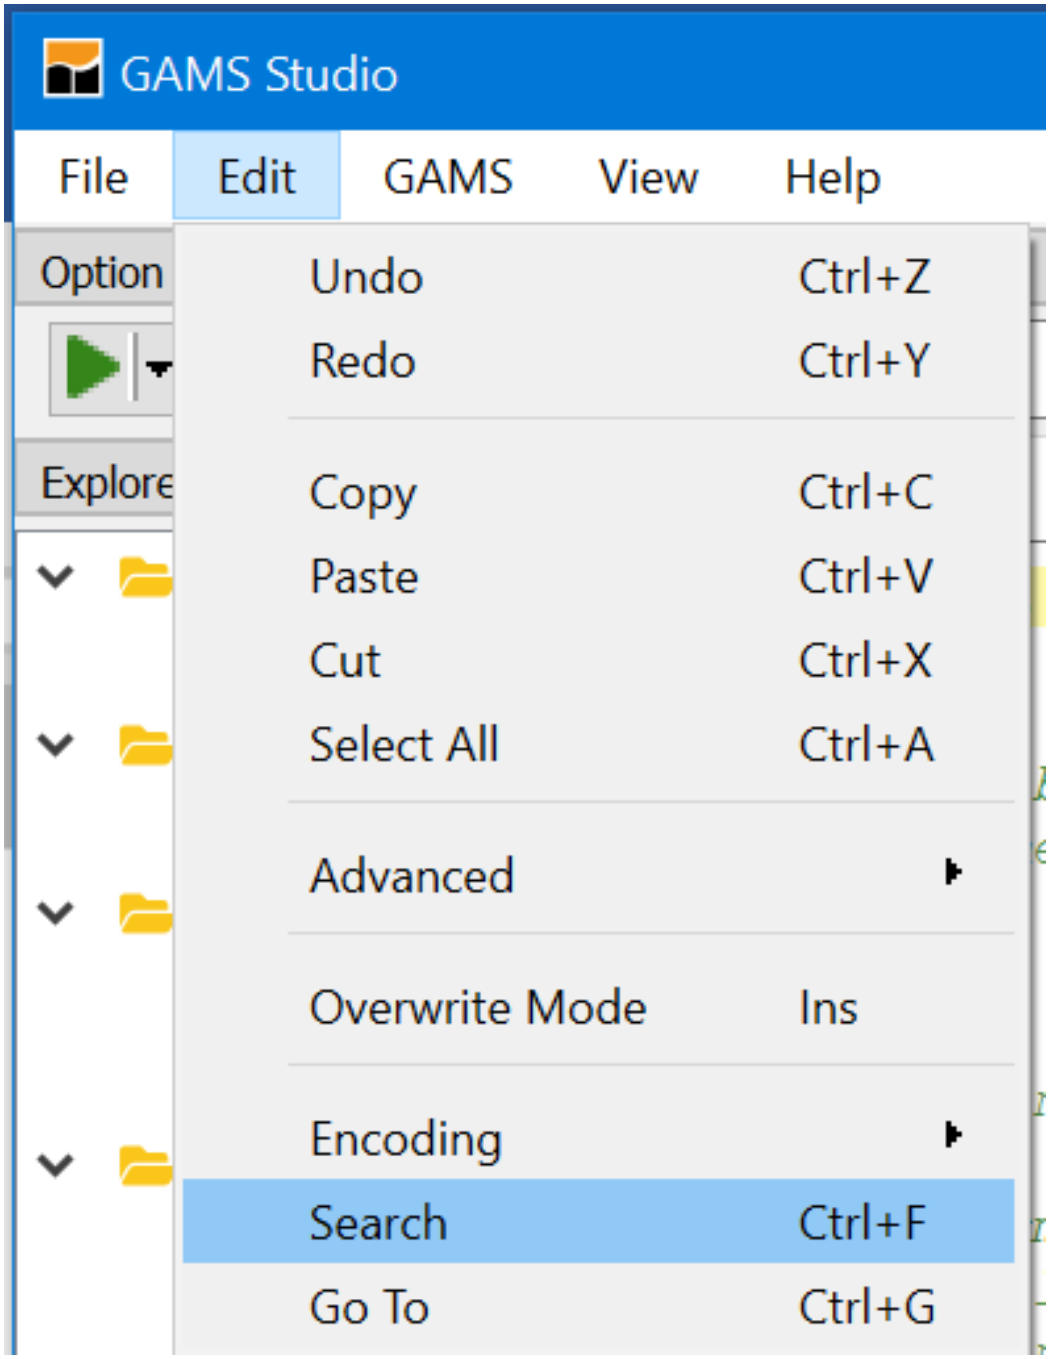
Clicking on that transfers you to the LST file where the error message appears.



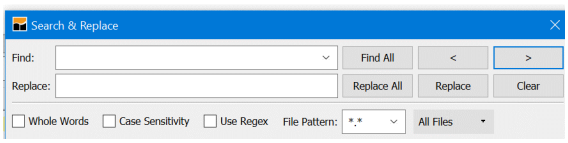
And there a small gray circle with an arrow in it that when clicked on will transfer you back to the source file

4.20.6 Ways to find and/or replace text strings

For finding you can use the search menu under the Edit tab or control F

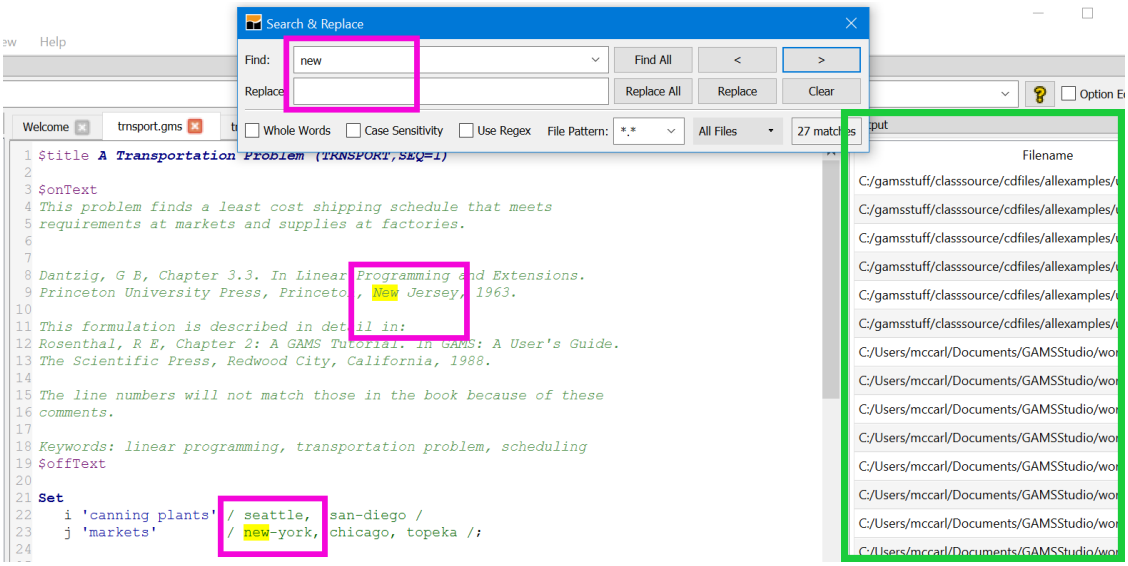


Subsequently you get



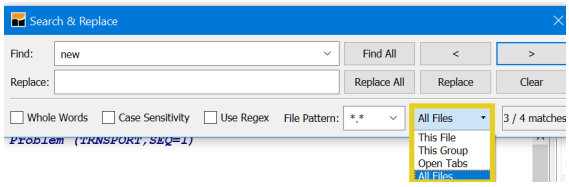
Which allows both search and replace. As of now this opens with the last option you used and may start with initially with an all files setting.

After the search you find



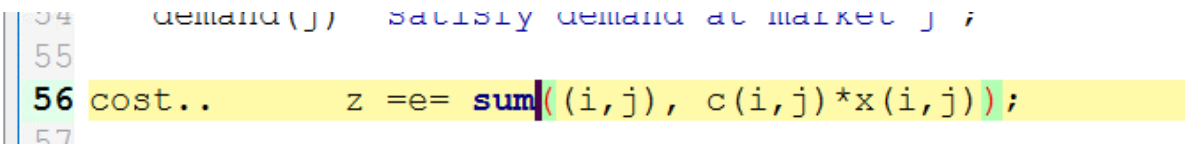
Where all occurrences of the **search term** in the current file are highlighted in yellow and to the right there is a **list of all files that contain that search term** (green) in all of the **directories corresponding to files opened in the explorer**.

The search dialogue is straight forward with arrow keys to jump to next (F3 also works for forward and shift F3 for backward) and the **all files can be manipulated as shown** (in yellow).

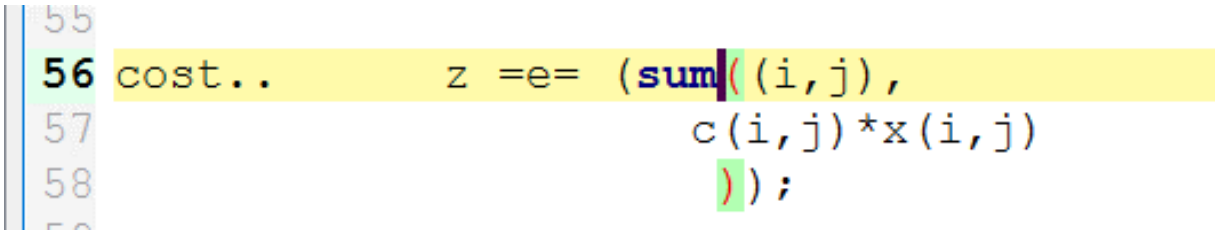


4.20.7 Matching Parentheses

The STUDIO provides you with a way of checking on how the **parentheses match up** in your GAMS code. This involves positioning your cursor just before an open parentheses or just after a close (Just after also works if there are not multiple parentheses). In either case the corresponding close or open is highlighted in **green**. Additionally positioning the cursor right before the beginning parentheses and tapping `Ctrl + b` will lead you to the matching ending parentheses whether it be 1, 100, or 1000+ lines away and vice versa.



When the expression in parentheses carries on the several lines the marking is in multiple lines and `Ctrl + b` will transfer position back and forth

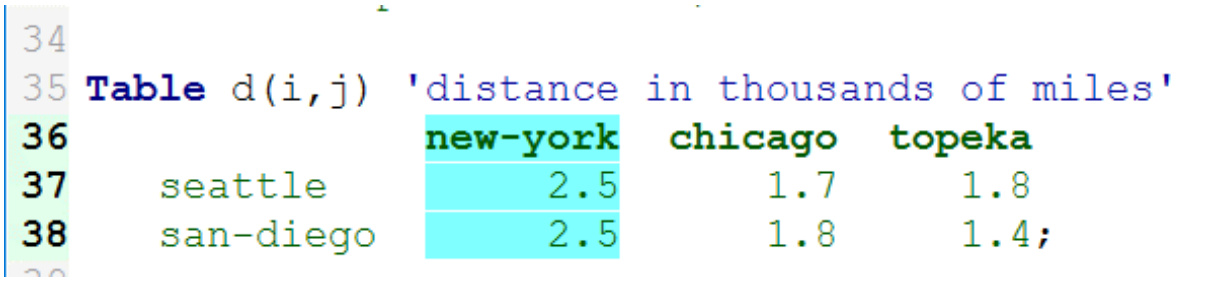


This feature will also match up { } or `[ ]` with a red marking if the types don't match.

4.20.8 Moving Blocks

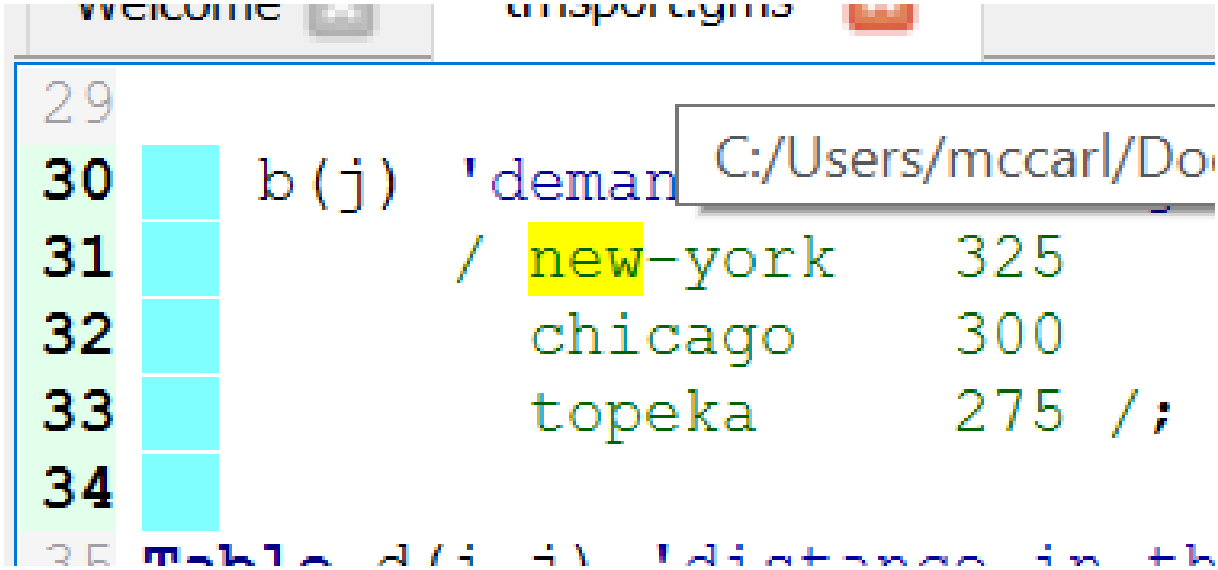
The STUDIO allows one to move text blocks through standard Cut and Paste Operations in two fashions.

1. One can identify a continuous block of text with the mouse or the keyboard (the latter involves putting the cursor at a beginning point then hold the shift key down and use the arrow keys).
2. One can identify a **column block of text** (blue) with the mouse or the keyboard (these involve holding **alt and shift down** then moving the mouse or the cursor with the arrow keys.



In turn copy, cut, and paste can be done with the Edit menu or with control c, x and v respectively as in normal windows. Control insert also pastes.

Also if one types with a column block highlighted than the character goes in all rows of the block and replaces what was there before



with an * typed becomes

```
29
30 *  b(j) 'demand at market j in cases'
31 *       / new-york    325
32 *         chicago     300
33 *         topeka      275 /;
34 *
```

4.20.9 Syntax Coloring

A feature in the STUDIO is syntax coloring. The STUDIO recognizes a subset of the GAMS syntax and reflects this in the display colors. Note in the display below that commands, explanatory text and set elements are differentially colored.

```
25 Parameter
26    a(i) 'capacity of plant i in cases'
27         / seattle    350
28           san-diego  600 /
29
30  b(j) 'demand at market j in cases'
31       / new-york   325
32         chicago    300
33         topeka     275 /;
34
35 Table d(i,j) 'distance in thousands of miles'
36                new-york  chicago  topeka
37    seattle          2.5      1.7     1.8
38    san-diego        2.5      1.8     1.4;
39
40 Scalar f 'freight in dollars per case per thousand miles' / 90 /;
41
42 Parameter c(i,j) 'transport cost in thousands of dollars per case';
43 c(i,j) = f*d(i,j)/1000;
44
45 Variable
46    x(i,j) 'shipment quantities in cases'
47    z      'total transportation costs in thousands of dollars';
48
49 Positive Variable x;
50
51 Equation
52    cost      'define objective function'
53    supply(i) 'observe supply limit at plant i'
54    demand(j) 'satisfy demand at market j';
55
56 cost..      z =e= [sum((i,j),
```

For now unlike in the IDE one cannot alter these syntax colors.

4.20.10 Showing where a symbol appears

Studio has a feature that identifies where a symbol is used. Taking the library file *agreste.gms* and positioning the cursor over a symbol like **c** (blue) then double clicking places a (gray) highlight over all visible instances of that symbol

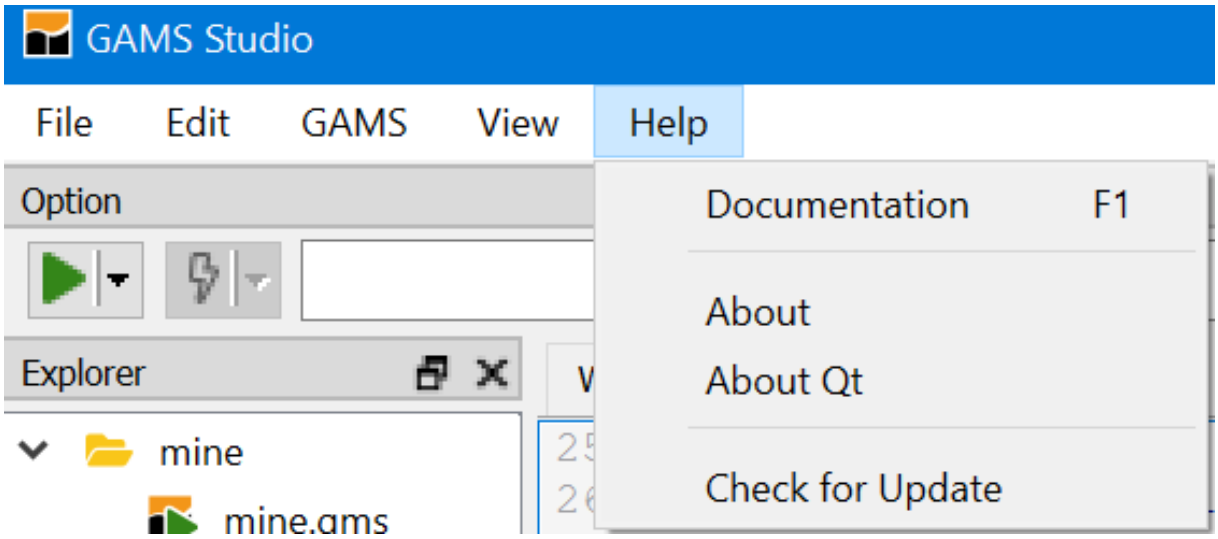
```
$sTitle Model Definition
Variable
   xcrop(p,s) 'cropping activities                                (ha)'
   xliver(r)  'livestock activity defined on feed techniques (head)'
   xlive      'livestock production                            (head)'
   lswitch(s) 'land downgrading                                  (ha)'
   xprod(c)   'crop production                                  (ton)'
   cons(dr)   'on-farm consumption                              (ton)'
   sales(c)   'crop sales                                       (ton)'
   flab(tm)   'family labor                                (man-days)'
   tlab(tm)   'temporary labor                             (man-days)'
   plab       'permanent labor                              (workers)'
   rationr    'livestock ration requirements                     (cr)'
   pdev(ty)   'positive price deviations                         (cr)'
   ndev(ty)   'negative price deviations                         (cr)'
   yfarm      'farm income                                       (cr)'
   revenue    'from crop and livestock sales                     (cr)'
   cropcost   'accounting: cropping activities cost              (cr)'
   labcost    'accounting: labor costs - including family        (cr)'
   vetcost    'accounting: veterinary services cost              (cr)';

Positive Variable xcrop, xliver, lswitch, sales, cons, flab, tlab, plab,

Equation
   landb(s) 'land balance'
   lbal     'livestock balance                          ( )'
   rliv     'livestock ration requirements definition ( )'
   mbalc(c) 'material balance: crops                    ( )'
   dprod(c) 'crop production definition                 ( )'
   cond     'on farm consumption definition             ( )'
   labc(tm) 'labor supply-demand relation               ( )'
   ddev(ty) 'crop price deviation definition            ( )'
```

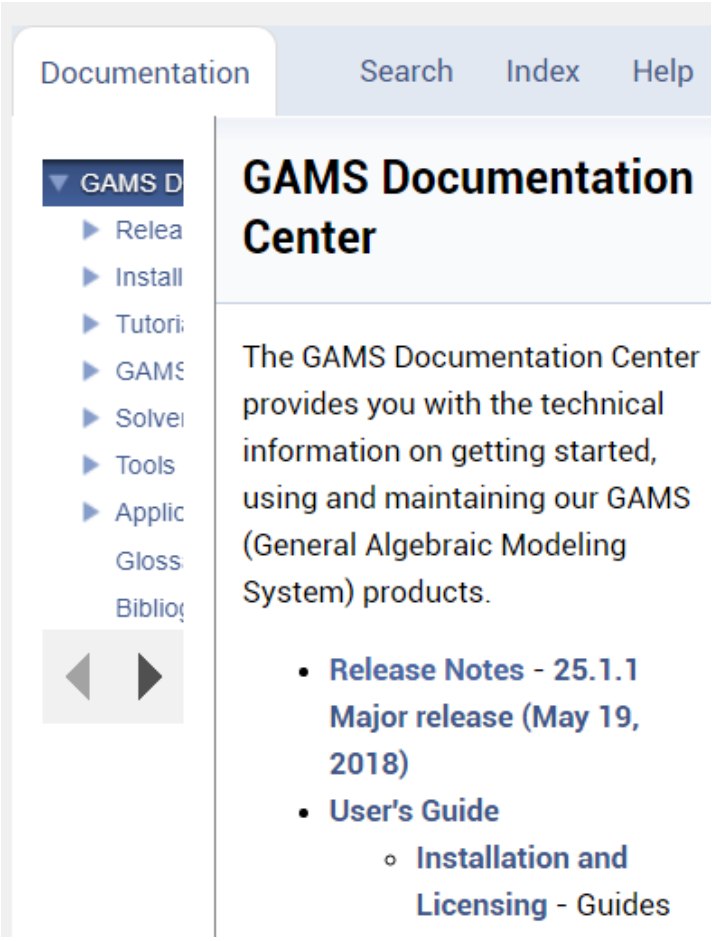
4.20.11 Accessing Documentation Via the Help

To access GAMS documentation choose help or F1



And if you choose documentation you get access through a window in lower right corner as shown. Therein you can navigate, search, and look at the index.

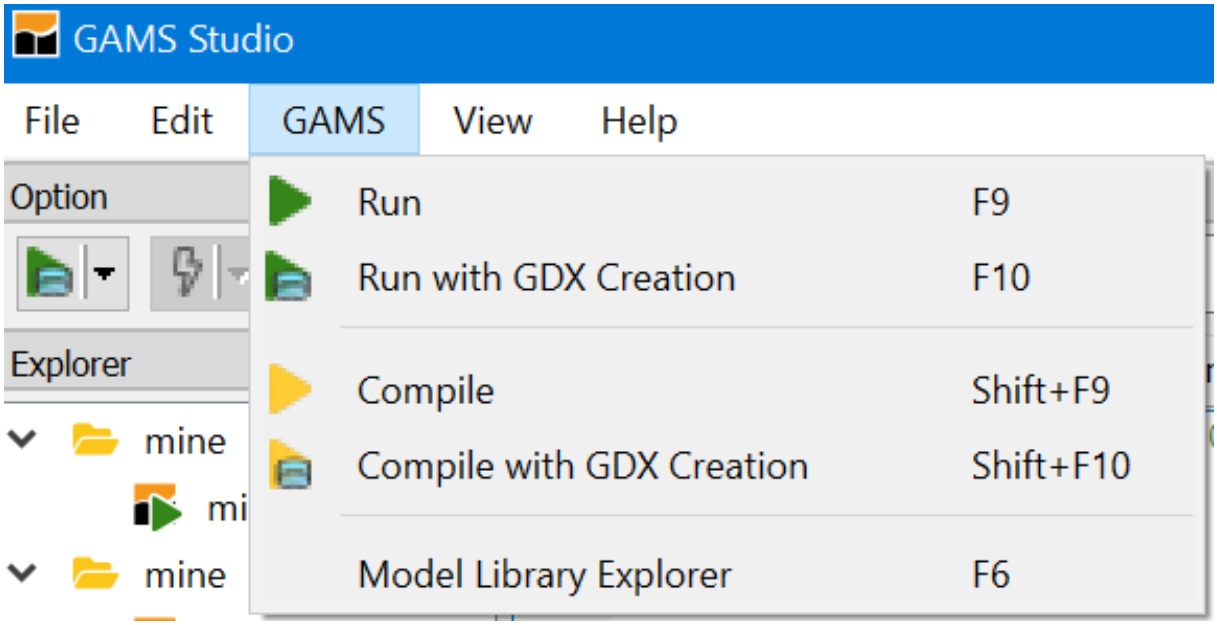
If your cursor is on a reserved word in the source file and you press F1 an index opens to all treatments of that word although in some strange places.



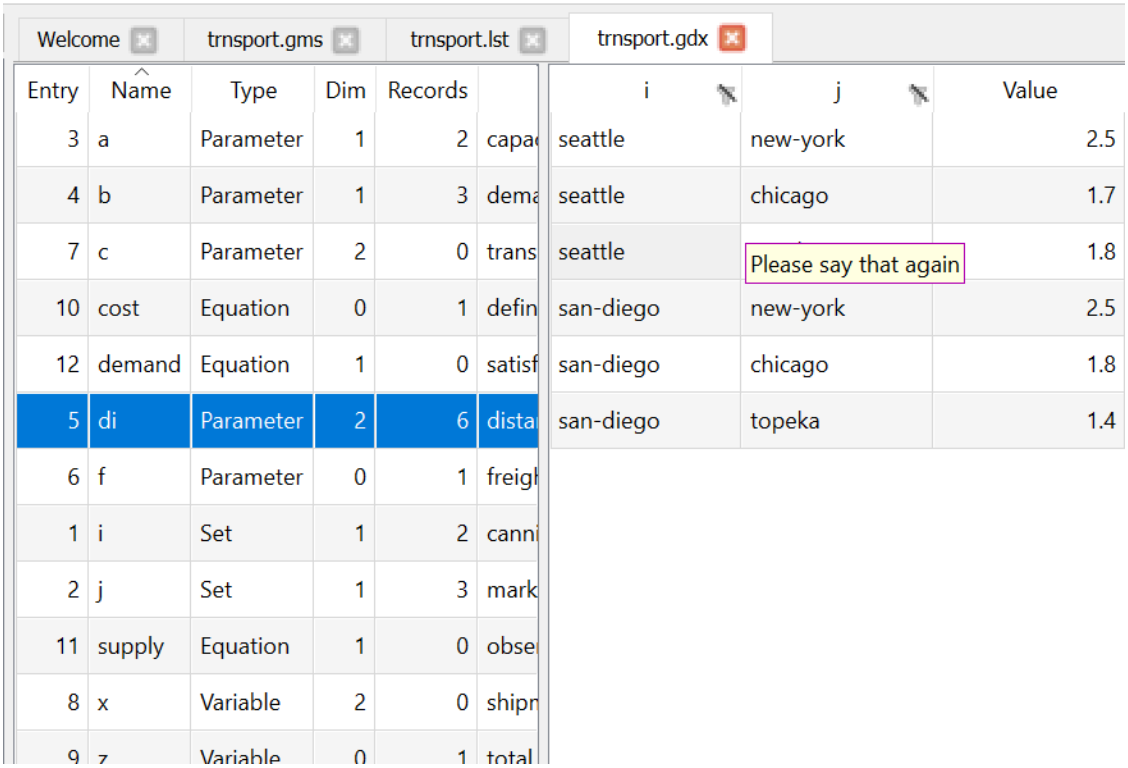
There is a document that explains features in the STUDIO and a `YouTube video` that can be accessed through the welcome page or in the general GAMS documentation under Tools.

4.20.12 Making GDX files

STUDIO can create and show GDX files. To create in STUDIO use the GAMS tab and choose a GDX creating choice. Alternatively use one of the other ways in the language as we will discuss elsewhere.



To browse a GDX file open it with the file open dialogue or click on green lines for ones created during a run in the process window and then for the transport example



Here in the left-hand panel one gets an alphabetical listing of the items in the GDX file and their characteristics. Then clicking on a left-hand panel item leads to the item contents being revealed in the right hand panel. As of now you can reorder columns and filter values then in table mode can move things in rows into columns and vice versa.

4.20.13 Examining GDX files

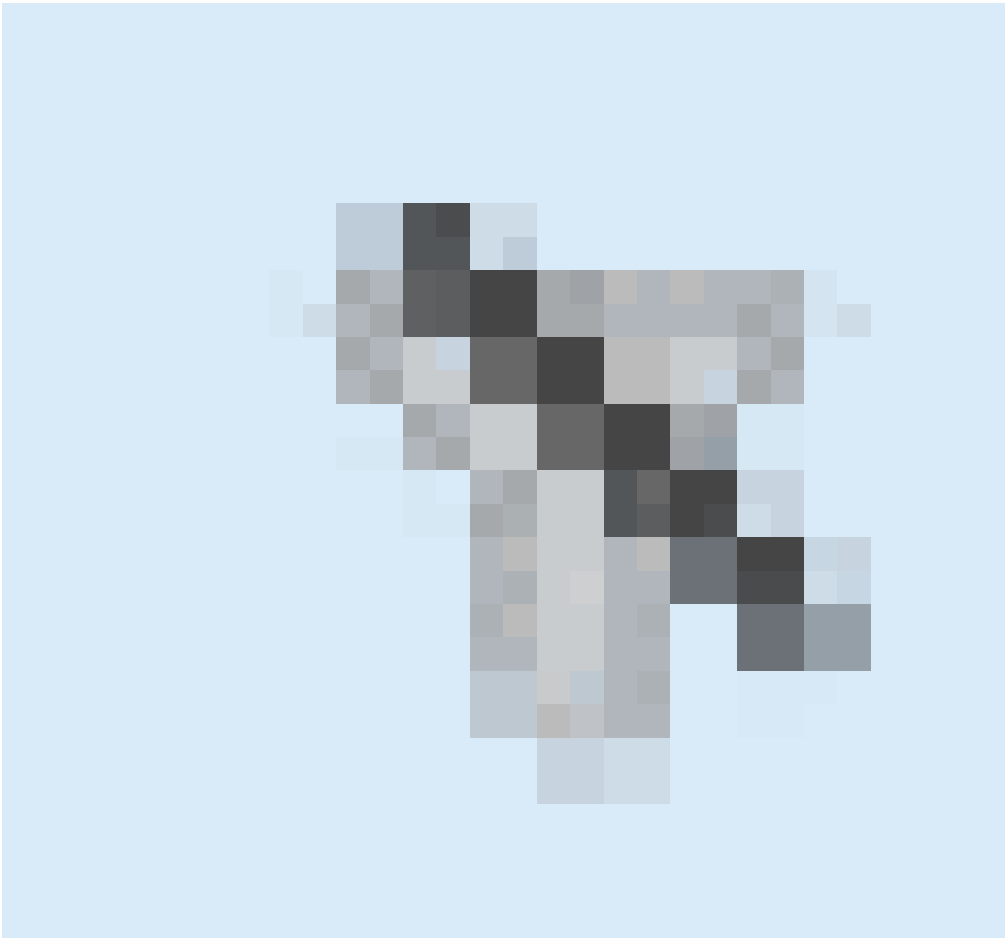
When you have opened a GDX file and selected an item then you get a window like that on the previous page

Entry	Name	Type	Dim	Records	Text	i	j	Value
3	a	Parameter	1	2	capacity of pla...	seattle	new-york	2.5
4	b	Parameter	1	3	demand at mar..	seattle	chicago	1.7
7	c	Parameter	2	0	transport cost i..	seattle	topeka	1.8
10	cost	Equation	0	1	define objectiv..	san-diego	new-york	2.5
12	demand	Equation	1	0	satisfy demand..	san-diego	chicago	1.8
5	di	Parameter	2	6	distance in tho..	san-diego	topeka	1.4

If in the right-hand panel you dragged **i to the right of value** (brown below) you get

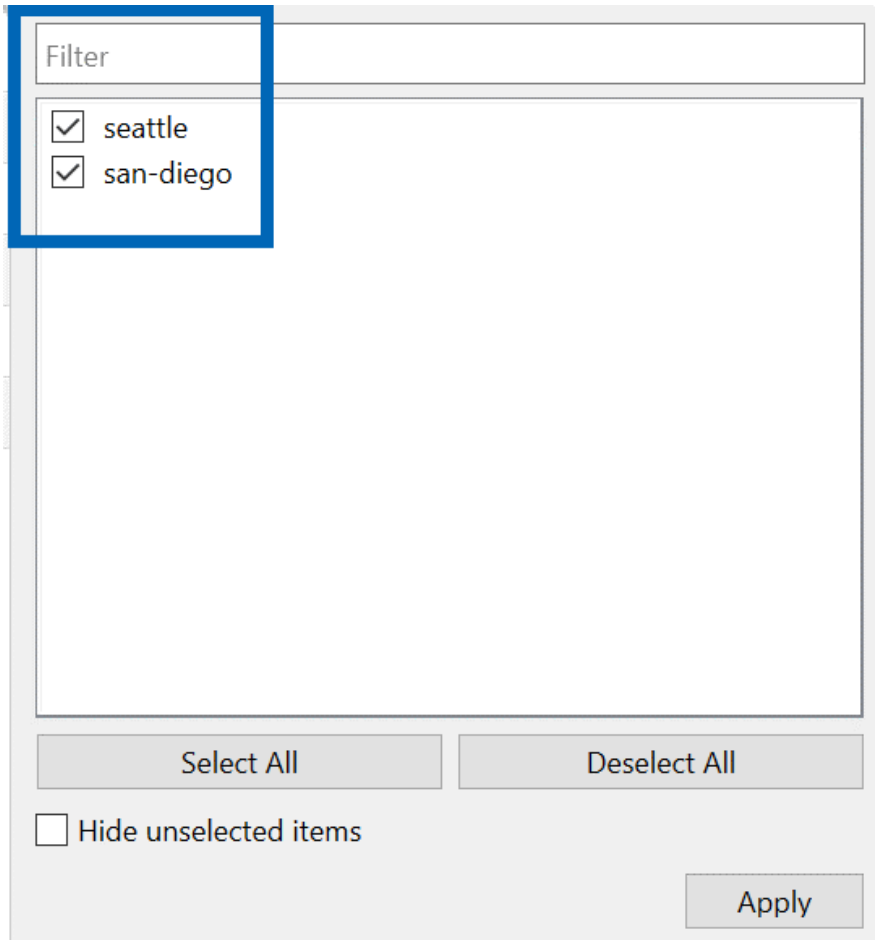
j	Value	i
new-york	2.5	seattle
chicago	1.7	seattle
topeka	1.8	seattle
new-york	2.5	san-diego
chicago	1.8	san-diego
topeka	1.4	san-diego

Also **by clicking on the header** you **cause the array to be sorted with a ^ marking the sort order** and **by clicking on**



you can **establish a filter** (green above and brown below) and **choose what elements to display** (blue below).

j	Value	i
chicago	1.7	seattle
chicago	1.8	san-diego
new-york	2.5	seattle
new-york	2.5	san-diego
topeka	1.8	seattle
topeka	1.4	san-diego



4.20.14 A difficulty you will have

When using and teaching both the IDE and STUDIO, I find that file locations sometimes gives me fits. I have a rule of thumb to avoid problems, but you will most likely inadvertently not follow it.

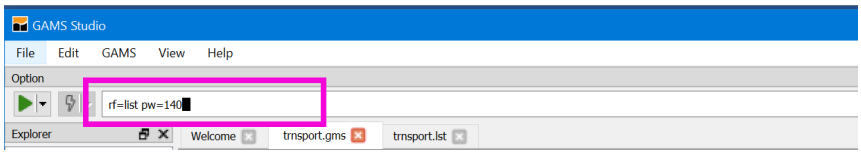
When working with a model with multiple files make sure they are located in the same directory location.

You do not have to follow this rule but deviations are the same as asking for trouble. When you are actively working on a file that you have opened from a directory then STUDIO will look for files in **the directory where active file is located**.

Also when you run a file which contains includes GAMS will look **in the directory where the active file is located**.

4.20.15 Command Line Parameters

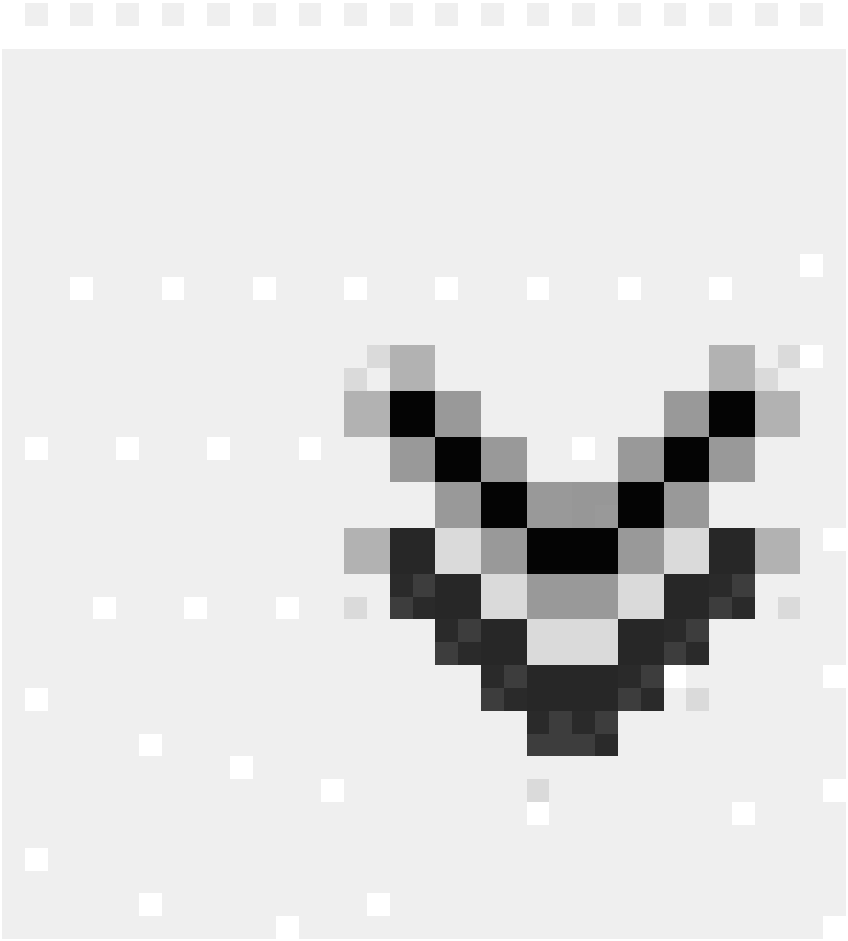
Experienced DOS or UNIX based GAMS users are used to having command line parameters associated with their GAMS execution commands. In STUDIO a **command line parameter entry box** (magenta) is available just to the right of the execute button. The parameters are associated with a file and STUDIO will remember these whenever the file is opened.



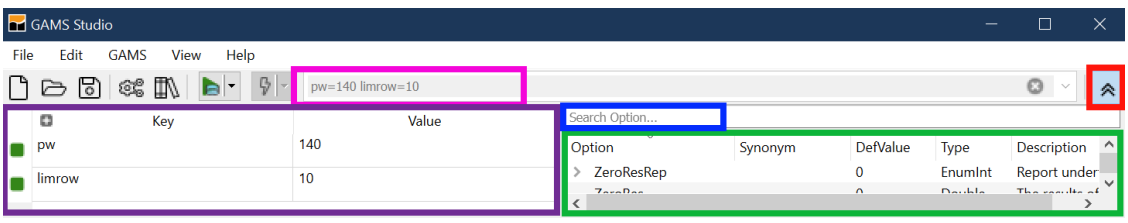
This is particularly useful for save, restart, limrow, limcol, pw and rf parameters as once they are defined they are associated with every subsequent use of the file.

As of now there is no way to provide command line parameters for use in every run (like a wide page width) as there was in the IDE.

GAMS provides assistance with command line parameters through the command line parameter editor. To activate it **check the**



symbol at the far right (red) up top. Then part of the screen becomes as below. In the left hand part **existing command line parameters** (purple) **in use** (magenta) **are listed along with their values**. On the right all possible **command line parameters are listed with definitions** (green) and a **search dialogue is provided** (blue).



The search dialogue looks for text in any of the fields, thus typing in **wid** brings up page width as does **pw** and **maxi** brings up those with maximum in the description.

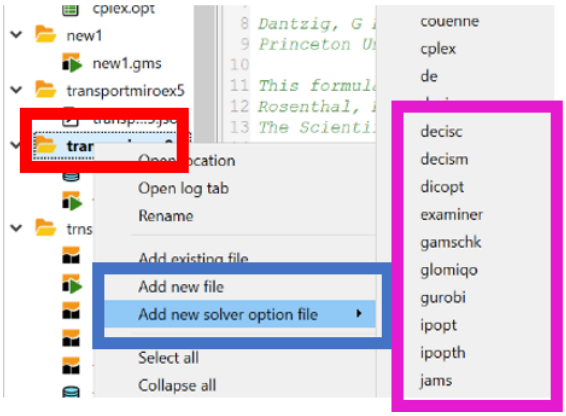
Note pressing F1 while the cursor is on a command line entry opens help to a place with a detailed description of that parameter.

4.20.16 Solver Option Files

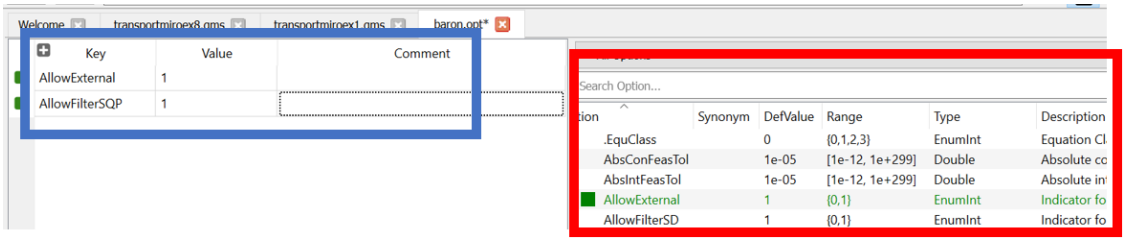
STUDIO allows you to edit or create a solver option file. When using the solver **Conopt** you create `conopt.opt` or with **Cplex** use `cplex.opt` (or `.op1` or `.o10` or `.111`) and more generally `solvername.opt`. Specifying such a file allows you to manipulate the way the solver works on the model. For example, you can alter scaling, tolerances, iteration limits, solver algorithm, and branch and bound strategy along with many other things.

Now in Studio the option file editor is accessed by either

- Right clicking on the **group name** (red) for a group where you want an option file then choosing **add new solver option file** (blue) and picking the **appropriate solver name** (magenta)

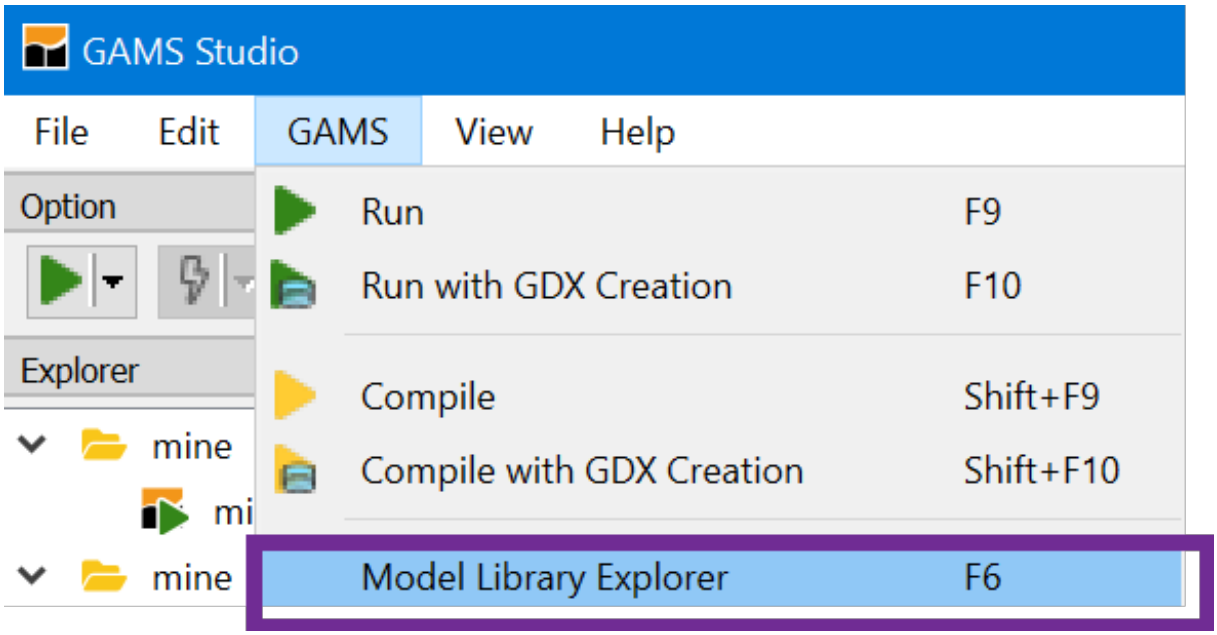


- Creating a file like `baron.opt` then when you bring that up in the editor the option file editor appears. In the editor you see **options in use** (blue), **possibilities and definitions** (red)

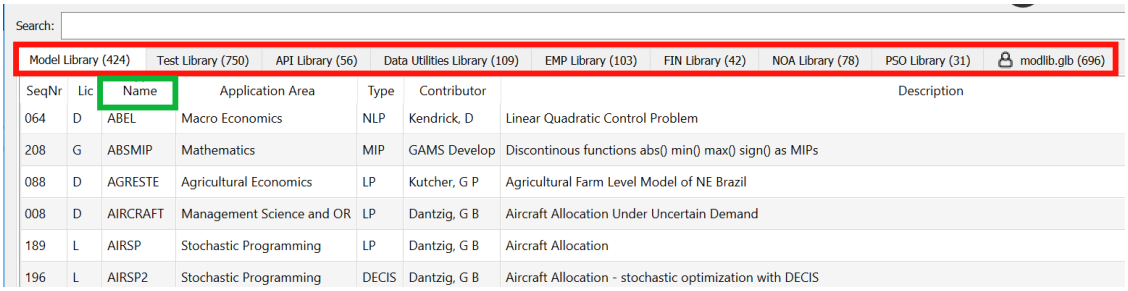


4.20.17 Using Libraries

STUDIO allows one to access libraries under the GAMS menu item and choosing the **Model Library Explorer** (purple).



In turn this opens a screen which identifies names of the libraries in tabs with a count of included files and, for the tab selected, the **library contents**. Furthermore across the top are tabs that when clicked on cause sorts. The picture below came after I clicked on the tab name with the model library active



SeqNr	Lic	Name	Application Area	Type	Contributor	Description
064	D	ABEL	Macro Economics	NLP	Kendrick, D	Linear Quadratic Control Problem
208	G	ABSMIP	Mathematics	MIP	GAMS Develop	Discontinous functions abs() min() max() sign() as MIPs
088	D	AGRESTE	Agricultural Economics	LP	Kutcher, G P	Agricultural Farm Level Model of NE Brazil
008	D	AIRCRAFT	Management Science and OR	LP	Dantzig, G B	Aircraft Allocation Under Uncertain Demand
189	L	AIRSP	Stochastic Programming	LP	Dantzig, G B	Aircraft Allocation
196	L	AIRSP2	Stochastic Programming	DECIS	Dantzig, G B	Aircraft Allocation - stochastic optimization with DECIS

Users can define their own libraries. They have to define what's called a GLB file and the formatting creation of this is discussed in my newsletter in the second issue: https://www.gams.com/mccarl/newsletter/news2.htm.

4.20.18 Using reference files - Listing and Unraveling Data items

GAMS has a command line parameter to create reference files (aka. `.ref` files) called reference (short: rf). These files give information on where things are defined and used.

Why? GAMS Modelers sometimes have to deal with complex implementations that

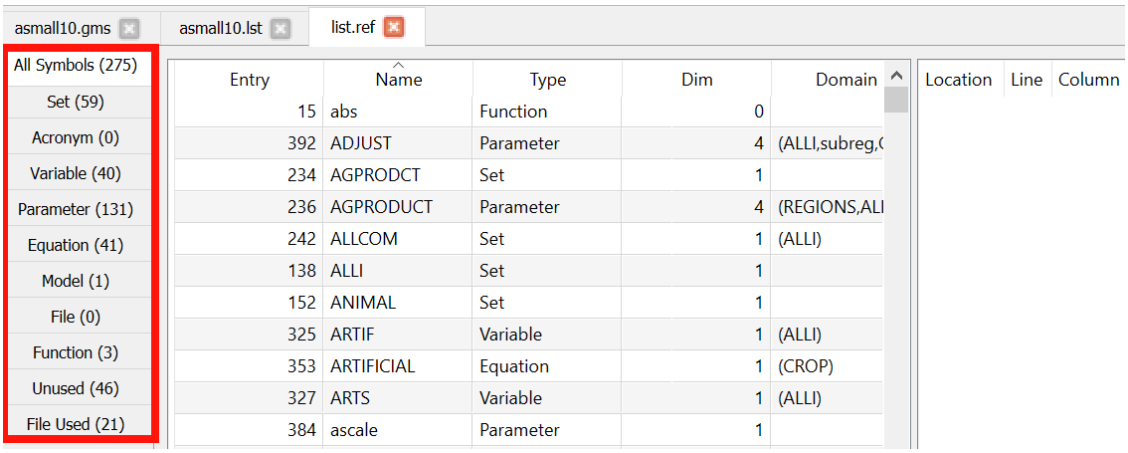
- Use include statements to incorporate numerous files.
- Have been developed by others.
- Have a complex structure with definitions and uses of items widely spread in a file or files.
- Contain items that are defined but never used.
- Were developed some time ago but are not extensively documented.

When faced with such cases one often asks

- Are there items defined in the program that are not used and if so what are they and where are they?
- In what files is an item defined, declared and used?

To resolve these questions some years ago I wrote a Fortran program called GAMSMAP but never made it widely available. Subsequently it was included into the GAMSIDE and then STUDIO.

When a `.ref` file is opened it creates a window as follows

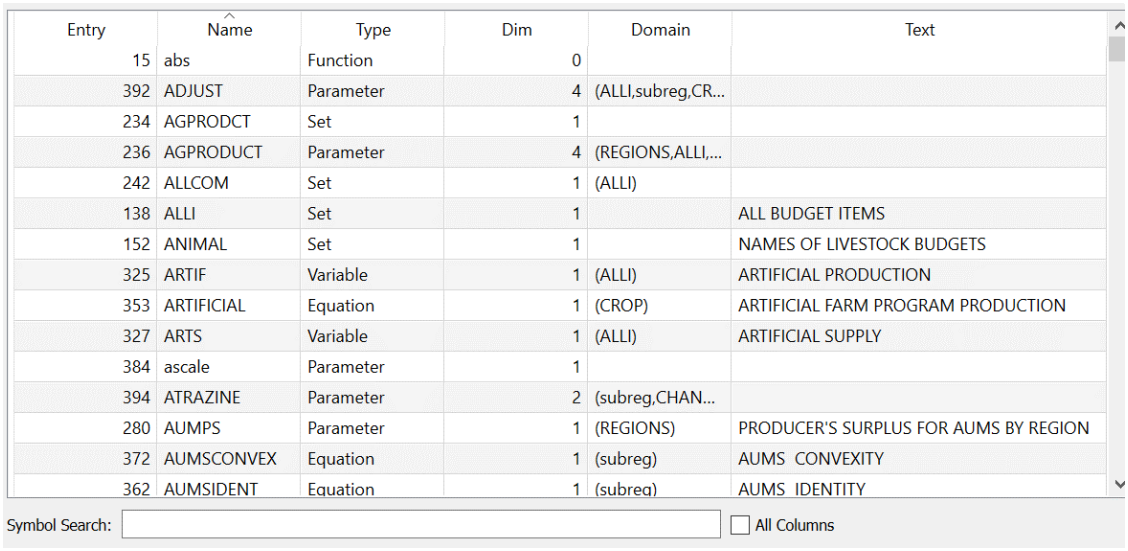


The **column on the left** (red) gives tags that can be clicked on and the key ones are

Column	Description
All Symbols	a list of items that are declared and a count of them
Set	a list of the sets that exist in the program and a count
Variable	a list of the variables in the program and a count
Parameter	a list of the parameters (items defined in scalar, parameter or table statements) and a count.
Equation	a list of the equations in the program and the names of files in which they appear
Model	a list of the models that exist in the program and the names of files in which they appear
Unused	a list of items that are declared or that are not used anywhere in the model
File used	a list of the files included into the model

4.20.18.1 All Symbols Tab

The all symbols tab causes the output to appear as follows:



Entry	Name	Type	Dim	Domain	Text
15	abs	Function	0		
392	ADJUST	Parameter	4	(ALLI,subreg,CR...	
234	AGPRODCT	Set	1		
236	AGPRODUCT	Parameter	4	(REGIONS,ALLI,...	
242	ALLCOM	Set	1	(ALLI)	
138	ALLI	Set	1		ALL BUDGET ITEMS
152	ANIMAL	Set	1		NAMES OF LIVESTOCK BUDGETS
325	ARTIF	Variable	1	(ALLI)	ARTIFICIAL PRODUCTION
353	ARTIFICIAL	Equation	1	(CROP)	ARTIFICIAL FARM PROGRAM PRODUCTION
327	ARTS	Variable	1	(ALLI)	ARTIFICIAL SUPPLY
384	ascale	Parameter	1		
394	ATRAZINE	Parameter	2	(subreg,CHAN...	
280	AUMPS	Parameter	1	(REGIONS)	PRODUCER'S SURPLUS FOR AUMS BY REGION
372	AUMSCONVEX	Equation	1	(subreg)	AUMS CONVEXITY
362	AUMSIDENT	Equation	1	(subreg)	AUMS IDENTITY

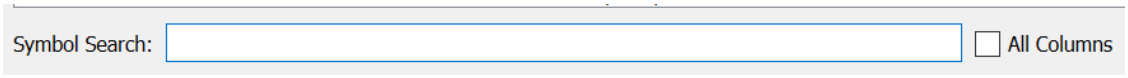
Symbol Search: All Columns

This shows all symbols used. The columns give

- the symbol name (Name),
- it's type(Type),
- its dimension (Dim),
- the sets over which it is dimensioned (Domain)
- the explanatory text used in it's declaration (Text).

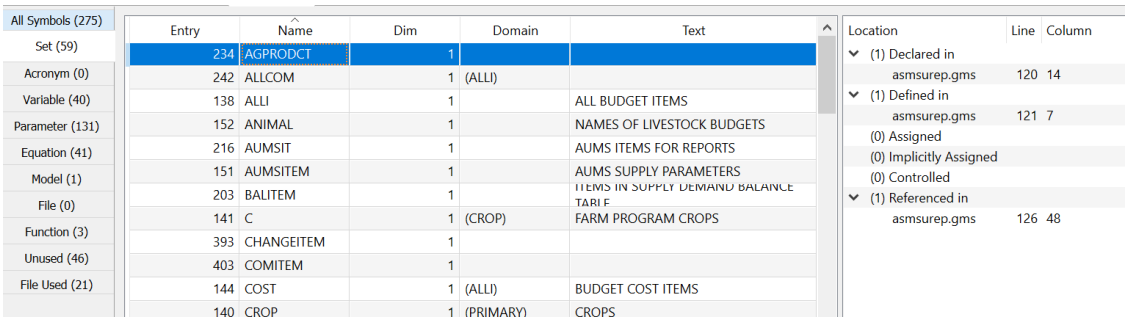
Things can be sorted by clicking on the column headings.

One can search for symbols using the box at the bottom



4.20.18.2 Sets, Parameters etc. Tabs

The display contains 5 lines that when activated give information for sets, parameters etc. The resultant display lists all items falling in a class (for all things that are sets or parameters etc.) and information on their characteristics and use. Specifically one gets output as follows (for the sets in this case)

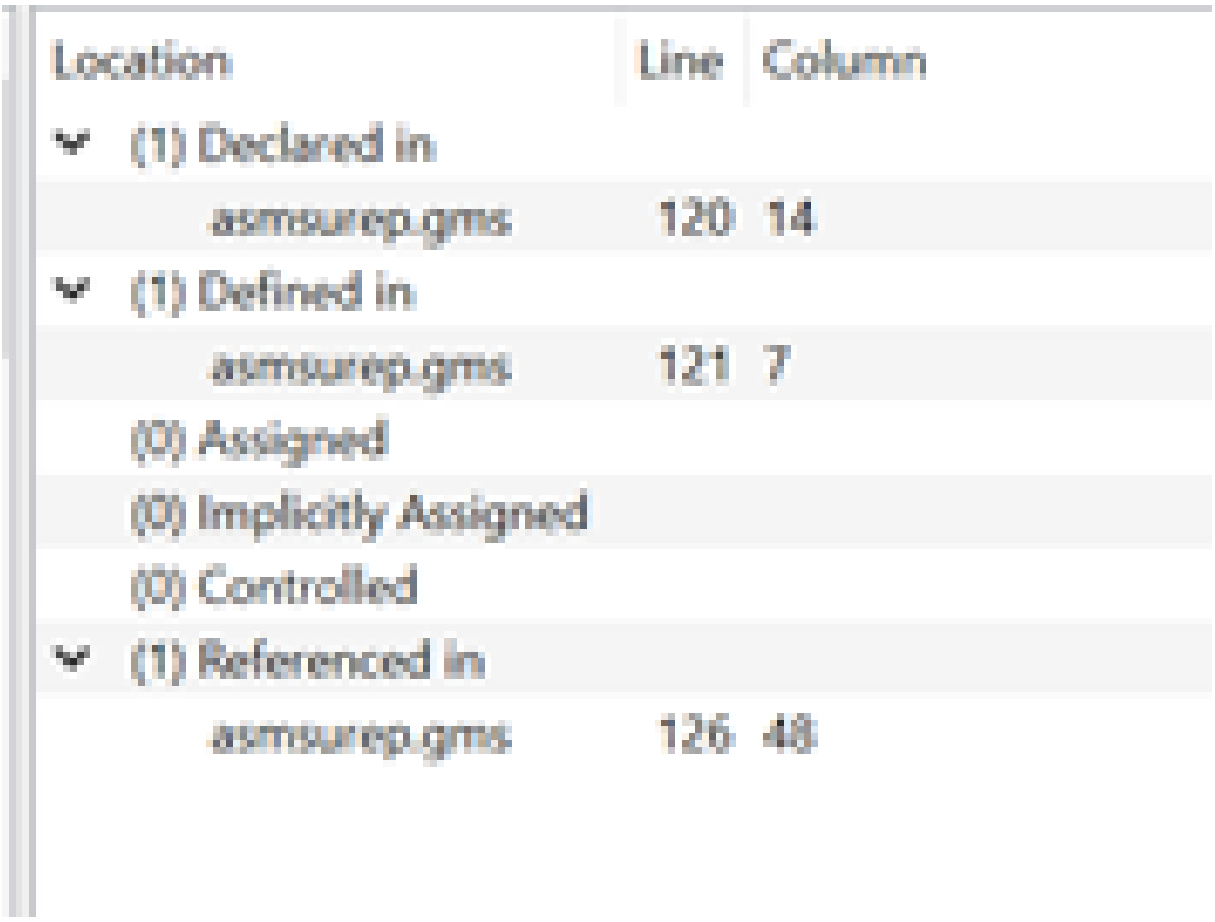


In this output once clicked on the entries tell the names of the files in which certain things happen relative to the identified items. The categories of things include the file name, line and column where items are declared, defined and used as discussed below.

Clicking on a line takes you to the file and place where the item appears.

Clicking on a column name causes it to be sorted.

After clicking on an item one gets



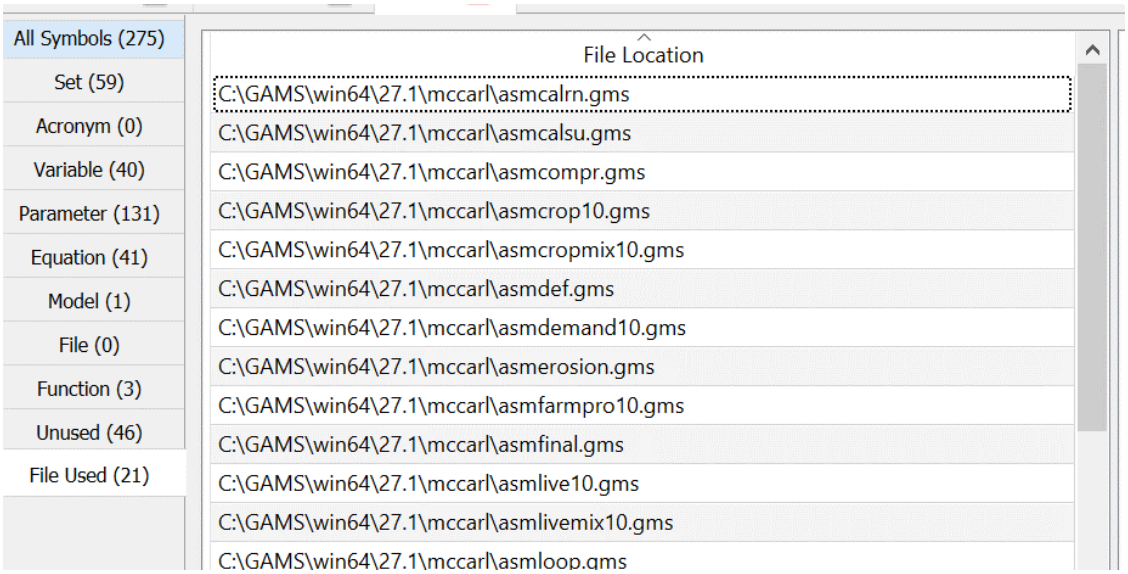
Entries in location columns identify files where items are

Column	Description
Declared	places where the named item is declared in a Set, Parameter, Table, Scalar, Variable, Equation, Acronym, File or Model command. This will be the first appearance.
Defined	places set elements or data are explicitly entered. For equations this tells where the .. specification begins.
Assigned	places where items appear on left hand side of an assignment statement
Implicitly-Assigned	places where an equation or variable has data put into it by the results of a solve statement.
Controlled	places where set is used in controlling a sum or defining an equation
Ref	places where item is on left hand side of assignment statement or in a model equation

Clicking on lines here opens the subject file in the specific place

4.20.18.3 File used Tab

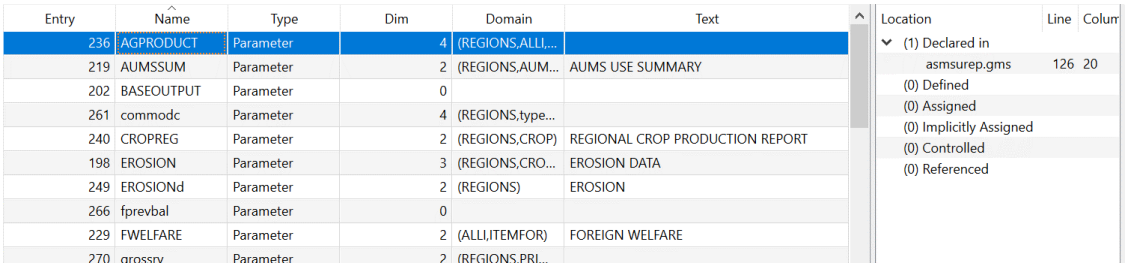
The file used tab causes the output to appear as follows:



This gives the names of the files included in the program with their full path references.

4.20.18.4 Unused Tab

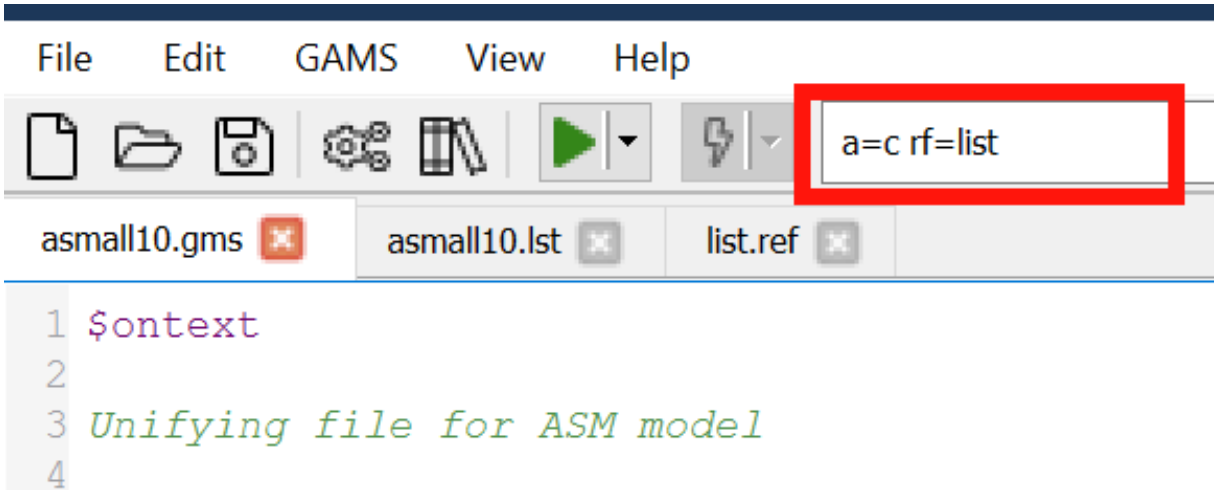
The unused tab identifies items that are declared (in set parameter etc. statements) but are never used on the right hand side of an assignment (=) statement or in a model equation:



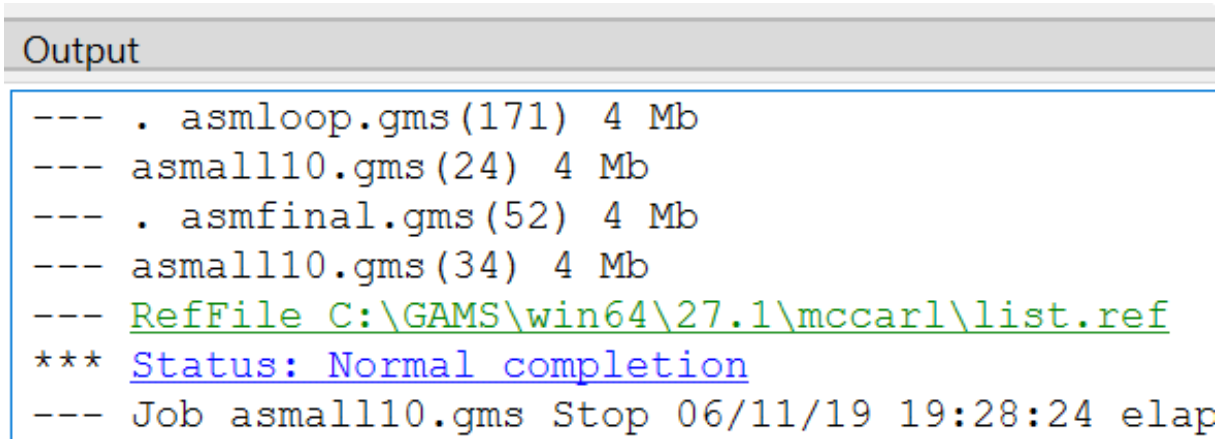
which shows the same information as in the All Symbols tab except when an item is clicked on one gets information on the files where it is declared.

4.20.18.5 Steps to use the Reference File Viewer

The Reference File Viewer will only work after a particular "reference file" has been created by a GAMS run. The file is generated by adding the `rf` option to the command line call entering a command in the command line box of Studio as follows (a=c cause compilation only)



Once the file has been run with the `rf` option the logfile is augmented with the (green) line identifying the `.ref` file name as below



Double clicking on this opens the Reference File Viewer window.

The run of GAMS with the `rf` option places the name of the `.ref` file in green in the GAMS log file and double clicking on that line causes the Reference File Viewer to be opened.

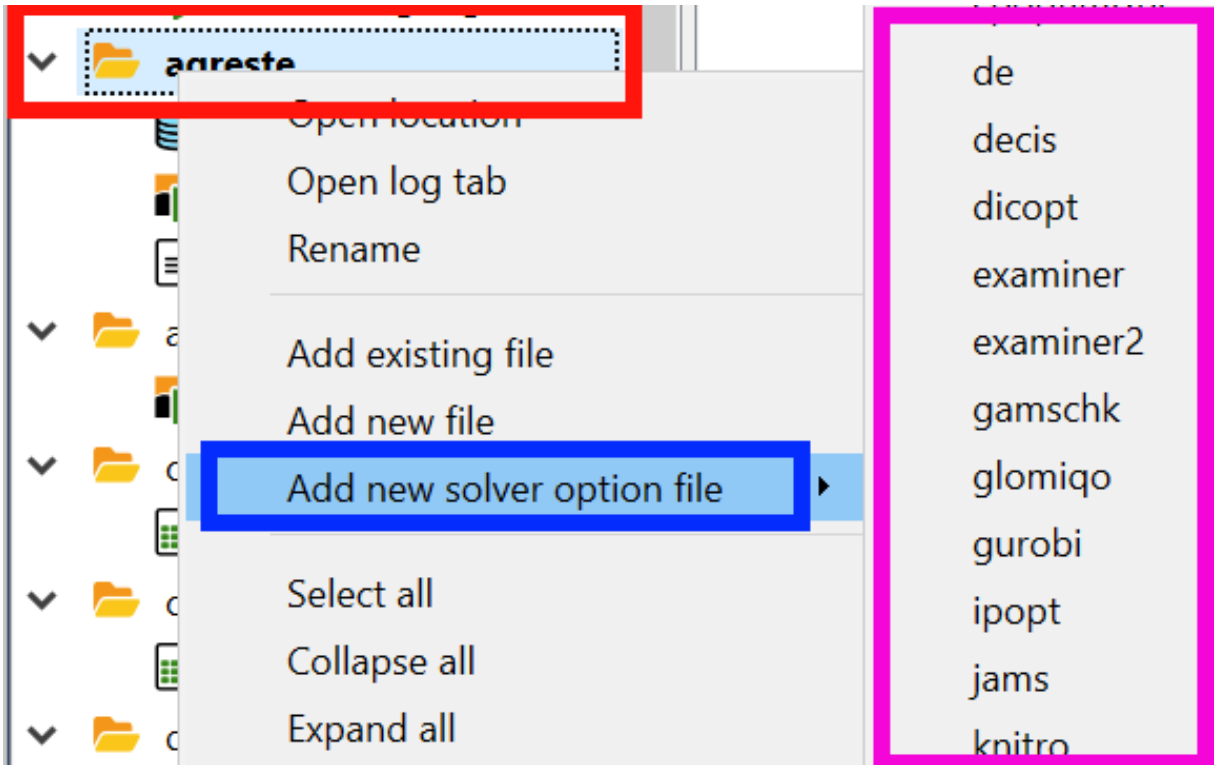
Several notes about the run

- The `rf=` command specifies the name of the file the Reference File Viewer will use. Generally, the Reference File Viewer expects it to have the extension `.ref`.
- The `.ref` file only covers the program components in a run and does not include any information from restart files. In general it is best to explicitly use all the files in one program without use of save and restart.
- It is often useful to just generate the reference file without any execution on behalf of the GAMS program. This is done by including the `a=c` option on the command line or in the command parameter IDE box.

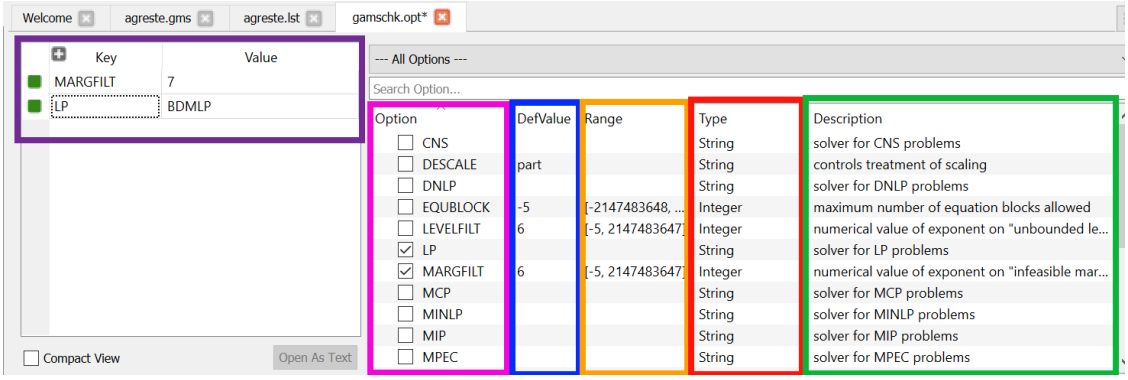
4.20.19 Editing Solver Option Files

Sometimes it is desirable to change solver specific options. This includes modifying things like branch and bound strategy, degree of scaling, barrier versus simplex solution approach, solution tolerances etc. The specific options allowed are described in the solver manuals. In addition Studio contains a solver option file editor that presents a solver specific menu of all possible options, default values and ones that have been altered. This is activated by either

- Opening or saving a file with solvername.opt (Like MINOS.opt)
- Right clicking on a **group file name** (red) in the Studio Explorer then selecting **add new solver option file** (blue) and subsequently selecting one of the many available **solver names** (magenta and only a few shown). This will create a file you then need to save.



Once it opens the general format of the solve option editor is as follows. Note the specific content depends on the solver chosen and in this case I use GAMSCHK.



Here in the right part we see a list of all **possible options** (magenta) for this solver with boxes checked for those that are in the option file. A brief description of **default values** (blue), **entry type** (red), if relevant **allowable settings** (yellow) and a **one sentence description of the option** (green). In the left part we see the **current entries** (purple) in the option file and **their settings** (purple).

Subsequently when this file is opened or its tab activated then this solver option editor appears.

Note, pressing F1 while on an option opens help to a place with a detailed description of that option.

4.20.20 When is it Not Worth Using?

There are costs and benefits of these approaches.

The STUDIO is much easier for simple models and can run across platforms.

The DOS/command line approach is generally better for models in customized environments.

A **development strategy** for more complex implementations

1. Use the STUDIO to get it right
2. Debug components of large models using save and restart
3. Then use script files or DOS/UNIX with batch files such as
   - `GAMS mymodel  -lo 0 -s ./t/save1`
   - `call myprogram.exe`
   - `GAMS moremod  -lo 0 -r ./t/save1`

4.20.21 What does it not do?

A number of IDE features are currently missing. Just to inventory (note the last three are pretty unimportant to me.)

- Ability to save output from the reference files
- Ability to change the file associations when clicking on them in Windows Explorer (you get more than I like at the moment and sometimes I want more)
- Project files (mixed blessing)
- Text file differencing (can use other programs)
- Spell checking

4.20.22 What does it not do so well?

Here are also some difficulties with it as of today

- Washed out colors – on my machine the syntax and error coloring is not very prominent.
- Excessive library choices and no way to put the ones you have no interest in somewhere out of the way. Plus any user defined libraries are at the end and there is no way to reorder.

4.21 Introduction

4.21.1 Summary

Today, algebraic modeling languages are widely accepted as the best way to represent and solve mathematical programming problems. Their main distinguishing features are the use of relational algebra and the ability to provide partial derivatives on multidimensional, very large and sparse structures. In this chapter we will briefly describe some of the origins of GAMS and provide background information that shaped early design decisions.

4.21.2 The Origins of GAMS

The initial Research and Development of GAMS was funded by the International Bank for Reconstruction and Development, usually referred to as The World Bank. Since 1987, further Research and Development has been funded by GAMS Development Corporation. GAMS was developed in close cooperation of mathematical economists who were and still are an important group of GAMS users. The synergy between economics, computer science and operations research was the most important success factor in the development of the system. Mathematical Programming and economics theory are closely intertwined. The Nobel Prize in Economics awarded to Leonid Kantorovich and Tjalling Koopmans in 1975 for their "contribution to the theory of optimal allocation of resources" was really a prize in mathematical programming. Other Nobel laureates like Kenneth Arrow in 1972, Wassily Leontief in 1973, and Harry Markowitz in 1990 are well known names in math programming. Another early example of this synergy is the use of LP in refining operations, which was started by Alan Manne, an economist, with his book on Scheduling of Petroleum Refinery Operations in 1956.

The origins of linear programming algorithms all go back to George Dantzig's early work in the 1940s and 1950s. Computing technology and algorithmic theory had developed at a rapid pace. Thirty years later, we could solve problems of practical size and complexity that allowed us to test of the economic theory on real life problems. The research agenda at the World Bank in the 1970s and 1980s created the perfect environment to bring different disciplines together to apply mathematical programming to research and operational questions in Economic Development.

4.21.3 Background and Motivation

From the very beginning, the driving force behind the development of the General Algebraic Modeling System (GAMS) has been the users of mathematical programming who believed in optimization as a the powerful and elegant framework for solving real life problems in the sciences and engineering. At the same time, these users were frustrated with the high cost, skill requirements, and overall low reliability of applying optimization tools. Most of our initiatives and support for new development came from the worlds of economics, finance, and chemical engineering. These disciplines find it natural to view and understand the world and its behavior as a mathematical program.

GAMS's impetus for development arose out of the frustrating experiences of a large economic modeling group at the World Bank. In hindsight, one may call it a historical accident that in the 1970s mathematical economists and statisticians were assembled to address problems of development. They used the best techniques available at the time to solve multisectoral economy-wide models and large simulation and optimization models in agriculture, steel, fertilizer, power, water use, and other sectors. Although the group produced impressive research, initial successes were difficult to reproduce outside their well functioning research environment. The existing techniques to construct, manipulate, and solve such models required several manual, time-consuming, and error-prone translations into the different, problem-specific representations required by each solution method. During seminar presentations, modelers had to defend the existing versions of their models, sometimes quite irrationally, because the time and money needed to make proposed changes were prohibitive. Their models just could not be moved to other environments,

because special programming knowledge was needed, and data formats and solution methods were not portable.

The idea of an algebraic approach to represent, manipulate, and solve largescale mathematical models fused old and new paradigms into a consistent and computationally tractable system. Using matrix generators (see appendix GAMS versus Fortran Matrix Generators) for linear programs taught us the importance of naming rows and columns in a consistent manner. The connection to the emerging relational data model became evident. Painful experience using traditional programming languages to manage those name spaces naturally lead one to think in terms of sets and tuples, and this led to the relational data model. Combining multidimensional algebraic notation with the relational data model was the obvious answer. Compiler writing techniques were by now widespread, and languages like GAMS could be implemented relatively quickly. However, translating this rigorous mathematical representation into the algorithm specific format required the computation of partial derivatives on very large systems. In the 1970s, TRW developed a system called PROSE that took the ideas of chemical engineers to compute point derivatives that were exact derivatives at a given point, and to embed them in a consistent, Fortran-style calculus modeling language. The resulting system allowed the user to use automatically generated exact first and second order derivatives. This was a pioneering system and an important demonstration of a concept. However, in our opinion PROSE had a number of shortcomings: it could not handle large systems, problem representation was tied to an array-type data structure that required address calculations, and the system did not provide access to state-of-the-art solution methods. From linear programming, we learned that exploitation of sparsity was the key to solve large problems. Thus, the final piece of the puzzle was the use of sparse data structures.

With all pieces in place, all we had to do was adopt the techniques to fit into one consistent framework and make it work for large problems

4.21.4 Design Goals and Changing Focus

The original and still valid goal is to improve the model builder's productivity, reduce costs, and improve reliability and overall credibility of the modeling process. To achieve this, we established the following key principles to guide the GAMS development:

- The problem representation is independent of the solution method.
- The data representation follows the relational data model.
- The problem and data representations are independent of computing platforms.
- The problem and data representations are independent of user interfaces.
- Optimization methods will fail, and systems have to be designed to be fail-safe.

Another way to express these principles is to think in terms of layers of representations and capabilities that have clearly defined interfaces and functions. The oldest and most basic layer is the solver layer or implementation of a specific algorithm. Above the solver is the model layer, expressed in an algebraic modeling language. The modeling layer translates the mathematical representation into a computational structure required by a specific solution method and provides various services such as function and derivative evaluations and error recovery. Above the modeling layer is the application or domain layer, which is highly context sensitive and has knowledge about the problem to be solved and the kind of user interacting with the system.

The representation of the model in GAMS is in a form that can be easily read by humans and by machines. This means that the GAMS program itself is the documentation of the model, and that the separate description required in the past (which was a burden to maintain, and which was seldom up-to-date) is no longer needed. Moreover, the design of GAMS incorporates the following features that specifically address the user's documentation needs:

- A GAMS model representation is concise, and makes full use of the elegance of the mathematical representation.
- All data transformations are specified concisely and algebraically. This means that all data can be entered in their most elemental form and that all transformations made in constructing the model and in reporting are available for inspection.
- Explanatory text can be made part of the definition of all symbols and is reproduced whenever associated values are displayed.
- All information needed to understand the model is in one document.

Of course some discipline is needed to take full advantage of these design features, but the aim is to make models more accessible, more understandable, more verifiable, and hence more credible.

It is instructive to put the development of modeling systems into some historic perspective and see how the focus and technical constraints have changed in the last 30 years. We can observe three major phases that shift the emphasis from computational issues to modeling issues and finally the application or the real problems. Each phase defined one of the main system layers discussed above. The dominant constraints in the first phase were the computational limits of our algorithms. Problem representation had to abide by algorithmic convenience, centralized expert groups managed large, expensive and long lasting projects and end users were effectively left out. The second phase has the model in focus. Applications are limited by modeling skill, project groups are much smaller and decentralized, the computational cost are low and the users are involved in the design of the application. Applications are designed to be independent of computing platforms and frequently operate in a client-server environment.

We believe that we are entering a third phase which has the application as its focus and the optimization model is just one of many analytic tools that help making better decisions. The users are often completely unaware of any optimization model or use a mental model that is different from the actual model to solved by optimization techniques. User interfaces are build with off-the-shelf components and frequently change to adjust to evolving environments and new computing technologies. As with databases, modeling components have a much longer life than user interfaces. We have observed cases where the model has remained basically unchanged over many years, whereas the computing environments and user interfaces have changed several times. The solvers used to solve the models have changed, the computing platforms have changed, the user interfaces have changed and the overall performance of the model has changed without any change in the model representation.

4.22 GAMS Programs

4.22.1 Introduction

This chapter provides a look at the structure of the GAMS language and its components. It should be emphasized again that GAMS is a programming language, and that programs must be written in the language to use it. A GAMS program is contained in a disk file, which is usually constructed with a text editor of choice (e.g. GAMS Studio). When GAMS is 'run', the file containing the program (the input file) is submitted to be processed. After this processing has finished, the results, which are in the output file(s), can be inspected. By default the GAMS log appears on the screen while GAMS runs, keeping the user informed about progress and error detection. It is the responsibility of the user to inspect the output file(s) carefully to see the results and to diagnose any errors.

4.22.2 The Structure of GAMS Programs

GAMS programs consist of one or more statements (sentences) that define data structures, initial values, data modifications, and symbolic relationships (equations). While there is no fixed order in which statements have to be arranged, the order in which data modifications are carried out is important. Symbols must be declared as to type before they are used, and must have values assigned before they can be referenced in assignment statements. Each statement is followed by a semicolon except the last statement, where a semicolon is optional.

Note

The semicolon at the end of a statement can be omitted if a new GAMS keyword follows. However, to improve readability of the code, it is recommended to use the semicolon at the end of a statement anyway.

4.22.2.1 Format of GAMS Input

GAMS input is free format. A statement may be placed anywhere on a line, multiple statements may appear on a line, or a statement may be continued over any number of lines as follows:

```
statement;
statement;
statement; statement; statement;
the words that you are now reading is an example of a very
long statement which is stretched over two lines;
```

Blanks and end-of-lines may generally be used freely between individual symbols or words. GAMS is not case sensitive. This means that lower and upper case letters may be mixed freely but are treated identically. Up to 80,000 characters may be placed on a line and completely blank lines may be inserted for easier reading.

Not all lines are a part of the GAMS language. Two special symbols, the asterisk `'*'` and the dollar symbol `'$'` may be used in the first position on a line to indicate a non-language input line. An asterisk in column one means that the line will not be processed, but treated as a comment. For more on comments, see section Comments. A dollar symbol in the first position indicates that compiler options or directives are contained in the rest of the line (see chapter Dollar Control Options for more information).

For example, multiple files may be used as input through the use of the $include facility. In short, the statement

```
$include file1
```

inserts the contents of the specified file (`file1` in this case) at the location of the call. A more complex versions of this is the option $batinclude. Both options are introduced and discussed in details in chapter Dollar Control Options.

4.22.2.2 Classification of GAMS Statements

Each statement in GAMS is classified into one of two groups:

1. Declaration and definition statements.
2. Execution statements.

A declaration statement describes the class of a symbol. Often initial values are provided in a declaration, then it may be called a definition. The specification of symbolic relationships for an equation is a definition. The declaration and definition statements are:

- acronym
- alias
- equation declaration
- equation definition
- file
- function
- model
- parameter
- scalar
- set
- table
- variable

Execution statements are instructions to carry out actions such as data transformation, model solution, and report generation. The execution statements are:

- abort
- assignment
- break
- continue
- display
- execute
- for
- if
- loop
- option
- put
- put_utility

- putclear
- putclose
- puthd
- putpage
- puttl
- repeat
- solve
- while

Note

While an assignment is an execution statement, it also defines the symbol on the left hand side of the assignment.

Although there is great freedom about the order in which statements may be placed in a GAMS program, certain arrangements are commonly used. The two most common are discussed next.

4.22.2.3 Organization of GAMS Programs

One common style of organizing GAMS statements places the data first, followed by the model and the solution statements.

Style 1:

Data:

Set declarations and definitions

Parameter declarations and definitions

Assignments

Displays

Model:

Variable declarations

Equation declarations

Equation definitions

Model definition(s)

Solution:

Solve(s)

Displays

In this style of organization, the sets are placed first. Then the data is specified with parameter, scalar, and table statements. Next, the model is defined with the variable declarations, equation declarations, equation definitions and one or more model statements. Finally, the model is / models are solved and the results are displayed. One can refer to the model **trnsport** as an example for this style.

A second style emphasizes the model by placing it before the data. This is a particularly useful order when the model is to be solved repeatedly with different data sets.

Style 2:

Model:

Set declarations

Parameter declarations

Variable declarations

Equation declaration

Equation definition

Model definition

Data:

Set definitions

Parameter definitions

Assignments

Displays

Solution:

Solve

Displays

Here, there is a separation between declaration and definition. For example, sets and parameters may be declared first with the following statements:

```
Set       c         "crops" ;
Parameter yield(c)  "crop yield" ;
```

Later they may be defined with the statements:

```
Set        c        / wheat, clover, beans / ;
Parameter  yield(c) / wheat     1.5
                      clover    6.5
                      beans     1.0  / ;
```

The first statement declares that the identifier `c` is a set and the later statement defines the elements in this set. Similarly, in the second statement `yield` is declared to be a parameter and later the corresponding data is given.

Note

Sets and parameters that are used in equations must be *declared* before the equations are specified. However, they may be *defined* after the equation specifications but before the specific equation is used in a solve statement. This gives GAMS programs substantial organizational flexibility.

4.22.3 Data Types and Definitions

Each symbol or identifier has exactly one of the following basic GAMS data types:

- acronyms
- equations
- files
- functions
- models
- parameters
- sets
- variables

Note

- `Scalars` and `tables` are not separate data types but convenient input formats for the data type `parameter`. For details see the overview Parameters, Scalars and Tables.
- GAMS uses shorthand symbols for each data type in the output. For details see the overview GAMS Data Types and their Shorthand Symbols.

Declarations have common characteristics. The following example has a typical structure:

```
Parameter    a(i,j)        "input-output matrix" ;
```

The structure is:

```
Keyword for data type - identifier (with index list) - explanatory text ;.
```

Note that the index list (or domain list) and the explanatory text are always optional characteristics. However, we recommend to specify the index list if the data type is defined over a domain; the advantages of this practice are outlined in section Domain Checking.

Note

Variables, sets, parameters and equations may be declared and defined over one or more indices or dimensions. Currently the maximum number of dimensions for all these data types is 20.

It is also recommend to add an explanatory text for reasons of clarity. For more on explanatory texts, see section Text below. Other examples for declarations follow:

```
Set         time     "time periods" ;
Model       turkey   "turkish fertilizer model" ;
Variables   x,y,z ;
```

Observe that in the last example a number of identifiers (separated by commas) is declared in one statement.

4.22.4 Language Items

Before proceeding with more language details, a few basic symbols need to be defined and the rules for recognizing and writing them in GAMS established. These basic symbols are often called lexical elements and form the building blocks of the language. They are:

- characters
- comments
- delimiters
- identifiers (idents)
- labels
- numbers
- reserved words and tokens
- text

Each of these items is discussed in detail in the following subsections.

Attention

As noted previously, GAMS is not case sensitive, so we may use any mix of lower and upper case.

4.22.4.1 Characters

A few characters are not allowed in a GAMS program, because they are illegal or ambiguous on some machines. Generally, all unprintable and control characters are illegal. The only place where any character is legal, is in an `$ontext-$offtext` block as illustrated in section Block Comments below. For completeness, the full set of legal characters are listed in Table 1. Note that most of the uncommon punctuation characters are not part of the language, but they may be used freely in the context of explanatory texts, comments, and labels (if quoted). Similarly, special language specific characters (e.g. ä, ß, à, é, ç, ț, ș) may also be used freely in explanatory texts, comments, and labels (if quoted).

Table 1: Legal Characters

Legal Characters	Description
A to Z	alphabet
a to z	alphabet
0 to 9	numerals
+	plus
-	minus
=	equals
<	less than
>	greater than
( )	parenthesis
[ ]	square brackets
{ }	braces
'	single quote
"	double quote

Legal Characters	Description
\	back slash
/	slash
,	comma
:	colon
;	semicolon
.	dot
?	question mark
!	exclamation mark
	space
_	underscore
&	ampersand
^	circumflex
#	pound sign
*	asterisk
%	percent
@	at
$	dollar

Note

Not every character listed above is allowed to be used in every place (for example, identifiers have certain limitations).

4.22.4.2 Reserved Words

GAMS, like other programming languages such as C and Java, uses reserved words (often also called keywords) that have predefined meanings. Users are in general not permitted to use these for their own definitions, neither as identifiers nor labels. The complete list of reserved words is given below. In addition, a small number of symbols constructed from non-alphanumeric characters have a meaning in GAMS.

Note

While it is not allowed to use reserved words as identifiers and labels in general, it is still possible (put not recommended) in certain cases which are explained in more detail further below.

- abort
- acronym[s]
- alias
- all
- and
- binary
- break
- card
- continue
- diag

- display
- do*
- else
- elseif
- endfor*
- endif*
- endloop*
- endwhile*
- eps
- equation[s]
- execute
- execute_load
- execute_loaddc
- execute_loadhandle
- execute_loadpoint
- execute_unload
- execute_unloaddi
- execute_unloadidx
- file[s]
- for
- free
- function[s]
- gdxLoad
- if
- inf
- integer
- logic
- loop
- model[s]
- na
- negative
- nonnegative
- no
- not
- option[s]
- or

- ord
- parameter[s]
- positive
- procedure[s] (deprecated)
- prod
- put
- put_utility/put_utilities
- putclear
- putclose
- putfmcl
- puthd
- putheader
- putpage
- puttitle
- puttl
- repeat
- sameas
- sand
- scalar[s]
- semicont
- semiint
- set[s]
- singleton
- smax
- smin
- solve
- sor
- sos1
- sos2
- sum
- system
- table[s]
- then∗
- undf
- until
- variable[s]

- while
- xor
- yes

Attention

Some of the keywords above can actually be used as an identifier (e.g. `sameas`). But if they get used as identifier, their built-in meaning as part of the GAMS language can not be accessed anymore.

Note

The words marked with $*$ in the list above are no reserved words by default. However, they get a special meaning if the dollar control option $onEnd is set.

The following list shows words which have a special meaning in GAMS (e.g. they are part of the solve statement), but can be used as identifiers anyway:

- eq
- eqv
- ge
- gt
- imp
- le
- lt
- maximizing
- minimizing
- ne
- scenario
- using

The reserved non-alphanumeric symbols are:

- ..
- =l=
- =g=

4.22.4.3 Identifiers

Identifiers are the names given to sets, parameters, variables, models, etc. GAMS requires an identifier to start with a letter followed by more letters or digits. The length of an identifier is currently limited to 63 characters. Identifiers may only contain alphanumeric characters (letters or numbers) or underscores (_). Examples of legal identifiers are:

```
a   a15   revenue   x0051
```

Note that the following identifiers are incorrect:

```
15   $casg      milk&meat
```

Attention

A name used for one data type cannot be reused for another.

4.22.4.4 Labels

Labels are set elements. They may be up to 63 characters long and may be used in quoted or unquoted form.

The unquoted form is simpler to use but places restrictions on characters allowed, in that any unquoted label must start with a letter or digit and can only be followed by letters, digits, underscores (_) or the sign characters + and -. Examples of valid unquoted labels are:

```
Phos-Acid      1986      1952-53   A
September      H2S04      Line-1
```

Quotes can be used to delimit labels. Quoted labels may begin with and include *any* legal character. Either single or double quotes may be used but the closing quote has to match the opening quote. A label quoted with double quotes may contain a single quote (and vice versa). Most experienced users avoid quoted labels because they can be tedious to enter and confusing to read. There are a couple of special circumstances though. If we want to make a label stand out, we could put asterisks in it and indent it. A more subtle example is that GAMS keywords may be used as labels if they are quoted. So labels like `parameter`, `put` or `while` may be used if they are quoted. Some examples of quoted labels follow:

```
'  *TOTAL*'   "MATCH"   '10%-INCR'   '12" / FOOT'   "line 1"
```

Note

- Labels do not have any numerical value. The label '1986' does not have the numerical value 1986 and the label '01' is different from the label '1'. One can access the numerical value of a label with the Set Attributes `.val` attribute.
- Leading blanks in a label are significant and preserved while trailing blanks are trimmed. So `' label1'` is different from `'label1'`, but `'label2 '` is identical to `'label2'`.
- Labels are, like the rest of the GAMS language, case insensitive. Note, however, that case insensitivity for labels applies only to ASCII characters. Labels with non-ASCII characters are case sensitive:

```
* This defines two different labels
Set i / "Ä", "ä" /;
display i;

* This gives a compilation error
Set j / "A", "a" /;
```

To summarize, set names are identifiers and set elements are labels. An overview of the rules for constructing identifiers and labels is given in the following table.

	Identifiers	Unquoted Labels	Quoted Labels
Number of characters	63	63	63
Must begin with	A letter	A letter or a number	Any character
Permitted special characters	Underscore (_)	Underscore (_) and the characters + and –	Any but the starting quote

Table 2: Rules for constructing identifiers and labels

4.22.4.5 Text

Identifiers and set elements may also be associated with a line of descriptive text. This text is more than a comment: it is retained by GAMS and is displayed whenever results are written for the identifier.

Text may be quoted or unquoted. Quoted text may contain any character except the quote character used. Single or double quotes may be used but they must match. Text has to fit on one line and cannot exceed 255 characters in length. Text used in unquoted form must follow a number of mild restrictions. Unquoted text cannot start with a reserved word, `'..'` or `'='` and must not include semicolons `';'`, commas `','`, or slashes `'/'`. End of lines terminate a text. These restrictions are a direct consequence of the GAMS syntax and are usually followed naturally by the user. Some examples are:

```
this is text
final product shipment (tpy)
"quoted text containing otherwise illegal characters ; /,"
'use single quotes to put a "double" quote in text'
```

4.22.4.6 Numbers

Numeric values are entered in a style similar to that used in other computer languages

Attention

- Blanks cannot be used in a number: GAMS treats a blank as a separator.
- The common distinction between real and integer data types does not exist in GAMS. If a number is used without a decimal point it is still stored as a real number.

In addition, GAMS uses an extended range arithmetic that contains special symbols for infinity (`INF`), negative infinity (`-INF`), undefined (`UNDF`), epsilon (`EPS`), and not available (`NA`). The user cannot enter `UNDF`; it is only produced by an operation that does not have a proper result, such as division by zero. All the other special symbols may be entered and used as if they were ordinary numbers. For more details, see section Extended Range Arithmetic.

The following example shows various legal ways of entering numbers:

```
0       156.70    -135       .095      1.
2e10    2e+10     15.e+10    .314e5    +1.7
0.0     .0        0.         INF       -INF
EPS     NA
```

The letter `e` denotes the well-known scientific notation allowing convenient representation of very large or small numbers. For example,

```
1e-5 = 1 * 10^{-5} = 0.00001;
3.56e6 = 3.56 * 10^6 = 3,560,000;
```

Note

- GAMS uses a smaller range of numbers than many computers are able to handle. This has been done to ensure that GAMS programs will behave in the same way on a wide variety of machines, including personal computers. GAMS will create an error if a number with an absolute value greater or equal to `1.0e+300` is used.
- A number may be entered with up to 16 significant digits. The dollar control option $offDigit can be used to control the behavior if this number is exceeded.

4.22.4.7 Delimiters

As mentioned before, statements are separated by a semicolon `';'`. However, if the next statement begins with a reserved word (often called keyword in succeeding chapters), then GAMS does not require that the semicolon is used.

The characters comma `','` and slash `'/'` are used as delimiters in data lists, to be introduced later. The comma terminates a data element (as does an end-of-line) and the slash terminates a data list.

4.22.4.8 Comments

A comment is an explanatory text that is not processed or retained by the computer. There are several ways to include comments in a GAMS program.

Blank Lines

The user may freely enter blank lines to set off certain sections and enhance readability. For example, in **trnsport** there are blank lines between the different parameters:

```
Sets
     i   "canning plants"   / seattle, san-diego /
     j   "markets"          / new-york, chicago, topeka / ;

Parameters

     a(i)  "capacity of plant i in cases"
       /    seattle     350
            san-diego   600  /

     b(j)  "demand at market j in cases"
       /    new-york    325
            chicago     300
            topeka      275  / ;
```

Single Line Comments

Users may insert a single line comment on any line by placing an asterisk * in column 1. The text that follows the asterisk is the comment and may contain GAMS reserved words, messages or any other content. It is completely ignored by the GAMS compiler. Note that several successive lines may be single line comments as in the example below.

The default asterisk * may be replaced by other symbols. GAMS provides the dollar control option $comment to customize the comment character (for more on dollar control options, see chapter Dollar Control Options). The new comment character cannot be used in column 1 as before, since now it has a special meaning. The change of comment character should be used with great care. An example can be seen here:

```
*normal comment
*next line is a deactivated GAMS statement
*  x=sum(I,z(i));
$comment !
!comment with new character
$comment *
*now we are back to how it should be
```

In the fourth line, the new comment character ! replaces the GAMS default * as the comment delimiter. Note that single line comments appear in the echo print of the GAMS output as numbered lines. For details see section The Echo Print of the Input File.

Block Comments

For longer comments special 'block' delimiters may be used that cause GAMS to ignore an entire section of the program. The dollar control option $ontext marks the beginning of the comment block and the option $offtext marks the end. Note that the $ symbol must be in the first character position. The example below illustrates the use of the block comment and also contains some useful information. For more on dollar control options, see chapter Dollar Control Options.

```
$ontext
Following a $ontext directive in column 1 all lines are
ignored by GAMS but printed on the output file until the matching $offtext is encountered, also
in column 1. This facility is often used to logically remove parts of programs
that are not used every time, such as statements producing voluminous reports.
Every $ontext must have a matching $offtext in the same file
$offtext
```

Note that block comments appear in the echo print without line numbers. For details see section The Echo Print of the Input File.

End-of-Line Comments

Comments may also be placed at the end of a line that contains GAMS code. The dollar control option $onEolCom activates end-of-line comments. The default symbol to indicate that the comment begins is a double exclamation mark !!. This symbol may be reset with the option $eolCom followed by the desired symbol which may be one character or a two-character sequence. The following example serves as illustration. For more on dollar control options, see chapter Dollar Control Options.

```
Scalar x /0/;
$onEolCom
x=x+1;        !! eol comment
x = x         !! eol comment in line of GAMS statement, where the GAMS statement continues  to the nex
   +1;
$eolCom &&
x=x+1;        && eol comment with new symbol
```

Note that the option to add end-of-line comments may be deactivated with the dollar control option $offEolCom. End-of-line comments appear in the echo print on the appropriate lines. For details see section The Echo Print of the Input File.

In-Line Comments

Comments may also appear *in* a line of GAMS code. The dollar control option $onInline activates in-line comments. By default, the in-line comment symbols are set to the two character pairs ' /*' and ' */', where ' /*' indicates that the in-line comment begins and ' */' indicates that the in-line comment ends. The comment may span lines till the end-of-comment characters are encountered. The in-line comment symbols may be reset with the option $inLineCom followed by the desired pair of characters. The following example serves as illustration. For more on dollar control options, see chapter Dollar Control Options.

```
Scalar x /0/;
$onInLine
x=x      /* in-line comment*/ +1;
x=x      /* in-line comment in line
            that continues to next line */
   +1;
$inLineCom /&  &/
x=x      /& in-line comment with new character &/ +1;
```

Note that the option to add in-line comments may be deactivated with the dollar control option $offInline. In-line comments appear in the echo print on the appropriate lines. For details see section The Echo Print of the Input File. Note that in-line comments may be allowed to be nested using the dollar control option $onNestCom.

Outside Margin Comments

GAMS provides the facility to define margins. The active code is within the margins, everything outside the set margins is ignored by the compiler and treated as comment. The dollar control option $onMargin activates margin marking and $offMargin deactivates it. The option $minCol is used to specify the first column, where GAMS code that is to be compiled may appear. Similarly, the option $maxCol is used to specify the last column for GAMS code. The following example shows how this works. For more on dollar control options, see chapter Dollar Control Options.

```
$ontext
         1         2         3         4         5         6
12345678901234567890123456789012345678901234567890123456789012345678901234567890
$offtext

$onMargin minCol 20 maxCol 45
Now I have          Set i plant /US, UK/     This defines i
turned on the       Scalar x / 3.145 /       A scalar example.
margin marking.     Parameter a, b;          Define some
                                             parameters.
$offMargin
```

The text before column 20 and after column 45 is treated as a comment. Note that the full content of the lines is copied to the echo print, including everything outside the margins. For details see section The Echo Print of the Input File.

Hidden Comments

Finally, GAMS also allows hidden comments, that are not copied to the echo print of the GAMS output file. These comments contain information that is only relevant for the person manipulating the file. They are single line comments starting with the dollar control option $hidden. An example follows. For more on dollar control options, see chapter Dollar Control Options.

```
$hidden a comment I do not want in LST file
set a /a1,a2/;
set b /a2,c2/;
set c /a3,d3/;
```

4.22.5 Summary

This completes the discussion of the components of the GAMS language. Many unfamiliar terms used in this chapter are further explained in the Glossary.

4.23 Set Definition

4.23.1 Introduction

Sets are fundamental building blocks in any GAMS model. They allow the model to be succinctly stated and easily read. In this chapter we will introduce how sets are declared and initialized. More advanced set concepts, such as assignments to sets, and lag and lead operations are covered in the chapters Dynamic Sets and Sets as Sequences. The topics discussed in this chapter will be enough to provide a good start on most models. We will introduce simple sets, subsets, multi-dimensional sets, singleton sets and the universal set. The chapter will be concluded by a topic on domain checking, a very important feature of GAMS, and a section about Domain Defining Symbol Declarations.

4.23.2 Simple Sets

Using common mathematical notation, a set S that contains the elements a, b and c is written as:

$$S = \{a, b, c\}$$

Using GAMS notation, the same set is defined in the following way:

```
Set S / a, b, c /;
```

The set statement begins with the keyword `set`, `S` is the name of the set, and its members are `a`, `b`, and `c`. They are labels, but are often referred to as elements or members.

4.23.2.1 Defining a Simple Set: The Syntax

In general, the syntax for *simple* sets in GAMS is as follows:

```
set[s] set_name ["text"] [/element [text] {,element [text]} /]
     {,set_name ["text"] [/element [text] {,element [text]} /] } ;
```

`Set[s]` is the keyword that indicates that this is a set statement. `Set_name` is the internal name of the set in GAMS, it is an identifier. The optional explanatory text may be used to describe the set or a specific set element for future reference and to ease readability. The list of set elements is delimited by forward slashes. `Element` is the name of the set element(s). Note that each element in a set must be separated from other elements by a comma or by an end-of-line, and each element is separated from any associated text by a blank.

Consider the following example from the Egyptian fertilizer model **[FERTS]**, where the set of fertilizer nutrients could be written as

```
Set cq "nutrients" / N,  P2O5 /;
```

or as

```
Set cq "nutrients" / N
                     P2O5  /;
```

The order in which the set members are listed is usually not important. However, if the members represent, for example, time periods, then it may be useful to refer to the *next* or *previous* member. There are special operations to do this, and they are discussed in chapter Sets as Sequences: Ordered Sets. For now, it is enough to remember that the order in which set elements are specified is not relevant, unless and until some operation implying order is used. At that time, the rules change, and the set becomes what we will later call an *ordered set*.

Note

- The data statement, i.e. specification of set elements in forward slashes can be omitted. In such cases a set is declared without being defined.
- More than one set may be declared and defined in one set statement. Examples are given in subsection Declaring Multiple Sets below.

4.23.2.2 Illustrative Examples

Consider the following example based on the model [**SHALE**]:

```
Set cf "final products" / syncrude "refined crude (mil bbls)"
                          lpg      "liquefied petroleum gas (million bbls)"
                          ammonia  "ammonia (mil tons)"
                          coke     "coke (mil tons)"
                          sulfur   "sulfur (mil tons)" /;
```

The set statement is introduced with the keyword `set`, the name of the set is `cf` and the explanatory text `"final products"` describes the set. The set has five elements with explanatory texts that contain details of the units of measurement.

Usually sets are declared and defined once and then referenced in the model. There are two exceptions: the dollar control option onMulti allows adding more elements later, and dynamic sets. For details on dynamic sets, see chapter Dynamic Sets. The following code sightly varies the previous example to demonstrate the option `$onMulti:`

```
Set cf "final products"      / syncrude "refined crude (mil bbls)"
                               lpg      "liquefied petroleum gas (million bbls)"
                               ammonia  "ammonia (mil tons)" /;
$onmulti
Set cf "more final products" / coke     "coke (mil tons)"
                               sulfur   "sulfur (mil tons)" /;
```

After `$onmulti` additional elements are added to the set `cf`. Note that without the dollar control option `$onMulti` that would generate an error as per default a symbol can have at most one data statement.

4.23.2.3 Sequences as Set Elements

The asterisk `'*'` plays a special role in set definitions. It is used to relieve the tedium of typing a sequence of elements for a set, and to make intent clearer. For example, in a simulation model there might be ten annual time periods from 1991 to 2000. Instead of typing ten years, the elements of this set can be written as:

```
Set t "time" / 1991 * 2000 /;
```

This means that the set includes the ten elements `1991`, `1992`, ..., `2000`. GAMS builds up these label lists by looking at the differences between the two labels. If the only characters that differ are digits, with the number `L` formed by these digits in the left and `R` in the right, then a label is constructed for every integer in the sequence `L` to `R`. Any non-numeric differences or other inconsistencies cause errors.

The following example illustrates the most general form of the *'asterisked'* definition:

```
Set g1 / a1bc * a20bc /;
```

Note that this is not the same as:

```
Set g2 / a01bc * a20bc /;
```

Both sets have 20 members, but they have only 11 members in common.

Lists in decreasing order are also possible:

```
Set y "years in decreasing order" / 2000 * 1991 /;
```

As a last example, the following set definitions are both illegal because they are not consistent with the rule given above for making lists:

```
Set illegal1 / a1x1 * a9x9 /
    illegal2 / a1 * b9 /;
```

4.23.2.4 Declaring Multiple Sets

The keyword set does not need to be used for each set, rather only at the beginning of a group of sets. It is often convenient to put a group of set declarations (and definitions) together at the beginning of the program. When this is done the set keyword needs only be used once. Those who prefer to intermingle set declarations with other statements, have to use a new set statement for each additional group of sets. Note that the keywords `set` and `sets` are equivalent. The following example below shows how two sets can be declared together. Note that the semicolon is used only after the last set is declared.

```
Sets s "Sectors" / manuf, agri, services, government /
     r "Regions" / north, eastcoast, midwest, sunbelt / ;
```

4.23.2.5 Using Previously Defined Sets in Set Definitions

The following notation allows previously defined sets to be used in a new set definition:

```
Set i / i1 * i4 /
    j / j6 * j9 /
    k / #i, set.j /;
```

The set `k` contains all elements of the sets `i` and `j`. Note that the hash sign '#' followed by a set name is a shorthand for referring to all the elements in a set. The notation `set.set_name` works identically and is just a different way to refer to all elements in a previously defined set.

4.23.3 The Alias Statement: Multiple Names for a Set

Sometimes it is necessary to have more than one name for the same set. In input-output models for example, each commodity may be used in the production of all other commodities and it is necessary to have two names for the set of commodities to specify the problem without ambiguity. In the general equilibrium model [**ORANI**], the set of commodities `c` is written as

```
Set c "Commodities" / food, clothing /;
```

A second name for the set `c` is established with either of the following statements:

```
Alias (c, cp) ;
Alias (cp, c) ;
```

Here `cp` is the new set name that can be used instead of the original set name `c`.

Note

The newly introduced set name may be used as an alternative name for the original set; the associated set will always contain the same elements as the original set.

With the `alias` statement more than one new name may be introduced for the original set:

```
Alias (c,cp, cpp, cppp);
```

Here `cp`, `cpp`, `cppp` are all new names for the original set `c`.

Note

The order of the set names in the alias statement does not matter. The only restriction is that exactly one of the sets in the statement must be defined earlier. All the other sets are introduced by the alias statement.

Typical examples for the usage of aliases are problems where transportation costs between members of one set have to be modeled. The following code snippet is adapted from the Andean fertilizer model [**ANDEAN**]:

```
Set i "plant locations" / palmasola, pto-suarez, potosi, baranquill, cartagena /;
Alias(i,ip);

Table tran(i,i) "transport cost for interplant shipments (us$ per ton)"
              palmasola    pto-suarez     potosi  baranquill
 pto-suarez       87.22
 potosi           31.25         55.97
 baranquill       89.80        114.56      70.68
 cartagena        89.80        114.56      70.68        5.00
;
Parameter mui(i,ip) "transport cost: interplant shipments (us$ per ton)";
mui(i,ip) = (tran(i,ip) + tran(ip,i));
```

The alias statement introduces `ip` as another name for the set `i`. The table `tran` is two-dimensional and both indices are the set `i`. The data for the transport cost between the plants is given in this table; note that the transport costs are given only for one direction here, i.e. the costs from `pto-suarez` to `palmasola` are explicitly specified in the table while the costs in the opposite direction are not given at all. The parameter `mui` is also two-dimensional and both indices refer to the set `i`, but this time the alias `ip` is used in the second position. The parameter `mui` is defined with the assignment statement in the next line: `mui` contains the transport costs from one plant location to the other, in both directions. Note that if `mui` were defined without the alias, then all its entries would have been zero. For other examples where aliases are used, see sections The Universal Set and Finding Sets from Data below.

4.23.4 Subsets

It is often necessary to define sets whose members must all be members of some larger set. The syntax is:

```
set set_ident1(set_ident2) ;
```

Here `set` is the keyword indicating that this is a set statement, and `set_ident1` is a subset of the larger set `set_ident2`. The larger set is also called superset.

For instance, we may wish to define the sectors in an economic model following the style in [**CHENERY**].

```
Set i    "all sectors"        / light-ind, food+agr, heavy-ind, services /
    t(i) "traded sectors"     / light-ind, food+agr, heavy-ind /
    nt   "non-traded sectors" / services /;
```

Some types of economic activity, for example exporting and importing, may be logically restricted to a subset of all sectors. In order to model the trade balance we need to know which sectors are traded, and one obvious way is to list them explicitly, as in the definition of the set `t` above. The specification `t(i)` means that each member of the set `t` must also be a member of the set `i`. GAMS will enforce this relationship, which is called domain checking. Obviously, the order of declaration and definition is important: the membership of `i` must be known before `t` is defined, otherwise checking cannot be done.

Note

All elements of the subset must also be elements of the superset.

It is legal but unwise to define a subset without reference to the larger set, as is done above for the set `nt`. In this case domain checking cannot be performed: if `services` were misspelled no error would be marked, but the model may give incorrect results. Hence, it is recommended to use domain checking whenever possible. It catches errors and allows to write models that are conceptually cleaner because logical relationships are made explicit.

An alternative way to define elements of a subset is with assignments:

```
Set i    "all sectors"    / light-ind, food+agr, heavy-ind, services /
    t(i) "traded sectors" / light-ind,  heavy-ind /;
t('food+agr') = yes;
```

In the last line the element `food+agr` of the set `i` is assigned to the subset `t`. Assignments may also be used to *remove* an element from a subset:

```
t('light-ind') = no;
```

Note that `yes` and `no` are reserved words in GAMS. Note further that if a subset is assigned to, it then becomes a dynamic set. For more on assignments in GAMS in general, see section The Assignment Statement.

Attention

A subset can be used as a domain in the declaration of other sets, variables, parameters and in equations as long as it is no dynamic set.

This completes the discussion of sets in which the elements are simple. This is sufficient for many GAMS applications. However, there are a variety of problems for which it is useful to have sets that are defined in terms of two or more other sets.

4.23.5 Multi-Dimensional Sets

It is often necessary to provide mappings between elements of different sets. For this purpose, GAMS allows the use of multi-dimensional sets. For the current maximum number of permitted dimensions, see Dimensions. The next two subsections explain how to express one-to-one and many-to-many mappings between sets.

4.23.5.1 One-to-one Mapping

Consider a set whose elements are pairs: $A = \{(b, d),\ (a, c),\ (c, e)\}$. In this set there are three elements and each element consists of a pair of letters. This kind of set is useful in many types of modeling. For example, in the world aluminum model [**ALUM**] a port has to be associated with a nearby mining region

```
Set i       "mining regions"     / china, ghana, ee+ussr, s-leone /
    n       "ports"              / accra, freetown, leningrad, shanghai /
    in(i,n) "mines to ports map" / china  .shanghai
                                   ghana  .accra
                                   ee+ussr.leningrad
                                   s-leone.freetown /;
```

Here `i` is the set of mining regions, `n` is the set of ports and `in` is a two dimensional set that associates each port with a mining region. The dot between `china` and `shanghai` is used to create one such pair. Blanks may be used freely around the dot for readability. The set `in` has four elements, and each element consists of a region-port pair. The notation `(i,n)` after the set name `in` indicates that the first member of each pair must be a member of the set `i` of mining regions, and that the second must be in the set `n` of ports. GAMS will domain check the set elements to ensure that all members belong to the appropriate sets.

4.23.5.2 Many-to-Many Mapping

A many-to-many mapping is needed in certain cases. Consider the following sets:

```
Set  i         / a, b /
     j         / c, d, e /
     ij1(i,j)  / a.c, a.d /
     ij2(i,j)  / a.c, b.c /
     ij3(i,j)  / a.c, b.c, a.d, b.d /;
```

Here the set `ij1` presents a *one-to-many* mapping where one element of the set `i` maps onto many elements of the set `j`. The set `ij2` represents a *many-to-one* mapping where many elements of the set `i` map onto one element of the set `j`. The set `ij3` is the most general case: a *many-to-many* mapping where many elements of the set `i` map to many elements of the set `j`.

These sets may be written compactly as:

```
Set  i        / a, b /
     j        / c, d, e /
     ij1(i,j) / a.(c,d) /
     ij2(i,j) / (a,b).c /
     ij3(I,j) / (a,b).(c,d) /;
```

The parenthesis provides a list of elements that is expanded when creating pairs. Note that the dot '.', if used like above, acts as *product operator* and supports building the Cartesian product of sets.

Attention

> When complex sets like this are created, it is important to check that the desired set has been obtained. The checking can for example be done be done by using a display statement.

GAMS provides more notation to define multi-dimensional sets in a succinct way. As introduced above the hash sign `'#'` followed by a set name is a shorthand for referring to all the elements in a set. The matching operator `':'` may be used to map ordered sets. This operator is similar to the product operator `'.'`. However, in this case elements are matched pairwise by mapping elements with the same order number. The examples below demonstrate these concepts.

```
Set
i         / a, b /
j         / c, d, e /

ij4a(i,j) / a.#j /
ij4b(i,j) / a.c, a.d, a.e /

ij5a(i,j) / #i.#j /
ij5b(i,j) / a.c, a.d, a.e, b.c, b.d, b.e /

ij6a(i,j) / #i:#j /
ij6b(i,j) / a.c, b.d /;
```

Note that set names that differ only by the last letter denote identical sets. For example, set `ij4a` is identical to set `ij4b`. Observe that set `i` has two elements and set `j` has three elements, where `e` is the element with the highest order. Set `ij6a` is an ordered mapping of all elements of set `i` to all elements of set `j`. However, since there is a mismatch in the number of elements, element `e` is not mapped to.

These concepts may be generalized to sets with higher dimensions. Mathematically, these are called 3-tuples, 4-tuples, or more generally, n-tuples. Some examples for the compact representation of sets of n-tuples using combinations of dots, parentheses, and commas are shown in Table 1.

Compact Notation	Result
(a,b).c.d	a.c.d, b.c.d
(a,b).(c,d) .e	a.c.e, b.c.e, a.d.e, b.d.e
(a.1*3).c	(a.1, a.2, a.3).c or a.1.c, a.2.c, a.3.c
1*3. 1*3. 1*3	1.1.1, 1.1.2, 1.1.3, ..., 3.3.3

Table 1: Examples for compact representation of multi-dimensional sets

Note that the asterisk may also be used in conjunction with the dot. Recall that the elements of the list 1*4 are $\{1, 2, 3, 4\}$.

A powerful and very compact way to define multi-dimensional sets is with a special option that takes an identifier as value and carries out identifier operations like index matching using the matching operator ':'. The following example illustrates the method.

```
Set i / i1*i4 /
    j / j1*j5 /
    k / k1,k2 /
    h / h1*h3 /;

Set b(i,j,k), c(i,j,k,h);

Option b(i:j,k), c(b:h);
display b, c;
```

The set b is a three-dimensional set, the option statement specifies which permutations of the elements of i, j, and k are elements of b. The matching operator ':' is between i and j, so we must first match the elements of the sets i and j. That gives us the the first two positions. For the third position we cycle through all elements of the set k. This results in the following elements for the set b:

```
i1.j1.k1, i1.j1,k2, i2.j2.k1, ... , i4.j4.k2
```

The set c is a four-dimensional set. Note that the first three dimensions are identical to the domain of the set b. The option statement specifies that in the first three positions we will have elements of the set b and and these are matched with the elements of the set h which are in the fourth position. Now, the set h has only three elements, so only the first three elements of the set b are matched with the members of the set h. This results in the following set:

```
i1.j1.k1.h1, i1.j1.k2.h2, i2.j2.k1.h3
```

As recommended above, it is important to always check whether the multi-dimensional sets generated with compact statement like these are indeed the sets that were intended.

For more sophisticated examples of how to use the matching operator within an option statement please see section Index Matching .

4.23.5.3 The Table Format for Multi-Dimensional Sets

An alternative way to declare multi-dimensional sets is with tables. We show by example how tables may be used in the context of set definitions:

```
Set origins      / Berlin, Paris /
    destinations / London, Chicago, Budapest /
    linked_1(origins,destinations) "cities linked by railways"
                 / Berlin.London, Berlin.Budapest,
                   Paris .London, Paris .Budapest /;

Set Table linked_2(origins,destinations)
           London       Chicago     Budapest
Berlin       yes          no          yes
Paris        yes                      yes  ;
```

The set `linked_1` is a two-dimensional set that is defined with the dot notation introduced above. The set `linked_2` is the same set defined using the table notation: the keyword `set` is followed by the keyword `table` and the name of the set with its domain. The table itself consists of the elements of the first index in the first column, the elements of the second index in the first row, and the data in the grid positions. Note that the keyword `yes` indicates that a label combination is part of the two-dimensional set and the keyword `no` or a blank indicates that the label combination is not contained in the new set. Please see section Tables for detailed requirements for inputting data in the table format.

Alternatively, the multi-dimensional set may be declared first without any elements, and the elements are added later in a separate table statement:

```
Set   origins      / Berlin, Paris /
      destinations / London, Chicago, Budapest /
      linked_2(origins,destinations) "cities linked by railways";
Table linked_2(origins,destinations)
           London       Chicago     Budapest
Berlin       yes          no          yes
Paris        yes                      yes;
```

Instead of the keywords `yes` and `no` users may also use numbers to specify membership in the two-dimensional set: nonzero numeric entries mean that a label combination is part of the set and zero or a blank indicates that the label combination is not contained in the set.

4.23.5.4 Projection and Aggregation of Sets

In GAMS, projection and aggregation operations on sets can be performed in two different ways: with an option statement and with an assignment. For a detailed discussion, see section Projection and Aggregation of Sets and Parameters.

4.23.6 Singleton Sets

A *singleton set* in GAMS is a special set that has at most one element (zero elements are allowed as well). Like other sets, singleton sets may have a domain with several dimensions. For the current maximum number of permitted dimensions, see Dimensions. Singleton sets are declared and defined with the keyword `singleton` that acts as a modifier to the keyword `set:`

```
Set            i      / a, b, c /;
Singleton Set  j      / d       /
               k(i)   / b       /
               l(i,i) / b.c     /;
```

The sets `j`, `k` and `l` are declared as singleton sets, each of them has just one element. The set `k` is a subset of the set `i` and the set `l` is a two-dimensional set.

Note that a data statement for a singleton set with more than one element will create a compilation error:

```
   1  Singleton Set s / s1*s3 /;
****                           $844
   2  display s;

Error Messages
844  Singleton with more than one entry (see $onStrictSingleton)
```

It also possible to assign an element to a singleton set. In this case the singleton set is automatically cleared of the previous element first. For example, adding the following line to the code above will result in set `k` containing only element `a` after execution:

```
k('a') = yes;
```

The dollar control option offStrictSingleton may be used to allow sets that are declared as singleton sets to have more than one element in compile time definitions. However, in this case only the first listed element is a valid element of the set. Note that the value of zero for the command line parameter strictSingleton has the same effect for execution time definitions of singleton sets via assignment statements.

For more on dollar control options, see chapter Dollar Control Options. For more on GAMS command line parameters,see chapter The GAMS Call and Command Line Parameters. For more on compilation errors, see section Compilation Errors.

Singleton sets can be especially useful in assignment statements since they do not need to be controlled by a controlling index or an indexed operator like other sets. Consider the following examples:

```
Set            i      / a, b, c /;
Singleton Set  k(i)   / b /
               h(i)   / a /;
Parameter      n(i)   / a 2, b 3, c 5 /;
Scalar z1, z2;

z1 = n(k);
z2 = n(k) + 100*n(h);
```

The singleton sets `k` and `h` are both subsets of the set `i`. The parameter `n` is defined over the set `i`. The scalar `z1` is assigned a value of the parameter `n` without naming the respective label explicitly in the assignment. It is already specified in the definition of the singleton set `k`. The assignment statement for the scalar `z2` contains an expression where the singleton sets `k` and `h` are referenced without a controlling index or an indexed operation.

Note

Singleton sets cannot be used as domains.

4.23.7 The Universal Set: * as Set Identifier

GAMS provides the *universal set* denoted by '*' for cases where the user wishes not to specify an index but have only a placeholder for it. The following examples show two ways how the universal set is introduced in a model. We will discuss the advantages and disadvantages of using the universal set later. The first example is from the production and inventory model [**ROBERT**]:

```
Sets   r          "raw materials"  / scrap, new /;
Table  misc(*,r)  "other data"
           scrap  new
max-stock    400  275
storage-c     .5    2
res-value     15   25;
```

A `table` is an input format for the data type `parameter` and has at least two dimensions. For details see section Tables. In our example, the first index is the universal set '*' and the second index is the previously defined set `r`. Since the first index is the universal set any entry whatsoever is allowed in this position. In the second position elements of the set `r` must appear, they are domain checked, as usual.

The second example illustrates how the universal set is introduced in a model with an alias statement.

```
Alias (new_universe,*);
Set k(new_universe)    / Chicago / ;
```

The alias statement links the universal set with the set name `new_universe`. Set `k` is a subset of the universal set and `Chicago` is declared to be an element of `k`. Any item may be added freely to `k`.

The universal set is particularly useful for generating reports, since it allows the use of any labels without having to define special sets for them. For an example, see section Set Attributes below. For more on report writing, see chapter The Put Writing Facility.

Attention

> It is recommended to not use the universal set for data input, since there is no domain checking and thus typos will not be detected and data that the user intends to be in the model might actually not be part of it.

Observe that in GAMS a simple set is always regarded as a subset of the universal set. Thus the set definition

```
Set i / i1*i10 /;
```

is the same as

```
Set i(*)  / i1*i10 /;
```

GAMS follows the concept of a domain tree for domains in GAMS. It is assumed that a set and its subset are connected by an arc where the two sets are nodes. Now consider the following one dimensional subsets:

```
Set i, ii(i), j(i), jj(j), jjj(jj);
```

These subsets are connected with arcs to the set `i` and thus form a *domain tree* that is rooted in the universe node '*'. This particular domain tree may be represented as follows:

```
* - i - ii
      |
      - j - jj - jjj
```

Note that with the construct `i(jjj)` we may access `ii` iterating through the members of `jjj`. For an example, see domain tree in the loop statement.

Observe that the universal set is assumed to be *ordered* and operators for ordered sets such ord, lag and lead may be applied to any sets aliased with the universal set.

4.23.8 Set and Set Element Referencing

Sets or set elements are referenced in many contexts, including assignments, calculations, equation definitions and loops. Usually GAMS statements refer to the whole set or a single set element. In addition, GAMS provides several ways to refer to more than one, but not all elements of a set. In the following subsections we will show by example how this is done. GAMS also has set functions that specifically reference sets and are introduced in the chapter about logical conditions.

4.23.8.1 Referencing the Whole Set

Most commonly whole sets are referenced as in the following examples:

```
Set i / i1*i100 /;
Parameter k(i);
k(i) = 4;
Scalar z;
z = sum(i, k(i));
```

The parameter `k` is declared over the set `i`, in the assignment statement in the next line *all* elements of the set `i` are assigned the value 4. The scalar `z` is defined to be the sum of *all* values of the parameter `k(i)`.

4.23.8.2 Referencing a Single Element

Sometimes it is necessary to refer to specific set elements. This is done by using single or double quotes around the label(s). We may add the following line to the example above:

```
k('i77') = 15;
```

This statement changes the value of `k('i77')` to 15, all the other values of `k` remain 4.

4.23.8.3 Referencing a Part of a Set

There are multiple ways to restrict the domain to more than one element, e.g. subsets, conditionals and tuples. Suppose we want the parameter `k` from the example above to be assigned the value 10 for the first 8 elements of the set `i`. The following two lines of code illustrate how easily this may be accomplished with a subset:

```
Set j(i) / i1*i8 /;
k(j) = 10;
```

First we define the set `j` to be a subset of the set `i` with exactly the elements we are interested in. Then we assign the new value to the elements of this subset. The other values of the parameter `k` remain unchanged. For examples using conditionals and tuples, see sections Restricting the Domain: Conditionals and Restricting the Domain: Tuples respectively.

4.23.9 Set Attributes

A GAMS set element has several numbers attached to it. These values are called *attributes*; they may be recovered during execution. The attributes are listed in Table 3.

Set Attribute	Symbol	Description
Position	.pos	Element position in the current set (set does not have to be ordered), starting with 1.
Ord	.ord	Same as .pos but for ordered sets only.
Offset	.off	Element position in the current set minus 1. So .off = .pos - 1 (set does not have to be ordered).
Reverse	.rev	Reverse element position in the current set, so the value for the last element is 0, the value for the penultimate is 1, etc. (set does not have to be ordered)
Unique Element	.uel	Element position in the unique element list. For details see section Ordered and Unordered Sets
Length	.len	Length of the set element name (a count of the number of characters).
Text Length	.tlen	Length of the set element text (a count of the number of characters).
Value	.val	If a set element is a number, this attribute gives the value of the number. For extended range arithmetic symbols, the symbols are reproduced. If a set element is a string that is not a number, then this attribute is not defined and trying to use it results in an error.
Text Value	.tval	If a set element text is a number, this attribute gives the value of the number. For extended range arithmetic symbols, the symbols are reproduced. If a set element text is a string that is not a number, then this attribute is not defined and trying to use it results in an error.
First set element	.first	Returns 1 for the first set element, otherwise 0.
Last set element	.last	Returns 1 for the last set element, otherwise 0.

Table 3: Set Attributes

The attributes may be accessed with an assignment statement:

```
data(set_name) = set_name.attribute ;
```

Here data is a parameter, set_name is the name of the set and .attribute is one of the attributes listed above. The following example serves as illustration:

```
Set       id             "example set"            / Madison 'Wisconsin', tea-time '5', '-inf', '-7',
Parameter report(id,*)   "set attribute values";

report(id,'position')    = id.pos ;
report(id,'reverse')     = id.rev ;
report(id,'offset')      = id.off ;
report(id,'length')      = id.len ;
report(id,'textLength')  = id.tlen ;
report(id,'first')       = id.first;
report(id,'last')        = id.last ;

display report;
```

The parameter report is declared to have two dimensions with the set id in the first position and the universal set in the second position. In the following seven statements the values of report are defined for seven entries of the universal set. Note how the flexibility of the universal set is used here to make reporting easy. The display statement generates the output that follows.

```
----     11 PARAMETER report  set attribute values

            position     reverse      offset      length  textLength       first        last

Madison        1.000       4.000                   7.000       9.000       1.000
tea-time       2.000       3.000       1.000       8.000       1.000
-inf           3.000       2.000       2.000       4.000
-7             4.000       1.000       3.000       2.000
13.14          5.000                   4.000       5.000                                1.000
```

4.23.10 Finding Sets from Data

Sometimes it is desirable to find a set from the available data in order to use it later in the model. We will show by example how this may be accomplished using the alias statement, the universal set and conditionals. Suppose we have only the data related to the transportation model [**TRNSPORT**] and we want to identify the sets. We can tell from the data that there are two sets that we are interested in. First, we define these two sets as aliases of the universal set, which means that no elements are specified:

```
Alias(sources, places, *);
```

Then we enter the data that contain an indicator of which set elements are valid entries in the sets to be computed. We use the table format.

```
Table trandata (sources,places)    "data from spreadsheet"
                     Newyork     Chicago    totalsupply
      Seattle          2.5          1.7         350
      Sandiego         2.5          1.8         300
      totalneed        325           75                              ;
```

Next we define subsets that we will need in the calculations that follow:

```
Set  source(sources)       "sources in spreadsheet data"
     destination(places)   "destination in spreadsheet data";
```

Now we have everything that we need to do the calculation using the data on hand. In our case, a label qualifies as an element of the set `source` if it has an entry for `totalsupply` in the table above, and a label is an element of the set `destination` if it has an entry for `totalneed` in the table `trandata`:

```
source(sources)$(trandata(sources,"totalsupply"))    =  yes;
destination(places)$(trandata("totalneed", places )) =  yes;
```

These conditional assignments define the elements of the sets `source` and `destination`. From this point on these sets may be used in the model. However, note that the resulting sets are dynamic sets. Hence they cannot be used as domains in *declaration* statements of other sets, parameters, variables and equations. But they may be referenced and used in equation *definitions*.

Such computations may for example be useful if the user gets a data table from elsewhere and needs to specify the sets. Alternatively, if the data is available in gdx format, the dollar control option load provides functionality to project sets from data contained in a GDX file.

See also section Implicit Set Definition (or: Domain Defining Symbol Declarations).

4.23.11 Domain Checking

The GAMS compiler performs a check to ensure that each label quoted as a member of a set is indeed an element of the respective set, and each element defined in a subset is in fact a member of the superset. This screening for consistency is called *domain checking*. It is done whenever a domain is referenced, be it in set, variable, parameter or equation declarations and definitions, or in assignments. The following examples serve as illustration.

```
Set   i     "all cities"      / Lima, Toronto, Wuhan, Shanghai /
      as(i) "Asian cities"    / Wuhan, Shanhai, Calcutta /
      am    "American cities" / Lima, Toront /;
```

The set `as` is declared to be a subset of the set `i`, therefore domain checking will test every label for inconsistencies. It will catch two errors: there is a typo in `Shanhai` and `Calcutta` is not a member of the set `i`, so it cannot legally be a member of a subset.

```
   1  Set   i     "all cities"      / Lima, Toronto, Wuhan, Shanghai /
   2        as(i) "Asian cities"    / Wuhan, Shanhai, Calcutta /
****                                            $170      $170
**** 170  Domain violation for element
   3        am    "American cities" / Lima, Toront /;
```

The user can rectify the spelling error, and either delete `Calcutta` from the subset `as` or add it to the superset `i`. The following line will pass domain checking:

```
Set   as(i) "Asian cities"    / Wuhan, Shanghai /;
```

Note that `am` is not declared as a subset of the set `i` even though it apparently should contain cities contained in `i`. Hence, `am` cannot be domain checked and the typo in `Toront` will go undetected. This has consequences for the next line:

```
Parameter pam(am) "population in millions"  / Lima 8.9, Toronto 5.6 /;
```

In this parameter definition the domain of the parameter `pam` is the set `am`. GAMS will report an error here, since domain checking does not recognize the label `Toronto`. `Toront`, as specified in the definition of the set `am` above would be accepted.

A further example for domain checking concerns multi-dimensional domains where the user accidentally switches the positions of the indices:

```
Parameter  h(as,am) / Wuhan.Lima  10, Wuhan.Toronto 12, Shanghai.Lima 7/;
Parameter  d(as,am);
d(as,am) = 5*h(am,as) + 78;
```

Observe that we assume that the typo in the label `Toronto` has been rectified. The parameter `h` is defined over the domain `(as,am)`. However, in the assignment statement in the last line above, it is referenced with the domain `(am,as)`. This mistake is caught by domain checking and an error is reported.

As we have seen in the definition of the set `am` above, domain checking is not compulsory. If the following statement is entered, GAMS makes no assumptions about `rho` until further information is provided.

```
set       t   years         / 1988 * 1995 /;
Parameter rho discount rate ;
```

The modeler may later choose to domain check `rho` by continuing the definition with the following line:

```
Parameter rho(t)  / 1988 0.07, 1989*1994 0.10, 1995 0.09 /;
```

Alternatively, the modeler may choose not to domain check the paramter `rho`, as is shown in the deliberately nonsensical (but legal) statement that follows:

```
Parameter rho / 1988.January 0.07, strategy-1.cost 44, cat.capacity 99 /;
```

If a parameter is not domain-checked, the only restriction is that the dimensionality must be constant. Once the number of labels per data item has been established it is frozen; to refer to the parameter differently is an error.

Note

Domain checking is automatic; it is only suppressed in two cases:

1. The index is the universal set or a set aliased to the universal set, see the examples above.
2. The dollar control option $onWarning is used. It has the effect that warnings rather than errors are reported for domain violations.

We urge modelers to use domain checking whenever possible. It catches errors and allows users to write models that are conceptually cleaner because logical relationships are made explicit.

Note that the dollar control option $load is available in several variations to enable domain checking when loading data from a GDX file. For details, see $loadDC, $loadDCM and $loadDCR and chapter GAMS Data eXchange (GDX).

4.23.12 Implicit Set Definition (or: Domain Defining Symbol Declarations)

As seen above, sets can be defined through data statements in the declaration. Alternatively, sets can be defined implicitly through data statements of other symbols which use these sets as domains. This is illustrated in the following example, which is derived from the **[TRNSPORT]** model:

```
Set
   i 'canning plants'
   j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5      1.7     1.8
   san-diego       2.5      1.8     1.4;

Display i,j;
```

Note the < signs in the domain list of the declaration of `d` (`d(i<,j<)`). These signal, that the set `i` will contain all elements which define the first dimension of symbol `d` and that the set `j` will contain all elements which define the second dimension of symbol `d`, respectively. So, this is the output of the `Display` statement at the end:

```
----     10 SET i  canning plants

seattle  ,    san-diego

----     10 SET j  markets

new-york,    chicago ,    topeka
```

This syntax is not limited to the table statement, but can be used with any symbol declaration. Also, one domain set can be defined through multiple symbols using the same domain, when using the dollar control option onMulti:

```
Set
   food
   fruits(food<)    / apple, orange       /
$onMulti
   vegetable(food<) / carrot, cauliflower /
   meat(food<)      / beef, pork          /;

Display food;
```

This is the output of the `Display` statement:

```
----      8 SET food

apple      ,    orange     ,    carrot     ,    cauliflower,    beef       ,    pork
```

Note

If the < sign is used to mark a declaration as "domain defining", this attribute is not limited to the data statement following this declaration, but also influences other ways to define data at compile time like the dollar control option load, as shown in the following example:

```
Set
   i 'canning plants'
   j 'markets';

Parameter d(i<,j<) 'distance in thousands of miles';

$gdxIn data.gdx
$load d
```

Attention

Only non-zero elements in a symbol will add elements to an implicitly defined set. This is illustrated in the following two examples.

```
Set
   i 'canning plants'
   j 'markets';

Table d(i<,j<) 'distance in thousands of miles'
              new-york  chicago  topeka
   seattle         2.5              1.8
   san-diego       2.5              1.4;

Display i,j;
```

Note the empty column for `chicago`. Since there is no data, `chicago` will not end up in the set `j`, which can be seen in the output of the `Display` statement:

```
----     10 SET j  markets

new-york,    topeka
```

Also, an explicit `0` in a data statement does not add elements to an an implicitly defined set (in contrast to an `eps`). This is shown in the following GAMS code and output:

```
Set
   j 'markets';

Parameter
   b(j<) 'demand at market j in cases'
        / new-york   325
          chicago      0
          topeka     eps /;

Display j;
```

```
----     10 SET j  markets

new-york,    topeka
```

See also section Finding Sets from Data.

4.23.13 Summary

In GAMS, a simple set consists of a set name and the elements of the set. Both the name and the elements may have associated text that explains the name or the elements in more detail. More complex sets have elements that are pairs or even n-tuples. These sets with pairs and n-tuples are ideal for establishing relationships between the elements in different sets. GAMS also uses a domain checking capability to help catch labeling inconsistencies and typographical errors made during the definition of related sets.

The discussion here has been limited to sets whose members are all specified as the set is being declared. For many models this is all the user needs to know about sets. Later we will discuss more complicated concepts, such as sets whose membership changes in different parts of the model (assignment to sets) and other set operations such as unions, complements and intersections.

4.24 Dynamic Sets

4.24.1 Introduction

Sets in general are covered in chapter Set Definition. In this chapter we introduce a special type of sets: *dynamic sets*. The sets that we discuss in detail in chapter Set Definition have their elements stated at compile time (e.g. enclosed in slashes at the set declaration or when loading a set from gdx via $load) and during execution time the membership is never changed. Therefore they are called *static sets*. In contrast, the elements of *dynamic sets* are not fixed, but may be added and removed during execution of the program. Dynamic sets are most often used as *controlling indices* in assignments or equation definitions and as the conditional set in a dollar-controlled indexed operation. We will first show how assignments are used to change set membership in dynamic sets. Then we will introduce set operations and the last part of this chapter covers dynamic sets in the context of dollar conditions.

4.24.2 Assigning Membership to Dynamic Sets

Dynamic Sets may be assigned to in a similar way as other data types. There are only two possible values: `yes` and `no`. Note that arithmetic operations *cannot* be performed on sets in the same way as on *value typed* identifiers (parameters, variables and equations subtypes). However, there are special set operations.

4.24.2.1 The Syntax

Like any other set, a dynamic set has to be declared before it may be used in the model. Often, a dynamic set is declared as subset of a static set. Dynamic sets in GAMS may also be multi-dimensional like static sets. The maximum number of permitted dimensions follows the rules of the basic Data Types and Definitions. For multi-dimensional dynamic sets the index sets can also be specified explicitly at declaration. That way dynamic sets are domain checked. Of course it is also possible to use dynamic sets that are not domain checked. This provides additional power and flexibility but also a lack of intelligibility and danger. Any label is legal as long as such a set's dimension, once established, is preserved.

In general, the syntax for assigning membership to dynamic sets in GAMS is:

```
set_name(index_list | label) = yes | no ;
```

`Set_name` is the internal name of the set in GAMS, `index_list` refers to the domain of the dynamic set and `label` is one specific element of the domain. An assignment statement may assign membership to the dynamic set either to the whole domain or to a subset of the domain or to one specific element. Note that, as usual, a label must appear in double or single quotes. `Yes` and `no` are keywords in GAMS. They are used to add members to or remove them from the dynamic set. Examples are given in the following subsections.

4.24.2.2 Illustrative Example

Throughout this chapter we will use examples adapted from the database model **[ZLOOF]** to illustrate the introduced concepts. Here we start with assignments of membership to dynamic sets.

```
Set  item            "all items"              / dish, ink, lipstick, pen, pencil, perfume /
     subitem1(item)  "first subset of item"   / pen, pencil /
     subitem2(item)  "second subset of item";

subitem1('ink')      = yes ;
subitem1('lipstick') = yes ;
subitem2(item)       = yes  ;
subitem2('perfume')  = no ;
display subitem1, subitem2;
```

Note that the sets `subitem1` and `subitem2` are declared like any other set. The two sets become dynamic as soon as they are assigned to a few lines later. They are also domain checked: the only members they will ever be able to have must also be members of the set `item`. The first assignment not only makes the set `subitem1` dynamic, it also has the effect that its superset `item` becomes a static set and from then on its membership is frozen. The first two assignments each add one new element to `subitem1`. Note that both are also elements of `item`, as required. The third assignment is an example of the familiar indexed assignment: `subitem2` is assigned all the members of `item`. The last assignment removes the label `'perfume'` from the dynamic set `subitem2`. The output generated by the display statement is shown below:

```
----      9 SET subitem1  first subset of item

ink     ,    lipstick,    pen     ,    pencil

----      9 SET subitem2  second subset of item

dish    ,    ink     ,    lipstick,    pen     ,    pencil
```

Note that even though the labels `'pen'` and `'pencil'` were declared to be members of the set `subitem1` *before* the assignment statements that added the labels `'ink'` and `'lipstick'` to the set, they appear in the listing above at the end. The reason is that elements are displayed in the internal order, which in this case is the order specified in the declaration of the set `item`.

Alternatively, the elements of the set `subitem2` could be assigned in the following way:

```
subitem2(item)     = no;
subitem2(subitem1) = yes;
subitem2('dish')   = yes;
```

The first statement removes all elements from the set `subitem2`. The second statement adds all elements of the set `subitem1`. Note that this assignment is permitted since the set `subitem1` is a proper subset of the set `item` (which is the domain of `subitem2`). The third statement adds one additional element.

4.24.2.3 Dynamic Sets with Multiple Indices

As mentioned earlier, dynamic sets may be multi-dimensional. The following lines continue the example above and illustrate assignments for multi-dimensional sets.

```
Sets sold(item)        "items sold" / pencil, pen /
     sup               "suppliers"  / bic, parker, waterman /
     supply(sold,sup) ;

supply('pencil','bic')  = yes ;
supply('pen',sup)       = yes ;
```

Note that `supply` is a two-dimensional dynamic set. It links sold items with their respective suppliers. Other examples with multi-dimensional dynamic sets are in subsections Dynamic Sets in Conditional Assignments and Conditional Indexed Operations with Dynamic Sets below.

All the mechanisms using asterisks and parenthesized lists that were introduced in section Multi-Dimensional Sets in chapter Set Definition are available for dynamic sets as well.

4.24.2.4 Equations Defined over the Domain of Dynamic Sets

Generally, dynamic sets are not permitted as domains in *declarations* of sets, variables, parameters and equations. However, they may be *referenced* and sometimes it is necessary to *define* an equation over a dynamic set.

Note

The trick is to *declare* the equation over the entire domain but *define* it over the dynamic set.

For example, defining an equation over a dynamic set can be necessary in models that will be solved for arbitrary groupings of regions simultaneously. We assume there are no explicit links between regions, but that we have a number of independent models with a common data definition and common logic. We illustrate with an artificial example, leaving out lots of details.

```
Set        allr            "all  regions"  /  N, S, W, E, N-E, S-W  /
           r(allr)         "region subset for particular solution"
           type            "set for various types of data" ;

Scalar     price                          /10/ ;
Parameter  revenue(allr);
Table      data(allr,type) "all other data ..." ;

Variables  activity1(allr) "first activity"
           activity2(allr) "second activity"
           revenue(allr)   "revenue"          ;

Equations  resource1(allr) "first resource constraint ..."
           prodbal1(allr)  "first production balance ..." ;

resource1(r)..  activity1(r)       =l=  data(r,'resource-1');
prodbal1(r)..   activity2(r)*price =e= revenue(r) ;
```

To repeat the important point: the equation is *declared* over the set `allr`, but *defined* over `r`, a subset. Note that the variables and data are *declared* over `allr` but *referenced* over `r`. Then the set `r` may be assigned arbitrary combinations of elements of the set `allr`, and the model may be solved any number of times for the chosen groupings of regions.

4.24.2.5 Assigning Membership to Singleton Sets

Singleton sets have only one element. Hence any assignment to a singleton set first clears or empties the set, no explicit action to clear the set is necessary. This is illustrated with the following example:

```
Set            i     "Static Set"            / a, b, c /
               ii(i) "Dynamic Set"           /    b    /;
Singleton Set  si(i) "Dynamic Singleton Set" /    b    /;

ii('c') = yes;
si('c') = yes;
display ii, si;
```

Note that both `ii` and `si` are subsets of the set `i`, but only `si` is declared as a singleton set. The assignment statements assign to both sets the element `'c'`. While `'c'` is *added* to the set `ii`, it *replaces* the original element in the singleton set `si`. The output from the display statement confirms this:

```
----      8 SET ii  Dynamic Set
b,    c

----      8 SET si  Dynamic Singleton Set
c
```

For more information on singleton sets in GAMS, see section Singleton Sets.

Attention

That an assignment to a `singleton set` first clears the set always, means that it is even cleared if there would be no change at all for a regular set:

```
Singleton Set s / 1 /;
s(s)$0 = yes;
display s;
```

Here is the output from the `display` statement in the listing file:

```
----      3 SET s

                                                    ( EMPTY )
```

The assignment behavior can be changed with the option and command line parameter strictSingleton which affects the behavior of a membership assignment to a Singleton Set. With `strictSingleton=0` GAMS does not complain about an assignment with more than one element on the right hand side but takes the first one. With `strictSingleton=1` (default), such an assignment raises an error. Consider the following example:

```
Set            i     "Static Set"            / a, b, c /
Singleton Set  si(i) "Dynamic Singleton Set";
si(i) = ord(i) > 1;
display si;
```

By default, the above code will trigger an error as an assignment to a singleton set with more than one element on the right hand side is forbidden:

```
*** Error at line 3: Multiple assignment to Singleton Set not allowed (see option strictSingleton)
```

However, with option (or command line parameter) `strictSingleton=0` GAMS does not complain about such an assignment with more than one element on the right hand side but takes the first one:

```
Set            i     "Static Set"            / a, b, c /
Singleton Set  si(i) "Dynamic Singleton Set";
option strictSingleton = 0;
si(i) = ord(i) > 1;
display si;
```

The output from the display statement confirms this:

```
----      5 SET si  Dynamic Singleton Set

b
```

4.24.3 Set Operations

GAMS provides symbols for arithmetic set operations that may be used with dynamic sets. An overview of the set operations in GAMS is given in Table 1. Examples and alternative formulations for each operation follow. Note that in the table below the set `i` is the static superset and the sets `j` and `k` are dynamic sets.

Set Operation	Operator	Description
Set Union	`j(i) + k(i)`	Returns a subset of `i` that contains all the elements of the sets `j` and `k`.
Set Intersection	`j(i) * k(i)`	Returns a subset of `i` that contains the elements of the set `j` that are also elements of the set `k`.
Set Complement	`not j(i)`	Returns a subset of `i` that contains all the elements of the set `i` that are *not* elements of the set `j`.
Set Difference	`j(i) - k(i)`	Returns a subset of `i` that contains all the elements of the set `j` that are *not* elements of the set `k`.

Table 1: Set Operations with Dynamic Sets

The following examples draw on the database model **[ZLOOF]** that we introduced above. Recall that the set `item` is the superset of the dynamic sets `subitem1` and `subitem2`. We add new dynamic sets for the results of the respective set operations. The following example illustrates that the dynamic set operations are equivalent to the following alternative ways of representation.

```
Sets union1(item), intersection1(item), complement1(item), difference1(item)
     union2(item), intersection2(item), complement2(item), difference2(item);

union1(item) = subitem1(item) + subitem2(item); display union1;
union2(subitem1) = yes; union2(subitem2) = yes; display union2;

intersection1(item) = subitem1(item) * subitem2(item);          display intersection1;
intersection2(item) = yes$(subitem1(item) and subitem2(item));  display intersection2;

complement1(item) = not subitem1(item);              display complement1;
complement2(item) = yes; complement2(subitem1) = no; display complement2;

difference1(item) = subitem2(item) - subitem1(item);                  display difference1;
difference2(item) = yes$(subitem2(item)); difference2(subitem1) = no; display difference2;
```

The display statements will show that the above assignment statements for each operation result in the same dynamic set like using the set operator. Observe that the alternative formulations for the set intersection and set difference involve conditional assignments. Conditional assignments in the context of dynamic sets are discussed in depth in the next section.

Note

> The indexed operation `sum` may be used for set unions. Similarly, the indexed operation `prod` may be used for set intersections. For examples see section Conditional Indexed Operations with Dynamic Sets below.

4.24.4 Using Dollar Controls with Dynamic Sets

The remainder of this chapter assumes familiarity with the dollar condition that is introduced in chapter Conditional Expressions, Assignments and Equations. All the dollar control machinery is available for use with dynamic sets. In fact, the full power of dynamic sets can be exploited using these dollar controls.

Recall that set membership of subsets and dynamic sets may be used as a logical condition; see subsection Logical Conditions: Set Membership and Set Functions for details. Set membership may also be a building block in complex logical conditions that are constructed using the logical operators not, and, or, xor, imp and eqv. Moreover, the set operations introduced in the previous section may also be used in logical conditions. Like other dollar conditions, dollar conditions with dynamic sets are used in the context of assignments, indexed operations and equations. We will discuss in detail each of these in the following subsections.

Apart from being part of logical conditions, dynamic sets may be assigned members with conditional assignments. Examples are given in the next subsection.

4.24.4.1 Dynamic Sets in Conditional Assignments

Dynamic sets may be used in two ways in conditional assignments: they may be the item on the left-hand side that is assigned to and they may be part of the logical condition. Below we present examples for both. The examples are again based on the database model [**ZLOOF**] that we introduced above.

```
Set  item            "all items"              / dish, ink, lipstick, pen, pencil, perfume /
     subitem1(item)  "first subset of item"   /       ink, lipstick, pen, pencil          /
     subitem2(item)  "second subset of item";

subitem2(item)$subitem1(item) = yes;
display subitem2;
```

The conditional assignment adds the members of dynamic set `subitem1` to the dynamic set `subitem2`. Thus `subitem2` will have the following elements:

```
----      6 SET subitem2  second subset of item

ink     ,    lipstick,    pen     ,    pencil
```

Note that instead of using `subitem1` in a dollar condition we could also write:

```
subitem2(subitem1) = yes;
```

In the next example of a conditional assignment, a dynamic set features in the logical condition on the right-hand side. The first statement clears the set `subitem2` of any previously assigned members and the second statement assigns all members of `subitem1` to `subitem2`. The following conditional assignment will have the same result:

```
subitem2(item) = no;
subitem2(item) = yes$subitem1(item);
```

The logical condition in this assignment is `subitem1(item)`. It is satisfied for all members of the set `subitem1`. Hence the statement assigns all elements of the domain `item` that are members of the set `subitem1` to the dynamic set `subitem2`. Note that in this assignment the dollar operator is on the right. In the section Dollar on the Right we show that conditional assignments with the dollar operator on the right-hand side imply an `if-then-else` structure where the `else` case is automatically zero. Unlike parameters, dynamic sets cannot be assigned the value of zero, they are assigned the value `no` instead. Therefore a more explicit formulation of the conditional assignment above would be:

```
subitem2(item) = no;
subitem2(item) = yes$subitem1(item) + no$(not subitem1(item));
```

For more on sets in logical conditions, see section Logical Conditions: Set Membership and Set Functions. For more on conditional assignments, see section Conditional Assignments.

4.24.4.2 Conditional Indexed Operations with Dynamic Sets

Indexed operations in GAMS are introduced in section Indexed Operations. They may be controlled by dollar conditions as discussed in section Conditional Indexed Operations. The domain of conditional indexed operations is often restricted by a set, called the conditional set. Dynamic sets may be used as conditional sets or they may be assigned to with a statement that features a conditional indexed operation on the right-hand side. We will illustrate both cases with examples.

Suppose we have a set of origins, a set of destinations and a table specifying the flight distance between them:

```
Set   i           "origins"       / Chicago, Philadelphia /
      j           "destinations"  / Vancouver, Bogota, Dublin, Rio, Marrakech / ;

Table d(i,j)      "distance (miles)"
                  Vancouver   Bogota   Dublin    Rio    Marrakech
    Chicago          1777      2691     3709     5202      4352
    Philadelphia     2438      2419     3306     4695      3757          ;
```

We wish to find the longest distance that we can travel given that we have a limit of 3500 miles.

```
Set   can_do(i,j) "connections with less than 3500 miles";
can_do(i,j)$(d(i,j) < 3500) = yes;
display can_do;
Scalar maxd  "longest distance possible"
maxd = smax((i,j)$can_do(i,j), d(i,j));
display maxd;
```

The dynamic set `can_do` contains all connections that are less than 3500 miles. The scalar `maxd` is defined by a conditional assignment where the indexed operation `smax` scans all entries of the parameter `d` whose label combinations are members of the set `can_do` and chooses the largest value. The output generated by the display statements is shown below:

```
----     11 SET can_do  connections with less than 3500 miles

               Vancouver      Bogota      Dublin

Chicago              YES         YES
Philadelphia         YES         YES         YES

----     15 PARAMETER maxd                =     3306.000  longest distance possible
```

There is a shorter alternative formulation for this assignment; see subsection Filtering through Dynamic Sets below for details.

Finally, we also wish to know which flight connection is linked to the longest possible distance. Consider the following two lines:

```
Singleton set maxc(i,j)  "maximum distance connection";
maxc(i,j) = yes$can_do(i,j) and (d(i,j) = maxd);
```

The dynamic singleton set is assigned the member of the dynamic set `can_do` whose distance equals the maximum distance.

The full power of indexed operators becomes apparent with multi-dimensional dynamic sets. As earlier in this chapter, we illustrate with fragments of code adapted from the relational database model [**ZLOOF**].

```
Set  dep         "departments"  / cosmetics, hardware, houshold, stationary, toy /
     sup         "suppliers"    / bic, dupont, parker, revlon /
     item        "items sold"   / dish, ink, lipstick, pen, pencil, perfume /

sales(dep,item)  "departments and items sold"  /
                 cosmetics.  (lipstick,perfume)
                 hardware.    ink
                 houshold.   (dish,pen)
                 stationary. (dish,ink,pen,pencil)
                 toy.        (ink,pen,pencil)         /

supply(item,sup) "items and suppliers"   /
                 dish.(bic,dupont)   , ink.(bic,parker)    , lipstick.revlon
                 pen.(parker,revlon) , pencil.(bic,parker) , perfume.revlon  /

Set g03(dep)    "departments selling items supplied by Parker";

g03(dep) = sum(item$supply(item,'parker'), sales(dep,item));
display g03;
```

The assignment above is used to create the set of departments that sell items supplied by `'parker'`. Note that the set `g03` is a subset of the set `dep`. Its members are specified by assignment, hence it is a dynamic set. Note that the assignment is made to a set, therefore the indexed operator `sum` refers to a set union (and not to an addition as would be the case if the assignment were made to a parameter). The indexed operation is controlled by the two-dimensional set `supply` with the label `'parker'` in the second index position. This logical condition is `TRUE` for all members of the set `supply` where the second index is `'parker'`. Hence the summation is over all items sold, provided that the supplier is `'parker'`. Given the declaration of the set `supply`, this means `'ink'`, `'pen'` and `'pencil'`. The associated departments are thus all departments except for `'cosmetics'`:

```
----     19 SET g03  departments selling items supplied by Parker

hardware  ,    houshold  ,    stationary,    toy
```

Now suppose we are interested in the departments that are selling *only* items supplied by `'parker'`. We introduce a new dynamic set `g11` and the following assignment adds the desired departments:

```
Set g11(dep) "departments only selling items supplied by parker";
g11(dep) = prod(sales(dep,item), supply(item,"parker"));
display g11;
```

Note that the indexed operation `prod` refers to set intersections in the context of assignments to dynamic sets. From all departments linked with items only those are included where *all* items sold are supplied by `'parker'`. This means that departments that additionally sell items that are not supplied by `'parker'` are excluded. Hence, only `'hardware'` and `'toy'` are added to `g11`.

4.24.4.3 Conditional Equations with Dynamic Sets

Recall that dollar conditions in the context of equations may restrict the domain of the equation and they may also feature in the algebraic formulation of the equation; see section Conditional Equations for more information. In both instances dynamic sets may be used as part of the logical condition. Dollar conditions with dynamic sets in the algebra of equations are similar to conditional assignments with dynamic sets; see section Dynamic Sets in Conditional Assignments above. The example that follows illustrates the use of a dynamic set to restrict the domain of definition of an equation. In section Equations Defined over the Domain of Dynamic Sets above we had the following equation definition:

```
prodbal1(r)..            activity2(r)*price    =e= revenue(r)    ;
```

Recall that `r` is a dynamic set and a subset of the set `allr`. Hence this equation may be rewritten in the following way:

```
prodbal1(allr)$r(allr).. activity2(allr)*price =e= revenue(allr) ;
```

Note that both formulations achieve the same result: restricting the domain of definition to those elements that belong to the dynamic set `r`. While in the second formulation the condition is specified explicitly, in the first formulation the domain is *filtered* through the dynamic set `r`. This is the topic of the next subsection.

4.24.4.4 Filtering through Dynamic Sets

The filtering process is introduced and explained in section Filtering Sets in chapter Conditional Expressions, Assignments a
In certain circumstances it is an alternative to the dollar condition to restrict the domain of equations, sets, variables, parameters and indexed operations. We already saw an example for restricting the domain of definition of an equation in the previous subsection. The next example refers to restricting the domain in an indexed operation. In section Conditional Indexed Operations with Dynamic Sets we had the following assignment:

```
maxd = smax((i,j)$can_do(i,j), d(i,j));
```

Recall that `maxd` is a scalar, `i` and `j` are sets, `can_do` is a dynamic set and `d` is a two-dimensional parameter. Note that the conditional set is the dynamic set `can_do`. The assignment may be rewritten in the following way:

```
maxd = smax(can_do(i,j), d(i,j));
```

Here the indexed operation is filtered through the dynamic set `can_do`, a dollar condition is not necessary.

4.25 Sets as Sequences: Ordered Sets

4.25.1 Introduction

Sets are introduced in chapter Set Definition. There we state that in general, sets in GAMS are regarded as an unordered collection of labels. However, in some contexts, say, multi-period planning models, some sets need to be treated as if they were sequences. In this chapter we will establish the notion of *ordered sets* and we will cover their special features and the associated operations.

Examples where ordered sets are needed include economic models that explicitly represent conditions in different time periods that are linked, location problems where the formulation may require a representation of contiguous areas, as in a grid representation of a city, scheduling problems and programs that model stocks of capital with equations of the form '*stocks at the end of period n are equal to stocks at the end of period* $n-1$ *plus net gains during period n*'.

Note

Models involving sequences of time periods are often called *dynamic models*, because they describe how conditions change over time. This use of the word *dynamic* unfortunately has a different meaning from that used in connection with dynamic sets, but this is unavoidable.

4.25.2 Ordered and Unordered Sets

Certain one-dimensional sets may be treated as if they were a sequence. Those sets need to be ordered and static. A one-dimensional set is ordered if the definition or initialization of the elements in the set corresponds to the order of the labels in the GAMS Entry order.

Note

- The GAMS entry order is the order in which the individual labels first appear in the GAMS program, either explicitly or as a result of using the shorthand asterisk notation.
- For the sake of simplicity, sets that are static and ordered are often just referred to as *ordered sets*.

GAMS maintains a *unique element* list where all labels that are used as elements in one or more sets are listed. The order of the elements in any one set is the same as the order of those elements in the unique element list. This means that the order of a set may not be what it appears to be if some of the labels were used in an earlier definition. The internal GAMS order of the labels can be made visible with the dollar control option $onUELlist. This directive generates a map that is shown in the compilation output of the listing file. For details on the listing file and GAMS output in general, see chapter GAMS Output. A good rule of thumb is that if the user wants a set to be ordered and the labels in the set have not been used already, then they will be ordered.

In the example below we show ordered and unordered sets and the map showing the order. The input is:

```
$onUELlist
Set    t1  / 1987, 1988, 1989, 1990, 1991 /
       t2  / 1983, 1984, 1985, 1986, 1987 /
       t3  / 1987, 1989, 1991, 1983, 1985 / ;
```

Note that the label "1987" is the first label seen by GAMS. It appears again as the last label in the initialization list for the set t2. This means that the set t2 is *not* ordered and any attempt to use t2 in a context implying order, such as the operations introduced later in this chapter, will cause error messages. Observe that the set t3 is ordered, as all the members of t3 have appeared in the GAMS program before, and in the same order that they are listed in the definition of t3.

The unique element listing below shows the entry order (the important one) and the sorted order, obtained by sorting the labels into dictionary order. The single digits on the left are the sequence numbers of the first label on that line.

```
G e n e r a l   A l g e b r a i c   M o d e l i n g   S y s t e m
Unique Element Listing

Unique Elements in Entry Order
    1   1987       1988       1989       1990       1991       1983
    7   1984       1985       1986

Unique Elements in Sorted Order
    1   1983       1984       1985       1986       1987       1988
    7   1989       1990       1991
```

A set can always be made ordered by moving its declaration closer to the beginning of the program. With these restrictions in mind, we will continue in the next section with the operations that may be used with ordered sets.

4.25.3 Sorting a Set

Note that besides the entry order of unique elements there is also a sorted (alphabetical) order. To obtain the sorted order (of an ordered or unordered set) the special predefined two-dimensional set SortedUELs(*,*) can be used. Consider the following example where set j is reported in an alphabetically sorted format:

```
set j / c, a, b, 1, 2, 11 /;
display j;
alias(*,u);
file ordered /ordered.txt/;
loop(SortedUels(u,j), put ordered j.tl:0 '  ');
putclose ordered;
```

The output generated by the display statement follows:

```
----      2 SET j

c ,    a ,    b ,    1 ,    2 ,    11
```

Note that, as expected, the display statement shows the elements of set j in the entry order *not* in alphabetical order. However, the elements are listed in alphabetical order in the file ordered.txt. Note furthermore, that alphabetical sorting leads to an order where e.g. 11 precedes 2.

```
1  11  2  a  b  c
```

In the example above u is aliased with the Universal Set. For an introduction to writing external files with put, see chapter The Put Writing Facility.

4.25.4 Ord and Card Operators

As stated in section Labels in chapter GAMS Programs, labels in GAMS do not have a numerical value. The examples used were that the label '1986' does not have a numerical value of 1986 and the label '01' is different from the label '1'. This section introduces two operators - ord and card - that return integer values when applied to sets. While the integer values returned do not represent the numerical value of the label, they can be used for the same purpose.

Note

GAMS provides some string manipulation capability by extending the card and ord operators to also work on strings.

4.25.4.1 The Ord Operator

The operator ord returns the relative position of a member in a set.

Attention

By default the operator ord may be used only with one-dimensional sets that are static and ordered.

Some examples show the usage.

```
Set       t      "time periods"  / 1985*1995 / ;
Parameter val(t) ;
val(t)  =  ord(t);
```

Note that as a result of the statements above, the value of val('1985') will be 1, val('1986') will be 2 and so on.

A common use of ord is in setting up vectors that represent quantities growing in some analytically specified way. For example, suppose a country has 56 million people in the base period and the population is growing at the rate of 1.5 percent per year. Then the population in succeeding years can be calculated as follows:

```
population(t)  =  56*(1.015**(ord(t) - 1)) ;
```

It is often useful to simulate general matrix operations in GAMS. The first index of a two dimensional parameter can conveniently represent the rows, the second the columns and order is necessary. The example below shows how to set the upper triangle of a matrix equal to the row index plus the column index, and the diagonal and lower triangle to zero.

```
Set       i       "row and column labels"        / x1*x10 /;
alias (i,j);
Parameter a(i,j)  "a general square matrix";
a(i,j) $ (ord(i) < ord(j)) = ord(i) + ord(j);
```

Note that in the assignment statement the logical condition `(ord(i) < ord(j))` restricts the assignment to the entries of the upper triangle. For more information on logical conditions and conditional assignments in GAMS, see sections Logical Conditions and Conditional Assignments respectively.

Note that the strict requirement that the set needs to be ordered for the operator `ord` to be used may be relaxed with a dollar control option called offOrder. Consider the following lines where we revisit the example from the previous section.

```
$offOrder
Set       t1    / 1987, 1988, 1989, 1990, 1991 /
          t2    / 1983, 1984, 1985, 1986, 1987 /;
Parameter p(t2);
p(t2) = ord(t2);
display p;
```

Note that, as we explained above, the set `t2` is *not* ordered. Therefore using `ord(t2)` somewhere in the model will usually cause the program to be terminated with an error message. However, with the dollar control option `offOrder` active, the set `t2` is treated as if it were ordered and the display statement will generate the following output:

```
----      6 PARAMETER p
1987 1.000,    1983 2.000,    1984 3.000,    1985 4.000,    1986 5.000
```

While this may be useful in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the `ord` operator can be turned on again via onOrder.

4.25.4.2 The Card Operator

The operator `card` returns the number of elements in a set.

Note

The operator `card` may be used with any set: static and dynamic sets, ordered and unordered sets.

The following example illustrates its use:

```
Set    t  "time periods"  / 1985*1995 /;
Scalar s;
s  =  card(t);
Display s;
```

Note that `s` will be assigned the value 11 since the set `t` has 11 elements.

A common use of `card` is to specify some condition only for the final period, for example to fix a variable. Consider the following artificial example:

```
c.fx(t)$(ord(t) = card(t)) = demand(t);
```

Note that the logical condition `(ord(t) = card(t))` restricts the assignment to the last element of the set `t:` no assignment is made for other members of `t`. The advantage of this way of fixing the variable `c` is that the membership of `t` can be changed safely and this statement will always fix `c` for the last element. For more information on logical conditions and conditional assignments in GAMS, see sections Logical Conditions and Conditional Assignments respectively.

4.25.5 Lag and Lead Operators

Lag and lead operators are used to relate the *current* member of an ordered set to the *previous* or *next* member of the set. GAMS provides two forms of lag and lead operators (linear and circular), they are summarized in Table 1. Note that in the table below `t` is a member of an ordered set and `n` is a positive integer.

Operation	Symbol	Description
Linear Lag	`t - n`	Refers to the element of the ordered set whose relative position in the set is `ord(t)-n`.
Linear Lead	`t + n`	Refers to the element of the ordered set whose relative position in the set is `ord(t)+n`.
Circular Lag	`t -- n`	Same as `t - n`, only here the first element of the set is assumed to be preceded by the last element of the set, thus forming a circle of elements.
Circular Lead	`t ++ n`	Same as `t + n`, only here the last element of the set is assumed to be followed by the first element of the set, thus forming a circle of elements.

Table 1: Linear and Circular Lag and Lead Operators

Note that the only difference between *linear* and *circular* lag and lead operators is how endpoints are treated. *Linear* operators assume that there are no members preceding the first and following the last member of the ordered set. This assumption may result in elements of the set being referenced that actually do not exist. Therefore the user must think carefully about the treatment of endpoints: models with linear lag and lead operators will need special exception handling logic to deal with them. The next two sections will describe how this issue is handled in GAMS in the context in which these operators are typically used: assignments and equations. Linear lag and lead operators are useful for modeling time periods that do not repeat, like a set of years (say 1990 to 1997).

Circular lag and lead operators assume that the first and last members of the set are adjacent, so as to form a circular sequence of members. This means that `'first--1'` is a reference to `'last'` and `'last++2'` is the same as `'first++1'`. All references and assignments are defined. The assumption of circularity is useful for modeling time periods that repeat, such as months of the year or hours in the day. It is quite natural to think of January as the month following December. Agricultural farm budget models and workforce scheduling models are examples of applications where circular leads occur naturally.

Note

- GAMS is able to distinguish the linear lag and lead operators `'-'` and `'+'` from arithmetic operators by context. To avoid ambiguity, GAMS does not allow to mix lag and lead operators with arithmetic operators. For example, `i+1+1` is not allowed, but writing `i+(1+1)` would work.
- Observe that the lag (or lead) value `n` does not have to be an explicit constant: it can be an arbitrary expression, provided that it evaluates to an integer. If it does not, error messages will be produced. A negative result causes a switch in sense (from lag to lead, for example).

Note that if lag and lead operators are used with an *unordered* set, the program will terminate with an error message. The strict requirement that the set be ordered may be relaxed with the dollar control option offOrder. If the directive `$offOrder` is added, in the lines that follow unordered sets are treated as if they were ordered and therefore lag and lead operators may be used with them. While this may be advantageous in some circumstances, the option comes with a price, since the system will not be able to diagnose odd and incorrect formulations and data sets. The strict requirement that the set needs to be ordered for the use of lag and lead operators can be turned on again via onOrder.

The next two subsections will give some illustrative examples on the use of lag and lead operators in assignment statements and in equations respectively.

4.25.5.1 Lags and Leads in Assignments

Lag and lead operators may be used in assignment statements. The use of a lag or lead operator on the right-hand side of an assignment is called a *reference*, while their use on the left-hand side is called an *assignment* and involves the definition of a domain of the assignment. The concepts behind reference and assignment are equally valid for the linear and circular forms of the lag and lead operators. However, the importance of the distinction between reference and assignment is not pronounced for circular lag and lead operators, because non-existent elements are not referred to in this case.

Note

A reference to a non-existent element causes the default value zero to be used, whereas an attempt to assign to a non-existent element results in no assignment being made.

We will first illustrate *linear* lag and lead operators for reference and assignment. Then we will turn to the *circular* form of the operators.

Linear Lag and Lead Operators in Assignments - Reference

Consider the following example, where the lag operator is used on the right-hand side of an assignment statement:

```
Set       t             "time sequence"  / y-1987*y-1991 /;
Parameter a(t), b(t);
a(t)  =  1986 + ord(t);
b(t)  =  -1;
b(t)  =  a(t-1);
option decimals = 0;
display a, b;
```

Note that the option statement suppresses the decimal places from the display statement.

```
----      7 PARAMETER a
y-1987 1987,    y-1988 1988,    y-1989 1989,    y-1990 1990,    y-1991 1991

----      7 PARAMETER b
y-1988 1987,    y-1989 1988,    y-1990 1989,    y-1991 1990
```

Note that, as expected, the values for the parameter `a` are 1987, 1988 up to 1991 corresponding to the labels `"y-1987"`, `"y-1988"` and so on. Observe that the parameter `b` is initialized to −1 so that the result of the next assignment can be seen clearly. Note that in the last assignment the lag operator `'-'` is used on the right-hand side, resulting in the values for `b` to equal the values for `a` from the *previous* period. If there is no previous period, as with the first element, `"y-1987"`, the value zero is assigned, replacing the previous value of −1 (values of zero for parameters are not displayed).

Linear Lag and Lead Operators in Assignments - Assignment

Consider the following variation of the previous example. Here the lead operator is used on the left-hand side of an assignment statement:

```
Set       t            "time sequence"  / y-1987*y-1991 / ;
Parameter a(t), c(t) ;
a(t)    =  1986 + ord(t) ;
c(t)    =  -1;
c(t+2)  =  a(t) ;
option decimals = 0;
display a, c ;
```

Note that, as before, the option statement suppresses the decimal places from the display statement.

```
----      7 PARAMETER a
y-1987 1987,    y-1988 1988,    y-1989 1989,    y-1990 1990,    y-1991 1991

----      7 PARAMETER c
y-1987   -1,    y-1988   -1,    y-1989 1987,    y-1990 1988,    y-1991 1989
```

The assignment to `a` is explained in the previous subsection. Note that the parameter `c` is initialized to −1. The assignment to `c` involving the lead operator on the left-hand side needs special attention. It is best to spell out step by step how this assignment is made. For each member of `t` in sequence, find the member of `c` associated with `t+2`. If it exists, replace its value with the value of `a(t)`. If not (as with labels `"y-1990"` and `"y-1991"`) make no assignment. The first member of the set `t` is `"y-1987"`, therefore the first assignment is made to `c("y-1989")` which takes the value of `a("y-1987")`, that is 1987. No assignments at all are made to `c("y-1987")` and `c("y-1988")`: these two retain their previous values of −1.

Circular Lag and Lead Operators in Assignments

The following example illustrates the use of circular lag and lead operators in assignment statements.

```
Set       s          "seasons" / spring, summer, autumn, winter /;
Parameter val(s)                / spring 10, summer 15, autumn 12, winter 8 /
          lagval(s)
          leadval(s);
lagval(s)     = -1 ;
lagval(s)     = val(s--2) ;
leadval(s)    = -1 ;
leadval(s++1) = val(s) ;
option decimals = 0;
display val, lagval, leadval;
```

Note that, as before, the option statement suppresses the decimal places from the display statement. The results are shown below.

```
-----     10 PARAMETER val

spring 10,    summer 15,    autumn 12,    winter  8

----     10 PARAMETER lagval

spring 12,    summer  8,    autumn 10,    winter 15

----     10 PARAMETER leadval

spring  8,    summer 10,    autumn 15,    winter 12
```

In the example parameter `lagval` is used for reference while `leadval` is used for assignment. Notice that the case of circular lag and lead operators does not refer to any non-existent elements. The difference between reference and assignment is therefore not important. Note that the following two statements from the example above,

```
lagval(s)     = val(s--2) ;
leadval(s++1) = val(s) ;
```

are equivalent to

```
lagval(s++2)  = val(s) ;
leadval(s)    = val(s--1) ;
```

The use of reference and assignment have been reversed with no difference in effect.

4.25.5.2 Lags and Leads in Equations

The principles established in the previous section follow quite naturally into equation definitions. A lag or lead to the left of the `'..'` symbol is a modification of the domain of definition of the equation. The linear form may cause one or more individual equations to be suppressed. A lag or lead operation in the body of an equation (to the right of the `'..'` symbol) is a reference. If the associated label is not defined, the term vanishes.

Note

> All lag and lead operands must be *exogenous*. For more information, see section Functions in Equation Definitions.

In the next two subsections we will provide examples illustrating the use of the *linear* form of the lag and lead operators in equations to modify the domain of definition and for reference respectively. In the last subsection we will turn to *circular* lag and lead operators in equations.

Linear Lag and Lead Operators in Equations - Domain Control

Consider the following simple artificial multi-period example. We specify a complete model and encourage users to solve it and further explore it.

```
Sets      t           / t1*t5 /
          tfirst(t);
Parameter i(t)        / #t 1 /;
Scalar    k0          / 3.00 /;

tfirst(t)  =  yes$(ord(t) = 1);

Variables k(t), z;
k.fx(tfirst) = k0;

Equations kk(t), dummy;
dummy..      z =e= 0;
kk(t+1)..    k(t+1) =e=  k(t) + i(t);

model m /all/;
option limrow = 10;
solve m using lp min z;
```

Note that the equation `kk` is declared over the set `t`, but it is defined over the domain `(t+1)`. Therefore the first equation that will be generated is the following:

```
k('t2')  =e=  k('t1') + i('t1');
```

Note that the value of the variable `k('t1')` is fixed at the value of scalar `k0`. Observe that for the last element of `t`, the term `k(t+1)` is not defined and therefore the equation will not be generated. If lag or lead operators are used in the domain of definition of an equation, the equation listing can be a useful tool to verify whether the equations that have been generated are those that were intended:

```
kk(t2)..  - k(t1) + k(t2) =E= 1 ; (LHS = 0, INFES = 1 ****)
kk(t3)..  - k(t2) + k(t3) =E= 1 ; (LHS = 0, INFES = 1 ****)
kk(t4)..  - k(t3) + k(t4) =E= 1 ; (LHS = 0, INFES = 1 ****)
kk(t5)..  - k(t4) + k(t5) =E= 1 ; (LHS = 0, INFES = 1 ****)
```

To summarize, the lead operator in the domain of definition has restricted the number of constraints generated so that there are no references to non-existent variables.

For a more realistic model that illustrates the usage of linear lag operators in equations, see for example the optimal economic growth model [**RAMSEY**].

Linear Lag and Lead Operators in Equations - Reference

In the previous subsection we showed how to write the equation `kk` using the lead operator for domain control in combination with fixing the variable `k(tfirst)` to `k0`. An alternative formulation could neglect the fixing of `k(tfirst)` and use a lag operator and a dollar condition in the *body* of the equation while the *domain* of definition is unrestricted:

```
kk(t)..  k(t) =e= k(t-1) + i(t-1) + k0$tfirst(t);
```

Note that for the first element of the set `t` the terms `k(t-1)` and `i(t-1)` are not defined and therefore vanish. Without the conditional term, the resulting equation would be:

```
k('t1') =e= 0;
```

However, this would lead to different results as `k('t1')` would not be set to the value of `k0` anymore. Therefore the conditional expression `k0$tfirst(t)` is added. Observe that in this formulation equations are generated for *all* time periods, no equation is suppressed.

In general, the choice between using lag and lead operators as reference like in the last example or in domain control is often a matter of taste.

Circular Lag and Lead Operators in Equations

In the case of circular lag and lead operators, the difference between their use in domain control and as reference is not important because it does not lead to any equations or terms being suppressed. Consider the following artificial example.

```
Set      s        "seasons" / spring, summer, autumn, winter /;

Variable produ(s) "amount of goods produced in each season"
         avail(s) "amount of goods available in each season"
         sold(s)  "amount of goods sold in each season";

Equation matbal(s);

matbal(s)..  avail(s++1) =e= avail(s) + produ(s) - sold(s);
```

In this example four individual equations are generated. They are listed below.

```
avail('summer')  =e=  avail('spring') + produ('spring') - sold('spring');
avail('autumn')  =e=  avail('summer') + produ('summer') - sold('summer');
avail('winter')  =e=  avail('autumn') + produ('autumn') - sold('autumn');
avail('spring')  =e=  avail('winter') + produ('winter') - sold('winter');
```

Note that for the last element of the set `s` the term `avail(s++1)` is evaluated to `avail('spring')`. This term is well defined and therefore it does not vanish. Similarly, using the circular lead operator in the domain of definition like in the following line will result in the same four equations being generated as above and no equation being suppressed.

```
matbal(s++1)..  avail(s++1) =e= avail(s) + produ(s) - sold(s);
```

4.25.6 Summary

This chapter introduced the concept of ordered sets. All the features in GAMS that deal with this issue including the `ord` and `card` operators, as well as the linear and circular forms of the lag and lead operators were described in detail.

4.26 Data Manipulations with Parameters

4.26.1 Introduction

In this chapter we explicitly cover only *parameter* manipulation, including all aspects of data handling. Much of this material is relevant elsewhere (e.g. to sets), but for specifics related to assignment to sets, to conditions, and to assignments within flow control constructs such as the `loop` statement, see chapters Dynamic Sets, Conditional Expressions, Assignments and Equations and Programming Flow Control Features respectively.

Once initialized, data often requires manipulation in order to bring it into a form most suitable for use in a model or an application. The assignment statement is the way to do this. All the possible components of the assignment statement except conditions are introduced and discussed in this chapter.

4.26.2 The Assignment Statement

The assignment statement is the fundamental data manipulation statement in GAMS. It may be used to define or alter values associated with sets, parameters, variables or equations.

A simple assignment is written in the style associated with many other computer languages. GAMS uses the traditional symbols for addition `(+)`, subtraction `(-)`, multiplication `(*)` and division `(/)`. We will use them in the examples that follow, and give more details in section Expressions.

4.26.2.1 Scalar Assignments

Consider the following artificial sequence:

```
scalar x / 1.5 /;
x = 1.2;
x = x + 2;
```

The scalar `x` is initialized to be 1.5. The second statement changes the value to 1.2, and the third changes it to 3.2. The second and third statements are assignments: each replaces the current value of `x` with a new one.

Note that the same symbol can be used on the left and right of the `=` sign. The new value is not available until the calculation is complete, and the operation gives the expected result.

Note

> An assignment cannot start with a reserved word. A semicolon is therefore required as a delimiter before all assignments.

Note that extended range identifiers (e.g. `INF`) and acronyms may also be used in assignment statements. For specific details, see sections Extended Range Arithmetic and Acronym Usage respectively.

4.26.2.2 Indexed Assignments

The GAMS syntax for performing indexed assignments is extremely powerful. This operation offers what may be thought of as simultaneous or parallel assignments and provides a concise way of specifying large amounts of data. Consider the mathematical statement $DJ_d = 2.75 \cdot DA_d$ for all elements of d. This means that for every member of the set d, a value is assigned to DJ. This can be written in GAMS as follows:

```
dj(d) = 2.75*da(d) ;
```

This assignment is known technically as an *indexed assignment* and set `d` as the controlling index or controlling set.

Attention

> The index set(s) on the left hand side of an indexed assignment are referred to synonymously as the controlling indices, controlling sets, or controlling domain of the assignment.

The extension to two or more controlling indices should be obvious. There will be an assignment made for each label combination that can be constructed using the indices inside the parentheses. Consider the following example of an assignment to all 100 data elements of the parameter `a`.

```
sets  row            / r-1*r-10 /
      col            / c-1*c-10 /
      sro(row)       / r-7*r-10 / ;
parameters  r(row)   /r-1*r-7 4, r-8*r-10 5/
            c(col)   /c-1*c-5 3, c-6*c-10 2/;
parameters  a(row,col);
a(row,col)  =  13.2 + r(row)*c(col)  ;
```

The calculation in the last statement is carried out for each of the 100 unique two-label combinations that can be formed from the elements of `row` and `col`. An explicit formulation of the first of these assignments follows:

```
a('r-1','c-1') = 13.2 + r('r-1')*c('c-1');
```

Note that for indexed assignments a copy of the symbols on the right hand side is installed before the assignment is carried out. That means it does not work "in-place" or recursively. Consider the following example where we compute the first ten Fibonacci numbers and store them in parameter `f` using a loop. The example also illustrates how such a recursive calculation does not work with a parallel assignment statement for parameter `g`.

```
set i / i1*i10 /
parameter
    f(i) / i1 1 /
    g(i) / i1 1 /;
loop(i$(ord(i)>=2),
  f(i) = f(i-2) + f(i-1);
);
g(i)$(ord(i)>=2) = g(i-2) + g(i-1)
display f,g;
```

The display statement results in the following output.

```
----      9 PARAMETER f

i1   1.000,    i2   1.000,    i3   2.000,    i4   3.000,    i5   5.000
i6   8.000,    i7  13.000,    i8  21.000,    i9  34.000,    i10 55.000

----      9 PARAMETER g

i1 1.000,    i2 1.000,    i3 1.000
```

4.26.2.3 Restricting the Domain in Assignments

Sometimes it is necessary to make assignments over selected elements of a set instead of over the entire domain. There are several ways to accomplish this: using explicit labels, subsets, conditionals and tuples.

Restricting the Domain: Explicit Labels

The strongest restriction of the domain is assigning a value to just one element. Labels may be used explicitly in the context of assignments to accomplish this. The following example illustrates:

```
a('r-7','c-4') = -2.36 ;
```

This statement assigns a constant value to just one element of the parameter `a`. All other elements of `a` remain unchanged. Labels must be quoted when used in this way.

Restricting the Domain: Subsets

In general, wherever a set name may occur in an indexed assignment, a subset may be used instead.

Consider the following example:

```
a(sro,'col-10') = 2.44 -33*r(sro) ;
```

Since the set `sro` was declared as a subset of the set `row`, we can use `sro` as a controlling index in the assignment above to make the assignment only for the elements of `sro`.

Restricting the Domain: Conditionals

Conditional assignments are discussed in detail in section Conditional Assignments in chapter Conditional Expressions, Assignments and Equations. For details on the types of logical conditions, see section Logical Conditions. Here we present a simple example to illustrate:

```
a(row,col)$[a(row,col) >= 100] = INF ;
```

This assignment has the following effect: all elements of the parameter `a` whose value was at least 100 are assigned the value INF, while all other elements of `a` remain unchanged.

Restricting the Domain: Tuples

Tuples or multi-dimensional sets are introduced in section Many-to-Many Mapping. In this simple example we show how they may be used to restrict the domain. The example builds on the first example in this section. We repeat the whole code here for clarity.

```
sets  row            / r-1*r-10 /
      col            / c-1*c-10 /
      sro(row)       / r-7*r-10 / ;
set tuple(row,col)   /r-1.c-1, r-1.c-10, r-10.c-1, r-10.c-10/;
parameters  r(row)   /r-1*r-7 4, r-8*r-10 5/
            c(col)   /c-1*c-5 3, c-6*c-10 2/;
parameters  a(row,col), b(row,row);
a(row,col)  =  13.2 + r(row)*c(col)  ;
a(tuple(row,col)) = 7 + r(row)*c(col)  ;
a(tuple) = 0.25 * a(tuple)  ;
```

Note that we have introduced the new set `tuple`. It is two-dimensional and contains just four elements. As before, the parameter `a` is first assigned values for all its 100 elements. We then change some of these values using the set `tuple` as domain. The values of the elements of the parameter `a` that are not elements of the set `tuple` remain unchanged.

For a more elaborate example involving tuples, see section Filtering Sets in Assignments.

4.26.2.4 Issues with Controlling Indices

Attention

> The number of controlling indices on the left of the `=` sign should be at least as large as the number of indices on the right. There should be no index on the right-hand side of the assignment that is not present on the left unless it is operated on by an indexed operator. For more on indexed operators, see section Indexed Operations.

Consider the following statement:

```
a(row,'col-2') = 22 - c(col) ;
```

GAMS will flag this statement as an error since `col` is an index on the right-hand side of the equation but not on the left.

Note that there would be no error here if `col` were a `singleton set`. Since there is only one element in a singleton set, the intent and behavior is well-defined even when `col` is not under control.

Attention

> Each set is counted only once to determine the number of controlling indices. If the intent is for a set to appear independently more than once within the controlling domain, the second and subsequent occurrences of the set should be `aliases` of the original set, so that the number of controlling indices is equal to the number of indices. For details on aliases, see section The Alias Statement: Multiple Names for a Set.

Consider the following statement as an illustration:

```
b(row,row) = 7.7 - r(row) ;
```

This statement has only one controlling index, namely `row`. One element (on the diagonal of `b`) is assigned for each element of `row`, for a total of 10 assigned values. None of the off-diagonal elements of `b` will be changed!

If the intent is to assign values to each element of `b`, this can be done by introducing an alias `rowp` for `row` and using this alias in the second index position. There will then be two controlling indices and GAMS will make assignments over all 100 values of the full Cartesian product. The following example illustrates this method:

```
alias(row,rowp) ;
b(row,rowp) = 7.7 - (r(row) + r(rowp))/2 ;
```

4.26.3 Expressions

An expression is an arbitrarily complicated specification for a calculation, with parentheses nested as needed for clarity and intent. In this section the discussion of parameter assignments will continue by showing in more detail the expressions that may be used on the right of the = sign. We will cover standard arithmetic operations and indexed operations here, and functions and extended range arithmetic in the next two sections.

4.26.3.1 Standard Arithmetic Operations

The standard arithmetic symbols and operations and their order of precedence are given in Table 1. Note that 1 denotes the highest order of precedence and 3 denotes the lowest order of precedence. Parentheses can be used to override the default precedence order in the usual way. Operators (including exponentiation) on the same level are evaluated from left to right.

Operation	Symbol	Order of Precedence
Exponentiation	**	1
Multiplication	*	2
Division	/	2
Addition	+	3
Subtraction	-	3

Table 1: Standard Arithmetic Operations

Note that the full GAMS operator precedence hierarchy also includes logical operators; it is given in section Mixed Logical Conditions. Note further that the symbols for addition, subtraction and multiplication

have a different meaning if they are used in the context of sets. For details see sections Set Operations and Lag and Lead Operators.

Attention

The operation `x**y` is equivalent to the function rPower(x,y) and is calculated internally as $e^{y \times \log(x)}$. This operation is not defined if x is negative; an error will result in this case. If the possibility of negative values for x is to be admitted *and* the exponent is known to be an integer, then the function power(x,n) may be used.

Like many GAMS intrinsic functions, the operation `x**y` is not defined for all possible input values. When evaluating nonlinear functions and operators GAMS guards against evaluating at or very near singular points and in such cases signals an error or returns an appropriate function value.

Note

As usual, operations within parentheses or brackets are evaluated before other numerical calculations, where the innermost parentheses are resolved first. Any of the pairs `()`, `[]` and {} are allowed.

Consider for example:

```
x = 5 + 4*3**2;
```

For clarity, this could have been written as follows:

```
x = 5 + (4*[3**2]) ;
```

In both cases the result is 41.

Note

It is often better to use parentheses than to rely on the order of precedence of operators, since this prevents errors and clarifies intentions.

Note that expressions may be freely continued over many lines: an end of line is permissible at any point where a blank may be used. Blanks may be used for readability around identifiers, parentheses and operation symbols. Blanks are not allowed within identifiers or numbers, and are significant inside the quotes used to delimit labels.

4.26.3.2 Indexed Operations

In addition to the simple operations in Table 1, GAMS also provides the following six indexed operations.

Operation	Keyword
Summation	`sum`
Product	`prod`
Minimum value	`smin`
Maximum value	`smax`
Conjunction	`sand`
Disjunction	`sor`

Table 2: Indexed Operations

These six operations are performed over one or more controlling indices. The syntax in GAMS for these operations is:

```
indexed_op( (index_list), expression);
```

`Indexed_op` is one of the four keywords for indexed operations, `index_list` is the list of the controlling indices and `expression` is the expression to be evaluated. If there is only one controlling index, the parentheses around it may be removed. Consider the following simple example adapted from [**ANDEAN**]:

```
sets i   plants  / cartagena, callao, moron /
     m   product / nitr-acid, sulf-acid, amm-sulf /;

parameter capacity(i,m) capacity in tons per day
          totcap(m)     total capacity by process ;

totcap(m) = sum(i, capacity(i,m));
```

The index over which the summation is done, `i`, is separated from the reserved word `sum` by a left parenthesis and from the data term `capacity(i,m)` by a comma. The set `i` is called the controlling index for this operation. The scope of the control is the pair of parentheses `()` that start immediately after the sum. Note that using normal mathematical representation the last line could be written as: $totC_m = \sum_i C_{im}$.

It is also possible to sum simultaneously over the domain of two or more sets as in the first assignment that follows. The second assignment demonstrates the use of a less trivial expression than an identifier within the indexed operation.

```
count = sum((i,j), a(i,j)) ;
emp = sum(t, l(t)*m(t)) ;
```

The equivalent mathematical forms are:

$$count = \sum_i \sum_j A_{ij} \quad \text{and} \quad emp = \sum_t L_t M_t.$$

Note that the following alternative notation may be used for the first assignment above:

```
count = sum(i, sum(j, a(i,j)));
```

In the context of sets the `sum` operator may be used to compute the number of elements in a set and for projections. For details see section Projection and Aggregation of Sets.

The `smin` and `smax` operations are used to find the largest and smallest values over the domain of the index set or sets. The index for the `smin` and `smax` operators is specified in the same manner as in the index for the `sum` operator. In the following example we want to find the largest capacity:

```
lrgunit = smax((i,m),capacity(i,m));
```

Attention

The indexed operations `smin` and `smax` may be used in equation definitions only if the corresponding model is of type DNLP. For more on GAMS model types, see GAMS Model Types.

Note

- In the context of assignment statements, the attributes of variables and equations (e.g. `x.up(i,j)`) may be used in indexed operations just as scalars and parameters are used. For more on variable and equations attributes, see sections Variable Attributes and Equation Attributes respectively.
- In the context of equation definitions, scalars, parameters and variables may appear freely in indexed operations. For more on equation definitions, see section Defining Equations.

Sometimes it is necessary to restrict the domain of indexed operations. This may be done with the same techniques as in indexed assignments, see section Restricting the Domain in Assignments for details. See also section Conditional Indexed Operations for more details on conditions in the context of indexed operations.

We now turn to two additional capabilities that are available in GAMS to add power and flexibility to expression calculations: functions and extended range arithmetic.

4.26.4 Functions

Functions play an important role in the GAMS language, especially for nonlinear models. Like other programming languages, GAMS provides a number of built-in or intrinsic functions. GAMS is used in an extremely diverse set of application areas and this creates frequent requests for the addition of new and quite sophisticated or specialized functions. There is a trade-off between satisfying these requests and avoiding a complexity not needed by most users. The GAMS Function Library Facility provides the means for managing this trade-off, see subsection Extrinsic Functions below.

4.26.4.1 Intrinsic Functions

GAMS provides many functions, ranging from commonly used standard functions like exponentiation, logarithms, and trigonometric functions to utility functions for controlling and querying the running GAMS job or process. The complete list of available functions is given in the following tables: Mathematical Functions, String Manipulation Functions, Logical Functions, Time and Calendar Functions, and GAMS Utility and Performance Functions. For details specific to using these functions in equations, see the section on Expressions in Equation Definitions.

Some of the tables that follow contain an endogenous classification column "End. Classif." that specifies in which models the function may legally appear. In order of least to most restrictive, the choices are *DNLP*, *NLP*, *any*, *none*. See section Classification of Models for details on model types in GAMS. Note well: functions classified as *any* are only permitted with exogenous (constant) arguments.

Functions are typically used in assignment statements and equations. In these cases, they are only evaluated at execution time. Some functions can also be used at compile time, e.g. to compute the factorial or square root of a scalar. Some of the tables below contain a column "Compile Time" indicating which functions can be used at compile time.

A word on the notation in the tables below: for function arguments, lower case indicates that an endogenous variable is allowed. For details on endogenous variables, see section Functions in Equation Definitions. Upper case function arguments indicate that a constant is required. Arguments in square brackets may be omitted: the default values used in such cases are specified in the function description provided.

Mathematical Functions

Mathematical functions may be used as expressions in assignment statements and in equation definitions. We start with some simple examples to illustrate. A list with all mathematical functions available in GAMS is given in Table 3.

Exp(x)

```
a = exp(t);
b = exp(t+2);
```

The GAMS function `exp(x)` returns the exponential e^x of its argument. The assignments above set $a = e^t$ and $b = e^{t+2}$ respectively.

Log(x)

```
z(j) = log(y(j));
```

The GAMS function `log(x)` returns the natural logarithm of its argument. The assignment above evaluates the logarithm once for each element of the controlling domain `j`.

Max(x1,x2,x3,...)

```
x = max(y+2, t, t*t);
```

The function `max` returns the maximum of a set of expressions or terms. In the assignment above, `x` will be assigned the maximum of $y + 2$, t, and $t \cdot t$.

Round(x[,DECPL])

The function `round` rounds its argument `x` to the specified number `DECPL` of places, where positive values of `DECPL` indicating rounding to the right of the decimal point. If the argument `DECPL` is not specified, it defaults to zero, and the function rounds its argument to the nearest integer value. For example,

```
x = round(q);
y = round(q,d);
z = round(12.432,2);
h = round(515.5,-1);
```

In the first assignment `q` is rounded to the nearest integer value, while in the second `q` is rounded to the number of decimals specified by `d`. The result of the third assignment is 12.43, while the final assignment results in a value of 520.

Table 3: ***Mathematical Functions***

Function	Description	End. Classif.	Compile Time
`abs(x)`	**Absolute value** of the argument x.	DNLP	yes

Function	Description	End. Classif.	Compile Time
`arccos(x)`	**Inverse cosine** of the argument x, where x is a real number between -1 and 1 and the output is in radians, see MathWorld	NLP	no
`arcsin(x)`	**Inverse sine** of the argument x, where x is a real number between -1 and 1 and the output is in radians, see MathWorld	NLP	no
`arctan(x)`	**Inverse tangent** of the argument x, where x is a real number and the output is in radians, see MathWorld	NLP	no
`arctan2(y,x)`	**Four-quadrant arctan function** yielding $\arctan(\frac{y}{x})$ which is the angle the vector (x, y) makes with (1,0) in radians.	NLP	no
`beta(x,y)`	**Beta function**: $B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$, see MathWorld	DNLP	no
`betaReg(x,y,z)`	**Regularized beta function**, see MathWorld	NLP	no
`binomial(n,k)`	(Generalized) **Binomial coefficient** for $n > -1$, $-1 < k < n + 1$.	NLP	no
`ceil(x)`	**Ceiling**: returns the smallest integer greater than or equal to x.	DNLP	yes
`centropy(x,y[,Z])`	**Cross-entropy**: $\begin{cases} x \cdot \ln(\frac{x+Z}{y+Z}), & \text{if } x > 0, \\ 0, & \text{if } x = 0, \end{cases}$ where $y > 0$, $Z \geq 0$. Default $Z = 10^{-20}$.	NLP	no
`cos(x)`	**Cosine** of the argument x, where x must be in radians, see MathWorld	NLP	yes
`cosh(x)`	**Hyperbolic Cosine** of x, where x must be in radians, see MathWorld	NLP	no
`cvPower(X,y)`	**Real power**: $\begin{cases} X^y, & \text{if } X > 0, \\ 0, & \text{if } X = 0 \text{ (also for } y \leq 0!). \end{cases}$	NLP	no
`div(dividend,divisor)`	Returns $\frac{\text{dividend}}{\text{divisor}}$, but undefined for divisor $= 0$.	NLP	no
`div0(dividend,divisor)`	Returns $\frac{\text{dividend}}{\text{divisor}}$, but 10^{299} for divisor $= 0$.	NLP	no
`eDist(x1[,x2,x3,...])`	**Euclidean or L-2 Norm**: $\sqrt{x_1^2 + x_2^2 + \ldots}$.	NLP	no
`entropy(x)`	**Entropy**: $\begin{cases} -x \cdot \ln(x), & \text{if } x > 0, \\ 0, & \text{if } x = 0. \end{cases}$	NLP	no

Function	Description	End. Classif.	Compile Time
`errorf(x)`	**Integral of the standard normal distribution** from negative infinity to x: $\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{\frac{-t^2}{2}} dt$.	NLP	no
`execSeed`	Reads or resets the **seed** for the random number generator (RNG). Note that the state of the RNG cannot typically be captured in one seed value; in such cases "reading" the seed involves harvesting a seed from the RNG, resetting the RNG with this seed, and returning the seed.	none	no
`exp(x)`	**Exponential** of x: e^x, see MathWorld	NLP	yes
`fact(N)`	**Factorial** of N, where $N \geq 0$ is an integer. $0! = 1$.	any	yes
`floor(x)`	**Floor**: greatest integer less than or equal to x.	DNLP	yes
`frac(x)`	Returns the **fractional part** of x, s.t. `x = trunc(x) + frac(x)`	DNLP	yes
`gamma(x)`	**Gamma function** : $\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} dt$, see MathWorld	NLP	no
`gammaReg(x,a)`	**Lower Incomplete Regularized Gamma function**, see `GammaRegularized[a,0,x]` in MathWorld	NLP	no
`log(x)`	**Natural logarithm**: logarithm base e, see MathWorld	NLP	yes
`logBeta(x,y)`	**Log Beta function**: $\log(B(x,y))$.	NLP	no
`logGamma(x)`	**Log Gamma function** as discussed in MathWorld	NLP	no
`logit(x)`	**Logit Transformation**: $\log(x/(1-x))$, see MathWorld	NLP	yes
`log10(x)`	**Common logarithm**: logarithm base 10, see MathWorld	NLP	yes
`log2(x)`	**Binary logarithm**: logarithm base 2, see MathWorld	NLP	yes
`lseMax(x1[,x2,x3,...])`	Smoothed **Max** via the **L**ogarithm of the **S**um of **E**xponentials: $\ln(e^{x_1} + e^{x_2} + ...)$, see Wikipedia	NLP	no
`lseMaxSc(T,x1[,x2,x3,...])`	**Sc**aled smoothed **Max** via the **L**ogarithm of the **S**um of **E**xponentials: `lseMaxSc(T,x) = lseMax(Tx)/T`, see Wikipedia	NLP	no

Function	Description	End. Classif.	Compile Time
`lseMin(x1[,x2,x3,...])`	Smoothed **Min** via the **L**ogarithm of the **S**um of **E**xponentials: $-\ln(e^{-x_1}+e^{-x_2}+...)$, see Wikipedia	NLP	no
`lseMinSc(T,x1[,x2,x3,...])`	**Sc**aled smoothed **Min** via the **L**ogarithm of the **S**um of **E**xponentials: `lseMinSc(T,x) = lseMin(Tx)/T`, see Wikipedia	NLP	no
`max(x1,x2,x3,...)`	**Maximum** value of the arguments, where the number of arguments may vary.	DNLP	yes
`min(x1,x2,x3,...)`	**Minimum** value of the arguments, where the number of arguments may vary.	DNLP	yes
`mod(x,y)`	**Remainder** of x divided by y.	DNLP	yes
`ncpCM(x,y,Z)`	**Chen-Mangasarian smoothing**: $x - Z \cdot \ln(1 + e^{\frac{x-y}{Z}})$.	NLP	no
`ncpF(x,y[,Z])`	**Fisher-Burmeister smoothing**: $\sqrt{(x^2+y^2+2\cdot Z)}-x-y$, $Z \geq 0$. Default $Z=0$.	NLP	no
`ncpVUpow(r,s[,`μ`])`	**NCP Veelken-Ulbrich** (smoothed min(r,s)): $\begin{cases}\frac{1}{2}(r+s-\lvert r-s\rvert), & \text{if } \lvert r-s\rvert \geq \mu \geq 0,\\ \frac{1}{2}(r+s-\frac{\mu}{8}\cdot(-(\frac{r-s}{\mu})^4+6(\frac{r-s}{\mu})^2+3)), & \text{otherwise.}\end{cases}$ Default $\mu=0$.	NLP	no
`ncpVUsin(r,s[,`μ`])`	**NCP Veelken-Ulbrich** (smoothed min(r,s)): $\begin{cases}\frac{1}{2}(r+s-\lvert r-s\rvert), & \text{if } \lvert r-s\rvert \geq \mu \geq 0,\\ \frac{1}{2}(r+s-(\frac{2\mu}{\pi}\sin(\frac{\pi}{2\mu}+\frac{3\pi}{2})+\mu)), & \text{otherwise.}\end{cases}$ Default $\mu=0$.	NLP	no
`normal(MEAN,STDDEV)`	Generate a **random number** from the **normal distribution** with mean `MEAN` and standard deviation `STDDEV`, see MathWorld	none	no
`pi`	Value of $\pi =$ **3.141593**....	any	yes
`poly(x,A0,A1,A2[,A3,...])`	Returns $p(x)$, where the **polynomial** $p(x) = A_0 + A_1x + A_2x^2 + A_3x^3 + ... + A_{20}x^{20}$. By default $A_3, ..., A_{20} = 0$.	NLP	no
`power(x,Y)`	Returns x^Y, where Y must be an integer. $0^Y = \begin{cases}0, & \text{if } Y>0,\\ 1, & \text{if } Y=0,\\ \text{undefined}, & \text{if } Y<0.\end{cases}$	NLP	no

Function	Description	End. Classif.	Compile Time
`randBinomial(N,P)`	Generate a **random number** from the **binomial distribution**, where N is the number of trials and P the probability of success for each trial, see MathWorld	none	no
`randLinear(LOW,SLOPE,HIGH)`	Generate a **random number** between `LOW` and `HIGH` with **linear distribution**, `SLOPE` must be greater than $\frac{2}{\text{HIGH}-\text{LOW}}$	none	no
`randTriangle(LOW,MID,HIGH)`	Generate a **random number** between `LOW` and `HIGH` with **triangular distribution**, `MID` is the most probable number, see MathWorld	none	no
`round(x[,DECPL])`	**Round** x to `DECPL` decimal places. Default `DECPL=0`	DNLP	yes
`rPower(x,y)`	Returns $\begin{cases} x^y, & \text{if } x > 0, \\ 0, & \text{if } x = 0, y > 0, \\ 1, & \text{if } x = y = 0. \end{cases}$ This function is equivalent to the operation `x**y`, see Standard Arithmetic Operations.	NLP	no
`sigmoid(x)`	**Sigmoid:** $\frac{1}{1+e^{-x}}$, see MathWorld	NLP	no
`sign(x)`	**Sign** of x: $\begin{cases} 1, & \text{if } x > 0, \\ 0, & \text{if } x = 0, \\ -1, & \text{if } x < 0. \end{cases}$	DNLP	yes
`signPower(x,Y)`	**Signed power**: $\text{sign}(x)\lvert x\rvert^Y$ for $Y > 0$.	NLP	no
`sin(x)`	**Sine** of the argument x, where x must be in radians, see MathWorld	NLP	yes
`sinh(x)`	**Hyperbolic sine** of x, where x must be in radians, see MathWorld	NLP	no
`slexp(x[,S])`	**Smooth (linear) exponential**: $\begin{cases} e^x, & \text{if } x \leq S, \\ e^x \cdot (1 + (x - S)), & \text{otherwise,} \end{cases}$ where $S \leq 150$. Default $S = 150$.	NLP	no
`sllog10(x[,S])`	**Smooth (linear) logarithm base 10**: $\begin{cases} \log_{10}(x), & \text{if } x \geq S, \\ \frac{1}{\ln(10)} \cdot (\ln S + \frac{x-S}{S}), & \text{otherwise,} \end{cases}$ where $S \geq 10^{-150}$. Default $S = 10^{-150}$.	NLP	no

Function	Description	End. Classif.	Compile Time
`slrec(x[,S])`	**Smooth (linear) reciprocal**: $\begin{cases}\frac{1}{x}, & \text{if } x \geq S,\\ \frac{1}{S} - \frac{x-S}{S^2}, & \text{otherwise,}\end{cases}$ where $S \geq 10^{-10}$. Default $S = 10^{-10}$.	NLP	no
`sqexp(x[,S])`	**Smooth (quadratic) exponential**: $\begin{cases}e^x, & \text{if } x \leq S,\\ e^x \cdot (1 + (x-S) + \frac{(x-S)^2}{2}), & \text{otherwise,}\end{cases}$ where $S \leq 150$. Default $S = 150$.	NLP	no
`sqlog10(x[,S])`	**Smooth (quadratic) logarithm base 10**: $\begin{cases}\log_{10}(x), & \text{if } x \geq S,\\ \frac{1}{\ln(10)} \cdot (\ln S + \frac{x-S}{S} - \frac{(x-S)^2}{2S^2}), & \text{otherwise,}\end{cases}$ where $S \geq 10^{-150}$. Default $S = 10^{-150}$.	NLP	no
`sqrec(x[,S])`	**Smooth (quadratic) reciprocal**: $\begin{cases}\frac{1}{x}, & \text{if } x \geq S,\\ \frac{1}{S} - \frac{x-S}{S^2} + \frac{(x-S)^2}{S^3}, & \text{otherwise,}\end{cases}$ where $S \geq 10^{-10}$. Default $S = 10^{-10}$.	NLP	no
`sqr(x)`	**Square** of argument x.	NLP	yes
`sqrt(x)`	**Square root** of x, see MathWorld	NLP	yes
`tan(x)`	**Tangent** of the argument x, where x must be in radians, see MathWorld	NLP	yes
`tanh(x)`	**Hyperbolic tangent** of x, where x must be in radians, see MathWorld	NLP	no
`trunc(x)`	**Truncation:** returns the integer part of x, truncating towards zero.	DNLP	yes
`uniform(LOW,HIGH)`	Generates a **random number** from the **uniform distribution** between `LOW` and `HIGH`, see MathWorld	none	no
`uniformInt(LOW,HIGH)`	Generates an **integer random number** from the **discrete uniform distribution** whose outcomes are the integers between `LOW` and `HIGH`, inclusive, see MathWorld	none	no
`vcPower(x,Y)`	Returns x^Y for $x \geq 0$. $0^0 = 1$.	NLP	no

String Manipulation Functions

GAMS provides some string manipulation capability by extending the card and ord operators to work on strings as well as sets. In Table 4 the extended behavior is described. In this context, the functions take

strings and *places* as arguments, and the numeric *places* argument must be a constant. This behavior only applies to execution-time usage of these functions.

Table 4: ***String Manipulation Functions***

Function	Description
`card(STRING)`	Returns the **number of characters** in the `string`.
`ord(STRING[,PLACE])`	Returns the **ASCII code number of a character** in a position in a `string`. The optional `place` entry defaults to 1 if omitted and identifies the character position within the `string` to be examined (1 for the first, 2 for the second, etc.)

There are four types or sources of strings in this context. A string may be a string literal, i.e. a concatenation of letters and blanks as in `"drink it"` in the example that follows. It may be the symbol text (aka the explanatory text) associated with any symbol. Or it may be the labels or text associated with the elements of a set. The following table gives an overview:

Table 5: ***String Types***

Notation	Description	Comments
`characters`	A concatenation of characters and blanks: all legal GAMS characters are allowed, see section Characters for details.	The characters must be surrounded by double or single quotes.
`symbol_name.ts`	The string is the explanatory text associated with a symbol name.	If the explanatory text is missing, the value of `card` is 0.
`set_name.tl`	The string is the label for a set element.	This string type may be used only when `set_name` is part of the controlling domain.
`set_name.te`	The string is the explanatory text associated with a set element.	This string type may be used only when `set_name` is part of the controlling domain. If the explanatory text is missing, the value of `card` is 0.

The string types are illustrated in the following example. Note that the directive in the first line activates the end-of-line comment option, see eolCom.

```
$oneolcom
variable z 'any symbol can have explanatory text';
set teas "teas available to order"  / black "English Breakfast",  green, peppermint /;
scalar p;

p = card("drink it");       !! result: p=8
p = card(z.ts);             !! result: p=36
p = card(teas.ts);          !! result: p=23

loop{teas,
    p = card(teas.tl)       !! length of set element label from the set "teas": "teas" is the controll
    display "length of set element label", p;
    p = card(teas.te)       !! length of set element explanatory text: "teas" is the controlling set
    display "length of set element explanatory text", p;
};
```

Note that the strings `teas.tl` and `teas.te` are used in the context of a `loop` statement (see section The Loop Statement). This is a typical usage pattern.

Logical Functions

Logical functions may be used as expressions in assignment statements as in the following example.

```
x = ifthen(tt=2, 3, 4+y);
```

Here $x = 3$ if $tt = 2$, otherwise $x = 4 + y$.

The logical functions available in GAMS are given in Table 6. Note that logical functions may also be used in conditions and logic equations, see sections Logical Conditions and Logic Equations respectively. Most of the logical functions can also be indicated using the familiar operator notation, e.g. (x and y), (x >= y), etc. In such cases, the operator notation is allowed at compile time. The last column in Table 6 indicates if a logical function can be used at compile time (yes) or if only its alternative notation is available (alt). Further, note that the inputs and outputs of these functions are often logical/Boolean values, so GAMS does implicit conversions as necessary. As expected, false becomes 0 and true becomes 1 when converting logical values to numeric, and 0 becomes false and nonzero becomes true when numeric values are converted to logicals. For details on behavior when the inputs are special values, see sections Extended Range Arithmetic and Acronym Usage, but note that EPS, +INF, -INF, and acronyms become true when converted to logicals.

Table 6: ***Logical Functions***

Function	Alternative Notation 1	Alternative Notation 2	Description	Return Values	End. Classif.	Compile Time
bool_and(x,y)	x and y		**Boolean** AND	Returns true iff both x and y are true	DNLP	alt
bool_eqv(x,y)	x eqv y	x <=> y	**Boolean equivalence**	Returns false iff *exactly* one argument is false	DNLP	alt
bool_imp(x,y)	x imp y	x -> y	**Boolean implication**	Returns true iff x is false or y is true	DNLP	alt
bool_not(x)	not x		**Boolean** NOT	Returns true iff x is false	DNLP	alt
bool_or(x,y)	x or y		**Boolean** OR	Returns true iff x is true or y is true	DNLP	alt
bool_xor(x,y)	x xor y		**Boolean** XOR	Returns true iff *exactly* one argument is false	DNLP	alt

Function	Alternative Notation 1	Alternative Notation 2	Description	Return Values	End. Classif.	Compile Time
`ifThen(cond,iftrue,else)`			**Condition**	If the logical condition (first argument) is true, the function returns `iftrue`, else it returns `else`. See example above.	DNLP	yes
`rel_eq(x,y)`	`x eq y`	`x = y`	**Numeric Relation: Equal**	Returns true iff $x = y$	DNLP	alt
`rel_ge(x,y)`	`x ge y`	`x >= y`	**Numeric Relation: Greater Equal**	Returns true iff $x \geq y$	DNLP	alt
`rel_gt(x,y)`	`x gt y`	`x > y`	**Numeric Relation: Greater Than**	Returns true iff $x > y$	DNLP	alt
`rel_le(x,y)`	`x le y`	`x <= y`	**Numeric Relation: Less Equal**	Returns true iff $x \leq y$	DNLP	alt
`rel_lt(x,y)`	`x lt y`	`x < y`	**Numeric Relation: Less Than**	Returns true iff $x < y$	DNLP	alt
`rel_ne(x,y)`	`x ne y`	`x <> y`	**Numeric Relation: Not Equal**	Returns true iff $x \neq y$	DNLP	alt

Time and Calendar Functions

GAMS offers several functions that relate to time and dates. The fundamental measurement of time in GAMS is the serial day number beginning with January 1, 1900. This serial day number is a real number whose integer part contains a unique number for each day and whose fractional part contains information about hours, minutes, and seconds. We can think of the serial day number as being a `date.time` pair. The day information extracted from serial day numbers is based on the Gregorian calendar.

Note

In all functions given in Table 7, *serial day 1* is *January 1, 1900*.

All of the functions in Table 7 can be used at compile time.

Table 7: ***Time and Calendar Functions***

Function	Description	End. Classif.
gday(SDAY)	Returns **Gregorian day** from a serial day number date.time.	any
gdow(SDAY)	Returns **Gregorian day of week** from a serial day number date.time.	any
ghour(SDAY)	Returns **Gregorian hour** of day from a serial day number date.time.	any
gleap(SDAY)	Returns 1 if the year that corresponds to a serial day number date.time, is a **leap year**, else returns 0.	any
gmillisec(SDAY)	Returns **Gregorian milli second** from a serial day number date.time.	any
gminute(SDAY)	Returns **Gregorian minute** of hour from a serial day number date.time.	any
gmonth(SDAY)	Returns **Gregorian month** from a serial day number date.time.	any
gsecond(SDAY)	Returns **Gregorian second** of minute from a serial day number date.time.	any
gyear(SDAY)	Returns **Gregorian year** from a serial day number date.time.	any
jdate(YEAR,MONTH,DAY)	Returns a **serial day number**.	any
jnow	Returns the **current time** as a serial day number.	none
jstart	Returns the **time of the start of the GAMS job** as a serial day number.	none
jtime(HOUR,MIN,SEC)	Returns **fraction of a day** that corresponds to hour, minute and second.	any

GAMS Utility and Performance Functions

GAMS provides several functions that may be used to get (and in some cases set) GAMS system information, for example:

```
scalar o;
o = heapLimit;
heapLimit = 1024;
```

Table 8: ***GAMS Utility and Performance Functions***

Function	Description	End. Classif.	Compile Time
embeddedHandle	Returns the handle for the last embedded code section executed, see section Syntax in chapter Embedded Code Facility for details.	none	no
errorLevel	**Return code** of the most recently used command.	none	yes
execError	Get or set the **number of execution errors**.	none	no
gamsRelease	Returns the **release number** of the running GAMS system, for example 24.7.	none	yes

Function	Description	End. Classif.	Compile Time
`gamsVersion`	Returns the **version number** of the running GAMS system, for example 247.	none	yes
`handleCollect(HANDLE)`	Tests if the solve of the model instance identified by the calling argument `HANDLE` is done: if so, it loads the solution into GAMS. For details, see Table 1 in section Grid Computing.	none	no
`handleDelete(HANDLE)`	Deletes the model instance identified by `HANDLE`. For details, see Table 1 in section Grid Computing.	none	no
`handleStatus(HANDLE)`	Tests if the solve of the model instance identified by `HANDLE` is done: if so, it loads the solution into a GDX file. For details, see Table 1 in section Grid Computing.	none	no
`handleSubmit(HANDLE)`	Resubmits the model instance identified by `HANDLE` for solution. For details, see Table 1 in section Grid Computing.	none	no
`heapFree`	Get the amount of **free memory** in the heap in MB, i.e. memory allocated to the process and available for future use by GAMS.	none	no
`heapLimit`	Get or set the current **heap limit** (maximum allowable dynamic memory usage) in Mb.	none	no
`heapSize`	Get the current **heap size** in Mb.	none	no
`jobHandle`	Returns the **process ID** (`PID`) of the last job started.	none	yes
`jobKill(PID)`	Sends a **kill signal** to the job with process ID `PID`. The return value is 1 if this was successful, 0 otherwise.	none	yes
`jobStatus(PID)`	Get the **status** of the job with process ID `PID`. Possible return values are: 0: error (input is not a valid `PID` or access is denied) 1: process is still running 2: process is finished with return code which could be accessed by errorlevel 3: process not running anymore or was never running, no return code available	none	yes
`jobTerminate(PID)`	Sends an **interrupt signal** to the job with process ID `PID`. The return value is 1 if this was successful, 0 otherwise.	none	yes

Function	Description	End. Classif.	Compile Time
`licenseLevel`	Get an indicator for the **type of license**: 0: demo license, limited to small models 1: full unlimited developer license 2: run time license, no new variables or equations can be introduced besides those inherited from a work file 3: application license, only works with a specific work file which is locked to the license file 5: community license, limited to somewhat bigger models compared to demo license.	any	no
`licenseStatus`	Returns non-zero if a **license error** has occurred.	any	no
`mapVal(x)`	Returns an integer value that indicates what special value (if any) is stored in the input x. Possible results: 0: x is not a special value 4: x is `UNDF` (undefined) 5: x is `NA` (not available) 6: x is `INF` (∞) 7: x is `-INF` ($-\infty$) 8: x is `EPS` >8: x is an acronym	any	no
`maxExecError`	Get or set the **maximum number of execution errors**. See also maxExecError.	none	no
`numCores`	Get the number of logical CPU cores in the system	any	yes
`platformCode`	Returns an integer indicating the current platform. Possible return values can be seen here.	any	yes
`readyCollect(HANDLES[,MAXWAIT])`	Waits until a model solution is ready to be collected. For details, see Table 1 in section Grid Computing.	none	no
`sleep(SEC)`	Pause or **sleep** execution for `SEC` seconds.	none	yes
`timeClose`	Returns the **accumulated closedown time**, i.e. the time GAMS uses to save its state to disk prior to a solve.	none	no
`timeComp`	Returns the **compilation time** in seconds.	none	no
`timeElapsed`	Returns the **elapsed time** since the start of a GAMS run in seconds.	none	no
`timeExec`	Returns the **execution time** in seconds.	none	no

Function	Description	End. Classif.	Compile Time
timeStart	Returns the **accumulated startup time**, i.e. the time GAMS uses to restore its state from disk after a solve.	none	no

4.26.4.2 Extrinsic Functions

Using the GAMS Function Library Facility, functions may be imported from an external library into a GAMS model. Apart from the import syntax, the imported functions may be used in the same way as intrinsic functions. In particular, they may be used in equation definitions. Some function libraries are included with the standard GAMS software distribution, but GAMS users can also create their own libraries using an open programming interface. The GAMS Test Library instances **[TRILIB01]**, **[TRILIB02]**, **[TRILIB03]**, and **[CPPLIB00]** are simple examples (in the programming languages C, Delphi, Fortran and C++, respectively) that come with every GAMS system.

For details on using and creating extrinsic function libraries, and on the extrinsic function libraries that are provided with GAMS, see the chapter on Extrinsic Functions.

4.26.4.3 Function Suffixes

Up to this point, this section has described and discussed functions without mentioning their derivatives. These derivatives are very important, though: most of the nonlinear solvers integrated with GAMS will require first derivatives to solve models, and many will also use or require second derivatives as well. It is sometimes useful (e.g. when testing an extrinsic function) to evaluate the derivatives of GAMS functions instead of the functions themselves. This can be done via function suffixes.

Function suffixes can specify the evaluation of a gradient (i.e. first derivative), a Hessian (i.e. second derivative), a minimum or maximum value of the function over a given range, or the minimum or maximum value of the gradient over a given range. A full list of function suffixes is given in Table 9. For functions whose arguments are constant, the derivatives are zero, so typically `func` is a mathematical function listed in Table 3 above. Note that function suffixes are *not* defined for functions without arguments (for example, `pi`), so specifying something like `pi.grad` results in a compilation error.

Table 9: ***Function Suffixes***

Function Suffix	Description
func.value(x)	Value of the function `func` at `x`, equals `func(x)`.
func.grad(x)	Value of the gradient of the function `func` at `x`.
func.gradn(x)	Value of the gradient of the function `func` at `x`, computed numerically.
func.hess(x)	Value of the Hessian of the function `func` at `x`.
func.hessn(x)	Value of the Hessian of the function `func` at `x`, computed numerically.
func.low(x1:x2)	Lower bound of the function `func(x)` on the interval `[x1,x2]`.
func.high(x1:x2)	Upper bound of the function `func(x)` on the interval `[x1,x2]`.
func.gradL(x1:x2)	Lower bound of the gradient of the function `func(x)` on the interval `[x1,x2]`.
func.gradH(x1:x2)	Upper bound of the gradient of the function `func(x)` on the interval `[x1,x2]`.

Consider the following simple example:

```
scalars g, l, h, gl, gh;

g  = sin.grad(0);
l  = sin.low(pi/3:pi/2);
h  = sin.high(pi/3:pi/2);
gl = sin.gradL(pi/3:pi/2);
gh = sin.gradH(pi/3:pi/2);

display g, l, h, gl, gh;
```

For univariate functions like sine or cosine, there is no need to specify a variable index when evaluating derivatives. For multivariate functions, the default is to take partial derivatives w.r.t. the first variable. To specify other variables, the colon syntax in the example below is used.

```
scalars
  x   / 1 /
  ylo / -1 /
  yup / 2 /
  e0, e1, elo, ehi
  e_1, e_2
  e_11, e_22, e_21
  ;
e0 = edist(x,ylo);
e1 = edist(x,yup);
elo = edist.low (x,ylo:x,yup);
ehi = edist.high(x,ylo:x,yup);

e_1 = edist.grad(x,yup);
* e_1 = edist.grad(1:x,yup);  same as above
e_2 = edist.grad(2:x,yup);

e_11 = edist.hess(x,yup);
* e_11 = edist.hess(1:1:x,yup);  same as above
e_22 = edist.hess(2:2:x,yup);
e_21 = edist.hess(2:1:x,yup);

display x, ylo, yup, e0, e1, elo, ehi, e_1, e_2, e_11, e_22, e_21;
```

For more examples, see model **[FUNCS4]** in the GAMS Test Library.

Note

- The function suffixes `value`, `grad`, `gradn`, `hess` and `hessn` are also defined for extrinsic functions. When implementing an extrinsic function, be aware that missing derivatives will be computed numerically: see model **[TRILIB01]** for an example.

To compute derivatives numerically, GAMS uses finite difference approximations. This computation can be controlled with two options: the FDOpt option controls which variant of the finite difference method is used, while the FDDelta option controls the step size.

4.26.5 Extended Range Arithmetic and Error Handling

GAMS uses an *extended range* arithmetic to handle missing data, the results of undefined operations, infinite values, and zeros that are stored explicitly. The *special values* used in this arithmetic are listed and described in Table 10 below, along with the value of the mapVal function that corresponds to these values. We can think of special values as any value for which mapVal does not return 0.

Special value	Description	mapVal
INF	Plus infinity. Similar to IEEE plus infinity. Behaves in the expected way in computations, so that e.g. min(x,INF) = x unless x is also special.	6
-INF	Minus infinity. Similar to IEEE minus infinity. Behaves in the expected way in computations, so that e.g. max(x,INF) = x unless x is also special.	7
NA	Not available - used to indicate missing data. It is a sticky value: e.g. max(x,NA) = NA even for x = INF	5
UNDF	Undefined - indicates the result of an undefined or illegal operation. Similar to IEEE NaN. A user cannot directly set a value to UNDF unless the dollar control option onUNDF is active. For details, see the chapter on Dollar Control Options.	4
EPS	A *stored* zero value. If the dollar control option onEPS is active, zeros in a parameter or table statement are treated as EPS. For details on dollar control options, see chapter Dollar Control Options.	8

Table 10: Special Values for Extended Range Arithmetic

Attention

Avoid creating or using numbers with very large (1.0e299 or above) or very small (1.0e-299 or below) magnitudes. Large numbers may be treated by GAMS as undefined (UNDF) or other special values, leading to unpredictable and unusable results. Always use INF (or -INF) explicitly for arbitrarily large (or small) numbers.

GAMS has defined the results of all arithmetic operations and all function evaluations that use these special values. The behavior is designed to both maximize utility and minimize surprise, and is illustrated in the library model [**CRAZY**]. For example: 1+INF evaluates to INF, 1-EPS to 1, NA $*$ 2 to NA, and EPS$*$INF to UNDF.

The following table shows a selection of results for exponentiation and division for a variety of input parameters including NA and INF.

a	b	a**b	power(a,b)	a/b
2	2	4	4	1
-2	2	UNDF	4	-1
2	2.1	4.28	UNDF	.952
NA	2.5	NA	NA	NA
3	0	1	1	UNDF
INF	2	INF	INF	INF
2	INF	UNDF	UNDF	0

Table 11: Extended Range Arithmetic in Exponentiation and Division

Note that most extended range identifiers may be used in assignment statements, as illustrated below.

```
a(row,'col-3') =  NA;
a(row,'col-4') =  INF;
a(row,'col-5') = -INF;
```

The values most often used in assignments are NA in incomplete tables and INF for variable bounds.

The special value EPS is numerically equal to zero, so when used in the context of numerical comparisons, it behaves as zero. For example, the logical expressions x > 0 and x > EPS have the same result. However, EPS is a *stored* zero, so setting a parameter to zero (e.g. a(row,col)=0) results in no values being stored for a, while setting a parameter to EPS (e.g. a(row,col)=EPS) results in the value EPS being stored for every (row,col) tuple. This is sometimes useful, especially if a is used later in loops (see Programming Flow Control Features) or dollar conditions (see Conditional Expressions, Assignments and Equations). For example, consider the statement

```
a(row,col)$[a(row,col)] = INF ;
```

In the case where a was originally assigned to be zero, the dollar-condition is always false so no infinities are assigned. If a was originally assigned the value EPS, the dollar-condition is always true and every tuple in a will be set to infinity.

When an attempted arithmetic operation is illegal or has undefined results because of the value of arguments (division by zero is the normal example), an error is reported and the result is set to undefined (UNDF). The error is marked on the output file with a row of four asterisks '****' making this sequence a good search target in the editor. GAMS will also report the line number of the offending statement and give as much detail as possible about the cause. From there on, the resulting UNDF is treated as a proper data value and does not trigger additional error messages. For more on error messages, see chapter GAMS Output.

Note

GAMS will not solve a model if an error has been detected, and it will terminate with an error condition.

It is therefore wise to anticipate and avoid operations like division by zero that will cause errors. This is most easily done with the dollar control, and is discussed in section The Dollar Condition.

4.26.6 Predefined Symbols

GAMS offers several *predefined* symbols including: sameAs, diag, sortedUels, solvers, licenseCodes, and solverCapabilities. With the exception of sameAs, diag, and sortedUels these predefined symbols are for very special (and mostly internal) purposes, but the way they work is identical.

These symbols can be used in a GAMS program without being declared but work in an idiosyncratic way. For example, the complete program

```
display solvers, sameAs;
```

compiles and executes without error and produces the following result in the listing file:

```
----      1 SET Solvers  Available Solvers

                                                    ( EMPTY )

----      1 SET SameAs  Set Element Comparison Without Checking

                                                    ( EMPTY )
```

However, if labels have been declared (in any set) that corresponds to a solver name, then set solvers will contain this label. Consider the following example:

```
Set titles / Lord, Baron, Duke /;
Set greeks / Euclid, Pythagoras, Antigone /;
display solvers, sameAs;
```

Note that `Antigone` and `Baron` are the names of solvers in GAMS and therefore they will be displayed as a member of the set `solvers`. Also note that the set `sameAs` contains the diagonal elements for both sets:

```
----      3 SET Solvers  Available Solvers
Baron    ,    Antigone

----      3 SET SameAs  Set Element Comparison Without Checking
                 Lord       Baron        Duke      Euclid  Pythagoras    Antigone
Lord              YES
Baron                         YES
Duke                                     YES
Euclid                                               YES
Pythagoras                                                        YES
Antigone                                                                       YES
```

User defined symbols can have the same name as a predefined symbol. In this case the user symbol *hides* the predefined symbols as demonstrated in the following example:

```
Set diag / 1*3 /;
$if setType diag $log diag is a set
$if preType diag $log diag is a predefined type
```

The log will only contain the line `diag is a set`. The test `$if preType diag` fails.

The list of all predefined symbols can be retrieved by declaring and displaying a set using some system data `set pre /system.predefinedSymbols/; display pre;` which results in

```
----      1 SET pre
SameAs                ,    Diag                  ,    Solvers
LicenseCodes          ,    SolverCapabilities    ,    SortedUels
```

4.26.7 Summary

GAMS provides powerful facilities for data manipulation with parallel assignment statements, built-in functions and extended range arithmetic.

4.27 Data Entry: Parameters, Scalars and Tables

4.27.1 Introduction

Data handling is of crucial importance in all modeling applications. The quality of the numbers and the intelligence with which they are used is likely to be at least as important as the logic of the model in determining if an application is successful or not. GAMS has been designed to have a complete set of facilities for entering information, manipulating it and reporting on the results. In this chapter we will concentrate on data entry. Chapter Data Manipulations with Parameters introduces and discusses data manipulations. For details on reporting, see chapters GAMS Output, The Display Statement, The Put Writing Facility, and GAMS Data eXchange (GDX).

One very important principle will motivate all our discussions on data:

Note

Data should be entered in its most basic form and each data item should be entered only once.

There are two reasons for adopting this principle. Numbers are almost certain to change, and when they do we want to be able to make the process of changing them as easy and safe as possible. We also want to make our model easy for others to read and understand. Keeping the amount of data as small as possible will certainly help. All the data transformations are shown explicitly in the GAMS representation, which makes it possible to reproduce the results of a study and shows the reader all the assumptions made during data manipulation. Another advantage is that everything needed to run or change the model is included in one program that can easily be moved from place to place or from one machine to another.

This chapter deals with the data type *parameter*. For other data types, see section Data Types and Definitions. Data for *parameters* can be entered in three basic formats: scalar, list oriented, or tables of two or more dimensions. For each of these formats, GAMS offers a separate keyword:

Keyword	Description
Scalar	Single (scalar) data entry.
Parameter	List oriented data, defined over one or more sets.
Table	Table oriented data, must involve two or more dimensions.

Table 1: Parameters, Scalars and Tables

Note that the term *parameter* is used in two ways: as data type and as keyword, so one could also see `scalars` and `tables` as special formats of *parameters*. Each of the data input formats will be introduced and discussed in the following sections. At the end of the chapter the special data type acronym is introduced.

Note

- By default, parameters in all input formats may only be initialized once, thereafter data must be modified with assignment statements. This can be changed using the dollar control option $onMulti.
- This chapters explains the complete syntax to declare *parameters* which includes the optional initialization. So, while it is possible to initialize the data at declaration, often the data is read from other sources like databases or spreadsheets. More information about this can be found in the chapter Data Exchange with Other Applications.

4.27.2 Scalars

The `scalar` statement is used to declare and (optionally) initialize a GAMS parameter of dimensionality zero. This means that there are no associated sets, so there is exactly one number associated with the parameter.

4.27.2.1 The Syntax

In general, the syntax for a `scalar` declaration in GAMS is as follows:

```
scalar[s] scalar_name [text] [/numerical_value/]
       {  scalar_name [text] [/numerical_value/]} ;
```

The keyword `scalar[s]` indicates that this is a `scalar` statement and `scalar_name` is the internal name of the scalar in GAMS, it is an identifier. The optional explanatory text is used to describe the scalar and the optional `numerical_value` is assigned to be the value of `scalar_name`. `Numerical_value` can be given as fixed number or as constant evaluation. Alternatively, the special data type `acronym` may be used as value. For details on acronyms, see section Acronyms.

Note that more than one scalar may be declared in one scalar statement. The entries have to be separated by commas or by end of line. For advice on explanatory text and how to choose a `scalar_name`, see the tutorial Good Coding Practices.

Note that scalars may be declared but not initialized in the scalar statement. A value can also be assigned later as illustrated in the example that follows.

4.27.2.2 An Illustrative Example

An example of a `scalar` definition in GAMS is shown below.

```
Scalar
    rho  "discount rate"                            / .15 /
    irr  "internal rate of return"
    life "financial lifetime of productive units"  / 20  /;
```

The statement above initializes `rho` and `life`, but not `irr`. Later on another scalar statement can be used to initialize `irr` or an assignment statement could be used to provide the value:

```
irr  =  0.07;
```

For more on scalar assignments and parameter assignments in general, see section Data Entry by Assignment.

4.27.3 Parameters

The parameter format is used to enter list oriented data which can be indexed over one or several sets.

4.27.3.1 The Syntax

In general, the syntax for a `parameter` declaration in GAMS is as follows:

```
parameter[s] param_name[(index_list)] [text] [/ element [=] numerical_value
                                               {,element [=] numerical_value} /]
           {,param_name[(index_list)] [text] [/ element [=] numerical_value
                                               {,element [=] numerical_value} /]} ;
```

The keyword `parameter[s]` indicates that this is a parameter statement and `param_name` is the internal name of the parameter in GAMS, it is an identifier. A parameter may be defined over one or more sets that may be specified in the `index_list`. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section Domain Checking. The optional explanatory text is used to describe the parameter.

Parameter initialization requires a list of data elements, each consisting of a label or label-tuple and a value. `Element` is an element of the defining set or - if there is more than one defining set - a combination of the elements of the defining sets. The referenced set elements must belong to the set that the parameter is indexed over. Finally, `numerical_value` is the value assigned to the record defined by the set element or element tuple. It can be given as fixed number or as constant evaluation. Alternatively, the special data type `acronym` may be entered as value. For details on acronyms, see section Acronyms.

Note

The default value of a `parameter` is 0.

Slashes must be used at the beginning and end of the list, and commas must be used if several data elements are listed in one line. An equals sign or a blank separates the label tuple from its associated value. A parameter can be defined in a similar syntax to that used for a set. For advice on explanatory text and how to choose a parameter name, see the tutorial Good Coding Practices.

Note

Several parameters may be declared in one parameter statement.

4.27.3.2 Illustrative Examples

The following example illustrates the parameter statement. It is adapted from [**MEXSS**]. We also show the set definitions because they make the example clearer. For more on sets definitions, see chapter Set Definition.

```
Set i     "steel plants"   / hylsa      monterrey
                             hylsap     puebla  /
    j     "markets"        / mexico-df, monterrey, guadalaja /;

Parameter
    dd(j) "distribution of demand"
                         /  mexico-df   55,
                            guadalaja   15 /;
```

The index specification for the parameter `dd` means that there will be a vector of data associated with it, one number corresponding to every member of the set `j`. The numbers are specified along with the declaration in a format very reminiscent of the way we specify sets: in this simple case a label followed by a blank separator and then a value. Any of the legal number entry formats are allowable for the value. For details on number formats in GAMS, see subsection Numbers. The default data value is zero. Since `monterrey` has been left out of the data list, the value associated with `dd('monterrey')` is zero. As with sets, commas are optional at end of line.

We may also list several data elements on a line, separated by commas as in the following example:

```
Parameter
    a(i)  / seattle  =  350,  san-diego  =  600 /
    b(i)  / seattle    2000,  san-diego    4500 /;
```

If a parameter is defined over a set and all elements of the set are assigned the same value, then the following notation may be used as a shortcut:

```
parameter param_name[(set_name)]  [text]  /(#|set.)set_name numerical_value/;
```

Here `set` is a reserved word and `set_name` is the name of the set as it has been declared in a previous set declaration statement. Instead of `set`. one could also use the `#` sign. The following artificial example illustrates this notation:

```
Set        j      /j1, j2/;
Parameter  hh(j)  /set.j 10/
           gg     /#j    10/;
```

This resolves in `hh('j1') = hh('j2') = gg('j1') = gg('j2') = 10`.

Note

By default it is not possible to define an empty parameter at declaration. This may be changed using the dollar control option $onEmpty, as shown in the following example:

```
Set i     / seattle,  san-diego /;
$onEmpty
Parameter
    a(i)  /  /;
```

That initializes a('seattle') and a('san-diego') to 0. So it is not the same as this:

```
Set i     / seattle,  san-diego /;
Parameter
    a(i);
```

Here, a is declared, but not initialized (so, it is not defined yet) and one would get an error when trying to read it.

4.27.3.3 Parameter Data for Higher Dimensions

A parameter may have several dimensions. For the current maximum number of permitted dimensions, see Dimensions. The list oriented data initialization through the parameter statement can be easily extended to data of higher dimensionality. The label that appears on each line in the one-dimensional case is replaced by a label tuple for higher dimensions. The elements in the n-tuple are separated by dots (.) just like in the case of multi-dimensional sets.

The following example illustrates the use of parameter data for higher dimensions:

```
Parameter
    salaries(employee,manager,department)
        / anderson   .murphy   .toy          = 6000
          hendry     .smith    .toy          = 9000
          hoffman    .morgan   .cosmetics    = 8000 /;
```

All the mechanisms using asterisks and parenthesized lists that we introduced in our discussion of sets are available here as well. For details see section Multi-Dimensional Sets. Below is an artificial example, in which a very small fraction of the total data points are initialized. GAMS will mark an error if the same label combination (or label-tuple) appears more than once in a data list.

```
Set row / row1*row10 /
    col / col1*col10 /;
Parameter
    a(row, col)
        /  (row1,row4) . col2*col7    12
            row10      . col10        17
            row1*row7  . col10        33 /;
```

In this example the twelve elements row1.col2 to row1.col7 and row4.col2 to row4.col7 are all initialized at 12, the single element row10.col10 at 17, and the seven elements rows1.col10 to row7.col10 at 33. The other 80 elements (out of a total of 100) remain at their default value, which is 0. This example shows the ability of GAMS to provide a concise initialization or definition for a sparse data structure.

4.27.4 Tables

Tabular data can be declared and initialized in GAMS using a table statement. For two and higher-dimensional parameters this provides an easier and more concise method of data entry than the list based approach, since - at least in smaller tables - each label appears only once.

4.27.4.1 The Syntax

In general, the syntax for a `table` declaration in GAMS is as follows:

```
table table_name[(index_list)]  [text] [EOL
                element                { element }     EOL
  element    numerical_value       { numerical_value} EOL
 {element    numerical_value       { numerical_value} EOL}] ;
```

The keyword `table` indicates that this is a `table` declaration and `table_name` is the internal name of the table in GAMS, it is an identifier. The name of the parameter can be followed by the `index_list`. In the `index_list` the sets are specified over which the table is defined. Note that the specification of the index list in the declaration is optional. However, mostly it is advisable to specify it for reasons of clarity and to enable domain checking. For more on domain checking, see section Domain Checking. The optional explanatory text is used to describe the table, followed by `EOL` which means "end of line", a line break. `Element` is an element of one of the driving sets. More details follow below. `Numerical_value` is the value of the entry associated with the corresponding element combination. It can be given as fixed number or as constant evaluation. Alternatively, the special data type `acronym` may be used as value. For details on acronyms, see section Acronyms. For advice on explanatory text and how to choose a `table_name`, see the tutorial Good Coding Practices.

Attention

> By default, the table statement is the only statement in the GAMS language that is not free format. This may be changed using the dollar control option $onDelim.

The following rules apply:

- The relative positions of all entries in a table are significant. This is the only statement where end of line (EOL) has meaning. The character positions of the numeric table entries must overlap the character positions of the column headings.
- The column section has to fit on one line.
- The sequence of values forming a row must be on the same line.
- The element definition of a row can span more than one line.
- A specific column can appear only once in the entire table.

The rules for building simple tables are straightforward. The components of the header line are

```
keyword - identifier - index_list - text
```

Note that the `index_list` and the `text` are optional. Labels are used on the top and the left to map out a rectangular grid that contains the data values. The order of labels is unimportant, but if domain checking has been specified (i.e. the `index_list` has been given in the first line of the table declaration) each label must match one in the associated set. Labels must not be repeated, but can be left out if the corresponding numbers are all zero or not needed. At least one blank must separate all labels and data entries. Blank entries imply that the default value (zero) will be associated with that label combination.

Note

- Tables must have at least two dimensions. For the current maximum number of permitted dimensions, see Dimensions.
- The `table` statement can also be terminated with a `;` in the first line, so without entering data. In this case the parameter `table_name` would be declared but not initialized.
- In contrast to the `set`, `scalar`, and `parameter` statements, only one identifier may be initialized in a `table` statement, though multiple ones could be declared.

4.27.4.2 An Illustrative Example

In the following example a simple table is presented. It is adapted from [**KORPET**], the relevant set definitions are also given.

```
Set i   "plants"
        / inchon, ulsan, yosu /
    m   "productive units"
        / atmos-dist   "atmospheric distillation unit"
          steam-cr     "steam cracker"
          aromatics    "aromatics unit"
          hydrodeal    "hydrodealkylator"  /;

Table ka(m,i) "initial cap. of productive units (100 tons per yr)"
                     inchon      ulsan      yosu
    atmos-dist         3702      12910      9875
    steam-cr                       517      1207
    aromatics                      181       148
    hydrodeal                      180
;
```

In this example the row labels are drawn from the set `m` and those on the column from the set `i`. Note that the data for each row is aligned under the corresponding column headings. Entries that are not specified are assigned the default value zero.

Note

If there is any uncertainty about which column a number belongs to, GAMS will protest with an error message and mark the ambiguous entry.

Attention

Special care has to be taken, if tabs are used. The GAMS command line option TabIn controls the tab spacing. Note that this spacing might be different form the spacing that the editor is showing, hence the visible alignment might be different from the alignment that GAMS is actually using.

4.27.4.3 Continued Tables

If a table has too many columns to fit nicely on a single line, then the columns that don't fit may be continued on additional lines. We use the same example to illustrate:

```
Table ka(m,i) "initial cap. of productive units (100 tons per yr)"
                    inchon    ulsan
    atmos-dist      3702      12910
    steam-cr                    517
    aromatics                   181
    hydrodeal                   180

        +           yosu
    atmos-dist      9875
    steam-cr        1207
    aromatics        148
;
```

The crucial item is the plus `'+'` sign above the row labels and to the left of the column labels in the continued part of the table. The row labels have been duplicated, except that `hydroreal` has been left out, since it does not have any associated data. Tables may be continued as many times as necessary.

4.27.4.4 Tables with more than Two Dimensions

Tables may have more than two dimensions. For the current maximum number of permitted dimensions, see Dimensions. As usual, dots are used to separate adjacent labels and may be used in the row or column position. The label on the left of the row corresponds to the first set in the index list, and that on the right of each column header to the last. Obviously, there must be the same number of labels associated with each number in the table, as there are sets in the index list.

The best layout depends on the size of the defining sets and the amount of data. It should provide the most intuitively satisfactory way of organizing and inspecting the data. For most people it is easier to look down a column of numbers than across a row. However, putting extra labels on the row has the advantage of greater density of information.

The following example, adapted from [**MARCO**], illustrates the use of tables with more than two dimensions.

```
Set ci   "commodities :   intermediate"
         / naphtha    "naphtha"
           dist       "distillate"
           gas-oil    "gas-oil"  /
    cr   "commodities :   crude oils"
         / mid-c       "mid-continent"
           w-tex       "west-texas"  /
    q    "attributes of intermediate products"
         / density, sulfur /;

Table attrib(ci, cr, q) "blending attributes"
                          density    sulfur
    naphtha. mid-c          272        .283
    naphtha. w-tex          272       1.48
    dist   . mid-c          292        .526
    dist   . w-tex          297       2.83
    gas-oil. mid-c          295        .98
    gas-oil. w-tex          303       5.05
;
```

The table `attrib` could also be laid out as shown below:

```
Table attrib (ci,cr,q) "blending attributes"
            w-tex.density  mid-c.density  w-tex.sulfur  mid-c.sulfur
     naphtha      272             272         1.48          .283
     dist         297             292         2.83          .526
     gas-oil      303             295         5.05          .98
;
```

4.27.4.5 Condensing Tables

All the mechanisms using asterisks and parenthesized lists that were introduced in the discussion of sets are available here as well. For details on these mechanisms, see section Multi-Dimensional Sets. The following example shows how repeated columns or rows can be condensed with asterisks and lists in parentheses. The set membership is not shown, but can easily be inferred.

```
Table upgrade(strat,size,tech)
                small.tech1  small.tech2  medium.tech1  medium.tech2
    strategy-1       .05          .05          .05           .05
    strategy-2       .2           .2            .2           .2
    strategy-3       .2           .2            .2           .2
    strategy-4                                  .2           .2

Table upgradex(strat,size,tech) "alternative way of writing table"
                                          tech1*tech2
    strategy-1.(small,medium)                 .05
    strategy-2*strategy-3.(small,medium)      .2
    strategy-4.medium                         .2;
```

4.27.4.6 Handling Long Row Labels

It is possible to continue the row labels in a table on a second, or even third line in order to accommodate a reasonable number of columns. The break must come after a dot, and the rest of each line containing an incomplete row label-tuple must be blank.

The following example, adapted from [**INDUS**], is used to illustrate. This table actually has nine columns and many rows, here we have reproduced just a small part to show continued row label-tuples.

```
Table yield (c,t,s,w,z) "crop yield (metric tons per acre)"
                                                          nwfp     pmw
    wheat.(bullock, semi-mech).la-plant.
                                    (heavy, january)     .385     .338
    wheat.(bullock, semi-mech).la-plant. light           .506     .446
    wheat.(bullock, semi-mech).la-plant. standard        .592     .524
    wheat.(bullock, semi-mech).(qk-harv, standard).
                                    (heavy, january)     .439     .387
```

4.27.5 Constant Evaluation

Instead of fixed numerical values, one can also use constant expressions to assign values to parameters in a data statement. The syntax of constant expressions used in data statements follows the GAMS syntax as described in Data Manipulations with Parameters, but is restricted to scalar values and a subset of the GAMS intrinsic functions, as summarized below:

- Real numbers only
- Evaluation left to right
- Operator precedence:
  - ^ **
  - * /
  - + - binary and unary
  - < <= = <> >= > LE LE EQ NE GE GT
  - NOT
  - AND
  - OR XOR EQV IMP
- See Functions for list of supported functions

When used in a data statement, the constant expressions have to be enclosed in a pair of square brackets [ ] or curly brackets { }. Spaces can be used freely inside those brackets. Here is a little example:

```
Scalars x "PI half"       / [pi/2] /
        e "famous number" / [ exp( 1 ) ] /;

Parameter y "demo" / USA.(high,low) [1/3]
                     USA.medium {1/4}    /;
```

4.27.6 Data Entry by Assignment

Data may also be entered using assignment statements. Assignments are introduced and discussed in detail in section The Assignment Statement. This section here is a short outlook and shows how parameters that have already been declared may be assigned values. The general assignment statement has the following form:

```
parameter_name[(index_list)] = expression;
```

Here `parameter_name` is the name of a parameter that has been declared previously in a scalar, parameter or table statement, `index_list` indicates the controlling indices and may either contain a set or sets, a label or label tuple or a combination of those, and `expression` may be a number, a numerical expression or an acronym. For details on numerical expressions, see section Expressions.

The following examples illustrate how assignments may be used for data entry.

```
Set             j       /j1, j2, j3/;
Scalar          a1;
Scalars         a2      /11/;
Parameter       cc(j),
                bc(j)   /j2 22/;
a1 = 10;
a2 = 5;
cc(j) = bc(j)+10;
cc("j1") = 1;
```

The scalar `a1` is declared but not initialized in the first scalar statement. It is assigned the value of 10 in the first assignment. The scalar `a2` is initialized in the second scalar statement and this value is changed to 5 in the second assignment. Note that the original data is not retained. In the parameter statement the parameter `cc(j)` is declared but not initialized and the parameter `bc(j)` is only initialized for `j2`. This means that `bc('j2') = 22` and `bc('j1') = bc('j3') = 0`, the default value. Now, the third assignment sets the parameter `cc(j)` and assigns to all elements of the set `j` the value of the parameter `bc(j)` plus 10. So we have `cc('j2') = 32` and `cc('j1') = cc('j2') = 10`. Note that in this example the set `j` has only three elements so only 3 assignments are made simultaneously. However, suppose that the number of set elements is large, say 100,000, then to each element a value is assigned with just one assignment statement. Finally, the value of `cc('j1')` is changed to 1.

Observe that in the examples above assignments either refer to one specific set element or to the whole set. It is also possible to make assignments to only a part of the set. The mechanisms for partial set references are discussed in section Restricting the Domain in Assignments. Set elements that are not assigned new values in an assignment with a partial set reference retain their previous values. Recall that these may be the default value, values from the parameter or table statement, or values resulting from previous calculations.

4.27.7 Acronyms

An acronym is a special data type that allows the use of strings as values. Note that acronyms have *no numeric values* and are treated as character strings only.

4.27.7.1 The Syntax

The declaration for an acronym is similar to a set or parameter declaration. The basic format is as follows:

```
Acronym[s]  acronym_name [text] {, acronym_name [text]};
```

The keyword `acronym[s]` indicates that this is an `acronym` statement and `acronym_name` is the internal name of the acronym in GAMS, it is an identifier. The optional explanatory text is used to describe the acronym. For advice on explanatory text and how to choose an `acronym_name`, see the tutorial Good Coding Practices.

Note that more than one acronym may be declared in one acronym statement. The entries have to be separated by commas or by end of line. A simple example illustrates this:

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
```

4.27.7.2 Acronym Usage

Acronyms may be used as data in scalar, parameter and table statements. An example for acronyms in a parameter statement follows.

```
Set machines / m-1*m-5 / ;
Acronym
    Monday, Tuesday, Wednesday, Thursday, Friday;
Parameter
    shutdown(machines)
     /   m-1  Tuesday
         m-2  Wednesday
         m-3  Friday
         m-4  Monday
         m-5  Thursday /;
```

Acronyms may also be used in assignments as in the example below. For more on assignments, see section The Assignment Statement.

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek;
dayOfWeek = Wednesday;
```

Note that *numerical* operations like addition or subtraction are not allowed with acronyms. Such operations would be meaningless since acronyms do not have numeric values.

Another context where acronyms may be used is in logical conditions. For more on logical conditions, see chapter Conditional Expressions, Assignments and Equations. This is shown in the following example:

```
Acronym Monday, Tuesday, Wednesday, Thursday, Friday;
Scalar dayOfWeek
       workHours /6/;
dayOfWeek = Wednesday;
workHours$(dayOfWeek <> Friday) = 8;
```

Note that only the equality and inequality operators may be used with acronyms. Other operations like addition and division are meaningless since acronyms do not have numeric values.

Acronyms are specific to GAMS and hence difficult to deal with when exchanging data with other systems. Users often replace parameters that contain acronyms with dynamic sets that have an additional index whose values correspond to the acronyms found in the original parameter. The machine shutdown data from above can be represented via a two-dimensional set as follows:

```
Set machines / m-1*m-5 /
    weekdays / Monday, Tuesday, Wednesday, Thursday, Friday /
    shutdown(machines,weekdays)
     /   m-1.Tuesday
         m-2.Wednesday
         m-3.Friday
         m-4.Monday
         m-5.Thursday /;
```

4.27.8 Summary

In this chapter, the declaration and initialization of parameters with the Scalar, Parameter, and Table statement have been discussed. Chapter Data Manipulations with Parameters will describe how this data can be changed with assignment statements.

4.28 Variables

4.28.1 Introduction

This chapter covers the declaration and manipulation of GAMS `variables`. Many of the concepts covered in the previous chapters are directly applicable here.

A `variable` is the GAMS name for what are called *endogenous variables* by economists, *columns* or *activities* by linear programming experts, and *decision variables* by industrial Operations Research practitioners. They are the entities whose values are generally unknown until after a model has been solved. A crucial difference between GAMS variables and columns in traditional mathematical programming terminology is that one GAMS variable is likely to be associated with many columns in the traditional formulation.

4.28.2 Variable Declarations

A GAMS variable, like all other identifiers, must be declared before it may be referenced.

4.28.2.1 The Syntax

The declaration of a `variable` is similar to a `set` or `parameter` declaration, in that domain lists and explanatory text are allowed and recommended, and several variables may be declared in one statement. The syntax is given below.

```
[var_type] variable[s] var_name [(index_list)] [text] [/var_data/] {, var_name [(index_list)] [text]
```

The keyword `var_type` denotes the optional variable type that is explained in detail in the next subsection. `Variable[s]` is the keyword that indicates that this is a variable statement. `Var_name` is the internal name of the variable in GAMS, it is an identifier. In the optional `index_list` the set or sets may be specified over which an indexed variable is declared. The optional explanatory text may be used to describe the variable for future reference and to ease readability. Specifying variable data is another optional element in the variable statement. Variable data allows to initialize variable attributes at compile time. For an example and details on variable attributes, see section Variable Attributes.

A typical variable statement adapted from the model [**RAMSEY**] is shown below for illustration:

```
Variables
   k(t)      capital stock (trillion rupees)
   c(t)      consumption (trillion rupees per year)
   i(t)      investment (trillion rupees per year)
   utility   utility measure;
```

The declaration of `k` above implies, as usual, that references to `k` are restricted to the domain of the set `t`. A model that includes `k` will probably have several corresponding variables in the associated mathematical programming problem: most likely one for each member of `t`. In this way, very large models can be constructed using a small number of variables. (It is quite unusual for a model to have as many as 50 distinct variables.) It is still unclear from the declaration whether `utility` is not domain checked or whether it is a scalar variable, i.e., one without associated sets. Later references will be used to settle the issue. For more details on domain checking, see section Domain Checking.

As the syntax indicates, the explanatory text is optional. However, it is important that variable declarations include explanatory text and that this be as descriptive as possible, since the text is used to annotate the solution output. Note the use of `'per'` instead of `'/'` in the text above: slashes are illegal in all unquoted text.

Note

- Variable names, the contained set element names plus the explanatory text must obey the general rules for language items.
- Variables can be defined over from 0 up to 20 sets
- The sets over which variables are declared indicate that these variables are potentially defined for every element of the defining sets. However the actual definition of variables does not occur until variables appear in an equation definition where the equation needs to be part of a model that in turn occurs in a solve statement.

4.28.2.2 Variable Types

There are nine basic types of variables that may be used in variable statements. These are shown in table Table 1.

Keyword	Description	Default Lower Bound	Default Upper Bound
`free` (default)	No bounds on variable. Both bounds may be changed from the default values by the user.	`-inf`	`+inf`
`positive` or `nonnegative`	No negative values are allowed for variable. The user may change both bounds from the default value.	`0`	`+inf`
`negative`	No positive values are allowed for variables. The user may change both bounds from the default value.	`-inf`	`0`
`binary`	Discrete variable that can only take values of 0 or 1. For details see section Types of Discrete Variables. In relaxed Model types the integrality requirement is relaxed.	`0`	`1`

Keyword	Description	Default Lower Bound	Default Upper Bound
integer	Discrete variable that can only take integer values between the bounds. The user may change both bounds from the default value. The default upper bound inside GAMS is +inf but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default +inf) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.	0	+inf
sos1	A set of variables, such that at most one variable within a group may have a non-zero value. For details see section Types of Discrete Variables.	0	+inf
sos2	A set of variables, such that at most two variables within a group may have non-zero values and the two non-zero values are adjacent. For details see section Types of Discrete Variables.	0	+inf
semicont	Semi-continuous, must be zero or above a given minimum level. For details see section Types of Discrete Variables.	1	+inf

Keyword	Description	Default Lower Bound	Default Upper Bound
`semiint`	Semi-integer, must be zero or above a given minimum level and integer. For details see section Types of Discrete Variables. The default upper bound inside GAMS is `+inf` but when the variable is passed on to the solver, the option or command line parameter IntVarUp decides what upper bound (by default `+inf`) is passed on to the solver in case GAMS has upper bound +inf. In relaxed Model types the integrality requirement is relaxed.	1	`+inf`

Table 1: Variable types and default bounds

The default type is `free`, which means that if the type of the variable is not specified, it will not be bounded at all. The most frequently used types are `free` and `positive`. The type `positive variables` is used for variables for which negative values are meaningless, such as capacities, quantities or prices. Note that bounds may be changed using variable attributes and assignment statements, see section Variable Attributes.

Note

- Every optimization model must contain at least one unrestricted named variable (i.e. one declared with the keywords `Variable` or `Free Variable`). This variable is the objective variable. Even an objective variable can have lower and upper bounds assigned via the `.lo` and `.up` variable attribute.
- If a model is unbounded, a frequent cause for the unboundedness is that the modeler forgot to make a variable positive.

4.28.2.3 Styles for Variable Declaration

Two styles are commonly used to declare variable types. The first is to list all variables with domain specifications and explanatory text as a group, and later to group them separately as to type. The example shown below is adapted from [**MEXSS**]. The default type is `free`, so `phi` and `phipsi` will be `free` variables in the example below. Note the use of variable names derived from the original mathematical representation.

```
Variables
    u(c,i)  "purchase of domestic materials (mill units per yr)"
    v(c,j)  "imports            (mill tpy)"
    e(c,i)  "exports            (mill tpy)"
    phi     "total cost         (mill us$)"
    phipsi  "raw material cost  (mill us$)";
Positive Variables  u, v, e;
```

The commas in the list of positive variables are required separators.

Attention

It is possible to declare an identifier more than once. However, the second and any subsequent declarations should only add new information that does not contradict what has already been entered.

The second popular way of declaring variables is to list them in groups by type. We rewrite the example above using this second method:

```
Free Variables
    phi     "total cost         (mill us$)"
    phipsi  "raw material cost  (mill us$)"

Positive Variables
    u(c,i)  "purchase of domestic materials (mill units per yr)"
    v(c,j)  "imports   (mill typ)"
    e(c,i)  "exports   (mill typ)";
```

The choice between the two approaches is best based on clarity.

4.28.3 Variable Attributes

While a GAMS parameter has one number associated with each unique label combination, a variable has several. They represent:

Variable Attribute	Symbol	Description
Lower bound	`.lo`	Lower bound for the variable. Set by the user either explicitly or through default values associated with the variable type.
Upper bound	`.up`	Upper bound for the variable. Set by the user either explicitly or through default values associated with the variable type.
Fixed value	`.fx`	A fixed value for the variable. If set it results in the upper and lower bounds of the variable to be set to the value of the `.fx` attribute.
Activity level	`.l`	Activity level for the variable, also the current value or starting point. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.
Marginal	`.m`	The marginal value (or reduced cost) for the variable. This attribute is reset to a new value when a model containing the variable is solved. The activity level is used to construct a basis for the model.
Scale factor	`.scale`	Numerical scaling factor for all coefficients associated with the variable if the model attribute `scaleopt` is set to 1. For more on scaling, see section Model Scaling - The Scale Option. Only applicable for continuous variables.
Branching priority	`.prior`	Branching priority value used in mixed integer programming models if the model attribute prioropt is set to 1. For details see section Setting Priorities for Branching. It can also be used to relax discrete restrictions by setting `.prior = +inf` regardless of the `prioropt` setting. Only applicable for discrete variables.
Stage	`.stage`	This attribute allows to assign variables to stages in a stochastic program or other block structured model. Thus, among other places, it is used for 2-stage stochastic programs solved with DECIS or the Benders partition in Cplex.

Table 2: Variable Attributes

Users distinguish between these values when necessary by appending the suffix to the variable name. Examples are given below.

It is possible to specify initial values for these variable attributes at compile time. This can be done within the variable declaration statement as illustrated in the following example or during execution time as explained in section Assigning Values to Variable Attributes.

```
Variable x1(j) my first  / j1.up 10 , j1.lo 5, j1.l 7, j1.m 0, j1.scale 20 /;
```

The upper bound of the variable `x1("j1")` is set to 10, the lower bound is set to 5, the starting value for the activity level is set to 7 and the starting value for the marginal is set to 0. The variable is also scaled by the factor 20, which means it is *multiplied* by 20.

Note that it is also possible to use a table structure to assign values to variable attributes. The following example is adapted from model [**TRNSPORT**].

```
Variable Table x(i,j) initial values
                            l      m
    seattle.  new-york      50
    seattle.  chicago      300
    san-diego.new-york     275
    san-diego.chicago           0.009;
```

Note

- `.fx` and attributes `.lo` and `.up` on the same variable cannot be in a data statement. `.fx` sets both `.lo` and `.up` and hence we would have a double definition of the same attribute. Since attribute `.scale` is applicable for continuous variables and attribute `.prior` for discrete variables, they share the same internal space in a GAMS variable. Some solvers can make use of priorities even for continuous variables (e.g. BARON). Such priorities need to be supplied via a solver option file.
- The attribute `.stage` uses the same internal space as `.scale` and `.prior`. So a model cannot specify scale factor and branching priorities together with stages.
- Fixing a semi-continuous or semi-integer variable to a non-zero value like `x.fx = 4` does not result in a truly fixed variable. The domain of the variable remains {0,4}. To really fix a semi-continuous or semi-integer variable, the discrete restriction could be relaxed by setting the branching priority to infinity (`x.prior=inf`).
- For variables in discrete models (such as MIP, MINLP), the `.m` attribute provides the marginals obtained by fixing all the discrete variables and solving the resulting continuous problem (such as LP, NLP). Many solvers allow to enable/disable solving such a fixed problem. When disabled, no marginals will be provided for discrete models.

In addition to the variable attributes introduced above, there are a number of variable attributes that cannot be assigned or exported via execute_unload∗ but may be used in computations. They are given in Table 3.

Variable Attribute	Symbol	Description
Range	`.range`	The difference between the lower and upper bounds for a variable. It becomes zero if the lower equals the upper bound, e.g. if the `fx` attribute is set.

Variable Attribute	Symbol	Description
Slack upper bound	`.slackup`	Slack from variable upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of a variable.
Slack lower bound	`.slacklo`	Slack from variable lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of a variable.
Slack	`.slack`	Minimum slack from variable bound. This is defined as the minimum of two values: the slack from the variable lower bound and the slack from the variable upper bound.
Infeasibility	`.infeas`	Amount by which a variable is infeasible falling below its lower bound or above its upper bound. This is defined as the smallest of three values: zero, the difference between the lower bound and the level value, the difference between the level value and the upper bound of a variable, i.e. max(0, lower-level, level-upper).

Table 3: Additional Variable Attributes that Cannot Be Assigned but May Be Used in Computations.

4.28.3.1 Bounds on Variables

All default bounds set at declaration time may be changed using assignment statements.

Attention

> For discrete variable types, the consequences of the type declaration cannot be completely undone (e.g. the `scale` attribute is not available) but their value domain can be changed to continuous by setting attribute `prior` to infinity.

Bounds on variables are the responsibility of the user. After variables have been declared, default bounds have already been assigned: for many purposes, especially in linear models, the default bounds are sufficient. In nonlinear models, however, bounds play a far more important role. It may be necessary to provide bounds to prevent undefined operations, such as division by zero. In nonlinear programming it is often necessary to define a 'reasonable' solution space that will assist in efficiently finding a solution.

Attention

> The lower bound cannot be greater than the upper bound: if you happen to impose such a condition, GAMS will generate an execution error, namely "`**** Matrix error - lower bound > upper bound`" when executing a solve statement.

Note that the upper bound on integer and semi-integer variables needs special consideration. The default upper bound is `+inf` and the option or command line parameter IntVarUp controls what upper bound is sent to the solver. With the current default value (0) of IntVarUp, an upper bound of `+inf` is sent to the solver. Setting IntVarUp to one will pass 100 as the default upper bound to the solver. The other available values for IntVarUp work like zero, but enable special reports/execution errors in case the solution reports a level value greater than 100 for any integer variable with a default bound of `+inf`.

4.28.3.2 Fixing Variables

GAMS allows the user to fix variables through the `.fx` variable suffix. This is almost equivalent to setting the lower bound and upper bound equal to the fixed value. The attribute .fx also resets the activity level .l to the fixed value. When setting .lo and .up the activity level remains unchanged. A `solve` statement will project the activity level within the active bounds. Fixed variables can subsequently be freed by changing the lower and upper bounds.

4.28.3.3 Activity Levels of Variables

GAMS allows the user to set the activity levels of variables through the `.l` variable suffix. These activity levels of the variables prior to the solve statement serve as initial value for the solver. This is particularly important for nonlinear programming problems. For discrete models in many cases the solver needs an additional indicator to interpret the activity levels as a feasible integer solution via a solver option (e.g. Cplex' mipstart).

Attention

- GAMS only stores variables with non-default values (similar to storing only non-zero values of parameters). Non-default variables can be accidentally created by using harmlessly looking assignments like

  ```
  x.up(i,j,k,l) = 0;
  ```

  Even if the equations only reference such variables over a small subset of `(i,j,k,l)` this statement creates `card(i)*card(j)*card(k)*card(l)` variable records in the GAMS database. Such fixings of `x(i,j,k,l)` to 0 can be avoided by using dynamic sets or dollar conditions in the equation algebra to only reference tuples of `(i,j,k,l)` for which `x(i,j,k,l)` can possible have a non-zero value.
- In order to filter only necessary tuples for an equation the filtering conditions needs to be provided only once when defining the equation (`equ(i,j,k)`). This is different for variables because they appear in many equations and the filtering condition needs to be potentially repeated many time. Therefore it is good practice and reduces GAMS model generation time if the filtering of the variables is governed by a dynamic set:

  ```
  sum((i,j)$(ord(i)>ord(j) and cap(i,j)>0), x(i,j))
  ```

  versus

  ```
  set net(i,j); net(i,j) = ord(i)>ord(j) and cap(i,j)>0;
  sum(net(i,j), x(i,j))
  ```

4.28.4 Variables in Display and Assignment Statements

GAMS allows the modeler to use the values associated with the various attributes of each variable in assignment and `display` statements. The next two subsections explain the use of variables on the left and right-hand sides of assignment statements respectively. Then we will explain the use of variables in `display` statements.

4.28.4.1 Assigning Values to Variable Attributes

Assignment statements operate on one variable attribute at a time, and require the suffix to specify which attribute is being used. Any index list comes after the suffix.

The following code snippets are from models [**MEXSS**] and [**RAMSEY**]. The first example illustrates the use of assignment statements to set upper and lower bounds on variables.

```
x.up(c,i,j)  =  1000 ;  phi.lo  =  inf  ;
```

A very common use is to bound one particular entry individually:

```
p.up('pellets', 'ahmsa', 'mexico-df')  = 200  ;
```

Or to put small lower bounds on a variable identifier used as a divisor in a nonlinear program:

```
c.lo(t)   =  0.01  ;
```

Or to provide initial values for a nonlinear problem:

```
c.l(t)   =  4*cinit(t)  ;
```

Remember that the order is important in assignments, and notice that the two pairs of statements below produce very different results. In the first case, the lower bound for `c('1985')` will be 0.01, but in the second, the lower bound is 1.

```
c.fx('1985') = 1;              c.lo(t)       = 0.01 ;
c.lo(t)      = 0.01 ;          c.fx ('1985') = 1 ;
```

Everything works as described in the previous chapter, including the various mechanisms described there of indexed operations, dollar operations, subset assignments and so on. An example from model LOCATION follows.

```
ship_sm.lo(sl,m)$(ord(sl) = 1 and ord(m) = 1) = 1;
```

The lower bound of the variable `ship_sm(sl,m)` is set to 1 and this assignment is only valid for `ship_sm('s1','d1')`, the realization of the variable where both indices are the first members of their respective sets.

4.28.4.2 Variable Attributes in Assignments

Using variable attributes on the right-hand side of assignment statements is important for a variety of reasons. Two common uses are for generating reports and for generating initial values for some variables based on the values of other variables. For more on variable attributes in report writing, see section Displaying Variable Attributes below and especially chapter The Put Writing Facility.

The following examples adapted from model **[CHENERY]** illustrate the use of variable attributes on the right-hand side of assignment statements:

```
* initial values for variables

y.l(i) = 250 ; x.l(i) = 200 ;
e.l(t) =   0 ; m.l(t) =   0 ;

g.l(t) = mew(t) + xsi(t)*m.l(t) ;
h.l(t) = gam(t) - alp(t)*e.l(t) ;

[...]

* generating report after solve

Scalar
    cva   "total value added at current prices"
    rva   "real value added"
    cli   "cost of living index"  ;

cva  =  sum (i, v.l(i)*x.l(i))  ;
cli  =  sum(i, p.l(i)*ynot(i))/sum(i, ynot(i))  ;
rva  =  cva/cli  ;

Display cli, cva, rva ;
```

As with parameters, a variable must have some non-default data values associated with it before it can be used in a `display` statement or on the right-hand side of an assignment statement. After a `solve` statement has been processed or if non-default values have been set with an assignment statement, this condition is satisfied. `Solve` statements are introduced and discussed in chapter Model and Solve Statements.

Attention

The `.fx` suffix is mostly just a shorthand for `.lo` and `.up` and can therefore only be used only on the left-hand side of an assignment statement.

Note

In general, the variable level needs to be specified via the attribute `.l` for assignment statements. However, the dollar control option $on/offDotL allows the implicit use of the attribute `.l` in assignment statements, thus it facilitates using the same algebra in model definitions and assignment statements. This is especially useful in the context of macros.

4.28.4.3 Displaying Variable Attributes

The `display` statement is introduced and discussed in detail in chapter The Display Statement. Here we demonstrate how variable attributes are used in `display` statements.

Since several values are associated with each variable, the user must specify which attribute should be displayed when using variables in `display` statements. As before, appending the appropriate suffix to the variable name does this and no domain specification may appear. As an example, we show how to `display` the level of `phi` and the level and the marginal values of `v` from [**MEXSS**]:

```
display phi.l, v.l, v.m;
```

The output looks similar, except that (of course) the listing shows which of the values is being displayed. Because zeroes, and especially all zero rows or columns, are suppressed, the patterns seen in the level and marginal displays will be quite different, since non-zero marginal values are often associated with activity levels of zero.

```
Mexico Steel - Small Static   (MEXSS,SEQ=15)
E x e c u t i o n

----    203 VARIABLE  PHI.L                =      538.811 total cost
                                                         (mill us$)
----    203 VARIABLE  V.L           imports
                                     (mill tpy)
                     ( ALL       0.000 )

----    203 VARIABLE  V.M           imports
                                     (mill tpy)
        mexico-df   monterrey   guadalaja
steel       7.018      18.822       6.606
```

We should mention here a clarification of our previous discussion of displays. It is actually the default values that are suppressed on display output. For parameters and variable levels and marginals, the default is zero, and so zero entries are not shown. For bounds, however, the defaults can be non-zero. The default value for the upper bound of a positive variable is `+INF`, and if we would also display `v.up` above, for example, we would see:

```
----    203 VARIABLE  V.UP          imports
                                    (mill tpy)
                    ( ALL        +INF )
```

If any of the bounds have been changed from the default value, then only the entries for the changed elements will be shown. This may sound confusing, but since few users display bounds it has not proved troublesome in practice.

Note

The attribute `.range` may be used in `display` statements. It provides a convenient way to check whether a variable is fixed as it lists the 0 values explicate because the default for range (which won't be displayed) is +inf.

4.28.5 Summary

Remember that wherever a parameter may appear in a display or an assignment statement, a variable may also appear - provided that it is qualified with one of the suffixes. The only places where a variable name may appear without a suffix is in a variable declaration, as has been shown in this chapter, in an equation definition, which is discussed in chapter Equations, or in a $on/offDotL block.

4.29 Equations

4.29.1 Introduction

The keyword `equation` defines GAMS names that may be used in the model statement. A GAMS equation name is associated with the symbolic algebraic relationships that will be used to generate the constraints in a model. The algebraic relationships are defined by using constants, mathematical operators, functions, sets, parameters and variables. As with variables, one GAMS equation may be defined over a group of sets and in turn map into several individual constraints associated with the elements of those sets. Most of the example code in this chapter is from the model `location`.

This chapter is organized as follows. First, we introduce how equations are declared and defined, then we discuss expressions in equation definitions, followed by a section on equation attributes. A summary and quick reference conclude the chapter.

4.29.2 Declaring Equations

An `equation` must be declared before it can be defined and used in a model.

4.29.2.1 The Syntax

The declaration of an `equation` is similar to a `set` or `parameter` declaration. The syntax is given below.

```
Equation[s] eqn_name [(index_list)] [explanatory text] [/eqn_data/] {, eqn_name [(index_list)] [expla
```

`Equation[s]` is the reserved word that indicates that one or more blocks of equations are about to be declared. A block of equations may initiate one or more individual constraints. `Eqn_name` is the internal name of the equation, an identifier in GAMS. In the optional `index_list` the set or sets are specified over which an indexed equation is declared. The optional explanatory text may be used to describe the equation for future reference and to ease readability. Specifying equation data is another optional element in the equation declaration. Equation data allows to initialize equation attributes at compile time. For an example see the next section. For more on equation attributes see section Equation Attributes.

One or more equations may be declared in one `equation` statement. The equation names have to be separated by commas or by a line break as in the example that follows. The end of the declaration statement is indicated by a semicolon.

Note

> It is good practice to end the equation declaration with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

For advice on choosing equation names and phrasing the explanatory text see chapter Good Modeling Practices.

4.29.2.2 An Illustrative Example

The following example is from the model `location`. In addition to the equation declarations the relevant set definitions are given.

```
Sets
  sl                    'supply locations'              /s1, s2/
  wh                    'warehouse locations'           /a, b, c/;

Equations
  tcost_eq              'total cost accounting equation'
  supply_eq(sl)         'limit on supply available at supply location'
  capacity_eq(wh)       'warehouse capacity'  /a.scale 50, a.l 10, b.m 20/;
```

The keyword `Equations` marks the beginning of the equation declaration. Each equation name is optionally followed by its domain (associated set or sets) unless it is a *scalar equation*. It is possible but not good practice to declare indexed equations without their domains. The name of the first equation is `tcost_eq` and it is followed by the explanatory text '`total cost accounting equation`'. The name of the equation `tcost_eq` is not followed by any associated sets. Since we follow good practice here we assume that `tcost_eq` is a scalar equation. Scalar equations do not have any associated sets and will generally produce one equation in the model. For more on scalar equations see subsection Scalar Equations.

The other two equations are *indexed equations*, they are declared over a set. The equation `supply_eq` is declared over the set `sl` and the equation `capacity_eq` is declared over the set `wh`. In typical circumstances an indexed equation declaration implies that a block of constraints will be generated. For example, equation `supply_eq(sl)` implies that two constraints will be generated, one for each element of the set `sl`. For more on indexed equations see subsection Indexed Equations.

The declaration of the equation `capacity_eq` specifies some equation attributes. The first entry indicates that the equation `capacity_eq('a')` is scaled by a factor of 50, which means division of all entries in that equation by 50 upon model passage to the solver. For more on scaling see section Model Scaling - The Scale Option. The second entry sets the initial value of the equation `capacity_eq('a')` to 10 and `b.m` means that the initial marginal value of the equation `capacity_eq('b')` is set to 20. Alternatively, a table structure may be used to specify the values of equation attributes. The following table may replace the notation above.

```
Equation Table capacity_eq(wh)  'warehouse capacity'
      scale    l       m
   a   50      10
   b                   20 ;
```

For more on equation attributes see section Equation Attributes.

Note

An equation may be declared over more than one set.

4.29.3 Defining Equations

After declaring equations they have to be defined. The definition of an equation specifies the algebraic structure of the equation in GAMS. The syntax is given first, an illustrative example follows and in the remainder of this section some of the key components of equation definitions are discussed.

4.29.3.1 The Syntax

The syntax for defining an equation is as follows:

```
eqn_name(index_list)[$logical_condition(s)].. expression eqn_type expression ;
```

`Eqn_name` is the name of the equation as introduced in the equation declaration, that may be followed by an `index_list` for indexed equations. In the `index_list` the set or sets are specified over which an indexed equation is defined. These sets are also called *domain of definition* of the equation. One or more logical conditions are optional. For an example see Indexed Equations. For more on logical conditions in equation definitions see Dollar Control over the Domain of Definition. The two dots `'..'` are mandatory and indicate the start of the algebra. It is good practice to end the definition of an equation with a semicolon, even though it is not mandatory if the next statement starts with a GAMS keyword.

Attention

An equation must be declared before it is defined.

`Expression` refers to an algebraic expression which may include variables, parameters, functions, and constants among other items. For details on expressions in GAMS, see section Expressions.

Attention

Only variables that appear at least once with a nonzero coefficient in an equation definition will appear in a model.

`Eqn_type` refers to the equation type denoted by the symbol between the right-hand side and left-hand side expressions that form the equation. The symbols that are allowed are given in Table 1.

Type	Description
`=e=`	Equality: right-hand side must equal left-hand side.
`=g=`	Greater than: left-hand side must be greater than or equal to right-hand side.
`=l=`	Less than: left-hand side must be less than or equal to right-hand side.
`=n=`	No relationship implied between left-hand side and right-hand side. This equation type is ideally suited for use in MCP models and in variational inequalities.
	Equation is defined by external programs. See External Equations.

Table 1: Equation Types

Equation definitions may be carried over as many lines of input as needed. Blanks may be inserted to improve readability, and expressions may be arbitrarily complicated.

Note that an equation can only be defined once. By using logical conditions it is possible to control which constraints are generated. In addition, the components of an equation may be modified by changing the data it uses. However, if the logic of the equation needs to be changed then a new equation with a new name has to be declared and defined.

4.29.3.2 An Illustrative Example

Consider the following example adapted from the model [**mexss**]. The associated variable and equation declarations are also included.

```
Variables  phi, phipsi, philam, phipi, phieps ;
Equations  obj ;
obj.. phi  =e=  phipsi + philam + phipi - phieps ;
```

The name of the equation being defined is `obj` and the symbol `=e=` indicates that this is an equality. Any of the following forms of the equation are mathematically equivalent.

```
obj..  phipsi + philam + phipi - phieps =e= phi  ;
obj..  phieps - phipsi  =e=  philam - phi + phipi  ;
obj..  phi + phieps - phipsi - philam - phipi  =e=  0 ;
obj..  0 =e= phi + phieps - phipsi - philam - phipi  ;
```

Note

The arrangement of the terms in the equation is a matter of choice, but often a particular one is chosen because it makes the model easier to understand.

4.29.3.3 Scalar Equations

A scalar equation will produce one equation in the associated optimization problem. The equation `obj` defined above is an example of a scalar equation which contains only scalar variables. Note that scalar equations may contain indexed variables. However, they must occur with an indexed operator such as `sum` or `prod`, unless the indexed variables refer to a singleton set (a set with only one element). Consider the following example from the model `location`. Note that the set `wh` has three elements.

```
configure_eq..  sum(wh,build(wh)) =l= 1;
```

The variable `build` is defined over the set `wh`, it is an indexed variable. It may be used in the scalar equation `configure_eq` since it occurs in conjunction with the indexed operator `sum`.

4.29.3.4 Indexed Equations

All the set references in scalar equations are within the scope of indexed operators or they refer to singleton sets; thus many variable, set and parameter references can be included in one equation. In addition, GAMS also allows for equations to be defined over a domain, thereby developing a compact representation for constraints. The index sets to the left of '..' are called the *domain of definition* of the equation.

Note

- Domain checking ensures that the domain over which an equation is defined is the set (or the sets) or a subset of the set (or the sets) over which the equation was declared.
- As a corollary, domain checking also catches the error of the indices being listed in an inconsistent order. For example, declaring an equation as `myequation(s,t)` and then naming it in the definition as `myequation(t,s)` causes an error (unless `s` and `t` are aliases of the same set). For more information, see section Domain Checking.

The following indexed equation with a single index generates a separate constraint for each member of the driving (or controlling) set. It is taken from the model [**chenery**]. In this example, `t` is a set with three members, `mew` and `xsi` are parameters and `m` and `g` are variables.

```
dg(t)..  g(t)  =e= mew(t) + xsi(t)*m(t)  ;
```

As the set `t` has three members, three constraints will be generated, one for each member of `t` specifying the dependence of `g` on `m`. The data associated with the parameters `mew` and `xsi` are used to build the individual constraints. This data does not have to be known when the equation is defined, but it has to be populated before a model containing the equation is solved.

The extension to two or more indices on the left of '..' is obvious. There will be one constraint generated for each combination of set elements that can be constructed using the indices inside the parenthesis. Here are two examples from the model [**aircraft**], a scheduling model.

```
bd(j,h)..  b(j,h)  =e=  dd(j,h) - y(j,h) ;
yd(j,h)..  y(j,h)  =l=  sum(i, p(i,j)*x(i,j)) ;
```

The domain of definition of both equations is the Cartesian product of `j` and `h`: constraints will be generated for every set element pair that can be constructed from the members of these two sets.

The next example illustrates the use of the optional logical conditions in the definition of equations. It is taken from the production and distribution model [**ferts**].

```
CC(m,i)$mpos(m,i)..  sum(p$ppos(p,i), b(m,p)*z(p,i)) =l= util*k(m,i) ;
```

`CC` is a capacity constraint defined for elements of the sets `m` and `i`. However, in this case not all cases of `m` exist at each location `i`, and the mapping set `mpos(m,i)` tells the cases where `m` exists at `i` and thus is used to restrict the domain cases for which the constraints are actually generated. The control of the summation over `p` with `ppos(p,i)` is an additional logical condition, and is required because not all processes `p` are possible at all locations `i`.

The equation may alternatively written in the following way:

```
CC(mpos(m,i))..  sum(ppos(p,i), b(m,p)*z(p,i)) =l= util*k(m,i) ;
```

Instead of defining the equation over the indices `(m,i)` the equation is defined over the set `mpos` that is itself defined over the indices `(m,i)`. A similar logic applies to restricting the summation.

Conditional expressions are introduced and discussed in the section Conditional Expressions, Assignments and Equations. See specifically Dollar Control over the Domain of Definition for logical conditions in equation definitions.

4.29.3.5 Using Labels Explicitly in Equations

Sometimes it can be necessary to refer to specific set elements in equations. This can be done as with parameters - by using quotes or double quotes around the label. Consider the following example from the model `location`:

```
sum(m, ship_wm(wh,m)) =l= build(wh)*data(wh,"capacity") ;
```

4.29.3.6 Logic Equations

Logic equations use Boolean algebra and have to evaluate to `TRUE` (or 1) to be feasible. The Boolean functions available in GAMS and the default order of precedence of the operators are given in Table 2. Note that 1 denotes the highest order of precedence or the most binding operator and 3 denotes the lowest order of precedence or the least binding operators. As usual, the default order of precedence holds only in the absence of parentheses and operators on the same level are evaluated from left to right.

Function	Operator	Alternative Notation	Return Values	Order of precedence
Negation	`not x`	`bool_not(x)`	returns 1 if $x = 0$, else returns 0	1
Logical conjunction	`x and y`	`bool_and(x,y)`	returns 1 if $x \neq 0$ and $y \neq 0$, else returns 0	2
Logical disjunction	`x or y`	`bool_or(x,y)`	returns 0 if $x = y = 0$, else returns 1	3
Exclusive disjunction	`x xor y`	`bool_xor(x,y)`	returns 1 if *exactly* one argument is $\neq 0$, else returns 0	3
Material implication	`x imp y` or `x -> y`	`bool_imp(x,y)`	returns 0 if $x \neq 0$ and $y = 0$, else returns 1	3
Material equivalence	`x eqv y` or `x <=> y`	`bool_eqv(x,y)`	returns 0 if *exactly* one argument is 0, else returns 1	3

Table 2: Boolean Functions and Operator Precedence

There are three ways to declare and define logic equations:

1. The logic equation is declared using the keyword `Logic Equation` and the definition contains only Boolean algebra symbols.
2. The logic equation is declared like any other equation using the keyword `Equation` and in the definition the symbol `=b=` appears indicating that it is a logic equation.
3. This is a combination of the first two options: the equation is declared with the keyword `Logic Equation` and defined using the symbol `=b=`.

The following example demonstrates the first way to declare and define a logic equation. It is adapted from the food manufacturing problem [**foodemp**]. In this problem the blending of oils is modeled.

```
Sets
  m             "planning period (month)"    / m1*m6 /
  p             "raw oils"                   / v1*v2, o1*o3 / ;

Variables
  induse(m,p)   "indicator for usage of raw oil per month" ;
Binary variable induse;

Logic Equation
  deflogic(m)  "if some vegetable raw oil is used we also need to use the non-vegetable oil o3" ;

deflogic(m)..  induse(m,'v1') or  induse(m,'v2') -> induse(m,'o3');
```

The variable `induse` is a binary variable, it can only take the values 0 and 1. The equation ensures that in an optimal solution if either vegetable oil `v1` or vegetable oil `v2` is blended in a product, then non-vegetable oil `o3` is also blended in that product.

An alternative formulation of the equation `deflogic` using the `=b=` notation is given below.

```
deflogic(m)..  induse(m,'v1') or induse(m,'v2') -> induse(m,'o3') =b= 1;
```

Note that the value of 1 on the right-hand side means that the logic expression on the left-hand side must evaluate to `TRUE` in a feasible solution. To illustrate further, we could negate the left-hand side expression using the logic operator `not` and then the right-hand side would have to evaluate to zero or `FALSE` to yield the same result as above. The respective equation definition follows.

```
deflogic(m)..  not (induse(m,'v1') or  induse(m,'v2') -> induse(m,'o3')) =b= 0;
```

Logic equations with binary variables and boolean functions/operators are reformulated into linear constraints by the LOGMip solver using GAMS model type `EMP`. Solver CONVERT writes scalar models with logic equations, but no other solver currently can utilize logic equations. In principle (but currently not implemented), logic constraints can be used to express complex algebra, like indicator constraints:

```
defindic(m)..  induse(m,'v1') = 1 -> sum(p, use(m,p)) >= minuse(m);
```

4.29.4 Expressions in Equation Definitions

The arithmetic operators and some of the functions that are described in section Expressions may be used in equation definitions.

Consider the following example adapted from the model **[chenery]** demonstrating the use of parentheses and exponentiation.

```
dem(i) ..    y(i)  =e= ynot(i)*(pd*p(i))**thet(i)  ;
```

A list of arithmetic operators is given in subsections Standard Arithmetic Operations and Indexed Operations.

4.29.4.1 Functions in Equation Definitions

All available GAMS functions are listed in the section Functions. Some functions are not allowed at all in equation definitions. They include random distribution functions and are marked with *none* in the third column of the tables listing all functions.

Attention

Some functions like `uniform` and `normal` are not allowed in equation definitions.

The use of the other functions is determined by the type of arguments in the model. There are two types of arguments:

1. *Exogenous arguments:* The arguments are known. Parameters and variable attributes (for example, `.l` and `.m` attributes) are used as arguments. The expression is evaluated once when the model is being set up and most mathematical functions as well as time and calendar functions are allowed.
2. *Endogenous arguments:* The arguments are variables and therefore unknown at the time of model setup. The function will be evaluated many times at intermediate points while the model is being solved. Note that the occurrence of any function with endogenous arguments implies that the model is not linear.

Functions that are allowed only with exogenous arguments are marked with *any* in the tables listing all functions.

There are two types of functions allowing endogenous arguments: *smooth* functions and *discontinuous* functions. Smooth functions are continuous functions with continuous derivatives (like `sin`, `exp`, `log`). Discontinuous functions include continuous functions with discontinuous derivatives (like `max`, `min`, `abs`) and discontinuous functions (like `ceil`, `sign`). Smooth functions may be used routinely in nonlinear models. However, discontinuous functions may cause numerical problems and should be used only if unavoidable, and only in a special model type called `DNLP`. For more details on model types see section Classification of Models.

Attention

The best way to model discontinuous functions is with binary variables. The result is a model of the type `MINLP`. The model **[ABSMIP]** demonstrates this formulation technique for the functions `abs`, `min`, `max` and `sign`. See also section Reformulating DNLP Models. We strongly discourage the use of the `DNLP` model type.

In Table 3 the use of functions in equation definitions is summarized.

Functions are allowed ...	Description of Functions
not at all	Functions that are marked *none* in the third column of the tables listing all functions in section Functions.
only with exogenous arguments	Functions that are marked *any* in the third column of the tables listing all functions in section Functions.
with endogenous arguments	Smooth functions. They are marked *NLP* in the third column of the tables listing all functions in section Functions.
with endogenous arguments	Discontinuous functions. They are marked *DNLP* in the third column of the tables listing all functions in section Functions.

Table 3: Functions in Equation Definitions

4.29.4.2 Preventing Undefined Operations in Equations

Some operations are not defined at particular values of the arguments. Two examples are division by 0 and the `log-` of 0. While this can easily be identified at model setup for exogenous functions and expressions, it is a lot more difficult when the terms involve variables. The expression may be evaluated many times when the problem is being solved and the undefined result may arise only under certain cases. One way to avoid an expression becoming undefined is adding bounds to the respective variables. Consider the following example from the model [**ramsey**]:

```
c.lo(t) = 0.01 ;
util ..   utility  =e= sum(t, beta(t)*log(c(t))) ;
```

Specifying a lower bound for `c(t)` that is slightly larger than 0 prevents the `log`-function from becoming undefined.

4.29.5 Equation Attributes

Equation attributes may be specified in a similar way as variable attributes. Five values are associated with each unique label combination of every equation. They are denoted by the suffixes `.l`, `.m`, `.lo`, `.up` and `.scale`. A list of the attributes and their description is given in Table 4.

Equation Attribute	Symbol	Description
Lower bound	`.lo`	Negative infinity for `=l=` equations. Right hand side value for `=g=`, `=e=`, and `=b=` equations. Zero for `=c=` equations.
Upper bound	`.up`	Positive infinity for `=g=` and `=c=` equations. Right hand side value for `=l=`, `=e=`, and `=b=` equations.
Equation level	`.l`	Level of the equation in the current solution, equal to the level of all terms involving variables.
Marginal	`.m`	Marginal value for equation. This attribute is reset to a new value when a model containing the equation is solved. The marginal value for an equation is also known as the shadow price for the equation and in general not defined before solution but if present it can help to provide a basis for the model
Scale factor	`.scale`	Numerical scaling factor that scales all coefficients in the equation. This is only used when the model attribute `scaleopt` is set to 1. For more on scaling, see section Model Scaling - The Scale Option.
Stage	`.stage`	This attribute allows to assign equations to stages in a stochastic program or other block structured model. Its current use is limited to 2-stage stochastic programs solved with DECIS.

Table 4: Equation Attributes

Note that all attributes except for `.scale` and `.stage` contain the attribute values of equations *after* a solution of the model has been obtained. For some solvers it can be useful to specify marginal values `.m` and level values `.l` on input to provide starting information. Also note that the marginal value is also known as the *dual* or *shadow price*. Roughly speaking, the marginal value `.m` of an equation is the amount by which the value of the objective variable would change if the equation level were moved one unit.

Equation attributes may be referenced in expressions and can be used to specify starting values (see section Declaring Equations). In addition, they serve for scaling purposes and for reporting after a model was solved. For example, they may be displayed using the `display` statement. The following example is from the model `location`.

```
Model warehouse 'warehouse location model'  /all/;
solve warehouse using mip min tcost;
display supply_eq.l;
```

The `display` statement generates the following output at the end of the listing file:

```
----    108 EQUATION supply_eq.L  limit on supply available at supply location

s1 50.000,    s2 75.000
```

The level values of the equation `supply_eq` are displayed. As expected, there are two level values, one for each member of the set `sl` over which the equation `supply_eq` was defined.

Note

By default, all equation attributes introduced above except for `.scale` are echoed to the solution report that is part of the listing file.

In addition to the equation attributes introduced above, there are a number of equation attributes that cannot be assigned or exported via execute_unload∗ but may be used in computations. They are given in Table 5.

Equation Attribute	Symbol	Description
Range	`.range`	The difference between the lower and upper bounds of an equation.
Slack lower bound	`.slacklo`	Slack from equation lower bound. This is defined as the greater of two values: zero or the difference between the level value and the lower bound of an equation.
Slack upper bound	`.slackup`	Slack from equation upper bound. This is defined as the greater of two values: zero or the difference between the upper bound and the level value of an equation.
Slack	`.slack`	Minimum slack from equation bound. This is defined as the minimum of two values: the slack from equation lower bound and the slack from equation upper bound.
Infeasibility	`.infeas`	Amount by which an equation is infeasible falling below its lower bound or above its upper bound. This is defined as max(0, lower bound - level, level - upper bound).

Table 5: Additional Equation Attributes that Cannot Be Assigned but May Be Used in Computations.

4.29.6 Summary and Quick Reference

In this chapter we have covered the declaration and definition of `equations` in GAMS, arithmetic operations and functions that may be used in equations and equation attributes. A list summarizing the main points to keep in mind follows.

- Equations must be declared before they may be defined. [1]
- It is good practice to add an explanatory text to the declaration. [2]
- More than one equation may be declared at once. The equation names have to be separated by commas or by a line break. [3]
- Equations may be declared and defined over sets which are called the domain of definition of the equation. [4]
- One indexed equation may generate many constraints depending on the size of the set(s) over which it is defined. [5]
- Equations may be defined over subsets. The dollar condition may be used to filter the members of a set so that only a subset of the members are considered. [6]
- The set(s) over which an equation is defined must be consistent with the set(s) over which the equation was declared, being the set(s) themselves or a subset of the set(s). [7]
- The arrangement of terms in an equation is up to the other. Variables can appear on both sides of an equation. [8]
- Labels of specific set elements may be used explicitly in equations. [9]
- All arithmetic operations that may be used to evaluate expressions are also allowed in equations. [10]
- Many functions that are defined in GAMS may be used in equations. [11]
- It is good practice to set bounds for variables to avoid undefined operations if equations contain operations that are undefined at certain values. [12]
- Equations have attributes similar to variables (`.l`, `.m`, `.lo`, `.up` and `.scale`). [13]

4.30 Model and Solve Statements

4.30.1 Introduction

This chapter brings together all the concepts discussed in previous chapters by explaining how to specify a model and solve it.

4.30.2 The Model Statement

The model statement is used to collect equations into groups and to label them so that they can be solved. The simplest form of the model statement uses the keyword `all`: the model consists of all equations declared before the model statement is entered. For most simple applications this is all the user needs to know about the model statement.

4.30.2.1 The Syntax

In general, the syntax for a model declaration in GAMS is as follows:

```
model[s] model_name [text] [/ (all | eqn_name {, eqn_name}) {, var_name(set_name)} /]
       {,model_name [text] [/ (all | eqn_name {, eqn_name}) {, var_name(set_name)} /]} ;
```

The keyword `model[s]` indicates that this is a `model` statement and `model_name` is the internal name of the model in GAMS, it is an identifier. The optional explanatory text is used to describe the model, `all` is a keyword as introduced above and `eqn_name` is the name of an equation that has been declared prior to the model statement. `Var_name(set_name)` is a couple of previous declared variable and and set to limit the domain of variables in the model. More details about this are described in the following subsection. For advice on explanatory text and how to choose a `model_name`, see the tutorial Good Coding Practices.

Note

Model statements for Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC) models require a slightly different notation, since complementarity relationships need to be included. For details see subsections Mixed Complementarity Problem (MCP) and Mathematical Program with Equilibrium Constraints (MPEC).

An example of a model definition in GAMS is shown below.

```
Model transport "a transportation model" / all /;
```

The `model` is called `transport` and the keyword `all` is a shorthand for all known (declared) equations.

Several models may be declared (and defined) in one model statement. This is useful when experimenting with different ways of writing a model, or if one has different models that draw on the same data. Consider the following example, adapted from **[PROLOG]**, in which different groups of the equations are used in alternative versions of the problem. Three versions are solved: the linear, nonlinear, and 'expenditure' versions. The model statement to define all three is:

```
Model  nortonl   "linear version"      / cb,rc,dfl,bc,obj /
       nortonn   "nonlinear version"   / cb,rc,dfn,bc,obj /
       nortone   "expenditure version" / cb,rc,dfe,bc,obj /  ;
```

Here `cb`, `rc`, etc. are the names of the equations. We will describe below how to obtain the solution to each of the three models.

Note

If several models are declared and defined with one model statement, the models have to be separated by commas or linefeeds and a semicolon terminates the entire statement.

If several models are declared then it is possible to use one previously declared model in the declaration of another. The following examples illustrate this:

```
Model one   "first model"                          / tcost_eq, supply_eq, demand_eq /
      two   "second model that nests first"        / one, balance_eq /
      three "third model that nests first and second" / two, capacity_eq, configure_eq /;
```

Model one is declared and defined using the general syntax, model two contains all the equations of model one and the equation balance_eq, and model three contains all of model two and the equations capacity_eq and configure_eq.

In addition to nesting models as illustrated above, it is also possible to use the symbols + and - to augment or remove items relative to models that were previously defined. The following examples serve as illustration:

```
Model four "fourth model: model three minus model one"          / three-one /
      five "fifth model: model three without eqn configure_eq" / three-configure_eq /
      six  "sixth model: model four plus model two"            / four+two /;
```

Model four contains the equations from model three except for those that belong to model one. Model five contains all equations from model three except for equation configure_eq. Model six contains the union of the equations in model four and two. Note that both model names and equation names may be used in association with the symbols + and -.

Limited domain for variables

As mentioned above, it is possible to limit the domain of variables used in a model in the model statement. This allows to restrict the generation of blocks of variables in a single place instead of using, e.g., dollar conditions at every place where this variable block is used in equations (which might be required for an efficient model generation).

The following examples is based on the basic transportation model [**TRNSPORT**]. To limit the transportation network in that model to certain links (e.g. because some are blocked because of some reason) one could introduce a subset of the free links and use that with dollar conditions in the equations like this:

```
* Initialize whole network as free
Set freeLinks(i,j) Useable links in the network / #i.#j /;

cost..      z =e= sum((i,j), c(i,j)*x(i,j)$freeLinks(i,j));

supply(i).. sum(j, x(i,j)$freeLinks(i,j)) =l= a(i);

demand(j).. sum(i, x(i,j)$freeLinks(i,j)) =g= b(j);

* Block a particular link
freeLinks('san-diego','topeka') = no;

Model transport / all /;
solve transport using lp minimizing z;
```

Now, instead of adding the dollar condition to each appearance of x in the model, one could simply add a domain restriction for that variable to the model statement directly by specifying a variable and the set that limits its domain. Using this approach, the previous example looks like this:

```
* Initialize whole network as free
Set freeLinks(i,j) Useable links in the network / #i.#j /;

cost..      z =e= sum((i,j), c(i,j)*x(i,j));
```

```
supply(i).. sum(j, x(i,j)) =l= a(i);

demand(j).. sum(i, x(i,j)) =g= b(j);

* Block a particular link
freeLinks('san-diego','topeka') = no;

Model transport / all, x(freeLinks) /;
solve transport using lp minimizing z;
```

Note

If one adds the domain restriction to the model statement, internally GAMS inserts a dollar condition to every appearance of the restricted variables in equations of the model. When doing this, the indices are copied as they appear with the variable. So, in the example above, `x(i,j)` becomes `x(i,j)$freeLinks(i,j)`. In the same way `x(i-1,j+1)` becomes `x(i-1,j+1)$freeLinks(i-1,j+1)` and `x('seattle','chicago')` becomes `x('seattle','chicago')$freeLinks('seattle','chicago')`.

Attention

As a consequence of above's note one could see some unexpected results, like "division by zero errors", if it is not done carefully. For example, the following dummy model, will trigger such an error, since we sum over all `i`, but some `x` were excluded leaving a `0` as divisor:

```
Set i      / i1*i3 /
    sub(i) / i2    /;

Positive Variable x(i);
Variable          z;
Equation          obj;

obj.. z =e= sum(i, 1/x(i));
x.lo(i) = 1;
Model m / obj, x(sub) /;
solve m min z use nlp;
```

4.30.2.2 Classification of Models

Various types of problems can be solved with GAMS. Note that the type of the model must be known before it may be solved. The model types are briefly discussed in this section. GAMS checks that the model is in fact the type the user thinks it is, and issues explanatory error messages if it discovers a mismatch - for instance, that a supposedly linear model contains nonlinear terms. Some problems may be solved in more than one way, and the user has to choose which way to use. For instance, if there are binary or integer variables in the model, it can be solved either as a `MIP` or as a `RMIP`.

The model types and their identifiers, which are needed in the a solve statement, are given in Table 1. For details on the solve statement, see section The Solve Statement.

GAMS Model Type	Model Type Description	Requirements and Comments
LP	Linear Program	Model with no nonlinear terms or discrete (i.e. binary, integer, etc) variables.

GAMS Model Type	Model Type Description	Requirements and Comments
NLP	Nonlinear Program	Model with general nonlinear terms involving only *smooth* functions, but no discrete variables. For a classification of functions as to smoothness, see section Functions.
QCP	Quadratically Constrained Program	Model with linear and quadratic terms, but no general nonlinear terms or discrete variables.
DNLP	Discontinuous Nonlinear Program	Model with *non-smooth* nonlinear terms with discontinuous derivatives, but no discrete variables. This is the same as `NLP`, except that non-smooth functions may appear as well. These models are more difficult to solve than normal `NLP` models and we strongly advise not to use this model type.
MIP	Mixed Integer Program	Model with binary, integer, SOS and/or semi variables, but no nonlinear terms.
RMIP	Relaxed Mixed Integer Program	Like `MIP`, except that the discrete variable requirement is relaxed. See the note below on relaxed model types.
MINLP	Mixed Integer Nonlinear Program	Model with both nonlinear terms *and* discrete variables.
RMINLP	Relaxed Mixed Integer Nonlinear Program	Like `MINLP` except that the discrete variable requirement is relaxed. See the note below on relaxed model types.
MIQCP	Mixed Integer Quadratically Constrained Program	Model with both quadratic terms *and* discrete variables, but no general nonlinear term.
RMIQCP	Relaxed Mixed Integer Quadratically Constrained Program	Like `MIQCP` except that the discrete variable requirement is relaxed. See the note below on relaxed model types.
MCP	Mixed Complementarity Problem	A square, possibly nonlinear, model that generalizes a system of equations. Rows and columns are matched in one-to-one complementary relationships.
CNS	Constrained Nonlinear System	Model solving a square, possibly nonlinear system of equations, with an equal number of variables and constraints.
MPEC	Mathematical Programs with Equilibrium Constraints	A difficult model type for which solvers and reformulations are currently being developed.
RMPEC	Relaxed Mathematical Program with Equilibrium Constraints	A difficult model type for which solvers and reformulations are currently being developed. See the note below on relaxed model types.
EMP	Extended Mathematical Program	A family of mathematical programming extensions.

GAMS Model Type	Model Type Description	Requirements and Comments
MPSGE	General Equilibrium	Not actually a model type but mentioned for completeness, see MPSGE.

Table 1: GAMS Model Types

Note

- The relaxed model types RMIP, RMINLP, RMIQCP, and RMPEC solve the problem as the corresponding model type (e.g. MIP for RMIP) but *relax* the discrete requirement of the discrete variables. This means that integer and binary variables may assume any values between their bounds. SemiInteger and SemiCont variables may assume any values between 0 and their upper bound. For SOS1 and SOS2 variables the restriction of the number of non-zero values is removed.
- Many "LP" solvers like Cplex offer the functionality of solving *convex* quadratic models. So the Q matrices in the model need to be positive semidefinite. An extension to to this are the second-order cone programs (SOCP) with either symmetric or rotated cones. See the solver manuals (e.g. on MOSEK) for details.
- Unlike other checks on the model algebra (e.g. existence of discrete variables or general non-linear terms), the GAMS *compiler* does not enforce a quadratic model to only consist of quadratic and linear terms. This requirement is enforced at *runtime* for a particular model instance.

Linear Programming (LP)

Mathematically, the Linear Programming (LP) problem looks like:

$$\begin{array}{ll} \text{Minimize or maximize} & cx \\ \text{subject to} & Ax \;\alpha\; b \\ & L \leq x \leq U, \end{array}$$

where x is a vector of variables that are continuous real numbers, cx is the objective function, and $Ax\,\alpha\,b$ represents the set of constraints. Here, α is an equation operator. For details on the equation types allowed in GAMS, see Equation Types. L and U are vectors of lower and upper bounds on the variables.

GAMS supports free (unrestricted) variables, positive variables, and negative variables. Note that users may customize lower and upper bounds, for details see section Bounds on Variables.

For information on LP solvers that can be used through GAMS see the Solver/Model type Matrix.

Nonlinear Programming (NLP)

Mathematically, the Nonlinear Programming (NLP) problem looks like:

$$\begin{array}{ll} \text{Minimize or Maximize} & f(x) \\ \text{subject to} & g(x) \;\alpha\; 0 \\ & L \leq x \leq U, \end{array}$$

where x is a vector of variables that are continuous real numbers, $f(x)$ is the objective function, and $g(x)\,\alpha\,0$ represents the set of constraints. For details on the equation types allowed in GAMS, see Equation Types. Note that the functions $f(x)$ and $g(x)$ have to be differentiable. L and U are vectors of lower and upper bounds on the variables.

For information on NLP solvers that can be used through GAMS see the Solver/Model type Matrix. See also the tutorial Good NLP Formulations.

Note

NLP models may have the nonlinear terms inactive. In this case setting the model attribute TryLinear to 1 causes GAMS to check the model and use the default LP solver if possible. For details on model attributes, see subsection Model Attributes.

Quadratically Constrained Programs (QCP)

Mathematically, the Quadratically Constrained Programming (QCP) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & cx + x'Qx \\ \text{subject to} & A_i x + x'R_i x \ \alpha \ b_i \quad \text{for all } i \\ & L \leq x \leq U, \end{array}$$

where x denotes a vector of variables that are continuous real numbers, cx is the linear part of the objective function, $x'Qx$ is the quadratic part of the objective function, $A_i x$ represents the linear part of the ith constraint, $x'R_i x$ its quadratic part and b_i its right-hand side. For details on the equation types allowed in GAMS, see Equation Types. Further, L and U are vectors of lower and upper bounds on the variables.

Note that a QCP is a special case of the NLP in which all the nonlinearities are required to be quadratic. As such, any QCP model can also be solved as an NLP. However, most "LP" vendors provide routines to solve LP models with a quadratic objective. Some allow quadratic constraints as well. Solving a model using the QCP model type allows these "LP" solvers to be used to solve quadratic models as well as linear ones. Some NLP solvers may also take advantage of the special (quadratic) form when solving QCP models.

Attention

In case a model with quadratic *constraints* is passed to a QCP solver that only allows a quadratic *objective*, a capability error will be returned (`solver status 6 CAPABILITY PROBLEMS`). Some solvers will fail when asked to solve a non-convex quadratic problems as described above.

Note

Using the model attribute TryLinear causes GAMS to see if the problem can be solved as an LP problem. For details on model attributes, see subsection Model Attributes.

For information on QCP solvers that can be used through GAMS see the Solver/Model type Matrix.

Nonlinear Programming with Discontinuous Derivatives (DNLP)

Mathematically, the Nonlinear Programming with Discontinuous Derivatives (DNLP) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & f(x) \\ \text{subject to} & g(x) \ \alpha \ 0 \\ & L \leq x \leq U, \end{array}$$

where x is a vector of variables that are continuous real numbers, $f(x)$ is the objective function, $g(x)\,\alpha\,0$ represents the set of constraints, and L and U are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see Equation Types. Note that this is the same as NLP, except that non-smooth functions, like `abs`, `min`, `max` may appear in $f(x)$ and $g(x)$.

For information on DNLP solvers that can be used through GAMS see the Solver/Model type Matrix.

Attention

- We strongly advise against using the model type `DNLP`. The best way to model discontinuous functions is with binary variables, which results in a model of the type MINLP. The model **[ABSMIP]** demonstrates this formulation technique for the functions `abs`, `min`, `max` and `sign`. See also section Reformulating DNLP Models.
- Solvers may have difficulties when dealing with the discontinuities, since they are really NLP solvers and the optimality conditions and the reliance on derivatives may be problematic. Using a global solver may alleviate this problem.

Mixed Integer Programming (MIP)

Mathematically, the Mixed Integer Linear Programming (MIP) problem looks like:

$$
\begin{array}{lrcllll}
\text{Maximize or Minimize} & c_1t + c_2u + c_3v + c_4w + c_5x + c_6y + c_7z & & & & & \\
\text{subject to} & A_1t + A_2u + A_3v + A_4w + A_5x + A_6y + A_7z & \alpha & b & & & \\
& t & \in & \mathbb{R} & & & \\
& u & \geq & 0 & \text{and } u \leq L_2 & \text{and } u \in \mathbb{Z} & \\
& v & \in & (0,1) & & & \\
& w & \in & \text{SOS1} & & & \\
& x & \in & \text{SOS2} & & & \\
& y & = & 0 & \text{or } L_6 \leq y & & \\
& z & = & 0 & \text{or } L_7 \leq z & \text{and } z \in \mathbb{Z}, &
\end{array}
$$

where

- $c_1t + c_2u + c_3v + c_4w + c_5x + c_6y + c_7z$ is the objective function,
- $A_1t + A_2u + A_3v + A_4w + A_5x + A_6y + A_7z \ \alpha \ b$ represents the set of constraints of various equality and inequality forms,
- t is a vector of variables that are continuous real numbers,
- u is a vector of variables that can only take integer values smaller than L_2,
- v is a vector of binary variables,
- w is a vector of variables that belong to `SOS1` sets; this means that at most one variable in the set is nonzero,
- x is a vector of variables that belong to `SOS2` sets; this means that at most two adjacent variables in the set are nonzero,
- y is a vector of variables that are semi-continuous; they are either zero or larger than L_6,
- z is a vector of variables that are semi-integer; they are integer and either zero or larger than L_7.

For details on the equation types allowed in GAMS, see Equation Types. For more details on MIPs in GAMS, especially the use of `SOS` and `semi` variables, see section Special Mixed Integer Programming (MIP) Features.

For information on MIP solvers that can be used through GAMS, see the Solver/Model type Matrix.

Attention

> Not all MIP solvers cover all the cases associated with `SOS` and `semi` variables. Please consult the solver manuals for details on capabilities.

Mixed Integer Nonlinear Programming (MINLP)

Mathematically, the Mixed Integer Nonlinear Programming (MINLP) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & f(x) + Dy \\ \text{subject to} & g(x) + Hy \ \alpha \ 0 \\ & L \leq x \leq U \\ & y = \{0, 1, 2, \cdots\}, \end{array}$$

where x is a vector of variables that are continuous real numbers, y denotes a vector of variables that can only take integer values, $f(x)+Dy$ is the objective function, $g(x)+Hy \ \alpha \, 0$ represents the set of constraints, and L and U are vectors of lower and upper bounds on the variables. For details on the equation types allowed in GAMS, see Equation Types. Further, $y = \{0, 1, 2, \cdots\}$ is the integrality restriction on y.

For information on MINLP solvers that can be used through GAMS see the Solver/Model type Matrix.

Note

- `SOS` and `semi` variables can also be accommodated by some solvers. Please consult the solver manuals for details on capabilities.
- The model attribute TryLinear causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection Model Attributes.

Mixed Integer Quadratically Constrained Programs (MIQCP)

A Mixed Integer Quadratically Constrained Program (MIQCP) is a special case of the MINLP in which all the nonlinearities are required to be quadratic. For details see the description of the QCP, a special case of the NLP.

For information on MIQCP solvers that can be used through GAMS, see the Solver/Model type Matrix.

Note

The model attribute TryLinear causes GAMS to examine whether the problem may be solved as a MIP problem. For details on model attributes, see subsection Model Attributes.

Mixed Complementarity Problem (MCP)

Unlike the other model types we have introduced so far, the Mixed Complementarity Problem (MCP) does not have an objective function. An MCP is specified by three pieces of data: a function $F(z) : \mathbb{R}^n \mapsto \mathbb{R}^n$, lower bounds $l \in \{\mathbb{R} \cup \{-\infty\}\}^n$ and upper bounds $u \in \{\mathbb{R} \cup \{\infty\}\}^n$. A solution is a vector $z \in \mathbb{R}^n$ such that for each $i \in \{1, \ldots, n\}$, one of the following three conditions hold:

$$\begin{array}{lll} F_i(z) = 0 & \text{and} & \ell_i \leq z_i \leq u_i \quad \text{or} \\ F_i(z) > 0 & \text{and} & z_i = \ell_i \quad \text{or} \\ F_i(z) < 0 & \text{and} & z_i = u_i. \end{array}$$

This problem can be written compactly as

$$F(z) \ \perp \ L \leq z \leq U,$$

where the symbol $\perp$ (which means "perpendicular to", shortened to "perp to") indicates pair-wise complementarity between the function F and the variable z and its bounds.

The following special case is an important and illustrative example:

$$F(z) \perp z \geq 0.$$

In this example, the unstated but implied upper bound u is infinity. Since z is finite, we cannot have $z_i = u_i$ and the third condition above cannot hold: this implies $F(z) >= 0$. The remaining two conditions imply pair-wise complementarity between $z >= 0$ and $F(z) >= 0$. This is exactly the Nonlinear Complementarity Problem, often written as

$$F(z) \geq 0, \quad z \geq 0, \quad \langle F(z), z \rangle = 0.$$

None of this rules out the degenerate case (i.e. $F_i(z)$ and z_i both zero). In practice, these can be difficult models to solve.

Another special case arises when the bounds L and U are infinite. In this case, the second and third conditions above cannot hold, so we are left with $F(z) = 0$, a square system of nonlinear equations. And finally, we should mention a special case that occurs frequently in practice: if $\ell_i = u_i$ (i.e. z_i is fixed) then we have a complementary pair: one of the three conditions will hold as long as $F_i(z)$ is defined. Essentially, fixing a variable removes or obviates the matching equation. This is often useful when modeling with MCP.

The definition above describes the canonical MCP model as it exists when GAMS passes it to an MCP solver. Some models have exactly this form even in the GAMS code, but usually some processing is done by the GAMS system to arrive at a model in this form. Here we'll describe the steps of this process and illustrate with an example from the model library.

1. The process starts with the list of rows (aka single equations) and columns (aka single variables) that make up the MCP model, and potentially some matching information.
   - The usual rules apply: rows are part of the model because their associated equations are included in the model statement, but columns only become part of the model by use: a column enters the model only if it is used in some row of the model. Therefore including a variable symbol as part of a match in the model statement will not influence the set of columns belonging to the model.
   - Matches (where they exist) are pointers from rows to columns.
   - Technically, the MCP is defined via a function F while a model contains constraints. Given a constraint, we define an associated function as LHS - RHS, so e.g. $F_i \geq 0$ is consistent with a `=G=` constraint.
2. The explicit matches are processed: each match creates a complementary pair. What remains after the explicit matches are consumed are the unmatched rows and unmatched columns.
   - It is an error for any column to be matched to multiple rows, so the row-column matching is one-to-one.
   - For each match some consistency checks between the column bounds and the row type are made. For details, see Table 2.
   - For example, matching an =N= row with any column is good, matching an =E= row with a free column is good, matching an =E= row with a lower-bounded column is allowed, and matching a =G= row with an upper-bounded column results in an error.
3. Any fixed columns remaining are ignored: these columns can be treated like exogenous variables or parameters.
4. If what remains is a set of =E= rows and an *equal number* of unbounded columns, these can be matched up in any order and we have a well-defined MCP. If this is not what remains, an error is triggered.

To illustrate how this works, consider the spatial equilibrium model **[SPATEQU]** with the following model statement:

```
Model  P2R3_MCP        / dem, sup, in_out.p, dom_trad.x /;
```

1. The model P2R3_MCP includes the rows from equations dem, sup, in_out and dom_trad and exactly the columns used by these rows. Checking the listing file, we see columns for Qd, Qs, x, and p. In addition, the model statement specifies two matches: in_out.p and dom_trad.x. These matches always take the form of an equation.variable pair, with no indices or domains included.
2. In this example, the rows corresponding to the equation in_out match up perfectly with the columns from the variable p: there are no holes in the set of rows or columns because of some dollar conditions in the equation definition. We have a one-to-one match so all the rows of in_out and columns of p are consumed by the match in the model statement. The same holds for the dom_trad.x pair, so what is left are the rows of dem and sup and the columns of Qd and Qs, all of which are unmatched.
3. There are no fixed variables to remove.
4. Since dem and sup are =E= constraints and Qd and Qs are free variables, we can match them in any order without changing the solution set for this model. The counts of these unmatched equality rows and unmatched free variables are equal, so we get a well-defined MCP.

When rows are matched explicitly to columns, some care must be taken to match them consistently. For example, consider a row-column match *g.y*. The row g can be of several types: =N=, =E=, =G=, or =L=. An =N= row can be matched to any sort of variable: the =N= doesn't imply any sort of relationship, which works perfectly with our definition of $\perp$ above: the allowed sign or direction of g is determined completely by the bounds on the complementary variable y. If g is an =E= row, this is consistent with a free variable y, but what if y has an active lower bound? By definition we allow g to be positive at solution, but this violates the declaration as an =E= row. Such cases can be handled by marking the row with a ***redef***. The total number of redefs for a given model is available via the NumRedef model attribute and is shown in the report summary. Note that the set of rows marked depends on the solution: in the example above, if g is zero at solution it will not be marked as a redef, regardless of what the bounds are on y. Finally, some combinations are simply not allowed: they will result in a model generation error. The table below lists the outcome for all possible combinations.

Table 2: ***MCP Matching***

Column Bounds	=N=	=E=	=G=	=L=
lower	OK	redef	OK	ERROR
upper	OK	redef	ERROR	OK
free	OK	OK	OK	OK
double	OK	redef	redef	redef
fixed	OK	redef	redef	redef

The definition, process, and rules above have several implications for valid MCP models:

- It is always acceptable to use the =N= notation when defining the equations in an MCP model, *provided these equations are matched explicitly*. In this case the bounds on F(z) are implied by the bounds on the matching columns, and redefs will never occur.
- Variables that are known to be lower-bounded (no upper bound) will match consistently with =G= equations.
- Variables that are known to be upper-bounded (no lower bound) will match consistently with =L= equations.
- Variables that are known to be unbounded will match consistently with =E= equations.
- Where the bound structure is not known in advance, or both upper and lower bounds exist, a match with an =N= equation will always be consistent. Other equation types will result in errors or redefs.

- The model may initially have fewer rows than columns, as long as the "extra" columns are unmatched fixed columns that ultimately get removed from the MCP passed to the solver.
- Any bounded-but-not-fixed column must be matched explicitly to a row.
- The only rows that may be unmatched are =E= rows.
- It is customary to re-use the constraints of an LP or NLP model when formulating the MCP corresponding to the Karush-Kuhn-Tucker (KKT) conditions. If the original model is a *minimization*, the LP/NLP marginals `.m` and the variables for these marginals in the MCP will use the same sign convention, and the orientation for the constraints will be consistent between the two models, making re-use easier.

As mentioned above, it is typical to use the same equations in both NLP and MCP models. Sometimes, it is not the original equation that is wanted for the MCP, but rather the reoriented (aka negated or flipped) equation. For example, the flipped version of `x**1.5 =L= y` is `y =G= x**1.5`, while `sqr(u) - sqr(v) =E= 5` becomes `- sqr(u) + sqr(v) =E= -5`. Instead of re-implementing the equation in flipped form, the same result can be achieved by prefixing the equation name with a `-` in the model statement. See the **[mcp10]** model for an example of such usage. When equations are used in flipped form, they are marked with a ***redir*** in the listing file's solution listing.

An example of complementarity that should be familiar to many is the relationship between a constraint and its associated dual multiplier: if the constraint is non-binding, its dual multiplier must be zero (i.e. at bound) while if a dual multiplier is nonzero the associated constraint must be binding. In fact, the KKT or first-order optimality conditions for LP and NLP models can be expressed and solved as an MCP.

These complementarity relationships found in optimization problems are useful in understanding the marginal values assigned to rows and columns in the GAMS solution for MCP. With no objective function, the usual definition for marginal values and their interpretation isn't useful. Instead, the GAMS MCP convention for the marginal values of columns is to return the slack of the associated row (i.e. its value when interpreted and evaluated as a function). For the marginal values of rows, the level value (*not* the slack) of the associated column is returned. When we apply this convention to the NCP ($F(z) \geq 0, z \geq 0, \langle F(z), z \rangle = 0$) we see pairwise complementarity between the levels and marginals returned for each of the rows and columns in the model. This is also the case if we take the KKT conditions of an LP in a suitable standard form: minimization, $x \geq 0, Ax \geq b$.

MCPs arise in many application areas including applied economics, game theory, structural engineering and chemical engineering. For further details on this class of problems, see http://www.neos-guide.org/content/complementarity-problems.

For information on MCP solvers that can be used through GAMS, see Solver/Model type Matrix.

Constrained Nonlinear System (CNS)

The Constrained Nonlinear System (CNS) is the second GAMS model type that does not have an objective function. Mathematically, a CNS model looks like:

$$\begin{array}{ll} \text{Find} & x \\ \text{subject to} & F(x) = 0 \\ & L \leq x \leq U \\ & G(x) \ \alpha \ b, \end{array} \tag{4.1}$$

where x is a set of continuous variables and F is a set of nonlinear equations of the same dimension as x. This is a key property of this model type: the number of equations equals the number of variables, so we have a square system. The (possibly empty) constraints $L \leq x \leq U$ are not intended to be binding at the solution, but instead are included to constrain the solution to a particular domain, to avoid regions where $F(x)$ is undefined, or perhaps just to give the solver a push in the right direction. The (possibly

empty) constraints $G(x)\ \alpha\ b$ are intended to serve the same purpose as the variable bounds and are silently converted to equations with bounded slacks.

Note that since there is no objective in a CNS model, there are no marginal values for variables and equations. Any marginal values already stored in the GAMS database will remain untouched. CNS models also make use of some model status values that allow a solver to indicate if the solution is unique (e.g. for a non-singular linear system) or if the linearization is singular at the solution. For singular models (solved or otherwise), the solver can mark one or more dependent rows with a ***depnd***. The total number of rows so marked for a given model is available via the NumDepnd model attribute and is shown in the report summary.

The CNS model is a generalization of a square system of equations $F(x) = 0$. Such a system could also be modeled as an NLP with a dummy objective. However, there are a number of advantages to using the CNS model type, including:

- A check by GAMS that the model is really square,
- solution/model diagnostics by the solver (e.g. singular at solution, (locally) unique solution),
- CNS-specific warnings if the side constraints $L \leq x \leq U$ or $G(x)\ \alpha\ b$ are active at a solution,
- and potential improvement in solution times, by taking better advantage of the model properties.

For information on CNS solvers that can be used through GAMS, see the Solver/Model type Matrix.

Mathematical Program with Equilibrium Constraints (MPEC)

Mathematically, the Mathematical Program with Equilibrium Constraints (MPEC) problem looks like:

$$\begin{array}{ll} \text{Maximize or Minimize} & f(x,y) \\ \text{subject to} & g(x,y)\ \alpha\ 0 \\ & L_x \leq x \leq U_x \\ & F(x,y) \perp L_y \leq y \leq U_y, \end{array}$$

where x and y are vectors of continuous real variables. The variables x are often called the *control* or *upper-level* variables, while the variables y are called the *state* or *lower-level* variables. $f(x,y)$ is the objective function. $g(x,y)\,\alpha\,0$ represents the set of traditional (i.e. NLP-type) constraints; some solvers may require that these constraints only involve the control variables x. The function $F(x,y)$ and the bounds L_y and U_y define the equilibrium constraints. If x is fixed, then $F(x,y)$ and the bounds L_y and U_y define an MCP; the discussion of the "perp to" symbol $\perp$ in that section applies here as well. From this definition, we see that the MPEC model type contains NLP and MCP models as special cases of MPEC.

A simple example of an entire MPEC model is given below.

```
variable z, x1, x2, y1, y2;
positive variable y1;
y2.lo = -1;
y2.up =  1;

equations cost, g, h1, h2;

cost..  z =E= x1 + x2;
g..     sqr(x1) + sqr(x2) =L= 1;
h1..    x1 =G= y1 - y2 + 1;
h2..    x2 + y2 =N= 0;

model example / cost, g, h1.y1, h2.y2 /;
solve example using mpec min z;
```

Note that as in the MCP, the complementarity relationships in an MPEC are specified in the model statement via equation-variable pairs: the `h1.y1` specifies that the equation `h1` is perpendicular to the variable `y1` and the `h2.y2` specifies that the equation `h2` is perpendicular to the variable `y2`. For details on the solve statement, see section The Solve Statement.

While the MPEC model formulation is very general, it also results in problems that can be very difficult to solve. The state-of-the-art for MPEC solvers is not nearly as advanced as that for other model types. As a result, you should expect the MPEC solvers to be more limited by problem size and/or robustness issues than solvers for other model types.

For information on MPEC solvers that can be used through GAMS, see the Solver/Model type Matrix. For more details on MPECs and solver development, see `https://neos-guide.org/guide/types/mpec/`.

Extended Mathematical Programs (EMP)

Extended Mathematical Programming (EMP) is an (experimental) framework for automated mathematical programming reformulations. Using EMP, model formulations that GAMS cannot currently handle directly or for which no robust and mature solver technology exists can be automatically and reliably reformulated or transformed into models for which robust and mature solver technology does exist within the GAMS system. For more details, see the chapter on EMP. Currently EMP supports:

- Equilibrium problems including variational inequalities, Nash games, and Multiple Optimization Problems with Equilibrium Constraints (MOPECs).
- Hierarchical optimization problems such as bilevel programs.
- Disjunctive programs for modeling discrete choices with binary variables.
- Stochastic programs including two-stage and multi-stage stochastic programs, chance constraints and risk measures such as Variance at Risk (VaR) and Conditional Variance at Risk (CVaR).

Apart from the disjunctive and stochastic programming models mentioned above, EMP models are typically processed (aka solved) via the JAMS solver: this solver does the work of reformulation/transformation, calling GAMS to solve this reformulation, and post-processing the solution that results to bring it back in terms of the original EMP model.

Examples demonstrating how to use the EMP framework and the JAMS and DE solvers are available in the GAMS **EMP Library**. These solvers require no license of their own to run but can and do call subsolvers that *do* require a license.

4.30.2.3 Model Attributes

Models have attributes that hold a variety of information, including

- information about the results of a solve performed, a solve statement, the solution of a model,
- information about certain features to be used by GAMS or the solver,
- information passed to GAMS or the solver specifying various settings that are also subject to option statements.

Model attributes are accessed in the following way:

```
model_name.attribute
```

Here `model_name` is the name of the model in GAMS and `.attribute` is the specific attribute that is to be accessed. Model attributes may be used on the left-hand side and the right-hand side of assignments. Consider the following example:

```
transport.resLim = 600;
x = transport.modelStat;
```

In the first line the attribute `.resLim` of the model `transport` is specified to be 600 (seconds). In the second line the value of the attribute `.modelStat` of the model `transport` is assigned to the scalar `x`. Note that model attributes may also be used in display statements.

Some of the attributes are mainly used before the solve statement to provide information to GAMS or the solver link. Others are set by GAMS or the solver link and hence are mainly used after a solve statement.

Moreover, some of the attributes used before the solve may also be set via an option statement or the command line. Consider the following example:

```
option ResLim=10;
```

This line is an option statement and applies to all models. One can set the model attribute `.ResLim` to overwrite the global `ResLim` option. In order to revert the individual `.ResLim` to the global `ResLim` option, one needs to set the model attribute to `NA`. For more on option statements, see chapter The Option Statement.

```
gams mymodel ResLim=10
```

This sets the global `ResLim` option when invoking the gams run (e.g. from the command line). For more on command line parameters, see chapter The GAMS Call and Command Line Parameters.

Note that a model-specific option takes precedence over the global setting specified with an option statement and that a setting via an option statement takes precedence over a setting via the command line parameter.

The complete list of model attributes is given below. Observe that each entry is linked to a detailed description of the respective attribute, including information of whether the attribute is also available as command line parameter or option statement. Note that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section Detailed Descriptions of All Options.

Model Attributes Mainly Used Before Solve

Attribute	Description
bRatio	Basis detection threshold
cheat	Cheat value, i.e. minimum solution improvement threshold
cutOff	Cutoff value for branch and bound
defPoint	Indicator for passing on default point
dictFile	Force writing of a dictionary file if dictfile > 0
domLim	Domain violation limit solver default
fdDelta	Step size for finite differences
fdOpt	Options for finite differences
holdFixed	Treat fixed variables as constants
integer1..5	Integer communication cells
iterLim	Iteration limit of solver

Attribute	Description
limCol	Maximum number of columns listed in one variable block
limRow	Maximum number of rows listed in one equation block
MCPRHoldFx	Print list of rows that are perpendicular to variables removed due to the holdfixed setting
nodLim	Node limit in branch and bound tree
optCA	Absolute Optimality criterion solver default
optCR	Relative Optimality criterion solver default
optFile	Default option file
priorOpt	Priority option for variable attribute .prior
real1..5	Real communication cells
reform	Reformulation level
resLim	Wall-clock time limit for solver
savePoint	Save solver point in GDX file
scaleOpt	Employ user specified variable and equation scaling factors
solPrint	Solution report print option
solveLink	Solver link option
solveOpt	Multiple solve management
sysOut	Solver Status file reporting option
threads	Number of processors to be used by a solver
tolInfeas	Infeasibility tolerance for an empty row of the form a.. 0∗x =e= 0.0001;
tolInfRep	This attribute sets the tolerance for marking infeasible in the equation listing
tolProj	Tolerance for setting solution values to a nearby bound when reading a solution
tryInt	Whether solver should make use of a partial integer-feasible solution
tryLinear	Examine empirical NLP model to see if there are any NLP terms active. If there are none the default LP solver will be used
workFactor	Memory Estimate multiplier for some solvers
workSpace	Work space for some solvers in MB

Model Attributes Mainly Used After Solve

Attribute	Description
domUsd	Number of domain violations
etAlg	Solver dependent timing information
etSolve	Elapsed time it took to execute a solve statement in total
etSolver	Elapsed time taken by the solver only
handle	Unique handle number of SOLVE statement
iterUsd	Number of iterations used
line	Line number of last solve of the corresponding model
linkUsed	Integer number that indicates the value of SolveLink used for the last solve
marginals	Indicator for marginals present
maxInfes	Maximum of infeasibilities
meanInfes	Mean of infeasibilities
modelStat	Integer number that indicates the model status
nodUsd	Number of nodes used by the MIP solver
number	Model instance serial number
numDepnd	Number of dependencies in a CNS model
numDVar	Number of discrete variables
numEqu	Number of equations

Attribute	Description
numInfes	Number of infeasibilities
numNLIns	Number of nonlinear instructions
numNLNZ	Number of nonlinear nonzeros
numNOpt	Number of nonoptimalities
numNZ	Number of nonzero entries in the model coefficient matrix
numRedef	Number of MCP redefinitions
numVar	Number of variables
numVarProj	Number of bound projections during model generation
objEst	Estimate of the best possible solution for a mixed-integer model
objVal	Objective function value
procUsed	Integer number that indicates the used model type
resCalc	Time spent in function and derivative calculations (deprecated)
resDeriv	Time spent in derivative calculations (deprecated)
resGen	Time GAMS took to generate the model in wall-clock seconds
resIn	Time to import model (deprecated)
resOut	Time to export solution (deprecated)
resUsd	Time the solver used to solve the model in seconds
rngBndMax	Maximum absolute non-zero value of bounds passed to the solver (excluding infinity)
rngBndMin	Minimum absolute non-zero value of bounds passed to the solver
rngMatMax	Maximum absolute non-zero value of coefficients in the model matrix passed to the solver (excluding infinity)
rngMatMin	Minimum absolute non-zero value of coefficients in the model matrix passed to the solver
rngRhsMax	Maximum absolute non-zero value of right hand sides passed to the solver (excluding infinity)
rngRhsMin	Minimum absolute non-zero value of right hand sides passed to the solver
rObj	Objective function value from the relaxed solve of a mixed-integer model when the integer solver did not finish
solveStat	Indicates the solver termination condition
sumInfes	Sum of infeasibilities
sysIdent	Solver identification number
sysVer	Solver version

4.30.3 The Solve Statement

Once a model has been defined using the model statement, the solve statement prompts GAMS to call one of the available solvers for the particular model type. This section introduces and discusses the solve statement in detail. For a list of GAMS model types, see Table 1. For information on how to specify desired solvers, see section Choosing a Solver.

Note

It is important to remember that GAMS does *not* solve the problem, but passes the problem definition to one of a number of separate solver programs that are integrated with the GAMS system.

4.30.3.1 The Syntax of the Solve Statement

In general, the syntax for a `solve` statement is as follows. Note that there are two alternatives that are equally valid:

```
solve model_name using model_type maximizing|minimizing var_name;
solve model_name maximizing|minimizing var_name using model_type ;
```

The keyword `solve` indicates that this is a `solve` statement. `Model_name` is the name of the model as defined by a `model` statement. Note that the `model` statement must be placed before the `solve` statement in the program. The keyword `using` is followed by `model_type`, which is one of the GAMS model types described above, see Table 1. The keywords `maximizing` or `minimizing` indicate the direction of the optimization. `Var_name` is the name of the objective variable that is being optimized. An example of a `solve` statement in GAMS is shown below.

```
Solve transport using lp minimizing cost ;
```

`Solve` and `using` are reserved words, `transport` is the name of the model, `lp` is the model type, `minimizing` is the direction of optimization, and `cost` is the objective variable. Note that an objective variable is used instead of an objective row or function.

Attention

> The objective variable must be scalar and of type `free`, and must appear in at least one of the equations in the model.

Recall that some model types (e.g. the Constrained Nonlinear System (CNS) or the Mixed Complementarity Problem (MCP)) do not have an objective variable. So their `solve` statement syntax is slightly different:

```
solve model_name using model_type;
```

As before, `solve` and `using` are keywords, `model_name` is the name of the model as defined by a `model` statement and `model_type` is the GAMS model type CNS or MCP. There is no objective variable and consequently no direction of optimization. An example from the spatial equilibrium model **[SPATEQU]** illustrates this `solve` statement:

```
Solve P2R3_MCP using mcp;
```

`P2R3_MCP` is the model name, the model type is `MCP` and as expected, there is no objective variable.

The EMP model type serves many purposes including some experimental ones. The solve statement with model type EMP can be with or without the objective variable and optimization direction. For more information, see chapter Extended Mathematical Programming (EMP).

4.30.3.2 Actions Triggered by the Solve Statement

When GAMS encounters a solve statement during compilation (the syntactic check of the input file) or execution (actual execution of the program), it initiates a number of special actions. The purpose is to prevent waste that would be caused by solving a model that has apparently been incorrectly specified. During compilation the following are verified:

1. All symbolic equations have been defined and the objective variable is used in at least one of the equations.
2. The objective variable is scalar and of type `free` (even though lower and upper bounds may have been specified)
3. `MCP` models are checked for appropriate complementarity and squareness.
4. Each equation fits into the specified problem class (linearity for `LP`, continuous derivatives for `NLP`, as outlined above).
5. All sets and parameters in the equations have values assigned.

Note

GAMS issues explanatory error messages if it discovers that the model is not according to type; for example, the presence of nonlinear terms in a supposedly LP model. For details on error messages, see chapter GAMS Output.

At execution time the solve statement triggers the following sequence of steps:

1. The model is translated into the representation required by the solution system to be used.
2. Debugging and comprehension aids that the user wishes to see are produced and written to the output file (`EQUATION LISTING`, etc). For customizing options (e.g. LimRow and LimCol), see chapter The Option Statement.
3. GAMS verifies that there are no inconsistent bounds or unacceptable values (for example, `NA` or `UNDF`) in the problem.
4. Any errors detected at this stage cause termination with as much explanation as possible, using the GAMS names for the identifiers causing the trouble.
5. GAMS designs a solution strategy based on the possible availability of level values or basis information from a previous solution: all available information is used to provide efficiency and robustness of operation. Any specifications provided by the user (Iteration limits etc.) are incorporated. A solver is chosen which is either the default solver for that problem type, the solver specified on the command line or the solver chosen by an option statement. For details see section Choosing a Solver.
6. GAMS passes control to the solution subsystem and waits while the problem is being solved.
7. GAMS reports on the status of the solution process and loads solution values back into the GAMS database. This causes new values to be assigned to the `.l` and `.m` fields for all individual equations and variables in the model. In addition, the post solution model attributes are assigned. The procedure for loading back the data associated with level and marginal values may be customized using the SolveOpt model attribute and option. A row by row and column by column listing of the solution is provided by default. It may be suppressed by the SolPrint model attribute or option. Any apparent difficulty with the solution process will cause explanatory messages to be displayed. Errors caused by forbidden nonlinear operations are reported at this stage.

Note

When the solver does not provide a dual solution (.m), then GAMS does not print the marginal column in the solution listing and set the marginal field in variables and equations to NA.

The outputs from these steps, including any possible error messages, are discussed in detail in chapter GAMS Output.

4.30.4 Programs with Several Solve Statements

Several solve statements can be processed in the same program. The next few subsections discuss various instances where several `solve` statements may be needed in the same file. If sequences of expensive or difficult models are to be solved, it might be useful to interrupt program execution and continue later. For details on this topic, see chapter The Save and Restart Feature.

4.30.4.1 Several Models

If there are different models then the solves may be sequential, as below. Each of the models in [PROLOG] consists of a different set of equations, but the data are identical, so the three solves appear in sequence with no intervening assignments:

```
Solve nortonl using nlp maximizing z;
Solve nortonn using nlp maximizing z;
Solve nortone using nlp maximizing z;
```

When there is more than one `solve` statement in the program, GAMS uses as much information as possible from the previous solution to provide a starting point or basis in the search for the next solution.

4.30.4.2 Loop: One Model, Different Data

Multiple solves may also occur as a result of a solve statement within a `loop` statement. Loop statements are introduced and discussed in detail in chapter Programming Flow Control Features; here we show that they may contain a solve statement and thus lead to multiple solves within one model. The example from [**MEANVAR**] computes the efficient frontier for return and variance for a portfolio selection problem at equidistance points.

```
loop(p(pp),
   v.fx = vmin + (vmax-vmin)/(card(pp)+1)*ord(pp) ;
   Solve var1 maximizing m using nlp ;
   xres(i,p)         = x.l(i);
   xres('mean',p)    = m.l;
   xres('var',p)     = v.l;
);
```

The set `p` is a set of point between the minimum and maximum variance, it is the driving set of the loop. A variance variable v is fixed at a equidistance points. With each iteration through the loop another variance level is used, the `NLP` model var1 is solved for each iteration and the outputs are stored in the parameter `xres(*,pp)`, to be used later for reporting. As often for reporting purposes, the universal set $*$ is used.

This example demonstrates how to solve the same model (in terms of variables and equations) multiple times with slightly different data. For such situations the Gather-Update-Solve-Scatter (GUSS) facility improves on the loop implementation by saving generation time and minimizing the communication with the solver. GUSS is activated by the additional keyword `scenario` in the solve statement followed by a set name that provides mapping information between parameters in the model and the scenario containers. A GUSS implementation of the loop would look as follows:

```
parameter vfx(p), px(p,i), pm(p);
set dict / p  .scenario.''
           v  .fixed   .vfx
           x  .level   .px
           m  .level   .pm /;
vfx(p(pp)) = vmin + (vmax-vmin)/(card(pp)+1)*ord(pp);
Solve var1 maximizing m using nlp scenario dict;
xres(i,p)      = px(p,i);
xres('mean',p) = pm(p);
xres('var',p)  = vfx(p);
```

4.30.4.3 Customizing Solution Management: SolveOpt

It is important to consider how GAMS manages solutions if multiple models are solved. By default, GAMS merges subsequent solutions with prior solutions. This is not an issue if all models operate over the same set of variables. However, recursive procedures, different equation inclusions or logical conditions may cause only part of the variables or different variables to appear in the models to be solved. In such a case it might be useful to modify the solution management procedure using the model attribute or option SolveOpt.

4.30.4.4 Sensitivity or Scenario Analysis

Multiple solve statements can be used not only to solve different models, but also to conduct sensitivity tests, or to perform case (or scenario) analyses of models by changing data or bounds and then solving the same model again. While some commercial LP systems allow access to "sensitivity analysis" through GAMS it is possible to be far more general and not restrict the analysis to either solver or model type. This facility is even more useful for studying many scenarios since no commercial solver will provide this information.

An example of sensitivity testing is in the simple oil-refining model [**MARCO**]. Because of pollution control, one of the key parameters in oil refinery models is an upper bound on the sulfur content of the fuel oil produced by the refinery. In this example, the upper bound on the sulfur content of fuel oil was set to 3.5 percent in the original data for the problem. First, the model is solved with this value. Next, a slightly lower value of 3.4 percent is used and the model is solved again. Finally, the considerably higher value of 5 percent is used and the model is solved for the last time. Key solution values are saved for later reporting after each solve. This is necessary because a following solve replaces any existing values. The key solution values are the activity levels of the process level `z`, a variable that is defined over a set of processes `p` and a set of crude oils `cr`. The complete sequence is:

```
parameter report(*,*,*) "process level report";

qs('upper','fuel-oil','sulfur') = 3.5  ;
Solve oil using lp maximizing phi;
report(cr,p,'base')  =  z.l(cr,p) ;
report('sulfur','limit','base') = qs('upper','fuel-oil','sulfur');

qs ('upper','fuel-oil','sulfur') = 3.4  ;
Solve oil using lp maximizing phi ;
report(cr,p,'one') = z.l(cr,p) ;
report('sulfur','limit','one') = qs ('upper','fuel-oil','sulfur');

qs('upper','fuel-oil','sulfur') = 5.0  ;
Solve oil using lp maximizing phi ;
report(cr,p,'two') = z.l(cr,p) ;
report('sulfur','limit','two') = qs('upper','fuel-oil','sulfur');

Display report ;
```

Note that the parameter `report` is defined over the universal set or short *universe*. In general, the universe is useful when generating reports, otherwise it would be necessary to provide special sets containing the labels used in the report. Any mistakes made in spelling labels used only in the report should be immediately apparent, and their effects should be limited to the report. The parameter `qs` is used to set the upper bound on the `sulfur` content in the `fuel-oil`, and the value is retrieved for the report. Note that the `display` statement in the final line is introduced and discussed in detail in chapter The Display Statement. This example shows not only how simply sensitivity analysis can be done, but also how the associated multi-case reporting can be handled.

The output from the `display` statement is shown below. Observe that there is no production at all if the permissible sulfur content is lowered. The *case attributes* have been listed in the row `SULFUR.LIMIT`. Section Global Display Controls contains more details on how to arrange reports in a variety of ways.

```
----    225 PARAMETER report  process level report

                          base         one         two

mid-c .a-dist           89.718                   35.139
mid-c .n-reform         20.000                    6.772
mid-c .cc-dist           7.805                    3.057
w-tex .cc-gas-oil                                 5.902
w-tex .a-dist                                    64.861
w-tex .n-reform                                  12.713
w-tex .cc-dist                                    4.735
w-tex .hydro                                     28.733
sulfur.limit             3.500       3.400        5.000
```

Note

For other ways to do comparative analyses with GAMS, see the tutorial Comparative Analyses with GAMS.

4.30.4.5 Iterative Implementation of Non-Standard Algorithms

Another use of multiple solve statements is to permit iterative solution of different blocks of equations, most often using solution values from the first solve as data for the next solve. These decomposition methods are useful for certain classes of problems because the subproblems being solved are smaller, and therefore more tractable. One of the most common examples of such a method is the Dantzig-Wolfe decomposition.

An example of a problem that is solved in this way is a multi-commodity network flow problem in [**DANWOLFE**].

4.30.5 Choosing a Solver

After a model has been checked and prepared as described above, GAMS passes the model to a solver. When the GAMS system is installed default solvers for all model types are specified and these solvers are used if the user doesn't specify anything else. It is easy to switch to other appropriate solvers provided the user has the corresponding license. There are multiple ways to switch solvers:

1. Using a command line parameter of the following form:

   ```
   gams mymodel model_type=solver name
   ```

   For example,

   ```
   gams mymodel lp=cbc
   ```

2. With an option command of the following form that is placed before the `solve` statement:

   ```
   Option model_type=solver_name;
   ```

   Here `option` is a keyword, `model_type` is the same model type that is used in the `solve` statement and `solver_name` is the name of one of the available solvers. For example,

   ```
   Option LP=cbc, NLP=conopt, MIP=cbc, MINLP=default;
   ```

   The `MINLP=default` switches back to the default solver for the MINLP model type.

3. Instead of providing a particular solver for a model type, the option Solver can be used to use a given solver for all model types this solver can handle.

```
Option Solver=cbc;
```

4. (Re)running `gamsinst` at any time and altering the choice of default solver as described in the installation notes.

Note

A list of all solvers and current default solvers may be generated in the `listing` file with `Option SubSystems;`.

4.30.6 Making New Solvers Available with GAMS

This short section is to encourage those of you who have a favorite solver not available through GAMS. Linking a solver program with GAMS requires some programming skills and the use of libraries provided by GAMS. There is a collection of open source solver links to GAMS at the COIN-OR project GAMSLinks. The benefits of a link with GAMS to the developer of a solver are several. They include:

- Immediate access to a wide variety of test problems.
- An easy way of making performance comparisons between solvers.
- The guarantee that a user has not somehow provided an illegal input specification.
- Elaborate documentation, particularly of input formats, is not needed.
- Access to the existing community of GAMS users, for marketing or testing.

This completes the discussion of the model and solve statements.

4.31 Conditional Expressions, Assignments and Equations

4.31.1 Introduction

This chapter deals with the way in which conditional assignments, expressions and equations are made in GAMS. The index operations already described are very powerful, but it is necessary to allow for exceptions of one sort or another. For example, heavy trucks may not be able to use a particular route because of a weak bridge, or some sectors in an economy may not produce exportable products. Exceptions such as these may easily be modeled with a logical condition combined with the dollar operator `'$'`, a very powerful feature of GAMS introduced in this chapter.

This chapter is organized as follows: We will introduce the general form of the dollar condition first and then we will focus on the various types of logical conditions. Next, we will discuss how dollar conditions are used to build conditional assignments, conditional indexed operations and conditional equations. We will conclude the chapter by showing that in certain cases conditions may be modeled using filtering sets instead of the dollar operator. Programming flow control features such as the if statement, the loop, the while statement, and the for statement are not covered in this chapter. These can be found in the chapter Programming Flow Control Features.

4.31.2 The Dollar Condition

The dollar operator is one of the most powerful features in GAMS. The general syntax for a conditional expression is:

```
term $ logical_condition
```

Here, `term` can be a number, a (indexed) symbol, and also a complex expression. The dollar operator may be read as *under the condition that* the following `logical_condition` evaluates to `TRUE` (or is unequal 0).

Consider the following simple condition, where `a` and `b` are scalars.

```
if (b > 1.5), then a = 2
```

This can be written in GAMS using the dollar operator as follows.

```
a $ (b > 1.5) = 2 ;
```

Note that the `term` is the scalar `a` and the `logical condition` is the expression ($b > 1.5$). If the condition is not satisfied, no assignment is made. To make it clear, this conditional assignment may be read as: '*given that b is greater than 1.5, a equals 2*'.

Logical conditions may take various forms, they are introduced in the next section. Conditional expressions may be used in the context of assignments, indexed operations and equations. These topics are covered in later sections of this chapter.

Note

Logical conditions used with the dollar operator cannot contain variables. However, variable attributes are allowed.

4.31.3 Logical Conditions

Logical conditions are special expressions that evaluate to a value of either `TRUE` or `FALSE`. Logical conditions may be numerical expressions and numerical relations, they may refer to set membership and they may also contain acronyms. In the following subsections this is shown in the context of simple conditional assignments with the dollar operator on the left-hand side (compare section Dollar on the Left).

In this section we use many examples to illustrate the concepts that are being introduced. In all these examples `a` and `b` are scalars, `s`, `t`, `u` and `v` are parameters, and `i` and `j` are sets.

4.31.3.1 Logical Conditions: Numerical Expressions

Numerical expressions may serve as logical conditions: a result of zero is treated as the logical value `FALSE` and a non-zero result is treated as the logical value `TRUE`. The following example illustrates this point.

```
b $ (2*a - 4) = 7;
```

Here the numerical expression $(2 * a - 4)$ is the logical condition. The numerical expression is zero if `a` equals 2, and non-zero otherwise. Hence the logical value of the expression is `FALSE` for $a = 2$ and `TRUE` for all other values of `a`. The assignment is only made if the numerical expression evaluates to `TRUE`, otherwise no assignment is made.

Attention

> Values of the extended range arithmetic such as `inf` are also allowed in logical conditions. If the result of a numerical expression used as a logical condition takes any of these values, the logical value is `TRUE`, even for e.g. `eps`, which is numerically 0.

Observe that functions are also allowed in logical conditions. If they evaluate to zero, the logical condition is `FALSE`, otherwise it is `TRUE`. Consider the following example:

```
b $ cos(a) = 7;
```

Note that the assignment is only made if the cosine of `a` does not equal zero.

4.31.3.2 Logical Conditions: Numerical Relational Operators

Numerical relational operators compare two numerical expressions and return a logical value. For completeness, all numerical relational operators are listed in Table 1.

Relation	Operator	Alternative Notation	Return Values
Strictly less than	`x < y`	`x lt y`	Returns `TRUE` if $x < y$, else returns `FALSE`.
Less than or equal to	`x <= y`	`x le y`	Returns `TRUE` if $x \leq y$, else returns `FALSE`.
Equal to	`x = y`	`x eq y`	Returns `TRUE` if $x = y$, else returns `FALSE`.
Not equal to	`x <> y`	`x ne y`	Returns `TRUE` if $x \neq y$, else returns `FALSE`.
Greater than or equal to	`x >= y`	`x ge y`	Returns `TRUE` if $x \geq y$, else returns `FALSE`.
Strictly greater than	`x > y`	`x gt y`	Returns `TRUE` if $x > y$, else returns `FALSE`.

Table 1: Numerical Relational Operators

Consider the following examples.

```
b $ (a < 0) = 10;
```

```
b $ (sqr(a) > a) = 12;
a $ ( sum(i, s(i)) > 0 ) = 7;
t(i) $ (a <> 0) = t(i) + 1;
```

In the first line the logical condition is the relational expression ($a < 0$). The assignment is only made if this expression is TRUE, that is, if the scalar a is negative. The logical condition in the second line is a bit more complex. It evaluates to FALSE if $0 \leq a \leq 1$. For all other values of a, it evaluates to TRUE. So the assignment is made for all values of a, except for those values of a that are in the closed interval $[0, 1]$. Note that if $a = -3$, then the logical condition in the first line will be TRUE, so b will become 10. In addition, the logical condition in the second line will be TRUE, so b will change to 12. The logical condition in the third line evaluates to TRUE if the sum of all values of the parameter s is strictly positive. Then a is assigned the value of 7. The assignment in the last line depends on whether a is non-zero. If a is zero no assignment is made, otherwise all entries of the parameter t are updated.

Note that acronyms may also be used with relational operators to build logical conditions. However, only the equality operator = and inequality operator <> are allowed in the context of acronyms, since they have no numerical values and the other operators would be meaningless. For an example, see section Acronym Usage.

4.31.3.3 Logical Conditions: Logical Operators

GAMS offers standard logical operators that may combine two or more logical conditions to build complex logical expressions. For example, if several expressions are required to be TRUE simultaneously, they may be connected with the operator and. The logical operators available in GAMS are listed in Table 2 and Table 3. Another way to construct complex logical conditions is by nesting them. For details, see subsection Nested Dollar Conditions below.

Operation	Operator	Alternative Notation	Description
Negation	not x		The logical condition x has to be FALSE, in order for the expression to be TRUE.
Logical conjunction	x and y		Two logical conditions are TRUE simultaneously.
Logical disjunction	x or y		At least one of two logical conditions applies.
Exclusive disjunction	x xor y		Exactly one of two logical conditions applies.
Logical implication	x imp y	x -> y	If the logical condition x is TRUE but at the same time the logical condition y is FALSE, then the whole expression is FALSE, in all other cases the expression evaluates to TRUE.
Logical equivalence	x eqv y	x <=> y	Both logical conditions are either TRUE simultaneously or FALSE simultaneously for the whole expression to be TRUE.

Table 2: Logical Operators

The logical values of these operators are summarized in the following truth table.

x	y	not x	x and y	x or y	x xor y	x imp y	x eqv y
FALSE	FALSE	TRUE	FALSE	FALSE	FALSE	TRUE	TRUE

x	y	not x	x and y	x or y	x xor y	x imp y	x eqv y
FALSE	TRUE	TRUE	FALSE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	FALSE	TRUE	TRUE	FALSE	FALSE
TRUE	TRUE	FALSE	TRUE	TRUE	FALSE	TRUE	TRUE

Table 3: Truth Table of Logical Operators

The following somewhat artificial examples serve as illustration.

```
Set       i     / i1*i5 /;
Parameter s(i)  / i1 3, i2 5, i4 8 /
          t(i)  / i1*i4 13 /
          u(i)  / i2 1 /
          v(i)  / i1 7, i3 2 /;

u(i) $ (not s(i))               = v(i);
u(i) $ (s(i) and u(i) and t(i)) = s(i);
u(i) $ (s(i) or v(i) or t(i))   = 4;
```

Note that there are three conditional assignments for the parameter `u`. In the first assignment the logical condition is `(not s(i))`. This condition holds for all entries of `s` that are not specified and therefore zero by default: `s('i3')` and `s('i5')`. Hence `u('i3')` and `u('i5')` are assigned the values of `v('i3')` and `v('i5')` respectively. The value of `v('i3')` is 2 and the value of `v('i5')` is zero by default. After the first assignment we have `u('i2')=1` and `u('i3')=2`, all other values of `u` are zero. Note that the logical condition failed for `u('i2')` and therefore its value remained unchanged. The logical condition in the second assignment is `TRUE` for those labels of the set `i` that have non-zero entries in the parameters `s`, `u` and `t` simultaneously. This condition holds only for `i2`. Therefore `u('i2')=s('i2')=5` and all other values of `u` remain unchanged, resulting in non-zero values only for `u('i2')` and `u('i3')`. The logical condition in the last assignment evaluates to `TRUE` for all labels of the set `i` that have at least one non-zero entry in the parameters `s`, `v` and `t`. This holds for all labels except for `i5`. Therefore `u('i5')` stays zero and all other values of `u` are changed to 4. These examples demonstrate the power of the dollar operator combined with logical operators. Even more complex logical conditions are possible; see subsection Mixed Logical Conditions below for details.

4.31.3.4 Logical Conditions: Set Membership and Set Functions

Apart from numerical and relational expressions, set membership and functions referencing set elements may be used as a logical condition. Consider the following example as illustration for set membership as logical condition.

```
Set        i     / i1*i5 /
           j(i)  / i1*i3 / ;
Parameter  s(i)  / i1 3, i2 5, i3 11, i4 8, i5 1 /
           t(i);
t(i) $ j(i) = s(i) + 3;
```

Note that the set `j` is a subset of the set `i` and that the parameter `t` is declared but not defined. The conditional expression `t(i)$j(i)` in the last line restricts the assignment to the members of the subset `j` since only they satisfy the condition `j(i)`. The values for `t('i4')` and `t('i5')` remain unchanged. In this case this means that they are zero (by default). Note that there is an alternative formulation for this type of conditional assignment; for details see subsection Filtering Sets in Assignments below.

Note

Only the membership of subsets and dynamic sets may be used as logical conditions.

The use of set membership as a logical condition is an extremely powerful feature of GAMS, see section Conditional Equations below for more examples.

Logical conditions may contain predefined symbols or operators that return particular values depending on the position of elements in sets, the size of sets or the comparison of set elements to each other or text strings:

Predefined Symbol / Operator	Description and Comments
`sameAs(element1,element2)` or `sameAs("text",element2)` or `sameAs(element1,"text")`	Predefined symbol that returns `TRUE` if `element1` is identical to `element2` or `element1` is identical to `text`, and `FALSE` otherwise.
`diag(element1,element2)` or `diag("text",element2)` or `diag(element1,"text")`	Like `sameAs`, but returns numerical value 1 for `TRUE` and 0 for `FALSE`.
`card(set_name)`	Returns the number of elements in a set. Note that this can also be called with a quoted text and returns the number of characters of that text in that case. For more details, see section The Card Operator.
`ord(set_name)`	Returns the relative position of an element in a set. Note that `ord` may be used *only* with one-dimensional, static, ordered sets. For more details, see section The Ord Operator.

Table 4: Predefined Symbols / Operators Referencing Sets

In the following example we have two sets of cities and we want to know how many of them feature in both sets.

```
Set     i     / Beijing, Calcutta, Mumbai, Sydney, Johannesburg, Cairo /;
Set     j     / Rome, Paris, Boston, Cairo, Munich, Calcutta, Barcelona /;
Scalar  b;
b = sum((i,j)$sameAs(i,j),1);
```

Note that in the assignment statement we sum over both sets and we use the predefined symbol `sameAs` to restrict the domain of the indexed operation to those label combinations `(i,j)` where `sameAs` evaluates to `TRUE`. Thus only identical elements are counted.

Note that in this example the predefined symbol `diag` could have been used with the same result.

The operators `ord` and `card` are frequently used to single out the first or last element of an ordered set. For example, we may want to fix a variable for the first and last elements of a set:

```
x.fx(i) $ (ord(i) = 1)       = 3;
x.fx(i) $ (ord(i) = card(i)) = 7;
```

In the first assignment the variable `x` is fixed for the first element of the set `i` and in the second assignment `x` is fixed for the final element of `i`.

Note

As an alternative to the formulation above, one could also use the set attributes `first` and `last` to get the same result:

```
x.fx(i) $ (i.first) = 3;
x.fx(i) $ (i.last)  = 7;
```

4.31.3.5 Numerical Values of Logical Conditions

We have seen that logical conditions may take the form of numerical expressions, expressions with relational operators, complex expressions using logical operators, set membership and set functions. However, GAMS does not have a Boolean data type.

Attention

GAMS follows the convention that the result of a relational operation is zero if the assertion is `FALSE`, and 1 if it is `TRUE`.

Consider the following example as illustration.

```
x = (1 < 2) + (2 < 3);
```

The expression to the right of the assignment evaluates to 2 since both logical conditions within parentheses are `TRUE` and therefore assume a value of 1. Note that this is different from the assignment below:

```
x = (1 < 2) or (2 < 3)
```

This assignment evaluates to 1, since both statements to the left and right of `or` are `TRUE` and therefore the whole expression is `TRUE`.

4.31.3.6 Mixed Logical Conditions

The building blocks introduced in the subsections above may be combined to generate more complex logical conditions. These may contain standard arithmetic operations, numerical relational operations and logical operations. All operations, their symbols and their order of precedence are given in Table 5. Note that 1 denotes the highest order of precedence and 7 denotes the lowest order of precedence. As usual, the default order of precedence holds only in the absence of parentheses and operators (symbols) on the same level are evaluated from left to right.

Type of Operation	Operation	Operator	Order of precedence
Standard arithmetic operation	Exponentiation	**	1
Standard arithmetic operation	Multiplication, Division	*, /	2
Standard arithmetic operation	Unary operators: Plus, Minus	+, -	3
Standard arithmetic operation	Binary operators: Addition, Subtraction	+, -	3
Numerical Relational operation	All	<, <=, =, <>, >=, >	4
Logical operation	Negation	not	5
Logical operation	Logical Conjunction	and	6
Logical operation	All other logical opera-	or, xor, imp, eqv	7

Table 5: Complete Hierarchy for Operator Precedence in GAMS

Note

We recommend to use parentheses rather than relying on the order of precedence of operators. Parentheses prevent errors and make the intention clear.

Consider the following example:

```
x - 5*y and z - 5
(x - (5*y)) and (z-5)
```

These two complex logical conditions are equivalent. However, the parentheses make the second expression easier to understand.

Some simple examples of complex logical conditions, their numerical values and their logical values are given in Table 6.

Logical Condition	Numerical Value	Logical Value
(1 < 2) + (3 < 4)	2	TRUE
(2 < 1) and (3 < 4)	0	FALSE
(4*5 - 3) + (10/8)	18.25	TRUE
(4*5 - 3) or (10 - 8)	1	TRUE
(4 and 5) + (2*3 <= 6)	2	TRUE
(4 and 0) + (2*3 < 6)	0	FALSE

Table 6: Examples of Complex Logical Conditions

4.31.3.7 Nested Dollar Conditions

An alternative way to model complex logical conditions is by nesting them. The syntax is:

```
term $ (logical_condition1$(logical_condition2$(...)))
```

Note that in nested dollar conditions all succeeding expressions after the dollar operator must be enclosed in parentheses. The nested expression is equivalent to the following conditional expression that uses the logical operator `and` instead of the nesting:

```
term $ (logical_condition1 and logical_condition2 and ...)
```

Consider the following example. Note that `i`, `j(i)` and `k(i)` are sets, and `u(i)` and `v(i)` are parameters.

```
u(i) $ (j(i)$k(i)) = v(i) ;
```

The assignment will be made only for those members of the set `i` that are members of both sets `j` and `k`. Note the position of the parentheses in the dollar condition. The assignment statement above can be rewritten in the following way.

```
u(i) $ (j(i) and k(i)) = v(i) ;
```

Note

We recommend to use the logical `and` operator instead of nesting dollar operators, because this formulation is easier to read.

4.31.4 Conditional Assignments

A conditional assignment is an assignment statement with a dollar condition on the left-hand side or on the right-hand side. Most examples until now were conditional assignments with the dollar operator on the left.

Attention

> The effect of the dollar condition is significantly different depending on which side of the assignment it is located.

The next two subsections describe the use of the dollar condition on each side of the assignment. Note that in many cases it may be possible to use either of the two forms of the dollar condition to describe an assignment. We recommend to choose the clearer formulation.

Note that if the logical condition in an assignment statement refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering Sets in Assignments below.

4.31.4.1 Dollar on the Left

If the dollar condition is on the left-hand side of an assignment, an assignment is made only in case the logical condition is satisfied. If the logical condition is not satisfied then no assignment is made and the previous content of the parameter on the left will remain unchanged. In case the parameter on the left-hand side of the assignment has not previously been initialized or assigned any values, zeros will be used for any label for which the assignment was suppressed.

Consider the following example adapted from [**CHENERY**]. Note that the parameter `sig` has been previously defined in the model.

```
rho(i) $ (sig(i) <> 0) = (1./sig(i)) - 1. ;
```

In this assignment `rho(i)` is calculated and the dollar condition on the left protects against dividing by zero. If any of the values associated with the parameter `sig` turns out to be zero, no assignment is made and the previous values of `rho(i)` remain. As it happens, `rho(i)` was not previously initialized, and therefore all the labels for which `sig(i)` is zero will result in a value of zero.

Now recall the convention that non-zero implies `TRUE` and zero implies `FALSE`. The assignment above could therefore be written as:

```
rho(i) $ sig(i)  =  (1./sig(i)) - 1. ;
```

In the following examples `i` is a set and `s` and `t` are parameters.

```
s(i) $ t(i) = t(i);
s(i) $ ((t(i)-1) > 0) = t(i)**0.5;
```

Note that the first assignment is suppressed if the value of the parameter `t` equals zero. The second assignment is suppressed for values of the parameter `t` that are smaller or equal to 1.

Note

> The first of the last two examples is special in the way that the logical condition used with the dollar on the left and the expression on the right hand side of the assignment are actually the same. This allows to use a shorter notation using the combined `$=` assignment. That assignment is equivalent to the following one (which called sparse assignment):
>
> ```
> s(i) $= t(i);
> ```

4.31.4.2 Sparse Assignments

Sparse assignments will assign a value to the left-hand side of the = sign only if the right-hand side is nonzero. This behavior is triggered using the $= notation as in the following example.

```
Set       i                                          /a,b,c/
Parameter d1(i)  "Initial data"                      /a 1, b  1, c 1/
          d2(i)  "Data to be used to overwrite d1"   /a 0, b -2 /
          d3(i)  "Empty data parameter";

* Initialize d3 to d1
d3(i) = d1(i);
* Use dollar on the left to overwrite d3 with non-zero values from d2
d3(i)$d2(i) = d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;

* Re-Initialize d3 to d1
d3(i) = d1(i);
* Use sparse assignment to overwrite d3 with non-zero values from d2
d3(i) $= d2(i);
* Result: d3('a')=1; d3('b')=-2; d3('c')=1;
```

Note that in the final assignments above, the values of the parameter d3(i) are replaced with values from parameter d2(i) only if the entry in d2(i) is non-zero, the other values are left untouched. Both assignments are equivalent.

4.31.4.3 Dollar on the Right

If the dollar condition is on the right-hand side of an assignment statement, an assignment will *always* be made. In case the logical condition is not satisfied the value of zero is assigned.

Above we had the following simple conditional assignment:

```
a $ (b > 1.5) = 2;
```

Now we move the dollar condition to the right-hand side:

```
a = 2 $ (b > 1.5)  ;
```

This is equivalent to:

```
if (b > 1.5)   then (a = 2),    else (a = 0)
```

Note that an if-then-else type of construct is implied, but the else operation is predefined and never made explicit. The else could be made explicit with the following formulation:

```
a = 2 $ (b > 1.5) + 0 $ (b <= 1.5) ;
```

The use of this feature is more apparent in instances when an `else` condition needs to be made explicit. Consider the next example adapted from the fertilizer model [**FERTD**] . The set `i` is the set of plants, and we are calculating `mur(i)`, the cost of transporting imported raw materials. In some cases a barge trip must be followed by a road trip because the plant is not alongside the river and we must combine the separate costs. The assignment is:

```
mur(i) = (1.0 +. 0030*ied(i,'barge')) $ ied(i,'barge')
       + (0.5 + .0144*ied(i,'road' )) $ ied(i,'road' );
```

This means that if the entry in the distance table `ied` is not zero, then the cost of shipping using that link is added to the total cost. If there is no distance entry, there is no contribution to the cost, presumably because that mode is not used.

Consider another example for a conditional assignment with the dollar operator on the right:

```
b = sum(i,t(i)) $ (a > 0) + 4;
```

Here `a` and `b` are scalars, `i` is a set and `t` is a parameter. If the scalar `a` is positive, the scalar `b` is assigned the sum of all values of the parameter `t` plus 4. If `a` is zero or negative, `b` becomes just 4. Note that the sum is only computed if the condition holds, this potentially makes the program faster.

4.31.5 Conditional Indexed Operations

We have seen how exceptions in assignments are modeled with dollar conditions. Dollar conditions are also used in indexed operations, where they control the domain of operation. This is conceptually similar to the conditional assignment with the dollar on the left.

Consider the following example adapted from [**GTM**], a gas trade model for interrelated gas markets. Here the set `i` contains supply regions and the parameter `supc` models supply capacities. The scalar `tsupc` is computed with the following statement:

```
tsupc  =  sum(i $ (supc(i) <> inf), supc(i))  ;
```

This assignment restricts the sum to the *finite* values of the parameter `supc`.

In indexed operations the logical condition is often a set. This set is called the *conditional set* and assignments are made only for labels that are elements of the conditional set. This concept plays an important role in dynamic sets.

Multi-dimensional sets are introduced in section Multi-Dimensional Sets. In the example used there a two-dimensional set is used to define the mapping between countries and ports. Another typical example for a multi-dimensional set is a set-to-set mapping that defines the relationship between states and regions. This is useful for aggregating data from the state to the regional level. Consider the following example:

```
Sets r          "regions" / north, south /
     s          "states"  / florida, texas, vermont, maine /
     corr(r,s)            / north.(vermont,maine)
                            south.(florida,texas) /;

Parameter y(r)      "income for each region"
          income(s) "income of each state"
                          / florida   4.5, vermont   4.2
                            texas     6.4, maine     4.1 / ;
```

The set corr links the states to their respective regions, the parameter income is the income of each state. The parameter y is computed with the following assignment statement:

```
y(r) = sum(s $ corr(r,s), income(s)) ;
```

The conditional set corr(r,s) restricts the domain of the summation: for each region r the summation over the set s is restricted to the label combinations (r,s) that are elements of the set corr(r,s). Conceptually, this is analogous to the Boolean value TRUE or the arithmetic value non-zero. The effect is that only the contributions of vermont and maine are included in the total for north, and south is the sum of the incomes from only texas and florida.

Note that the summation above can also be written as:

```
y(r) = sum(s,income(s) $ corr(r,s));
```

In this formulation the parameter income is controlled by the conditional set corr instead of the index s. Note that both formulations yield the same result, but the second alternative is more difficult to read.

In the next example the logical condition on the right-hand side appears in the context of an indexed operation, but it does not refer to the index. Thus it is treated similarly to a dollar on the right logical condition. Note that a and b are scalars, i is a set and s is a parameter.

```
b = sum(i $ a, s(i));
```

Here the scalar b is assigned the sum of the values of the parameter s only if a does not equal zero. Otherwise b will be assigned the value zero. Observe that the following alternative formulation will generally be faster than the assignment above:

```
b = sum(i, s(i)) $ a;
```

Note that if the logical condition in the context of indexed operations refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering Controlling Indices in Indexed Operations below.

4.31.6 Conditional Equations

The dollar operator is also used for exception handling in equations. The next two subsections discuss the two main uses of dollar operators in the context of equations: in the body of an equation and over the domain of definition.

4.31.6.1 Dollar Operators within the Algebra of Equations

A dollar operator in the algebraic formulation of an equation is analogous to the dollar control on the right of assignments, as presented in section Dollar on the Right. Assuming that "the right" means the right of the `'..'` then the analogy is even closer. As in the context of assignments, an `if-else` operation is implied. It is used to exclude parts of the definition from some of the generated constraints.

Consider the following example adapted from the production model [**CHENERY**].

```
Set         i       "sectors"     / light-ind, food+agr, heavy-ind, services /
            t(i)    "tradables"   / light-ind, food+agr, heavy-ind /;

Variables   x(i)    "quantity of output"
            y(i)    "final consumption"
            e(i)    "quantity of exports"
            m(i)    "quantity of imports";

Equations   mb(i)   "material balance";

mb(i)..     x(i) =g= y(i) + (e(i) - m(i)) $ t(i) ;
```

Note that in the equation definition in the last line, the term `(e(i) - m(i))` on the right-hand side of the equation is added only for those elements of the set `i` that also belong to the subset `t(i)`, so that the element `services` is excluded.

Further, conditional indexed operations may also feature in expressions in equation definitions. The supply balance equation from the gas trade model [**GTM**] is an example. Note that the set `i` contains the supply regions, the set `j` contains the demand regions, and the two-dimensional set `ij` is the set of feasible links; the variable `x` denotes the shipment of natural gas and the variable `s` denotes the regional supply.

```
sb(i)..  sum(j $ ij(i,j), x(i,j))  =l=  s(i)  ;
```

Similar to the assignment example seen before, the conditional set `ij(i,j)` restricts the domain of the summation: for each supply region `i` the summation over the demand regions `j` is restricted to the label combinations `(i,j)` that are elements of the set of feasible links `ij(i,j)`.

4.31.6.2 Dollar Control over the Domain of Definition

In case constraints should only be included in the model if particular conditions are met, a dollar condition in the domain of definition of an equation may be used to model this restriction. Such a dollar condition is analogous to the dollar control on the left of assignments. Assuming that "the left" means the left of the symbols `'..'` then the analogy is even closer.

Note

> The dollar control over the domain of definition of equations restricts the number of constraints generated to less than the number implied by the domain of the defining sets.

Consider the following example adapted from the Andean fertilizer model [**ANDEAN**] :

```
gple(w,wp,te) $ ple(w,wp)..  yw(w,te) - yw(wp,te) =l= dpack;
```

Here `w`, `wp` and `te` are sets, `ple` is a two-dimensional parameter, `yw` is a variable and `dpack` is a scalar. Note that the dollar condition restricts the first two indices of the domain of the equation to those label combinations that have non-zero entries in the two-dimensional parameter `ple`.

Sometimes the desired restriction of an equation may be achieved either way: through a condition in the algebra or a condition in the domain of definition. Compare the following two lines, where `eq1` and `eq2` are equations, `i` and `j` are sets, `b` is a scalar, `s` is a parameter and `x` is a two-dimensional variable.

```
eq1(i) $ b..  sum(j, x(i,j))     =g=  -s(i);
eq2(i)..      sum(j, x(i,j)) $ b =g=  -s(i) $ b;
```

In the first line the dollar condition is in the domain of definition, in the second line the dollar conditions are in the algebraic formulation of the equation. If `b` is non-zero, the generated equations `eq1` and `eq2` will be identical. However, if `b` is 0, no equation `eq1` will be generated, but for each `i` we will see a trivial equation `eq2` of the form `0 =g= 0;`.

Note that if the logical condition in the domain of definition of an equation refers to set membership, then under certain conditions the restriction may be expressed without the use of the dollar operator. For details, see section Filtering the Domain of Definition below.

4.31.7 Filtering Sets

If the logical condition refers to set membership, the restriction modeled with a dollar condition may sometimes be achieved *without* the dollar operator. Consider the following statement, where `i` and `j(i)` are sets, and `u` and `s` are parameters:

```
u(i) $ j(i) = s(i) ;
```

Note that the assignment is made only for those elements of the set `i` that are also elements of the subset `j`. This conditional assignment may be rewritten in a shorter way:

```
u(j) = s(j) ;
```

In this statement the assignment has been filtered through the condition without the dollar operator by using the subset `j` as the domain for the parameters `u` and `s`. This formulation is cleaner and easier to understand. It is particularly useful in the context of multi-dimensional sets (tuples), and it may be used in assignments, indexed operations and the domain of definition of equations.

4.31.7.1 Filtering Sets in Assignments

Suppose we want to compute the transportation cost between local collection sites and regional transportation hubs for a fictional parcel delivery service. We define sets for the collection sites and transportation hubs and a two-dimensional set where the collection sites are matched with their respective hubs:

```
Set i       "local collection sites"       / miami, boston, chicago, houston, phoenix /
    j       "regional transportation hubs" / newyork, detroit, losangeles, atlanta    / ;

Set r(i,j)  "regional transportation hub for each local collection site"  /
    boston   .newyork
    miami    .atlanta
    houston  .atlanta
    chicago  .detroit
    phoenix  .losangeles  / ;

Table distance(i,j)     "distance in miles"
           newyork     detroit  losangeles     atlanta
miami         1327        1387        2737         665
boston         216         699        3052        1068
chicago        843         275        2095         695
houston       1636        1337        1553         814
phoenix       2459        1977         398        1810;

Parameter factor        "cost estimate per unit mile"
          shipcost(i,j) "cost of transporting parcels from a local collection site to a regional hub

factor = 0.009 ;
shipcost(i,j) $ r(i,j) = factor*distance(i,j) ;
```

The distance between collection sites and transportation hubs is given in the table. The last line is a conditional assignment for the parameter `shipcost`. This assignment is only made if the label combination `(i,j)` is an element of the set `r`. Note that in each instance the indices `i` and `j` appear together. Thus the assignment may be simply written as:

```
shipcost(r) = factor*distance(r) ;
```

Note that the assignment is explicitly restricted to the members of the set `r`; the dollar operator is not necessary. Observe that if the indices `i` or `j` appear separately in any assignment, the above simplification cannot be made. For example, consider the case where the shipping cost depends not only on the parameter `factor` and the distance between collection sites and regional hubs, but also on the congestion at the regional hub. We introduce a new parameter `congestfac` that models the congestion at each regional hub and is indexed only over the set `j`:

```
Parameter congestfac(j)   "congestion factor"  /
   newyork      1.5
   detroit      0.7
   losangeles   1.2
   atlanta      0.9/ ;
```

The new cost of shipment is computed as follows:

```
shipcost(i,j) $ r(i,j) = factor*congestfac(j)*distance(i,j) ;
```

Note that this conditional assignment *cannot* be reformulated as:

```
shipcost(r) = factor*congestfac(j)*distance(r) ;
```

In the representation above the index `j` appears on the right-hand side, but not on the left-hand side. GAMS will flag this assignment as an error. However, the following representation will work:

```
shipcost(r(i,j)) = factor*congestfac(j)*distance(r) ;
```

In this formulation the set `r` is explicitly denoted as a tuple of the sets `i` and `j`. The set `j` may then appear on the right-hand side.

4.31.7.2 Filtering Controlling Indices in Indexed Operations

Similarly, the controlling indices in indexed operations may be filtered through the conditional set without the use of the dollar operator. We continue with the shipping cost example from the last subsection. The total cost of shipment is obtained through the equation that follows. We also include the variable definitions for clarity.

```
Variable shipped(i,j), totcost ;
Equation costequ ;

costequ.. totcost =e= sum((i,j) $ r(i,j), shipcost(i,j)*shipped(i,j));
```

Here the variable `shipped` is the number of parcels shipped from the local collection site `i` to the regional transportation hub `j`, and the variable `totcost` is the total cost of all shipments. Note that she summation in the equation is restricted to the label combinations that are elements of the set `r`. Alternatively, the equation above may be written as:

```
costequ.. totcost =e= sum(r, shipcost(r)*shipped(r));
```

In this formulation the summation is performed explicitly only over the elements of the set `r`, no dollar condition is necessary. However, if the expression in the equation included a term dependent only on index `j`, then we would have to reformulate differently. Suppose the equation included also the congestion factor `congestfac` that is indexed only over `j`:

```
cost.. totcost =e= sum((i,j) $ r(i,j), factor*congestfac(j)*distance(i,j)*shipped(i,j));
```

In this case the equation needs to be simplified in the following way:

```
cost.. totcost =e= sum(r(i,j), factor*congestfac(j)*distance(r)*shipped(r));
```

Like before, the domain of the indexed operation `sum` is the set `r`. But this time the domain of `r` has to be named explicitly, so that the parameter `congestfac` which is indexed only over the set `j` is permitted in the scope of the indexed operation. Note that this reasoning is analogous to the reasoning for filtering sets in assignments in the subsection above.

4.31.7.3 Filtering the Domain of Definition

The rules for filtering sets that we have introduced in subsections Filtering Sets in Assignments and Filtering Controlling Indices in Indexed Operations also apply in the context of equation domains. We continue with the parcel transport example introduced above and add a binary variable `bin`, the parameter `bigM` and the equation `connect` to the model. Recall that `shipped(i,j)` is a variable and `r(i,j)` is a set.

```
Parameter        bigM(i,j) ;
Binary variable  bin(i,j) ;

Equation         connect(i,j) ;

connect(i,j) $ r(i,j).. shipped(i,j) =l= bigM(i,j)*bin(i,j) ;
```

The dollar condition restricts the domain of definition of the equation `connect` to those label combinations of the sets `i` and `j` that are elements of the set `r`. The equation relates the continuous variable `shipped(i,j)` to the binary variable `bin(i,j)`. Note that each domain in the equation is the index pair `(i,j)`. So the equation may be simplified as follows:

```
connect(r).. shipped(r) =l= bigM(r)*bin(r) ;
```

In this formulation the domain of the equation is explicitly restricted to the members of the set `r`, without the use of a dollar condition. Note that if the right-hand side of the equation contained any term that was indexed over `i` or `j` separately, then the domain of definition of the equation would have to be simplified as:

```
connect(r(i,j))
```

The reasoning is the same as in the case of assignments and indexed operations.

4.32 The Display Statement

4.32.1 Introduction

The `display` statement in GAMS is a quick way to write data into the listing file. It does not provide a publication quality reporting function, but is instead aimed at functionality that is easy to use and provides graceful defaults. These defaults may be modified by the user to control the layout and appearance of the output. Both defaults and customization options are presented in this chapter. For information on the listing file, see chapter GAMS Output. In addition to the `display` statement, GAMS offers the put writing facility, a more sophisticated way to generate reports, where the user has much more flexibility and control over the output of individual items.

4.32.2 The Syntax

In general, the syntax for the `display` statement in GAMS is as follows:

```
display ident | quoted text {, ident | quoted text};
```

The keyword `display` indicates that this is a `display` statement. It is followed by an identifier. If the identifier is a set or a parameter, only the name of the set or parameter itself is specified. If the identifier is a variable, an equation or a model, it must be followed by a suffix, i.e. a variable attribute, equation attribute or model attribute respectively. As usual, `quoted text` must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines. For conditional displays a dollar condition may follow the keyword `display`.

The output produced by a display statement consists of labels and data. For multi-dimensional sets the keyword `yes` (indicating membership) is used instead of values.

Note

Only the non-default values are displayed for all data types.

The default value is generally zero. Exceptions are some upper and lower bounds of variables and equations (the attributes `.lo` and `.up`). Their default values are listed in sections Variable Attributes and Equation Attributes respectively.

The syntax of the display statement is illustrated by the following example:

```
Sets       s       / s1*s4 /
           t       / t5*t7 /
           st(s,t) / s1.t5, s1.t7, s2.t6, s3.t7, s4.t5 / ;
Parameters p(s)    / s1  0.33, s3  0.67 /
           q(t)    / t5  0.33, t7  0.67 / ;
Variable   v(s,t) ;
v.l(s,t) = p(s)*q(t);
display 'first a simple set', s, 'then a two-dimensional set', st, 'then a parameter', p,
        'then the activity level of a variable', v.l;
```

The display statement will generate the following lines in the listing file:

```
----      8 first a simple set

----      8 SET s

s1,    s2,    s3,    s4

----      8 then a two-dimensional set

----      8 SET st

            t5          t6          t7

s1         YES                     YES
s2                     YES
s3                                 YES
s4         YES

----      8 then a parameter

----      8 PARAMETER p

s1 0.330,    s3 0.670

----      8 then the activity level of a variable

----      8 VARIABLE v.L

            t5          t7

s1       0.109       0.221
s3       0.221       0.449
```

In the case of multi-dimensional identifiers like the set st and the level values of the variable v, the data is by default reported in a tabular form that is easy to read. Note that only the non-default values are displayed. To display zero values, the special value EPS can be used. In the example above, all values of the parameter p can be displayed by adding the following lines.

```
display 'display all values';
p(s)$(not p(s)) = EPS;
display p;
```

The following lines will be displayed in the listing file.

```
----     11 display all values

----     13 PARAMETER p

s1 0.330,    s2   EPS,    s3 0.670,    s4   EPS
```

An alternative to displaying EPS is to use acronym but computations cannot be done with the resulting parameters.

4.32.3 Displaying Multi-Dimensional Identifiers: Label Order

We have seen that two-dimensional identifiers are displayed in table format. The default layout for displaying multi-dimensional identifiers is summarized in Table 1. Note that the default format may be modified with the local display control. The figures in the table refer to the index position in the domain list of the identifier. For example, if we display x, where x has been declared as x(i,j,k,l), then the i labels (the first index) will by default be associated with the individual subtables, the j and k with the row labels and the l (the fourth and last index) with the column headings.

Number of Indices	Subtable	Index Position(s) on the Row	Column
1		list format	
2	-	1	2
3	-	1,2	3
4	1	2,3	4
5	1,2	3,4	5
6	1,2,3	4,5	6

Table 1: Default Layout for Displaying Multi-Dimensional Identifiers

For 7 to the maximum number of indices the natural progression is followed. For the current maximum number of indices, see Dimensions. The labels vary slowest for the first index position and quickest for the highest. Within each index position the order of the label is the GAMS entry order of the labels. Some users may need to manipulate the order of the labels.

Note

The only way to change the order in which the labels for each index position appear in the display output is to change the order of appearance of the labels in the GAMS program.

This is most easily done by declaring a set whose only purpose is to list all the labels in the order that is needed. Make this set the very first declaration in the GAMS program.

Note that the order of the indices in an identifier is always as the order in the declaration statement. One can declare them in the order that is found appealing, or make an assignment to a new identifier with a different order, as illustrated in the example below.

4.32.3.1 Example for Multi-Dimensional Displays

Consider the following example. The parameter x has four dimensions or index positions. It is initialized using parameter format and then displayed as shown below.

```
Set i   first index      / first, second /
    j   second index     / one, two, three /
    k   third index      / a, b /
    l   fourth index     / i, ii /  ;

Parameter
    x(i,j,k,l) a four dimensional structure /
               second.one.a.i      0.00013,   first .three.b.i       -6.3161
               first .one.b.i      5.63559,   second.two  .b.i    20000.00
               second.one.b.ii   -17.29948,   first .two  .b.ii      10.3457
               first .two.a.ii     0.02873,   second.one  .a.ii       1.0037
               second.two.a.ii        +inf,   first .two  .a.i       -2.9393
               first .one.a.ii     0.00000  /
    y(k,l,i,j) a four dimensional structure with changed index order;
y(k,l,i,j) = x(i,j,k,l);
display x, y;
```

For variable x the code fragment produces the following output:

```
----     16 PARAMETER x  a four dimensional structure

INDEX 1 = first

                  i          ii

one  .b       5.636
two  .a      -2.939       0.029
two  .b                   10.346
three.b      -6.316

INDEX 1 = second

                i          ii

one.a 1.300000E-4       1.004
one.b                 -17.299
two.a                    +INF
two.b   20000.000
```

Notice that there are two subtables, one for each label in the first index position. Note further that the order of the labels is not the same as in the input data list of the parameter `x`, but is according to the label order in the driving sets. Observe that the numbers closer in magnitude to one are displayed in fixed format, rounded to three digits (the default). This default may be modified with display controls, the topic of the next section. In contrast, the especially small value appears in E-format: it would display as all zeros in fixed format. Note also that the zero in the list for `x('first','one','a','ii')` has vanished, since default values are not shown. Similarly, rows and columns containing only zero values are suppressed in each subtable separately.

Notice furthermore how parameter y can be used to display the same data with a different index order.

4.32.4 Display Controls

GAMS allows the user to modify the number of row and column labels in the display listing as well as the accuracy of the data being displayed. There are global and local display controls. Global display controls allow the user to affect more than one display statement. The local display control may be used to override the global controls if specific data need to be listed in a particular format. Both controls are expressed with option statements.

4.32.4.1 Global Display Controls

The first option for global display controls specifies the number of digits shown after the decimal point. It affects the numbers appearing in all display output following the option statement, unless it is changed for a specific identifier as shown below. The general form of this option statement is:

```
option decimals = value;
```

The keyword `option` indicates that this is an option statement, `decimals` is the specific option and `value` is an integer between 0 and 8. The value 0 supresses decimals as well as the decimal point. Note that the default is `decimals=3`, and that setting this option does not change the field width, just the number of decimals. Increasing `decimals` results in more digits being displayed; this may in turn cause numbers to appear in E-format if the longer fixed-format result would exceed the field width.

A word about rounding for display purposes is in order. In the event of ties, the display routines use the **round-to-even** tie-breaking rule. So for example, with `decimals=0`, both 1.5 and 2.5 will display as **2**. Similarly, with `decimals=1`, 2.25 displays as **2.2** while 2.75 displays as **2.8**.

Consider the following extension to the example discussed in the previous section.

```
option decimals = 1;  display x;
```

GAMS will display numbers using E-format where necessary to avoid exceeding the display width or showing all zeros. The output is as follows:

```
----     14 PARAMETER x  a four dimensional structure

INDEX 1 = first

                  i          ii

one  .b         5.6
```

```
two  .a        -2.9 2.873000E-2
two  .b                    10.3
three.b        -6.3

INDEX 1 = second

                i          ii

one.a 1.300000E-4         1.0
one.b                    -17.3
two.a                     +INF
two.b     20000.0
```

Note that GAMS overrode the decimal choice for `x('first','two','a','ii')` to ensure that small numbers are not displayed as zeroes.

Another option for global display control modifies the width of the display. This is particularly important for longer label names. Label names that are headers of columns are cut off after 9 characters when data is displayed in table format. The following option may be used to display longer names in full:

```
option dispwidth = value;
```

The name of the option is `dispwidth` and `value` is a positive integer smaller or equal to 31. An illustrative example follows.

```
Set i      'South African cities'       / Johannesburg, Cape_Town /
    j      'other African cities'       / Maputo, Dar_es_Salaam  /
    f(i,j) 'direct flight connections'  / Johannesburg.Maputo, Johannesburg.Dar_es_Salaam, Cape_Town
display f ;
```

The display statement generates the following output:

```
----      4 SET f  direct flight connections

                  Maputo  Dar_es_Sa~

Johannesburg         YES         YES
Cape_Town            YES
```

Note that only the label `'Dar_es_Salaam'` is cut off since it is heading a column. The label `'Johannesburg'` is not cut off as it is the label for a row. Now we add the following line to change the width of the display statement:

```
option dispwidth = 15; display f;
```

As expected, the output changes and the label `'Dar_es_Salaam'` is no longer cut off:

```
----      5 SET f  direct flight connections

                       Maputo    Dar_es_Salaam

Johannesburg              YES              YES
Cape_Town                 YES
```

4.32.4.2 Local Display Control

It is often useful to control the number of decimals for specific identifiers separately. The following option statement accomplishes this:

```
option ident:d-value;
```

`Ident` denotes the name of the identifier and `d-value` is an integer in the range 0 to 8. The number of decimal places shown on all displays of `ident` that follow will be `d-value`.

This option statement can be extended to control the layout of the data in addition to the decimal places. The general form is as follows:

```
option ident:d-value:r-value:c-value ;
```

Here `r-value` denotes the number of index positions that are combined to form the row label and `c-value` means the number of indices on the column headers.

The example discussed in the previous section is further extended in order to illustrate the local display control.

```
option x:5:3:1; display  x;
```

These two statements generate the following output:

```
----     17 PARAMETER x  a four dimensional structure

                           i          ii

first .one  .b     5.63559
first .two  .a    -2.93930     0.02873
first .two  .b                10.34570
first .three.b    -6.31610
second.one  .a     0.00013     1.00370
second.one  .b                -17.29948
second.two  .a                    +INF
second.two  .b 20000.00000
```

Note that five decimal places are shown, three labels are used to mark the rows and one label acts as head of the column. Since this is a four-dimensional structure, all indices are accounted for.

The next example places two indices on each of the row and and column labels and retains five decimal places:

```
option x:5:2:2; display x;
```

The output is:

```
----     18 PARAMETER x  a four dimensional structure

                      a.i        a.ii         b.i        b.ii

first .one                                  5.63559
first .two      -2.93930     0.02873                 10.34570
first .three                              -6.31610
second.one       0.00013     1.00370               -17.29948
second.two                      +INF 20000.00000
```

If in the option statement less dimensions are specified than the number of indices in the domain, then subtables will be generated for the labels of the beginning indices. Observe how the display layout will change if we use the following statement:

```
option x:0:1:1;  display x;
```

The output follows.

```
----     19 PARAMETER x  a four dimensional structure

INDEX 1 = first  INDEX 2 = one

            i

b           6

INDEX 1 = first  INDEX 2 = two

            i          ii

a          -3 2.873000E-2
b                      10

INDEX 1 = first  INDEX 2 = three

            i

b          -6

INDEX 1 = second  INDEX 2 = one

            i          ii

a 1.300000E-4           1
b                     -17

INDEX 1 = second  INDEX 2 = two

            i          ii

a                     +INF
b       20000
```

The option statement is checked for consistency against the dimensionality of the identifier and error messages will be issued if the number of the dimensions specified in the option statement is larger than the number of indices in the domain of the identifier.

4.32.4.3 Display Statement to Generate Data in List Format

The option statement for local display controls may be used to generate data in list format by setting the `r-value` to zero:

```
option ident:d-value:0:c-value;
```

In this case the `c-value` specifies the maximum number of items displayed on a line. The actual number will depend on the page width and the number and length of the labels.

Using the same example as in the previous sections, we change the `r-value` to zero in the option statement:

```
option x:5:0:1; display x;
option x:5:0:2; display x;
```

Note that we specified one and two columns to illustrate the impact of different `c-value` settings. These statements will generate the following output:

```
----     20 PARAMETER x  a four dimensional structure

first .one  .b.i      5.63559
first .two  .a.i     -2.93930
first .two  .a.ii     0.02873
first .two  .b.ii    10.34570
first .three.b.i     -6.31610
second.one  .a.i      0.00013
second.one  .a.ii     1.00370
second.one  .b.ii   -17.29948
second.two  .a.ii        +INF
second.two  .b.i  20000.00000

----     21 PARAMETER x  a four dimensional structure

first .one  .b.i      5.63559,    first .two  .a.i     -2.93930
first .two  .a.ii     0.02873,    first .two  .b.ii    10.34570
first .three.b.i     -6.31610,    second.one  .a.i      0.00013
second.one  .a.ii     1.00370,    second.one  .b.ii   -17.29948
second.two  .a.ii        +INF,    second.two  .b.i  20000.00000
```

This output nicely illustrates the label order used. The first index varies the slowest, the last the fastest, and each one runs from beginning to end before the next one to the left advances. This ordering scheme is also used in equation and column lists and in the solution report which are all generated by the solve statement.

4.32.5 Conditional Displays

This section assumes familiarity with the if statement and the dollar condition.

The display statement may be controlled by conditional expressions. Conditionals have the effect that the items are displayed only if a logical condition is satisfied. There are two ways to express conditional displays in GAMS: with dollar conditions and using `if` statements. The syntax using a dollar condition is as follows:

```
display$logical_condition ident | quoted text {, ident | quoted text};
```

Note that the dollar condition is inserted after the keyword `display`. For details on the various forms of conditional expressions in GAMS, see sections Logical Conditions and Filtering Sets. Consider the following simple example:

```
Scalars x, y;
x = 7;
y = 3;
display$(x-y < 0) "display if x minus y is less than 0", x, y;
```

The logical condition `(x-y < 0)` controls the display statement. In this case it is not satisfied, hence there will be no display output. If the value of `y` is changed to, say 10, then the logical condition will be satisfied and the display statement will generate the following output:

```
----      4 display if x minus y is less than 0
            PARAMETER x                    =        7.000
            PARAMETER y                    =       10.000
```

The syntax for conditional displays using an `if` statement is as follows:

```
if( logical_condition, display statement );
```

The simple example above may be reformulated as follows:

```
Scalars x, y;
x = 7;
y = 3;
if( x-y < 0,
  display "display if x minus y is less than 0", x, y;
);
```

4.33 Programming Flow Control Features

4.33.1 Introduction

In this chapter we will describe the programming flow control features available in GAMS. The if statement facilitates expressing complex conditional statements (see also chapter Conditional Expressions, Assignments and Equations
In addition, GAMS offers four loop constructs to handle looping requirements: the loop statement, the while statement, the for statement and the repeat statement. At the end of this chapter we will introduce the break, and continue statements, which give additional control over the execution of loop structures, and the abort statement, a statement that may be used to terminate the execution of a program.

Note that this chapter deals with programming flow control features at execution time. In addition, GAMS provides a dollar control option that allows for *conditional processing of input files at compile time*. For more information, see the detailed description of the option $if. For details on dollar control options in general, see chapter Dollar Control Options.

4.33.2 The If Statement

The `if` statement is useful to branch conditionally around a group of statements. In some cases this can also be written as a set of dollar conditions, but the `if` statement may make the GAMS code more readable. An optional `else` and/or `elseif` part allows the user to formulate traditional `if-then-else` constructs.

4.33.2.1 The If Statement: Syntax

The syntax for an `if` statement in GAMS is as follows:

```
if (logical_condition,
    statement; {statement;}
{ elseif logical_condition,
    statement; {statement;} }
[ else
    statement; {statement;} ]
);
```

The keyword `if` indicates that this is an `if` statement. The logical condition is followed by one or more statements that are executed if the logical condition is satisfied. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. The `if` statement may end at this point, without any specifications for cases when the logical condition is `FALSE` and no action is taken in these cases. However, GAMS also allows further specifications: optional alternative `if` tests and optional statements for cases when all previous `if` tests have failed. The keyword `elseif` introduces an alternative `if` test with a logical condition and one or more statements. Note that the `elseif` case is optional and may be repeated multiple times. Note further that the `elseif` case implies that the logical condition of the `if` case has not been satisfied. The keyword `else` introduces the final part of the construct. It is optional and allows specification for cases when the logical condition of the `if` case (and possibly the `elseif` case(es)) has not been satisfied.

Attention

> Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside an `if` statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

4.33.2.2 The If Statement: Examples

Consider the following set of conditional assignment statements that use dollar conditions:

```
p(i)$(f <= 0) = -1 ;
p(i)$((f > 0) and (f < 1)) = p(i)**2 ;
p(i)$(f >= 1) = p(i)**3 ;
q(j)$(f <= 0) = -1 ;
q(j)$((f > 0) and (f < 1)) = q(j)**2 ;
q(j)$(f >= 1) = q(j)**3 ;
```

They may be expressed using an `if-elseif-else` statement:

```
if (f <= 0,
    p(i) = -1 ;
    q(j) = -1 ;
elseif ((f > 0) and (f < 1)),
    p(i) = p(i)**2 ;
    q(j) = q(j)**2 ;
else
    p(i) = p(i)**3 ;
    q(j) = q(j)**3 ;
) ;
```

Note that the body of the `if` statement may contain `solve` statements. For instance, consider the bit of GAMS code that follows. Note that `ml` is a GAMS model, `z` is a free variable, `j` is a set and `x` is a variable.

```
solve ml using lp minimizing z;
if (ml.modelstat = 4,
     display "model ml was infeasible, relax bounds on x and solve again";
     x.up(j) = 2*x.up(j) ;
     solve ml using lp minimizing z ;
else
    if (ml.modelstat <> 1,
        abort "error solving model ml" ;
    );
);
```

First the model `ml` is solved. For details on `solve` statements in GAMS, see section The Solve Statement. Then a post solution analysis is done with the `if` statement. If the model is infeasible, the upper bound on the variable `x` is relaxed and the model is solved again. If the original model is not infeasible and it is not optimal either, then the compilation is aborted and the error message above is reported. For more information on GAMS output, see chapter GAMS Output, particularly subsection Model Status for a list of all GAMS model statuses. The `display` statement is introduced in chapter The Display Statement. For details on the `abort` command, see abort.

The following GAMS code is illegal since it is not permitted to define equations inside an `if` statement.

```
if (s > 0,
    eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside an `if` statement are not allowed.

```
if (s > 0,
   scalar y ; y = 5 ;
);
```

4.33.3 The Loop Statement

The `loop` statement facilitates executing a group of statements for each member of a set. `Loop` statements are particularly useful for cases when parallel assignments are not sufficient. This is the case most often when there is no analytic relationship between the values to be assigned to a parameter. It is, of course, also useful to have a looping statement for general programming.

4.33.3.1 The Loop Statement: Syntax

The syntax for the `loop` statement in GAMS is as follows:

```
loop(index_list[$(logical_condition)],
     statement; {statement;}
) ;
```

The keyword `loop` indicates that this is a loop statement. The `index_list` is the controlling domain of the loop. Note that loops may be controlled by more than one set. In this case parentheses are required around the index list, which is also called the *loop set(s)*. Observe that dynamic sets are allowed as loop sets. The loop set(s) may be restricted by a logical condition. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. For an introduction to dollar conditions in general, see chapter Conditional Expressions, Assignments and Equations. The index list is followed by one or more statements. Except for the final statement, each statement must end with a semicolon `';'`. The loop statements are executed for each member of the controlling domain in turn. The order of evaluation is the entry order of the labels. A loop is thus another, more general, type of indexed operation.

Attention

- Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `loop` statement.
- It is illegal to modify any controlling set inside the body of the loop.

`Loop` statements in GAMS are often used for iterative calculations, generating reports with put statements and doing scenario based studies with solve statements. Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

4.33.3.2 The Loop Statement: Examples

Consider a hypothetical case when a growth rate is empirical:

```
Set        t          / 1985*1990 /;
Parameter  pop(t)     / 1985  3456 /
           growth(t)  / 1985  25.3,  1986  27.3,  1987  26.2
                        1988  27.1,  1989  26.6,  1990  26.6 /;
```

The `loop` statement is then used to calculate the cumulative sums iteratively:

```
loop(t, pop(t+1)  = pop(t) + growth(t) ) ;
```

In this example the driving set is `t` and we have just one statement in the scope of the loop.

The following small artificial examples illustrate the effects of a dollar condition in a `loop` statement.

```
Sets       i       / i1*i3 /
           j       / j1*j5 /
           k(i,j)  / i1.j1, i1.j3, i3.j3, i3.j5 /;
Parameter  c(i)    / i1 3, i2 1 /
           q(i,j)  / i1.j1 1, i1.j2 3, i1.j4 2 / ;
Scalars    x, y, z;
x = 1; y = 3; z = 1;

loop ( (i,j) $ (q(i,j) > 0), x = x + q(i,j));
loop ( i $ (c(i) + c(i)**2), z = z + 1);
loop ( i $ sum(j, abs(q(i,j))), z = z + 1);
loop ( j $ (ord(j) > 1 and ord(j) < card(j)), z = z + 1);
loop ( (i,j) $ k(i,j), y = y + ord(i) + 2*ord(j));
```

In the first `loop` statement the controlling domain is the set pair `(i,j)`. It is restricted to those label combinations whose values associated with the parameter `q` are greater than zero. The logical condition in the second `loop` statement is $c(i) + c(i)^2$. This is shorthand for $c(i) + c(i)^2 \neq 0$. The domain in the third `loop` statement is restricted to those elements of the set `i` where the sum over `j` of the absolute values of the parameter `q` does not equal zero. Note that this condition is satisfied only for the label `"i1"`. Observe that `i` and `j` are both ordered sets. In the fourth `loop` statement the first and the last element of the set `j` are excluded. For more on the set operators `ord` and `card`, see sections The Ord Operator and The Card Operator respectively. The dollar control in the last `loop` statement excludes all label combinations that are not members of the set `k`. For further details on dollar conditions, see chapter Conditional Expressions, Assignments and Equations.

Note

The dollar condition may be replaced by an if statement; see the example below.

The next example shows how a model can be solved for each element of a set `i` with different data using a `loop` statement. Note that `problemdata` is a scalar, `g(i)` and `d(i)` are parameters, `mymodel` is a GAMS model and `profit` is a free variable.

```
loop (i,
  problemdata = g(i);
  solve mymodel using lp maximizing profit;
  d(i) = profit.l;
);
```

In the first statement some data in the model is updated in accordance with the i^{th} element of the parameter `g`. In the second statement the model is solved. For details on the `solve` statement, see section The Solve Statement. The objective value for each iteration is saved in the parameter `d` in the third statement.

A loop is often used to perform iterative calculations. Consider the following example, which finds square roots by Newton's method. This example is purely for illustration - in practice, the function `sqrt` should be used. Newton's method is based on the assertion that if x is an approximation to the square root of v, then $(x + v/x)/2$ is a better approximation.

```
Set       i         "set to drive iterations"                 / i-1*i-100 /;
Parameter value(i)  "used to hold successive approximations";
Scalars   target    "number whose square root is needed"      / 23.456 /
          sqrtval   "final approximation to sqrt(target)"
          curacc    "accuracy of current approximation"
          reltol    "required relative accuracy"              / 1.0e-06 /;
```

```
abort$(target <= 0) "argument to newton must be positive";
value("i-1") = target/2  ;
curacc       =  1  ;
loop(i$(curacc > reltol),
       value(i+1) =  0.5*(value(i) + target/value(i));
       sqrtval    =  value(i+1);
       curacc     =  abs (value(i+1)-value(i))/(1+abs(value(i+1)))
) ;
abort$(curacc > reltol) "square root not found"
option decimals=8;
display  "square root found within tolerance",  sqrtval, value;
```

Note that in this example the dollar condition in the loop does not restrict the driving set `i`, but it is used to terminate the loop procedure. The scalar `curacc` is updated in every iteration. As soon as it becomes equal to or smaller than the required relative accuracy `reltol` the loop stops. As the output below shows, this is the case after seven iterations. The body of the `loop` statement consists of three statements. The first statement calculates the current approximation and assigns it to the parameter `value`. The second statement updates the scalar `sqrtval`, and the third statements computes the accuracy of the current approximation in each iteration. Note that before and after the loop statement we added lines to account for special cases. For details on the `abort` statement, see section The Abort Statement at the end of this chapter. The output generated by the display statement is given below.

```
----     19 square root found within tolerance

----     19 PARAMETER SQRTVAL              =   4.84313948 final approximation
                                                 to sqrt(target)

----     19 PARAMETER VALUE         used to hold successive approximations

i-1 11.72800000,    i-2  6.86400000,    i-3  5.14062471,    i-4  4.85174713
i-5  4.84314711,    i-6  4.84313948,    i-7  4.84313948
```

Note that a statement within the body of a loop may be an if statement (or any other programming flow control statement). Moreover, the logical condition in a `loop` statement may be expressed with an `if` statement instead of a dollar condition. The following example serves as illustration. Observe that `k` is a set and `s`, `t`, `u` and `a` are parameters.

```
loop (k,
   if((s(k) < 0 and t(k)),
      u(k) = a(k);
   );
);
```

Note that if the logical condition is not satisfied the assignment is not made and the parameter `u` remains unchanged.

Recall that subsets are connected with their supersets by arcs thus building a domain tree where the root node is the universal set. The following example demonstrates how the domain tree may be used in a loop statement.

```
Set i       / i1*i10 /
    ii(i)
    j(i)    / i1*i9 /
    jj(j)   / i1*i8 /
    jjj(jj) / i1*i7 /;

loop(i(jjj), ii(i) = yes;);
display ii;
```

Observe that the looping set is `i(jjj)`. This means that we loop over those elements of `i` that are also elements of the set `jjj`. This construct is permitted since `i` is in the domain tree on the path from `jjj` to the universe or universal set. It is allowed to go up the domain tree on one path and go down on another path. Therefore all the elements of `jjj` are assigned to `ii`. The outcome of the display statement confirms this:

```
----      8 SET ii

i1,    i2,    i3,    i4,    i5,    i6,    i7
```

4.33.4 The While Statement

The `while` statement facilitates the repeated execution of one or more statements as long as a logical condition is satisfied.

4.33.4.1 The While Statement: Syntax

The syntax for the `while` statement in GAMS is as follows:

```
while(logical_condition,
      statement; {statement;}
);
```

The keyword `while` indicates that this is a `while` statement. Inside the `while` statement a logical condition is followed by one or more statements. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets. The statements are executed as long as the logical condition is `TRUE`.

Attention

> Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `while` statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

4.33.4.2 The While Statement: Examples

Consider the following simple example:

```
Scalar x; x = 1;
while ( round(x,2) < 10,
   x = x + 0.01;
);
display x;
```

Note that the scalar x is increased in each iteration until it equals 10. Note further, that to ensure an exact result, in numerical comparisons we need a stable check like we have above (round(x,2) < 10), otherwise rounding errors may occur. As soon as x reaches 10, the logical condition is no longer satisfied and therefore there will be no further passes. Hence the final value of x equals 10.

Note that the number of passes in a while statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

While statements may be used to control the solve statement. For instance, consider the following implementation of a random multi-start method for non-convex optimization.

```
scalar count   /  1  /;
scalar globmin / inf /;
option bratio = 1 ;
while(count <= 1000,
      x.l(j) = uniform(x.lo(j),x.up(j)) ;
      solve ml using nlp minimizing obj ;
      if (obj.l < globmin,
          globmin = obj.l ;
          bestsol(j) = x.l(j) ;
      ) ;
      count = count+1 ;
) ;
```

Note that we start from a random starting point by setting the initial level values randomly between the upper and lower bounds. This assumes that the bounds have been previously specified and are not infinity. When the method improves, that is, if the logical condition (obj.l < globmin) is satisfied, the best known solution is stored in the scalar globmin. The level values associated with the best known solution so far are then saved in the parameter bestsol. This procedure is repeated 1000 times. The model [**PRIME**] is another example where the use of the while statement is illustrated. In this model the set of all prime numbers smaller than 200 is generated.

The following GAMS code is illegal since equation definitions inside a while statement are not permitted.

```
while(s > 0,
      eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside a while statement are not allowed.

```
while(s > 0,
      scalar y ; y = 5 ;
);
```

4.33.5 The For Statement

The `for` statement provides a compact way to iterate over a range of values and execute one or more statements each time.

4.33.5.1 The For Statement: Syntax

The syntax for the `for` statement in GAMS is as follows:

```
for (a = start_value to|downto end_value [by incr],
     statement; {statement;}
);
```

The keyword `for` indicates that this is a `for` statement. The scalar `a` begins with the real number `start_value` and is changed after each pass of the loop by the increment `incr` until it reaches the real number `end_value`. Note that the specification of an increment is optional, the default is 1. If the increment is given, it has to be a positive real number. Note further that `to` indicates that the scalar `a` is *increased* and `downto` indicates that it is *decreased*. In each iteration one or more statements are executed.

Attention

> Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `for` statement.

Examples are given in the next subsection. Note that there is an alternative syntax that is more in line with the syntax of some popular programming languages. For more information, see the detailed description of the dollar control option onEnd.

4.33.5.2 The For Statement: Examples

Consider the following simple example:

```
Scalar s;
for (s = -3.8 to -0.1 by 1.4,
     display s ;
);
```

Note that *negative* real numbers are possible for the start and end values. The resulting listing file will contain the following lines:

```
----      3 PARAMETER s                  =       -3.800
----      3 PARAMETER s                  =       -2.400
----      3 PARAMETER s                  =       -1.000
```

Observe that the value of `s` was increased by 1.4 with each pass of the loop as long as it did not exceed -0.1. In the next example the value of `s` is *decreased:*

```
Scalar s;
for (s = 3 downto -0.1 by 1.4,
     display s ;
);
```

Note that the number of passes in a `for` statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

Like `while` statements, `for` statements may be used to control the `solve` statement. The following example illustrates the use of the `for` statement by replicating the random search for a global optimum of a non-convex model that we discussed above.

```
scalar i ;
scalar globmin / inf / ;
option bratio = 1 ;
for (i = 1 to 1000,
     x.l(j) = uniform(x.lo(j),x.up(j)) ;
     solve m1 using nlp minimizing obj ;
     if (obj.l < globmin,
         globmin = obj.l ;
         bestsol(j) = x.l(j) ;
     );
);
```

Note that the logical condition in the `while` loop (`count <= 1000`) is replaced by the specification of the range of values for the scalar `i`. The body of the `for` loop is identical to the body of the `while` loop, except for the statement to update the scalar `count` that we needed in the `while` loop. This demonstrates the similarities and differences between the two loops.

The following GAMS code is illegal since it is not allowed to define equations inside a `for` statement.

```
for (s = 1 to 5,
     eq.. sum(i,x(i)) =g= 2 ;
);
```

The following GAMS code is also illegal since declarations inside a `for` statement are not permitted.

```
for (s = 1 to 5,
     scalar y ; y = 5 ;
);
```

4.33.6 The Repeat Statement

The `repeat` statement facilitates the repeated execution of one or more statements. This is done unconditionally at least once and stopped when a logical condition is satisfied.

4.33.6.1 The Repeat Statement: Syntax

The syntax for the `repeat` statement in GAMS is as follows:

```
repeat (
    statement; {statement;}
until logical_condition );
```

The keyword `repeat` indicates that this is a `repeat` statement. One or more statements are executed in each iteration. The keyword `until` introduces the termination criterion: if the logical condition is satisfied, the `repeat` loop is terminated. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

Note that the `repeat` statement is similar to the `while` statement, but a `repeat` loop is guaranteed to be executed at least one time since the logical condition is stated *after* the statements.

Attention

> Only *execution* statements are permitted in programming flow control statements. Consequently declaration statements and equation definitions are not allowed inside a `repeat` statement.

Examples are given in the next subsection.

4.33.6.2 The Repeat Statement: Examples

Consider the following simple example:

```
Scalar a / 1 /;
repeat (
    a = a + 1;
    display a;
until a = 5 );
```

The scalar `a` is increased in each iteration by 1. If `a` equals 5, the termination criterion is satisfied and the loop stops. Note that this example works nicely since both, the scalar and the increment, are integer. In case the entity on the right-hand side of the termination condition is not an integer or the increment is not an integer, we recommend a formulation of the check that is more stable to avoid rounding errors. An example for a stable termination condition follows.

```
Scalar a / 1 /;
repeat (
    a = a + 0.1;
    display a;
until abs(a-5) < 1e-6 );
```

Observe that in the next example the termination condition is `TRUE` from the start. In this case the statement in the body of the `repeat` statement is executed once and then the loop is terminated. Hence the final value of `a` will be 5.

```
Scalar a / 4 /;
repeat (
    a = a + 1;
    display a;
until a >= 3 );
```

Note that the number of passes in a while statement may be restricted using the command line parameter or option forlim. For details on command line parameters and options, see section Specifying Options Through the Command Line and chapter The Option Statement respectively.

Here is a little more complex example. A `repeat` statement is used to narrow the interval where a quadratic function passes through zero. Note that, as is often the case, one of the statements in the `repeat` loop is another programming flow control statement, in this case an `if` statement.

```
Scalar max             "current upper boundary of interval"   /10/
       min             "current lower boundary of interval"   /-10/
       root            "value where function equals zero"
       function_value1 "function value at min"
       function_value2 "function value at max"
       tolerance       "tolerance for root"                   /0.00000001/
       signswitch      "indicates that sign switch was found" /0/
       inc             "increment to try to find sign switch" ;

function_value1 = 6 - 5*min + sqr(min);
inc             = (max - min)/37;
root            = min;

repeat (
   root = root + inc;
   function_value2 = 6 - 5*root + sqr(root);

   if((    sign(function_value1) <> sign(function_value2)
       and abs(function_value1) > 0
       and abs(function_value2) > tolerance ),
      max = root;
      signswitch = 1;
   else
      if(abs(function_value2) > tolerance,
         function_value1 = function_value2;
         min = root;
      );
   );
until (signswitch > 0) or (root > max) );
display min, max, function_value1, function_value2;
```

The result of the `display` statement shows that the value of `min` is 1.892 and the value of `max` is 2.432, the interval was narrowed to 0.54, which is just a little less than the value of `inc`. As expected, `function_value1` and `function_value2` differ in sign, confirming that the root of the quadratic function is indeed in the interval.

4.33.7 The Break Statement

The `break` statement gives additional control over the execution of loop structures, namely the loop statement, the while statement, the for statement and the repeat statement. It allows to break the execution of a loop structure prematurely.

4.33.7.1 The Break Statement: Syntax

The syntax for the `break` statement is as follows:

```
break [n];
```

The keyword `break` indicates that this is a break statement. It terminates the `n` inner most control structures. `n` is optional and if it is omitted, it is set to 1.

Most often `break` statements are used in the context of if statements or with dollar conditions. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

4.33.7.2 The Break Statement: Examples

This is a simple, artificial example using the `break` statement to exit a `loop` statement:

```
Set    i   / i1*i10 /;
Scalar cnt / 0 /;

loop(i,
  break$sameas('i6',i);
  cnt = cnt+1;
);

display cnt;
```

The `break` statement in combination with the dollar condition terminates the execution of the loop body in the 6th iteration. This can be seen looking at the value of `cnt` after the loop, which will be 5.

Here is a little more complex example which uses the optional argument `n` to terminate more than one loop structure at once:

```
Set    i   / i1*i10 /;
Scalar x, y,
       cnt / 0 /;

for(x = 1 to 10,
  y = 0;
  while(y < 10,
    y = y+1;
    loop(i,
      break$sameas('i6',i) 2;
      cnt = cnt+1;
    );
  );
);
display cnt;
```

In this example, `cnt` will be 50 at the end. As in the previous example, it is increased 5 times in the inner most loop, before the `break` statement is executed. This time `break` is called with the argument `2`, which causes the two inner most control structures (namely the `loop` and the `while`) to be terminated. The outer most control structure (the `for`) is not influenced, so that its body gets executed 10 times, which results in a total of 50 increments for the scalar `cnt`.

Note, if `break` would be called with the argument 3 instead of 2, also the `for` loop would be terminated, so that `cnt` would be 5 at the end. If `break` would be called with 1 (or without additional argument) instead of 2, only the inner most `loop` would be terminated so that `cnt` would be 500 at the end.

4.33.8 The Continue Statement

The `continue` statement gives additional control over the execution of loop structures, namely the loop statement, the while statement, the for statement and the repeat statement. It allows to jump to the end of the inner most loop structure without executing the remaining statements in the body.

4.33.8.1 The Continue Statement: Syntax

The syntax for the `continue` statement is as follows:

```
continue;
```

The keyword `continue` indicates that this is a continue statement. It jumps to the end of the inner most control structure.

Most often `continue` statements are used in the context of if statements or with dollar conditions. For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

4.33.8.2 The Continue Statement: Examples

This is a simple, artificial example using the `continue` statement to skip parts of a `loop` body:

```
Set    i   / i1*i10 /;
Scalar cnt / 0 /;

loop(i,
  continue$(mod(ord(i),2)=0);
  cnt=cnt+1
);

display cnt;
```

In that example, every 2nd iteration of the `loop` statement is skipped. Therefore, `cnt` will be 5 at the end of the `loop`.

4.33.9 The Abort Statement

The `abort` statement is used to terminate the *execution* of a program. Most often the abort statement is used in the context of conditionals. Examples are given below. Also it may be used to display a text or an identifier in the listing file similar to the display statement but mostly to present the reason for the termination of the execution.

Note that the `abort` statement is to be distinguished from the dollar control option $abort which may be used to terminate the *compilation* of a program.

4.33.9.1 The Abort Statement: Syntax

The syntax for the `abort` statement is as follows:

```
abort ident | quoted text {, ident | quoted text};
```

The keyword `abort` indicates that this is an abort statement. `Ident` denotes an identifier. If the identifier is a set or a parameter, only the name of the set or parameter itself is specified, without any domains. If the identifier is a variable, an equation or a model, it must be followed by a suffix, since only *attributes* of variables, equations and models can be displayed. For more on variable and equation attributes including full lists, see sections Variable Attributes and Equation Attributes respectively. For details on model attributes, see section Model Attributes. Recall that sets also have attributes, they may also be displayed using the suffix notation. For details on set attributes, see section Set Attributes. As usual, `quoted text` must be surrounded by single or double quotes. The identifiers and the text may be mixed and matched in any order, and the whole statement may be continued over several lines.

An abort statement causes the termination of the execution with an execution error and the information in the statement will be displayed.

There is also a variant with the extension `.noError` that terminates the execution and displays the information, but does not cause an execution error. The syntax is as follows:

```
abort.noError ident | quoted text {, ident | quoted text};
```

Most often `abort` statements are used in the context of if statements or with dollar conditions. The syntax is as follows:

```
if (logical_condition, abort ident | quoted text {, ident | quoted text}; );
```

or

```
abort$logical_condition ident | quoted text {, ident | quoted text};
```

For details on the various forms of logical conditions in GAMS, see sections Logical Conditions and Filtering Sets.

4.33.9.2 The Abort Statement: Examples

Consider the following artificial example:

```
Set       i    / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
   if (p(i) > 3, abort "Parameter larger than 3", p);
   p(i) = p(i) + 2;
);
```

Note that the abort statement is part of an if statement which is part of a loop statement. The execution of this program will be terminated with the following display and error message:

```
----      4 Parameter larger than 3

----      4 PARAMETER p

i1 3.000,    i2 4.000,    i3 5.000,    i4 5.000,    i5 8.000

**** Exec Error at line 4: Execution halted: abort 'Parameter larger than 3'
```

Observe that the values of `p('1')`, `p('2')` and `p('3')` were updated, but the values of `p('4')` and `p('5')` are equal to the initialization values since the program was terminated before they could be updated.

If the extension `.noError` is used in the example above, the following lines will appear in the listing file:

```
----      4 Parameter larger than 3

----      4 PARAMETER p

i1 3.000,    i2 4.000,    i3 5.000,    i4 5.000,    i5 8.000

****
**** Execution halted from line 4: abort.noError 'Parameter larger than 3'
****
```

Note that the execution of the program is aborted as before, but there is no execution error in this case.

Instead of an if statement we may use a dollar condition in the loop:

```
Set       i    / i1*i5 /;
Parameter p(i) / i1 1, i2 2, i3 3, i4 5, i5 8 /;
loop(i,
   abort$(p(i) > 3) "Parameter larger than 3", p;
   p(i) = p(i) + 2;
);
```

Observe that this alternative formulation has the same outcome as above.

4.34 The Option Statement

4.34.1 Introduction

The `option` statement is used to set various global system parameters to control among other things output detail, the solution process and the layout of displays. GAMS provides default values for global system parameters that are adequate for the most purposes. However, there are always cases when the user would like to maintain control of some aspects of the run. In addition, the option statement provides an efficient and compact syntax to perform powerful operations on identifiers. Observe that option statements are processed at execution time unlike dollar control options that are processed at compile time.

This chapter is organized as follows. We will first introduce the general syntax of the option statement, then we will continue with a list of all available options that may be used with option statements and provide links to their detailed explanations in the GAMS Call chapter. Finally we turn to the special options that involve identifiers.

4.34.1.1 The Syntax of the Option Statement

The general form of an option statement is as follows:

```
option(s) key1 [= value1] { ,|EOL  key2 [= value2] } ;
```

The keyword `option` or `options` indicates that this is an option statement. It is followed by `key1`, which is one of the options that are listed in this chapter. Consider the following simple example:

```
option reslim=800;
```

Here the keyword `option` is followed by the `key` reslim. The option `reslim` specifies the maximum time in seconds that a solver may run before it terminates. Thus, in this example we give the solver 800 seconds to come up with a solution.

Note

- Option names are not reserved words and therefore they do not conflict with other uses of their names.
- Option statements do not allow expressions. It is therefore not possible to assign parameter values to an option.
  The following doesn't work:

  ```
  scalar p /3/;
  option reslim=p;
  ```

  However, if the desired option is available as model attribute, one can assign parameter values there:

  ```
  scalar p /3/;
  transport.reslim = p;
  ```

Observe that it depends on the respective option whether a value is expected and if so, what type of value. There are six different cases. An overview is given in Table 1.

Key	Value	Type of Value	Examples
yes	no	-	dmpOpt, eject, memoryStat
yes	yes	integer number	decimals, limcol, seed
yes	yes	real number	FDDelta, optCR, resLim
yes	yes	text string	LP, solPrint, sysout
yes	yes	identifier	See identifier options.
no	no	-	See identifier operations.

Table 1: Types of Options

Note that the last type is special: it does not involve a named option or `key`, but the keyword `option` is followed by identifiers and identifier operators. These special option statements are discussed in detail in section Special Options: Identifier Operations.

Observe that the value of an option may be reset as often as necessary, the new value will replace the previous value each time. Further, more than one option may be specified with one option statement and commas or end-of-line characters are both legal separators between options.

We will demonstrate with the following example how several options may be used. The code snippet may be added to the model [**DICE**].

```
option measure, limcol = 100
       optcr = 0.00, mip = xpress ;
solve xdice using mip max wnx;
option clear = comp;
```

Note that in the first option statement four options are specified: option measure has no associated value, option limcol expects an integer value, option optcr expects a real value and option MIP expects a text string as value. The second option statement specifies just one identifier option: clear, which has the variable `comp` as value.

Attention

> Option statements are executed in sequence with other instructions. Therefore, if an option statement is located between two solve statements, the new values will be assigned between the solves and thus they will apply only to the second solve statement.

4.34.2 List of Options

The options available through the option statement are grouped into the following functional categories:

- Options that affect output details
- Solver specific parameters
- Options that control choice of solver
- Options that affect input program control
- Other options
- Special options that involve identifiers

In the following subsections we will offer brief descriptions of the options in the first five categories. Note that each entry is linked to a detailed description of the respective option. Observe that detailed descriptions of all GAMS command line parameters, options and model attributes are given in section Detailed Descriptions of All Options. The options that belong to the last category are special, they are introduced and discussed in section Special Options that Involve Identifiers below.

4.34.2.1 Options that Control Output Details

Option	Description
asyncSolLst	Print solution listing when asynchronous solve (Grid or Threads) is used
decimals	Decimal places for display statements
dispWidth	Number of characters to be printed in the column labels of all subsequent display statements
eject	Inject a page break into the LST file
epsToZero	Treat eps as zero when unloading to GDX
limCol	Maximum number of columns listed in one variable block
limRow	Maximum number of rows listed in one equation block

Option	Description
maxGenericFiles	Maximum number of generic file names tried at execution time file creation
MCPRHoldFx	Print list of rows that are perpendicular to variables removed due to the holdfixed setting
profile	Execution profiling
profileTol	Minimum time a statement must use to appear in profile generated output
solPrint	Solution report print option
solSlack	Causes the equation output in the listing file to contain slack variable values instead of level values
sysOut	Solver Status file reporting option

4.34.2.2 Options that Control Solver-Specific Parameters

Option	Description
bRatio	Basis detection threshold
domLim	Domain violation limit solver default
holdFixedAsync	Allow HoldFixed for models solved asynchronously as well
intVarUp	Set mode for default upper bounds on integer variables
iterLim	Iteration limit of solver
optCA	Absolute Optimality criterion solver default
optCR	Relative Optimality criterion solver default
reform	Reformulation level
resLim	Wall-clock time limit for solver
savePoint	Save solver point in GDX file
solveLink	Solver link option
sys12	Pass model with generation errors to solver
threads	Number of processors to be used by a solver

4.34.2.3 Options that Control the Choice of Solver

Option	Description
CNS	Constrained Nonlinear Systems - default solver
DNLP	Non-Linear Programming with Discontinuous Derivatives - default solver
EMP	Extended Mathematical Programs - default solver
LP	Linear Programming - default solver
MCP	Mixed Complementarity Problems - default solver
MINLP	Mixed-Integer Non-Linear Programming - default solver
MIP	Mixed-Integer Programming - default solver
MIQCP	Mixed Integer Quadratically Constrained Programs - default solver
MPEC	Mathematical Programs with Equilibrium Constraints - default solver
NLP	Non-Linear Programming - default solver
QCP	Quadratically Constrained Programs - default solver
RMINLP	Relaxed Mixed-Integer Non-Linear Programming - default solver
RMIP	Relaxed Mixed-Integer Programming - default solver
RMIQCP	Relaxed Mixed Integer Quadratically Constrained Programs - default solver
RMPEC	Relaxed Mathematical Programs with Equilibrium Constraints - default solver
solver	Default solver for all model types that the solver is capable to process

4.34.2.4 Options that Affect Input Program Control

Option	Description
ECImplicitLoad	Allow implicit loading of symbols from embedded code or not
fdDelta	Step size for finite differences
fdOpt	Options for finite differences
gdxUels	Unload labels or UELs to GDX either squeezed or full
seed	Random number seed
solveOpt	Multiple solve management
strictSingleton	Error if assignment to singleton set has multiple elements
sys18	Use backward compatible (i.e. pre-GAMS 31) scheme for reading floating-point numbers
zeroToEps	Treat zero as eps

4.34.2.5 Other Options

Option	Description
checkErrorLevel	Check errorLevel automatically after executing external program
dmpOpt	Debugging option: causes GAMS to echo the runtime option settings
dmpSym	Debugging option: causes GAMS to echo the symbol table to the listing file
dmpUserSym	Debugging option: causes GAMS to echo the symbol table to the listing file for user defined symbols only
dualCheck	Output on the reduced cost condition
forLim	GAMS looping limit
integer1..5	Integer communication cells
measure	Output of time and memory use since the last measure statement or the program beginning
memoryStat	Show memory statistics in the LST file
real1..5	Real communication cells
subSystems	Lists all solvers available as well as the current default and active solvers in the LST file
sys10	Changes rpower to ipower when the exponent is constant and within 1e-12 of an integer
sys11	Dynamic resorting if indices in assignment/data statements are not in natural order
sys15	Automatic switching of data structures used in search records
sys16	Disable search record memory (aka execute this as pre-GAMS 24.5)
sys17	Disable sparsity trees growing with permutation (aka execute this as pre-GAMS 24.5)
sys19	Disable permutation on Column Generation (aka execute this as pre-GAMS 36)
threadsAsync	Limit on number of threads to be used for asynchronous solves (solveLink=6)

4.34.2.6 Special Options that Involve Identifiers

Several options involve identifiers: they either take identifiers as values or have no key and value, but perform an operation on an identifier. In the following two subsections we will introduce and discuss these special options.

Special Options: Identifier Options

The value of identifier options is not a string or a number, but an identifier. In this subsection we will describe these options in detail.

clear

This option resets an identifier to its default value to free memory. The syntax is as follows:

```
option clear = identifier;
```

The following identifier types may be reset: sets, parameters, equations and variables. The option will free up memory to the GAMS heap manager, thus the memory may be used by GAMS but not by the operating system. To force the memory to be freed up to the operating system, the GAMS process needs to be terminated. One way to do this is to restart the execution system by solving a dummy model with the option solveLink set to zero.

kill

This option is a synonym to option clear. Observe that the dollar control option $kill is *not* a synonym to $clear.

shuffle

This option rearranges the values of a parameter in a random order. The syntax is as follows:

```
option shuffle = itemname;
```

Here `itemname` is a one-dimensional parameter. One-dimensional parameters may be declared (and defined) in four different ways, depending on the domain and the data. The following table gives an overview of the effect of the option `shuffle` in the four cases.

	No Data	Has Data
Universal set as domain	Use the universal set to initialize the data (case 1 in the example below).	Use the universal set to add zero values before shuffling the data (case 3 in the example below).
Specific set as domain	Use the domain to initialize the data (case 2 in the example below).	Use the domain to add zero values before shuffling the data (case 4 in the example below).

If the parameter was declared without data (the second column in the table above), the domain or the universal set will be used to assign the numbers 1 to `N`, where `N` is the number of elements in the domain or the universal set. If the parameter was declared with data (the third column in the table above), the domain or the universal set will be used to add zeroes for possibly missing entries. These zero values will participate in the random shuffle, but they will not be stored in the parameter. The following example serves as illustration:

```
Set i / i1*i5 /
    j / j1*j5 /;
option decimals = 0;
```

```
*Case 1: universal set as domain and no data
Parameter A(*) "The universe is used to fill the parameter";
option shuffle = A;
display A;

*Case 2: set j as domain and no data
Parameter B(j) "The set j is used to fill the parameter";
option shuffle = B;
display B;

*Case 3: universal set as domain and has data
Parameter C(*) "The universe is used to add zeroes" / j2 2, j4 4 /;
option shuffle = C;
display C;

*Case 4: set i as domain and has data
Parameter D(i) "The set i is used to add zeroes" / i1 10, i3 30, i5 50 /;
option shuffle = D;
display D;
```

The code above will generate the output that follows. Observe that in this example, the universal set is the union of the sets `i` and `j`, which means that all elements of the sets `i` and `j` are members of the universal set. Note that we use random numbers, therefore the outcomes from a different run may vary.

```
----      9 PARAMETER A  The universe is used to fill the parameter

i1  4,    i2  1,    i3  7,    i4  9,    i5  6,    j1 10,    j2  3,    j3  5
j4  8,    j5  2

----     14 PARAMETER B  The set j is used to fill the parameter

j1 1,    j2 5,    j3 2,    j4 4,    j5 3

----     19 PARAMETER C  The universe is used to add zeroes

j1 2,    j2 4

----     24 PARAMETER D  The set i is used to add zeroes

i2 30,    i4 50,    i5 10
```

In the next example we will demonstrate how to generate a random mapping of a set:

```
Set i        / i1*i6 /,
    rmi(i,i) "random mapping";
Parameter A(i);
option shuffle = A;

rmi(i, i + (- Ord(i) + A(i))) = yes;
display rmi;
```

A display of the set `rmi` follows. Note that there is exactly one element in each row and each column:

```
----      7 SET rmi  random mapping

            i1          i2          i3          i4          i5          i6

i1                                                                      YES
i2                                              YES
i3          YES
i4                                  YES
i5                                                          YES
i6                      YES
```

Observe that each use of the option `shuffle` will generate a new random data rearrangement.

Special Options: Identifier Operations

In some cases the keyword `option` in an option statement is followed by an identifier and one or more operators to perform identifier operations like display control, index matching, projection and aggregation of sets and parameters and permutation of sets and parameters.

Display Control

The display statement is introduced and discussed in chapter The Display Statement. While GAMS provides defaults for the displayed identifiers that suffice in most cases, the print format may be customized with the following option statement:

```
option ident:d;
option ident:d:r:c;
```

The keyword `option` is followed by the name of an identifier `ident`, a colon and an integer value `d`. Note that `d` may be between 0 and 8 and specifies the number of decimal places that will be displayed for the respective identifier. The specifications `r` and `c` are optional. They denote the number of index positions printed as row labels and the number of index positions printed as column labels respectively. Note that if `r` is zero, a list format will be used. For more information and examples, see sections Local Display Control and Display Statement to Generate Data in List Format.

Index Matching

Index matching is a very compact way to define multi-dimensional sets. The general syntax is as follows:

```
option set_name(index1:index2[:index3:...]);
```

The keyword `option` is followed by the name of the set, `set_name`, and two (or more) indices in parentheses that are linked with the matching operator `':'`. Note that the set must have been declared earlier in the program. If the set has also been defined earlier in the program, it will be cleared first and then the matching operation will be processed. Note furthermore that the list of identifiers may be expanded to more than two and that besides the matching operator `':'` also `','` may be used and will be interpreted as product operator. Consider the following example which also makes use of display control:

```
Set i / i1,i2/
    j / j1,j2,j3 /
    k / k1*k5 /
    ij(i,j), ijk(i,j,k), kij(k,i,j);
* index matching
Option ij(i:j), ijk(i,j:k), kij(k:i,j);
* display control
Option ij:0:0:1, ijk:0:0:1, kij:0:0:1;
Display ij, ijk, kij;
```

In its simplest form the matching operator is used to create the two dimensional set `ij`.

```
----      9 SET ij

i1.j1
i2.j2
```

Note that each member of the index `i` has been matched with a member of the index `j` until one of the indices ran out of members.

The index matching operations to define the three-dimensional sets `ijk` and `kij` illustrate a more sophisticated usage of the index operator. The sets `ijk` and `kij` are built with the indices from left to right using the product operator when a `','` is encountered or the matching operator when a `':'` is found.

For `ijk` the first operator is the `','` which is interpreted as product operator for the sets `i` and `j` and hence builds the Cartesian product of the two sets which has six 2-tuples as elements (`i1.j1, i1.j2, i1.j3, i2.j1, i2.j2, i2.j3`). The matching operator `':'` is then applied to match those 2-tuples with the five set elements in `k`. The resulting sets are:

```
----      9 SET ijk

i1.j1.k1
i1.j2.k2
i1.j3.k3
i2.j1.k4
i2.j2.k5

----      9 SET kij

k1.i1.j1
k1.i1.j2
k1.i1.j3
k2.i2.j1
k2.i2.j2
k2.i2.j3
```

The previous example can be extended to define sets of even higher dimension in the following way:

```
set h / h1*h4 /
    hijk_1(h,i,j,k)
    hijk_2(h,i,j,k);
* index matching
Option hijk_1(h:ijk);
Option hijk_2(h:i,j:k);
* display control
Option hijk_1:0:0:1, hijk_2:0:0:1;
Display hijk_1, hijk_2;
```

Note that sets hijk_1 and hijk_2 will be different even though hijk_1 uses set ijk and hijk_2 uses the same matching and product operation used at definition of ijk but spelled out. As already mentioned above, the matching operator builds up the sets with the indices from left to right. Hence, as set ijk is build first and then used on the right of the matching operator the two sets are built up differently.

```
----     19 SET hijk_1

h1.i1.j1.k1
h2.i1.j2.k2
h3.i1.j3.k3
h4.i2.j1.k4

----     19 SET hijk_2

h1.i1.j1.k1
h1.i1.j2.k2
h1.i1.j3.k3
h2.i2.j1.k4
h2.i2.j2.k5
```

Projection and Aggregation of Sets and Parameters

In GAMS, projection and aggregation operations on sets may be performed in two different ways: with an assignment and the sum operator, and with an option statement.

Using an assignment and the sum operator is the slower but more intuitive way. Assignments and the sum operator are introduced and discussed in detail in chapter Data Manipulations with Parameters and section Indexed Operations respectively. Here we only show how they may be used in the context of sets to perform projections and aggregations. The following example serves as illustration.

```
Sets i            / i1*i3 /
     j            / j1*j2 /
     k            / k1*k4 /
     ijk(i,j,k)   / #i.#j.#k /
     ij1a(i,j)
     ij1b(i,j);

Scalars Count_1a, Count_1b, Count_2a, Count_2b;

* Method 1: Using an assignment and the sum operator for a projection
ij1a(i,j) = sum(k,ijk(i,j,k));

* Method 1: Using an assignment and the sum operator for aggregations
Count_2a  = sum(ijk(i,j,k),1);
Count_1a  = sum(ij1a(i,j),1);
```

Note that the set ijk is a three-dimensional set, its elements are 3-tuples and all permutations of the elements of the three sets i, j and k are in its domain. Thus the number of elements of the set ijk is 3 x 2 x 4 = 24. The sets ij1a and ij1b are two-dimensional sets that are declared in the set statement, but not defined. The first assignment statement defines the members of the set ij1a. This is a projection from the set ijk to the set ij1a where the three-tuples of the first set are mapped onto the pairs of the second set, such that the dimension k is eliminated. This means that the four elements "i1.j1.k1", "i1.j1.k2", "i1.j1.k3" and "i1.j1.k4" of the set ijk are all mapped to the element "i1.j1" of the set ij1a. Note

that in this context, the result of the `sum` operation is *not* a number but a set. The second and third assignments are aggregations, where the number of elements of the two sets are computed. As already mentioned, the result of the first aggregation is 24 and the result of the second aggregation is 6 = 24 / 4.

The second way to perform projections and aggregations is faster and more compact, it uses an option statement. The general syntax of this option statement is as follows.

```
option ident1 < ident2 ;
option ident1 <= ident2 ;
```

The keyword `option` is followed by the identifiers `ident1` and `ident2` which are linked by the symbol `'<'` or `'<='`. Observe that in most cases the two symbols have the same effect. The exception is the special case when both identifiers are defined over domains that use at least one shared index set more than once, see the example below. Note that in general the dimension of the item on the left has to be equal or less than the dimension of the item on the right. Further, the index space of the two identifiers must be matchable. If the dimensions of the two identifiers are equal, then the same indices must appear in both, albeit the order may differ. If the dimension of the left item is less than the dimension of the right item, then the indices on the left must also appear on the right.

Observe that if both identifiers are sets, the operation will be a *projection*. However, if the identifier on the left-hand side is a scalar or a parameter and the identifier on the right-hand side is a set it will be an *aggregation*. The example that follows shows how the projection and the two aggregations above are accomplished with the option statement.

```
* Method 2: Option statement performs a projection
Option ij1b < ijk;

* Method 2: Option statements performs aggregations (counting of elements)
Option Count_2b < ijk;
Option Count_1b < ij1b;

display ijk, ij1a, ij1b, Count_1a, Count_1b, Count_2a, Count_2b;
```

In the example above, the set on the left-hand side, `ij1b`, has fewer indices than the set on the right-hand side, `ijk`. Observe that if the two sets differ only in the *order* of the indices then a projection will have the effect of a *permutation* of the tuple.

Note

The option statement for projection and aggregation operations may also be applied to parameters.

Until now the indices in the domain of the sets were unique. A special case arises when sets are defined over a domain with the same indices, for example the set `s(i,i,i)`. In this case, a projection always has the effect of a permutation. Users may choose whether they wish to perform the permutation from left to right or from right to left. The option statement

```
Option item1 < item2 ;
```

means a right-to-left permutation, while the option statement

```
Option item1 <= item2 ;
```

entails a left-to-right permutation. The following example clarifies the difference:

```
Set   i         / i1*i3 /
      s(i,i,i)  "Set members" / i1.i2.i3, i3.i3.i1/
      pR1(i,i)  "projection right to left with assignment"
      pR2(i,i)  "projection right to left with option statement"
      pL1(i,i)  "projection left to right with assignment"
      pL2(i,i)  "projection left to right with option statement" ;
Alias (i,ii,iii);

* Right-to-left permutation, two ways
pR1(i,ii) = sum(s(iii,ii,i),1);
option pR2 < s;

* Left-to-right permutation, two ways
pL1(i,ii) = sum(s(i,ii,iii),1);
option pL2 <= s;

option s:0:0:1, pR1:0:0:1, pR2:0:0:1, pL1:0:0:1, pL2:0:0:1;
display s, pR1, pR2, pL1, pL2 ;
```

Note that in the right-to-left permutation, the element `"i1.i2.i3"` is projected to `"i3.i2"` and the element `"i3.i3.i1"` is projected to `"i1.i3"`. In the left-to-right permutation however, the the element `"i1.i2.i3"` is projected to `"i1.i2"` and the element `"i3.i3.i1"` is projected to `"i3.i3"`. Hence, the left-to-right permutation (`<=`) might be more intuitive.

Our examples so far involved only sets. As mentioned above, projections and aggregations may also be performed with parameters. However, there are some subtle differences. The first difference refers to the terminology: we *aggregate* sets, but we *count* parameters. The second difference is the result of the operation if the domain of the left symbol is just a permuted version of the domain of the right symbol. Consider the following example:

```
Set i / i1*i3 /
    j / j1*j2 /;

Table p(i,j)
    j1 j2
i1   1  2
i2   3  4
i3   5  6;

parameter pperm(j,i);
option pperm < p;
option decimals = 0;
display p, pperm;
```

The output generated by the display statement follows:

```
----     13 PARAMETER p

            j1          j2

i1           1           2
i2           3           4
i3           5           6
```

```
----     13 PARAMETER pperm

            i1          i2          i3

j1           1           3           5
j2           2           4           6
```

Permutation of Sets and Parameters

In GAMS, the > sign can be used to create complete permutations of one- and multi-dimensional sets and parameters. Consider the following example based on the test library model [**PERM1**]:

First, a set `i` for which all permutations should be computed is declared and defined. A permutation of a one-dimensional set `i` can be represented by a two-dimensional set like `perm(i,i)` where the `i` index is duplicated. In the example, set `perm(i,i)` represents permutation `(1 2)(3)` in cycle notation. For a set with three elements, there are `3*2*1=6` permutations. The statement `option pall > i;` results in all permutations of `i` being computed and stored in three-dimensional set `pall(p,i,i)` where the first index `p` serves as a counter to enumerate all permutations.

```
set i           'set to permute'        / i1*i3 /
    perm(i,i)   'exemplary permutation' / i1.i2, i2.i1, i3.i3 /
$eval pmax fact(card(i))
    p           'permutation index' / p1*p%pmax% /
    pall(p,i,i) 'permutation set';
option pall > i;
option pall:0:0:1;
display pall;
```

Note that we use display control such that the display statement results in:

```
----      8 SET pall  permutation set

p1.i1.i1
p1.i2.i2
p1.i3.i3
p2.i1.i1
p2.i2.i3
p2.i3.i2
p3.i1.i2
p3.i2.i1
p3.i3.i3
p4.i1.i2
p4.i2.i3
p4.i3.i1
p5.i1.i3
p5.i2.i1
p5.i3.i2
p6.i1.i3
p6.i2.i2
p6.i3.i1
```

For multi-dimensional sets, the permutation operator follows the same logic. Consider the following example:

Sets `j`, `k` and a two-dimensional set `jk(j,k)` are defined. In order to find all permutations of `jk(j,k)`, the indices are again duplicated and a permutation index is introduced:

```
set j / j1*j2 /, k / k1*k5 /
    jk(j,k) / j1.k3, j1.k5, j2.k1 /
$eval pmax fact(card(jk))
    p / p1*p%pmax% /
    pall(p,j,k,j,k);
option pall > jk;
option pall:0:0:1;
display pall;
```

The display statement results in:

```
----      8 SET pall

p1.j1.k3.j1.k3
p1.j1.k5.j1.k5
p1.j2.k1.j2.k1
p2.j1.k3.j1.k3
p2.j1.k5.j2.k1
p2.j2.k1.j1.k5
p3.j1.k3.j1.k5
p3.j1.k5.j1.k3
p3.j2.k1.j2.k1
p4.j1.k3.j1.k5
p4.j1.k5.j2.k1
p4.j2.k1.j1.k3
p5.j1.k3.j2.k1
p5.j1.k5.j1.k3
p5.j2.k1.j1.k5
p6.j1.k3.j2.k1
p6.j1.k5.j1.k5
p6.j2.k1.j1.k3
```

In addition to set elements, it is also possible to permute numerical data in a GAMS parameter. Consider the following example where all permutations of the numerical values stored in the one-dimensional parameter `a(i)` are computed:

```
set i  / i1*i3 /
$eval pmax fact(card(i))
    p  / p1*p%pmax% /;
Parameter a(i) /i1 1, i2 2, i3 3/
          pall_a(p,i);
option pall_a > a;
option pall_a:0:1:1;
display pall_a;
```

The display statement results in:

```
----      8 PARAMETER pall_a

            i1          i2          i3

p1           1           2           3
p2           1           3           2
p3           2           1           3
p4           2           3           1
p5           3           1           2
p6           3           2           1
```

The permutation can also be extended to multi-dimensional parameters. Consider the following example where all permutations of the numerical values stored in the two-dimensional parameter `b(j,k)` are computed:

```
set j / j1*j2 /, k / k1*k5 /;
Parameter b(j,k) /j1.k3 1, j1.k5 2, j2.k1 3/;
$eval pmax fact(card(b))
set p / p1*p%pmax% /;
parameter pall_b(p,j,k);
option pall_b > b;
option pall_b:0:1:2;
display pall_b;
```

The display statement results in:

```
----      8 PARAMETER pall_b

         j1.k3       j1.k5       j2.k1

p1           1           2           3
p2           1           3           2
p3           2           1           3
p4           2           3           1
p5           3           1           2
p6           3           2           1
```

4.35 System Attributes

4.35.1 Introduction

System attributes give access to string constants in the GAMS system environment. We will refer to these string constants as system suffixes. Moreover, there are attributes that can be used as data elements for user symbols. This way one can get access e.g. to the solvers (as set elements) in the system. We will refer to these data elements as system data. Two special system data attributes, namely `powerSetLeft` and `powerSetRight`, for a three dimensional set `setName(n,s,b)` create data which can be interpreted as a numbering system with base b and s digits. Finally, a system attribute can provide access to a system function that was hidden by the compiler because of a name conflict with a user symbol.

4.35.2 System Suffixes

System suffixes contain information about the GAMS system environment during a run. There are two ways to reference them: `system.suffix` and `%system.suffix%`. Here `system` is a keyword and `.suffix` is the name of the system suffix. A full list is given in section List of all System Suffixes below. Note that `system.suffix` references the *execution-time* version of the system suffix and `%system.suffix%` references the *compile-time* version resulting in a textual replacement. The execution-time system suffix can only be used in the context of put files. Consider the following example where both versions are used:

```
file fx;
put fx 'lp:' system.LP;
option lp=gurobi;
put  / 'lp:' system.LP
put  / 'lp:%system.LP%';
```

Observe that the compile-time string `%system.LP%` is evaluated at compile time and does not change. However, the execution-time system suffix `system.LP` is evaluated at execution time and it does change. It is first `CPLEX`, since CPLEX is the default LP solver. Then it changes to `GUROBI` as a result of the execution-time command `option LP=gurobi;`. The resulting `put` file `fx.put` follows:

```
lp:CPLEX
lp:GUROBI
lp:CPLEX
```

In the following two subsection we will discuss execution-time suffix in more detail.

4.35.2.1 Execution-Time System Suffixes

Execution-time system suffixes are only used in the context of the put writing facility with commands like put , putclose and put_utility. Consider the following simple example. We have the files `x.gms` and `dummy.gms`, where `x.gms` contains just the following line:

```
file fx; put fx system.version;
```

The file `dummy.gms` contains the following:

```
$exit;
```

We run these files with the following calls:

```
> c:\gams\win64\24.7\gams x.gms action=c s=putVersion
```

Note that the value `c` for the command-line parameter action causes the first input file to be compiled only. The result is saved in the work file `putVersion`. Then we restart and execute `dummy.gms`. Now, depending on the GAMS release version, the `put` file `fx` will have a different content:

```
c:\gams\win64\24.7\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 247
c:\gams\win64\24.8\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 248
```

In contrast, the value of the compile-time system suffix `%system.version%` is determined at compile time. Suppose we change the file `x.gms` to contain the following line:

```
file fx; put fx "%system.version%";
```

The file `dummy.gms` is not changed and we use the same calls as above. Note that the `put` file will have the same content for both versions of GAMS:

```
c:\gams\win64\24.7\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 247
c:\gams\win64\24.8\gams dummy.gms r=putVersion // this produces a put file with content "GAMS Rev 247
```

4.35.2.2 Compile-Time System Suffixes

Compile-time system suffixes may be placed anywhere a compile-time variables makes sense, including code for conditional compilation. The quoting of these compile-time system suffixes depends on their use in the code. Consider the following example:

```
$set systemDATE %system.date%
display "system.date", "%system.date%";
$ifi %system.LP% == Xpress $log "LP solver is Xpress."
```

The resulting output generated by the display statement follows:

```
----      3 system.DATE
            11/07/16
```

4.35.2.3 List of all System Suffixes

In the following table all system suffixes are listed.

System Suffix	Description
BuildCode	System build code
CNS	CNS solver that is active for CNS model type
ComputerName	Operating system computer name
Date	Job date
Date1	Job date format
DirSep	File or directory separator in file names
DNLP	DNLP solver that is active for DNLP model type
Elapsed	Elasped time in seconds since start of job
EMP	EMP solver that is active for EMP model type
Error	Used to indicate unknown suffix
ErrorLevel	System Errorlevel
FE	File extension
FileSys	Name of the operating system (MSNT for Windows, UNIX for Linux and macOS)
FN	File name
FP	File path
GamsRelease	GAMS Release number
GamsReleaseMaint	GAMS Release number with maintenance number suffix
GamsVersion	GAMS version number
GdxFileNameIn	GDX file name for input, set by put_utility command gdxin
GdxFileNameOut	GDX file name for output, set by put_utility command gdxout
GString	GAMS system audit string (exact GAMS version being used)
HostPlatform	Host platform
IFile	Input file
ILine	Current source line number beeing executed
IncLine	Include file line
IncName	Include file name
IncParent	Include file parent
IncParentL	Include file parent line number

System Suffix	Description
IsAlphaBeta	Indicates an Alpha or Beta bulid
JobHandle	Job handle of last async call
LicenseFileName	The file name of the license file currently used
LicenseLevel	GAMS license level
Line	Line number in source code
ListLine	Line number on listing file
LP	LP solver that is active for LP model type
MACAddress	MAC address of the first network adapter
MaxInput	Max input line length that can be processed
MCP	MCP solver that is active for MCP model type
Memory	Memory (in Mb) in use
MINLP	MINLP solver that is active for MINLP model type
MIP	MIP solver that is active for MIP model type
MIQCP	MIQCP solver that is active for MIQCP model type
MPEC	MPEC solver that is active for MPEC model type
NLP	NLP solver that is active for NLP model type
NullFile	The null filename
OFile	Output (Listing) file
OPage	Current page number in output (listing) file
Page	Current page number
PFile	Current put file
Platform	Job platform (DAX for macOS on ARM64, DEX for macOS on x86_64, LEX for Linux, WEX for Windows)
PrLine	Line on listing page
Procname	Model types LP MIP etc
PrPage	Listing page number
PutFileName	The filename of the currently active PUT file
QCP	QCP solver that is active for QCP model type
RDate	Restart file date
ReDirLog	Append redirection string into the logfile
RFile	Restart file name
RMINLP	RMINLP solver that is active for RMINLP model type
RMIP	RMIP solver that is active for RMIP model type
RMIQCP	RMIQCP solver that is active for RMIQCP model type
RMPEC	RMPEC solver that is active for RMPEC model type
RTime	Restart file time
SFile	Save file name
SString	Subsystem (Solver) audit (last solver used)
Tab	Tab character
TClose	Time to save GAMS
TComp	Time to compile
TExec	Time to execute
Time	Job time
Title	Current listing title
TStart	Time to restart GAMS
UserConfigDir	User writable directory that is searched for gamsconfig.yaml
UserDataDir	User writable directory that is searched for gamslice.txt and others
UserName	Operating system user name

System Suffix	Description
VerID	GAMS version ID
Version	GAMS compiler version

A model that prints all system suffixes with its current values to a put file can be found in model [**SSUFFIX**].

4.35.3 System Data

Some of the system relevant information does not fit into a single string. Such system data can be stored in GAMS symbols. The system data for this symbol can be accessed in the data statement of the symbol, e.g. `set allSolvers / system.solverNames /;`. Now you can work with the solver names as you can work with any set. The system data can be viewed as an internal set, so it can be used to create more complex GAMS symbols with this information. For example:

```
set seq / 1*1000 /;
set solvermap(seq,*)   / set.seq:system.solverNames /;
parameter solverpar(*) / system.solverNames 1 /;
```

Here is the list and dimensionality of the system data:

System Data	Dimension	Description
dollarOptions	1	Dollar control options
empty	1	Empty label
gamsFunctions	1	Intrinsic functions
gamsParameters	1	Command line parameters
gamsParameterSynonymMap	2	Map between command line parameters and their synonyms
gamsParameterSynonyms	1	Synonyms for command line parameters
GUSSModelAttributes	1	Model attributes stored for GUSS scenarios
modelTypes	1	Model types, e.g. LP, MIP, ...
platforms	1	Platform code
powerSetLeft	3	Numbering system with base b and s digits
powerSetRight	3	Numbering system with base b and s digits
predefinedSymbols	1	Predefined symbols, e.g. SameAs, Diag, ...
setConstants	1	System data names (this list)
solverNames	1	Names of solvers and tools
solverPlatformMap	2	Map between solvers and platforms
solverTypePlatformMap	3	Map between solvers, model types and platforms
systemSuffixes	1	System suffixes

4.35.3.1 Power Set

The very special system attribute `powerSetLeft` and `powerSetRight` do not provide access to static data relevant to the system but produce data based on existing sets `b` and `s`. This system data produced can be interpreted as a numbering system with base b and s digits. The total number of tuples created is

power(card(b),card(s)). The first index of the resulting set has to have at least this size. The following small example demonstrates the functionality of powerSetRight:

```
$set digits 3
set s / s1*s%digits% /, b / 0,1 /;
$eval nMax power(card(b),card(s))
set n        / n1*n%nMax% /
    x(n,s,b) / system.powerSetRight /;
option x:0:0:%digits%; display x;
```

With 3 digits the display results in the following output:

```
----      6 SET x
n1.s1.0,    n1.s2.0,    n1.s3.0
n2.s1.0,    n2.s2.0,    n2.s3.1
n3.s1.0,    n3.s2.1,    n3.s3.0
n4.s1.0,    n4.s2.1,    n4.s3.1
n5.s1.1,    n5.s2.0,    n5.s3.0
n6.s1.1,    n6.s2.0,    n6.s3.1
n7.s1.1,    n7.s2.1,    n7.s3.0
n8.s1.1,    n8.s2.1,    n8.s3.1
```

Changing powerSetRight to powerSetLeft reassigns the order of the digits. So the lowest digit is on the left:

```
----      6 SET x
n1.s1.0,    n1.s2.0,    n1.s3.0
n2.s1.1,    n2.s2.0,    n2.s3.0
n3.s1.0,    n3.s2.1,    n3.s3.0
n4.s1.1,    n4.s2.1,    n4.s3.0
n5.s1.0,    n5.s2.0,    n5.s3.1
n6.s1.1,    n6.s2.0,    n6.s3.1
n7.s1.0,    n7.s2.1,    n7.s3.1
n8.s1.1,    n8.s2.1,    n8.s3.1
```

4.35.4 Access to Hidden Functions

Intrinsic functions are not keywords but they are stored in a list of predefined names. If a user program uses such a predefined name of a function for a user symbol, GAMS will hide the original function. For example,

```
set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = uniform(0,1);
```

will result in a compilation error in the second line because GAMS expects uniform to be a set. The function uniform is hidden for this GAMS program. Renaming the user symbol that hides a function is often the best solution for this, but there are a few cases (including GAMS code already compiled and stored in a restart file) where renaming is not an option. A hidden function can be accessed via the system attribute system.functionName. So the following will successfully compile and execute:

```
set uniform 'School Uniform' / skirt, blouse, blazer, socks, shoes /;
scalar randomNumber;
randomNumber = system.uniform(0,1);
```

4.36 The Grid and Multi-Threading Solve Facility

4.36.1 Introduction

The GAMS Grid facility allows to take advantage of High Performance Computing Grids and systems with multiple CPUs. This language feature facilitates the management of asynchronous submission and collection of model solution tasks in a platform independent fashion. A simple architecture, relying on existing operating system functionality allows for rapid introduction of new environments and provides for an open research architecture.

A typical application uses a coarse grain approach involving hundreds or thousands of model solutions tasks which can be carried out in parallel. Examples include but are not limited to scenario analysis, Monte Carlo simulations, Lagrangian relaxation, decomposition algorithms and advanced solution approaches.

The grid features work on all GAMS platforms and have been tailored to many different environments, like the `Condor` Resource Manager, a system for high throughput computing from the University of Wisconsin-Madison. Researchers using Condor reported a delivery of 5000 CPU hours in 20 hours wall clock time.

Similarly, the GAMS Multi-Threading Solve Facility allows the asynchronous submission and collection of model solution tasks on a single, multi-threaded machine while using efficient in-memory communication between GAMS and the solver.

Disclaimer: The use of the term grid computing may be offensive to some purists in the computer science world. We use it very loosely to refer to a collection of computing components that allow us to provide high throughput to certain applications. One may also think of it as a resurrection of the commercial service bureau concept of some 30 years ago.

Caution: Although these features have been tested on all platforms and are part of our standard release we may change the approach and introduce alternative mechanisms in the future.

Acknowledgments: Prof. Monique Guignard-Spielberg and Antoine Sauré at that time at Wharton School at the University of Pennsylvania introduced us to parallel Lagrangian relaxation on the SUN Grid Environment. Prof. Michael Ferris from the University of Wisconsin-Madison adopted our original GAMS grid approach to the high throughput system Condor and helped to make this approach a practical proposition.

4.36.2 The Grid Facility: Basic Concepts

The Grid facility separates the solution process into several steps which then can be controlled separately. First we will review the steps taken during synchronous solution and then we will introduce the asynchronous or parallel solution steps.

When GAMS encounters a solve statement during execution it proceeds in three basic steps:

1. **Generation:** The symbolic equations of the model are used to instantiate the model using the current state of the GAMS data base. This instance contains all information and services needed by a solution method to attempt a solution. This representation is independent of the solver and computing platform.
2. **Solution:** The model instance is handed over to a solver and GAMS will wait until it terminates.
3. **Update:** The detailed solution and statistics are passed to GAMS from the solver to update the GAMS data base.

In most cases, the time taken to generate the model and update the data base with the solution will be much smaller than the actual time spent in a specific solver. The model generation will take a few seconds, whereas the time to obtain an optimal solution may take a few minutes to several hours or even longer. If sequential model solutions do not depend on each other, we can solve in parallel and update the data base in a random order. All we need is a facility to generate models, submit them for solution and continue. At a convenient point in our GAMS program we will then look for the completed solutions and update the data base accordingly. To summarize, solving in parallel entails two steps:

1. **Submission Loop:** In this phase we will generate and submit models for solutions that can be solved independently.
2. **Collection Loop:** The solutions of the previously submitted models are collected as soon as a solution is available. It may be necessary to wait for some solutions to complete by pausing the execution for some time.

Note that we have assumed that there will be no errors in any of these steps. Of course, this will not always be the case and elaborate mechanisms are in place to make the operation fail-safe.

Note

For scenario analysis the solver GUSS might be of particular interest. The model **[GUSSGRID]** demonstrates how GUSS is used together with the Grid facility.

4.36.3 The Grid Facility: A First Example

In this section we will illustrate the use of the basic grid facility with the model **[QMEANVAR]**. This model traces an efficiency frontier for restructuring an investment portfolio. Each point on the frontier requires the solution of independent quadratic mixed integer models. The *original solution loop* is shown below:

```
loop(p(pp),
   ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
   solve minvar min var using miqcp ;
   xres(i,p)         = x.l(i);
   report(p,i,'inc') = xi.l(i);
   report(p,i,'dec') = xd.l(i);
);
```

This loop will save the solutions of the model `minvar` for different returns `ret`. As the solutions do not depend on the order in which they are carried out, we can rewrite this loop to operate in parallel.

4.36.3.1 The Submission Loop

The first step for solving in parallel using the Grid facility is to write the submission loop:

```
Parameter h(pp)      'model handles';
minvar.solveLink = 3;
loop(p(pp),
   ret.fx = rmin + (rmax-rmin)/(card(pp)+1)*ord(pp) ;
   solve minvar min var using miqcp;
   h(pp) = minvar.handle;
);
```

The model attribute solveLink controls the behavior of the solve statement. The value of 3 (which is equivalent to the compile-time constant %solveLink.asyncGrid%) directs GAMS to generate the model and submit it for solution and then continue without waiting for the completion of the solution step. Thus with setting `minvar.solveLink` to 3 we activate grid computing.

A *handle* in the grid environment identifies the particular model and data instances available. The model attribute handle contains a unique identification of each submitted solution request and is typically stored in a parameter defined over a set that covers all model instances. The specific numerical values of handles are assigned by GAMS and may be used to recover solutions and manage models that are solved on the grid. In our example, the handle parameter is `h` and the set of all model instances is `pp`. The handle values that are stored in `h` are later used to collect the solutions once the solution processes are completed.

4.36.3.2 The Collection Loop

We collect the solutions with the following collection loop:

```
loop(pp$handleCollect(h(pp)),
   xres(i,pp)         = x.l(i);
   report(pp,i,'inc') = xi.l(i);
   report(pp,i,'dec') = xd.l(i);
);
```

Note that the dollar condition restricts the looping set `pp` to those elements which return a nonzero value to the function `handleCollect(h(pp))`. The function handleCollect tests the solution status for each element of the set `pp`. And if the solution is available, it is read into the GAMS data base. In this case the function returns a value of 1. If the solution is not ready to be retrieved, the value zero will be returned.

Observe that the collection loop above has one big flaw. If a solution has not been ready (that is if `handleCollect` equaled zero), it will not be retrieved. We need to call this loop several times until all solutions have been retrieved or we get tired of it and quit. We will use a repeat until construct and the handle parameter `h` to control the loop to look only for the solutions that have not been loaded yet. The code follows:

```
repeat
   loop(pp$handleCollect(h(pp)),
         xres(i,pp)         = x.l(i);
         report(pp,i,'inc') = xi.l(i);
         report(pp,i,'dec') = xd.l(i);
         display$handleDelete(h(pp)) 'trouble deleting handles' ;
         h(pp) = 0;
   ) ;
   display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
```

Once we have extracted a solution we will set the handle parameter `h` to zero. In addition, we want to remove the instance from the system by calling the function handleDelete which returns zero if successful. No harm is done if it fails but we want to be notified via the conditional display statement. Before running the collection loop again, we may want to wait a while to give the system time to complete more solution steps. This is done with the function readyCollect which waits until another model instance with a handle in `h` is ready to be collected (or the optionally defined number of seconds has passed). The final wrinkle is to terminate if all model instances have been deleted from the system since their solutions were retrieved or after 100 seconds have elapsed, even if we did not get all solutions. This is accomplished with the function timeElapsed and is important, because if one of the solution steps fails our program would never

terminate. Recall that the handle parameter `h` equals zero for all elements of the set `pp` whose related models have been solved and their solutions have been extracted. The last statement in the code above sets the results of the *missed* solves to `na` to signal the failed solve. The parameter `h` will now contain the handles of the failed solves for later analysis.

Alternatively, we could use the function handleStatus and collect the solutions that are stored in a GDX file. For example, we could write:

```
loop(pp$(handleStatus(h(pp)) = 2),
   minvar.handle = h(pp);
   execute_loadhandle minvar;
   xres(i,pp)         = x.l(i);
   report(pp,i,'inc') = xi.l(i);
   report(pp,i,'dec') = xd.l(i);
);
```

The function handleStatus tests the solution process and returns the value 2 if the solution process has been completed and the results can be retrieved. The solution is stored in a GDX file which can be loaded in a way similar to other GDX solution points. First, we need to specify which solution to retrieve by setting the the model attribute `minvar.handle` to the appropriate value. Then we can use the statement `execute_loadhandle minvar;` to load the solution for the model `minvar` back into the GAMS data base.

Note

Except for the requirement of a model with a previously specified handle, the command `execute_loadhandle` operates like the procedure execute_loadpoint.

Using the function `handleStatus` and the command `execute_loadhandle` instead of the simpler `handleCollect`, adds one more layer of control to the final collection loop. Now we need one additional if statement inside the collection loop above:

```
repeat
   loop(pp$h(pp),
      if(handleStatus(h(pp)) = 2,
         minvar.handle = h(pp);
         execute_loadhandle minvar;
         xres(i,pp)         = x.l(i);
         report(pp,i,'inc') = xi.l(i);
         report(pp,i,'dec') = xd.l(i);
         display$handleDelete(h(pp)) 'trouble deleting handles' ;
         h(pp) = 0;
      );
   ) ;
   display$readyCollect(h, 100) 'Problem waiting for next instance to complete';
until card(h) = 0 or timeelapsed > 100;
xres(i,pp)$h(pp) = na;
```

Finally, we are ready to run the modified model.

4.36.3.3 The Execution Log

The execution log will contain some new information that may be useful for more advanced applications:

```
--- LOOPS pp = p1
---   46 rows 37 columns 119 non-zeroes
---   311 nl-code 7 nl-non-zeroes
---   14 discrete-columns
--- Submitting model minvar with handle grid137000002
--- Executing after solve
...
--- GDXin=C:\answerv5\gams_srcdev\225j\grid137000003\gmsgrid.gdx
--- Removing handle grid137000003
```

Note that the log contains some additional information about the submission, retrieval and removal of the solution instance. In the following sections we will make use of this additional information.

The execution log does not cotain any solver log. Though, if a logOption value is set, that triggers writing to a file (i.e. `2` or `4`), the solver log of each job will be written to the corresponding folder in the Grid Directory. So, if the solver log should be inspected when the job is done, one needs to make sure, that these folders do not get cleaned automatically, e.g. by setting the gridDir command line parameter.

For a complete example for grid computing, see the grid enabled transport model [**TRNSGRID**].

Observe that we have made no assumptions about what kind of solvers and what kind of computing environment we will operate. The example above is completely platform and solver independent and it runs on a Windows laptop or on a massive grid network like the Condor system without any changes in the GAMS source code.

4.36.4 Advanced Use of Grid Features

In this section we will describe a few special application requirements and show how this can be handled with the current system. Some of those applications may involve thousands of model instances with solution times of many hours each. Some may fail and require resubmission. More complex examples require communication and the use of GAMS facilities like the Branch-and-Cut-and-Heuristic Facility (BCH), which submit other models from within a running solver.

Imagine a situation with thousands of model instances each taking between minutes and many hours to solve. We will break the master program into a *submitting* program, an *inquire* program and a final *collection* program. We will again use the model [**QMEANVAR**] to demonstrate the principle. We will split the code of the modified [**QMEANVAR**] GAMS code into three components: `qsubmit`, `qcheck` and `qreport`.

4.36.4.1 Very Long Job Durations: The Submitting Program

The file `qsubmit.gms` will include everything up to and including the new submission loop. To save the instances we will need a unique grid directory `gdir` and to restart the problem we will have to create a `save file`. For details on the save and restart facility in GAMS, see chapter The Save and Restart Feature. When running the first job, we will use the command line parameter save or its synonym `s` to create the required `save file`:

```
> gams qsubmit s=submit gdir=c:\test\grid
```

4.36.4.2 Very Long Job Durations: The Inquire Program

The solution of all the model instances may take hours. From time to time we may run a quick inquiry job to learn about the status. The following program `qcheck.gms` will list the current status:

```
Parameter status(pp,*);
Scalar    handle;
Acronym   BadHandle, Waiting, Ready;
loop(pp,
   handle = handleStatus(h(pp));
   if(handle=0,
      handle = BadHandle;
   elseif handle=2,
      handle = Ready;
      minvar.handle = h(pp);
      execute_loadhandle minvar;
      status(pp,'solvestat') = minvar.solvestat;
      status(pp,'modelstat') = minvar.modelstat;
      status(pp,'seconds') = minvar.resusd;
   else
      handle = Waiting;
   );
   status(pp,'status') = handle;
);
display status;
```

For details on the model attributes referenced in the code above, see handle, solveStat, modelStat and resUsd. To run the program above, we will restart from the previous `save file` by using the command line parameter restart or its synonym `r`.

```
> gams qcheck r=submit gdir=c:\test\grid
```

The output generated by the display statement may look like the following:

```
----   173 PARAMETER status

     solvestat   modelstat   seconds     status

p1       1.000       1.000     0.328      Ready
p2       1.000       1.000     0.171      Ready
p3                                      Waiting
p4                                      Waiting
p5       1.000       1.000     0.046      Ready
```

We may want to do some more detailed analysis on one of the solved model instances. The respective program, called `qanalyze.gms`, may inlcude the following lines of code:

```
$if not set instance $abort --instance is missing
if(not handleStatus(h('%instance%')),
     abort$yes 'model instance %instance% not ready');
minvar.handle = h('%instance%');
execute_loadhandle minvar;
display x.l,xi.l,xd.l;
...
```

For information on dollar control options, see chapter Dollar Control Options, especially the detailed descriptions of the options $if and $abort. Note that `instance` is a compile-time variable. The program may be called using a double dash paramter, which defines and sets a GAMS compile-time variable:

```
> gams qanalyze r=submit gdir=c:\test\grid --instance=p4
```

4.36.4.3 Very Long Job Durations: The Collection Program

Once all jobs are completed we are ready for the collection loop. For simplicity, we will not include the repeat loop, because we would not run the final collection program unless we were satisfied that we got most of the solutions that we wanted. The file `qreport.gms` could look like the following:

```
loop(pp$handleStatus(h(pp)),
   minvar.handle = h(pp);
   execute_loadhandle minvar;
   xres(i,pp)         = x.l(i);
   report(pp,i,'inc') = xi.l(i);
   report(pp,i,'dec') = xd.l(i);
   display$handleDelete(h(pp)) 'trouble deleting handles' ;
   h(pp) = 0;
);
xres(i,pp)$h(pp) = na;
...
```

We will restart the program above from the `save file` that was created earlier:

```
> gams qreport r=submit gdir=c:\test\grid
```

Note that it is not necessary to run the job from the same directory that we have used for the initial submission; it is even possible to use a different operating system.

4.36.5 Summary of Grid Features

We introduced several GAMS features to facilitate the asynchronous or parallel execution of the solve statement. These GAMS features are summarized in the following subsections.

In addition to the features described below, the option or command line parameter ThreadsAsync was introduced. `ThreadsAsync` controls the number of threads or CPU cores that are used in multi-threading computing.

4.36.5.1 Grid Handle Functions

The grid handle functions are listed in Table 1. For details on functions in GAMS in general and complete lists of all GAMS functions, see section Functions. Note that the desired return values - the return values that indicate that no error has occurred - are marked with bold letters.

Function	Description	Return Values
handleCollect(HANDLE)	Tests if the solve of the model instance identified by HANDLE is done: if so, it loads the solution into the GAMS data base. If the option asyncSolLst is active the solution listing is printed to the listing file. **Note** that handleCollect ignores the setting of the option SolveOpt and always uses the default value merge.	0: The model instance was not ready or could not be loaded. **>0: The model instance solution has been loaded**. (When using the Grid facility, this is always 1; when using the multi-threading option, this returns the thread ID used.)
handleStatus(HANDLE)	Tests if the solve of the model instance identified by HANDLE is done. Note that there are compile-time constants that are related to this function.	0: The model instance is not known to the system. 1: The model instance exists but the solution process is incomplete. **2: The solution process has terminated and the solution is ready for retrieval.** 3: The solution process signaled completion but the solution cannot be retrieved.
handleDelete(HANDLE)	Deletes the model instance identified by HANDLE and returns a numerical indicator of the status of the deletion. If the HANDLE given is not valid, an execution error is triggered.	**0: The model instance has been removed.** 1: The argument HANDLE is not a legal handle. 2: The model instance is not known to the system. 3: The deletion of the model instance encountered errors.
handleSubmit(HANDLE)	Resubmits the model instance identified by HANDLE for solution. In case of a nonzero return an execution error is triggered.	**0: The model instance has been resubmitted for solution.** 1: The argument HANDLE is not a legal handle. 2: The model instance is not known to the system. 3: The completion signal could not be removed. 4: The resubmit procedure could not be found. 5: The resubmit process could not be started.

Function	Description	Return Values
`readyCollect(HANDLES[,maxWait])`	Waits until a model solution is ready to be collected. `HANDLES` must be either a scalar or parameter containing one or more model handles or a model with its handle attribute. `MaxWait` specifies the maximum time to wait in seconds, the default value is `+inf`.	**0: One or more of the requested jobs is/are ready.** 1: There is neither an active job to wait for nor a job ready to be collected. 2: The handle symbol is empty. 3: The argument is not a legal handle. 4: User specified time-out (using a solveLink = 6 handle). 5: User specified time-out (using a solveLink = 3 handle). 8: Unknown error (should not happen).

Table 1: Grid Handle Functions

Note that GAMS might issue execution errors which could give additional information that may help to identify the source of problems. The function execError may be used to get and set the number of execution errors.

4.36.5.2 Grid Model Attributes

Model attributes are introduced in section Model Attributes. The following three model attributes are particularly relevant for grid computing:

Function	Description
solveLink	Specifies the solver linking conventions. The following values direct the solve statement to use grid computing or multi-thread computing: 3, 4, 6 and 7. Note that the default for this model attribute can be set as command line parameter and option statement. For more information, see the detailed description.
handle	Specifies the current instance handle. This is used to identify a specific model instance and to provide additional information needed for the process signal management (compare subsections The Submission Loop and The Collection Loop above).
number	Specifies the current instance number. Any time a solve is attempted for a model, the instance number is incremented by one and the handle is update accordingly. The instance number can be reset by the user which then resynchronizes the handle.

Table 2: Grid Handle Attributes

4.36.5.3 Grid Solution Retrieval

As an alternative to the function handleCollect a solution may be retrieved with the following statement:

```
execute_loadhandle mymodel;
```

This statement will update the GAMS data base with the status and solution for the current instance of `mymodel`. Note that the underlying mechanism is a GDX file. Except for the requirement of a model with a previously specified handle, this command operates like the procedure execute_loadpoint. If the option asyncSolLst is active the solution listing is printed to the listing file.

4.36.5.4 The Grid Directory

The instantiated (generated) models and their corresponding solutions are kept in unique directories that may be reached from the submitting system. Each GAMS job may have only one *grid directory*. By default, the grid directory is assumed to be the scratch directory. This may be overwritten by using the GAMS command line parameter GridDir, or short `GDir`. An example follows.

```
> gams myprogram ... GDir=gridpath
```

If `gridpath` is not a fully qualified name, the name will be completed using the current directory. If the grid path does not exist, an error will be issued and the GAMS job will be terminated. A related GAMS parameter is ScrDir or short `SD`.

Recall the following default mechanism: When a GAMS job is started a unique process directory is created in the current directory. These directories are named `225a` to `225zz`. When a GAMS job terminates, the system will remove the process directory at the completion of a GAMS job. Any file that has not been created by the GAMS core system will be flagged. If the call `gamskeep` instead of `gams` is used, another exit script will be activated that results in the process directory to be kept.

Note that if we do not specify a scratch directory, the scratch directory will be the same as the process directory. If we do not specify a grid directory, the grid directory will be the same as the scratch directory.

Observe that if we assume that some of the model instances may fail or we want to break the GAMS program into several pieces to run as separate jobs, we need to be careful not to remove the model instance we have not completely processed. In such cases we have to use the parameter GridDir, so that we may access previously created model instances.

4.36.6 The Grid Facility: Architecture and Customization

The current Grid facility relies on very basic operating system features and does not attempt to offer real and direct job or process control. The file system is used to signal the completion of a submitted task and GAMS has currently no other way to interact with the submitted process directly, like forcing termination or change the priority of a submitted task. This approach has its obvious advantages and disadvantages. There are a number of attempts to use grid computing to provide value added commercial remote computing services.

When GAMS executes a solve with the option solveLink set to 3 it will perform the following steps:

1. Create a subdirectory in the GridDir with the name `gridnnn`. Here `nnn` stands for the numeric value of the handle. The handle value is the internal symbol ID number x 1e6 + the model instance number. For example, in the **[QMEANVAR]** example the first grid subdirectory was `grid137000002`.
2. Remove the completion signal in case the file already exists. Currently the signal is a file called `finished`. For example, `grid137000002/finished`.
3. Create or replace a GDX file called `gmsgrid.gdx` which will contain a dummy solution with failed model and solver status. This file will be overwritten by the final step of the solution process and will be read when calling execute_loadhandle.
4. Place all standard GAMS solver interface files into the above instance directory.
5. Execute the submission wrapper called `gmsgrid.cmd` under Windows or `gmsgrid.run` under Unix. These submission scripts are usually located in the GAMS system directory, they may be located via the current path if they are not found in the GAMS system directory.

The grid submission script `gmsgrid.cmd` or `gmsgrid.run` is called with four arguments that are needed to make a standard GAMS solver call: the solver executable file name, the solver control file name, the solver scratch directory, and the solver name. The submission script then does the final submission to the operating system. This final script will perform the following steps:

1. call the solver,
2. call a utility that will create the final GDX file `gmsgrid.gdx`,
3. set the completion signal `finished`.

If we want to use the function handleSubmit we will also have to create the script `gmsrerun.cmd` or `gmsrerun.run`. This script could later be used to resubmit the job.

For example, the default submission script for Windows is shown below:

```
@echo off

: gams grid submission script
:
: arg1 solver executable
:    2 control file
:    3 scratch directory
:    4 solver name
:
: gmscr_nx.exe processes the solution and produces 'gmsgrid.gdx'
:
: note: %3 will be the short name, this is neeeded because
:       the START command cannot handle spaces or "...'
:       before we use %~3  will strip surrounding "..."
:       makes the name short
:
: gmsrerun.cmd will resubmit runit.cmd

echo @echo off                       > %3runit.cmd
echo %1 %2 %4                       >> %3runit.cmd
echo gmscr_nx.exe %2                >> %3runit.cmd
echo echo OK ^> %3finished ^& exit >> %3runit.cmd

echo @start /b /belownormal %3runit.cmd ^> nul  > %3gmsrerun.cmd

start /b /belownormal %3runit.cmd > nul

exit
```

4.36.6.1 Grid Submission Testing

The grid submission process can be tested on any GAMS program without having to change the source text. The option `solveLink=4` instructs the solve statement to use the grid submission process and then wait until the results are available. Note that the option solveLink may be set via a GAMS command line parameter, a GAMS option statement or via assignment to the model attribute. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the reslim seconds allocated for this optimization job and report a failure if this limit has been exceeded. After successful or failed retrieval of the solution, GAMS will remove the grid directory, unless we have used the call `gamskeep` or have set the GAMS command line parameter keep.

4.36.7 Multi-Threading

As we have described in this chapter, each solve is handled in its own process space with the Grid facility. Recall that the Grid facility is activated by setting the option or model attribute solveLink to 3 or 4. If `solveLink` is set to 6 (or the compile-time constant `%solveLink.asyncThreads%`) instead, a separate thread is used. This allows efficient in-memory communication between GAMS and the solver, like it is done if the option `solveLink` is set to 5 (or the compile-time constant `%solveLink.loadLibrary%`).

Apart from this, the multi-threading facility works in the same way as the Grid facility. The solve statement generates the model and passes it to the solver in a separate thread, then a handle of the model instance may be stored using the model attribute handle and the grid handle functions may be used to collect the solution and deal with the model instance, namely handleCollect, handleDelete, handleStatus and readyCollect.

Note that the option or command line parameter ThreadsAsync sets the maximum number of threads that should be used for the asynchronous solves.

The following matrix shows which solvers may be used with `solveLink = 6` on which platform:

Solver	x86 64bit MS Windows	x86 64bit Linux	x86 64bit macOS	arm 64bit macOS
CONOPT3	×	×	×	×
CONOPT4	×	×	×	×
CONVERT	×	×	×	×
COPT	×	×	×	×
CPLEX	×	×	×	×
GUROBI	×	×	×	×
HIGHS		×	×	×
IPOPT	×	×	×	×
MOSEK	×	×	×	×
ODHCPLEX	×	×		
SCIP	×	×	×	×
SHOT	×	×	×	×
SNOPT		×		
Soplex	×	×	×	×
XPRESS	×	×	×	

If a solver is selected for which `solveLink = 6` is not supported on the corresponding platform, `solveLink = 3` will be used instead and it will be noted in the log.

4.36.7.1 Multi-threading Submission Testing

The multi-threading submission process may be tested on any GAMS program without having to change the source text. The option solveLink = 7 (or, equivalently, the compile-time constant `%solveLink.threadsSimulate%`) instructs the solve statement to use the multi-threading submission process, wait until the results are available and then load the solution into the GAMS data base. Once the model instance has been submitted for solution, GAMS will check if the job has been completed. It will keep checking twice the reslim seconds allocated for this optimization job and report a failure if this limit has been exceed. After successful or failed retrieval of the solution GAMS will remove the thread handle.

4.37 Special Features for Mathematical Programs

4.37.1 Introduction

In this chapter we will introduce special GAMS features that are useful for specific model types. The features include model scaling, conic programming and features that facilitate mixed integer as well as indicator constraints, a feature that does not translate across solvers.

4.37.2 Special Mixed Integer Programming (MIP) Features

Some special features have been added to GAMS to help simplifying the modeling of Mixed Integer Programming (MIP) problems. In GAMS MIP is the model type for mixed integer *linear* programs, this section used MIP more generally, we consider model with discrete variables, including non-linear expressions and pure discrete problem. We will first present details on discrete variables in GAMS, then we will discuss how to customize priorities for the branching process. Next, we will cover the model attributes that are important for MIPs and we will conclude with some hints that will make mixed integer programming with GAMS easier.

4.37.2.1 Types of Discrete Variables

Variables and variable types are introduced in chapter Variables. GAMS provides six discrete variable types: `binary`, `integer`, `sos1`, `sos2`, `semicont` and `semiint`. In the following subsections we will present details and examples for each of these discrete variable types. Note that if any discrete variables feature in a model, it has to be a mixed integer model or one of the related model types, like MINLP or MIQCP. See section Classification of Models for a full listing of all GAMS model types.

Binary Variables

Binary variables can take values of 0 (zero) and 1 (one) only. They are declared as follows:

```
Binary Variable var_name [(index_list)] [text];
```

The keyword `binary` indicates that this is a binary variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as `binary` later. Consider the following code snippets from the orthogonal Latin Square model **[LATIN]**:

```
Sets k  "rows"      / row1*row4 /
     l  "columns"   / col1*col4 /
     v  "values"    / val1*val4 /;
alias (i,j,v);

Variables x(i,j,k,l) "pairs (i,j) allocated to cell(k,l)"
          z          "some objective";
Binary Variable x;

Equations c1(i,j)    "for each cell pick only one item pair";
c1(i,j).. sum((k,l), x(i,j,k,l)) =e= 1;
```

Note that the binary variable `x` is used in equation `c1` to model the restriction that in each cell only one item pair is allowed. Binary variables are often used to model logical conditions such as imposing mutual exclusivity or complementarity.

Note that the default lower bound is 0 (zero) and the default upper bound is 1 (one). If the relaxed versions of the discrete models is solved, binary variables are treated like positive variables with the upper bound of 1. In addition, an infinite priority may be used to override binary specifications, see section Setting Priorities for Branching below for more information.

Even though the only possible values are 0 and 1, a solver might return a value for binary variable that is only *close* to 0 or 1. Every solver works with tolerances and also uses a tolerance to determine if a value is *close enough* to an integer values. So it is unwise to use code as `a(i)$(b.l(i)=1) = yes;` because one will potentially miss some elements. A safe way to write such code is: `a(i)$(b.l(i)>0.5) = yes;`. Rounding the level of a binary variable after the solve is also possible, but it is not done by the solver or the solver link because even small rounding can lead to infeasibilities.

A binary variable can also have a truely fractional value after a solver if the model status does not indicate a feasible integer solution (model status 1 or 8).

Integer Variables

Integer variables are discrete variables that can take only values between their bounds. The user may change both bounds from the default value. The default lower bound is 0 (zero) and the default upper bound inside GAMS is `+inf`, and the same upper bound is passed on to the solver.

Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section Setting Priorities for Branching below for more information. Integer variables are declared as follows:

```
Integer Variable var_name [(index_list)] [text];
```

The keyword `integer` indicates that this is an integer variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as `integer` later. Consider the following code snippets from the power scheduling model [**MAGIC**]:

```
Sets t  "demand blocks" / 12pm-6am, 6am-9am, 9am-3pm, 3pm-6pm, 6pm-12pm /
     g  "generators"    / type-1, type-2, type-3 /;

Variables  x(g,t)  "generator output (1000mw)"
           n(g,t)  "number of generators in use"
           cost    "total operating cost (1)";
Integer Variable n;
```

The integer variable `n` models the number of generators of various types that are in use at any of the time blocks.

Special Order Sets of Type 1 (SOS1)

SOS1 variables are a set of variables, such that at most one variable within the group may have a nonzero value. This variable may take any positive value. Special ordered sets of type 1 are defined as follows:

```
SOS1 Variable var_name (index_list) [text];
```

The keyword SOS1 indicates that this is a SOS1 variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as SOS1 later. Consider the following example:

```
SOS1 Variable s1(i), t1(k,j), w1(i,j,k) ;
```

Note that the members of the innermost (the right-most) index belong to the same SOS set. For example in the sets defined above, s1 represents one special ordered set of type 1 with i elements, t1 defines k sets with j elements each and w1 defines (i,j) sets with k elements each.

The default bounds for SOS1 variables are zero and +inf. As with any other variable, the user may change these bounds. Further, the user may explicitly provide whatever convexity row that the problem may need through an equation that requires the members of the SOS1 set to be less than a certain value. Any such convexity row will implicitly define bounds on each of the variables.

Consider the following example:

```
SOS1 Variable s1(i); Equation defsoss1;
defsoss1.. sum(i,s1(i)) =l= 3.5 ;
```

The equation defsoss1 implicitly defines the nonzero value that one of the elements of the SOS1 variable s1 may take as equal to or smaller than 3.5. Note that it is also possible that all variables s1 equal zero.

A special case arises when one of the elements of the set has to be nonzero and equal to a number, say 3.5. In this case equation defsoss1 will be:

```
defsoss1.. sum(i,s1(i)) =e= 3.5 ;
```

Frequently the nonzero value equals 1. As a result, the SOS1 variable is effectively a binary variable. It is only treated differently by the solver at the level of the branch and bound algorithm. For example, consider the following example where we want to model that one out of n options has to be selected. This is expressed as:

```
SOS1 Variable x(i); Equation defx;
defx.. sum(i, x(i)) =e= 1 ;
```

The variable x can be made binary without any change in meaning and the solution provided by the solver will be indistinguishable from the SOS1 case.

The use of special ordered sets may not always improve the performance of the branch and bound algorithm. If there is no natural *order* the use of binary variables may be a better choice. A good example of this is the classical assignment problem (see [H.P. Williams (2013) Model Building in Mathematical Programming], Wiley, Section 9.3.

Note that any model with SOS1 variables requires a MIP solver, because the solution process needs to impose the restrictions of at most one nonzero level values may be present.

For an example where SOS1 variables are used, see the production scheduling model **[PRODSCHX]**.

Special Order Sets of Type 2 (SOS2)

SOS2 variables are a set of variables, such that at most two variables within the set may have nonzero values and these variables have to be adjacent. This requirement implies that the set is *ordered*, see chapter Sets as Sequences: Ordered Sets for details on ordered sets in GAMS. Note that the nonzero variables may take any positive value. Special ordered sets of type 2 are defined as follows:

```
SOS2 Variable var_name [(index_list)] [text];
```

The keyword SOS2 indicates that this is a SOS2 variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as SOS2 later. Consider the following example:

```
Set i  / i1*i5 /;
SOS2 Variable s2(i), t2(k,j), w2(i,j,k);
```

The members of the innermost (the right-most) index belong to the same set. For example, in the sets defined above, s2 represents one special ordered set of type 2 with elements for each member of the set i. At most two variables s2 may be nonzero and they must reference adjacent elements of the set i. Note that the variables s2('i1') and s2('i2') are adjacent, but the variables s2('i1') and s2('i3') are not. Further, t2 defines k sets of SOS2 variables with j elements each and the adjacency requirement refers to the set j which must be ordered. Similarly, w2 defines (i,j) sets with k elements each and the adjacency requirement refers to the set k which must be ordered.

The default bounds for SOS2 variables are zero and +inf. As with any other variable, the user may change these bounds. SOS2 variables are most often used to model piece-wise linear approximations to nonlinear functions. The production scheduling model [**PRODSCHX**] shows SOS type formulations with binary, SOS1 and SOS2 sets.

Note that any model with SOS2 variables requires a MIP solver, because the solution process needs to impose the restrictions of adjacency and that no more than two nonzero level values may be present.

Semi-Continuous Variables

Semi-continuous variables are either zero or above a given minimum level. This can be expressed algebraically as: either $x = 0$ or $L \leq x \leq U$. By default, the lower bound L is 1 and the upper bound U is +inf. As usual, these bounds may be changed with the variable attributes .lo and .up. Semi-continuous variables are defined as follows:

```
SemiCont Variable var_name [(index_list)] [text];
```

The keyword semicont indicates that this is a semi-continuous variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as semicont later. Consider the following example:

```
SemiCont Variable x;
x.lo = 1.5;  x.up = 23.1;
```

The slice of code above declares the variable x to be a semi-continuous variable that may either be zero or behave as a continuous variable between 1.5 and 23.1.

Note that any model with semi-continuous variables requires a MIP solver, because the solution process needs to impose the discontinuous jump between zero and the threshold value.

Note

- Not all MIP solvers allow semi-continuous variables. We recommend users to verify how the solver they are interested in handles semi-continuous variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-continuous variables.
- Semi-continuous variables are especially helpful if the upper bound is `+inf` and no implicit bound can be easily derived. If a finite upper bound is available it can be computational more efficient to replace the semi-continuous variable `sc` with lower bound `scLow` by a continuous variable `x` and binary variable b and the following equations:

```
Equation xForceLowerBnd   "Force x to be greater than scLow if b is 1"
         xForceZero       "Force x to be zero if b is zero";
xForceLowerBnd.. x =g= scLow*b;
xForceZero..     x =l= x.up*b;
```

Semi-Integer Variables

Semi-integer variables are either zero or integer and above a given minimum value. This can be expressed algebraically as: either $x = 0$ or $x \in \{L, \ldots, U\}$. By default, the lower bound L is 1 and the upper bound U inside GAMS is `+inf` and the same values are passed on to the solver. As usual, these default bounds may be changed with the variable attributes `.lo` and `.up`. Note that in relaxed model types the integrality requirement is relaxed. In addition, an infinite priority may be used to override integer specifications, see section Setting Priorities for Branching below for more information.

Semi-integer variables are defined as follows:

```
SemiInt Variable var_name [(index_list)] [text];
```

The keyword `semiint` indicates that this is a semi-integer variable and then the usual conventions for variable declarations are followed. Alternatively, the variable may be declared first and specified as `semiint` later. Consider the following example:

```
SemiInt Variable x;
x.lo = 2; x.up = 25;
```

The slice of code above declares the variable `x` to be a semi-integer variable that may either be zero or take any integer value between 2 and 25. Note that the bounds for `semiint` variables have to take integer values, otherwise GAMS will flag an error during model generation. Note further, that any model with semi-integer variables requires a MIP solver.

Note

- Not all MIP solvers allow semi-integer variables. We recommend users to verify how the solver they are interested in handles semi-integer variables by checking the relevant section of the respective solver manual.
- The lower bound has to be less than the upper bound, and both bounds have to be greater than zero, otherwise GAMS will report an error.
- The variable solution listing might show the level outside the lower and upper bound which for other variables indicates an infeasible variable, but not so for semi-integer variables.

- Semi-integer variables are especially helpful if the upper bound is `+inf` and no implicit bound can be easily derived (together with the appropriate IntVarUp setting). If a finite upper bound is available, it can be computationally more efficient to replace the semi-integer variable `si`, with lower bound `siLow`, by an integer variable `i` and a binary variable b and the following equations:

```
Equation iForceLowerBnd   "Force i to be greater than siLow if b is 1"
         iForceZero       "Force i to be zero if b is zero";
iForceLowerBnd.. i =g= siLow*b;
iForceZero..     i =l= i.up*b;
```

4.37.2.2 Setting Priorities for Branching

By setting priorities users may specify an order for choosing variables to branch on during a branch and bound search for MIP models. Without priorities the MIP algorithm will internally determine which variable is the most suitable to branch on. Priorities for individual variables may be used only if the model attribute `.prioropt` is set to 1; the respective GAMS statement is:

```
mymodel.prioropt = 1;
```

Here `mymodel` is the name of the model specified in the model statement. The default value is NA.

If the model attribute `.prioropt` is set to 1, the variable attribute `.prior` may be used to set the priorities of individual discrete variables. Note that there is one `.prior` value for each individual component of a multidimensional variable. Priorities may be set to any real value; the default value is 1. As a general rule, the most important variables should be given the highest priority. The highest priority is denoted by the lowest nonzero value in the `.prior` attribute. Functionally, the attribute `.prior` establishes in what order variables are to be branched on in the branch-and-bound algorithm while searching for a solution. Variables with a specific `.prior` value will branched on earlier until all fractional variables with higher `.prior` values have been branched on.

Note

> The variable attribute `.prior` of a *discrete* variable may be used to relax the discrete restriction on that variable: setting the `.prior` value to `+inf` will relax a variable permanently (or until `.prior` gets a finite value assigned). This relaxation is done independently of the model attribute `.prioropt`.

Consider the following example:

```
z.prior(i,'small')   = 3;
z.prior(i,'medium')  = 2;
z.prior(i,'large')   = 1;
```

In this example the variables `z(i,'large')` are branched on before the variables `z(i,'medium')`, which in turn are branched on before the variables `z(i,'small')`.

Note that knowledge about the problem may help to determine which variables should be considered first. For example, consider a problem with a binary variable `u` representing a yes/no decision whether to build a factory and other binary variables representing equipment selections within that factory. We would naturally want to explore whether or not the factory should be built before considering what specific equipment to be purchased within the factory. Therefore we would set the priority values lower for `u`. By assigning a higher priority - a lower value of the attribute `.prior` - to the build/nobuild decision variable `u`, we can force this logic into the tree search and thus speed up computation time since uninteresting portions of the tree are left unexplored.

Note

- The lower the value given to the `.prior` suffix, the higher the priority for branching.
- All members of any `SOS1` or `SOS2` set should be given the same priority value since it is the set itself which is branched upon rather than the individual members of the set.
- While any value is accepted for `.prior` many solvers scale all giving priorities in the integer range of $0, ..., 1000$.
- Branching priorities were a very important feature in the early days of mixed integer programming. Nowadays, it is not easy to find branching priorities that improve on the solvers default selection.
- Global non-linear optimization solvers branch on continuous variables too (see, for example BARON). In GAMS one cannot set the branching priority of a continuous variable. Such branching priorities need to be communicated via a solver option file.

4.37.2.3 Miscellaneous Hints

We will conclude the discussion of mixed integer models in GAMS with this section where we offer a variety of hints that are meant to make special facilities of mixed integer programming solvers more accessible.

Model Attributes for Mixed Integer Programming in GAMS

GAMS offers several model attributes that may be used to influence MIP solver performance or report on results of MIPs. These model attributes include Cheat, CutOff, NodLim, ObjEst, OptCA, OptCR, PriorOpt and TryInt.

The Branch and Cut and Heuristic Facility

Hard MIP problems can be solved faster with the help of user supplied routines that generate cutting planes and good integer feasible solutions. The GAMS Branch-and-Cut-and-Heuristic (BCH) automates all major steps necessary to define, execute and control the use of user defined routines within the framework of general purpose branch-and-cut codes. It is documented in Branch-and-Cut-and-Heuristic Facility (BCH).

Branch and Bound Output

While the log output for each solver differs, some key figures are usually displayed for branch-and-bound based solvers. For example, solving a linear mixed integer model with CPLEX will yield output like the following:

```
       Nodes                                          Cuts/
   Node  Left     Objective  IInf  Best Integer    Best Bound    ItCnt     Gap

*     0+    0                           0.0000   5.05646e+08             ---
Found incumbent of value 0.000000 after 0.01 sec. (0.73 ticks)
      0     0   2.23031e+07    12        0.0000   2.23031e+07       17     ---
      0     0   2.23031e+07     7        0.0000       Cuts: 8       23     ---
*     0+    0                       2.23031e+07   2.23031e+07             0.00%
Found incumbent of value 2.2303094e+07 after 0.02 sec. (1.08 ticks)
 ...

Fixing integer variables, and solving final LP...
```

```
...

Solution satisfies tolerances.

MIP Solution:     22303093.628684    (23 iterations, 0 nodes)
Final Solve:      22303093.628684    (0 iterations)

Best possible:    22303113.950091
Absolute gap:           20.321407
Relative gap:            0.000001
```

A brief explanation of the columns follows:

- `Node` is the number of branch and bound nodes so far.
- `Nodes Left` is the number of problems created during the branching process that are yet to be examined.
- `Objective` gives the current objective function value of the relaxes node problem.
- `IInf` gives the number of discrete variables with fractional solution levels.
- `Best Integer` gives the incumbent solution. Note the last solution in that column is not necessarily the global best solution.
- `Cuts/Best Bound` gives the current lower bound on the solution.
- `ItCnt` gives the accumulated LP iteration count
- `Gap` gives the maximum percentage difference from the theoretical optimum.

Note that it is common that solves of mixed integer models end with a gap between the solution found and the best possible solution. This may be controlled by limits (e.g. time), solver options and model attributes like .OptCR and .OptCA.

Nonlinear MIPs

Modelers may wish to impose integer restrictions on nonlinear formulations combining two hard model types: MIP and NLP. Such MINLP models can be solved with a selection of solvers. Many solvers, e.g. DICOPT and SBB, provide a local optimum where others, e.g. ANTIGONE and BARON provide a global optimum. In most cases both types of MINLP solver make use of MIP and NLP solvers to calculate a solution. Such *subsolvers* need to be licensed for the solver to succeed.

Model Termination Conditions and Recommended Actions

Recall that the termination condition of the model after the solution process has been completed is stored in the model attribute .modelStat. A list of all possible model statuses is given in section Model Status. We can easily check for the existence of a feasible solution (status 1 and 8). Linear models and MINLP problems solved with global solvers can achieve the "OPTIMAL" status, given sufficient resources (time) and a setting of OptCR and OptCA to 0. All other cases do not yield a feasible integer solution. If a problem is reported as infeasible (status 4,5,10, and 19), it might be a good idea to see if the relaxed version of the model is already infeasible. Debugging models that are relaxed feasible but integer infeasible is very difficult.

Frequent Problems

There are some problems users frequently encounter either due to GAMS settings or problem characteristics:

Default bounds

One needs to be aware that while the GAMS upper bound for integer and semi-integer variables is +inf, the bound that is passed to the solver can be different, namely 100 (see the discussion about integer variables). This can lead to unexpected results (e.g. infeasibilities or suboptimal solutions declared as optimal).

Ending with a gap – large default for `optCR` (10%)

MIP solves often end with a gap between the solution found and the best possible solution. This is controlled by OptCR or OptCA or by non-convergence. Note that the default value of 0.1 for `optCR` is relatively large. Users may want to reduce this to a smaller value. We will discuss the other cause of a gap next.

The nonending quest

Integer programming is a quite desirable formulation technique. However, integer problems are theoretically hard and the solution process (in the worst case) of exponential complexity. There are many ways that focus on improving the solution time of the solver. As with all models scaling is important (especially when using bigM formulations). For particular problems many different formulations exist and the literature about a particular problem together with the ability of GAMS to rapidly prototype and experiment is the best constellation to get the best results for the problem at hand. For fine tuning, some MIP solvers provide automated tuning tools (see e.g. Cplex tuning) that tweak the solver options to get the best performance.

4.37.3 Model Scaling - The Scale Option

The rules for good scaling are exclusively based on algorithmic needs. GAMS has been developed to increase the efficiency of modelers, and one of the best ways seems to be to encourage modelers to write their models using a notation that is as *natural* as possible. The units of measurement are one part of this natural notation. However, there is a potential conflict between what the modeler thinks is a good unit and what constitutes a well-scaled model.

4.37.3.1 The Scale Option

To facilitate the translation between a natural model and a well scaled model, GAMS has introduced the concept of a *scale factor*, both for variables and equations. The notations and definitions are quite simple. Scaling is turned off by default. Setting the model attribute `.scaleopt` to 1 turns on the scaling feature. For example,

```
model mymodel /all/ ;
mymodel.scaleopt = 1 ;
solve mymodel using nlp maximizing dollars ;
```

The statement should be inserted somewhere after the `model` statement and before the `solve` statement. To turn scaling off again, `mymodel.scaleopt` has to be set to zero before the next solve.

In most respects GAMS scaling is hidden from the user. The solution values reported back from a solution algorithm are always reported in the notation of the user. The algorithm's internal representation of the equations and variables are only reflected in the derivatives in the equation and column listings in the GAMS output if the values of the options limrow and limcol are positive. In addition, the internal representations will appear in the debugging output from the solution algorithm if the option sysout is set to `on`.

4.37.3.2 Scaling Variables

The scale factor of a variable is defined using the variable attribute `.scale` in the following way:

```
myvar.scale(i,j) = c;
```

The scale factor `c` is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Note that there is one scale value for each individual component of a multidimensional variable.

Assume that c is the scale factor of a variable V_u. Assume further, that the variable seen by the algorithm is V_a. Then we have: $\mathbf{V_a} = \mathbf{V_u}/\mathbf{c}$. This means that each variable as seen by the user is *divided by* the scale factor.

For example, consider the following code snippet:

```
Positive Variables x1, x2;
Equation eq;
eq.. 200*x1 + 0.5*x2 =l= 5;
x1.up = 0.01;
x2.up = 10;
x1.scale = 0.01;
x2.scale = 10;
```

By setting `x1.scale` to 0.01 and `x2.scale` to 10, the model seen by the solver is:

```
Positive Variables xPrime1, xPrime2;
Equation eq;
eq.. 2*xPrime1 + 5*xPrime2 =l= 5;
xPrime1.up = 1;
xPrime2.up = 1;
```

Note that the solver does not see the variables `x1` or `x2`, but rather the scaled (and better-behaved) variables `xPrime1` and `xPrime2`. Note further, that upper and lower bounds on variables are automatically scaled in the same way as the variable itself.

Attention

- Discrete variables cannot be scaled.
- **Expert Note**. Internally, GAMS stores with each variable and equation one additional attribute or field (besides fields for level, marginal and lower and upper bound). Depending on the type of variable and sometimes even model type or solver, this field has different names in the GAMS language. For continuous variables, the field is called *scale*, while for discrete variable it is called *prior*. For stochastic 2-stage linear program models solved with DECIS, this field is called *stage*. The field `.stage` can lead to confusing results. Consider the following example:

  ```
  Variable x;
  x.scale = 0.1;
  display x.stage;
  ```

  The output is:

  ```
  ----      3 VARIABLE x.scale = 0.100
  ```

  The field `.scale` has to be in a certain range (>1e-20 and no special value), but this is only checked at model generation time. The field `.prior` can be any number and even `+inf` (but no other special values). For further information on `.prior`, see section Setting Priorities for Branching. For an introduction to variable and equation fields, see sections Variable Attributes and Equation Attributes respectively.

4.37.3.3 Scaling Equations

The scale factor of an equation is defined using the equation attribute `.scale` in the following way:

```
mzeqn.scale(i,j) = d;
```

The scale factor `d` is a number or a numerical expression that evaluates to a number. Note that the default scale factor is 1.

Assume that d is the scale factor of an equation G_u. Assume further, that the equation seen by the algorithm is G_a. Then we have: $\mathbf{G_a} = \mathbf{G_u}/\mathbf{d}$. This means that each equation as seen by the user is *divided by* the scale factor.

For example, consider the following equations:

```
Positive Variables y1, y2;
Equations eq1, eq2;
eq1..   200*y1 + 100*y2 =l= 500;
eq2..       3*y1 - 4*y2 =g= 6;
```

By setting `eq1.scale` to 100, the model seen by the solver is:

```
Positive Variables y1, y2;
Equations eqPrime1, eq2;
eqprime1..   2*y1 + 1*y2 =l= 5;
eq2..        3*y1 - 4*y2 =g= 6;
```

Note

> The user may have to perform a combination of equation and variable scaling to obtain a well-scaled model.

Consider the following example:

```
Positive variables x1, x2;
Equations  eq1, eq2;
eq1..   100*x1 + 5*x2 =g= 20;
eq2..   50*x1 - 10*x2 =l= 5;
x1.up = 0.2;
x2.up = 1.5;
```

Setting the following scale values:

```
x1.scale  = 0.1;
eq1.scale = 5;
eq2.scale = 5;
```

will result in the solver seeing the following well-scaled model:

```
Positive Variables xPrime1, x2;
Equations eqPrime1, eqPrime2;
eqPrime1..   2*xPrime1 + x2 =g= 4;
eqPrime2..   xPrime1 - 2*x2 =l= 1;
xPrime1.up = 2;
x2.up      = 1.5;
```

4.37.3.4 Scaling Derivatives

In nonlinear models the derivatives also need to be well-scaled. Assume that the derivatives in the model of the user are denoted by $d(G_u)/d(V_u)$. Assume further, that the derivatives in the scaled model seen by the algorithm are denoted by $d(G_a)/d(V_a)$. Then we have: $\mathbf{d(G_a)/d(V_a) = d(G_u)/d(V_u) \cdot c/d}$, where c is the scale factor for the variable and d is the scale factor for the equation.

The user may affect the scaling of derivatives by scaling both the equation and variable involved.

4.37.3.5 Scaling Data

Scaling input data is independent of the model attribute `.scaleopt` and may contribute considerably towards achieving a well-scaled model. We recommend users to try to define the units of the input data such that the largest values expected for decision variables and their marginals is under a million, if possible.

For example, in US agriculture about 325 million acres are cropped and the corn crop is 9-10 billion bushels per year. When defining production data, we could enter land in 1000's of acres and all other resources in 1000's of units. We could also define the corn crop in millions of bushels. The data will be simultaneously scaled, hence if resource endowments are quoted in 1000's, corn yields are divided by 1000. This scaling results in a corn production variable in the units of millions. Consumption statistics would need to be scaled accordingly. Money units could also be in millions or billions of dollars. Such data scaling generally greatly reduces the disparity of coefficients in the model.

4.37.4 Conic Programming in GAMS

Conic programming models minimize a linear function over the intersection of an affine set and the product of nonlinear cones. The problem class involving second order (quadratic) cones is known as Second Order Cone Programs (SOCP). These are nonlinear convex problems that include linear and (convex) quadratic programs as special cases.

Conic programs allow the formulation of a wide variety of application models, including problems in engineering and financial management. Examples are portfolio optimization, Truss topology design in structural engineering, Finite Impulse Response (FIR) filter design and signal processing, antenna array weight design, grasping force optimization, quadratic programming, robust linear programming and norm minimization problems.

For more information, see References and Links at the end of this section.

4.37.4.1 Introduction to Conic Programming

Conic programs can be thought of as generalized linear programs with the additional nonlinear constraint $x \in C$, where C is required to be a convex cone. The resulting class of problems is known as *conic optimization* and has the following form:

$$\begin{array}{rl} \text{minimize} & c^T x \\ \text{subject to} & Ax \leq r^c, \\ & x \in [l^x, u^x] \\ & x \in C \end{array}$$

where $A \in \mathbb{R}^{m \times n}$ is the constraint matrix, $x \in \mathbb{R}^n$ the decision variable and $c \in \mathbb{R}^n$ the objective function cost coefficients. The vector $r^c \in \mathbb{R}^m$ represents the right-hand side and the vectors $l^x, u^x \in \mathbb{R}^n$ are lower and upper bounds on the decision variable x.

Now partition the set of decision variables x into sets $S^t, t = 1, ..., k$, such that each decision variables x is a member of at most one set S^t. For example, we could have

$$S^1 = (x_1, x_4, x_7) \quad \text{and} \quad S^2 = (x_6, x_5, x_3, x_2).$$

Let x_{S^t} denote the variables x belonging to set S^t. Then define

$$C := \{x \in \mathbb{R}^n : x_{S^t} \in C_t, t = 1, ..., k\},$$

where C_t must have one of the following forms:

- **Quadratic cone** (also referred to as Lorentz or ice cream cone):

$$C_t = \left\{ x \in \mathbb{R}^{n^t} : x_1 \geq \sqrt{\sum_{j=2}^{n^t} x_j^2} \right\}.$$

- ***Rotated*** **quadratic cone** (also referred to as hyperbolic constraints):

$$C_t = \left\{ x \in \mathbb{R}^{n^t} : 2x_1 x_2 \geq \sum_{j=3}^{n^t} x_j^2,\ x_1, x_2 \geq 0 \right\}.$$

These two types of cones allow the formulation of quadratic, quadratically constrained and many other classes of nonlinear convex optimization problems.

4.37.4.2 Implementation of Conic Constraints in GAMS

The recommended way to write conic constraints is by using a quadratic formulation. Many solvers have the capability to identify the conic constraints in a QCP model even if it is not in perfect form but can be easily reformulated to fit in the described form. However, some solvers (namely MOSEK) expect the conic constraints to be precisely in the form given above. In earlier versions this form was enforced by a special type of equation, the `=c=` equation type. Moreover, such solvers have other requirements (e.g. disjunctive cones) that can be easily fulfilled by simple reformulation steps. Much progress is expected on the solver side in the coming years, so we don't go into much detail here.

Observe that we could formulate conic problems as regular NLPs using the following constraints:

- **Quadratic cone:**

```
x('1') =g= sqrt[ sum(i$[not sameas(i,'1')], sqr[x(i)]) ];
```

- **Rotated quadratic cone:**

```
2*x('1')*x('2') =g= sum(i$[not sameas(i,'1') and not sameas(i,'2')], sqr[x(i)]);
```

  Here `x('1')` and `x('2')` are positive variables.

The following example illustrates the different formulations for conic programming problems. Note that a conic optimizer usually outperforms a general NLP method for the reformulated (NLP) cone problems.

4.37.4.3 Example

Consider the following example, which illustrates the use of rotated conic constraints. We will give reformulations of the original problem in regular NLP form and in conic form (with conic constraints).

The original problem is:

$$\text{minimize} \sum_{i=1}^{n} \frac{d_i}{x_i} \tag{4.2}$$

$$\text{subject to } a\,x \leq b \tag{4.3}$$

$$x_i \in [l_i, u_i], \qquad i = 1, \ldots, n \tag{4.4}$$

where $x \in \mathbb{R}^n$ is the decision variable, $d, a, l, u \in \mathbb{R}^n$ are parameters with $l_i > 0$ and $d_i \geq 0$ and $b \in \mathbb{R}$ is a scalar parameter. The original model may be written in GAMS using the equations:

```
defobj..  sum(n, d(n)/x(n)) =e= obj;
e1..      sum(n, a(n)*x(n)) =l= b;
Model orig /defobj, e1/;
x.lo(n) = l(n);
x.up(n) = u(n);
```

We can write an equivalent QCP formulation by using the substitution $t_i = 1/x_i$ in the objective function and adding a constraint. As we are dealing with a minimization problem, $d_i \geq 0$ and $x_i \geq l_i > 0$, we can relax the equality $t_i x_i = 1$ into an inequality $t_i x_i \geq 1$, which results in an equivalent problem with a convex feasible set:

$$\text{minimize} \sum_{i=1}^{n} d_i t_i \tag{4.5}$$

$$\text{subject to } a\,x \leq b \tag{4.6}$$

$$t_i x_i \geq 1, \qquad i = 1, \ldots, n \tag{4.7}$$

$$x \in [l, u], \tag{4.8}$$

$$t \geq 0, \tag{4.9}$$

$$\tag{4.10}$$

where $t \in \mathbb{R}^n$ is a new decision variable. The GAMS formulation of this QCP is:

```
defobjc..     sum(n, d(n)*t(n)) =e= obj;
e1..          sum(n, a(n)*x(n)) =l= b;
coneqcp(n)..  t(n)*x(n)         =g= 1;

Model cqcp /defobjc, e1, coneqcp/;
t.lo(n) = 0;
x.lo(n) = l(n);
x.up(n) = u(n);
```

Note that the constraints $t_i x_i \geq 1$ are almost in rotated conic form. If we introduce a variable $z \in \mathbb{R}^n$ with $z_i = \sqrt{2}$, then we can reformulate the problem using conic constraints as:

$$\text{minimize} \sum_{i=1}^{n} d_i t_i \tag{4.11}$$

$$\text{subject to } a\,x \leq b \tag{4.12}$$

$$z_i = \sqrt{2}, \qquad i = 1, \ldots, n \tag{4.13}$$

$$2 t_i x_i \geq z_i^2, \qquad i = 1, \ldots, n \tag{4.14}$$

$$x \in [l, u], \tag{4.15}$$

$$t \geq 0, \tag{4.16}$$

$$\tag{4.17}$$

The GAMS formulation using conic equations is:

```
defobjc..        sum(n, d(n)*t(n)) =e= obj;
e1..             sum(n, a(n)*x(n)) =l= b;
e2(n)..          z(n) =e= sqrt(2);
coneperfect(n).. 2*x(n)*t(n) =g= sqr(z(n));

Model cperfect  /defobjc, e1, e2, coneperfect/;
t.lo(n) = 0;
x.lo(n) = l(n);
x.up(n) = u(n);
```

The complete model is listed below:

```
Set       n / n1*n10 /;
Parameter d(n), a(n), l(n), u(n);
Scalar    b;

d(n) = uniform(1,2);
a(n) = uniform (10,50);
l(n) = uniform(0.1,10);
u(n) = l(n) + uniform(0,12-l(n));

Variables x(n);
x.l(n) = uniform(l(n), u(n));
b      = sum(n, x.l(n)*a(n));

Variables t(n), z(n), obj;
Equations defobjc, defobj, e1, e2(n), coneqcp(n), coneperfect(n), conenlp(n);

defobjc..          sum(n, d(n)*t(n)) =e= obj;
defobj..           sum(n, d(n)/x(n)) =e= obj;
e1..               sum(n, a(n)*x(n)) =l= b;
coneqcp(n)..       t(n)*x(n) =g= 1;
e2(n)..            z(n) =e= sqrt(2);
coneperfect(n)..   2*x(n)*t(n) =g= sqr(z(n));

Model cqcp     /defobjc, e1, coneqcp/;
Model cperfect /defobjc, e1, e2, coneperfect/;
Model orig     /defobj, e1/;

t.lo(n) = 0;
x.lo(n) = l(n);
x.up(n) = u(n);

Option qcp=cplex;
Solve cqcp min obj using qcp;
Option qcp=mosek;
Solve cperfect min obj using qcp;
Solve orig min obj using nlp;
```

4.37.4.4 Sample Conic Models in GAMS

Conic models in the GAMS model library include:

- [**EMFL**]: A multiple facility location problem,
- [**FDESIGN**]: Linear Phase Lowpass Filter Design,
- [**IMMUN**]: Financial Optimization: Risk Management,
- [**PMEANVAR**]: Mean-Variance Models with variable upper and lower Bounds,
- [**QP7**]: A portfolio investment model using rotated quadratic cones (quadratic program using a Markowitz model),
- [**ROBUSTLP**]: Robust linear programming as an SOCP,
- [**SPRINGCHAIN**]: Equilibrium of System with Piecewise Linear Spring,
- [**TRUSSM**]: Truss Toplogy Design with Multiple Loads

4.37.5 Indicator Constraints

An indicator constraint is a way of expressing relationships between variables by specifying a binary variable to control whether or not a constraint takes effect. For example, indicator constraints are useful in problems where there are fixed charges to express only if a given variable comes into play.

So-called Big M formulations require to estimate an upper bound of an expression in a model. In most cases the model data can be used to determine relatively small number for such coefficients. In some cases it is not possible to find small Big M values and a resulting solution may exhibit trickle flow and have other unwanted side-effects. The main purpose of indicator constraints is to overcome these limitations of Big M formulations. Generally, the use of indicator constraints is not warranted when the unwanted side-effects of Big M formulations are not present.

Consider the following example:

```
constr01.. x1 + x2 + x3 =l= 1e+9*y; // may cause problems
```

Here we use a Big M formulation, that relies on the x values to sum to less than one billion. Note that this formulation may cause numeric instability or undesirable solutions in some situations. Alternatively, we could use an indicator constraint:

```
constr01$(y=0).. x1 + x2 + x3 =l= 0; // alternative
```

Note that y is a binary variable; the logical condition makes sure that the constraint is only active if $y = 0$. Unfortunately, the `$()` expressions do not allow endogenous variables and we need a different way to specify such implications. Indicators are supported by CPLEX, GUROBI, SCIP, and XPRESS.

We should mention a formulation of indicators without the explicit indicator constraints. We can use a SOS1 constraint to express that a constraint holds or not based on a binary variable by having a SOS1 set of a slack variable and the binary variable `SOS1(slack,1-y)`:

```
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack; // alternative
```

Recall that only one of the variables in a SOS1 constraint can be non-zero, so if `1-y` is non-zero (i.e. `y=0`) then `slack` must be zero, i.e. the constraint holds. If `1-y=0` is non-zero, i.e. `y=1` then `slack` can be used to make the constraint feasible for any setting of `x1`, `x2`, and `x3`. Here two unrelated variable, `slack` and `y` are part of an SOS1 constraint and some tricks are required to formulate this properly in GAMS:

```
Set oo / slack, yExpr /;
SOS1 variable indic(oo);
Equation iOn, iOff;
Positive variable slack;
constr01.. x1 + x2 + x3 =l= slack;
iOn..      indic('slack') =e= slack;
iOff..     indic('yExpr') =e= 1-y;
```

4.37.5.1 Indicator Constraints with GAMS

In the remainder of this section we will describe how to specify indicator constraints when using GAMS. Please consult the corresponding solver manual for information on whether indicator constraints are supported and possible differences in their specification.

The example from above will be implemented with a constraint in combination with additional information in a solver option file, e.g. CPLEX: `cplex.opt`:

```
constr01.. x1 + x2 + x3 =l= 0;
```

and the following entry in the option file:

```
indic constr01$y 0
```
