</tbody>
</table>
**advBasis** *(boolean)*: Use advanced basis provided by GAMS

Default: auto

**algAfterCrossover** *(integer)*: Algorithm to be used for the final clean up step after the crossover

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>2</td>
<td>Dual simplex.</td>
</tr>
<tr>
<td>3</td>
<td>Primal simplex.</td>
</tr>
<tr>
<td>4</td>
<td>Concurrent.</td>
</tr>
</tbody>
</table>

**autoPerturb** *(boolean)*: Simplex: Indicates whether automatic perturbation is performed

If this is set to 1, the problem will be perturbed whenever the simplex method encounters an excessive number of degenerate pivot steps, thus preventing the Optimizer being hindered by degeneracies.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No perturbation performed.</td>
</tr>
<tr>
<td>1</td>
<td>Automatic perturbation is performed.</td>
</tr>
</tbody>
</table>

**autoScaling** *(integer)*: Whether the Optimizer should automatically select between different scaling algorithms

If the scaling control is set, no automatic scaling will be applied.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic.</td>

</tr>
<tr>
<td>2</td>
<td>Moderate strategy.</td>
</tr>
<tr>
<td>3</td>
<td>Aggressive strategy. Standard scaling will only be selected if it appears to be clearly superior.</td>
</tr>
</tbody>
</table>

**backTrack** *(integer)*: Branch and Bound: Specifies how to select the next node to work on when a full backtrack is performed

Note When two nodes are rated the same according to the backTrack selection, a secondary rating is performed using the method set by backtrackTie.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>

<tr>
<td>12</td>
<td>Combination of 3 and 4.</td>
</tr>
</tbody>
</table>

**barAlg** *(integer)*: Determines which barrier algorithm is to be used to solve the problem.

The automatic setting uses 1 for LP and QP problems and 3 for QCQP problems. Usually the detection of primal or dual infeasibility is more robust with settings 2 or 3, therefore, it is advantageous to use one of these values if the model is presumably infeasible.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically.</td>
</tr>
<tr>
<td>0</td>
<td>Unused.</td>

</tr>
<tr>
<td>2</td>
<td>Use the homogeneous self-dual barrier algorithm.</td>
</tr>
<tr>
<td>3</td>
<td>Start with 2 and optionally switch to 1 during the execution.</td>
</tr>
</tbody>
</table>
**barCores (integer):** If set to a positive integer it determines the number of physical CPU cores assumed to be present in the system by the barrier algorithm.

- If the value is set to the default value (-1), Xpress will automatically detect the number of cores.
- The control is provided for cross-hardware reproducibility purposes. The count does not include logical cores created by Hyper-Threading.
- Range: \([-1, \ldots, \infty]\)
- Default: `auto`

**barCrash (integer):** Newton barrier: Determines the type of crash used for the crossover.

During the crash procedure, an initial basis is determined which attempts to speed up the crossover. A good choice at this stage will significantly reduce the number of iterations required to crossover to an optimal solution. The possible values increase proportionally to their time-consumption.

Default: 4

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Turns off all crash procedures.</td>
</tr>
<tr>
<td>1–6</td>
<td>Available strategies with 1 being conservative and 6 being aggressive.</td>
</tr>
</tbody>
</table>

**barDualStop (real):** Newton barrier: Convergence parameter, representing the tolerance for dual infeasibilities.

If the difference between the constraints and their bounds in the dual problem falls below this tolerance in absolute value, optimization will stop and the current solution will be returned.

- Range: \([0, \infty]\)
- Default: `auto`

**barFailIterLimit (integer):** Newton barrier: Maximum number of consecutive iterations that fail to improve the solution in the barrier algorithm.

Default: `auto`

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Maximum number of consecutive barrier iterations allowed without progress.</td>
</tr>
</tbody>
</table>

**barFreeScale (real):** Defines how the barrier algorithm scales free variables.

When using smaller values the barrier algorithm scales free variables more aggressively which can improve performance but may impact numerical stability.

- Range: \([0, \infty]\)
- Default: `1e-06`
**barGapStop** (real): Newton barrier: Convergence parameter, representing the tolerance for the relative duality gap

When the difference between the primal and dual objective function values falls below this tolerance, the Optimizer determines that the optimal solution has been found.

Range: $[0, \infty]$

Default: auto

**barGapTarget** (real): Newton barrier: Target tolerance for the relative duality gap

The barrier algorithm will keep iterating until either barGapTarget is satisfied or until no further improvements are possible. In the latter case, if barGapStop is satisfied, it will declare the problem optimal.

When a solution returned by the barrier algorithm has not converged tightly enough for an application, for example if the dual solution is not accurate enough or crossover is taking too long, setter barGapTarget to a small value often resolves the problem, without the risk of the solve failing due to a complementarity level not being numerically achievable. Typical suggested values can be between 1-10 and 1-18.

Range: $[0, \infty]$

Default: auto

**barIndefLimit** (integer): Newton Barrier: Limits the number of consecutive indefinite barrier iterations that will be performed

The optimizer will try to minimize (resp. maximize) a QP problem even if the Q matrix is not positive (resp. negative) semi-definite. However, the optimizer may detect that the Q matrix is indefinite and this can result in the optimizer not converging. This control specifies how many indefinite iterations may occur before the optimizer stops and reports that the problem is indefinite. It is usual to specify a value greater than one, and only stop after a series of indefinite matrices, as the problem may be found to be indefinite incorrectly on a few iterations for numerical reasons.

Range: $\{1, ..., \infty\}$

Default: 15

**barIterLimit** (integer): Newton barrier: Maximum number of iterations

While the simplex method usually performs a number of iterations which is proportional to the number of constraints (rows) in a problem, the barrier method standardly finds the optimal solution to a given accuracy after a number of iterations which is independent of the problem size. The penalty is rather that the time for each iteration increases with the size of the problem. barIterLimit specifies the maximum number of iterations which will be carried out by the barrier.

Range: $\{0, ..., \infty\}$

Default: 500

**barKernel** (real): Newton barrier: Defines how centrality is weighted in the barrier algorithm

Increasing this parameter may increase the number of iterations, therefore the recommended range is $[1,2]$ and $[-2,-1]$.

Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;=+1.0</td>
<td>Increases the emphasis on centrality when larger value is set.</td>
</tr>
<tr>
<td>&lt;=-1.0</td>
<td>Selects a value adaptively in every iteration from [+1, -barKernel].</td>
</tr>
</tbody>
</table>

**barObjScale** *(real)*: Defines how the barrier scales the objective $\leftrightarrow$

The scaling performed by the barrier is applied on top of any other scaling in the problem and only affects the barrier solve.

Default: **auto**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Let the optimizer decide.</td>
</tr>
<tr>
<td>0</td>
<td>Scale by geometric mean.</td>
</tr>
<tr>
<td>&gt;=0</td>
<td>Scale such that the largest objective coefficient’s largest element does not exceed this number. In quadratic problems, the quadratic diagonal is used as reference values instead of the linear objective.</td>
</tr>
</tbody>
</table>

**barOrder** *(integer)*: Newton barrier: Controls the Cholesky factorization in the Newton-Barrier $\leftrightarrow$

Default: **auto**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Choose automatically.</td>
</tr>
<tr>
<td>1</td>
<td>Minimum degree method. This selects diagonal elements with the smallest number of nonzeros in their rows or columns.</td>
</tr>
<tr>
<td>2</td>
<td>Minimum local fill method. This considers the adjacency graph of nonzeros in the matrix and seeks to eliminate nodes that minimize the creation of new edges.</td>
</tr>
<tr>
<td>3</td>
<td>Nested dissection method. This considers the adjacency graph and recursively seeks to separate it into non-adjacent pieces.</td>
</tr>
</tbody>
</table>

**barOrderThreads** *(integer)*: If set to a positive integer it determines the number of concurrent threads for the sparse matrix ordering algorithm in the Newton-barrier method $\leftrightarrow$

Larger values than **barCores** will be automatically reduced to the value of **barCores**.

Range: \{0, ..., $\infty$\}

Default: **auto**

**barOutput** *(boolean)*: Newton barrier: Level of solution output provided $\leftrightarrow$

Output is provided either after each iteration of the algorithm, or else can be turned off completely by this parameter.

Default: **1**

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No output.</td>
</tr>
<tr>
<td>1</td>
<td>At each iteration.</td>
</tr>
</tbody>
</table>
barPresolveOps (integer): Newton barrier: Controls the Newton-Barrier specific presolve operations

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use standard presolve.</td>
</tr>
<tr>
<td>1</td>
<td>Extra effort is spent in barrier specific presolve.</td>
</tr>
<tr>
<td>2</td>
<td>Do full matrix eliminations (reduce matrix size).</td>
</tr>
</tbody>
</table>

barPrimalStop (real): Newton barrier: Convergence parameter, indicating the tolerance for primal infeasibilities

If the difference between the constraints and their bounds in the primal problem falls below this tolerance in absolute value, the Optimizer will terminate and return the current solution.

Range: $[0, \infty]$  

Default: auto

barRegularize (integer): Determines how the barrier algorithm applies regularization on the KKT system

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically.</td>
</tr>
<tr>
<td>bit 0 = 1</td>
<td>Standard regularization is turned on/off.</td>
</tr>
<tr>
<td>bit 1 = 2</td>
<td>Reduced regularization is turned on/off. This option reduces the perturbation effect of the standard regularization.</td>
</tr>
<tr>
<td>bit 2 = 4</td>
<td>Forces to keep dependent rows in the KKT system.</td>
</tr>
<tr>
<td>bit 3 = 8</td>
<td>Forces to preserve degenerate rows in the KKT system.</td>
</tr>
</tbody>
</table>

barRhsScale (real): Defines how the barrier scales the right hand side

The scaling performed by the barrier is applied on top of any other scaling in the problem and only affects the barrier solve.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Let the optimizer decide.</td>
</tr>
<tr>
<td>0</td>
<td>Scale by geometric mean.</td>
</tr>
<tr>
<td>&gt;=0</td>
<td>Scale such that the largest right hand side coefficient's largest element does not exceed this number.</td>
</tr>
</tbody>
</table>

barStart (integer): Newton barrier: Controls the computation of the starting point for the barrier algorithm

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Uses the available solution for warm-start.</td>
</tr>
<tr>
<td>value</td>
<td>meaning</td>
</tr>
<tr>
<td>-------</td>
<td>---------</td>
</tr>
<tr>
<td>0</td>
<td>Determine automatically.</td>
</tr>
<tr>
<td>1</td>
<td>Uses simple heuristics to compute the starting point based on the magnitudes of the matrix entries.</td>
</tr>
<tr>
<td>2</td>
<td>Uses the pseudoinverse of the constraint matrix to determine primal and dual initial solutions. Less sensitive to scaling and numerically more robust, but in several case less efficient than 1.</td>
</tr>
<tr>
<td>3</td>
<td>Uses the unit starting point for the homogeneous self-dual barrier algorithm.</td>
</tr>
</tbody>
</table>

barStepStop (real): Newton barrier: Convergence parameter, representing the minimal step size

On each iteration of the barrier algorithm, a step is taken along a computed search direction. If that step size is smaller than barStepStop, the Optimizer will terminate and return the current solution.

If the barrier method is making small improvements on barGapStop on later iterations, it may be better to set this value higher, to return a solution after a close approximation to the optimum has been found.

Range: $[0, \infty]$  
Default: $1e^{-16}$

barThreads (integer): If set to a positive integer it determines the number of threads implemented to run the Newton-barrier algorithm

If the value is set to the default value (-1), the threads control will determine the number of threads used.

There is a practical upper limit of 50 on the number of parallel threads the optimizer will create.

Range: \{-1, ..., \infty\}  
Default: auto

basisOut (string): Directs optimizer to output an MPS basis file

In general this option is not used in a GAMS environment, as GAMS maintains basis information for you automatically.

Default: none

bigM (real): Infeasibility penalty used if the "Big M" method is implemented

Range: $[0, \infty]$  
Default: auto

bigMMethod (boolean): Simplex: Whether to use the "Big M" method, or the standard phase I (achieving feasibility) and phase II (achieving optimality)

In the "Big M" method, the objective coefficients of the variables are considered during the feasibility phase, possibly leading to an initial feasible basis which is closer to optimal. The side-effects involve possible round-off errors due to the presence of the "Big M" factor in the problem.

Default: 1
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>For phase I / phase II.</td>
</tr>
<tr>
<td>1</td>
<td>If &quot;Big M&quot; method to be used.</td>
</tr>
</tbody>
</table>

**branchChoice (integer):** Once a global entity has been selected for branching, this control determines which of the branches is solved first \(\rightarrow\)

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Minimum estimate branch first.</td>
</tr>
<tr>
<td>1</td>
<td>Maximum estimate branch first.</td>
</tr>
<tr>
<td>2</td>
<td>If an incumbent solution exists, solve the branch satisfied by that solution first. Otherwise solve the minimum estimate branch first (option 0).</td>
</tr>
<tr>
<td>3</td>
<td>Solve first the branch that forces the value of the branching variable to move farther away from the value it had at the root node. If the branching entity is not a simple variable, solve the minimum estimate branch first (option 0).</td>
</tr>
</tbody>
</table>

**branchDisj (integer):** Branch and Bound: Determines whether the optimizer should attempt to branch on general split disjunctions during the branch and bound search \(\rightarrow\)

Note: Split disjunctions are a special form of disjunctions that can be written as \(\sum_{j} m_{j} x_{j} \leq m_{0} v \sum_{j} m_{j} x_{j} \geq m_{0} + 1\). The split disjunctions created by the optimizer will use a combination of binary or integer variables \(x_{j}\), with integer coefficients \(m_{j}\). Split disjunctions for branching will always be created with a default priority value of 400 instead of the default value of 500 for regular entity branches.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic selection of the strategy.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Cautious strategy. Disjunctive branches will be created only for general integers with a wide range.</td>
</tr>
<tr>
<td>2</td>
<td>Moderate strategy.</td>
</tr>
<tr>
<td>3</td>
<td>Aggressive strategy. Disjunctive branches will be created for both binaries and integers.</td>
</tr>
</tbody>
</table>

**branchStructural (integer):** Branch and Bound: Determines whether the optimizer should search for special structure in the problem to branch on during the branch and bound search \(\rightarrow\)

Structural branches will often involve branching on more than a single global entity at a time. As a result of a structural branch, a parent node could therefore end up with more than two child nodes, unlike the standard single entity branches. Structural branches will always be created with a default priority value of 400 instead of the default value of 500 for regular entity branches.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Enabled.</td>
</tr>
</tbody>
</table>
**breadthFirst** *(integer):* Number of nodes to include in the best-first search before switching to the local first search *(nodeSelection = 4)*

Range: \(\{0, \ldots, \infty\}\)

Default: 11

**cacheSize** *(integer):* Newton Barrier: L2 or L3 (see notes) cache size in kB (kilobytes) of the CPU

On Intel (or compatible) platforms a value of -1 may be used to determine the cache size automatically. If the CPU model is new then the cache size may not be correctly detected by an older release of the software.

Specifying the correct cache size can give a significant performance advantage with the Newton barrier algorithm. If the size is unknown, it is better to specify a smaller size. If the size cannot be determined automatically, a default size of 128kB is assumed. Where present, the L3 cache size should be chosen rather than the L2 cache size. For multi-core CPUs, the cache is shared between a subset of the cores. The Optimizer will divide the cacheSize value by the number of cores sharing the cache if >1 Barrier threads are running. Where the CPU is described as having multiple caches ie. 2x6M then the correct cache size to use is 6M not 12M. Examples: Intel Core 2 Duo E6400 (2M Cache, 2.13GHz), cacheSize=2048 Intel Xeon x5570 (8M Cache, 2.93GHz), cacheSize=8192 Intel Core 2 QX6700 (2x4M Cache, 2.93 GHz), cacheSize=4096 If in doubt, please contact Xpress Support for advice.

Range: \([-1, \ldots, \infty]\)

Default: auto

**choleskyAlg** *(integer):* Newton barrier: Type of Cholesky factorization used

Default: auto

**choleskyTol** *(real):* Newton barrier: Tolerance for pivot elements in the Cholesky decomposition of the normal equations coefficient matrix, computed at each iteration of the barrier algorithm

If the absolute value of the pivot element is less than or equal to **choleskyTol**, it merits special treatment in the Cholesky decomposition process.

Range: \([0, \infty]\)

Default: 1e-15
**concurrentThreads** (*integer*): Determines the number of threads used by the concurrent solver

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Number of threads to use.</td>

<tr>
<td>3</td>
<td>Aggressive application of conflict cuts.</td>
</tr>
</tbody>
</table>

**coresPerCpu** (*integer*): Used to override the detected value of the number of cores on a CPU

The cache size (either detected or specified via the `cacheSize` control) used in Barrier methods will be divided by this amount, and this scaled-down value will be the amount of cache allocated to each Barrier thread.

Range: {-1, ..., ∞}

Default: auto

**coverCuts** (*integer*): Branch and Bound: Number of rounds of lifted cover inequalities at the top node

A lifted cover inequality is an additional constraint that can be particularly effective at reducing the size of the feasible region without removing potential integral solutions. The process of generating these can be carried out a number of times, further reducing the feasible region, albeit incurring a time penalty. There is usually a good payoff from generating these at the top node, since these inequalities then apply to every subsequent node in the tree search.

Range: {-1, ..., ∞}

Default: auto

**cpuPlatform** (*integer*): Newton Barrier: Selects the AMD or Intel x86 vectorization instruction set that Barrier should run optimized code for

Generic code, SSE2 and AVX optimized code will all result in the same solution path. Using AVX2 might result in a different solution path.

Default: -1
**value** | **meaning**
--- | ---
-2 | Highest supported [Generic, SSE2, AVX or AVX2].
-1 | Highest supported solve path consistent code [Generic, SSE2 or AVX].
0 | Use generic code compatible with all CPUs.
1 | Use SSE2 optimized code.
2 | Use AVX optimized code.
3 | Use AVX2 optimized code.

**cpuTime** *(integer)*: How time should be measured when timings are reported in the log and when checking against time limits

Default: 0

---

**value** | **meaning**
--- | ---
-1 | Disable the timer.
0 | Use elapsed time.
1 | Use process time.

**crash** *(integer)*: Simplex: Determines the type of crash used when the algorithm begins (only relevant when no advanced basis is available)

During the crash procedure, an initial basis is determined which is as close to feasibility and triangularity as possible. A good choice at this stage will significantly reduce the number of iterations required to find an optimal solution. The possible values increase proportionally to their time-consumption.

Default: 2

---

**value** | **meaning**
--- | ---
0 | Turns off all crash procedures.
1 | For singletons only (one pass).
2 | For singletons only (multi pass).
3 | Multiple passes through the matrix considering slacks.
4 | Multiple (≤ 10) passes through the matrix but only doing slacks at the very end.
\(n > 10\) | As for value 4 but performing at most \(n - 10\) passes.

**crossover** *(integer)*: Newton barrier: Determines whether the barrier method will cross over to the simplex method when at optimal solution has been found, to provide an end basis and advanced sensitivity analysis information

The full primal and dual solution is available whether or not crossover is used. The crossover must not be disabled if the barrier is used to reoptimize nodes of a MIP. By default crossover will not be performed on QP and MIQP problems.

Default: auto

---

**value** | **meaning**
--- | ---
-1 | Determined automatically.
0 | No crossover.
1 | Primal crossover first.
2 | Dual crossover first.
**crossoverAccuracyTol** *(real):* Newton barrier: Determines how crossover adjusts the default relative pivot tolerance

When re-inversion is necessary, crossover will compare the recalculated working basic solution with the assumed ones just before re-inversion took place. If the error is above this threshold, crossover will adjust the relative pivot tolerance to address the build-up of numerical inaccuracies.

The full primal and dual solution is available whether or not crossover is used. The crossover must not be disabled if the barrier is used to reoptimize nodes of a MIP. By default crossover will not be performed on QP and MIQP problems.

Range: \([0, \infty]\)

Default: \(1e-06\)

**crossoverIterLimit** *(integer):* Newton barrier: Maximum number of iterations that will be performed in the crossover procedure before the optimization process terminates

Range: \(\{0, ..., \infty\}\)

Default: \(2147483647\)

**crossoverOps** *(integer):* Newton barrier: Bit vector for adjusting the behavior of the crossover procedure

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Returned solution when the crossover terminates prematurely: 0: Return the last basis from the crossover; 1: Return the barrier solution.</td>
</tr>
<tr>
<td>bit 1 = 2</td>
<td>Select the crossover stages to be performed: 0: Perform both crossover stages; 1: Skip second crossover stage.</td>
</tr>
<tr>
<td>bit 2 = 4</td>
<td>Set crossover behaviour: 0: Force to perform all pivots; 1: Skip pivots that are numerically less reliable.</td>
</tr>
<tr>
<td>bit 3 = 8</td>
<td>Set crossover behaviour: 0: Perform standard crossover; 1: Perform a slower, but numerically more careful crossover.</td>
</tr>
</tbody>
</table>

**crossoverThreads** *(integer):* Determines the maximum number of threads that parallel crossover is allowed to use

If **crossoverThreads** is set to the default value (-1), the **barThreads** control will determine the number of threads used.

Range: \(\{-1, ..., \infty\}\)

Default: **auto**

**cutDepth** *(integer):* Branch and Bound: Sets the maximum depth in the tree search at which cuts will be generated

Generating cuts can take a lot of time, and is often less important at deeper levels of the tree since tighter bounds on the variables have already reduced the feasible region. A value of 0 signifies that no cuts will be generated.

Does not affect cutting on the root node.

Range: \(\{-1, ..., \infty\}\)

Default: **auto**
**cutFactor** *(real)*: Limit on the number of cuts and cut coefficients the optimizer is allowed to add to the matrix during global search →

The cuts and cut coefficients are limited by cutFactor times the number of rows and coefficients in the initial matrix.

A value of 0.0 prevents cuts from being added, and a value of e.g. 1.0 will allow the problem to grow to twice the initial number of rows and coefficients.

Default: *auto*

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Let the optimizer decide on the maximum amount of cuts based on cutStrategy.</td>
</tr>
<tr>
<td>&gt;=0</td>
<td>Multiple of number of rows and coefficients to use.</td>
</tr>
</tbody>
</table>

**cutFreq** *(integer)*: Branch and Bound: Frequency at which cuts are generated in the tree search →

If the depth of the node modulo cutFreq is zero, then cuts will be generated.

Range: {-1, ..., ∞}

Default: *auto*

**cutSelect** *(integer)*: Bit vector providing detailed control of the cuts created for the root node of a global solve →

Use treeCutSelect to control cuts during the tree search.

The default value is -1 which enables all bits. Any bits not listed in the above table should be left in their default 'on' state, since the interpretation of such bits might change in future versions of the optimizer.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tr>
</tbody>
</table>

**cutSelect_clique** *(boolean)*: Clique cuts →

See also cutSelect.

Default: 1
cutSelect_cover (boolean): Lifted cover cuts

See also cutSelect.

Default: 1

cutSelect_disableCutRows (boolean): Disable cutting from cut rows

See also cutSelect.

Default: 1

cutSelect_flowpath (boolean): Flow path cuts

See also cutSelect.

Default: 1

cutSelect_gubCover (boolean): Lifted GUB cover cuts

See also cutSelect.

Default: 1

cutSelect_implication (boolean): Implication cuts

See also cutSelect.

Default: 1

cutSelect_indicator (boolean): Indicator constraint cuts

See also cutSelect.

Default: 1

cutSelect_liftAndProject (boolean): Turn on automatic Lift-and-Project cutting strategy

See also cutSelect.

Default: 1

cutSelect_mir (boolean): Mixed Integer Rounding (MIR) cuts

See also cutSelect.

Default: 1

cutSelect_mirRowAggregation (boolean): Turn on row aggregation for MIR cuts

See also cutSelect.

Default: 1

cutSelect_zeroHalf (boolean): Zero-half cuts

See also cutSelect.

Default: 1

cutStrategy (integer): Branch and Bound: Cut strategy

A more aggressive cut strategy, generating a greater number of cuts, will result in fewer nodes
to be explored, but with an associated time cost in generating the cuts. The fewer cuts
generated, the less time taken, but the greater subsequent number of nodes to be explored.

Default: auto
**defaultAlg** *(integer)*: Selects the algorithm that will be used to solve the LP

Please note that this will affect how the MIP node LP problems are solved during the global search.

Default: *auto*

<table>
<thead>
<tr>
<th>value</th>

</tbody>
</table>

dualizeOps (boolean): Bit-vector control for adjusting the behavior when a problem is dualized

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Swap the simplex algorithm to run. If dual simplex is selected for the original problem then primal simplex will be run on the dualized problem, and similarly if primal simplex is selected.</td>
</tr>
</tbody>
</table>

dualPerturb (real): Factor by which the problem will be perturbed prior to optimization by dual simplex

A value of 0.0 results in no perturbation prior to optimization. Note the interconnection to the autoPerturb control. If autoPerturb is set to 1, the decision whether to perturb or not is left to the Optimizer. When the problem is automatically perturbed in dual simplex, however, the value of dualPerturb will be used for perturbation.

Range: \([-\infty, \infty]\)

Default: auto

dualStrategy (integer): Bit-vector control specifies the dual simplex strategy

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Switch to primal when re-optimization goes dual infeasible and numerically unstable.</td>
</tr>
<tr>
<td>bit 1 = 2</td>
<td>When dual intend to switch to primal, stop the solve instead of switching to primal.</td>
</tr>
<tr>
<td>bit 2 = 4</td>
<td>Use more aggressive cut-off in MIP search.</td>
</tr>
<tr>
<td>bit 3 = 8</td>
<td>Use dual simplex to remove cost perturbations.</td>
</tr>
<tr>
<td>bit 4 = 16</td>
<td>Enable more aggressive dual pivoting strategy.</td>
</tr>
<tr>
<td>bit 5 = 32</td>
<td>Keep using dual simplex even when it’s numerically unstable.</td>
</tr>
</tbody>
</table>

dualThreads (integer): Determines the maximum number of threads that dual simplex is allowed to use

If dualThreads is set to the default value (-1), the threads control will determine the number of threads used.

When solving a linear MIP, the dual simplex algorithm will use multiple threads only when solving the initial LP relaxation or when reoptimizing between rounds of cuts on the root
node. The parallel dual simplex algorithm differs from the sequential dual simplex algorithm and might follow a different solve path. For `dualThreads > 1` the solve path is independent of the number of threads used, although the practical limit for observing performance benefits is around `dualThreads = 8`.

Range: `{−1, ..., ∞}`

Default: `auto`

eigenvalueTol (real): Quadratic matrix is considered not to be positive semi-definite, if its smallest eigenvalue is smaller than the negative of this value ←

Range: `[0, ∞]`

Default: `1e-06`

elimFillin (integer): Amount of fill-in allowed when performing an elimination in presolve ←

Range: `{0, ..., ∞}`

Default: `10`

elimTol (real): Markowitz tolerance for the elimination phase of the presolve ←

Range: `[0, ∞]`

Default: `0.001`

etaTol (real): Tolerance on eta elements ←

During each iteration, the basis inverse is premultiplied by an elementary matrix, which is the identity except for one column - the eta vector. Elements of eta vectors whose absolute value is smaller than `etaTol` are taken to be zero in this step.

Range: `[0, ∞]`

Default: `1e-13`

feasibilityPump (integer): Branch and Bound: Decides if the Feasibility Pump heuristic should be run at the top node ←

Default: `auto`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>−1</td>
<td>Automatic.</td>
</tr>
<tr>
<td>0</td>
<td>Turned off.</td>
</tr>
<tr>
<td>1</td>
<td>Always try the Feasibility Pump.</td>
</tr>
<tr>
<td>2</td>
<td>Try the Feasibility Pump only if other heuristics have failed to find an integer solution.</td>
</tr>
</tbody>
</table>

feasTol (real): Determines when a solution is treated as feasible ←

If the amount by which a constraint’s activity violates its right-hand side or ranged bound is less in absolute magnitude than `feasTol`, then the constraint is treated as satisfied. Similarly, if the amount by which a column violates its bounds is less in absolute magnitude than `feasTol`, those bounds are also treated as satisfied.
Range: \([0, \infty]\)

Default: \(1e^{-06}\)

\textbf{feasTolPerturb} \textit{(real)}: Determines how much a feasible primal basic solution is allowed to be perturbed when performing basis changes ⍟

The tolerance \textit{feasTol} is always considered as an upper limit for the perturbations, but in some cases smaller value can be more desirable.

Range: \([0, \infty]\)

Default: \(1e^{-06}\)

\textbf{feasTolTarget} \textit{(real)}: Target feasibility tolerance for the solution refiner ⍟

Zero and negative values are ignored, and the value of \textit{feasTol} is used.

Use very small values like \(1e-100\) to state the refinement should continue as long as an improvement is made. Use very large values like \(1e+100\) to disable only this aspect of the refiner.

Range: \([-\infty, \infty]\)

Default: 0

\textbf{forceParallelDual} \textit{(boolean)}: Dual simplex: Specifies whether the dual simplex solver should always use the parallel simplex algorithm ⍟

By default, when using a single thread, the dual simplex solver will execute a dedicated sequential simplex algorithm.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Enabled. Force the dual simplex solver to use the parallel algorithm.</td>
</tr>
</tbody>
</table>

\textbf{genConsDualReductions} \textit{(boolean)}: Parameter specifies whether dual reductions should be applied to reduce the number of columns and rows added when transforming general constraints to MIP structs ⍟

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disabled. No dual reductions, add columns and rows.</td>
</tr>
<tr>
<td>1</td>
<td>Enabled. Only add necessary columns and rows, drop those implied by the objective sense.</td>
</tr>
</tbody>
</table>

\textbf{gomCuts} \textit{(integer)}: Branch and Bound: Number of rounds of Gomory or lift-and-project cuts at the top node ⍟

Range: \([-1, ..., \infty]\)

Default: \textit{auto}
heurBeforeLp (integer): Branch and Bound: Determines whether primal heuristics should be run before the initial LP relaxation has been solved

It is possible that a heuristic will find an optimal integer solution that will result in the LP relaxation solution being cut off. If dedicated heuristic threads are enabled through the heurThreads control, then the initial heuristics will be run in parallel with the LP solve, instead of before.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic - let the optimizer decide if heuristics should be run.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Enabled.</td>
</tr>
</tbody>
</table>

heurDiveIterLimit (real): Branch and Bound: Simplex iteration limit for reoptimizing during the diving heuristic

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No iteration limit.</td>
</tr>
<tr>
<td>&gt;1</td>
<td>Fixed iteration limit.</td>
</tr>
<tr>
<td>&lt;0</td>
<td>Automatic selection of the iteration limit based on the problem size. The absolute value is used as a multiplier on the automatic selection.</td>
</tr>
</tbody>
</table>

heurDiveRandomize (real): Level of randomization to apply in the diving heuristic

The diving heuristic uses priority weights on rows and columns to determine the order in which to e.g. round fractional columns, or the direction in which to round them. This control determines by how large a random factor these weights should be changed.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0-1.0</td>
<td>Amount of randomization (0.0=none, 1.0=full)</td>
</tr>
</tbody>
</table>

heurDiveSoftRounding (integer): Branch and Bound: Enables a more cautious strategy for the diving heuristic, where it tries to push binaries and integer variables to their bounds using the objective, instead of directly fixing them

This can be useful when the default diving heuristics fail to find any feasible solutions.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic selection.</td>
</tr>
<tr>
<td>0</td>
<td>Do not use soft rounding.</td>
</tr>
<tr>
<td>1</td>
<td>Cautious use of the soft rounding strategy.</td>
</tr>
<tr>
<td>2</td>
<td>More aggressive use of the soft rounding strategy.</td>
</tr>
</tbody>
</table>
heurDiveSpeedUp (integer): Branch and Bound: Changes the emphasis of the diving heuristic from solution quality to diving speed

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Automatic selection biased towards quality</td>
</tr>
<tr>
<td>-1</td>
<td>Automatic selection biased towards speed.</td>
</tr>
<tr>
<td>0–4</td>
<td>Manual emphasis bias from emphasis on quality (0) to emphasis on speed (4).</td>
</tr>
</tbody>
</table>

heurDiveStrategy (integer): Branch and Bound: Chooses the strategy for the diving heuristic

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic selection of strategy.</td>
</tr>
<tr>
<td>0</td>
<td>Disables the diving heuristic.</td>
</tr>
<tr>
<td>1–18</td>
<td>Available pre-set strategies for rounding infeasible global entities and reoptimizing during the heuristic dive.</td>
</tr>
</tbody>
</table>

heurForceSpecialObj (boolean): Branch and Bound: Whether local search heuristics without objective or with an auxiliary objective should always be used, despite the automatic selection of the Optimizer

By default, they will only be run on small problems and when no solution has been found yet.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Enabled. Run special objective heuristics on large problems and even if incumbent exists.</td>
</tr>
</tbody>
</table>

heurFreq (integer): Branch and Bound: Frequency at which heuristics are used in the tree search

Heuristics will only be used at a node if the depth of the node is a multiple of heurFreq.

Range: \{−1, ..., ∞\}

Default: -1

heurSearchEffort (real): Adjusts the overall level of the local search heuristics

heurSearchEffort is used as a multiplier on the default amount of work the local search heuristics should do. A higher value means the local search heuristics will be run more often and that they are allowed to search larger neighborhoods.

Range: [0, ∞]

Default: 1

heurSearchFreq (integer): Branch and Bound: How often the local search heuristic should be run in the tree

Default: auto
**heurSearchRootCutFreq** (*integer*): How frequently to run the local search heuristic during root cutting

This is given as how many cut rounds to perform between runs of the heuristic. Set to zero to avoid applying the heuristic during root cutting. Branch and Bound: This specifies how often the local search heuristic should be run in the tree.

Default: `auto`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled in the tree.</td>
</tr>
<tr>
<td>n&gt;0</td>
<td>Number of nodes between each run.</td>
</tr>
</tbody>
</table>

**heurSearchRootSelect** (*integer*): Bit vector control for selecting which local search heuristics to apply on the root node of a global solve

Use **heurSearchTreeSelect** to control local search heuristics during the tree search.

Some of the local search heuristics will benefit from having an existing incumbent solution, but it is not required.

Default: `117`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Local search with a large neighborhood. Potentially slow but is good for finding solutions that differs significantly from the incumbent.</td>
</tr>
<tr>
<td>bit 1 = 2</td>
<td>Local search with a small neighborhood centered around a node LP solution.</td>
</tr>
<tr>
<td>bit 2 = 4</td>
<td>Local search with a small neighborhood centered around an integer solution. This heuristic will often provide smaller, incremental improvements to an incumbent solution.</td>
</tr>
<tr>
<td>bit 3 = 8</td>
<td>Local search with a neighborhood set up through the combination of multiple integer solutions.</td>
</tr>
<tr>
<td>bit 4 = 16</td>
<td>Unused</td>
</tr>
<tr>
<td>bit 5 = 32</td>
<td>Local search without an objective function. Called seldom and only when no feasible solution is available.</td>
</tr>
<tr>
<td>bit 6 = 64</td>
<td>Local search with an auxiliary objective function. Called seldom and only when no feasible solution is available.</td>
</tr>
</tbody>
</table>

**heurSearchTreeSelect** (*integer*): Bit vector control for selecting which local search heuristics to apply during the tree search of a global solve

Use **heurSearchRootSelect** to control local search heuristics on the root node.

Some of the local search heuristics will benefit from having an existing incumbent solution, but it is not required.

Default: `17`
value | meaning
---|---
bit 0 = 1 | Local search with a large neighborhood. Potentially slow but is good for finding solutions that differs significantly from the incumbent.
bit 1 = 2 | Local search with a small neighborhood centered around a node LP solution.
bit 2 = 4 | Local search with a small neighborhood centered around an integer solution. This heuristic will often provide smaller, incremental improvements to an incumbent solution.
bit 3 = 8 | Local search with a neighborhood set up through the combination of multiple integer solutions.
bit 4 = 16 | Unused
bit 5 = 32 | Local search without an objective function. Called seldom and only when no feasible solution is available.
bit 6 = 64 | Local search with an auxiliary objective function. Called seldom and only when no feasible solution is available.

**heurStrategy (integer):** Branch and Bound: Heuristic strategy

On some problems it is worth trying more comprehensive heuristic strategies by setting `heurStrategy` to 2 or 3.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>

</tbody>
</table>

**heurThreads (integer):** Branch and Bound: Number of threads to dedicate to running heuristics on the root node

When heuristic threads are enabled, the heuristics will be run in parallel with the initial LP solve, if possible, and in parallel with the root cutting.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined from the <code>threads</code> control.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled. Heuristics will be run sequentially with the root LP solve and cutting.</td>
</tr>
<tr>
<td>&gt;=1</td>
<td>Number of root threads to dedicate to parallel heuristics.</td>
</tr>
</tbody>
</table>

**historyCosts (integer):** Branch and Bound: How to update the pseudo cost for a global entity when a strong branch or a regular branch is applied

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>No update.</td>

</tr>
</tbody>
</table>

**ifCheckConvexity** *(boolean)*: Determines if the convexity of the problem is checked before optimization

Applies to quadratic, mixed integer quadratic and quadratically constrained problems. Checking convexity takes some time, thus for problems that are known to be convex it might be reasonable to switch the checking off.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Turn off convexity checking.</td>
</tr>
<tr>
<td>1</td>
<td>Turn on convexity checking.</td>
</tr>
</tbody>
</table>

**indLinBigM** *(real)*: Indicator constraints can be internally converted to regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value

Range: \([0, \infty]\)

Default: 100000

**indPreLinBigM** *(real)*: During presolve, indicator constraints can be internally replaced with regular rows (i.e. linearized) using a BigM coefficient whenever the BigM coefficient is smaller or equal to this value

Replacing an indicator constraint with a BigM row has a side effect on tolerances. In the indicator constraint form, the constraint part is satisfied with feasTol tolerance; while after changing it to BigM form, the constraint also includes the binary indicator variable (with a coefficient up to indPreLinBigM and an integrality tolerance of mipTol), therefore the constraint part of the indicator contraint is satisfied with tolerance feasTol+mipTol*indPreLinBigM.

Range: \([0, \infty]\)

Default: 100

**invertFreq** *(integer)*: Simplex: Frequency with which the basis will be inverted

The basis is maintained in a factorized form and on most simplex iterations it is incrementally updated to reflect the step just taken. This is considerably faster than computing the full inverted matrix at each iteration, although after a number of iterations the basis becomes less well-conditioned and it becomes necessary to compute the full inverted matrix. The value of invertFreq specifies the maximum number of iterations between full inversions.

Range: \([-1, ..., \infty]\)

Default: auto

**invertMin** *(integer)*: Simplex: Minimum number of iterations between full inversions of the basis matrix
See the description of `invertFreq` for details.

Range: \( \{0, \ldots, \infty\} \)

Default: 3

**knitroOptFile** *(string)*: Option file for NLP solver KNITRO

Syonym: `slpKnitroOptFile`

**l1Cache** *(integer)*: Newton barrier: L1 cache size in kB (kilo bytes) of the CPU

On Intel (or compatible) platforms a value of -1 may be used to determine the cache size automatically.

Specifying the correct L1 cache size can give a significant performance advantage with the Newton barrier algorithm. If the size is unknown, it is better to specify a smaller size. If the size cannot be determined automatically on Intel (or compatible) platforms, a default size of 8 kB is assumed.

Range: \( \{-1, \ldots, \infty\} \)

Default: `auto`

**lnpBest** *(integer)*: Number of infeasible global entities to create lift-and-project cuts for during each round of Gomory cuts at the top node (see `gomCuts`)

Range: \( \{0, \ldots, \infty\} \)

Default: 50

**lnpIterLimit** *(integer)*: Number of iterations to perform in improving each lift-and-project cut

By setting the number to zero a Gomory cut will be created instead.

Range: \( \{-1, \ldots, \infty\} \)

Default: `auto`

**loadMipSol** *(boolean)*: Loads a MIP solution (the initial point)

If true, the initial point provided by GAMS will be passed to the optimizer to be treated as an integer feasible point. The optimizer uses the values for the discrete variables only: the level values for the continuous variables are ignored and are calculated by fixing the integer variables and reoptimizing. In some cases, loading an initial MIP solution can improve performance. In addition, there will always be a feasible solution to return.

Default: 0

**localChoice** *(integer)*: Controls when to perform a local backtrack between the two child nodes during a dive in the branch and bound tree

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Never backtrack from the first child, unless it is dropped (infeasible or cut off).</td>
</tr>
<tr>
<td>2</td>
<td>Always solve both child nodes before deciding which child to continue with.</td>
</tr>
<tr>
<td>3</td>
<td>Automatically determined.</td>
</tr>
</tbody>
</table>
lpFlags (integer): Bit-vector control which defines the algorithm for solving an LP problem or the initial LP relaxation of a MIP problem

When more than one bit is set, then the LP problem will be solved with the concurrent solver. When this control and algorithm is set at the same time, algorithm will overrule the value of this control.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Equivalent to lpFlags_dual.</td>
</tr>
<tr>
<td>bit 1 = 2</td>
<td>Equivalent to lpFlags_primal.</td>
</tr>
<tr>
<td>bit 2 = 4</td>
<td>Equivalent to lpFlags_barrier.</td>
</tr>
<tr>
<td>bit 3 = 8</td>
<td>Equivalent to lpFlags_network.</td>
</tr>
</tbody>
</table>

lpFlags_barrier (boolean): Use the barrier method

See also lpFlags.

Default: 0

lpFlags_dual (boolean): Use the dual simplex method

See also lpFlags.

Default: 0

lpFlags_network (boolean): Use the network simplex method

See also lpFlags.

Default: 0

lpFlags_primal (boolean): Use the primal simplex method

See also lpFlags.

Default: 0

lpFolding (integer): Simplex and barrier: Whether to fold an LP problem before solving it

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic.</td>
</tr>
<tr>
<td>0</td>
<td>Disable LP folding.</td>
</tr>
<tr>
<td>1</td>
<td>Enable LP folding. Attempt to fold all LP problems and MIP initial relaxations.</td>
</tr>
</tbody>
</table>

lpIterLimit (integer): Maximum number of iterations that will be performed by primal simplex or dual simplex before the optimization process terminates

Synonym: iterlim
For MIP problems, this is the maximum total number of iterations over all nodes explored by
the Branch and Bound method.

Range: \{0, ..., \infty\}

Default: maxint

**lpLog** (integer): Simplex: Frequency at which the simplex log is printed

This control only has an effect if **lpLogStyle** is set to 0.

Default: 100

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Log displayed at the end of the optimization only.</td>
</tr>
<tr>
<td>n&lt;0</td>
<td>Detailed output every - n iterations.</td>
</tr>
<tr>
<td>n&gt;0</td>
<td>Summary output every n iterations.</td>
</tr>
</tbody>
</table>

**lpLogDelay** (real): Time interval between two LP log lines

This control only has an effect if **lpLogStyle** is set to 1.

Range: \([0, \infty]\)

Default: 1

**lpLogStyle** (boolean): Simplex: Style of the simplex log

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Simplex log is printed based on simplex iteration count, at a fixed frequency as specified by the <strong>lpLog</strong> control.</td>
</tr>
<tr>
<td>1</td>
<td>Simplex Log is printed based on an estimation of elapsed time, determined by an internal deterministic timer.</td>
</tr>
</tbody>
</table>

**lpRefineIterLimit** (integer): Simplex iteration limit the solution refiner can spend in attempting to increase the accuracy of an LP solution

The solution refiner iteratively attempts to increase the accuracy of the solution until either both **feasTolTarget** and **optimalityTolTarget** is satisfied, or accuracy cannot further be increased, or the effort limit determined by **lpRefineIterLimit** is exhausted.

Range: \{-1, ..., \infty\}

Default: auto

**markowitzTol** (real): Markowitz tolerance used for the factorization of the basis matrix

Range: \([0, \infty]\)

Default: 0.01

**matrixTol** (real): Zero tolerance on matrix elements
If the value of a matrix element is less than or equal to \texttt{matrixTol} in absolute value, it is treated as zero.

Range: \([0, \infty]\)

Default: \(1e-09\)

\textbf{maxCutTime} (\textit{integer}): Maximum amount of time allowed for generation of cutting planes and reoptimization \leftarrow

The limit is checked during generation and no further cuts are added once this limit has been exceeded.

Default: 0

\begin{table}[h]
\begin{tabular}{|c|l|}
\hline
\textbf{value} & \textbf{meaning} \\
\hline
0 & No time limit. \\
\textit{n}>0 & Stop cut generation after \(n\) seconds. \\
\hline
\end{tabular}
\end{table}

\textbf{maxImpliedBound} (\textit{real}): Presolve: When tighter bounds are calculated during MIP preprocessing, only bounds whose absolute value are smaller than \texttt{maxImpliedBound} will be applied to the problem \leftarrow

For numerically challenging MIP problems, it can sometimes help make the solve more stable by reducing the value of \texttt{maxImpliedBound} to something smaller - e.g. 1.0E+06. It is not recommended to increase this parameter beyond the default of 1.0E+08.

Range: \([0, \infty]\)

Default: \(1e+08\)

\textbf{maxLocalBacktrack} (\textit{integer}): Branch-and-Bound: How far back up the current dive path the optimizer is allowed to look for a local backtrack candidate node \leftarrow

If this control is set to \(k\), then the candidate set of nodes for a local backtrack will consist of all active nodes in the subtree rooted at height \(k\) above the current node. For example, a setting of 1 will result in only sibling nodes of the current node being considered.

Range: \([-1, ..., \infty]\)

Default: \(-1\)

\textbf{maxMemoryHard} (\textit{integer}): Sets the maximum amount of memory in megabytes the optimizer should allocate \leftarrow

If this limit is exceeded, the solve will terminate. This control is designed to make the optimizer stop in a controlled manner, so that the problem object is valid once termination occurs. The solve state will be set to incomplete. This is different to an out of memory condition in which case the optimizer returns an error. The optimizer may still allocate memory once the limit is exceeded to be able to finish the operations and stop in a controlled manner. When \texttt{resourceStrategy} is enabled, the control also has the same effect as \texttt{maxMemorySoft} and will cause the optimizer to try preserving memory when possible.

Range: \(\{0, ..., \infty\}\)

Default: \textit{unlimited}
**maxMemorySoft** *(integer):* When `resourceStrategy` is enabled, this control sets the maximum amount of memory in megabytes the optimizer targets to allocate ←

This may change the solving path, but will not cause the solve to terminate early. To set a hard version of the same, please set `maxMemoryHard`.

Range: \{0, ..., \infty\}

Default: unlimited

**maxMipSol** *(integer):* Branch and Bound: Limit on the number of integer solutions to be found by the Optimizer ←

It is possible that during optimization the Optimizer will find the same objective solution from different nodes. However, `maxMipSol` refers to the total number of integer solutions found, and not necessarily the number of distinct solutions.

Setting `maxMipSol=1` can alter the solution path as this will put the emphasis on finding any feasible solution by triggering additional heuristics.

Range: \{0, ..., \infty\}

Default: 0

**maxMipTasks** *(integer):* Branch-and-Bound: The maximum number of tasks to run in parallel during a MIP solve ←

The MIP solver will create smaller tasks from individual active nodes or based on local search heuristics. These are tasks that will be executed in parallel by the number of threads set by `mipThreads`.

If `maxMipTasks` is set to a fixed, positive value, the branch-and-bound tree nodes will always be solved in the same deterministic way, independent of the actual number of executing threads implied by `mipThreads`. How a MIP is solved will still depend on the number of threads used for solving the continuous relaxation and therefore on the settings for the controls `barThreads`, `dualThreads` and `concurrentThreads`). To obtain a MIP solve that is completely independent of the number of threads, it is sufficient to set `maxMipTasks`, `forceParallelDual` and `barThreads`. The concurrent LP solver should be avoided in this case.

The number of MIP tasks that can be defined for a 32-bit system is limited to 32 for performance reasons.

Default: *auto*

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Task limit determined automatically from <code>mipThreads</code>.</td>
</tr>
<tr>
<td>&gt;0</td>
<td>Fixed task limit.</td>
</tr>
</tbody>
</table>

**maxNode** *(integer):* Branch and Bound: Maximum number of nodes that will be explored ←

Range: \{0, ..., \infty\}

Default: `maxint`

**maxScaleFactor** *(integer):* Determines the maximum scaling factor that can be applied during scaling ←
The maximum is provided as an exponent of a power of 2.

Default: 64
maxTime (integer): Maximum time in seconds that the Optimizer will run before it terminates, including the problem setup time and solution time

For MIP problems, this is the total time taken to solve all the nodes.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No time limit.</td>
</tr>
<tr>
<td>n&lt;0</td>
<td>Stop in LP or MIP search after n seconds.</td>
</tr>
<tr>
<td>n&gt;0</td>
<td>If an integer solution has been found, stop MIP search after n seconds, otherwise continue until an integer solution is finally found.</td>
</tr>
</tbody>
</table>

mipAbsCutoff (real): Branch and Bound: If the user knows that they are interested only in values of the objective function which are better than some value, this can be assigned to mipAbsCutoff

Synonym: cutoff

This allows the Optimizer to ignore solving any nodes which may yield worse objective values, saving solution time.

Range: [-∞, ∞]

Default: auto

mipAbsStop (real): Branch and Bound: Absolute tolerance determining whether the global search will continue or not

It will terminate if | MIPOBJVAL - BESTBOUND | ≤ mipAbsStop where MIPOBJVAL is the value of the best solution’s objective function, and BESTBOUND is the current best solution bound. For example, to stop the global search when a MIP solution has been found and the Optimizer can guarantee it is within 100 of the optimal solution, set mipAbsStop to 100.

Range: [0, ∞]

Default: 0

mipAddCutoff (real): Branch and Bound: Amount to add to the objective function of the best integer solution found to give the new CURRMIPCUTOFF

Once an integer solution has been found whose objective function is equal to or better than CURRMIPCUTOFF, improvements on this value may not be interesting unless they are better by at least a certain amount. If mipAddCutoff is nonzero, it will be added to CURRMIPCUTOFF each time an integer solution is found which is better than this new value. This cuts off sections of the tree whose solutions would not represent substantial improvements in the objective function, saving processor time. The control mipAbsStop provides a similar function but works in a different way.

Range: [-∞, ∞]

Default: -1e-05
mipCleanup (boolean): Clean up the MIP solution (round-fix-solve) to get duals

If nonzero, clean up the integer solution obtained, i.e. round and fix the discrete variables and re-solve as an LP to get some marginal values for the discrete vars.

Default: 1

mipDualReductions (integer): Branch and Bound: Limits operations that can reduce the MIP solution space

The mipDualReductions control, when set to a value different from 1 will adjust the values of other controls in order to prevent MIP solver operations that can result in the removal of dominated solutions. For example, dual reductions during preprocessing attempts to remove dominated solutions based on objective arguments, assuming that all constraints are known to the Optimizer. If a problem is detected to have symmetries, the solver might also remove some symmetrical solutions from the search space. In both cases, the set of feasible MIP solutions might be reduced. With default settings, it is only guaranteed that at least one optimal solution remains.

When attempting to collect the n-best solutions, it is recommended to set mipDualReductions=2. This will ensure that the only solutions missed by the enumeration are those that only differ from an existing solution in the values of the continuous variables.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Prevent all dual reductions.</td>
</tr>
<tr>
<td>1</td>
<td>Allow all dual reductions.</td>
</tr>
<tr>
<td>2</td>
<td>Allow dual reductions on continuous variables only.</td>
</tr>
</tbody>
</table>

mipFracReduce (integer): Branch and Bound: Specifies how often the optimizer should run a heuristic to reduce the number of fractional integer variables in the node LP solutions

This heuristic is only applicable to problems that are dual degenerate. These are problems that contain multiple solutions with identical objective function value. The more dual degenerate a problem is, the more likely it will be for this heuristic to have an improving effect.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Run before and after cutting on the root node.</td>
</tr>
<tr>
<td>2</td>
<td>Run also during root cutting.</td>
</tr>
<tr>
<td>3</td>
<td>Run also during the tree search.</td>
</tr>
</tbody>
</table>

mipKappaFreq (integer): Branch and Bound: Specifies how frequently the basis condition number (also known as kappa) should be calculated during the branch-and-bound search

The condition number is calculated as the norm of the basis matrix multiplied by the norm of its inverse. This uses the Froebenius norm.

A summary will be printed at the end of the solve, summarizing the collected condition numbers collected:
- Nodes kappa stable: No. of stable sampled nodes (kappa < $10^{-7}$)
- Nodes kappa suspicious: No. of suspicious sampled nodes ($10^{-7} \leq \text{kappa} < 10^{-10}$)
- Nodes kappa unstable: No. of unstable sampled nodes ($10^{-10} \leq \text{kappa} < 10^{-13}$)
- Nodes kappa ill-posed: No. of ill-posed sampled nodes ($10^{-13} \leq \text{kappa}$)
- Largest kappa seen: The largest condition number calculated through all sampled nodes.
- Kappa attention level: A measure of how ill-posed the problem is (between 0 and 1).

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not calculate condition numbers.</td>
</tr>
<tr>
<td>1</td>

<td>Equivalent to <code>mipPresolve_allowTreeRestart</code>.</td>
</tr>
<tr>
<td>bit 8 = 256</td>
<td>Equivalent to <code>mipPresolve_symmetryReductions</code>.</td>
</tr>
</tbody>
</table>

**mipPresolve_allowChangeBounds (boolean):** If node preprocessing is allowed to change bounds on continuous columns
See also `mipPresolve`.

Default: 1

**mipPresolve_allowTreeRestart (boolean):** Allow the branch-and-bound tree search to be restarted if it appears to be advantageous

See also `mipPresolve`.

Default: 1

**mipPresolve_dualReductions (boolean):** Dual reductions will be performed at each node

See also `mipPresolve`.

Default: 1

**mipPresolve_globalCoefTightening (boolean):** Allow global (non-bound) tightening of the problem during the tree search

See also `mipPresolve`.

Default: 1

**mipPresolve_logicPreprocessing (boolean):** Primal reductions will be performed at each node

Uses constraints of the node to tighten the range of variables, often resulting in fixing their values. This greatly simplifies the problem and may even determine optimality or infeasibility of the node.

See also `mipPresolve`.

Default: 1

**mipPresolve_objBasedReductions (boolean):** Objective function will be used to find reductions at each node

See also `mipPresolve`.

Default: 1

**mipPresolve_reducedCostFixing (boolean):** Reduced cost fixing will be performed at each node

This can simplify the node before it is solved, by deducing that certain variables’ values can be fixed based on additional bounds imposed on other variables at this node.

See also `mipPresolve`.

Default: 1

**mipPresolve_symmetryReductions (boolean):** Allow that symmetry is used to presolve the node problem

See also `mipPresolve`.

Default: 0

**mipRampUp (integer):** Controls the strategy used by the parallel MIP solver during the ramp-up phase of a branch-and-bound tree search

The branch-and-bound tree search starts from the single root node, and only through branching on this root node and the resulting child nodes, are enough active nodes created to produce sufficient tasks to keep all MIP workers busy. This is referred to as the ramp-up phase of a parallel MIP. In a typical MIP solve, the solutions found during the initial dives will typically provide a significant improvement over the root heuristic solutions. It can therefore be advantageous to let these initial dives run as fast as possible, by limiting resource contention. This can be accomplished by restricting the number of parallel tasks and thereby reducing the memory bus contention. The `mipRampUp` control can be used to turn this initial task restriction of a parallel MIP solve on or off.

Default: auto
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>No special treatment during the ramp-up phase. Always run with the maximal number of tasks.</td>
</tr>
<tr>
<td>1</td>
<td>Limit the number of tasks until the initial dives have completed.</td>
</tr>
</tbody>
</table>

**mipRefineIterLimit (integer):** Defines an effort limit expressed as simplex iterations for the MIP solution refiner.

The limit is per reoptimizations in the MIP refiner.

Range: \([-1, \infty]\)

Default: `auto`

**mipRelCutoff (real):** Branch and Bound: Percentage of the LP solution value to be added to the value of the objective function when an integer solution is found, to give the new value of `CURRMIPCUTOFF`.

The effect is to cut off the search in parts of the tree whose best possible objective function would not be substantially better than the current solution. The control `mipRelStop` provides a similar functionality but works in a different way.

Range: \([0, \infty]\)

Default: 0.0001

**mipRelStop (real):** Branch and Bound: Determines when the global search will terminate.

Global search will stop if:

\[
| \text{MIPOBJVAL} - \text{BESTBOUND} | \leq \text{mipRelStop} \times \max(\| \text{BESTBOUND} \|, | \text{MIPOBJVAL} | )
\]

where `MIPOBJVAL` is the value of the best solution’s objective function and `BESTBOUND` is the current best solution bound. For example, to stop the global search when a MIP solution has been found and the Optimizer can guarantee it is within 5% of the optimal solution, set `mipRelStop` to 0.05.

This control is a stopping criteria only and different values of the control will not affect the solution path before termination. Unlike other stopping criteria, like time and node count, termination on `mipRelStop` will cause the final solution to be declared optimal and the problem to be returned to its original state.

Tolerances, such as `mipRelCutoff` and `mipAbsCutoff`, determine how much the objective value of a new MIP solution has to differ from the incumbent for it to be accepted. These controls therefore also influence the final gap at the end of a MIP solve.

Range: \([0, \infty]\)

Default: 0.0001

**mipRestart (integer):** Branch and Bound: Controls strategy for in-tree restarts.

Default: `auto`
mipstopexpr (string): Stopping expression for branch and bound

If the provided logical expression is true, the branch-and-bound is aborted. Supported values are: resusd, nodusd, objest, objval. Supported operators are: +, -, *, /, ^, %, !=, ==, <, <=, >, >=, !, &,&, ||, (), abs, ceil, exp, floor, log, log10, pow, sqrt. Example:

```
resusd >= 1000 && abs(objest - objval) / abs(objval) < 0.1
```

mipThreads (integer): If set to a positive integer it determines the number of threads implemented to run the parallel MIP code

If mipThreads is set to the default value -1, the threads control will determine the number of threads used.

Range: \{-1, ..., \infty\}

Default: auto

mipTol (real): Branch and Bound: Tolerance within which a decision variable’s value is considered to be integral

Range: \[0, \infty\]

Default: 5e-06

mipTolTarget (real): Target mipTol value used by the automatic MIP solution refiner as defined by refineOps

Negative and zero values are ignored.

Range: \ [-\infty, \infty\] 

Default: 0

mipTrace (string): Name of MIP trace file

A miptrace file with the specified name will be created. This file records the best integer and best bound values every mipTraceNode nodes and at mipTraceTime-second intervals.

Default: none

mipTraceNode (integer): Node interval between MIP trace file entries

Default: 100

mipTraceTime (real): Time interval, in seconds, between MIP trace file entries

Default: 5

miqcpAlg (integer): Determines which algorithm is to be used to solve mixed integer quadratic constrained and mixed integer second order cone problems

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically.</td>
</tr>
<tr>
<td>0</td>
<td>Use the barrier algorithm in the branch and bound algorithm.</td>
</tr>
<tr>
<td>1</td>
<td>Use outer approximations in the branch and bound algorithm.</td>
</tr>
</tbody>
</table>
mpsNameLength (integer): Maximum length of MPS names in characters

Internally it is rounded up to the smallest multiple of 8. MPS names are right padded with blanks. Maximum value is 64.

Range: \( \{0, \ldots, \infty\} \)

Default: 0

mpsOutputFile (string): Name of MPS output file

If specified XPRESS-MP will generate an MPS file corresponding to the GAMS model: the argument is the file name to be used. You can prefix the file name with an absolute or relative path.

Default: none

netCuts (integer): Determines the addition of multi-commodity network cuts to a problem

The parameter is defined as a bit string, and values 1, 2, 4 can be summed up if the user wants more classes of cuts to be added.

If the user wants to add both cut-set inequalities and lifted flow-cover inequalities but not node cut-set inequalities, the value of the control should be set to 1+4=5.

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Do not add these cuts.</td>
</tr>
<tr>
<td>1</td>
<td>Add cut-set inequalities.</td>
</tr>
<tr>
<td>2</td>
<td>Add node cut-set inequalities, i.e., cut-set inequalities that are based on a network cut defined on a single network node.</td>
</tr>
<tr>
<td>4</td>
<td>Add lifted flow-cover inequalities.</td>
</tr>
</tbody>
</table>

nodeSelection (integer): Branch and Bound: Determines which nodes will be considered for solution once the current node has been solved

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Local first: Choose between descendant and sibling nodes if available; choose from all outstanding nodes otherwise.</td>
</tr>
<tr>
<td>2</td>
<td>Best first: Choose from all outstanding nodes.</td>
</tr>
<tr>
<td>3</td>
<td>Local depth first: Choose between descendant and sibling nodes if available; choose from the deepest nodes otherwise.</td>
</tr>
<tr>
<td>4</td>
<td>Best first, then local first: Best first is used for the first breadthFirst nodes, after which local first is used.</td>
</tr>
<tr>
<td>5</td>
<td>Pure depth first: Choose from the deepest outstanding nodes.</td>
</tr>
</tbody>
</table>

objGoodEnough (real): Stop once an objective this good is found

Default: none
**objScaleFactor** *(integer)*: Custom global objective scaling factor, expressed as a power of 2

When set, it overwrites the automatic global objective scaling factor. A value of 0 means no objective scaling. This control is applied for the full solve, and is independent of any extra scaling that may occur specifically for the barrier or simplex solvers. As it is a power of 2, to scale by 16, set the value of the control to 4.

Range: \(\{0, \ldots, \infty\}\)

Default: 0

**optimalityTol** *(real)*: Simplex: Zero tolerance for reduced costs

On each iteration, the simplex method searches for a variable to enter the basis which has a negative reduced cost. The candidates are only those variables which have reduced costs less than the negative value of **optimalityTol**.

Range: \([0, \infty]\)

Default: \(1e-06\)

**optimalityTolTarget** *(real)*: Target optimality tolerance for the solution refiner

Zero and negative values are ignored, and the value of **optimalityTol** is used.

Use very small values like \(1e-100\) to state the refinement should continue as long as an improvement is made. Use very large values like \(1e+100\) to disable only this aspect of the refiner.

Range: \([-\infty, \infty]\)

Default: 0

**outputLog** *(integer)*: Controls the level of output produced by the Optimizer during optimization

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Turn all output off.</td>
</tr>
<tr>
<td>1</td>
<td>Print all messages.</td>
</tr>
<tr>
<td>3</td>
<td>Print error and warning messages.</td>
</tr>
<tr>
<td>4</td>
<td>Print error messages only.</td>
</tr>
</tbody>
</table>

**outputTol** *(real)*: Zero tolerance on print values

Range: \([0, \infty]\)

Default: \(1e-05\)

**penalty** *(real)*: Minimum absolute penalty variable coefficient

Range: \([0, \infty]\)

Default: **auto**

**pivotTol** *(real)*: Simplex: Zero tolerance for matrix elements
On each iteration, the simplex method seeks a nonzero matrix element to pivot on. Any element with absolute value less than pivotTol is treated as zero for this purpose.

Range: \([0, \infty]\)

Default: \(1e^{-09}\)

**preAnalyticCenter** *(integer)*: Determines if analytic centers should be computed and used for variable fixing and the generation of alternative reduced costs (-1: Auto 0: Off, 1: Fixing, 2: Redcost, 3: Both) ←

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Disable analytic center presolving.</td>
</tr>
<tr>
<td>1</td>
<td>Use analytic center for variable fixing only.</td>
</tr>
<tr>
<td>2</td>
<td>Use analytic center for reduced cost computation only.</td>
</tr>
<tr>
<td>3</td>
<td>Use analytic centers for both, variable fixing and reduced cost computation.</td>
</tr>
</tbody>
</table>

**preBasisRed** *(integer)*: Determines if a lattice basis reduction algorithm should be attempted as part of presolve ←

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Disable basis reduction.</td>
</tr>
<tr>
<td>1</td>
<td>Enable basis reduction.</td>
</tr>
</tbody>
</table>

**preBndRedCone** *(integer)*: Determines if second order cone constraints should be used for inferring bound reductions on variables when solving a MIP ←

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Disable bound reductions from second order cone constraints.</td>
</tr>
<tr>
<td>1</td>
<td>Enable bound reductions from second order cone constraints.</td>
</tr>
</tbody>
</table>

**preBndRedQuad** *(integer)*: Determines if convex quadratic constraints should be used for inferring bound reductions on variables when solving a MIP ←

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic</td>
</tr>
<tr>
<td>0</td>
<td>Disable bound reductions from quadratic constraints.</td>
</tr>
<tr>
<td>1</td>
<td>Enable bound reductions from quadratic constraints.</td>
</tr>
</tbody>
</table>

**preCoefElim** *(integer)*: Presolve: Specifies whether the optimizer should attempt to recombine constraints in order to reduce the number of non zero coefficients when presolving a mixed integer problem ←
Default: 2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Remove as many coefficients as possible.</td>
</tr>
<tr>
<td>2</td>
<td>Cautious eliminations. Will not perform a reduction if it might destroy problem structure useful to e.g. heuristics or cutting.</td>
</tr>
</tbody>
</table>

**preComponents** *(integer)*: Presolve: Determines whether small independent components should be detected and solved as individual subproblems during root node processing

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Disable detection of independent components.</td>
</tr>
<tr>
<td>1</td>
<td>Enable detection of independent components.</td>
</tr>
</tbody>
</table>

**preComponentsEffort** *(real)*: Presolve: Adjusts the overall effort for the independent component presolver

This control affects working limits for the subproblem solving as well as thresholds when it is called. Increase to put more emphasis on component presolving.

Range: \([0, \infty]\)

Default: 1

**preConeDecomp** *(integer)*: Presolve: Decompose regular and rotated cones with more than two elements and apply Outer Approximation on the resulting components

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Disable cone decomposition.</td>
</tr>
<tr>
<td>1</td>
<td>Enable cone decomposition by replacing large cones with small ones in the presolved problem.</td>
</tr>
<tr>
<td>2</td>
<td>Similar to 1, plus decomposition is enabled even if the cone variable is fixed.</td>
</tr>
<tr>
<td>3</td>
<td>Cones are decomposed within the Outer Approximation domain only, i.e., the problem maintains the original cones.</td>
</tr>
</tbody>
</table>

**preConvertSeparable** *(integer)*: Presolve: Reformulate problem with non-diagonal quadratic objective and/or constraints as diagonal quadratic or second-order conic constraints

This control is only used in MIQPs and MIQCQPs, and has no effect when used on continuous quadratic problems.

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
</tbody>
</table>
### preDomCol (integer)
Presolve: Determines the level of dominated column removal reductions to perform when presolving a mixed integer problem

Only binary columns will be checked.

Default: `auto`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Cautious strategy.</td>
</tr>
<tr>
<td>2</td>
<td>All candidate binaries will be checked for domination.</td>
</tr>
</tbody>
</table>

### preDomRow (integer)
Presolve: Determines the level of dominated row removal reductions to perform when presolving a problem

Duplicate rows can also be disabled by clearing the corresponding bit of the `presolveOps` integer control.

Default: `auto`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Cautious strategy.</td>
</tr>
<tr>
<td>2</td>
<td>Medium strategy.</td>
</tr>
<tr>
<td>3</td>
<td>Aggressive strategy. All candidate row combinations will be considered.</td>
</tr>
</tbody>
</table>

### preDupRow (integer)
Presolve: Determines the type of duplicate rows to look for and eliminate when presolving a problem

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Do not eliminate duplicate rows.</td>
</tr>
<tr>
<td>1</td>
<td>Eliminate only rows that are identical in all variables.</td>
</tr>
<tr>
<td>2</td>
<td>Same as option 1 plus eliminate duplicate rows with simple penalty variable expressions. (MIP only).</td>
</tr>
<tr>
<td>3</td>
<td>Same as option 2 plus eliminate duplicate rows with more complex penalty variable expressions. (MIP only).</td>
</tr>
</tbody>
</table>

### preElimQuad (integer)
Presolve: Allows for elimination of quadratic variables via doubleton rows

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable reformulation.</td>
</tr>
<tr>
<td>1</td>
<td>Enable reformulation to diagonal quadratic constraints.</td>
</tr>
<tr>
<td>2</td>
<td>Similar to 1, plus reduction to second-order cones.</td>
</tr>
<tr>
<td>3</td>
<td>Similar to 2, plus the objective function is converted to a constraint and treated as a quadratic constraint.</td>
</tr>
</tbody>
</table>
Default: \texttt{auto}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Do not eliminate duplicate rows.</td>
</tr>
<tr>
<td>1</td>
<td>Eliminate at least one quadratic variable for each doubleton row.</td>
</tr>
</tbody>
</table>

\textbf{preImplications} (integer): Presolve: Determines whether to use implication structures to remove redundant rows \[\rightarrow\]

If implication sequences are detected, they might also be used in probing.

Default: \texttt{auto}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Do not use implications for sparsification.</td>
</tr>
<tr>
<td>1</td>
<td>Use implications to remove redundant rows.</td>
</tr>
</tbody>
</table>

\textbf{preLinDep} (integer): Presolve: Determines whether to check for and remove linearly dependent equality constraints when presolving a problem \[\rightarrow\]

Default: \texttt{auto}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>0</td>
<td>Do not check for linearly dependent equality constraints.</td>
</tr>
<tr>
<td>1</td>
<td>Check for and remove linearly dependent equality constraints.</td>
</tr>
</tbody>
</table>

\textbf{preObjCutDetect} (boolean): Presolve: Determines whether to check for constraints that are parallel or near parallel to a linear objective function, and which can safely be removed \[\leftrightarrow\]

This reduction applies to MIPs only.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable check and reductions.</td>
</tr>
<tr>
<td>1</td>
<td>Enable check and reductions.</td>
</tr>
</tbody>
</table>

\textbf{preProbing} (integer): Presolve: Amount of probing to perform on binary variables during presolve \[\leftrightarrow\]

This is done by fixing a binary to each of its values in turn and analyzing the implications.

Default: \texttt{auto}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Let the optimizer decide on the amount of probing.</td>
</tr>
<tr>
<td>0</td>
<td>Disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Light probing — only few implications will be examined.</td>
</tr>
<tr>
<td>2</td>
<td>Full probing — all implications for all binaries will be examined.</td>
</tr>
<tr>
<td>3</td>
<td>Full probing and repeat as long as the problem is significantly reduced.</td>
</tr>
</tbody>
</table>
**presolve** *(integer)*: Determines whether presolving should be performed prior to starting the main algorithm

Presolve attempts to simplify the problem by detecting and removing redundant constraints, tightening variable bounds, etc. In some cases, infeasibility may even be determined at this stage, or the optimal solution found.

Memory for presolve is dynamically resized. If the Optimizer runs out of memory for presolve, an error message (245) is produced. Presolve settings 2 and 3 can sometimes make the barrier solves more efficient.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Presolve applied, but a problem will not be declared infeasible if primal infeasibilities are detected. The problem will be solved by the LP optimization algorithm, returning an infeasible solution, which can sometimes be helpful.</td>
</tr>
<tr>
<td>0</td>
<td>Presolve not applied.</td>
</tr>
<tr>
<td>1</td>
<td>Presolve applied.</td>
</tr>
<tr>
<td>2</td>
<td>Presolve applied, but redundant bounds are not removed. This can sometimes increase the efficiency of the barrier algorithm.</td>
</tr>
<tr>
<td>3</td>
<td>Presolve is applied, and bounds detected to be redundant are always removed.</td>
</tr>
</tbody>
</table>

**presolveMaxGrow** *(real)*: Limit on how much the number of non-zero coefficients is allowed to grow during presolve, specified as a ratio of the number of non-zero coefficients in the original problem

Range: \([0, \infty]\)

Default: 0.1

**presolveOps** *(integer)*: Specifies the operations which are performed during the presolve

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 511

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Equivalent to <code>presolveOps_singletonColRemoval</code>.</td>

</tr>
<tr>
<td>bit 9 = 512</td>
<td>Equivalent to <code>presolveOps_noIpReductions</code>.</td>
</tr>
<tr>
<td>bit 10 = 1024</td>
<td>Equivalent to <code>presolveOps_noGlobalDomainChange</code>.</td>
</tr>
<tr>
<td>bit 11 = 2048</td>
<td>Equivalent to <code>presolveOps_noAdvIpReductions</code>.</td>
</tr>
<tr>
<td>bit 12 = 4096</td>
<td>Equivalent to <code>presolveOps_noIntVarEliminations</code>.</td>
</tr>
<tr>
<td>bit 14 = 16384</td>
<td>Equivalent to <code>presolveOps_linDependRowRemoval</code>.</td>
</tr>
<tr>
<td>bit 15 = 32768</td>
<td>Equivalent to <code>presolveOps_noIntVarAndSosDetect</code>.</td>
</tr>
</tbody>
</table>
presolveOps_dualReductions (boolean): Dual reductions ↔

See also presolveOps.
Default: 1

presolveOps_duplicateColRemoval (boolean): Duplicate column removal ↔

See also presolveOps.
Default: 1

presolveOps_duplicateRowRemoval (boolean): Duplicate row removal ↔

See also presolveOps.
Default: 1

presolveOps_forcingRowRemoval (boolean): Forcing row removal ↔

See also presolveOps.
Default: 1

presolveOps_linDependRowRemoval (boolean): Linearly dependant row removal ↔

See also presolveOps.
Default: 0

presolveOps_noAdvIpReductions (boolean): No advanced IP reductions ↔

See also presolveOps.
Default: 0

presolveOps_noGlobalDomainChange (boolean): No semi-continuous variable detection ↔

See also presolveOps.
Default: 0

presolveOps_noIntVarAndSosDetect (boolean): No integer variable and SOS detection ↔

See also presolveOps.
Default: 0

presolveOps_noIntVarEliminations (boolean): No eliminations on integers ↔

See also presolveOps.
Default: 0

presolveOps_noIpReductions (boolean): No IP reductions ↔

See also presolveOps.
Default: 0
**presolveOps_redundantRowRemoval** *(boolean)*: Redundant row removal

See also `presolveOps`.

Default: 1

**presolveOps_singletonColRemoval** *(boolean)*: Singleton column removal

See also `presolveOps`.

Default: 1

**presolveOps_singletonRowRemoval** *(boolean)*: Singleton row removal

See also `presolveOps`.

Default: 1

**presolveOps_strongDualReductions** *(boolean)*: Strong dual reductions

See also `presolveOps`.

Default: 1

**presolveOps_variableEliminations** *(boolean)*: Variable eliminations

See also `presolveOps`.

Default: 1

**presolvePasses** *(integer)*: Number of reduction rounds to be performed in presolve

Range: \(\{0, \ldots, \infty\}\)

Default: 1

**pricingAlg** *(integer)*: Simplex: Determines the primal simplex pricing method

It is used to select which variable enters the basis on each iteration. In general Devex pricing requires more time on each iteration, but may reduce the total number of iterations, whereas partial pricing saves time on each iteration, but may result in more iterations.

Default: `auto`

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Partial pricing.</td>
</tr>
<tr>
<td>0</td>
<td>Determined automatically.</td>
</tr>

<td>Devex pricing.</td>
</tr>
<tr>
<td>2</td>
<td>Steepest edge.</td>
</tr>
<tr>
<td>3</td>
<td>Steepest edge with unit initial weights.</td>
</tr>
</tbody>
</table>

**primalPerturb** *(real)*: Factor by which the problem will be perturbed prior to optimization by primal simplex

A value of 0.0 results in no perturbation prior to optimization. Note the interconnection to the `autoPerturb` control. If `autoPerturb` is set to 1, the decision whether to perturb or not is left
to the Optimizer. When the problem is automatically perturbed in primal simplex, however, the value of \texttt{primalPerturb} will be used for perturbation.

Range: $[-\infty, \infty]$

Default: \texttt{auto}

\textbf{primalUnshift (boolean):} Determines whether primal is allowed to call dual to unshift

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Allow the dual algorithm to be used to unshift.</td>
</tr>
<tr>
<td>1</td>
<td>Don’t allow the dual algorithm to be used to unshift.</td>
</tr>
</tbody>
</table>

\textbf{pseudoCost (real):} Branch and Bound: Default pseudo cost used in estimation of the degradation associated with an unexplored node in the tree search

A pseudo cost is associated with each integer decision variable and is an estimate of the amount by which the objective function will be worse if that variable is forced to an integral value.

Range: $[0, \infty]$ Default: 0.01

\textbf{qcCuts (integer):} Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation

This control only has an effect for problems with quadratic or second order cone constraints, and only if outer approximation has not been disabled by setting \texttt{miqcpAlg} to 0.

Range: \{-1, ..., \infty\}

Default: \texttt{auto}

\textbf{qcRootAlg (integer):} Determines which algorithm is to be used to solve the root of a mixed integer quadratic constrained or mixed integer second order cone problem, when outer approximation is used

This control only has an effect if \texttt{miqcpAlg} is set to 1.

Default: \texttt{auto}

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Determined automatically.</td>
</tr>
<tr>
<td>0</td>
<td>Use the barrier algorithm.</td>
</tr>
<tr>
<td>1</td>
<td>Use the dual simplex on a relaxation of the problem constructed using outer approximation.</td>
</tr>
</tbody>
</table>

\textbf{qSimplexOps (integer):} Controls the behavior of the quadratic simplex solvers

Default: 0
### XPRESS 5.43

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Force traditional primal first phase.</td>

<tr>
<td>1</td>
<td>Always do the purification step.</td>
</tr>
</tbody>
</table>

#### randomSeed (integer)
Sets the initial seed to use for the pseudo-random number generator in the Optimizer

The sequence of random numbers is always reset using the seed when starting a new optimization run.

Range: \{-\infty, \ldots, \infty\}

Default: 1

#### refineOps (integer)
Specifies when the solution refiner should be executed to reduce solution infeasibilities

The refiner will attempt to satisfy the target tolerances for all original linear constraints before presolve or scaling has been applied.

If neither the 7th nor 8th bit is set, the refiner will use the primal simplex if the primal violations are larger than the dual violations, otherwise it will use the dual simplex. If both the 7th and 8th bit are set then the refiner will split the problem into a primal feasible and dual feasible part, and solve the first with primal simplex and the second with dual simplex.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 19

<table>
<thead>
<tr>

<tr>
<td>bit 10 = 1024</td>
<td>Equivalent to <code>refineOps_mipFixGlobalsTarget</code>.</td>
</tr>
</tbody>
</table>

`refineOps_iterativeRefiner` (boolean): Apply the iterative refiner to refine the solution

See also `refineOps`.

Default: 0

`refineOps_lpOptimal` (boolean): Run the solution refiner on an optimal solution of a non-global problem

See also `refineOps`.

Default: 1

`refineOps_lpPresolve` (boolean): Run the solution refiner on an optimal solution before postsolve on a non-global problem

See also `refineOps`.

Default: 1

`refineOps_mipFixGlobals` (boolean): Refine MIP solutions such that rounding them keeps the problem feasible when reoptimized

See also `refineOps`.

Default: 0

`refineOps_mipFixGlobalsTarget` (boolean): Attempt to refine MIP solutions such that rounding them keeps the problem feasible when reoptimized, but accept integers solutions even if refinement fails

See also `refineOps`.

Default: 0

`refineOps_mipNodeLp` (boolean): Run the solution refiner on each node of the MIP search

See also `refineOps`.

Default: 0

`refineOps_mipSolution` (boolean): Run the solution refiner when a new solution is found during a global search

The refiner will be applied to the presolved solution before any post-solve operations are applied.

See also `refineOps`.

Default: 1
**refineOps_refinerPrecision** *(boolean)*: Use higher precision in the iterative refinement

See also **refineOps**.

Default: 0

**refineOps_refinerUseDual** *(boolean)*: If set, the iterative refiner will use the dual simplex algorithm

See also **refineOps**.

Default: 0

**refineOps_refinerUsePrimal** *(boolean)*: If set, the iterative refiner will use the primal simplex algorithm

See also **refineOps**.

Default: 0

**reform** *(boolean)*: Substitute out objective var and equ when possible

Default: 1

**relaxTreeMemoryLimit** *(real)*: When the memory used by the branch and bound search tree exceeds the target specified by the **treeMemoryLimit** control, the optimizer will try to reduce this by writing nodes to the global file

In rare cases, usually where the solve has many millions of very small nodes, the tree structural data (which cannot be written to the global file) will grow large enough to approach or exceed the tree’s memory target. When this happens, optimizer performance can degrade greatly as the solver makes heavy use of the global file in preference to memory. To prevent this, the solver will automatically relax the tree memory limit when it detects this case; the **relaxTreeMemoryLimit** control specifies the proportion of the previous memory limit by which to relax it. Set **relaxTreeMemoryLimit** to 0.0 to force the Xpress Optimizer to never relax the tree memory limit in this way.

While setting higher values of **relaxTreeMemoryLimit** can improve performance significantly for a small number of models in low memory situations, the user is advised to use the **treeMemoryLimit** control to tune the memory usage of the branch and bound tree, according to the solve characteristics of their problem, rather than increasing **relaxTreeMemoryLimit**.

Range: \([0, \infty]\)

Default: 0.1

**relPivotTol** *(real)*: Simplex: Minimum size of pivot element relative to largest element in column

At each iteration a pivot element is chosen within a given column of the matrix. The relative pivot tolerance, **relPivotTol**, is the size of the element chosen relative to the largest possible pivot element in the same column.

Range: \([0, \infty]\)

Default: 1e-06

**repairIndefInitEq** *(boolean)*: Controls if the optimizer should make indefinite quadratic matrices positive definite when it is possible

Default: 1
### reRun (boolean): Rerun with primal simplex when not optimal/feasible

Applies only in cases where presolve is turned on and the model is diagnosed as infeasible or unbounded. If rerun is nonzero, we rerun the model using primal simplex with presolve turned off in hopes of getting better diagnostic information. If rerun is zero, no good diagnostic information exists, so we return no solution, only an indication of unboundedness/infeasibility.

Default: 0

### reslim (real): Overrides GAMS reslim option

Sets the resource limit. When the solver has used more than this amount of CPU time (in seconds) the system will stop the search and report the best solution found so far. maxTime overwrites this option.

### resourceStrategy (boolean): Controls whether the optimizer is allowed to make nondeterministic decisions if memory is running low in an effort to preserve memory and finish the solve

Available memory (or container limits) are automatically detected but can also be changed by maxMemorySoft and maxMemoryHard.

Default: 0

### rootPresolve (integer): Determines if presolving should be performed on the problem after the global search has finished with root cutting and heuristics

Default: auto

### sbBest (integer): Number of infeasible global entities to initialize pseudo costs for on each node

By default, strong branching will be performed only for infeasible global entities whose pseudo costs have not otherwise been initialized (see historyCosts). If sbBest is set to zero, the control historyCosts will also be treated as zero and no past branching or strong branching information will be used in the global entity selection.

Default: auto
sbEffort (real): Adjusts the overall amount of effort when using strong branching to select an infeasible global entity to branch on →

    sbEffort is used as a multiplier on other strong branching related controls, and affects the values used for sbBest, sbSelect and sbIterLimit when those are set to automatic.

    Range: \([0, \infty)\]
    Default: 1

sbEstimate (integer): Branch and Bound: How to calculate pseudo costs from the local node when selecting an infeasible global entity to branch on →

    These pseudo costs are used in combination with local strong branching and history costs to select the branch candidate.

    Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatically determined.</td>
</tr>
<tr>
<td>1-6</td>
<td>Different variants of local pseudo costs.</td>
</tr>
</tbody>
</table>

sbIterLimit (integer): Number of dual iterations to perform the strong branching for each entity →

    This control can be useful to increase or decrease the amount of effort (and thus time) spent performing strong branching at each node. Setting sbIterLimit=0 will disable dual strong branch iterations. Instead, the entity at the head of the candidate list will be selected for branching.

    Range: \([-1, \ldots, \infty}\)  
    Default: auto

sbSelect (integer): Size of the candidate list of global entities for strong branching →

    Before strong branching is applied on a node of the branch and bound tree, a list of candidates is selected among the infeasible global entities. These entities are then evaluated based on the local LP solution and prioritized. Strong branching will then be applied to the sbBest candidates. The evaluation is potentially expensive and for some problems it might improve performance if the size of the candidate list is reduced.

    Default: -2

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Automatic (low effort).</td>
</tr>
<tr>
<td>-1</td>
<td>Automatic (high effort).</td>
</tr>
<tr>
<td>n≥0</td>
<td>Include n entities in the candidate list (but always at least sbBest candidates).</td>
</tr>
</tbody>
</table>

scaling (integer): Determines how the Optimizer will rescale a model internally before optimization →

    If set to 0, no scaling will take place.

    Setting scaling to 0 will preserve the current scaling of the problem. Note that the Optimizer might automatically select a different scaling strategy, when the control autoScaling is not disabled. However, if scaling is set to any value by the user, autoScaling will be ignored.
Setting single boolean options will overwrite the single bits of this bit map option.

Default: 163

</tbody>
</table>

**solnpool** *(string)*: Solution pool file name. If set, the integer feasible solutions generated during the global search will be saved to a solution pool. A GDX file whose name is given by this option will be created and will contain an index to separate GDX files containing the individual solutions in the solution pool. Default: *none*

**solnpoolCapacity** *(integer)*: Limit on number of solutions to store. Range: `{1, ..., ∞}` Default: 999999999

**solnpoolCullDiversity** *(integer)*: Cull N solutions based on solution diversity. When performing a round of culls due to a full solution pool, this control sets the maximum number to cull based on the diversity of the solutions in the pool. Range: `{−1, ..., ∞}` Default: -1

**solnpoolCullObj** *(integer)*: Cull N solutions based on objective values. When performing a round of culls due to a full solution pool, this control sets the maximum number to cull based on the MIP objective function. Range: `{−1, ..., ∞}` Default: -1

**solnpoolCullRounds** *(integer)*: Terminate solution generation after N culling rounds. Limits the rounds of culls performed due to a full solution pool. Default: 999999999

**solnpoolDupPolicy** *(integer)*: Policy to use when handling storage of duplicate solutions. Default: 0
<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Keep all: All solutions are kept including duplicates.</td>
</tr>
<tr>
<td>1</td>

<tr>
<td>2</td>
<td>Discrete and continuous separate: Both the discrete component of a solution pair and the continuous solution variables are compared. The continuous variables are compared with an exact match. Duplicate solutions are discarded.</td>
</tr>
<tr>
<td>3</td>
<td>Discrete only: Only the discrete component of a solution pair is compared. Duplicate solutions are discarded.</td>
</tr>
</tbody>
</table>

solnpoolmerge (string): Solution pool file name for merged solutions

Default: none

solnpoolnumsym (integer): Maximum number of variable symbols when writing merged solutions

Range: \{1, ..., \infty\}

Default: 10

solnpoolPop (integer): Controls method used to populate the solution pool

By default the MIP solution pool merely stores the incumbent solutions that are found during the global search, without changing the behavior of the search itself. In contrast, the MIP solution enumerator makes it possible to enumerate all or many of the feasible solutions for the MIP, instead of searching for the best solution.

Default: 1

<table>

</tbody>
</table>

solnpoolPrefix (string): File name prefix for GDX solution files

Default: soln

solnpoolVerbosity (integer): Controls verbosity of solution pool routines

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>no output</td>
</tr>
<tr>
<td>0</td>
<td>output only messages coming from the XPRESS libraries</td>
</tr>
<tr>
<td>1</td>
<td>add some messages logging the effect of solution pool options</td>
</tr>
<tr>
<td>2</td>
<td>debugging mode</td>
</tr>
</tbody>
</table>

sosRefTol (real): Minimum relative gap between the ordering values of elements in a special ordered set

The gap divided by the absolute value of the larger of the two adjacent values must be at least sosRefTol.
This tolerance must not be set lower than 1.0E-06.

Range: $[0, \infty]$

Default: $1e^{-06}$

**symmetry** *(integer)*: Adjusts the overall amount of effort for symmetry detection

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No symmetry detection.</td>
</tr>
<tr>
<td>1</td>
<td>Conservative effort.</td>
</tr>
<tr>
<td>2</td>
<td>Intensive symmetry search.</td>
</tr>
</tbody>
</table>

**symSelect** *(integer)*: Adjusts the overall amount of effort for symmetry detection

Default: -1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Search the whole matrix (otherwise the 0, 1 and -1 coefficients only).</td>
</tr>
<tr>
<td>1</td>
<td>Search all entities (otherwise binaries only).</td>
</tr>
</tbody>
</table>

**threads** *(integer)*: Default number of threads used during optimization

Controls the number of threads to use. Positive values will be compared to the number of available cores detected and reduced if greater than this amount. Non-positive values are interpreted as the number of cores to leave free so setting `threads` to 0 uses all available cores while setting `threads` to -1 leaves one core free for other tasks.

Range: $\{-\infty, ..., \infty\}$

Default: 1

**trace** *(integer)*: Display the infeasibility diagnosis during presolve

If non-zero, an explanation of the logical deductions made by presolve to deduce infeasibility or unboundedness will be displayed on screen or sent to the message callback function.

Presolve is sometimes able to detect infeasibility and unboundedness in problems. The set of deductions made by presolve can allow the user to diagnose the cause of infeasibility or unboundedness in their problem. However, not all infeasibility or unboundedness can be detected and diagnosed in this way.

Range: $\{0, ..., \infty\}$

Default: 0

**treeCompression** *(integer)*: When writing nodes to the global file, the optimizer can try to use data-compression techniques to reduce the size of the global file on disk
The `treeCompression` control determines the strength of the data-compression algorithm used; higher values give superior data-compression at the affect of decreasing performance, while lower values compress quicker but not as effectively. Where `treeCompression` is set to 0, no data compression will be used on the global file.

Range: \( \{0, \ldots, \infty\} \)

Default: 2

**treeCoverCuts** *(integer)*: Branch and Bound: Number of rounds of lifted cover inequalities generated at nodes other than the top node in the tree

Compare with the description for `coverCuts`. A value of -1 indicates the number of rounds is determined automatically.

Range: \( \{-1, \ldots, \infty\} \)

Default: `auto`

**treeCutSelect** *(integer)*: Bit vector providing detailed control of the cuts created during the tree search of a global solve

Use `cutSelect` to control cuts on the root node.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: \(-257\)

| value         | meaning                                                        |

| bit 15 = 32768| Equivalent to `treeCutSelect_gubCover`.                       |
| bit 16 = 65536| Equivalent to `treeCutSelect_zeroHalf`.                       |
| bit 17 = 131072| Equivalent to `treeCutSelect_indicator`.                      |

**treeCutSelect_clique** *(boolean)*: Clique cuts

See also `treeCutSelect`.

Default: 1

**treeCutSelect_cover** *(boolean)*: Lifted cover cuts

See also `treeCutSelect`.

Default: 1

**treeCutSelect_disableCutRows** *(boolean)*: Disable cutting from cut rows
See also treeCutSelect.

Default: 1

treeCutSelect_flowpath (boolean): Flow path cuts

See also treeCutSelect.

Default: 1

treeCutSelect_gubCover (boolean): Lifted GUB cover cuts

See also treeCutSelect.

Default: 1

treeCutSelect_implication (boolean): Implication cuts

See also treeCutSelect.

Default: 1

treeCutSelect_indicator (boolean): Indicator constraint cuts

See also treeCutSelect.

Default: 1

treeCutSelect_liftAndProject (boolean): Turn on automatic Lift and Project cutting strategy

See also treeCutSelect.

Default: 1

treeCutSelect_mir (boolean): Mixed Integer Rounding (MIR) cuts

See also treeCutSelect.

Default: 1

treeCutSelect_mirRowAggregation (boolean): Turn on row aggregation for MIR cuts

See also treeCutSelect.

Default: 0

treeCutSelect_zeroHalf (boolean): Zero-half cuts

See also treeCutSelect.

Default: 1

treeGomCuts (integer): Branch and Bound: Number of rounds of Gomory cuts generated at nodes other than the first node in the tree
Compare with the description for gomCuts. A value of -1 indicates the number of rounds is determined automatically.

Range: \{-1, \ldots, \infty\}

Default: auto

treeMemoryLimit (integer): Soft limit, in megabytes, for the amount of memory to use in storing the branch and bound search tree

This doesn’t include memory used for presolve, heuristics, solving the LP relaxation, etc. When set to 0 (the default), the optimizer will calculate a limit automatically based on the amount of free physical memory detected in the machine. When the memory used by the branch and bound tree exceeds this limit, the optimizer will try to reduce the memory usage by writing lower-rated sections of the tree to a file called the "global file". Though the solve can continue if it cannot bring the tree memory usage below the specified limit, performance will be inhibited and a message will be printed to the log.

Range: \{0, \ldots, \infty\}

Default: auto

treeMemorySavingTarget (real): When the memory used by the branch-and-bound search tree exceeds the limit specified by the treeMemoryLimit control, the optimizer will try to save memory by writing lower-rated sections of the tree to the global file

The target amount of memory to save will be enough to bring memory usage back below the limit, plus enough extra to give the tree room to grow. The treeMemorySavingTarget control specifies the extra proportion of the tree’s size to try to save; for example, if the tree memory limit is 1000Mb and treeMemorySavingTarget is 0.1, when the tree size exceeds 1000Mb the optimizer will try to reduce the tree size to 900Mb. Reducing the value of treeMemorySavingTarget will cause less extra nodes of the tree to be written to the global file, but will result in the memory saving routine being triggered more often (as the tree will have less room in which to grow), which can reduce performance. Increasing the value of treeMemorySavingTarget will cause additional, more highly-rated nodes, of the tree to be written to the global file, which can cause performance issues if these nodes are required later in the solve.

Range: \{0, \infty\}

Default: 0.4

treePresolve (integer): Determines the amount of full presolving to apply to nodes of the branch-and-bound tree search

The presolving of nodes will restrict the handling of user cuts. If a node in the tree has been presolved, it will not be possible to call XPRSloadcuts to load user cuts from the global pool into the node or any of its descendants. Any user cuts already loaded into a node problem will automatically be presolved with the node, but will afterwards appear as new user cuts. User cuts can still be added to a presolved node or its descendants, but any such cut must be presolved to match the node it is being loaded into. A cut can be presolved by calling XPRSpresolverow, and this should be done immediately before calling XPRSaddrows to load the cut, to ensure that the cut is being presolved to match the current node.

Default: auto

<table>

</tr>
</tbody>
</table>

**treeQCCuts** *(integer)*: Branch and Bound: Limit on the number of rounds of outer approximation cuts generated for nodes other than the root node, when solving a mixed integer quadratic constrained or mixed integer second order conic problem with outer approximation

This control only has an effect for problems with quadratic or second order cone constraints, and only if outer approximation has not been disabled by setting `miqcpAlg` to 0.

Range: `{−1, ..., ∞}`

Default: `auto`

**varSelection** *(integer)*: Branch and Bound: Determines the formula used to calculate the estimate of each integer variable, and thus which integer variable is selected to be branched on at a given node

The variable selected to be branched on is the one with the maximum estimate.

Default: `auto`

<table>

<td>Equivalent to xslp_algorithm_clampExtendedAll.</td>
</tr>
</tbody>
</table>

**xslp_algorithm_cascadeBounds** *(boolean):* Step bounds are updated to accommodate cascaded values (otherwise cascaded values are pushed to respect step bounds) ←

Synonym: slpAlgorithmCascadeBounds

Normally, cascading will respect the step bounds of the SLP variable being cascaded. However, allowing the cascaded value to fall outside the step bounds (i.e. expanding the step bounds) can lead to better linearizations, as cascading will set better values for the SLP variables regarding their determining rows; note, that this later strategy might interfere with convergence of the cascaded variables.

See also **xslp_algorithm**.

Default: 0

**xslp_algorithm_clampExtendedActiveSB** *(boolean):* Apply clamping when converged on extended criteria only with some variables having active step bounds ←

Synonym: slpAlgorithmClampExtendedActiveSB

When clamping is applied, then in any iteration when the solution would normally be deemed converged on extended criteria only, an extra step bound shrinking step is applied to help imposing strict convergence. In this variant, clamping is only applied on variables that have converged on extended criteria only and have active step bounds.

See also **xslp_algorithm**.

Default: 0
**xslp.algorithm_clampExtendedAll** *(boolean)*: Apply clamping when converged on extended criteria only

```
Synonym: slpAlgorithmClampExtendedAll
```

When clamping is applied, then in any iteration when the solution would normally be deemed converged on extended criteria only, an extra step bound shrinking step is applied to help imposing strict convergence. In this variant, clamping is applied on all variables that have converged on extended criteria only.

See also **xslp.algorithm**.

Default: 0

**xslp.algorithm_dynamicDamping** *(boolean)*: Use dynamic damping

```
Synonym: slpAlgorithmDynamicDamping
```

Dynamic damping is sometimes an alternative to step bounding as a means of encouraging convergence, but it does not have the same power to force convergence as do step bounds.

See also **xslp.algorithm**.

Default: 0

**xslp.algorithm_escaltPenalties** *(boolean)*: Escalate penalties

```
Synonym: slpAlgorithmEscalatePenalties
```

Constraint penalties are increased after each SLP iteration where penalty vectors are present in the solution. Escalation applies an additional scaling factor to the penalty costs for active errors. This helps to prevent successive solutions becoming "stuck" because of a particular constraint, because its cost will be raised so that other constraints may become more attractive to violate instead and thus open up a new region to explore.

See also **xslp.algorithm**.

Default: 0

**xslp.algorithm_estimateStepBounds** *(boolean)*: Estimate step bounds from early SLP iterations

```
Synonym: slpAlgorithmEstimateStepBounds
```

If initial step bounds are not being explicitly provided, this gives a good method of calculating reasonable values. Values will tend to be larger rather than smaller, to reduce the risk of infeasibility caused by excessive tightness of the step bounds.

See also **xslp.algorithm**.

Default: 1

**xslp.algorithm_holdValues** *(boolean)*: Do not update values which are converged within strict tolerance

```
``
Synonym: slpAlgorithmHoldValues

Models which are numerically unstable may benefit from this setting, which does not update values which have effectively hardly changed. If a variable subsequently does move outside its strict convergence tolerance, it will be updated as usual.

See also xslp_algorithm.

Default: 0

**xslp_algorithm_maxCostOption** *(boolean):* Continue optimizing after penalty cost reaches maximum

Synonym: slpAlgorithmMaxCostOption

Normally if the penalty cost reaches its maximum (by default the value of infinity), the optimization will terminate with an unconverged solution. If the maximum value is set to a smaller value, then it may make sense to continue, using other means to determine when to stop.

See also xslp_algorithm.

Default: 0

**xslp_algorithm_noLPPolishing** *(boolean):* Skip the solution polishing step if the LP postsolve returns a slightly infeasible, but claimed optimal solution

Synonym: slpAlgorithmNoLPPolishing

Due to the nature of the SLP linearizations, and in particular because of the large differences in the objective function (model objective against penalty costs) some dual reductions in the linear presolver might introduce numerically instable reductions that cause slight infeasibilities to appear in postsolve. It is typically more efficient to remove these infeasibilities with an extra call to the linear optimizer; compared to switching these reductions off, which usually has a significant cost in performance. This bit is provided for numerically very hard problems, when the polishing step proves to be too expensive (Xpress SLP will report these if any in the final log summary).

See also xslp_algorithm.

Default: 0

**xslp_algorithm_noStepBounds** *(boolean):* Do not apply step bounds

Synonym: slpAlgorithmNoStepBounds

The default algorithm uses step bounds to force convergence. Step bounds may not be appropriate if dynamic damping is used.

See also xslp_algorithm.

Default: 0

**xslp_algorithm_quickConvergenceCheck** *(boolean):* Quick convergence check
Synonym: slpAlgorithmQuickConvergenceCheck

Normally, each variable is checked against all convergence criteria until either a criterion is found which it passes, or it is declared “not converged”. Later (extended convergence) criteria are more expensive to test and, once an unconverted variable has been found, the overall convergence status of the solution has been established. The quick convergence check carries out checks on the strict criteria, but omits checks on the extended criteria when an unconverted variable has been found.

See also xslp_algorithm.

Default: 1

**xslp_algorithm_resetDeltaZ (boolean):** Reset xslp_delta_z to zero when converged and continue SLP →

Synonym: slpAlgorithmResetDeltaZ

One of the mechanisms to avoid local optima is to retain small non-zero coefficients between delta vectors and constraints, even when the coefficient should strictly be zero. If this option is set, then a converged solution will be continued with zero coefficients as appropriate.

See also xslp_algorithm.

Default: 0

**xslp_algorithm_residualErrors (boolean):** Accept a solution which has converged even if there are still significant active penalty error vectors →

Synonym: slpAlgorithmResidualErrors

Normally, the optimization will continue if there are active penalty vectors in the solution. However, it may be that there is no feasible solution (and so active penalties will always be present). Setting bit 12 means that, if other convergence criteria are met, then the solution will be accepted as converged and the optimization will stop.

See also xslp_algorithm.

Default: 0

**xslp_algorithm_retainPreviousValue (boolean):** Retain previous value when cascading if determining row is zero ↔

Synonym: slpAlgorithmRetainPreviousValue

If the determining row is zero (that is, all the coefficients interacting with it are either zero or in columns with a zero activity), then it is impossible to calculate a new value for the vector being cascaded. The choice is to use the solution value as it is, or to revert to the assumed value.

See also xslp_algorithm.

Default: 1

**xslp_algorithm_stepBoundsAsRequired (boolean):** Apply step bounds to SLP delta vectors only when required ↔
Synonym: slpAlgorithmStepBoundsAsRequired

Step bounds can be applied to all vectors simultaneously, or applied only when oscillation of the delta vector (change in sign between successive SLP iterations) is detected.

See also xslp_algorithm.

Default: 1

**xslp_algorithm_switchToPrimal** *(boolean):* Use the primal simplex algorithm when all error vectors become inactive ←

Synonym: slpAlgorithmSwitchToPrimal

The primal simplex algorithm often performs better than dual during the final stages of SLP optimization when there are relatively few basis changes between successive solutions. As it is impossible to establish in advance when the final stages are being reached, the disappearance of error vectors from the solution is used as a proxy.

See also xslp_algorithm.

Default: 0

**xslp_analyze** *(integer):* Bit map activating additional options supporting model / solution path analysis ←

Synonym: slpAnalyze

Normally, the value of this control does not affect the solution process itself. However, bit 3 (extended summary) will cause SLP to do more function evaluations, and the presence of non-deterministic user functions might cause changes in the solution process. These options are off by default due to performance considerations.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

<table>

</tbody>
</table>

**xslp_analyze_autosavePool** *(boolean):* Save the solutions collected in the pool to disk ←

Synonym: slpAnalyzeAutosavePool

See also xslp_analyze.

Default: 0
**xslp_analyze_extendedFinalSummary** *(boolean):* Include an extended iteration summary →

Synonym: slpAnalyzeExtendedFinalSummary

See also `xslp_analyze`.

Default: 0

**xslp_analyze_infeasibleIteration** *(boolean):* Run infeasibility analysis on infeasible iterations →

Synonym: slpAnalyzeInfeasibleIteration

See also `xslp_analyze`.

Default: 0

**xslp_analyze_recordLinearization** *(boolean):* Add solutions of the linearizations to the solution pool →

Synonym: slpAnalyzeRecordLinearization

See also `xslp_analyze`.

Default: 0

**xslp_analyze_recordLinesearch** *(boolean):* Add line search solutions to the solution pool →

Synonym: slpAnalyzeRecordLinesearch

See also `xslp_analyze`.

Default: 0

**xslp_analyze_saveFile** *(boolean):* Create an Xpress SLP save file at every `xslp_autosave` iterations →

Synonym: slpAnalyzeSaveFile

See also `xslp_analyze`.

Default: 0

**xslp_analyze_saveIterBasis** *(boolean):* Write the initial basis of the linearizations to disk at every `xslp_autosave` iterations →

Synonym: slpAnalyzeSaveIterBasis

See also `xslp_analyze`.

Default: 0

**xslp_analyze_saveLinearizations** *(boolean):* Write the linearizations to disk at every `xslp_autosave` iterations →

Synonym: slpAnalyzeSaveLinearizations

See also `xslp_analyze`.

Default: 0

**xslp_aTol_a** *(real):* Absolute delta convergence tolerance →
Synonym: slpATolA

The absolute delta convergence criterion assesses the change in value of a variable ($\delta X$) against the absolute delta convergence tolerance. If $\delta X < xslp.aTol.a$ then the variable has converged on the absolute delta convergence criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target $xslp.validationTarget.r$. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$  
Default: auto

**xslp.aTol.r (real)**: Relative delta convergence tolerance ←

Synonym: slpATolR

The relative delta convergence criterion assesses the change in value of a variable ($\delta X$) relative to the value of the variable ($X$), against the relative delta convergence tolerance. If $\delta X < X \cdot xslp.aTol.r$ then the variable has converged on the relative delta convergence criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target $xslp.validationTarget.r$. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$  
Default: auto

**xslp_augmentation (integer)**: Bit map describing the SLP augmentation method(s) to be used ←

Synonym: slpAugment

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 12

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>bit 10 = 1024</td>
<td>Equivalent to $xslp.augmentation_{noUpdateIfOnlyIV}$.</td>
</tr>
</tbody>
</table>

**xslp_augmentation_allErrorVectors (boolean)**: Penalty error vectors on all non-linear inequality constraints ←

Synonym: slpAugmentAllErrorVectors

The linearization of a nonlinear constraint is inevitably an approximation and so may not be feasible except at the point of linearization. Adding penalty error vectors allows the linear approximation to be violated at a cost and so ensures that the linearized constraint is feasible.
See also `xslp_augmentation`.

Default: 1

**xslp_augmentation_allRowErrorVectors** *(boolean)*: Penalty error vectors on all constraints

Synonym: `slpAugmentAllRowErrorVectors`

If the linear portion of the underlying model may actually be infeasible, then applying penalty vectors to all rows may allow identification of the infeasibility and may also allow a useful solution to be found.

See also `xslp_augmentation`.

Default: 0

**xslp_augmentation_aMeanWeight** *(boolean)*: Use arithmetic means to estimate penalty weights

Synonym: `slpAugmentAMeanWeight`

Penalty weights are estimated from the magnitude of the elements in the constraint or interacting rows. Geometric means are normally used, so that a few excessively large or small values do not distort the weights significantly. Arithmetic means will value the coefficients more equally.

See also `xslp_augmentation`.

Default: 0

**xslp_augmentation_equalityErrorVectors** *(boolean)*: Penalty error vectors on all non-linear equality constraints

Synonym: `slpAugmentEqualityErrorVectors`

The linearization of a nonlinear equality constraint is inevitably an approximation and so will not generally be feasible except at the point of linearization. Adding penalty error vectors allows the linear approximation to be violated at a cost and so ensures that the linearized constraint is feasible.

See also `xslp_augmentation`.

Default: 1

**xslp_augmentation_evenHanded** *(boolean)*: Even handed augmentation

Synonym: `slpAugmentEvenHanded`

Standard augmentation treats variables which appear in non-constant coefficients in a different way from those which contain non-constant coefficients. Even- handed augmentation treats them all in the same way by replacing each non- constant coefficient \( C \) in a vector \( V \) by a new coefficient \( C \cdot V \) in the "equals" column (which has a fixed activity of 1) and creating delta vectors for all types of variable in the same way.

See also `xslp_augmentation`.

Default: 0

**xslp_augmentation_minimum** *(boolean)*: Minimum augmentation
Synonym: slpAugmentMinimum

Standard augmentation includes delta vectors for all variables involved in nonlinear terms (in non-constant coefficients or as vectors containing non-constant coefficients). Includes delta vectors only for variables in non-constant coefficients. This produces a smaller linearization, but there is less control on convergence, because convergence control (for example, step bounding) cannot be applied to variables without deltas.

See also xslp_augmentation.

Default: 0

**xslp_augmentation_noUpdateIfOnlyIV** *(boolean)*: Initial values do not imply an SLP variable

Synonym: slpAugmentNoUpdateIfOnlyIV

Having an initial value will not cause the augmentation to include the corresponding delta variable; i.e. treat the variable as an SLP variable. Useful to provide initial values necessary in the first linearization in case of a minimal augmentation, or as a convenience option when it’s easiest to set an initial value for all variables for some reason.

See also xslp_augmentation.

Default: 0

**xslp_augmentation_penaltyDeltaVectors** *(boolean)*: Penalty vectors to exceed step bounds

Synonym: slpAugmentPenaltyDeltaVectors

Although it has rarely been found necessary or desirable in practice, Xpress-SLP allows step bounds to be violated at a cost. This may help with feasibility but it generally slows down or prevents convergence, so it should be used only if found absolutely necessary.

See also xslp_augmentation.

Default: 0

**xslp_augmentation_sbFromAbsValues** *(boolean)*: Estimate step bounds from absolute values of row coefficients

Synonym: slpAugmentSBFromAbsValues

If step bounds are to be imposed from the start, the best approach is to provide explicit values for the bounds. Alternatively, Xpress-SLP can estimate the values from the largest estimated magnitude of the coefficients in the relevant rows.

See also xslp_augmentation.

Default: 0

**xslp_augmentation_sbFromValues** *(boolean)*: Estimate step bounds from values of row coefficients

Synonym: slpAugmentSBFromValues

If step bounds are to be imposed from the start, the best approach is to provide explicit values for the bounds. Alternatively, Xpress-SLP can estimate the values from the range of estimated coefficient sizes in the relevant rows.

See also xslp_augmentation.

Default: 0
**xslp_augmentation_stepBoundRows** *(boolean)*: Row-based step bounds ←

Synonym: slpAugmentStepBoundRows

Step bounds are normally applied as bounds on the delta variables. Some applications may find that using explicit rows to bound the delta vectors gives better results.

See also **xslp_augmentation**.

Default: 0

**xslp_autosave** *(integer)*: Frequency with which to save the model ←

Synonym: slpAutosave

A value of zero means that the model will not automatically be saved. A positive value of n will save model information at every nth SLP iteration as requested by **xslp_analyze**.

Range: \{0, ..., ∞\}

Default: 0

**xslp_barCrossOverStart** *(integer)*: Default crossover activation behaviour for barrier start ←

Synonym: slpBarCrossOverStart

When **xslp_barLimit** is set, **xslp_barCrossOverStart** offers an overwrite control on when crossover is applied. A positive value indicates that crossover should be disabled in iterations smaller than **xslp_barCrossOverStart** and should be enabled afterwards, or when stalling is detected as described in **xslp_barStartOps**. A value of 0 indicates to respect the value of crossover and only overwrite its value when stalling is detected. A value of -1 indicates to always rely on the value of crossover.

Range: \{0, ..., ∞\}

Default: 0

**xslp_barLimit** *(integer)*: Number of initial SLP iterations using the barrier method ←

Synonym: slpBarLimit

Particularly for larger models, using the Newton barrier method is faster in the earlier SLP iterations. Later on, when the basis information becomes more useful, a simplex method generally performs better. **xslp_barLimit** sets the number of SLP iterations which will be performed using the Newton barrier method.

Range: \{0, ..., ∞\}

Default: 0

**xslp_barStallingLimit** *(integer)*: Number of iterations to allow numerical failures in barrier before switching to dual ←

Synonym: slpBarStallingLimit

On large problems, it may be beneficial to warm start progress by running a number of iterations with the barrier solver as specified by \texttt{xslp\_barLimit}. On some numerically difficult problems, the barrier may stop prematurely due to numerical issues. Such solves can sometimes be finished if crossover is applied. After \texttt{xslp\_barStallingLimit} such attempts, SLP will automatically switch to use the dual simplex.

Range: \{0, ..., \infty\}

Default: 3

\textbf{\texttt{xslp\_barStallingObjLimit} (integer):} Number of iterations over which to measure the objective change for barrier iterations with no crossover

Synonym: slpBarStallingObjLimit

On large problems, it may be beneficial to warm start progress by running a number of iterations with the barrier solver without crossover by setting \texttt{xslp\_barLimit} to a positive value and setting \texttt{crossover} to 0. A potential drawback is slower convergence due to the interior point provided by the barrier solve keeping a higher number of variables active. This may lead to stalling in progress, negating the benefit of using the barrier. When in the last \texttt{xslp\_barStallingObjLimit} iterations no significant progress has been made, crossover is automatically enabled.

Range: \{0, ..., \infty\}

Default: 3

\textbf{\texttt{xslp\_barStallingTol} (real):} Required change in the objective when progress is measured in barrier iterations without crossover

Synonym: slpBarStallingTol

Minimum objective variability change required in relation to control \texttt{xslp\_barStallingObjLimit} for the iterations to be regarded as making progress. The net objective, error cost and error sum are taken into account.

Range: \([0, \infty]\)

Default: 0.05

\textbf{\texttt{xslp\_barStartOps} (integer):} Controls behaviour when the barrier is used to solve the linearizations

Synonym: slpBarStart

Setting single boolean options will overwrite the single bits of this bit map option.

Default: -1

\begin{center}
\begin{tabular}{|c|c|}
\hline
value & meaning \\
\hline
bit 0 = 1 & Equivalent to \texttt{xslp\_barStartOps\_stallingObjective}. \\
bit 1 = 2 & Equivalent to \texttt{xslp\_barStartOps\_stallingNumerical}. \\
bit 2 = 4 & Equivalent to \texttt{xslp\_barStartOps\_allowInteriorSol}. \\
\hline
\end{tabular}
\end{center}

\textbf{\texttt{xslp\_barStartOps\_allowInteriorSol} (boolean):} If a non-vertex converged solution found by barrier
without crossover can be returned as a final solution

Synonym: slpBarStartAllowInteriorSol

See also xslp_barStartOps.

Default: 1

**xslp_barStartOps_stallingNumerical** *(boolean)*: Fall back to dual simplex if too many numerical problems are reported by the barrier

Synonym: slpBarStartStallingNumerical

See also xslp_barStartOps.

Default: 1

**xslp_barStartOps_stallingObjective** *(boolean)*: Check objective progress when no crossover is applied

Synonym: slpBarStartStallingObjective

See also xslp_barStartOps.

Default: 1

**xslp_calcThreads** *(integer)*: Number of threads used for formula and derivatives evaluations

Synonym: slpCalcThreads

When beneficial, SLP can calculate formula values and partial derivative information in parallel.

Range: \{-1, ..., 1\}

Default: auto

**xslp_cdTol_a** *(real)*: Absolute tolerance for deducing constant derivatives

Synonym: slpCDTolA

The absolute tolerance test for constant derivatives is used as follows: If the value of the user function at point X0 is Y0 and the values at \((X0-\delta X)\) and \((X0+\delta X)\) are Yd and Yu respectively, then the numerical derivatives at X0 are: "down" derivative \(Dd = (Y0 - Yd) / \delta X\) "up" derivative \(Du = (Yu - Y0) / \delta X\) If \(|abs(Dd-Du)\leq xslp_cdTol_a|\) then the derivative is regarded as constant.

Range: \([0, \infty]\)

Default: 1e-08

**xslp_cdTol_r** *(real)*: Relative tolerance for deducing constant derivatives

Synonym: slpCDTolR

The relative tolerance test for constant derivatives is used as follows: If the value of the user function at point X0 is Y0 and the values at \((X0-\delta X)\) and \((X0+\delta X)\) are Yd and Yu respectively, then the numerical derivatives at X0 are: "down" derivative \(Dd = (Y0 - Yd) / \delta X\) "up" derivative \(Du = (Yu - Y0) / \delta X\) If \(|abs(Dd-Du)\leq xslp_cdTol_r*abs(Yd+Yu)/2|\) then the derivative is regarded as constant.

Range: \([0, \infty]\)

Default: 1e-08
**xslp_clampShrink** *(real)*: Shrink ratio used to impose strict convergence on variables converged in extended criteria only

Synonym: slpClampShrink

If the solution has converged but there are variables converged on extended criteria only, the `xslp_clampShrink` acts as a shrinking ratio on the step bounds and the problem is optimized (if necessary multiple times), with the purpose of expediting strict convergence on all variables. `xslp_algorithm` controls if this shrinking is applied at all, and if shrinking is applied to of the variables converged on extended criteria only with active step bounds only, or if on all variables.

Range: [0, 1]

Default: 0.3

**xslp_clampValidationTol_a** *(real)*: Absolute validation tolerance for applying `xslp_clampShrink`

Synonym: slpClampValidationTolA

If set and the absolute validation value is larger than this value, then control `xslp_clampShrink` is checked once the solution has converged, but there are variables converged on extended criteria only.

Range: [0, \( \infty \)]

Default: *not set*

**xslp_clampValidationTol_r** *(real)*: Relative validation tolerance for applying `xslp_clampShrink`

Synonym: slpClampValidationTolR

If set and the relative validation value is larger than this value, then control `xslp_clampShrink` is checked once the solution has converged, but there are variables converged on extended criteria only.

Range: [0, \( \infty \)]

Default: *not set*

**xslp_convergenceOps** *(integer)*: Bit map describing which convergence tests should be carried out

Synonym: slpConverge

Provides fine tuned control (over setting the related convergence tolerances) of which convergence checks are carried out.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 7167

Synonym: slpConvergeOTol

See also *xslp_convergenceOps*.  
Default: 1

**xslp_convergenceOps.sTol** *(boolean):* Execute the slack impact tolerance checks

Synonym: slpConvergeSTol

See also *xslp_convergenceOps*.  
Default: 1

**xslp_convergenceOps.validation** *(boolean):* Execute the validation target convergence checks
Synonym: slpConvergeValidation

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_validationK (boolean): Execute the first order optimality target convergence checks

Synonym: slpConvergeValidationK

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_vTol (boolean): Execute the objective range checks

Synonym: slpConvergeV Tol

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_wTol (boolean): Execute the convergence continuation check

Synonym: slpConvergeWTol

See also xslp_convergenceOps.

Default: 1

xslp_convergenceOps_xTol (boolean): Execute the objective range + constraint activity check

Synonym: slpConvergeXTol

See also xslp_convergenceOps.

Default: 1

xslp_cTol (real): Closure convergence tolerance

The closure convergence criterion measures the change in value of a variable (δX) relative to the value of its initial step bound (B), against the closure convergence tolerance. If δX < B * xslp_cTol then the variable has converged on the closure convergence criterion. If no explicit initial step bound is provided, then the test will not be applied and the variable can never converge on the closure criterion. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

xslp_cutStrategy (integer): Determines which cuts to apply in the MISLP search when the default SLP-in-MIP strategy is used
Synonym: mislpCutStrategy

Cuts are derived from the linearizations and are local cuts in that they are valid in the linearization and not necessarily valid for the full problem. The values mirror that of XPRS_CUTSTRATEGY.

Range: \{-1, ..., 3\}
Default: 0

\textbf{xslp\_damp (real)}: Damping factor for updating values of variables \leftrightharpoons

Synonym: slpDamp

The damping factor sets the next assumed value for a variable based on the previous assumed value (X0) and the actual value (X1). The new assumed value is given by X1*xslp\_damp + X0*(1-xslp\_damp)

Range: [0, 1]
Default: 1

\textbf{xslp\_dampExpand (real)}: Multiplier to increase damping factor during dynamic damping \leftrightharpoons

Synonym: slpDampExpand

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp\_sameDamp successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to D*xslp\_dampExpand + xslp\_dampMax*(1-xslp\_dampExpand)

Range: [0, 1]
Default: 1

\textbf{xslp\_dampMax (real)}: Maximum value for the damping factor of a variable during dynamic damping \leftrightharpoons

Synonym: slpDampMax

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp\_sameDamp successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to D*xslp\_dampExpand + xslp\_dampMax*(1-xslp\_dampExpand)

Range: [0, 1]
Default: 1

\textbf{xslp\_dampMin (real)}: Minimum value for the damping factor of a variable during dynamic damping \leftrightharpoons

Synonym: slpDampMin

If dynamic damping is enabled, the damping factor for a variable will be decreased if successive changes are in the opposite direction. More precisely, the damping factor (D) for the variable will be reset to D*xslp\_dampShrink + xslp\_dampMin*(1-xslp\_dampExpand)

Range: [0, 1]
Default: 1
**xsIp_dampShrink** *(real):* Multiplier to decrease damping factor during dynamic damping $\leftrightarrow$

Synonym: slpDampShrink

If dynamic damping is enabled, the damping factor for a variable will be decreased if successive changes are in the opposite direction. More precisely, the damping factor (D) for the variable will be reset to $D \times xsIp_dampShrink + xsIp_dampMin \times (1 - xsIp_dampExpand)$

Range: $[0, 1]$

Default: 1

**xsIp_dampStart** *(integer):* SLP iteration at which damping is activated $\leftrightarrow$

Synonym: slpDampStart

If damping is used as part of the SLP algorithm, it can be delayed until a specified SLP iteration. This may be appropriate when damping is used to encourage convergence after an un-damped algorithm has failed to converge.

Range: $\{0, ..., \infty\}$

Default: 0

**xsIp_defaultStepBound** *(real):* Minimum initial value for the step bound of an SLP variable if none is explicitly given $\leftrightarrow$

Synonym: slpDefaultStepBound

If no initial step bound value is given for an SLP variable, this will be used as a minimum value. If the algorithm is estimating step bounds, then the step bound actually used for a variable may be larger than the default. A default initial step bound is ignored when testing for the closure tolerance xsIp_cTol: if there is no specific value, then the test will not be applied.

Range: $[0, \infty]$  

Default: 16

**xsIp_deltaCost** *(real):* Initial penalty cost multiplier for penalty delta vectors $\leftrightarrow$

Synonym: slpDeltaCost

If penalty delta vectors are used, this parameter sets the initial cost factor. If there are active penalty delta vectors, then the penalty cost may be increased.

Range: $[0, \infty]$  

Default: 200

**xsIp_deltaCostFactor** *(real):* Factor for increasing cost multiplier on total penalty delta vectors $\leftrightarrow$

Synonym: slpDeltaCostFactor

If there are active penalty delta vectors, then the penalty cost multiplier will be increased by a factor of xsIp_deltaCostFactor up to a maximum of xsIp_deltaMaxCost.

Range: $[1, \infty]$  

Default: 1.3
**xlsp\_deltaMaxCost** *(real)*: Maximum penalty cost multiplier for penalty delta vectors

   Synonym: slpDeltaMaxCost

   If there are active penalty delta vectors, then the penalty cost multiplier will be increased by a factor of `xlsp\_deltaCostFactor` up to a maximum of `xlsp\_deltaMaxCost`

   Range: `[0, \infty)`

   Default: `1e+20`

**xlsp\_deltaZLimit** *(integer)*: Number of SLP iterations during which to apply `xlsp\_delta_z`

   Synonym: slpDeltaZLimit

   `xlsp\_delta_z` is used to retain small derivatives which would otherwise be regarded as zero. This is helpful in avoiding local optima, but may make the linearized problem more difficult to solve because of the number of small nonzero elements in the resulting matrix. `xlsp\_deltaZLimit` can be set to a nonzero value, which is then the number of iterations for which `xlsp\_delta_z` will be used. After that, small derivatives will be set to zero. A negative value indicates no automatic perturbations to the derivatives in any situation.

   Range: `{0, \ldots, \infty}`

   Default: `0`

**xlsp\_delta\_a** *(real)*: Absolute perturbation of values for calculating numerical derivatives

   Synonym: slpDeltaA

   First-order derivatives are calculated by perturbing the value of each variable in turn by a small amount. The amount is determined by the absolute and relative delta factors as follows: `xlsp\_delta\_a + abs(X)\times xlsp\_delta\_r` where `(X)` is the current value of the variable. If the perturbation takes the variable outside a bound, then the perturbation normally made only in the opposite direction.

   Range: `[0, \infty]`

   Default: `0.001`

**xlsp\_delta\_r** *(real)*: Relative perturbation of values for calculating numerical derivatives

   Synonym: slpDeltaR

   First-order derivatives are calculated by perturbing the value of each variable in turn by a small amount. The amount is determined by the absolute and relative delta factors as follows: `xlsp\_delta\_a + abs(X)\times xlsp\_delta\_r` where `(X)` is the current value of the variable. If the perturbation takes the variable outside a bound, then the perturbation normally made only in the opposite direction.

   Range: `[0, \infty]`

   Default: `0.001`

**xlsp\_delta\_x** *(real)*: Minimum absolute value of delta coefficients to be retained
Synonym: slpDeltaX

If the value of a coefficient in a delta column is less than this value, it will be reset to zero. Larger values of xslpDeltaZ will result in matrices with fewer elements, which may be easier to solve. However, there will be increased likelihood of local optima as some of the small relationships between variables and constraints are deleted. There may also be increased difficulties with singular bases resulting from deletion of pivot elements from the matrix.

Range: \([0, \infty)\]

Default: 1e-06

\textbf{xslp\_delta\_z} (real): Tolerance used when calculating derivatives

Synonym: slpDeltaZ

If the absolute value of a variable is less than this value, then a value of xslpDeltaZ will be used instead for calculating derivatives. If a nonzero derivative is calculated for a formula which always results in a matrix coefficient less than xslpDeltaZ, then a larger value will be substituted so that at least one of the coefficients is xslpDeltaZ in magnitude. If xslpDeltaZLimit is set to a positive number, then when that number of iterations have passed, values smaller than xslpDeltaZ will be set to zero.

Range: \([0, \infty)\]

Default: 1e-05

\textbf{xslp\_delta\_zero} (real): Absolute zero acceptance tolerance used when calculating derivatives

Synonym: slpDeltaZero

Provides an override value for the xslpDeltaZ behavior. Derivatives smaller than xslpDeltaZero will not be substituted by xslpDeltaZ, defining a range in which derivatives are deemed nonzero and are affected by xslpDeltaZ. A negative value means that this tolerance will not be applied.

Range: \([-\infty, \infty]\]

Default: -1

\textbf{xslp\_derivatives} (boolean): Bitmap describing the method of calculating derivatives

Synonym: slpDerivatives

If no bits are set then numerical derivatives are calculated using finite differences. Analytic derivatives cannot be used for formulae involving discontinuous functions. They may not work well with functions which are not smooth (such as MAX), or where the derivative changes very quickly with the value of the variable (such as LOG of small values). Both first and second order analytic derivatives can either be calculated as symbolic formulas, or by the means of auto-differentiation, with the exception that the second order symbolic derivatives require that the first order derivatives are also calculated using the symbolic method.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</table>
**xslp**_**djTol** (real): Tolerance on DJ value for determining if a variable is at its step bound →

Synonym: slpDJTol

If a variable is at its step bound and within the absolute delta tolerance xslp**_aTol_a** or closure tolerance xslp**_cTol** then the step bounds will not be further reduced. If the DJ is greater in magnitude than xslp**_djTol** then the step bound may be relaxed if it meets the necessary criteria.

Range: 

Default: 1e-06

**xslp**_**ecfCheck** (integer): Check feasibility at the point of linearization for extended convergence criteria →

Synonym: slpECFCheck

The extended convergence criteria measure the accuracy of the solution of the linear approximation compared to the solution of the original nonlinear problem. For this to work, the linear approximation needs to be reasonably good at the point of linearization. In particular, it needs to be reasonably close to feasibility. xslp**_ecfCheck** is used to determine what checking of feasibility is carried out at the point of linearization. If the point of linearization at the start of an SLP iteration is deemed to be infeasible, then the extended convergence criteria are not used to decide convergence at the end of that SLP iteration. If all that is required is to decide that the point of linearization is not feasible, then the search can stop after the first infeasible constraint is found (parameter is set to 1). If the actual number of infeasible constraints is required, then xslp**_ecfCheck** should be set to 2, and all constraints will be checked. The number of infeasible constraints found at the point of linearization is returned in XSLP**_ECFCOUNT**.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>

</tr>
<tr>
<td>2</td>
<td>Check all constraints.</td>
</tr>
</tbody>
</table>

**xslp**_**ecfTol_a** (real): Absolute tolerance on testing feasibility at the point of linearization →

Synonym: slpECFTolA

The extended convergence criteria test how well the linearization approximates the true problem. They depend on the point of linearization being a reasonable approximation — in particular, that it should be reasonably close to feasibility. Each constraint is tested at the point of linearization, and the total positive and negative contributions to the constraint from the columns in the problem are calculated. A feasibility tolerance is calculated as the largest of xslp**_ecfTol_a** and max(abs(Positive), abs(Negative)) * xslp**_ecfTol_r** If the calculated infeasibility is greater than the tolerance, the point of linearization is regarded as infeasible and the extended convergence criteria will not be applied. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp**_validationTarget_r**. Good values for the control are usually fall between 1e-1 and 1e-6.

Range: 

Default: auto
The extended convergence criteria test how well the linearization approximates the true problem. They depend on the point of linearization being a reasonable approximation — in particular, that it should be reasonably close to feasibility. Each constraint is tested at the point of linearization, and the total positive and negative contributions to the constraint from the columns in the problem are calculated. A feasibility tolerance is calculated as the largest of $\text{xslp\_ecf\_Tol\_a}$ and $\max(\text{abs}(\text{Positive}), \text{abs}(\text{Negative})) \times \text{xslp\_ecf\_Tol\_r}$. If the calculated infeasibility is greater than the tolerance, the point of linearization is regarded as infeasible and the extended convergence criteria will not be applied. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target $\text{xslp\_validation\_Target\_r}$. Good values for the control are usually fall between 1e-1 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

**xslp\_enforce\_Cost\_Shrink** *(real)*: Factor by which to decrease the current penalty multiplier when enforcing rows

Synonym: slp\_Enforce\_Cost\_Shrink

When feasibility of a row cannot be achieved by increasing the penalty cost on its error variable, removing the variable (fixing it to zero) can force the row to be satisfied, as set by $\text{xslp\_enforce\_Max\_Cost}$. After the error variables have been removed (which is equivalent to setting to row to be enforced) the penalties on the remaining error variables are rebalanced to allow for a reduction in the size of the penalties in the objective in order to achieve better numerical behaviour.

Range: $[0, 1]$

Default: 1e-05

**xslp\_enforce\_Max\_Cost** *(real)*: Maximum penalty cost in the objective before enforcing most violating rows

Synonym: slp\_Enforce\_Max\_Cost

When feasibility of a row cannot be achieved by increasing the penalty cost on its error variable, removing the variable (fixing it to zero) can force the row to be satisfied. After the error variables have been removed (which is equivalent to setting to row to be enforced) the penalties on the remaining error variables are rebalanced to allow for a reduction in the size of the penalties in the objective in order to achieve better numerical behaviour, controlled by $\text{xslp\_enforce\_Cost\_Shrink}$.

Range: $[0, \infty]$

Default: 1e+11

**xslp\_error\_Cost** *(real)*: Initial penalty cost multiplier for penalty error vectors

Synonym: slp\_Error\_Cost

If penalty error vectors are used, this parameter sets the initial cost factor. If there are active penalty error vectors, then the penalty cost may be increased.

Range: $[0, \infty]$

Default: 200
xslp_errorCostFactor (real): Factor for increasing cost multiplier on total penalty error vectors

Synonym: slpErrorCostFactor

If there are active penalty error vectors, then the penalty cost multiplier will be increased by a factor of xslp_errorCostFactor up to a maximum of xslp_errorMaxCost

Range: $[1, \infty)$
Default: 1.3

xslp_errorMaxCost (real): Maximum penalty cost multiplier for penalty error vectors

Synonym: slpErrorMaxCost

If there are active penalty error vectors, then the penalty cost multiplier will be increased by a factor of xslp_errorCostFactor up to a maximum of xslp_errorMaxCost

Range: $[0, \infty)$
Default: 1e+20

xslp_errorTol_a (real): Absolute tolerance for error vectors

Synonym: slpErrorTolA

The solution will be regarded as having no active error vectors if one of the following applies: every penalty error vector and penalty delta vector has an activity less than xslp_errorTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_a; the sum of the cost contributions from all the penalty error and penalty delta vectors is less than xslp_evTol_r * Obj where Obj is the current objective function value.

Range: $[0, \infty)$
Default: 1e-05

xslp_errorTol_p (real): Absolute tolerance for printing error vectors

Synonym: slpErrorTolP

The solution log includes a print of penalty delta and penalty error vectors with an activity greater than xslp_errorTol_p.

Range: $[0, \infty)$
Default: 0.0001

xslp_escalation (real): Factor for increasing cost multiplier on individual penalty error vectors

Synonym: slpEscalation

If penalty cost escalation is activated in xslp_algorithm then the penalty cost multiplier will be increased by a factor of xslp_escalation for any active error vector up to a maximum of xslp_maxWeight.

Range: $[1, \infty)$
Default: 1.25
**xslp_eTol_a (real):** Absolute tolerance on penalty vectors \( \rightarrow \)

*Synonym:* slpETolA

For each penalty error vector, the contribution to its constraint is calculated, together with the total positive and negative contributions to the constraint from other vectors. If its contribution is less than \( xslp_eTol_a \) or less than \( \text{Positive} \times xslp_eTol_r \) or less than \( \text{abs(Negative)} \times xslp_eTol_r \) then it will be regarded as insignificant and will not have its penalty increased. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \( xslp\_validationTarget_r \). Good values for the control are usually fall between \( 1e^{-3} \) and \( 1e^{-6} \).

*Range:* \([-\infty, \infty]\)

*Default:* \( 0.0001 \)

**xslp_eTol_r (real):** Relative tolerance on penalty vectors \( \leftrightarrow \)

*Synonym:* slpETolR

For each penalty error vector, the contribution to its constraint is calculated, together with the total positive and negative contributions to the constraint from other vectors. If its contribution is less than \( xslp_eTol_a \) or less than \( \text{Positive} \times xslp_eTol_r \) or less than \( \text{abs(Negative)} \times xslp_eTol_r \) then it will be regarded as insignificant and will not have its penalty increased. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \( xslp\_validationTarget_r \). Good values for the control are usually fall between \( 1e^{-3} \) and \( 1e^{-6} \).

*Range:* \([-\infty, \infty]\)

*Default:* \( 0.0001 \)

**xslp.evTol_a (real):** Absolute tolerance on total penalty costs \( \leftrightarrow \)

*Synonym:* slpEVToLA

The solution will be regarded as having no active error vectors if one of the following applies:
- every penalty error vector and penalty delta vector has an activity less than \( xslp\_errorTol_a \);
- the sum of the cost contributions from all the penalty error and penalty delta vectors is less than \( xslp\_evTol_a \);
- the sum of the cost contributions from all the penalty error and penalty delta vectors is less than \( \text{abs(error)} \times xslp\_evTol_r \times \text{Obj} \) where Obj is the current objective function value.

When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \( xslp\_validationTarget_r \). Good values for the control are usually fall between \( 1e^{-2} \) and \( 1e^{-6} \), but normally a magnitude larger than \( xslp.eTol_a \).

*Range:* \([-\infty, \infty]\)

*Default:* \(-1\)

**xslp.evTol_r (real):** Relative tolerance on total penalty costs \( \leftrightarrow \)

*Synonym:* slpEVToLR

The solution will be regarded as having no active error vectors if one of the following applies:
- every penalty error vector and penalty delta vector has an activity less than \( xslp\_errorTol_a \);
- the sum of the cost contributions from all the penalty error and penalty delta vectors is less than \( xslp\_evTol_a \);
- the sum of the cost contributions from all the penalty error and penalty delta vectors is less than \( \text{abs(error)} \times xslp\_evTol_r \times \text{Obj} \) where Obj is the current objective function value.

When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \( xslp\_validationTarget_r \). Good values for the control are usually fall between \( 1e^{-2} \) and \( 1e^{-6} \), but normally a magnitude larger than \( xslp.eTol_r \).

*Range:* \([-\infty, \infty]\)

*Default:* \(-1\)
**xslp\_expand** (real): Multiplier to increase a step bound

Synonym: slpExpand

If step bounding is enabled, the step bound for a variable will be increased if successive changes are in the same direction. More precisely, if there are xslp\_sameCount successive changes reaching the step bound and in the same direction for a variable, then the step bound (B) for the variable will be reset to B\*xslp\_expand.

Range: \([1, \infty]\)

Default: 2

**xslp\_feas\_Tol\_Target** (real): When set, this defines a target feasibility tolerance to which the linearizations are solved to

Synonym: slpFeasTolTarget

This is a soft version of XPRS\_FEASTOL, and will dynamically revert back to XPRS\_FEASTOL if the desired accuracy could not be achieved.

Range: \([0, \infty]\)

Default: **not set**

**xslp\_filter** (integer): Bit map for controlling solution updates

Synonym: slp_filter

Bits 0 determine if XSLP\_getslpsol should return the final converged solution, or the solution which had the best value according to the merit function. If bit 1 is set, a cascaded solution which does not improve the merit function will be rejected (Xpress SLP will revert to the solution of the linearization). Bits 2-3 determine the strategy for when the step direction is not improving according to the merit function.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 3

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 0 = 1</td>
<td>Equivalent to xslp_filterKeepBest.</td>
</tr>
<tr>
<td>bit 1 = 2</td>
<td>Check cascaded solutions against improvements in the merit function.</td>
</tr>

<tr>
<td>bit 3 = 8</td>
<td>Equivalent to xslp_filterZeroLineSearchTR.</td>
</tr>
</tbody>
</table>

**xslp\_filterKeepBest** (boolean): Retrain solution best according to the merit function

Synonym: slpFilterKeepBest

See also xslp\_filter.

Default: 1

**xslp\_filterZeroLineSearch** (boolean): Force minimum step sizes in line search
Synonym: slpFilterZeroLineSearch
See also xslp_filter.
Default: 0

\texttt{xslp\_filterZeroLineSearchTR (boolean):} Accept the trust region step is the line search returns a zero step size \( \rightarrow \)

Synonym: slpFilterZeroLineSearchTR
See also xslp_filter.
Default: 0

\texttt{xslp\_findIV (integer):} Option for running a heuristic to find a feasible initial point \( \rightarrow \)

Synonym: slpFindIV
The procedure uses bound reduction (and, up to an extent, probing) to obtain a point in the initial bounding box that is feasible for the bound reduction techniques. If an initial point is already specified and is found not to violate bound reduction, then the heuristic is not run and the given point is used as the initial solution.

Default: \texttt{auto}

<table>

</tr>
</tbody>
</table>

\texttt{xslp\_granularity (real):} Base for calculating penalty costs \( \rightarrow \)

Synonym: slpGranularity
If \texttt{xslp\_granularity} > 1, then initial penalty costs will be powers of \texttt{xslp\_granularity}.

Range: \([1, \infty]\)

Default: 4

\texttt{xslp\_hessian (integer):} Second order differentiation mode when using analytical derivatives \( \rightarrow \)

Synonym: slpHessian
Symbolic mode differentiation for the second order derivatives is only available when \texttt{xslp\_jacobian} is also set to symbolic mode.

Default: -1

<table>
<thead>

</tr>
</tbody>
</table>

**xslp_infeasLimit** *(integer):* Maximum number of consecutive infeasible SLP iterations which can occur before Xpress-SLP terminates

Synonym: slpInfeasLimit

An infeasible solution to an SLP iteration means that is likely that Xpress-SLP will create a poor linear approximation for the next SLP iteration. Sometimes, small infeasibilities arise because of numerical difficulties and do not seriously affect the solution process. However, if successive solutions remain infeasible, it is unlikely that Xpress-SLP will be able to find a feasible converged solution. **xslp_infeasLimit** sets the number of successive SLP iterations which must take place before Xpress-SLP terminates with a status of "infeasible solution".

Range: \{0, ..., \infty\}

Default: 3

**xslp_infinity** *(real):* Value returned by a divide-by-zero in a formula

Synonym: slpInfinity

Range: \[0, \infty\]

Default: \(1\times10^{10}\)

**xslp_iterLimit** *(integer):* Maximum number of SLP iterations

Synonym: slpIterLimit

If Xpress-SLP reaches **xslp_iterLimit** without finding a converged solution, it will stop. For MISLP, the limit is on the number of SLP iterations at each node.

Range: \{0, ..., \infty\}

Default: 1000

**xslp_iTol_a** *(real):* Absolute impact convergence tolerance
Synonym: slpITolA

The absolute impact convergence criterion assesses the change in the effect of a coefficient in a constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. \( E = X \times C \) where \( X \) is the activity of the matrix column in which the coefficient appears, and \( C \) is the value of the coefficient. The linearization approximates the effect of the coefficient as \( E_1 = X \times C_0 + \delta X \times C'0 \) where \( X \) is as before, \( C_0 \) is the value of the coefficient \( C \) calculated using the assumed values for the variables and \( C'0 \) is the value of \( \frac{\partial C}{\partial X} \) calculated using the assumed values for the variables. If \( C_1 \) is the value of the coefficient \( C \) calculated using the actual values for the variables, then the error in the effect of the coefficient is given by \( \delta E = X \times C_1 - (X \times C_0 + \delta X \times C'0) \). If \( \delta E < xslp\_ITol\_A \) then the variable has passed the absolute impact convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \( xslp\_validationTarget\_r \). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto

\texttt{xslp\_ITol\_r} (real): Relative impact convergence tolerance ↔

Synonym: slpITolR

The relative impact convergence criterion assesses the change in the effect of a coefficient in a constraint in relation to the magnitude of the constituents of the constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. \( E = X \times C \) where \( X \) is the activity of the matrix column in which the coefficient appears, and \( C \) is the value of the coefficient. The linearization approximates the effect of the coefficient as \( E_1 = X \times C_0 + \delta X \times C'0 \) where \( X \) is as before, \( C_0 \) is the value of the coefficient \( C \) calculated using the assumed values for the variables and \( C'0 \) is the value of \( \frac{\partial C}{\partial X} \) calculated using the assumed values for the variables. If \( C_1 \) is the value of the coefficient \( C \) calculated using the actual values for the variables, then the error in the effect of the coefficient is given by \( \delta E = X \times C_1 - (X \times C_0 + \delta X \times C'0) \). All the elements of the constraint are examined, excluding delta and error vectors: for each, the contribution to the constraint is evaluated as the element multiplied by the activity of the vector in which it appears; it is then included in a total positive contribution or total negative contribution depending on the sign of the contribution. If the predicted effect of the coefficient is positive, it is tested against the total positive contribution; if the effect of the coefficient is negative, it is tested against the total negative contribution. If \( T0 \) is the total positive or total negative contribution to the constraint (as appropriate) and \( \delta E < T0 \times xslp\_ITol\_r \) then the variable has passed the relative impact convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \( xslp\_validationTarget\_r \). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto

\texttt{xslp\_jacobian} (integer): First order differentiation mode when using analytical derivatives ↔

Synonym: slpJacobian

Symbolic mode differentiation for the second order derivatives is only available when \( xslp\_jacobian \) is set to symbolic mode.

Default: -1

**xslopLinQuadBR** *(integer)*: Use linear and quadratic constraints and objective function to further reduce bounds on all variables

Synonym: slpLinQuadBR

While bound reduction is effective when performed on nonlinear, nonquadratic constraints and objective function, it can be useful to obtain tightened bounds from linear and quadratic constraints, as the corresponding variables may appear in other nonlinear constraints. This option then allows for a slightly more expensive bound reduction procedure, at the benefit of further reduction in the problem’s bounds.

**xslopLSIterLimit** *(integer)*: Number of iterations in the line search

Synonym: slpLSIterLimit

The line search attempts to refine the step size suggested by the trust region step bounds. The line search is a local method; the control sets a maximum on the number of model evaluations during the line search.

Range: \{0, ..., ∞\}

Default: 0
**xsplp_patternLimit** *(integer)*: Number of iterations in the pattern search preceding the line search

Synonym: slpLSPatternLimit

When positive, defines the number of samples taken along the step size suggested by the trust region step bounds before initiating the line search. Useful for highly non-convex problems.

Range: \(\{0, ..., \infty\}\)

Default: 0

**xsplp_lsStart** *(integer)*: Iteration in which to active the line search

Synonym: slpLSStart

Range: \(\{0, ..., \infty\}\)

Default: 8

**xsplp_lsZeroLimit** *(integer)*: Maximum number of zero length line search steps before line search is deactivated

Synonym: slpLSZeroLimit

When the line search repeatedly returns a zero step size, counteracted by bits set on xsplp_filter, the effort spent in line search is redundant, and line search will be deactivated after xsplp_lsZeroLimit consecutive such iteration.

Range: \(\{0, ..., \infty\}\)

Default: 5

**xsplp_matrixTol** *(real)*: Provides an override value for matrixTol, which controls the smallest magnitude of matrix coefficients

Synonym: slpMatrixTol

Any value smaller than xsplp_matrixTol in magnitude will not be loaded into the linearization. This only applies to the matrix coefficients; bounds, right hand sides and objectives are not affected.

Range: \([0, \infty]\)

Default: 1e-30

**xsplp_maxWeight** *(real)*: Maximum penalty weight for delta or error vectors

Synonym: slpMaxWeight

When penalty vectors are created, or when their weight is increased by escalation, the maximum weight that will be used is given by xsplp_maxWeight.

Range: \([0, \infty]\)

Default: 100

**xsplp_meritLambda** *(real)*: Factor by which the net objective is taken into account in the merit function
Synonym: slpMeritLambda

The merit function is evaluated in the original, non-augmented / linearized space of the problem. A solution is deemed improved, if either feasibility improved, or if feasibility is not deteriorated but the net objective is improved, or if the combination of the two is improved, where the value of the xslpMeritLambda control is used to combine the two measures. A nonpositive value indicates that the combined effect should not be checked.

Range: \([0, \infty)\]
Default: 0

xslpMinSBFactor (real): Factor by which step bounds can be decreased beneath xslpATol.a

Synonym: slpMinSBFactor

Normally, step bounds are not decreased beneath xslpATol.a, as such variables are treated as converged. However, it may be beneficial to decrease step bounds further, as individual variable value changes might affect the convergence of other variables in the model, even if the variable itself is deemed converged.

Range: \([0, \infty)\]
Default: 1

xslpMinWeight (real): Minimum penalty weight for delta or error vectors

Synonym: slpMinWeight

When penalty vectors are created, the minimum weight that will be used is given by xslpMinWeight.

Range: \([0, \infty)\]
Default: 0.01

xslpMipAlgorithm (integer): Bitmap describing the MISLP algorithms to be used

Synonym: mislpAlgorithm

xslpMipAlgorithm determines the strategy of XSLPglobal for solving MINLP problems. The recommended approach is to solve the problem first without reference to the global variables. This can be handled automatically by setting bit 0 of xslpMipAlgorithm; if done manually, then optimize using the "l" option to prevent the Optimizer presolve from changing the problem. Some versions of the optimizer re-run the initial node as part of the global search; it is possible to initiate a new SLP optimization at this point by relaxing or fixing step bounds (use bits 2 and 3). If step bounds are fixed for a class of variable, then the variables in that class will not change their value in any child node. At each node, it is possible to relax or fix step bounds. It is recommended that step bounds are relaxed, so that the new problem can be solved starting from its parent, but without undue restrictions cased by step bounding (use bit 4). Exceptionally, it may be preferable to restrict the freedom of child nodes by relaxing fewer types of step bound or fixing the values of some classes of variable (use bit 5). When the optimal node has been found, it is possible to fix the global variables and then re-optimize with SLP. Step bounds can be relaxed or fixed for this optimization as well (use bits 7 and 8). Although it is ultimately necessary to solve the optimal node to convergence, individual nodes can be truncated after xslpMipIterLimit SLP iterations. Set bit 6 to activate this feature. The normal MISLP algorithm uses SLP at each node. One alternative strategy is to use the MIP optimizer for solving each SLP iteration. Set bit 9 to implement this strategy ("MIP within SLP"). Another strategy is to solve the problem to convergence ignoring the nature of the global variables. Then, fixing the linearization, use MIP to find the optimal setting of the global variables. Then, fixing the global variables, but varying the linearization, solve to convergence. Set bit 10 to implement this strategy ("SLP then MIP"). For mode details about MISLP algorithms and strategies, see the separate section.

Setting single boolean options will overwrite the single bits of this bit map option.

**xslp_mipAlgorithm_finalFixSLP** *(boolean)*: Fix step bounds according to `xslp_mipFixStepBounds` after MIP solution is found ←

Synonym: `mislpAlgorithmFinalFixSLP`

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_finalRelaxSLP** *(boolean)*: Relax step bounds according to `xslp_mipRelaxStepBounds` after MIP solution is found ←

Synonym: `mislpAlgorithmFinalRelaxSLP`

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_initialFixSLP** *(boolean)*: Fix step bounds according to `xslp_mipFixStepBounds` after initial node ←

Synonym: `mislpAlgorithmInitialFixSLP`

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_initialRelaxSLP** *(boolean)*: Relax step bounds according to `xslp_mipRelaxStepBounds` after initial node ←

Synonym: `mislpAlgorithmInitialRelaxSLP`

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_initialSLP** *(boolean)*: Solve initial SLP to convergence ←

Synonym: `mislpAlgorithmInitialSLP`

See also `xslp_mipAlgorithm`.

Default: 1
**xslp_mipAlgorithm_nodeFixSLP** *(boolean):* Fix step bounds according to `xslp_mipFixStepBounds` at each node

*Synonym: mislpAlgorithmNodeFixSLP*

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_nodeLimitSLP** *(boolean):* Limit iterations at each node to `xslp_mipIterLimit` at each node

*Synonym: mislpAlgorithmNodeLimitSLP*

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_nodeRelaxSLP** *(boolean):* Relax step bounds according to `xslp_mipRelaxStepBounds` at each node

*Synonym: mislpAlgorithmNodeRelaxSLP*

See also `xslp_mipAlgorithm`.

Default: 1

**xslp_mipAlgorithm_slpThenMIP** *(boolean):* Use MIP on converged SLP solution and then SLP on the resulting MIP solution

*Synonym: mislpAlgorithmSLPThenMIP*

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipAlgorithm_withinSLP** *(boolean):* Use MIP at each SLP iteration instead of SLP at each node

*Synonym: mislpAlgorithmWithinSLP*

See also `xslp_mipAlgorithm`.

Default: 0

**xslp_mipCutOffCount** *(integer):* Number of SLP iterations to check when considering a node for cutting off

*Synonym: mislpCutOffCount*

If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last `xslp_mipCutOffCount` SLP iterations are all worse than the best obtained so far, and the difference is greater than `xslp_mipCutOff_a` and `OBJ * xslp_mipCutOff_r` where `OBJ` is the best integer solution obtained so far. The test is not applied until at least `xslp_mipCutOffLimit` SLP iterations have been carried out at the current node.

Range: `{0, ..., ∞}`

Default: 5
xlsp_mipCutOffLimit (integer): Number of SLP iterations to check when considering a node for cutting off

    Synonym: mislpCutOffLimit

    If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xlsp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xlsp_mipCutOff_a and OBJ * xlsp_mipCutOff_r where OBJ is the best integer solution obtained so far. The test is not applied until at least xlsp_mipCutOffLimit SLP iterations have been carried out at the current node.

    Range: \( \{0, ..., \infty\} \)

    Default: 10

xlsp_mipCutOff_a (real): Absolute objective function cutoff for MIP termination

    Synonym: mislpCutOffA

    If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xlsp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xlsp_mipCutOff_a and OBJ * xlsp_mipCutOff_r where OBJ is the best integer solution obtained so far. The MIP cutoff tests are only applied after xlsp_mipCutOffLimit SLP iterations at the current node.

    Range: \([0, \infty]\)

    Default: 1e-05

xlsp_mipCutOff_r (real): Absolute objective function cutoff for MIP termination

    Synonym: mislpCutOffR

    If the objective function is worse by a defined amount than the best integer solution obtained so far, then the SLP will be terminated (and the node will be cut off). The node will be cut off at the current SLP iteration if the objective function for the last xlsp_mipCutOffCount SLP iterations are all worse than the best obtained so far, and the difference is greater than xlsp_mipCutOff_a and OBJ * xlsp_mipCutOff_r where OBJ is the best integer solution obtained so far. The MIP cutoff tests are only applied after xlsp_mipCutOffLimit SLP iterations at the current node.

    Range: \([0, \infty]\)

    Default: 1e-05

xlsp_mipDefaultAlgorithm (integer): Default algorithm to be used during the global search in MISLP

    Synonym: mislpDefaultAlgorithm

    The default algorithm used within SLP during the MISLP optimization can be set using xlsp_mipDefaultAlgorithm. It will not necessarily be the same as the one best suited to the initial SLP optimization.

    Range: \(\{1, ..., 5\}\)

    Default: 3
xslp\_mipErrorTol\_a \texttt{(real)}: Absolute penalty error cost tolerance for MIP cut-off $\leftrightarrow$

Synonym: mislpErrorTolA

The penalty error cost test is applied at each node where there are active penalties in the solution. If \texttt{xslp\_mipErrorTol\_a} is nonzero and the absolute value of the penalty costs is greater than \texttt{xslp\_mipErrorTol\_a}, the node will be declared infeasible. If \texttt{xslp\_mipErrorTol\_a} is zero then no test is made and the node will not be declared infeasible on this criterion.

Range: $[0, \infty)$

Default: 0

xslp\_mipErrorTol\_r \texttt{(real)}: Relative penalty error cost tolerance for MIP cut-off $\leftrightarrow$

Synonym: mislpErrorTolR

The penalty error cost test is applied at each node where there are active penalties in the solution. If \texttt{xslp\_mipErrorTol\_r} is nonzero and the absolute value of the penalty costs is greater than \texttt{xslp\_mipErrorTol\_r} $\times \text{abs(Obj)}$ where Obj is the value of the objective function, then the node will be declared infeasible. If \texttt{xslp\_mipErrorTol\_r} is zero then no test is made and the node will not be declared infeasible on this criterion.

Range: $[0, \infty)$

Default: 0

xslp\_mipFixStepBounds \texttt{(integer)}: Bitmap describing the step-bound fixing strategy during MISLP $\leftrightarrow$

Synonym: mislpFixStepBounds

At any node (including the initial and optimal nodes) it is possible to fix the step bounds of classes of variables so that the variables themselves will not change. This may help with convergence, but it does increase the chance of a local optimum because of excessive artificial restrictions on the variables.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 0

xslp\_mipFixStepBounds\_coef \texttt{(boolean)}: Fix step bounds on SLP variables appearing in coefficients $\leftrightarrow$

Synonym: mislpFixStepBoundsCoef

See also \texttt{xslp\_mipFixStepBounds}.

Default: 0

xslp\_mipFixStepBounds\_coefOnly \texttt{(boolean)}: Fix step bounds on SLP variables appearing only in coefficients $\leftrightarrow$
Synonym: mislpFixStepBoundsCoefOnly

See also xslp_mipFixStepBounds.

Default: 0

**xslp_mipFixStepBounds_structAll** *(boolean):* Fix step bounds on all structural SLP variables

Synonym: mislpFixStepBoundsStructAll

See also xslp_mipFixStepBounds.

Default: 0

**xslp_mipFixStepBounds_structNotCoef** *(boolean):* Fix step bounds on structural SLP variables which are not in coefficients

Synonym: mislpFixStepBoundsStructNotCoef

See also xslp_mipFixStepBounds.

Default: 0

**xslp_mipIterLimit** *(integer):* Maximum number of SLP iterations at each node

Synonym: mislpIterLimit

If bit 6 of xslp_mipAlgorithm is set, then the number of iterations at each node will be limited to xslp_mipIterLimit.

Range: \(\{0, ..., \infty\}\)

Default: 0

**xslp_mipLog** *(integer):* Frequency with which MIP status is printed

Synonym: mislpLog

By default (zero or negative value) the MIP status is printed after synchronization points. If xslp_mipLog is set to a positive integer, then the current MIP status (node number, best value, best bound) is printed every xslp_mipLog nodes.

Range: \(\{0, ..., \infty\}\)

Default: 0

**xslp_mipOCount** *(integer):* Number of SLP iterations at each node over which to measure objective function variation

Synonym: mislpOCount

The objective function test for MIP termination is applied only when step bounding has been applied (or xslp.sbStart SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last xslp_mipOCount SLP iterations is within xslp_mipOTolL or within OBJ * xslp_mipOTolR where OBJ is the average value of the objective function over those iterations.

Range: \(\{0, ..., \infty\}\)

Default: 5
**xslp.mipOTol_a** *(real)*: Absolute objective function tolerance for MIP termination ←

Synonym: mislpOTolA

The objective function test for MIP termination is applied only when step bounding has been applied (or **xslp.sbStart** SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last **xslp.mipOCount** SLP iterations is within **xslp.mipOTol_a** or within OBJ * **xslp.mipOTol_r** where OBJ is the average value of the objective function over those iterations.

Range: \([0, \infty]\)

Default: 1e-05

**xslp.mipOTol_r** *(real)*: Relative objective function tolerance for MIP termination ←

Synonym: mislpOTolR

The objective function test for MIP termination is applied only when step bounding has been applied (or **xslp.sbStart** SLP iterations have taken place if step bounding is not being used). The node will be terminated at the current SLP iteration if the range of the objective function values over the last **xslp.mipOCount** SLP iterations is within **xslp.mipOTol_a** or within OBJ * **xslp.mipOTol_r** where OBJ is the average value of the objective function over those iterations.

Range: \([0, \infty]\)

Default: 1e-05

**xslp.mipRelaxStepBounds** *(integer)*: Bitmap describing the step-bound relaxation strategy during MISLP ←

Synonym: mislpRelaxStepBounds

At any node (including the initial and optimal nodes) it is possible to relax the step bounds of classes of variables so that the variables themselves are completely free to change. This may help with finding a global optimum, but it may also increase the solution time, because more SLP iterations are necessary at each node to obtain a converged solution.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 15

<table>

**xslp.mipRelaxStepBounds.coef** *(boolean)*: Relax step bounds on SLP variables appearing in coefficients ←

Synonym: mislpRelaxStepBoundsCoef

See also **xslp.mipRelaxStepBounds**.

Default: 1
xslp_mipRelaxStepBounds_coefOnly (boolean): Relax step bounds on SLP variables appearing only in coefficients

Synonym: mislpRelaxStepBoundsCoefOnly

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_mipRelaxStepBounds_structAll (boolean): Relax step bounds on all structural SLP variables

Synonym: mislpRelaxStepBoundsStructAll

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_mipRelaxStepBounds_structNotCoef (boolean): Relax step bounds on structural SLP variables which are not in coefficients

Synonym: mislpRelaxStepBoundsStructNotCoef

See also xslp_mipRelaxStepBounds.

Default: 1

xslp_msMaxBoundRange (real): Defines the maximum range inside which initial points are generated by multistart presets

Synonym: slpMSMaxBoundRange

The is the maximum range in which initial points are generated; the actual range is expected to be smaller as bounds are domains are also considered.

Range: \([0, \infty]\)

Default: 1000

xslp_mTol_a (real): Absolute effective matrix element convergence tolerance

Synonym: slpMTolA

The absolute effective matrix element convergence criterion assesses the change in the effect of a coefficient in a constraint. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. \(E = X \ast C\) where \(X\) is the activity of the matrix column in which the coefficient appears, and \(C\) is the value of the coefficient. The linearization approximates the effect of the coefficient as \(E = X \ast C0 + \delta X \ast C'0\) where \(V\) is as before, \(C0\) is the value of the coefficient \(C\) calculated using the assumed values for the variables and \(C'0\) is the value of \(\partial C / \partial X\) calculated using the assumed values for the variables. If \(C1\) is the value of the coefficient \(C\) calculated using the actual values for the variables, then the error in the effect of the coefficient is given by \(\delta E = X \ast C1 - (X \ast C0 + \delta X \ast C'0)\) If \(\delta E < X \ast xslp_mTol_a\) then the variable has passed the absolute effective matrix element convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto
**xslp_mTol_r (real):** Relative effective matrix element convergence tolerance ↔

Synonym: slpMTolR

The relative effective matrix element convergence criterion assesses the change in the effect of a coefficient in a constraint relative to the magnitude of the coefficient. The effect of a coefficient is its value multiplied by the activity of the column in which it appears. $E = X \cdot C$ where $X$ is the activity of the matrix column in which the coefficient appears, and $C$ is the value of the coefficient. The linearization approximates the effect of the coefficient as $E_1 = X \cdot C_0 + \delta X \cdot C'$ where $V$ is as before, $C_0$ is the value of the coefficient $C$ calculated using the assumed values for the variables and $C'$ is the value of $\frac{\partial C}{\partial X}$ calculated using the assumed values for the variables. If $C_1$ is the value of the coefficient $C$ calculated using the actual values for the variables, then the error in the effect of the coefficient is given by $\delta E = X \cdot C_1 - (X \cdot C_0 + \delta X \cdot C')$ If $\delta E < E_1$ xslp_mTol_r then the variable has passed the relative effective matrix element convergence criterion for this coefficient. If a variable which has not converged on strict (closure or delta) criteria passes the (relative or absolute) impact or matrix criteria for all the coefficients in which it appears, then it is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: $[-\infty, \infty]$

Default: auto

**xslp_multistartPreset (integer):** Enable multistart ↔

Synonym: slpMultistartPreset

Default: 0

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable multistart preset.</td>
</tr>
<tr>
<td>1</td>
<td>Generate xslp_multistart_maxSolves number of random base points.</td>
</tr>
<tr>
<td>2</td>
<td>Generate xslp_multistart_maxSolves number of random base points, filtered by a merit function centred on initial feasibility.</td>
</tr>
<tr>
<td>3</td>
<td>Load the most typical SLP tuning settings. A maximum of xslp_multistart_maxSolves jobs are loaded.</td>
</tr>
<tr>
<td>4</td>
<td>Load a comprehensive set of SLP tuning settings. A maximum of xslp_multistart_maxSolves jobs are loaded.</td>
</tr>
</tbody>
</table>

**xslp_multistart_maxSolves (integer):** Maximum number of jobs to create during the multistart search ↔

Synonym: slpMultistartMaxSolves

This control can be increased on the fly during the multistart search: for example, if a job gets refused by a user callback, the callback may increase this limit to account for the rejected job.

Range: $\{-1, ..., \infty\}$

Default: unlimited

**xslp_multistart_maxTime (integer):** Maximum total time to be spent in the multistart search ↔
Synonym: slpMultistartMaxTime

XSLP.MAXTIME applies on a per job instance basis. There will be some time spent even after xslp_multistart_maxTime has elapsed, while the running jobs get terminated and their results collected.

Range: \{0, ..., \infty\}

Default: unlimited

**xslp_multistart_poolsize (integer)**: Maximum number of problem objects allowed to pool up before synchronization in the deterministic multistart

Synonym: slpMultistartPoolsize

Deterministic multistart is ensured by guaranteeing that the multistart solve results are evaluated in the same order every time. Solves that finish too soon can be pooled until all earlier started solves finish, allowing the system to start solving other multistart instances in the meantime on idle threads. Larger pool sizes will provide better speedups, but will require larger amounts of memory. Positive values are interpreted as a multiplier on the maximum number of active threads used, while negative values are interpreted as an absolute limit (and the absolute value is used). A value of zero will mean no result pooling.

Range: \{0, ..., \infty\}

Default: 2

**xslp_multistart_seed (integer)**: Random seed used for the automatic generation of initial point when loading multistart presets

Synonym: slpMultistartSeed

Range: \{-\infty, ..., \infty\}

Default: 0

**xslp_multistart_threads (integer)**: Maximum number of threads to be used in multistart

Synonym: slpMultistartThreads

The current hard upper limit on the number of threads to be sued in multistart is 64.

Range: \{-1, ..., \infty\}

Default: auto

**xslp_mvtol (real)**: Marginal value tolerance for determining if a constraint is slack

Synonym: slpMVTol

If the absolute value of the marginal value of a constraint is less than xslp_mvtol, then (1) the constraint is regarded as not constraining for the purposes of the slack tolerance convergence criteria; (2) the constraint is not regarded as an active constraint when identifying unconverted variables in active constraints. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target xslp_validationTarget_r. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \[-\infty, \infty\]

Default: auto
**xslp_objToPenaltyCost (real):** Factor to estimate initial penalty costs from objective function

Synonym: slpObjToPenaltyCost

The setting of initial penalty error costs can affect the path of the optimization and, indeed, whether a solution is achieved at all. If the penalty costs are too low, then unbounded solutions may result although Xpress-SLP will increase the costs in an attempt to recover. If the penalty costs are too high, then the requirement to achieve feasibility of the linearized constraints may be too strong to allow the system to explore the nonlinear feasible region. Low penalty costs can result in many SLP iterations, as feasibility of the nonlinear constraints is not achieved until the penalty costs become high enough; high penalty costs force feasibility of the linearizations, and so tend to find local optima close to an initial feasible point. Xpress-SLP can analyze the problem to estimate the size of penalty costs required to avoid an initial unbounded solution. xslp_objToPenaltyCost can be used in conjunction with this procedure to scale the costs and give an appropriate initial value for balancing the requirements of feasibility and optimality. Not all models are amenable to the Xpress-SLP analysis. As the analysis is initially concerned with establishing a cost level to avoid unboundedness, a model which is sufficiently constrained will never show unboundedness regardless of the cost. Also, as the analysis is done at the start of the optimization to establish a penalty cost, significant changes in the coefficients, or a high degree of nonlinearity, may invalidate the initial analysis. A setting for xslp_objToPenaltyCost of zero disables the analysis. A setting of 3 or 4 has proved successful for many models. If xslp_objToPenaltyCost cannot be used because of the problem structure, its effect can still be emulated by some initial experiments to establish the cost required to avoid unboundedness, and then manually applying a suitable factor. If the problem is initially unbounded, then the penalty cost will be increased until either it reaches its maximum or the problem becomes bounded.

Range: \([0, \infty]\)

Default: 0

**xslp_oCount (integer):** Number of SLP iterations over which to measure objective function variation for static objective (2) convergence criterion

Synonym: slpOCount

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least xslp_mvTol) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as \(\delta \text{Obj} = \text{MAXIter(Obj)} - \text{MINIter(Obj)}\) where Iter is the xslp_oCount most recent SLP iterations and Obj is the corresponding objective function value. If \(|\delta \text{Obj}| \leq xslp_oTol\) then the problem has converged on the absolute static objective (2) convergence criterion. The static objective function (2) test is applied only if xslp_oCount is at least 2.

Range: \(\{0, ..., \infty\}\)

Default: 5

**xslp_optimalityTolTarget (real):** When set, this defines a target optimality tolerance to which the linearizations are solved to

Synonym: slpOptimalityTolTarget

This is a soft version of optimalityTol, and will dynamically revert back to optimalityTol if the desired accuracy could not be achieved.

Range: \([0, \infty]\)

Default: not set
**xslp_oTol_a** *(real)*: Absolute static objective (2) convergence tolerance →

Synonym: slpOTolA

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least xslp_mvTol) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as \( \delta \text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj}) \) where Iter is the xslp_oCount most recent SLP iterations and Obj is the corresponding objective function value. If \( \text{ABS}(\delta \text{Obj}) \leq \text{xslp_oTol_a} \) then the problem has converged on the absolute static objective (2) convergence criterion. The static objective function (2) test is applied only if xslp_oCount is at least 2. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto

**xslp_oTol_r** *(real)*: Relative static objective (2) convergence tolerance →

Synonym: slpOTolR

The static objective (2) convergence criterion does not measure convergence of individual variables. Instead, it measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables interacting with active constraints (those that have a marginal value of at least xslp_mvTol) have converged. The rationale is that if the remaining unconverged variables are not involved in active constraints and if the objective function is not changing significantly between iterations, then the solution is more-or-less practical. The variation in the objective function is defined as \( \delta \text{Obj} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj}) \) where Iter is the xslp_oCount most recent SLP iterations and Obj is the corresponding objective function value. If \( \text{ABS}(\delta \text{Obj}) \leq \text{xslp_oTol_r} \) then the problem has converged on the relative static objective (2) convergence criterion. The static objective function (2) test is applied only if xslp_oCount is at least 2. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp_validationTarget_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto

**xslp_penaltyInfoStart** *(integer)*: Iteration from which to record row penalty information →

Synonym: slpPenaltyInfoStart

Information about the size (current and total) of active penalties of each row and the number of times a penalty vector has been active is recorded starting at the SLP iteration number given by xslp_penaltyInfoStart.

Range: \(\{0, ..., \infty\}\)

Default: 3

**xslp_postsolve** *(boolean)*: Determines whether postsolving should be performed automatically →

Synonym: slpPostsolve

Default: 0
xslp_presolve \((integer)\): Determines whether presolving should be performed prior to starting the main algorithm

<table>
<thead>
<tr>

<td>Equivalent to xslp_presolveOps_fixZero.</td>
</tr>
<tr>
<td>bit 2 = 4</td>
<td>Equivalent to xslp_presolveOps_fixAll.</td>
</tr>
</tbody>
</table>

Synonym: slpPresolveOps

The Xpress NonLinear nonlinear presolve (which is carried out once, before augmentation) is independent of the Optimizer presolve (which is carried out during each SLP iteration). Linear reductions are performed according to presolveOps if bit 12 is not set.

Setting single boolean options will overwrite the single bits of this bit map option.

Default: 2104

</tbody>
</table>

**xslp.presolveOps_domain** *(boolean):* Bound tightening based on function domains

Synonym: slpPresolveOpsDomain

See also xslp.presolveOps.

Default: 1

**xslp.presolveOps_eliminations** *(boolean):* Allow eliminations on determined variables

Synonym: slpPresolveOpsEliminations

See also xslp.presolveOps.

Default: 1

**xslp.presolveOps_fixAll** *(boolean):* Explicitly fix all columns identified as fixed

Synonym: slpPresolveOpsFixAll

See also xslp.presolveOps.

Default: 0

**xslp.presolveOps_fixZero** *(boolean):* Explicitly fix columns identified as fixed to zero

Synonym: slpPresolveOpsFixZero

See also xslp.presolveOps.

Default: 0

**xslp.presolveOps_general** *(boolean):* Generic SLP presolve

Synonym: slpPresolveOpsGeneral

See also xslp.presolveOps.

Default: 0

**xslp.presolveOps_intBounds** *(boolean):* MISLP bound tightening

Synonym: slpPresolveOpsIntBounds

See also xslp.presolveOps.

Default: 1
**xslp_presolveOps_noCoefficients** *(boolean):* Do not presolve coefficients

- **Synonym:** slpPresolveOpsNoCoefficients
- See also **xslp_presolveOps**.
- **Default:** 0

**xslp_presolveOps_noDeltas** *(boolean):* Do not remove delta variables

- **Synonym:** slpPresolveOpsNoDeltas
- See also **xslp_presolveOps**.
- **Default:** 0

**xslp_presolveOps_noDualSide** *(boolean):* Avoid reductions that can not be dual postsolved

- **Synonym:** slpPresolveOpsNoDualSide
- See also **xslp_presolveOps**.
- **Default:** 0

**xslp_presolveOps_setBounds** *(boolean):* SLP bound tightening

- **Synonym:** slpPresolveOpsSetBounds
- See also **xslp_presolveOps**.
- **Default:** 1

**xslp_presolvePassLimit** *(integer):* Maximum number of passes through the problem to improve SLP bounds

- **Synonym:** slpPresolvePassLimit
- The Xpress NonLinear nonlinear presolve (which is carried out once, before augmentation) is independent of the Optimizer presolve (which is carried out during each SLP iteration). The procedure carries out a number of passes through the SLP problem, seeking to tighten implied bounds or to identify fixed values. **xslp_presolvePassLimit** can be used to change the maximum number of passes carried out.
- **Range:** \{0, ..., \infty\}
- **Default:** 20

**xslp_presolveZero** *(real):* Minimum absolute value for a variable which is identified as nonzero during SLP presolve

- **Synonym:** slpPresolveZero
- During the SLP (nonlinear) presolve, a variable may be identified as being nonzero (for example, because it is used as a divisor). A bound of plus or minus **xslp_presolveZero** will be applied to the variable if it is identified as non-negative or non-positive.
- **Range:** \([0, \infty]\)
- **Default:** 1e-09
**xslp_primalIntegralRef** *(real)*: Reference solution value to take into account when calculating the primal integral

- **Synonym**: `slpPrimalIntegralRef`

When a global optimum is known, this can be used to calculate a globally valid primal integral. It can also be used to indicate the target objective value still to be taken into account in the integral.

- **Range**: $[-\infty, \infty]$
- **Default**: $1e+20$

**xslp_probing** *(integer)*: Determines whether probing on a subset of variables should be performed prior to starting the main algorithm

- **Synonym**: `slpProbing`

Probing runs multiple times bound reduction in order to further tighten the bounding box.

The Xpress NonLinear nonlinear probing, which is carried out once, is independent of the Optimizer presolve (which is carried out during each SLP iteration). The probing level allows for probing on an expanding set of variables, allowing for probing on all variables (level 5) or only those for which probing is more likely to be useful (binary variables).

- **Default**: `auto`

<table>
<thead>
<tr>

</tr>
<tr>
<td>5</td>
<td>Activate SLP probing on any variable.</td>
</tr>
</tbody>
</table>

**xslp_sameCount** *(integer)*: Number of steps reaching the step bound in the same direction before step bounds are increased

- **Synonym**: `slpSameCount`

If step bounding is enabled, the step bound for a variable will be increased if successive changes are in the same direction. More precisely, if there are `xslp_sameCount` successive changes reaching the step bound and in the same direction for a variable, then the step bound (B) for the variable will be reset to $B \times \text{xslp_expand}$.

- **Range**: $\{0, \ldots, \infty\}$
- **Default**: 3

**xslp_sameDamp** *(integer)*: Number of steps in same direction before damping factor is increased
Synonym: slpSameDamp

If dynamic damping is enabled, the damping factor for a variable will be increased if successive changes are in the same direction. More precisely, if there are \texttt{xslp\_sameDamp} successive changes in the same direction for a variable, then the damping factor (D) for the variable will be reset to \( D \times \texttt{xslp\_dampExpand} + \texttt{xslp\_dampMax} \times (1 - \texttt{xslp\_dampExpand}) \)

Range: \{0, ..., \( \infty \)\}

Default: 3

\texttt{xslp\_sbStart} (integer): SLP iteration after which step bounds are first applied

Synonym: slpSBStart

If step bounds are used, they can be applied for the whole of the SLP optimization process, or started after a number of SLP iterations. In general, it is better not to apply step bounds from the start unless one of the following applies: (1) the initial estimates are known to be good, and explicit values can be provided for initial step bounds on all variables; or (2) the problem is unbounded unless all variables are step-bounded.

Range: \{0, ..., \( \infty \)\}

Default: 8

\texttt{xslp\_scale} (integer): When to re-scale the SLP problem

Synonym: slpScale

During the SLP optimization, matrix entries can change considerably in magnitude, even when the formulae in the coefficients are not very nonlinear. Re-scaling of the matrix can reduce numerical errors, but may increase the time taken to achieve convergence.

Default: 1

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No re-scaling.</td>
</tr>
<tr>
<td>1</td>
<td>Re-scale every SLP iteration up to \texttt{xslp_scaleCount} iterations after the end of barrier optimization.</td>
</tr>
<tr>
<td>2</td>
<td>Re-scale every SLP iteration up to \texttt{xslp_scaleCount} iterations in total.</td>
</tr>
<tr>
<td>3</td>
<td>Re-scale every SLP iteration until primal simplex is automatically invoked.</td>
</tr>
<tr>
<td>4</td>
<td>Re-scale every SLP iteration.</td>
</tr>
<tr>
<td>5</td>
<td>Re-scale every \texttt{xslp_scaleCount} SLP iterations.</td>
</tr>
<tr>
<td>6</td>
<td>Re-scale every \texttt{xslp_scaleCount} SLP iterations after the end of barrier optimization.</td>
</tr>
</tbody>
</table>

\texttt{xslp\_scaleCount} (integer): Iteration limit used in determining when to re-scale the SLP matrix

Synonym: slpScaleCount

If \texttt{xslp\_scale} is set to 1 or 2, then \texttt{xslp\_scaleCount} determines the number of iterations (after the end of barrier optimization or in total) in which the matrix is automatically re-scaled.

Range: \{0, ..., \( \infty \)\}

Default: 0
**xslp_shrink (real):** Multiplier to reduce a step bound

Synonym: slpShrink

If step bounding is enabled, the step bound for a variable will be decreased if successive changes are in opposite directions. The step bound (B) for the variable will be reset to \( B \times xslp\_shrink \). If the step bound is already below the strict (delta or closure) tolerances, it will not be reduced further.

Range: \([0, 1]\)

Default: 0.5

**xslp_shrinkBias (real):** Defines an overwrite / adjustment of step bounds for improving iterations

Synonym: slpShrinkBias

Positive values overwrite \( xslp\_shrink \) only if the objective is improving. A negative value is used to scale all step bounds in improving iterations.

Range: \([-\infty, \infty]\)

Default: not set

**xslp_slpLog (integer):** Frequency with which SLP status is printed

Synonym: slpLogFreq

If \( xslp\_log \) is set to zero (minimal logging) then a nonzero value for \( xslp\_slpLog \) defines the frequency (in SLP iterations) when summary information is printed out.

Range: \( \{0, ..., \infty\} \)

Default: 1

**xslp_solver (integer):** First order differentiation mode when using analytical derivatives

Synonym: slpSolver

The presence of KNITRO is detected automatically. KNITRO can be used to solve any problem loaded into XSLP, independently from how the problem was loaded. \( xslp\_solver \) is set to automatic, Xpress SLP will be selected if any SLP specific construct has been loaded (these are ignored if KNITRO is selected manually).

Default: auto

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Automatic selection, based on model characteristics and solver availability</td>
</tr>
<tr>
<td>0</td>
<td>Use Xpress-SLP (always available)</td>
</tr>
<tr>
<td>1</td>
<td>Use Knitro if available</td>
</tr>
</tbody>
</table>

**xslp_sTol_a (real):** Absolute slack convergence tolerance

Synonym: slpSTolA
The slack convergence criterion is identical to the impact convergence criterion, except that the tolerances used are \texttt{xslp.sTol.a} (instead of \texttt{xslp.iTol.a}) and \texttt{xslp.sTol.r} (instead of \texttt{xslp.iTol.r}). See \texttt{xslp.iTol.a} for a description of the test. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \texttt{xslp.validationTarget.r}. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: \texttt{auto}

\texttt{xslp.sTol.r} (real): Relative slack convergence tolerance ↔

Synonym: \texttt{slpSTolR}

The slack convergence criterion is identical to the impact convergence criterion, except that the tolerances used are \texttt{xslp.sTol.a} (instead of \texttt{xslp.iTol.a}) and \texttt{xslp.sTol.r} (instead of \texttt{xslp.iTol.r}). See \texttt{xslp.iTol.r} for a description of the test. When the value is set to be negative, the value is adjusted automatically by SLP, based on the feasibility target \texttt{xslp.validationTarget.r}. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: \texttt{auto}

\texttt{xslp.stopOutOfRange} (boolean): Stop optimization and return error code if internal function argument is out of range ↔

Synonym: \texttt{slpStopOutOfRange}

If \texttt{xslp.stopOutOfRange} is set to 1, then if an internal function receives an argument which is out of its allowable range (for example, \texttt{LOG} of a negative number), an error code is set and the optimization is terminated.

Default: \texttt{0}

\texttt{xslp_threads} (integer): Default number of threads to be used ↔

Synonym: \texttt{slpThreads}

Overall thread control value, used to determine the number of threads used where parallel calculations are possible.

Range: \([-1, \ldots, \infty]\)

Default: \texttt{auto}

\texttt{xslp_timePrint} (boolean): Print additional timings during SLP optimization ↔

Synonym: \texttt{slpTimePrint}

Date and time printing can be useful for identifying slow procedures during the SLP optimization. Setting \texttt{xslp.timePrint} to 1 prints times at additional points during the optimization.

Default: \texttt{0}

\texttt{xslp_unfinishedLimit} (integer): Number of consecutive SLP iterations that may have an unfinished status before the solve is terminated ↔
If the optimization of the current linear approximation terminates with an "unfinished" status, then first a number of strategies are applied to attempt a successful solve of the same linearization. If this fails, then a new iteration is started to change the linearization itself. This control limits the number of such repeated attempts.

Range: \( \{0, \ldots, \infty\} \)

Default: 3

**xslp_validationTarget_k (real):** Optimality target tolerance

Primary optimality control for SLP. When the relevant optimality based convergence controls are left at their default values, SLP will adjust their value to match the target. The control defines a target value, that may not necessarily be attainable for problem with no strong constraint qualifications.

Range: \( [0, \infty] \)

Default: 1e-06

**xslp_validationTarget_r (real):** Feasibility target tolerance

Primary feasibility control for SLP. When the relevant feasibility based convergence controls are left at their default values, SLP will adjust their value to match the target. The control defines a target value, that may not necessarily be attainable.

Range: \( [0, \infty] \)

Default: 1e-06

**xslp_vCount (integer):** Number of SLP iterations over which to measure static objective (3) convergence

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as \( \delta_{\text{Obj}} = \text{MAXIter}(\text{Obj}) - \text{MINIter}(\text{Obj}) \) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If \( \text{ABS}(\delta_{\text{Obj}}) \leq \text{xslp_vTol_a} \) then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit + xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced.

Range: \( \{0, \ldots, \infty\} \)

Default: 0
**xslp_vLimit** *(integer)*: Number of SLP iterations after which static objective (3) convergence testing starts ←

Synonym: slpVLimit

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as \(\delta \text{Obj} = \text{MAXIter(Obj)} - \text{MINIter(Obj)}\) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If \(|\delta \text{Obj}| \leq xslp_vTol\_a\) then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit + xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced.

Range: \(\{0, \ldots, \infty\}\)

Default: 0

**xslp_vTol\_a** *(real)*: Absolute static objective (3) convergence tolerance ←

Synonym: slpVTolA

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as \(\delta \text{Obj} = \text{MAXIter(Obj)} - \text{MINIter(Obj)}\) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If \(|\delta \text{Obj}| \leq xslp_vTol\_a\) then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit + xslp_sbStart SLP iterations have taken place and only if xslp_vCount is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target xslp\_validationTarget\_k. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto

**xslp_vTol\_r** *(real)*: Relative static objective (3) convergence tolerance ←

Synonym: slpVTolR

The static objective (3) convergence criterion does not measure convergence of individual variables, and in fact does not in any way imply that the solution has converged. However, it is sometimes useful to be able to terminate an optimization once the objective function appears to have stabilized. One example is where a set of possible schedules are being evaluated and initially only a good estimate of the likely objective function value is required, to eliminate the worst candidates. The variation in the objective function is defined as \(\delta \text{Obj} = \text{MAXIter(Obj)} - \text{MINIter(Obj)}\) where Iter is the xslp_vCount most recent SLP iterations and Obj is the corresponding objective function value. If \(|\delta \text{Obj}| \leq \text{AVGIter(Obj)} \times xslp_vTol\_r\) then the problem has converged on the absolute static objective function (3) criterion. The static objective function (3) test is applied only if after at least xslp_vLimit
• `xslp sbStart` SLP iterations have taken place and only if `xslp vCount` is at least 2. Where step bounding is being used, this ensures that the test is not applied until after step bounding has been introduced. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target `xslp validationTarget k`. Good values for the control are usually fall between 1e-3 and 1e-6.

Range: [-∞, ∞]

Default: auto

`xslp wCount` (integer): Number of SLP iterations over which to measure the objective for the extended convergence continuation criterion ←

Synonym: `slpWCount`

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last converged solution is given by: \( \delta \text{Obj} = \text{Obj} - \text{LastConvergedObj} \) For a minimization problem, the sign is reversed. If \( \delta \text{Obj} > xslp wTol a \) and \( \delta \text{Obj} > \text{ABS(ConvergedObj)} \times xslp wTol r \) then the solution is deemed to have a significantly better objective function value than the converged solution. When a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the `xslp wCount` most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. If `xslp wCount` is zero, then the extended convergence continuation criterion is disabled.

Range: \( \{0, \ldots, \infty\} \)

Default: 0

`xslp wTol a` (real): Absolute extended convergence continuation tolerance ←

Synonym: `slpWTolA`

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last
converged solution is given by: \( \delta \text{Obj} = \text{Obj} - \text{LastConvergedObj} \) For a minimization problem, the sign is reversed. If \( \delta \text{Obj} > xslp_{wTol}^{a} \) and \( \delta \text{Obj} > \text{ABS} (\text{ConvergedObj}) \times xslp_{wTol}^{r} \) then the solution is deemed to have a significantly better objective function value than the converged solution. When a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the \( xslp_{wCount} \) most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target \( xslp_{validationTarget}^{k} \). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\]

Default: auto

\textit{xslp}_{wTol}^{r} (real): \ Relative extended convergence continuation tolerance

Synonym: \ slpWTolR

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. The extended convergence continuation criterion is applied after a converged solution has been found where at least one variable has converged on extended criteria and is at its step bound limit. The extended convergence continuation test measures whether any improvement is being achieved when additional SLP iterations are carried out. If not, then the last converged solution will be restored and the optimization will stop. For a maximization problem, the improvement in the objective function at the current iteration compared to the objective function at the last converged solution is given by: \( \delta \text{Obj} = \text{Obj} - \text{LastConvergedObj} \) For a minimization problem, the sign is reversed. If \( \delta \text{Obj} > xslp_{wTol}^{a} \) and \( \delta \text{Obj} > \text{ABS} (\text{ConvergedObj}) \times xslp_{wTol}^{r} \) then the solution is deemed to have a significantly better objective function value than the converged solution. If \( xslp_{wCount} \) is greater than zero, and a solution is found which converges on extended criteria and with active step bounds, the solution is saved and SLP optimization continues until one of the following: (1) a new solution is found which converges on some other criterion, in which case the SLP optimization stops with this new solution; (2) a new solution is found which converges on extended criteria and with active step bounds, and which has a significantly better objective function, in which case this is taken as the new saved solution; (3) none of the \( xslp_{wCount} \) most recent SLP iterations has a significantly better objective function than the saved solution, in which case the saved solution is restored and the SLP optimization stops. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target \( xslp_{validationTarget}^{k} \). Good values for the control are usually fall between 1e-4 and 1e-6.

Range: \([-\infty, \infty]\]

Default: auto

\textit{xslp}_{xCount} (integer): Number of SLP iterations over which to measure static objective (1) convergence

←
Synonym: slpXCount

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. Because all the variables have converged, the solution is already converged but the fact that some variables are at their step bound limit suggests that the objective function could be improved by going further. The variation in the objective function is defined as $\delta \text{Obj} = \max(\text{Iter}(\text{Obj})) - \min(\text{Iter}(\text{Obj}))$ where Iter is the xslp.xCount most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta \text{Obj}) \leq x\text{slp}.\text{xTol.a}$ then the objective function is deemed to be static according to the absolute static objective function (1) criterion. If $\text{ABS}(\delta \text{Obj}) \leq \text{AVGIter}(\text{Obj}) \times x\text{slp}.\text{xTol.r}$ then the objective function is deemed to be static according to the relative static objective function (1) criterion. The static objective function (1) test is applied only until xslp.xLimit SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged.

Range: \{0, ..., $\infty$\}

Default: 5

\textbf{xslp.xLimit (integer): Number of SLP iterations up to which static objective (1) convergence testing starts}

Synonym: slpXLimit

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. Because all the variables have converged, the solution is already converged but the fact that some variables are at their step bound limit suggests that the objective function could be improved by going further. The variation in the objective function is defined as $\delta \text{Obj} = \max(\text{Iter}(\text{Obj})) - \min(\text{Iter}(\text{Obj}))$ where Iter is the xslp.xCount most recent SLP iterations and Obj is the corresponding objective function value. If $\text{ABS}(\delta \text{Obj}) \leq x\text{slp}.\text{xTol.a}$ then the objective function is deemed to be static according to the absolute static objective function (1) criterion. If $\text{ABS}(\delta \text{Obj}) \leq \text{AVGIter}(\text{Obj}) \times x\text{slp}.\text{xTol.r}$ then the objective function is deemed to be static according to the relative static objective function (1) criterion. The static objective function (1) test is applied only until xslp.xLimit SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged.

Range: \{0, ..., $\infty$\}

Default: 100
**xslp_xTol_a** *(real): Absolute static objective function (1) tolerance*

Synonym: slpXTolA

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. Because all the variables have converged, the solution is already converged but the fact that some variables are at their step bound limit suggests that the objective function could be improved by going further. The variation in the objective function is defined as \( \delta \text{Obj} = \text{MAXIter(Obj)} - \text{MINIter(Obj)} \) where \( \text{Iter} \) is the \( \text{xslp_xCount} \) most recent SLP iterations and \( \text{Obj} \) is the corresponding objective function value. If \( \text{ABS}(\delta \text{Obj}) \leq \text{xslp_xTol_a} \) then the objective function is deemed to be static according to the absolute static objective function (1) criterion. If \( \text{ABS}(\delta \text{Obj}) \leq \text{AVGIter(Obj)} \times \text{xslp_xTol_r} \) then the objective function is deemed to be static according to the relative static objective function (1) criterion. The static objective function (1) test is applied only until \( \text{xslp_xLimit} \) SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged. When the value is set to be negative, the value is adjusted automatically by SLP, based on the optimality target \( \text{xslp_validationTarget_k} \). Good values for the control are usually fall between 1e-3 and 1e-6.

Range: \([-\infty, \infty]\)

Default: auto

**xslp_xTol_r** *(real): Relative static objective function (1) tolerance*

Synonym: slpXTolR

It may happen that all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. This means that, at least in the linearization, if the variable were to be allowed to move further the objective function would improve. This does not necessarily imply that the same is true of the original problem, but it is still possible that an improved result could be obtained by taking another SLP iteration. However, if the objective function has already been stable for several SLP iterations, then there is less likelihood of an improved result, and the converged solution can be accepted. The static objective function (1) test measures the significance of the changes in the objective function over recent SLP iterations. It is applied when all the variables have converged, but some have converged on extended criteria and at least one of these variables is at its step bound. Because all the variables have converged, the solution is already converged but the fact that some variables are at their step bound limit suggests that the objective function could be improved by going further. The variation in the objective function is defined as \( \delta \text{Obj} = \text{MAXIter(Obj)} - \text{MINIter(Obj)} \) where \( \text{Iter} \) is the \( \text{xslp_xCount} \) most recent SLP iterations and \( \text{Obj} \) is the corresponding objective function value. If \( \text{ABS}(\delta \text{Obj}) \leq \text{xslp_xTol_a} \) then the objective function is deemed to be static according to the absolute static objective function (1) criterion. If \( \text{ABS}(\delta \text{Obj}) \leq \text{AVGIter(Obj)} \times \text{xslp_xTol_r} \) then the objective function is deemed to be static according to the relative static objective function (1) criterion. The static objective function (1) test is applied only until \( \text{xslp_xLimit} \) SLP iterations have taken place. After that, if all the variables have converged on strict or extended criteria, the solution is deemed to have converged. If the objective function passes the relative or absolute static objective function (1) test then the solution is deemed to have converged. When the value is set to be negative, the
value is adjusted automatically by SLP, based on the optimality target \texttt{xslp\_validationTarget\_k}. Good values for the control are usually fall between 1e-4 and 1e-6.

Range: $[-\infty, \infty]$  
Default: \texttt{auto}

\texttt{xslp\_zero} (real): Absolute tolerance \leftrightarrow  

Synonym: \texttt{slpZero}

If a value is below \texttt{xslp\_zero} in magnitude, then it will be regarded as zero in certain formula calculations: an attempt to divide by such a value will give a "divide by zero" error; an exponent of a negative number will produce a "negative number, fractional exponent" error if the exponent differs from an integer by more than \texttt{xslp\_zero}.  

Range: $[0, \infty]$  
Default: \texttt{1e-15}

\texttt{xslp\_zeroCriterion} (integer): Bitmap determining the behavior of the placeholder deletion procedure \leftrightarrow  

Synonym: \texttt{slpZeroCriterion}

Setting single boolean options will overwrite the single bits of this bitmap option.

Default: 0

<table>
<thead>

</tbody>
</table>

\texttt{xslp\_zeroCriterionCount} (integer): Number of consecutive times a placeholder entry is zero before being considered for deletion \leftrightarrow  

Synonym: \texttt{slpZeroCriterionCount}

Range: \{0, ..., \infty\}  
Default: 0

\texttt{xslp\_zeroCriterionStart} (integer): SLP iteration at which criteria for deletion of placeholder entries are first activated \leftrightarrow  

Synonym: \texttt{slpZeroCriterionStart}

Range: \{0, ..., \infty\}  
Default: 0

\texttt{xslp\_zeroCriterion\_deltaNBDRRow} (boolean): Remove placeholders in a basic delta variable if the determining row for the corresponding SLP variable is nonbasic \leftrightarrow
Synonym: slpZeroCriterionDeltaNBDRRow

See also xslp_zeroCriterion.

Default: 0

**xslp_zeroCriterion_deltaNBUpdateRow** *(boolean)*: Remove placeholders in a basic delta variable if its update row is nonbasic and the corresponding SLP variable is nonbasic →

Synonym: slpZeroCriterionDeltaNBUpdateRow

See also xslp_zeroCriterion.

Default: 0

**xslp_zeroCriterion_nbDelta** *(boolean)*: Remove placeholders in nonbasic delta variables ←

Synonym: slpZeroCriterionNBDelta

See also xslp_zeroCriterion.

Default: 0

**xslp_zeroCriterion_nbSLPVar** *(boolean)*: Remove placeholders in nonbasic SLP variables ←

Synonym: slpZeroCriterionNBSLPVar

See also xslp_zeroCriterion.

Default: 0

**xslp_zeroCriterion_print** *(boolean)*: Print information about zero placeholders ←

Synonym: slpZeroCriterionPrint

See also xslp_zeroCriterion.

Default: 0

**xslp_zeroCriterion_slpVarNBUpdateRow** *(boolean)*: Remove placeholders in a basic SLP variable if its update row is nonbasic ←

Synonym: slpZeroCriterionSLPVarNBUpdateRow

See also xslp_zeroCriterion.

Default: 0
5.43.5 Helpful Hints

The comments below should help both novice and experienced GAMS users to better understand and make use of GAMS/XPRESS.

- **Infeasible and unbounded models** The fact that a model is infeasible/unbounded can be detected at two stages: during the presolve and during the simplex or barrier algorithm. In the first case we cannot recover a solution, nor is any information regarding the infeasible/unbounded constraint or variable provided (at least in a way that can be returned to GAMS). In such a situation, the GAMS link will automatically rerun the model using primal simplex with presolve turned off (this can be avoided by setting the rerun option to 0). It is possible (but very unlikely) that the simplex method will solve a model to optimality while the presolve claims the model is infeasible/unbounded (due to feasibility tolerances in the simplex and barrier algorithms).

- The barrier method does not make use of `iterlim`. Use `bariterlim` in an options file instead. The number of barrier iterations is echoed to the log and listing file. If the barrier iteration limit is reached during the barrier algorithm, XPRESS continues with a simplex algorithm, which will obey the `iterlim` setting.

- Semi-integer variables are not implemented in the link, nor are they supported by XPRESS; if present, they trigger an error message.

- SOS1 and SOS2 variables are required by XPRESS to have lower bounds of 0 and nonnegative upper bounds.

5.43.6 Setting up a GAMS/XPRESS-Link license

To use the GAMS/XPRESS solver with a GAMS/XPRESS-Link license you have to set up the XPRESS portion of the licensing. To do so, copy your XPRESS license `xpauth.xpr` to the GAMS system directory. As of version 24.2 GAMS already comes with a file `xpauth.xpr`. You might consider copying this file to `xpauth.xpr.bak` or similar before overwriting it with your own XPRESS license file.
Chapter 6

Tools Manuals

A large number of tools are included in GAMS distribution. Below are a functional categorization of all tools, an alphabetically sorted list of all tools, and a brief description of each tool with their Supported Platforms.

6.1 Tools Category

All tools included in GAMS distribution are categorized as

6.1.1 GAMS Integrated Development Environments

There are two integrated model development environments including a general text editor with the ability to launch and monitor the compilation and execution of GAMS models: The GAMS IDE and GAMS Studio.

6.1.2 Data Exchange

A collection of tools that provide functionality to exchange data between GAMS and other data sources. This category contains tools for popular data sources and high-level programming environment and like databases (GDX2ACCESS, GDX2SQLITE, MDB2GMS, SQL2GMS), Matlab (GDXMRW), and R (GDXRRW). There are also tools for specialized systems like HAR (GDX2HAR and HAR2GDX), TROLL (GDXTROLL), and VEDA (GDX2VEDA).

6.1.2.1 Excel

Tools to exchange data with Microsoft Excel are grouped in a subcategory Excel. The tools in this category are GDX2XLS, GDXXRW, MSAPPAVAIL, XLS2GMS, XLSDUMP, and XLSTALK. Many of the tools described here use the GAMS Data eXchange facility GAMS Data eXchange (GDX).

6.1.3 GDX Service

A collection of tools that operate directly on GAMS Data eXchange (GDX) containers to e.g. compare (GDXDIFF), copy (GDXCOPY), merge (GDXMERGE), and rename (GDXRENAME).
6.1.4 Data Transformation

A collection of tools that perform very specific tasks that are awkward or inefficient to implement in GAMS directly. Through GAMS Data eXchange (GDX) and the execution of the tools in this category allow to perform complex tasks from a GAMS model like identifying eigenvalues or the inverse of a matrix.

The tools in this category are CHOLESKY, CSDP, EIGENVECTOR, EIGENVALUE, GDXRANK, MessageReceiverWindow, INVERT, MCFILTER, SCENRED, and SCENRED2.

6.1.5 Other Tools

A collection of more exotic tools that can become handy in some some special circumstances. The tools in this category are ASK, BIB2GMS, CHK4UPD, ENDECRYPT, FINDTHISGAMS, GAMS Posix Utilities, MODEL2TEX, and ShellExecute. Most notably, the collection contains the tool MODEL2TEX to document the model algebra in LaTeX format.

6.2 List of Tools

The following table gives an alphabetically sorted list of all available tools.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASK</td>
<td>The utility can be used to get input from an user interactively.</td>
</tr>
<tr>
<td>BIB2GMS</td>
<td>Analyses BibTeX files with file extension .bib and writes GAMS source files that can be used to create various author, reference and cross reference reports.</td>
</tr>
<tr>
<td>CHK4UPD</td>
<td>Checks whether the user can update to a more recent GAMS version.</td>
</tr>
<tr>
<td>CHOLESKY</td>
<td>Calculates the Cholesky decomposition of a symmetric positive definite matrix.</td>
</tr>
<tr>
<td>CSDP</td>
<td>The semidefinite programming CSDP solver from COIN-OR. The communication with CSDP requires the setup of matrix data structures in a CSDP input file. In a sense a GAMS model functions as a matrix generator.</td>
</tr>
<tr>
<td>CSV2GDX</td>
<td>Reads a CSV file (comma separated values) and writes to a GDX file.</td>
</tr>
<tr>
<td>EIGENVALUE</td>
<td>Calculates eigenvalues of a symmetric matrix.</td>
</tr>
<tr>
<td>EIGENVECTOR</td>
<td>Calculates eigenvector of a symmetric matrix.</td>
</tr>
<tr>
<td>ENDECRYPT</td>
<td>A tool to encrypt and decrypt text files.</td>
</tr>
<tr>
<td>FINDTHISGAMS</td>
<td>Windows command line tool for modifying GAMS specific registry entries created by the GAMS installer.</td>
</tr>
<tr>
<td>GAMS IDE</td>
<td>Classic Integrated Development Environment.</td>
</tr>
<tr>
<td>GAMS STUDIO</td>
<td>Integrated Development Environment.</td>
</tr>
<tr>
<td>GDX2ACCESS</td>
<td>Converts GDX data to MS Access tables.</td>
</tr>
<tr>
<td>GDX2HAR</td>
<td>Translates files between GDX and HAR format.</td>
</tr>
<tr>
<td>GDX2SQLITE</td>
<td>Dumps the complete contents of a GDX file into a SQLite2 database. From Amsterdam Optimization Modeling Group.</td>
</tr>
<tr>
<td>GDX2VEDA</td>
<td>Translates a GDX file into the VEDA format.</td>
</tr>
<tr>
<td>GDX2XLS</td>
<td>Converts GDX data into a MS Excel spreadsheet.</td>
</tr>
<tr>
<td>GDXCOPY</td>
<td>Converts a GDX file into different GDX formats.</td>
</tr>
<tr>
<td>Tool</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GDXDIFF</td>
<td>Compares the data of symbols with the same name, type and dimension in two GDX files and writes the differences to a third GDX file.</td>
</tr>
<tr>
<td>GDXDUMP</td>
<td>Writes scalars, sets and parameters (tables) to standard output formatted as a GAMS program with data statements.</td>
</tr>
<tr>
<td>GDXMERGE</td>
<td>Combines multiple GDX files into one file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.</td>
</tr>
<tr>
<td>GDXMRW</td>
<td>A suite of utilities to import/export data between GAMS and MATLAB and to call GAMS models from MATLAB and get results back into MATLAB.</td>
</tr>
<tr>
<td>GDXRANK</td>
<td>Reads one or more one dimensional parameters from a GDX file, sorts each parameter and writes the sorted indices as a one dimensional parameters to the output GDX file.</td>
</tr>
<tr>
<td>GDXRENAME</td>
<td>Replaces UEL strings in GDX files.</td>
</tr>
<tr>
<td>GDXRRW</td>
<td>An interface between GAMS and R. It includes functions to transfer data between GDX and R and a function to call GAMS from R.</td>
</tr>
<tr>
<td>GDXTROLL</td>
<td>Translates a GDX file into the TROLL format.</td>
</tr>
<tr>
<td>GDXVIEWER</td>
<td>Views and converts data contained in GDX files.</td>
</tr>
<tr>
<td>GDXXRW</td>
<td>Preferred utility to read and write MS Excel spreadsheet data.</td>
</tr>
<tr>
<td>GMSUNZIP</td>
<td>A copy of the decompression tool unzip from Info-ZIP prefixed with ”gms” for clear identification.</td>
</tr>
<tr>
<td>GMSZIP</td>
<td>A copy of the compression and archiving tool zip from Info-ZIP prefixed with ”gms” for clear identification.</td>
</tr>
<tr>
<td>HAR2GDX</td>
<td>Translates files between GDX and HAR format.</td>
</tr>
<tr>
<td>IDECMD</td>
<td>Sends commands to the GAMSIDE.</td>
</tr>
<tr>
<td>INVERT</td>
<td>Inverts a matrix.</td>
</tr>
<tr>
<td>MCFILTER</td>
<td>Removal of duplicate and dominated points in a multi-criteria solution set.</td>
</tr>
<tr>
<td>MDB2GMS</td>
<td>Converts data from an MS Access database into a GAMS readable format.</td>
</tr>
<tr>
<td>MESSAGE RECEIVER WINDOW</td>
<td>A graphical tool that receives and displays Windows messages.ẽq);</td>
</tr>
<tr>
<td>MODEL2TEX</td>
<td>Translates a GAMS model into LaTeX.</td>
</tr>
<tr>
<td>MPS2GMS</td>
<td>Translates an MPS file into an equivalent short generic GAMS program using a GDX file to store data.</td>
</tr>
<tr>
<td>MSAPPAVAIL</td>
<td>Checks if a MS Office Application is available.</td>
</tr>
<tr>
<td>POSIX</td>
<td>A collection of POSIX utilities which are usually available for Windows and the different Unix systems and therefore help to write platform independent scripts.</td>
</tr>
<tr>
<td>SCENRED</td>
<td>A tool for the reduction of scenarios that model random data processes of a stochastic program. From Humboldt-University Berlin.</td>
</tr>
<tr>
<td>SCENRED2</td>
<td>Scenred2 is a fundamental update of Scenred and offers a scenario tree construction algorithm. From Humboldt-University Berlin.</td>
</tr>
<tr>
<td>SHELLEXECUTE</td>
<td>Launches external programs from the command line.</td>
</tr>
<tr>
<td>SQL2GMS</td>
<td>Converts data from an SQL database into a GAMS readable format.</td>
</tr>
<tr>
<td>XLS2GMS</td>
<td>Converts spreadsheet data from a MS Excel spreadsheet into a GAMS readable format.</td>
</tr>
</tbody>
</table>
### 6.3 Supported Platforms

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XLSDUMP</td>
<td>Writes all worksheets of a MS Excel workbook to a GDX file. Unlike gdxxrw, the program does not require that Excel is installed.</td>
</tr>
<tr>
<td>XLSTALK</td>
<td>Open/Close/Run macro in MS Excel.</td>
</tr>
</tbody>
</table>

6.4 ASK

Writing a GUI (Graphical User Interface) for a GAMS application requires some serious programming, and therefore place a burden on the knowledge and time of the modeler. In this section we show how extremely simple user interfaces can be built using a few simple tools. The main purpose of these tools is to allow a developer quickly put an application together such that an end-user does not have to edit GAMS files. We assume the end-user runs a GAMS model from the GAMS-IDE.

The ASK utility can be used to get input from an end-user and the GDXViewer tool can be used to present end-results. Together these tools allow you to build a minimalist GUI without any programming.

6.4.1 Usage

ask <options>

where the **options** are

T=string

where the **string** identifies the type of input item to go after and can be

- **integer** - when one wants an integer number
- **float** - when one wants a real number
- **radioinput** - when one wants a radio button choice
- **combobox** - when one wants a combo (drop down choice) box
- **checklistbox** - when one wants a check list box
- **fileopenbox** - when one wants the name of a file to open
- **filesavebox** - when one wants the name of a file to save

Example: T=integer

M="string"

where the **string** is the text to in the box.

Example: M="Enter a number"

O="filename"
where the filename is the name of a file in which to place the results for subsequent inclusion into GAMS.
Example: 0="file.inc"

D="string 1|string 2..."

where the "string 1|string 2|string 3|...|string n" gives the n strings to be associated with multiple choices when using checkbox, radiobutton, combobox, or checklistbox. The individual strings are separated by the delimiter "|".
Example: D="Small data set|Medium data set|Large data set"

E="number 1|number 2..."

where the "number 1|number 2|number 3|...|number n" gives the n numbers to be returned to GAMS associated with the choices made when using checkbox, radiobutton, combobox, or checklistbox. The individual numbers are separated by the delimiter "|".
Example: E="1|2|3|4|5"

I="filepath"

where filepath gives the path in which to look for the file under the fileopenbox and filesavebox dialogues. If not specified this is the project directory.
Example: I="C:\gams\mine"

F="filemask"

where filemask gives the mask for acceptable files under the fileopenbox and filesavebox dialogues. If not specified this is *..*.
Example: I="*.gdx"

R="string"

where the string gives a line of GAMS code to place in the include file. This can contain a s parameter in which the information to return is substituted.
Example: R="$include '\%s'" or R="set i /1990+\%s/;"

C="string"

A title for the dialogue box being used.
Example: C="Box to ask for a file"

L=number

where the number gives a lower bound on a numeric entry.
Example: L=15

U=number

where the number gives an upper bound on a numeric entry.
Example: U=15

@"filename"

where filename gives the name of a file of input instructions containing the options above in this table.
Example: @ask.opt

In addition a number by itself can be entered to put multiple entries into columns under the checkbox, radiobutton, combobox, or checklistbox entries.
6.4.2 Calling ASK utility from GAMS

The ASK utility is a simple tool to ask simple interactive questions to the end-user. For instance, if your model requires a scalar to be changed regularly, instead of letting the end-user change the .gms source file, it may be better to pop up a window, with a question text, where the required number can be entered. The ASK tool allows you to do this. As the ASK tool generates a standard GAMS include file, this file can then be used through a $include statement:

```gams
$call =ask T=integer M="Enter number of cities" o=n.inc
Scalar n 'number of cities' /
$include n.inc
display n;
```

The $call statement will invoke the ASK tool. If ASK.EXE is not located in the GAMS system directory but placed somewhere else you may have to provide a path, as in:

```gams
$call =d:\util\ask T=integer M="Enter number of cities" o=n.inc
```

The parameter T=integer indicates we want to ask for an integer number (T means type). The parameter M="text" specifies the question text. Finally O=filename sets the name of the include file that ASK should create.

When we run this GAMS fragment from the IDE, we will see:
After enter a number and hitting the OK button GAMS will continue. The listing file will demonstrate clearly how the include file was formed:

```
2 scalar n 'number of cities' /
include  D:\GAMS PROJECTS\ASK\N.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 12
7 /
8 display n;
```

Include File Summary

<table>
<thead>
<tr>
<th>SEQ</th>
<th>GLOBAL</th>
<th>TYPE</th>
<th>PARENT</th>
<th>LOCAL</th>
<th>FILENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>INPUT</td>
<td>0</td>
<td>0</td>
<td>D:\GAMS PROJECTS\ASK\X.GMS</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>CALL</td>
<td>1</td>
<td>1</td>
<td>=ask T=integer M=&quot;Enter number of cities&quot; o=n.inc</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>INCLUDE</td>
<td>1</td>
<td>3</td>
<td>.D:\GAMS PROJECTS\ASK\N.INC</td>
</tr>
</tbody>
</table>

In this case 12 was entered and the OK button was pressed. If the user pressed the CANCEL button, an error will be generated and the listing file will show that the CANCEL button was pressed:

```
2 scalar n 'number of cities' /
include  D:\GAMS PROJECTS\ASK\N.INC
4 * Ask Import Filter Version 1.0, Nov. 1999
5 * Erwin Kalvelagen, GAMS Development Corp.
6 12
7 /
* **** $1
* **** LINE 4 INPUT D:\GAMS PROJECTS\ASK\X.GMS
* **** 1 Real number expected
8 display n;
```

In case you want to limit the integer that the user is allowed to enter you can specify a lower and an upperbound as in:

```
$call =ask T=integer M="Give integer, between 0 and 5" L=0 U=5 O=n1.inc
scalar n1 'an integer 0..5' /
$include n1.inc
/
display n1;
```

This will only accept values between 0 and 5.

To allow the user to specify a floating point number, we can use T=float. An example is:

```
$call =ask T=float M="Give floating point number, no bounds" O=x.inc
scalar x 'real' /
$include x.inc
/
display x;
```

The floating point popup window can be told to make sure the number entered is within certain bounds, using the L=lowerbound and U=upperbound syntax:
Up to now, the include file generated by ASK just contained a single number. ASK can generate more complicated include files. Consider the example:

* import a set
$call =ask T=integer M="Give year between 1990 and 2010." C="My Title" L=1990 U=2010 R="set i /1990*%s/;" O=i.inc
$include i.inc
display i;

The parameters C="caption" and R="resultstring" are new. The caption is simple: it sets the name of the window. The result string is a string that is returned after ASK has substituted s for the result. I.e. if we enter 1991, then the result written to the include file is set i /1990*1991/;

The listing file can be used to check the correct behavior:
7  display i;
Include File Summary
SEQ  GLOBAL TYPE  PARENT  LOCAL  FILENAME
   1   1  INPUT    0   0  D:\GAMS PROJECTS\ASK\X.GMS
   2   2   CALL    1   2  =ask T=integer M="Give year between 1990 and 2010." C="My Title"
    R="set i /1990*%s/;"  O=i.inc
   3   3  INCLUDE    1   3  .D:\GAMS PROJECTS\ASK\I.INC

6.4.3 Radio Button

Radio buttons can be used through the parameter T=radiobuttons as in:

* import a number through radio buttons
$call =ask T=radiobuttons M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" E="1|2|3|4|5"
$include n2.inc
display n2;

![Image of Radio Button Dialog]

The parameter D="option 1|option 2|option 3|option 4|option 5" specifies the text of the options shown. The list E="1|2|3|4|5" gives the return (exit) strings when a certain option is chosen. I.e. if the second option os chosen in the list specified with the D parameter, then the second string in the E list is returned. The result is again substituted in the string specified in the R parameter if it exists.

In this example the command line became rather long and difficult to handle. In addition some Windows systems have restrictive maximum lengths for the command line. Therefore we offer the possibility to specify the command line arguments in a separate external text file. This text file is passed using

@filename

. Assume the file ask.opt looks like:

T=radiobuttons
M=Choose single option
D=option 1|option 2|option 3|option 4|option 5|option 6|option 7|option 8|option 9|option 10
E=1|2|3|4|5|6|7|8|9|10
2
R=scalar n3 option /%s/;
O=n3.inc
Every command line parameter is specified on a separate line. Notice the strange option 2; this tells ASK to display the radio buttons in two columns. We can use this option file as follows:

```
* id, now 2 columns and using a parameter file
$call =ask @"ask.opt"
$include n3.inc
display n3;
```

The quotes around the filename are optional, and really only needed if the filename contains blanks.

If you want to keep all the logic in one place, then one can use GAMS to generate the option file. It is noted that it is not possible to use the PUT facility for this. I.e.:

```
File f /asktest.opt/;
put f;
p
put 'T=checklistbox'/
   'M=Choose multiple options'/
   'D=option 1|option 2|option 3|option 4|option 5'/
   'E=1|2|3|4|5'/
   'R=%s checked list box choice'/
   '0=k2.inc'/;
putClose;
$call =ask @"asktest.opt"
Set k2 /
$include k2.inc
/;
display k2;
```
is not correct: the $call is handled at compile time, before the PUT statement has done its work. However, one could use the following:

```bash
$echo 'T=checklistbox' > asktest.opt
$echo 'M=Choose multiple options' >> asktest.opt
$echo 'D=option 1|option 2|option 3|option 4|option 5' >> asktest.opt
$echo 'E=1|2|3|4|5' >> asktest.opt
$echo 'R=%s checked list box choice' >> asktest.opt
$echo 'O=k2.inc' >> asktest.opt
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

or better:

```bash
$onEcho > asktest.opt
T=checklistbox
M=Choose multiple options
D=option 1|option 2|option 3|option 4|option 5
E=1|2|3|4|5
R=%s checked list box choice
O=k2.inc
$offEcho
$call =ask @asktest.opt
Set k2 /
$include k2.inc
/;
display k2;
```

### 6.4.4 Combo Box

The next type is T=comboxbox which also allows a single selection:

```bash
* import a number through a combo box
$call =ask T=comboxbox M="Choose single option" D="option 1|option 2|option 3|option 4|option 5" E="1|2|3|4|5"
$include n4.inc
display n4;
```
6.4 ASK

As an example consider the case where the model comes with three data sets: a small one, a medium sized one and a large data set. Each data set is stored in a separate include file: small.inc, medium.inc and large.inc. We want to ask the user which data set should be used and the correct include file should be used. This can be accomplished by:

```gams
$echo 'T=combobox' > ask.opt
$echo 'M=choose data set' >> ask.opt
$echo 'D=Small data set|Medium data set|Large data set' >> ask.opt
$echo 'E=small.inc|medium.inc|large.inc' >> ask.opt
$echo 'R=$include %s' >> ask.opt
$echo 'O=dataset.inc' >> ask.opt
$call =ask @ask.opt
$include dataset.inc

Newer GAMS systems allow:

```gams
$onEcho > ask.opt
T=combobox
M=choose data set
D=Small data set|Medium data set|Large data set
E=small.inc|medium.inc|large.inc
R=$include %s
O=dataset.inc
$offEcho
$call =ask @ask.opt
$include dataset.inc
```

In this case dataset.inc will contain a single line: another include statement, which is either `$include small.inc`, `$include medium.inc` or `$include large.inc`. 
6.4.5 List and Checklist Box

In some cases it may be useful to be able to select multiple items from a list. This can be done with 
T=listbox:

\* import a set through a listbox
\$call =ask T=listbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E="" 
Set k / 
$include k.inc 
/;
display k;

![Listbox Example](image1.png)

Selecting multiple entries involves holding down the CTRL key. Sometimes a convenient alternative is 
T=checklistbox:

\* import a set through a checked listbox
\$call =ask T=checklistbox M="Choose multiple options" D="option 1|option 2|option 3|option 4|option 5" E="" 
Set k2 / 
$include k2.inc 
/;
display k2;

![Checklist Example](image2.png)
When we select options 1, 3 and 5, the following include file is generated:

* Ask Import Filter Version 1.1, Aug. 2002
* Erwin Kalvelagen, GAMS Development Corp.
  1 'checked list box choice'
  3 'checked list box choice'
  5 'checked list box choice'

which will populate the set k2 as follows:

```
1 * import a set through a checked listbox
3 set k2 / D:\GAMS PROJECTS\ASK\K2.INC
5 * Ask Import Filter Version 1.1, Aug. 2002
6 * Erwin Kalvelagen, GAMS Development Corp.
7 1 'checked list box choice'
8 3 'checked list box choice'
9 5 'checked list box choice'
10 /;
11 display k2;
11 SET k2
1, 3, 5
```

The last type is the generic string type: T=string. This allows the user to enter any string, which is then copied to an include file as is.

### 6.4.6 File Open Dialog Box

The type T=fileopenbox will display a file open dialog box from which the user can select a file.
Related options are \texttt{I=InitialDirectory} and \texttt{F=Filter}. A complete example to ask for an include file could be:

\begin{verbatim}
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$include '%'s'" C="Select include file" $include fln.inc
\end{verbatim}

This will open a file open dialog box with the starting directory being the GAMS project/working directory (this is also where GAMS looks for include files by default). Only files with mask \texttt{SELECT*\_INC} are shown. The file \texttt{FLN.INC} will contain an include statement with the file the user has selected.

A related method would be:

\begin{verbatim}
$call =ask T=fileopenbox I="%system.fp%" F="select*.inc" o=fln.inc R="$setglobal incfile '%s'" C="Select include file" $include fln.inc
$include %incfile%
\end{verbatim}

where we use a \texttt{$setglobal} to set the macro \texttt{incfile} to contain the user-specified file name.

To let the user choose from a set of related GDX files, one could use something like:

\begin{verbatim}
$call =ask T=fileopenbox I="%system.fp%" F="myproject*.gdx" o=setgdxname.inc R="$setglobal gdxfile '%s'" C="Select GDX file" $include setgdxname.inc $gdxIn %gdxfile% $load i $load j
\end{verbatim}

In case you want to ask for a filename of a file to be written, use the type \texttt{T=filesavebox}. E.g.:

\begin{verbatim}
$call =ask T=filesavebox I="%system.fp%" o=fln.inc R="$setglobal gdxfile '%s'" C="Specify gdx file" $include fln.inc $set gdxfile %gdxfile% Set i / a, b, c /; execute_unload '%gdxfile%', i;
\end{verbatim}

In case you want to ask for a directory, use the type \texttt{T=selectdirectory}. In this case the filter option \texttt{F} is ignored. E.g.:

\begin{verbatim}
$call =ask T=selectdirectory I="%system.fp%" o=fln.inc R="$setglobal myInputdir '%s'" C="Select directory" $include fln.inc $log Selected directory "%myInputdir%"
\end{verbatim}

\section{BIB2GMS}

Analyses \texttt{BibTeX} files with file extension \texttt{.bib} and writes GAMS source files that can be used to create various author, reference and cross reference reports.
6.5 BIB2GMS

6.5.1 Usage

\texttt{ bib2gms bibinput [ option reference\textunderscore map [key=value] ] }

'Reads' BIB files and writes GAMS source files that can be used to create various author, reference and cross reference reports. The BibInput file usually contains many more entries then are needed for the specific GAMS application and the BIB document names need to be mapped into GAMS set elements. This mapping is specified in the ReferenceMap file.

\texttt{Bib2gms} will produce a number of gams include files and a GAMS main program that demonstrates the use of the include files.

6.5.2 Examples

\texttt{bib2gms myfile.bib}

\texttt{bib2gms "my blanks.abc" R=mymap GmsFile="my gams.gms"}

\texttt{bib2gms bibin i = stem}

The file ReferenceMap (R) contains the name of the BIB entries to be extracted from the BIB input file. If no (R) file names is given, all entries will be selected and the original BIB record names will be used. Each line contains the reference name of the entry to be included. You can enter a single name or the pair \texttt{<gams> <bib>} to rename the \texttt{<bib>} reference name to the new \texttt{<gams>} name.

Example of ReferenceMap file:

* lines starting with * or # are ignored
* empty lines are ignored as well
* spaces are ignored
* tabs , and . are all whitespace
r1 mybibref2
r2,mybibref5
r3.mybibref1
r4
* a single ref entry assumes the BIB record name is the same as the
* gams name, r4 r4
* 
* The GAMS maintained master BIB file has references named g00001, g00002,..
* A reference name consisting of digits only will be renamed
* to form one of those g0000x names. For example:
  r5 12

Output Files:

\texttt{bib2gms.gms} gams program that reads all include files shown below

<table>
<thead>
<tr>
<th>Include File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bib2gms.a</td>
<td>Authors</td>
</tr>
<tr>
<td>bib2gms.ca</td>
<td>Credit Authors</td>
</tr>
<tr>
<td>bib2gms.r</td>
<td>References</td>
</tr>
<tr>
<td>bib2gms.ro</td>
<td>Overflow References</td>
</tr>
<tr>
<td>bib2gms.ar</td>
<td>Author Cross reference</td>
</tr>
<tr>
<td>bib2gms.far</td>
<td>First Author Cross Reference</td>

</tbody>
</table>

6.6 CHK4UPD

The tool chk4upd checks if there is a newer version of GAMS available than the one you are running. It checks for the most recent version available as well as for the newest version you can run with your license in case your maintenance and support is expired.

By default it reads gamslice.txt located in a GAMS standard location. Alternatively, you can specify another license on the command line. In addition to the command line tool you will find an integration in GAMS Studio and the GAMS IDE in the Help menu.

6.7 CHOLESKY

CHOLESKY calculates the Cholesky decomposition of a symmetric positive definite matrix. Matrix decomposition \( A = LL^T \).

6.7.1 Usage

cholesky gdxin i a gdxout L

where

- **gdxin**
  - name of gdxfile with matrix
- **i**
  - name of set used in matrix
- **a**
  - name of 2 dimensional parameter inside gdxin
- **gdxout**
  - name of gdxfile for results (factor L)
- **L**
  - name of 2 dimensional parameter inside gdxout

Calculates the Cholesky decomposition \( A = LL^T \) of a symmetric positive definite matrix \( A = a(i,j) \) where \( i \) and \( j \) are aliased sets. \( L \) will contain the Cholesky factor \( L(i,j) \).
6.7.2 Example

$onText
Finds the Cholesky decomposition $A=LL'$ of a positive definite symmetric matrix $A$ through an external program.

Erwin Kalvelagen, may 2008
$offText

Set i / i1*i5 /;

Alias (i,j);

Table a(i,j) 'original matrix'
  i1  i2  i3  i4  i5
  i1  64  48  24  8  8
  i2  48  72  42  54  36
  i3  24  42  89 107  95
  i4  8  54 107 210 186
  i5  8  36  95 186 187;

Parameter L(i,j) 'cholesky factor';

execute_unload 'a.gdx', i, a;
execute '=cholesky.exe a.gdx i a b.gdx L';
execute_load 'b.gdx', L;

display a, L;

* 
* only lower triangular part of A is used 
*

Table a2(i,j) 'original matrix'
  i1  i2  i3  i4  i5
  i1  64
  i2  48  72
  i3  24  42  89
  i4  8  54 107 210
  i5  8  36  95 186 187;

Parameter L2(i,j) 'cholesky factor';

execute_unload 'a.gdx', i, a2;
execute '=cholesky.exe a.gdx i a2 b.gdx L2';
execute_load 'b.gdx', L2;

display a2, L2;

6.8 CSDP

The semidefinite programming CSDP solver from COIN-OR. The communication with CSDP requires the setup of matrix data structures in a CSDP input file. In a sense a GAMS model functions as a matrix generator.
6.8.1 Usage

csdp <input problem> [<final solution>] [<initial solution>]

<input problem>

the name of a file containing the SDP problem in SDPA sparse format.

<final solution>

the optional name of a file in which to save the final solution.

<initial solution>

the optional name of a file from which to take the initial solution.

See CSDP User’s Guide for more information.

6.9 CSV2GDX

CSV2GDX is a tool that reads a CSV file and writes to a GDX file. There are multiple ways to read CSV files (Comma Separated Values) inside GAMS (see Data Exchange with Text Files for instance), but a number of features available in CSV2GDX make it possible to read a CSV file where GAMS itself cannot be used. In addition to the syntax explanation and the basic functionalities demonstrated on some examples, this tutorial also discusses some advantages and disadvantages of CSV2GDX compared to the GAMS internal table statement.

6.9.1 Usage

CSV2GDX is called by specifying the CSV file and several options to define how to read the data.

csv2gdx filename {options}

Filename

The input file; the .csv file extension is assumed when no extension has been specified.

Parameters can also be read from a text file; the use of an external file for parameters is indicated by preceding the file name with a @ (at sign). When reading parameters from a text file, lines starting with an asterisk (*) will be ignored. See also Example 8.

6.9.2 Options

The following options can be used when calling CSV2GDX:
<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acceptBadUels</td>
<td>N</td>
<td>Indicate if bad UELs are accepted or result in an error return code.</td>
</tr>
<tr>
<td>autoCol</td>
<td>none</td>
<td>Generate automatic UELs for each column.</td>
</tr>
<tr>
<td>autoRow</td>
<td>none</td>
<td>Generate automatic UELs for each row.</td>
</tr>

</tbody>
</table>

Note

- The user has to specify an identifier for the symbol in the GDX file within the parameter `id`, regardless of the data structure in the CSV file.
- CSV2GDX determines the number of columns in the CSV file from the header row or from the user defined input specified in the parameter `colCount`. Therefore, the user must enable the option `useHeader` or has to specify the number of columns within `colCount` in any case.

Some more detailed remarks on the options:

**acceptBadUels** = boolean (default=N)

This option specifies how to proceed, when a bad UEL (e.g. too long) is encountered. If set to N, reading is stopped, and an error is signaled. When set to Y, a valid UEL is made up and reading is continued.

**autoCol** = string

Generate automatic UELs for each column. The autoCol string is used as the prefix for the column label numbers. This option overrides the use of a header row. However, if there is a header row, one must skip the row by enabling `useHeader`. This option is demonstrated in Example 3.

**autoRow** = string
Generate automatic UELs for each row. The autoRow string is used as the prefix for the row label numbers. The generated unique elements will be used in the first index position shifting other elements to the right. Using autoRow can be helpful when there are no labels that can be used as unique elements but also to store entries that would be a duplicate entry without an unique row label. This option is demonstrated in Example 3.

checkDate = boolean (default=N)

Write GDX file only if the CSV file is more recent than the GDX file to save resources when running the model containing the CSV2GDX call multiple times. This option is demonstrated in Example 5.

colCount = integer

Number of columns in the input file. This parameter is required if there is no header row, since CSV2GDX determines the number of columns from the header row. This option is demonstrated in Example 3. Note that the lastCol constant cannot be used for the colCount option.

decimalSep = [Period, Comma] (default=Period)

Specify a decimal separator. The decimal is normally a period, but this parameter allows a comma as the decimal separator, too. Special values recognized are Eps, NA resp. N/A, Inf, True, False, None, Null and Undef (case insensitive). A string that is not recognized as a valid number will be stored as Undef. This option is demonstrated in Example 2 and Example 6 (focusing on reading special values) for instance.

fieldSep = [Comma, SemiColon, Tab] (default=Comma)

Specify a field separator. Fields are normally separated by a comma, but this parameter allows some additional choices. Using tabs as delimiter should be avoided, since text editors act different on handling them. For instance, one must specify tabs in the GAMS IDE explicitly using %system.tab%:

```
$onEcho > tabSeparated.csv
USA%system.tab%100
GER%system.tab%70
$offEcho

$call csv2gdx tabSeparated.csv id=x fieldSep=tab index=1 colCount=2 value=lastCol
```

This option is demonstrated in Example 2 and Example 3 for instance.

id = string

Identifier for the symbol in the GDX file. Additional symbols, Dim1, Dim2, ... for the domain sets of the symbol id will be added automatically to the GDX file. Executing CSV2GDX without specifying an identifier will fail.

index = list of columns

Identify columns to get UELs from. The columns are represented as a list of integers separated by comma. For example index=1,2,3,4 resp. index=(1,2,3,4); in this case the notation 1..4 is allowed. Brackets can only be used on Windows systems. The index option is used in all examples.

output = filename (default=<CSVFilename>.gdx)
Optional output filename. If no output file is specified, CSV2GDX will use the input filename and change the file extension to .gdx. If no path is specified, the output file will be created in the current directory. This option is demonstrated in Example 2 for instance.

password = string

Password for an encrypted input file. Use ENDECRYPT to encrypt a file. This option is demonstrated in Example 7.

storeZero = boolean (default=N)

Indicate if zero values are ignored or written as EPS; an empty field is always ignored. This option is demonstrated in Example 6.

text = integer

Specify the column to get explanatory text from when reading a set. For example text=5. This option is demonstrated in Example 9.

trace = integer (default=1)

Controls the amount of information written to the log. Higher values will generate more output. Valid range is 0..3. Set trace=0 to prevent writing any information to the log. This feature is demonstrated in Example 6.

useHeader = boolean (default=N)

Indicate if the first row is a header row. The fields in the header row of the columns specified within the values option will be used as UELs. A header row is not needed or should be ignored when using the colCount or autoCol option. To skip one existing header row while using autoCol, enable useHeader. This option is demonstrated in Example 1 and Example 2 for instance.

value = integer

Specify the column to get the values from. For example value=5. This option is demonstrated in Example 2.

valueDim = boolean (default=N)

Indicate if an extra dimension for values is added to the parameter even if there is just one value column. This is ignored, if there is no value column. This feature is demonstrated in Example 2.

values = list of columns

Specify the columns to get the values from. When using a list of columns for the values and useHeader enabled, each field in the first row of the columns is used as UEL to identify the values in those columns. See also useHeader and autoCol below. If the number of columns is unknown, the symbolic constant lastCol can be useful: values=2..lastCol. This option is demonstrated in Example 1 and Example 5 for instance.
6.9.3 Advances and limitations

Advances

- **CSV2GDX** enables the user to read CSV data where the table statement cannot be used without doing further preprocessing, e.g. in case of semicolon- or tab separated data or comma separated decimals.
- In general, **CSV2GDX** is a quite performant tool compared to the GAMS internal table statement.

Limitations

- Suppose we want to skip some rows while reading the data. For example, if the CSV file contains some reference information in a specific row which we do not want to be stored in the domain sets or in the parameter. However, skipping rows cannot be done with **CSV2GDX**.
- There might be CSV files with no header and varying, unknown length of rows. Since **CSV2GDX** determines the number of columns based on the header row or by setting the `colCount` option in advance, **CSV2GDX** might return incorrect results or the execution is aborted.
- Reading several parameters from a CSV file cannot be done directly within the **CSV2GDX** call. The data must be split later on as demonstrated in Example 4.
- **CSV2GDX** cannot read CSV files containing line breaks within a (quoted) field. You will either get an error message - "Quoted field not terminated with closing quote" - or the result might not be correct for unquoted fields, because the field content will be cut by the line break.

6.9.4 Getting Started

We introduce the basic functionalities of **CSV2GDX** on some simple examples. Note that many CSV files can be read inside GAMS directly using a table statement, but a number of features available in **CSV2GDX** enable the user to read a CSV file where the table statement cannot be used, e.g. reading files with semicolon separated data or if the decimals are separated by comma instead of a period.

6.9.4.1 Example 1 - Reading CSV Files with **CSV2GDX**

The first example of this collection demonstrates the key commands of **CSV2GDX**. For instance, consider the table statement of the model [transport] from the GAMS Model Library:

```
Table d(i,j) 'distance in thousands of miles'
          new-york  chicago  topeka
    seattle    2.5     1.7     1.8
     san-diego  2.5     1.8     1.4;
```

The data can be stored in distance.csv like this:

```
d(i,j)        new-york  chicago  topeka
    seattle    2.5     1.7     1.8
     san-diego  2.5     1.8     1.4
```
First of all, **CSV2GDX** is called now, to generate distance.gdx by processing the input file distance.csv:

```
csv2gdx distance.csv id=d index=1 values=2..lastCol useHeader=y
```

**CSV2GDX** generates one single parameter `d` and two domain sets from the input file. The name of the parameter in the GDX file must be declared within the `id` option, while the domain sets for this parameter will be labeled with `Dim1` and `Dim2` automatically. Column number one is specified as the first domain set within the `index` option. The `values` option is used to specify the column numbers `2,3,4` containing the data values. By enabling the `useHeader` option, the fields of the first row of the columns specified within the `values` option will be handled as the second domain set. If the number of columns is unknown in advance, one can use the `lastCol` constant in the `values` or `index` option.

However, to complete the declaration of the sets and parameter for the model transport, one must load the data from distance.gdx:

```gams
Set
  i 'canning plants'
  j 'markets';
$gdxIn distance.gdx
$load i = Dim1
$load j = Dim2
Parameter d(i,j) 'distance in thousands of miles';
$load d
$gdxIn
display i, j, d;
```

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx2](#) for reference.
6.9.4.2 Example 2 - Reading Semicolon separated Data

In this example, the distances from the previous example are stored as a list. We want to read the cities and the column containing the miles measurement. Note, that the fields are separated by semicolon and the decimals by comma. As described in Data Exchange with Text Files the CSV file must be preprocessed with the POSIX tools in advance to replace commas by dots and semicolons by commas to read the data directly using a simple table statement.

```
i;j;miles
seattle;new-york;2,5
seattle;chicago;1,7
seattle;topeka;1,8
san-diego;new-york;2,5
san-diego;chicago;1,8
san-diego;topeka;1,4
```

The data will be stored as distanceOut.gdx by adding the output file option. One can specify the field and decimal separators within the fieldSep and decimalSep option. Domain sets for the parameter to be read are declared by index=1,2.

```
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHeader=y value=3
```

In order to load the data from the GDX file, execute the commands from the previous example. However, note that Dim2 does not contain the UELs from the header row this time, but the unique elements of the second column specified in the index option. The option useHeader is enabled to indicate that there is a header row to be skipped when reading the values. Also note, that the symbol d in the GDX file has exactly two dimensions. It may be useful to add an additional dimension to the parameter dmod, e.g. if different measurement units for the distances may become relevant later on and need to be calculated (kilometer for instance).

This can be done by adding the option valueDim:

```
csv2gdx distance.csv output=distanceOut.gdx id=d fieldSep=semiColon decimalSep=comma index=1,2 useHeader=y value=3 valueDim=y
```

The option adds a third dimension to d. Now we want to add the distances in kilometer by calculating the values inside the model:

```
Set m 'measurement unit' / miles, km /;

Parameter dmod(i,j,m);

$gdxIn distanceOut.gdx
$load dmod = d
$gdxIn
display dmod;

dmod(i,j,'km') = 1.852*dmod(i,j,'miles');
display dmod;
```

Parameter d (valueDim disabled):
---  36 PARAMETER d  distance in thousands of miles
  
<table>
<thead>
<tr>
<th>City</th>
<th>Chicago</th>
<th>Topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.500</td>
<td>1.800</td>
</tr>
<tr>
<td>San-Diego</td>
<td>2.500</td>
<td>1.400</td>
</tr>
</tbody>
</table>

Parameter dmod resp. d with valueDim enabled before calculating further measurements:

---  49 PARAMETER dmod

<table>
<thead>
<tr>
<th>City</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.500</td>
</tr>
<tr>
<td>Seattle</td>
<td>1.700</td>
</tr>
<tr>
<td>Seattle</td>
<td>1.800</td>
</tr>
<tr>
<td>San-Diego</td>
<td>2.500</td>
</tr>
<tr>
<td>San-Diego</td>
<td>1.800</td>
</tr>
<tr>
<td>San-Diego</td>
<td>1.400</td>
</tr>
</tbody>
</table>

Parameter dmod with valueDim enabled after calculating the distances in kilometer inside the GAMS model:

---  52 PARAMETER dmod

<table>
<thead>
<tr>
<th>City</th>
<th>Value</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seattle</td>
<td>2.500</td>
<td>4.630</td>
</tr>
<tr>
<td>Seattle</td>
<td>1.700</td>
<td>3.148</td>
</tr>
<tr>
<td>Seattle</td>
<td>1.800</td>
<td>3.334</td>
</tr>
<tr>
<td>San-Diego</td>
<td>2.500</td>
<td>4.630</td>
</tr>
<tr>
<td>San-Diego</td>
<td>1.800</td>
<td>3.334</td>
</tr>
<tr>
<td>San-Diego</td>
<td>1.400</td>
<td>2.593</td>
</tr>
</tbody>
</table>

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx3] for reference.

6.9.4.3 Example 3 - Dealing with missing Labels and Duplicates

Missing Labels

The file EUCData.csv contains the extracted euclidean coordinates of the first nine cities of berlin52.tsp from TSPLib. You might want to import the data to calculate a complete distance matrix inside GAMS to find an optimal traveling salesman tour for instance.

565.0;575.0
25.0;185.0
345.0;750.0
945.0;685.0
845.0;655.0
880.0;660.0
25.0;230.0
525.0;1000.0
580.0;1175.0
There is no header row, neither a column with labels to serve as domain sets for the coordinates of the cities. However, CSV2GDX automatically generates UELs for columns and rows by adding ascending numbers to an user-defined prefix specified within the autoCol and autoRow option. Also note, because of the missing header, the number of columns in the file must be manually determined and declared within colCount.

csv2gdx EUCData.csv id=coord fieldSep=semiColon autoCol=x autoRow=city colCount=2 values=1,2

The rows will be labeled with city1...city9, the columns with x1 and x2.

Load the parameter and sets from the GDX file to calculate the complete distance matrix. The set Dim1 contains the UELs city1...city9 for the set i of cities, Dim2 is the set of axes/coordinates i.e. containing the elements x1 and x2 to represent the x-axis and y-axis:

```gams
Set  
   i 'cities'  
   axes 'x1 and x2 axes';
$gdxIn EUCData.gdx
$load i = Dim1
$load axes = Dim2

Parameter coord(i,axes) 'coordinate of city i';
$load coord
$gdxIn
display coord;
```

The display statement generates the following output:

```
---- 43 PARAMETER coord coordinate of city i
      x1       x2
    city1  565.000  575.000
    city2   25.000  185.000
    city3  345.000  750.000
    city4  945.000  685.000
    city5  845.000  655.000
    city6  880.000  660.000
    city7   25.000  230.000
    city8  525.000 1000.000
    city9  580.000 1175.000
```

One could now easily proceed calculating a complete distance matrix:

```
Alias (i,j);

Parameter c(i,j) 'euclidean distance between city i and j';
c(i,j) = eDist(coord(i,"x1") - coord(j,"x1"),coord(i,"x2") - coord(j,"x2"));
```
Duplicates

In the previous example, using the `autoCol` and `autoRow` option had an additional benefit as we declared the set of the cities on the fly. However, one major advantage/purpose of these options is to prevent error messages or loss of data when reading rows with duplicate keys.

Consider the input file `duplicates.csv`:

```
red,red,1
red,red,2
red,green,3
blue,blue,4
```

Note the duplicate key in the first two rows. By the use of the `autoRow` parameter in the `CSV2GDX` call unique labels are added to each row. This way a GAMS program can store all data with duplicate keys and prepare for better error messages.

```
csv2gdx duplicates.csv id=data index=1,2 value=3 colCount=3 autoRow=row
```

Ascending numbers will be added to the 'row' prefix specified.

The data can be easily loaded into sets and parameter by executing the following lines:

```
Set
   row 'UELs generated by autoRow'
   color 'set of colors';
$gdxIn duplicates.gdx
$load row = Dim1
$load color = Dim2
$loadm color = Dim3
Parameter data(row,color,color);
$load data
$gdxIn
display row, color, data;
```

Note the usage of the `$loadm` command to merge all colors into one set of colors. The display statement generates the following output in the listing file:

```
---- 77 SET row UELs generated by autoRow
row1, row2, row3, row4
---- 77 SET color set of colors
red , blue , green
```
6.9.4.4 Example 4 - Reading several Parameters from a single Input File

This example demonstrates how to read the data from a single input file into different parameters. However, this cannot be done directly using the CSV2GDX tool, since CSV2GDX writes to a single parameter (see section limitations). For instance, an energy supplier plans to build new transmission lines from their power plants to some distribution stations. There are different stages for the transmissions lines. The relevant data to be read are the plant and station identifiers, the capacity bounds per transmissions line on a certain stage and the associated cost. The data is all stored in a single file:

plant;station;length;minCap;maxCap;stage;cost
p1;s1;100;50;100;1;1200
p1;s1;100;50;100;1;1800
p1;s1;100;50;100;1;2000
p2;s1;150;50;100;1;1400
p2;s1;150;50;100;1;2000
p2;s1;150;50;100;1;2350
p2;s2;75;25;50;1;600
p2;s2;75;25;50;2;800
p3;s1;80;40;100;1;1050

Read networkData.csv with CSV2GDX by calling:

```
csv2gdx networkData.csv id=dataPar useHeader=y fieldSep=semiColon index=1,2,6 values=4,5,7
```

Note that the stage stored in column six is a domain set, too, while the length of the transmission line in the third column is of no interest. Since CSV2GDX writes to a single parameter, one must split the data later on into minCap, maxCap and cost for instance:

Parameter dataPar
  minCap(plant,station,stage)
  maxCap(plant,station,stage)
  cost(plant,station,stage);

$gdxIn networkData.gdx
$load plant = Dim1
$load station = Dim2
6.9 CSV2GDX

$load stage = Dim3
$load dataPar
.gdxIn

minCap(plant, station, stage) = dataPar(plant, station, stage, 'minCap');
maxCap(plant, station, stage) = dataPar(plant, station, stage, 'maxCap');
cost(plant, station, stage) = dataPar(plant, station, stage, 'cost');

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx5] for reference.

6.9.4.5 Example 5 - Reading economic Data from the World Bank Data Catalog

This example demonstrates how to read some real CSV data from the World Bank Data Catalog. Suppose we want to read some time series data, e.g. GDP growth rates. The data is structured as follows (rows shortened for presentation):

"East Asia and Pacific","EAA","GDP growth, constant 2010 USD","NYGDPMKTPKDZ","","","","","","","","","","","","","","","","","","","","","","","","",

We are not interested in the "Country Code", "Indicator Name" and "Indicator Code". Since the annual GDP rate per country is unique, the CSV2GDX call is quite easy despite the large number of columns. Note that there are only a few limitations of CSV2GDX, discussed in the section Advances and limitations. Empty fields in the data will always be ignored, causing no trouble at all if the field separators are set correctly.

csv2gdx GDPData.csv id=GDPG index=1 values=5..lastCol useHeader=y checkDate=y

The option checkDate is enabled to save resources if you run the model multiple times, as the GDX file is only written if the CSV file is more recent than the GDX file. To load the sets and parameter from the GDX file, execute the following commands:

Set country, year;
.gdxIn GDPData.gdx
$load country = Dim1
$load year = Dim2

Parameter GDPRate(country,year);
$load GDPRate
.gdxIn
display country, year, GDPRate;

The display statement generates the following output in the listing file. Obviously, double quotes are removed from the fields of the value columns, but also from the index columns:
2568 Tools Manuals

---- 12 SET country

East Asia and Pacific, Europe and Central Asia, Latin America and the Caribbean, Middle East and North Africa, Afghanistan, Albania, Algeria, Angola

---- 12 SET year

---- 12 PARAMETER GDPR

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Europe and Central Asia</td>
<td>0.963</td>
<td>1.672</td>
<td>3.782</td>
<td>2.901</td>
<td>3.029</td>
<td>2.969</td>
</tr>
<tr>
<td>Latin America and the Caribbean</td>
<td>-0.562</td>
<td>-1.526</td>
<td>0.902</td>
<td>2.044</td>
<td>2.586</td>
<td>2.701</td>
</tr>
</tbody>
</table>

Note that the listings have been shortened for presentation. However, there is no data for the years 1999-2014.

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx6] for reference.

6.9.5 Additional Examples for extended Use

The examples in this section discuss some special features. Some topics were already mentioned briefly in the previous section like reading compressed and encrypted files or reading the CSV2GDX options from an external file.

6.9.5.1 Example 6 - Reading special Values

To illustrate how special values are interpreted, consider the following data:

```
one,two,three,four,five,six
red,red,,Undef,'3.3',red
red,red,"4.4",5.5,Eps,green
"red",'green',7.7e+02,8.8*,-Inf,blue
blue,blue,10,0,NA,purple
brown,blue,true,false,N/A,green
black,red,None,Null,"True",blue
```

Calling CSV2GDX to read the data and write to GDX:

```
csv2gdx data.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3
```

The GAMS log reports three occurrences of undefined values. Note that the amount of information written to the log was increased by setting the option trace=3.
--- call csv2gdx specialValues.csv id=A index=1,2,6 values=3..5 useHeader=y storeZero=y trace=3

CSV2GDX 25.2.0 r67638 ALFA Released 15Aug18 WEI x86 64bit/MS Windows

Header enabled, number of columns = 6
1: one
2: two
3: three
4: four
5: five
6: six

2: |red|, |red|, ||, |Undef|, |'3.3'|, |red|
3: |red|, |red|, |4.4|, |5.5|, |Eps|, |green|
4: |red|, |'green'|, |7.7e+02|, |8.8°|, |-Inf|, |blue|
5: |blue|, |blue|, |10|, |0|, |NA|, |purple|

Undef Count = 3, No errors, CSV2GDX time = 157ms

As mentioned in decimalSep, CSV2GDX fails to recognize the number 8.8 from the string 8.8° because of the unknown special character, while 7.7e+02 is interpreted as a number of course. Watch out if there are quotes in the values or index columns. The number 4.4 enclosed by double quotes is interpreted as a number, while '3.3' is not (as you can see in the log, the double quotes are eliminated, while the single quotes remain). In the first column, the double quotes enclosing the string red are removed, while the single quotes in the second column enclosing the string green are not removed. The zero value is stored as EPS by setting storeZero=y. Note that no error was reported, even though some of the values stored as Undef may cause some trouble in your model later on (use $onUndf to enable loading parameters with undefined values).

The booleans true and false in the second last row are represented by the numericals 1 resp. 0 within GAMS. The special values None and Null will be converted to 0. Since storeZore is enabled in this example, the value displayed for false, None and Null is EPS.

Suppose we want to declare the parameter A as: A(color,color,color,number). We can proceed as follows:

Set color, number;
$gdxIn data.gdx
$load color = Dim1
$loadm color = Dim2
$loadm color = Dim3
$load number = Dim4

Parameter A(color,color,color,number);
$onUndf
$load A
$offUndf
$gdxIn
display A;

Loading undefined values is enabled by adding $onUndf. This example is also part of the GAMS Data Utilities Library, see model [csv2gdx7] for reference.

6.9.5.2 Example 7 - Reading a compressed encrypted Input File

Reading a compressed input file is supported by CSV2GDX. The gzip program in the gbin sub-directory or ENDECRYPT must be used for compression. Call gzip to compress the CSV file by running the following command:
gzip compressMe.csv -c > compressedFile.csv.gz

Gzip writes to standard output by appending -c to keep the original file unchanged. The output is then redirected to compressedFile.csv.gz. To read the compressed file, call CSV2GDX with the same options as for processing the uncompressed file.

csv2gdx compressedFile.csv.gz output=unCompressedGzipFile.gdx id=d index=1 useHeader=y values=2..lastCol

The data in this example is taken from Example 1.

While the main purpose of Endecrypt is about encrypting and decrypting files, it also compresses the file. If you want to compress a file with Endecrypt, do not specify an password file:

cat compressMe.csv | endecrypt -W compressedFile.csv

The option -W encrypts standard input and writes to compressedFile.csv. Although there will be no encryption because of the missing password file, one must set the option -W. You can read the compressed file with CSV2GDX:

csv2gdx compressedFile.csv output=unCompressedEndycryptFile.gdx id=d index=1 useHeader=y values=2..lastCol

Note that there is no further file extension added.

By adding a password file (containing the password in the first line), Endecrypt encrypts and compresses the input file:

cat compressMe.csv | endecrypt -W compressedEncryptedFile.csv passwordFile.txt

The password file will be deleted. Execute the following command to read the compressed and encrypted file with CSV2GDX:

csv2gdx compressedEncryptedFile.csv output=unCompressedDecryptedFile.gdx password=Anton id=d index=1 useHeader=y values=2..lastCol

The password option is added. You must set the password directly within the option, in this case ”Anton”, not the password file. Note that CSV2GDX does not support .gz, .7z etc. compressed files!

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx8] for reference.
6.9.5.3 Example 8 - Reading Options from an external File

This example demonstrates how to read the options from an external text file as already mentioned in section Filename. The file distance.csv from the Getting Started Example 1 will be processed with CSV2GDX while reading the options from an external text file named howToRead.txt.

```bash
csv2gdx distance.csv @howToRead.txt
```

Swapping the order of the CSV filename and the instructions filename inside the call statement will cause an error. Note the leading @ (at sign) on the instructions file, containing the following options:

* These lines are interpreted as a comment
* This file specifies the options for reading distance.csv using CSV2GDX

```plaintext
id      = d
fieldSep = semiColon
decimalSep = comma
index   = i
useHeader = y
values  = 2..lastCol
```

This example is also part of the GAMS Data Utilities Library, see model [csv2gdx9] for reference.

6.9.5.4 Example 9 - Reading Set Elements with explanatory Text

In this example, we will demonstrate how to read explanatory text of set elements using the CSV2GDX option text.

Consider the input file data.csv:

```plaintext
a1,b1,explanatory text of a1.b1,10
a1,b2,explanatory text of a1.b2,20
a2,b1,explanatory text of a2.b1,30
a2,b2,explanatory text of a2.b2,40
```

The set elements are stored in the first and second column, the explanatory text is stored in the third column and there is a fourth column containing some values. Suppose we want to read a two-dimensional set with explanatory text. By default, CSV2GDX does not read explanatory text, i.e. by running the following command:

```bash
csv2gdx data.csv id=abOnlyUELs index=1,2 colCount=4
```

CSV2GDX creates a GDX file containing the two-dimensional set abOnlyUELs without explanatory text ( needless to say, we did not specify a column to get the explanatory text from). By specifying the third column within the index option, i.e. index=1..3, the result will be a three-dimensional set (without explanatory text, too). Using the value option is not suitable, as the data type will be a parameter instead of a set (in addition, CSV2GDX expects numeric data, potentially leading to undefined values). We can read the explanatory text easily by specifying column three within the text option:

```bash
csv2gdx data.csv id=abWithExpText index=1,2 text=3 colCount=4
```

The figure shows the set abOnlyUELs on the left without explanatory text and the set abWithExpText on the right:

Note that the text and value(s) options cannot be used at the same time (instead, use multiple CSV2GDX calls in scenarios when you wish to read set elements with explanatory text and parameters from a single data set).
6.10 EIGENVALUE

EIGENVALUE calculates eigenvalues of a symmetric matrix.

6.10.1 Usage

eigenvalue gdxin i a gdxout ev

where

  gdxin
  name of gdxfile with matrix

  i
  name of set used in matrix

  a
  name of 2 dimensional parameter inside gdxin

  gdxout
  name of gdxfile for results (eigenvalues)

  ev
  name of 1 dimensional parameter inside gdxout

Calculates eigenvalues of symmetric matrix a(i,j) where i and j are aliased sets.

6.10.2 Example

$onText
Eigenvalue example.

octave:1> a=[9 1 1; 1 9 1; 1 1 9]
a =
   9  1  1
   1  9  1
   1  1  9

octave:2> eig(a)
an =
   8
   8
   11
$offText

Set i / i1*i3 /;
6.11 EIGENVECTOR

EIGENVECTOR calculates eigenvalues/vectors of a symmetric matrix.

6.11.1 Usage

eigenvector gdxin i a gdxout eval evec

where

- **gdxin**
  - name of gdxfile with matrix

- **i**
  - name of set used in matrix

- **a**
  - name of 2 dimensional parameter inside gdxin

- **gdxout**
  - name of gdxfile for results (eigenvalues)

- **eval**
  - name of 1 dimensional parameter inside gdxout

- **evec**
  - name of 2 dimensional parameter inside gdxout

Calculates eigenvalues/vectors of symmetric matrix a(i,j) where i and j are aliased sets. eval will contain the eigenvalues and evec will contain the eigenvectors.
6.11.2 Example

Eigenvector example.

octave:1> a = [1 2 4 7 11; 2 3 5 8 12; 4 5 6 9 13; 7 8 9 10 14; 11 12 13 14 15]
a =
    1 2 4 7 11
    2 3 5 8 12
    4 5 6 9 13
    7 8 9 10 14
    11 12 13 14 15
octave:2> eig(a)
ans =
   -8.4644  -1.1163  -0.5121  -0.0275  45.1203
octave:3> [e1,e2] = eig(a)
e1 =
   0.5551  -0.2643  0.2893  0.6748  0.2879
   0.4821  -0.2582  0.2196  0.7349  0.3355
   0.2865  0.2159  0.3944  0.0412  0.4899
  -0.0993  0.7711  0.3944  0.0055  0.6379
 -0.6063  0.4715  0.0238  0.0521  0.6379

e2 =
   -8.4644  0.0000  0.0000  0.0000  0.0000
   0.0000  -1.1163  0.0000  0.0000  0.0000
   0.0000  0.0000  0.5121  0.0000  0.0000
   0.0000  0.0000  0.0000  -0.0275  0.0000
   0.0000  0.0000  0.0000  0.0000  45.1203

Set i / i1*i5 /;
Alias (i,j);
Table a(i,j)
   i1  i2  i3  i4  i5
  i1 1  2  4  7 11
  i2 2  3  5  8 12
  i3 4  5  6  9 13
  i4 7  8  9 10 14
  i5 11 12 13 14 15;
Parameter eval(i) 'eigenvalues'
evec(i,j) 'eigenvectors';
execute_unload 'mat.gdx', i, a;
execute '=eigenvector.exe mat.gdx i a ev.gdx eval evec';
execute_load 'ev.gdx', eval, evec;
display a, eval, evec;

6.12 ENDECRYPT

A tool to encrypt and decrypt text files.

6.12.1 Usage

endecrypt option xfile [passwdfile]

option

-W

to encrypt standard input and write to xfile

-R

to decrypt xfile and write to standard output

xfile

Text file to encrypt or decrypt.

passwdfile (optional)

First line is used as password; will be deleted after use

6.13 FINDTHISGAMS

6.13.1 Introduction

The Windows command line tool findthisgams is used for modifying GAMS specific registry entries created by the GAMS installer. These registry entries are primarily used for Windows file associations for GAMS related files (*.gms, *.gdx, *.gpr) and for the Object-oriented GAMS APIs which use the registry key gams.location for finding a valid GAMS system directory. This documentation uses the following registry hive abbreviations:

- HKCU: HKEY_CURRENT_USER
- HKLM: HKEY_LOCAL_MACHINE
- HKCR: HKEY_CLASSES_ROOT

Attention

This tool should be used with caution and only when necessary, as it changes the state of the registry. Reading this documentation carefully before use is advised.
6.13.2 Usage

findthisgams.exe [-q] [ list | delete (HKLM|HKCU) | write (HKLM|HKCU) ] [ide]

Without arguments: When findthisgams.exe is run without arguments, the tool tries to register the current GAMS system directory by either writing to HKCU (which takes precedence over HKLM) or by deleting entries in HKCU that hide the correct entries (current system directory) in HKLM.

-q: Run quietly. No pop-ups.
list: Print a summary of GAMS related registry entries (old and new).
delete (HKLM|HKCU): Deletes the registry entries in either HKLM or HKCU. The tool tries to delete both the old and the new style registry entries.
write (HKLM|HKCU): Writes the registry entries for the current GAMS system directory either to HKLM or HKCU.
ide: Per default, when findthisgams.exe writes to the registry, it uses GAMS Studio for file associations. Specifying ide will register the GAMS IDE instead.

6.13.3 Registry Keys

The registry entries created by the Windows installer have changed with GAMS 32. When running findthisgams with command line parameter list, the registry is queried for both the old and the new style registry keys. This gives a good overview of the current state of the registry before initiating any actual modifications to the registry:

Old registry keys (up to GAMS 31):

[HKCR|HKCU]\.gms
[HKCR|HKCU]\.gdx
[HKCR|HKCU]\gamside.file
[HKCR|HKCU]\gamside.file\shell\open\command
[HKCR|HKCU]\.gpr
[HKCR|HKCU]\gamside.project
[HKCR|HKCU]\gamside.project\shell\open\command
[HKCR|HKCU]\gams.location

New registry keys (GAMS 32 and later):

[HKL|HKCU]\Software\Classes\.gms
[HKL|HKCU]\Software\Classes\.gdx
[HKL|HKCU]\Software\Classes\gamside.file
[HKL|HKCU]\Software\Classes\gamside.file\DefaultIcon
[HKL|HKCU]\Software\Classes\gamside.file\shell\open\command
[HKL|HKCU]\Software\Classes\.gpr
[HKL|HKCU]\Software\Classes\gamside.project
[HKL|HKCU]\Software\Classes\gamside.project\DefaultIcon
[HKL|HKCU]\Software\Classes\gamside.project\shell\open\command
[HKL|HKCU]\Software\Classes\gams.location

Note

In order to access registry entries in HKLM, findthisgams needs to be run with administrative privileges.
6.14 GAMS Studio

GAMS Studio is a completely new integrated development environment for GAMS, which is available for Windows, Mac OS X, and Linux. It is based on C++ and Qt.

Note

In addition to this technical documentation, there is also a tutorial about the usage of GAMS Studio.

6.14.1 Motivation

The classic GAMS IDE has been shipped with the GAMS system for the last 20 years and is still the workhorse for many GAMS programmers. However, the existing IDE does not provide all the features we see in modern development environments. Due to its underlying software technology, implementing new features in the current IDE turned out to be a poor option, so work on a new development environment started from scratch. GAMS Studio is based on C++ and Qt, which makes it fast, reliable, and platform independent (Windows, Mac OS X, and Linux). An overview about the differences between GAMS Studio and the classic GAMS IDE can be seen at the end of this chapter (for long-time GAMSIDE users, especially the difference between IDE projects and Studio groups might be interesting).

6.14.2 Central Widgets

6.14.2.1 Welcome Page

The Welcome page is the starting point of GAMS Studio. It is designed to give quick access to common actions and to offer helpful information. It is divided into three columns.

On the very left there is a column labeled "Last Files" which lists all files that have been opened recently in Studio with the most recent file on top. A simple left click on an item in this list opens the corresponding file. The middle column named "Getting Started" offers useful actions and links for new users. The upper half contains shortcuts to create new files in user defined locations, open the GAMS Model Library Explorer or load the Transport example. The lower half has a link to the Studio introduction video on YouTube and two further links that open the integrated help view showing either this Studio documentation or the page with the GAMS tutorial overview. The rightmost column "Further Help" contains a link to the recent changes of GAMS Studio, the latest GAMS release notes, the GAMS World Forum for support and information about how to contact GAMS.
6.14.2.2 Code Editor

The Code Editor provides common functionality for editing with GAMS specific syntax highlighting. On the left side there is a special area displaying the line numbers and icons for links and errors generated by the compiler.

</table>

### 6.14.2.2.3 Navigation & Selection

The Code Editor looks for parenthesis to the right then to the left of the cursor and marks valid and invalid nesting. Hitting Ctrl - B moves the cursor to the matching parenthesis keeping the state inside/outside. To select the block to the matching parenthesis hit Ctrl - Shift - B.

To support navigating to files included by the gams source, place the mouse cursor over the file name and press the Ctrl - Left Mousebutton or place the cursor at the filename and hit F2. If found Studio will add the file to the current group and open it. Only plain text filenames can be detected this way, symbols are not resolved.

### 6.14.2.2.4 Code Folding

The Code Editor detects several kinds of sections in the source code that can be folded. These sections include all kinds of matching parentheses that extend over more than one line plus several $-control options that needs to come in pairs. To toggle the folding state of a section either the fold-marker can be clicked or the shortcut Alt - L can be pressed when the cursor is in a foldable line. To fold or unfold all foldable sections the main menu contains entries in the View menu. Additionally the shortcuts Alt - 0 to fold and Alt - Shift - 0 to unfold can be used.

To define individual blocks of folding the Dollar Control Options $onFold and $offFold can be added to the source.

List of $-control options that create a fold section:
6.14 GAMS Studio

6.14.2.2.5 Syntax Highlighting  The GAMS Studio syntax highlighter recognizes different kinds of source code like

- $\text{control option}$ with some special treatments (like $\text{OffText}$, $\text{OnText}$, etc.)
- comments, e.g. line comments and comment block
- keywords like declarations or loops
- description as descriptive text for identifiers
- data statements for identifiers or table data
- ...

To get the best highlight result it is recommended to use strict GAMS syntax.

6.14.2.2.6 Code Completion  GAMS Studio offers a static code completion for fixed internal keywords known by the compiler. The code completer pops up after pressing Ctrl - Space and shows keywords that matches the current syntax and starts with the already typed characters of the word to the left of the cursor. Moving the cursor to the left shortens the matching pattern while moving the cursor to the right extends it. The keys up/down, pageUp/pageDown, and home/end are processed by the results list during the completer is visible. The selected word can be inserted with the keys tab or enter/return or by double clicking a word in the list. To hide the completer, hit esc or click outside of the completer window. Additionally the completer hides if there is no match for the current start of word.

6.14.2.2.7 Automatic closing of brackets and quote characters  This feature is meant to improve convenience for users typing source code. In GAMS, as in pretty much every other programming language, opening brackets or quote characters are followed at some point by a closing equivalent. So when a user types one of the following characters the matching closing character will also be inserted after the text cursor. This allows the user to easily type the content in between. When typing the closing character which should be right after the cursor the already existing character will be jumped over. So when a user types the closing character by force of habit the autoclose feature does not interfere or causes syntax errors. Also possible is to make a text selection and then type a bracket or quote character. The selected text will then be surrounded by the chosen character pair. In the GAMS Studio under Settings > Editor > "Auto close opening brackets and quotes" a switch is available to turn this auto-close feature off.

List of characters that trigger insertion of a closing character:

- (  
- {  
- )  
- }  
- ]  
- }  
- ;  
- ,  
- :  
- ;
Other editors also close the < character but in the GAMS language context it is used in a different way, making it unnecessary to be closed automatically (e.g. as a comparison operator). In some cases user might not like the closing character to be inserted automatically however, this is hard to predict. Other editors - like Qt Creator - check what the next character after the cursor is. Only a limited set of characters allows the automatic insertion of the closing character.

Following characters allow auto closing when being the next char after the text cursor:

- Whitespaces
- ,
- ;
- )
- ]
- {
- }

All others will prevent the insertion of characters.

6.14.2.2.8 File Encoding  When opening a file Studio tries to assume the valid file-encoding. As it is not possible to safely determine the encoding the Edit > Encoding menu assists. To reload a file using another codec the reload with ... submenu can be used. With the convert to ... submenu the current file can be converted to another codec. A selection of encodings is preselected. This selection can be changed using the Select encoding submenu. It opens a dialog where the active encodings can be selected. One of them is marked as the Default encoding. Initially is is set to utf-8.

6.14.2.2.9 Bookmarks  The Code Editor provides the ability to set temporary bookmarks in the text files opened in main tabs. If Studio is closed they are dropped. Also if a file tab is closed the bookmarks for this file are dropped. A bookmark is placed at the current position of the current file using the toggle bookmark key. A line in the editor can only carry one bookmark. If this line has a bookmark already the existing one is removed. The keys for next/previous bookmark allow to navigate through the bookmarks beyond file bounds.

6.14.2.3 Listing Viewer

The Listing Viewer is used for displaying a GAMS output or listing file (*.lst) which is generated when running a GAMS (*.gms) file. The Listing Viewer consists of two sides. On the left side, the content of the listing file is presented in a tree structure that allows for convenient navigation within the listing file. The right side shows the listing file itself.

By clicking on a specific item in the tree on the left hand side, the listing file will automatically jump to the corresponding location. Changes of the cursor position in the listing file are dynamically reflected in the tree by selecting the item that belongs to the current section of the listing file.
When the GAMS process returns with a compilation error the Listing Viewer contains links to the source file. If the source file doesn't exist anymore the link is still shown but striked out.

The GDX Viewer is used to open and inspect GDX (GAMS Data eXchange) files. A GDX file contains GAMS symbols such as sets, parameters, variables, and equations in a binary format that serves as input and output to GAMS. The GDX Viewer component consists of two sides. The left side displays the symbol table of the open GDX file in a table format. Every entry represents a symbol and consists of the following information:

- **Entry**: The index of the symbol
- **Name**: The identifier of the symbol
- **Type**: The type of the symbol (Alias, Equation, Parameter, Set, or Variable)
- **Dim**: The dimension of the symbol
- **Records**: The number of records of the symbol
- **Text**: The explanatory text of the symbol
A specific column can be sorted by clicking on the respective column header. Clicking again toggles the sorting direction. The Filter facility provides dynamic filtering of the list of symbols contained in the GDX file using wildcard syntax. By default, only the Name column is taken into account by the filter. By selecting the All Columns check box, the search considers all other columns as well. The right side of the GDX Viewer displays the actual data of the symbol that is selected in the symbol table. Data can be displayed in either the List View or the Table View which can be toggled using the corresponding button in the upper part of the GDX Viewer.

6.14.2.4.1 List View  The List View is the default representation when looking at data using the GDX Viewer. The data is presented in the form of a table in which each row represents a record of the symbol. Each record consists of key columns corresponding to the symbols dimension. The value columns vary according to symbol type:

- **Set/Alias**: Column Text contains the explanatory text of a record, Y if no explanatory text is available.
- **Parameter**: Column Value contains the numerical value of a record.
- **Variable/Equation**: Five numerical columns: (Level, Marginal, Lower, Upper, Scale).
The header displays the individual domains as well as the original index position using superscript notation which is especially useful if the column order has been changed. Furthermore, it allows to manipulate the displayed data in several ways. By left clicking on a column header, the corresponding column is sorted using a stable sort mechanism that does not change the order of equal entries. Clicking again changes the sorting direction. Due to the Extended Range Arithmetic used by GAMS, columns containing numerical data can contain special values. Those values are treated in a special way when being sorted:

- **-INF**: Smallest numerical value.
- **EPS**: Treated as value very close but different from 0.
- **+INF**: Largest numerical value.
- **NA**: Treated as first non-numerical value (sorted as being greater than +INF).
- **UNDEF**: Sorted as being greater than NA.
- **ACRONYMS**: Sorted as being greater than UNDEF. Relative order of acronyms is by their internal number.

The order of columns can be changed by dragging a column header and dropping it at a different position. Dragging the border between column headers allows for resizing the widths of the involved columns. The columns in the List View offer a filter facility which can be opened either by right clicking on the column header or by left clicking on the filter icon. The Reset button in the top right corner can be used to reset the view to defaults. This removes all filters, resets the applied sorting as well as the applied numerical format and switches back to the List View in case the Table View was active.

The button Preferences opens a menu containing different settings for the current symbol. Squeeze Defaults can be used on variables and equations in order to hide all columns that have the default value of the respective variable or equation type. Squeeze Trailing Zeroes allows to turn on/off the truncation of trailing zeroes. The displaying format of numerical values can be specified using the Format drop down menu and the Precision spin box.

The available options for the Format are as follows:

- **g-format**: The display format is chosen automatically: **f-format** for numbers closer to one and **e-format** otherwise. The value in the Precision spin box specifies the number of significant digits. When precision is set to Full, the number of digits used is the least possible such that the displayed value would convert back to the value stored in GDX. Trailing zeros do not exist when precision=Full.
- **f-format**: Values are displayed in fixed format as long as appropriate. Large numbers are still displayed in scientific format. The value in the **Precision** spin box specifies the number of decimals.

- **e-format**: Values are displayed in scientific format. The value in the **Precision** spin box specifies the number of significant digits. When precision is set to **Full**, the number of digits used is the least possible such that the displayed value would convert back to the value stored in GDX. Trailing zeros do not exist when **precision=Full**.
The value in the **Precision** spin box specifies the number of decimals or the number of significant digits depending on the chosen format:

- **g-format**: Significant digits [1..17, Full]
- **f-format**: Decimals [0..14]
- **e-format**: Significant digits [1..17, Full]

Next to Preferences is the **Attributes** button. This button opens a menu that allows to hide certain attribute columns of variables and equations explicitly. This is especially useful when using the **Table View**.

### 6.14.2.4.2 Table View

Switching to the **Table View** is possible for symbols that have at least two dimensions. This mode consists of two parts: A separate header view that shows the domains and attributes of the symbol as well as the actual data. The header view also allows to access the filter facility and highlights the positions of specific domains by using visual separators (from left to right: rows, columns, attributes). The data itself is reshaped into a format where the labels of the last dimension are moved into the column header while the remaining dimensions go into the row header. The entries in the table are the numerical values (or explanatory text in case of GAMS sets) of the record with the corresponding labels of the headers. The following image shows the **List View** of a GAMS Parameter on the left side and its representation in the **Table View** on the right side:

![Two dimensional parameter as List View and Table View](image)

**Figure 6.10** Two dimensional parameter as List View and Table View

In case of GAMS variables and equations, a virtual dimension for the five numerical values (Level, Marginal, Lower Bound, Upper Bound, Scale) is introduced and displayed in the column header. When looking at the data of variables or equations it is most of the time useful to visualize only a specific attribute like the variable levels. This can be achieved by using the **Attributes** menu in the upper part of the GDX Viewer. The menu allows to hide specific attributes explicitly by disabling the corresponding checkboxes.

Both column and row header dimensions can be moved into different positions in order to reshape the table view. This can be done by performing a drag-and-drop operation that starts by clicking (and holding) the left mouse button while the mouse cursor is located on the index that should be moved. Moving the mouse to an arbitrary location will bring up a drop indicator (in the form of a thin line) that previews the position in which the index will be dropped as soon as the mouse button is released. In general all index positions can be moved to arbitrary new locations, but there are a few restrictions:

- The (virtual) numerical dimension of variables and equations (Level, Marginal, Lower Bound, Upper Bound, Scale) can not be moved and is always the last dimension in the column header.
• If a header (column or row) runs out of dimensions, a dummy header (Value, Text) is introduced which can not be moved but can be used as a drop target for further drag-and-drop operations.

<td>0.08</td>
</tr>
</tbody>
</table>

Figure 6.11 The table view representation of a GAMS parameter during a drag-and-drop operation that will move the dragged dimension into the position indicated by the drop indicator (thin black line)

While filters that have been applied in the List View will also be applied to the Table View and vice versa, sorting does not have any effect. The labels are sorted using the internal order which can not be changed by the user. For large data it is recommended to reduce the amount of visible records by applying filters in the List View and by disabling certain value columns in case of variables and equations. Once the data has been reduced, switching to the Table View allows to look at the data in a compact format.

6.14.2.4.3 Filter Facility Filters can be applied in both the List View and the Table View through the header view that contains the domains as well as the (numerical) attributes. In the List View, the header is part of the data view itself, while the Table View offers a separate header view above the actual data. The filter dialog can be opened either by right clicking on the header or by left clicking on the filter icon. Depending on the type of the column (key or value), the appropriate filter dialog for labels or numerical values is opened.

The filter dialog for a specific key column shows all occurring labels of that column in a list. Per default all labels in all columns are visible. Shrinking the displayed data can be achieved by unchecking one or more labels. The filter is applied by clicking the Apply button. Instead of selecting labels manually one can also use the wildcard string filter in the upper part of the filter dialog. The filter is automatically applied to the list of labels. Matching labels will be selected while all others will be deselected. The Hide unselected items checkbox can be used to automatically hide all deselected labels. This is especially useful for larger amounts of labels in combination with the wildcard string filter as only the matching labels will remain in the list while typing. The Select All and Deselect All buttons allow for selecting/deselecting all labels.
Numerical columns offer a different filter type that allows to specify an interval for values that should be included or excluded in the view for this specific column. The Min value is the lowest and the Max value is the largest one still included in the view. When the Exclude check box is activated, the specified range is excluded from the view instead of included. The lower part of the filter contains check boxes for special values like +INF or EPS. Checking/unchecking will show/hide the corresponding values in the view. Clicking the Apply button adds the filter to the column and refreshes the view accordingly. The Reset button removes an active filter.

Note

When a filter on a numerical column is applied, the values used for comparison are the actual values from the GDX file. Since the displayed values are influenced by the Format and the Precision setting, they can differ from the internal ones from the GDX file. Here is an example: Let’s assume we have a parameter p(i) with p("i1")=1.34 and p("i2")=2. With format set to g-format and precision set to 2, the values are displayed as 1.3 and 2. When applying a filter with the bounds (Min, Max) set to 1.33 and 2 both records are still shown even though 1.33 is greater than 1.3 (number shown in the GDX Viewer) since the internal GDX value used for comparison is actually 1.34.

### 6.14.2.4.4 Summary of Actions and Shortcuts

### 6.14.2.5 Reference File Viewer

The Reference File Viewer is a useful tool to navigate the source code of GAMS models via a reference file, especially when multiple files are involved. A reference file contains all symbol references of GAMS model and is created using the rf parameter when running the model.
When the model is compiled, the reference file with ".ref" extension is created and can be opened either using the menu: File > Open or double-clicking the "RefFile" entry in the Process Log:

![Figure 6.15 Process Log showing clickable entry for the reference file](image)

The Reference Viewer is categorized by a number of tabs:

- **All Symbols** shows an alphabetical listing of all symbols used in the model.
- **Set, Acronym, Variable, Parameter, Equation, and Model** shows an alphabetical listing of symbols of the same type. See Data Types and Definitions for more details on GAMS data types.
- **File** shows an alphabetical listing of all file statements used in the model.
- **Function** shows a list of GAMS built-in functions that has been used in the model.
- **Unused** shows an alphabetical listing of all symbols that have been declared in the model but are not used anywhere.
- **File used** shows an alphabetical listing of all files used in the model including the full file path. A double-click on an file entry of the table will jump to the beginning of the reference file.
The number next to the tab name indicates how many symbols in the category, where the number of All Symbols tab sums up the number of symbols in all other tabs except Unused tab and File used tab. A click on a symbol entry of the table in every tab (except File used tab) will show the detailed reference list containing the reference location in the right hand side of the reference viewer. A mouse-over on an entry of the reference list will show the tooltip of file location and position with the file that has been referenced. A double-click on an entry of the reference list will jump to the position in the corresponding file that has been referenced.

The reference list is organized by the following reference types:

<table>
<thead>
<tr>
<th>Reference Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>declared</td>
<td>Declaration of the symbol.</td>
</tr>
<tr>
<td>defined</td>
<td>Defined using a data statement.</td>
</tr>
<tr>
<td>assigned</td>
<td>When the symbol appears on the left side of an assignment statement.</td>
</tr>
<tr>
<td>implicitly assigned</td>
<td>Implicit assignment like a variable in a model.</td>
</tr>
<tr>
<td>control</td>
<td>When the set is used as a control set.</td>
</tr>
<tr>
<td>reference</td>
<td>Referenced in a statement.</td>
</tr>
</tbody>
</table>

The detailed description of the reference types and their shorthand symbols can be found in Reference Types in GAMS Output.

6.14.2.5.1 Sort and Filter referenced symbols

- **Sort**: A click on a table column header in the reference table will sort the symbol in the table by either Entry, Name, Type, Dim(ension), Domain, or Text.

- **Filter**: An input in the Filter box will search and display the symbol in the reference table by Name. A search in all columns can be enabled by checking All Columns next to the Filter box.

6.14.2.5.2 Summary of Actions and Shortcuts

6.14.2.6 Solver Option Editor

The Solver Option Editor is used to view and edit a solver-specific option file for controlling solver and interpreting results. See usage of The Solver Options File in Solver Usage and how to set optFile parameter to instruct gams to read an option file in The GAMS Call and Command Line Parameters. The Solver Option Editor provides an editor to edit the file contents in a table form where a row entry corresponds to a line in the solver option file. The Solver Option Editor also provides a browser of solver option definitions which can be displayed in group or be filtered by search and where the option can be directly added into or deleted from the editor.

The Solver Option Editor consists of the contents editor in the left pane, option definition browser in the right pane, as well as message and configuration tab in the bottom pane.
The left pane shows the contents editor of solver option file in a table form. Each row entry is either an option entry containing the option key, option value, as well as end-of-line comment (shown if there is definition of end-of-line comment characters for a solver option file) or a comment entry. Below the editor shows **Compact View** checkbox and **Open As Text** button

- An option key and value are shown in green color when defined correctly according to the definition, otherwise in red color when there is an error. An end-of-line comment (if defined) and a comment entry are shown in grey color. (see section **Toggle comment/option selection** on how to turn an option entry into a comment entry and vice versa)

- A comment row entry is shown in a merged cell as differences between option key and value are not identified in a comment line of a solver option file.

- The **Compact View** checkbox enables the editor to display the file contents without comments. Note that some editing actions are suppressed when the editor is in compact view (see section **Compact View** for more details).

- The **Show Messages** checkbox allows to display or hide the messages log at the bottom pane.

- The **Open As Text** button allows to reopen the file in the text editor once contents of the file has been saved (see **Open an existing solver option file** and **Save a solver option file** in section **Basic Operations** for more details).

The right pane shows a browser of solver option definitions.

- The lower part of the browser lists all option definitions, each contains **Option Name**, **Synonym**, **Default Value**, **Range**, **Type**, and **Description**. The list can be sorted alphabetically in ascending or descending order by clicking the **Option Name** header. A checkbox in front of an option entry indicates whether there is an option of this definition entry defined in the left pane editor. An entry with enumeration type (**EnumStr** or **EnumInt**) can be expanded to show all enumerated values of the option by clicking the bullet in front of the option entry, clicking the bullet again hides all enumerated values of the option. By double clicking the entry or dragging the entry and dropping in the left pane editor adds the option key with the default value defined by this option definition in the left pane editor (See section **Summary of Actions and Shortcuts** on how to add or insert an option).

- Above the list of all option definitions are a group of options and a search box. Option groups filters the list of option definitions by group name. By default all option definitions are displayed. Search box with placeholder text **Search Option...** allows a simple search through all option definitions. As a search keyword has been typed into the search box the results are displayed in the list of option definitions below. The search performs case insensitively on all fields of option definitions including enumerated values.
• The bottom pane shows the message log which reports the operations that have been carried out such as the contents have been loaded and saved as well as errors resulting from editing the contents. By default the message log is shown unless the Show Messages checkbox in the left pane has been unmarked to hide the message log.

6.14.2.6.1 Basic Operations

• Create a solver option file: via either the Studio menu or the project group context menu in project explorer.
  - From the Studio menu, choose File > New... then enter a valid solver option file name and suffix into the file dialog. Choosing Add new file by right clicking on project name in project explorer brings up the same file dialog for entering a valid solver option file name and suffix (See how to set different suffix values for solver option file from optFile parameter).
  - From the project group context menu, right clicking on project name in project explorer and choosing Add new solver option file brings up a list of solver names. Selecting a solver name from the list brings up a file dialog with the selected solver name as file name and the default option file suffix name opt (See how to set different suffix values for solver option file from optFile parameter).

• Open an existing solver option file: via either the Studio menu or project group context menu in project explorer.
  - From the Studio menu, choose File > Open... and select Option Files or All Files in the file dialog and then select a solver option file.
  - From the project group context menu, right click on project name then choose Add Existing file then choose Option Files or All Files in the open file dialog and then select a solver option file.
  - In case a solver option file is already opened with solver option editor, the file can be reopened in text editor by choosing Reopen File As Text from the file context menu in project explorer.
  - It is possible to open the solver option file in either solver option editor or text editor.
    * In case a solver option file has already been opened in solver option editor, choosing Reopen File As Text from the file context menu in project explorer closes the solver option editor and reopening the file in the text editor. Note that Open As Text button in the left pane editor performs the same function.
    * In case a solver option file is already opened in text editor, choosing Reopen File using Solver Option Editor from the file context menu in project explorer closes the text editor and reopening the file in the solver option editor.
    * In case a file is already listed under the project group entry but not yet opened, choosing Open File from the project group context menu opens the file in the solver option editor; however, choosing Open File As Text from the project group context menu opens the file in the text editor.

• Save a solver option file: activated by choosing either File > Save menu or Ctrl - S shortcut. Choosing File > Save As menu or Ctrl - S shortcut brings up a file dialog to choose a file with different name to be saved as (See also how to set different suffix values for solver option file from optFile parameter).

6.14.2.6.2 Navigating the contents When a component of the solver option editor in focus, it is possible to perform further actions (see section Summary of Actions and Shortcuts for the list of actions and shortcuts). Clicking the component area will bring the component into focus or in selection. In addition to using mouse to navigate the solver option editor components, it is also possible using keyboard. Press Tab key navigates the components of the solver option editor. For example, when left pane editor is in focus, pressing Tab navigates from the left pane editor, to the right pane option group box, to the right pane Search box, and to the right pane definition browser in the describing order. When the left
pane editor is in focus, press Up, Down, Left, and Right keys to navigate the left pane editor table. When the right pane browser is in focus, press Up and Down to navigate the definition entries, press Right to expand/show the enumerated entries of the definition, and press Left to collapse/hide the enumerated entries of the definition.

There is a connection between an option entry in the left pane editor and a definition entry in the right pane browser. When navigating the solver option editor, it is possible to identify this connection from both the left pane editor and the right pane browser.

- From the left pane editor, right click on the selected entry and choose show option definition from the context menu. The entry in the right pane browser that contains the definition of the selected entry is highlighted and selected. When a cell or a row is already selected the shortcut Ctrl - F1 delivers the same behavior.

- From the right pane browser, click or select on an entry. All entries in the left pane editor will be highlighted and selected if the definition has already been added. Otherwise there will be no selection in the left pane editor.

More editing actions can be performed on both the left pane editor and the right pane browser (See Editing the Contents for details).

6.14.2.6.3 Editing the Contents  The followings describe actions that can be performed when editing the contents:
• Edit option key, value, and comment: This action performs in the left pane editor.
  – when the cell in the left pane editor is selected, double click on the cell or press platform-dependent edit key (eg. F2) in order to edit option key, value, or comment (if available). A drop-down list suggests possible option keys and option values as when possible. Press Enter to confirm the edit and press Esc to cancel the edit.

  ![Figure 6.17 actions to be performed via the left pane editor and the right pane editor](image)

  Figure 6.17 actions to be performed via the left pane editor and the right pane editor

• Add new option: This action appends a new option entry as the last entry of the left pane editor.
  There are several ways to add a new option entry.
  – click on the plus icon in the header of the left pane editor, a new option entry with dummy option key [KEY], option value [VALUE], and option comment [comment] (if available) is appended as the last entry.
  – it is also possible to add new option from the the right pane browser. Select the definition entry in the right pane browser that has not been added/inserted into the left pane editor (a solid checkbox in front of the entry is not marked), double click or right click on the selection

  ![Figure 6.18 Drop-down lists suggest possible keys (left) and values (right)](image)

  Figure 6.18 Drop-down lists suggest possible keys (left) and values (right)
then choose **add this option**. A new option entry ith the option key and default value of this definition will be added as the last entry in the left pane editor. and dummy option value [VALUE] is appended as the last entry.

• **Insert new option and comment**: It is possible to perform this action from the left pane editor and from the the right pane browser and there are several ways to insert a new option or a comment entry.

  - right click on the selected entry in the left pane editor and choose **insert new option** from the context menu. A new option entry with dummy option key [KEY], option value [VALUE], and option comment [comment] (if available) will be inserted before the selected entry. When a cell or a row is already selected the shortcut Ctrl - Return delivers the same behavior.

  - right click on the selected entry in left pane editor and choose **insert new comment** from the context menu. A new option entry with dummy text [COMMENT] will be inserted before the selected entry. When a cell or a row is already selected the shortcut Ctrl - Shift - Return delivers the same behavior.

  - double click on a definition entry in right pane browser.
    - In case this definition has not yet been added/inserted (a checkbox in front of the entry is not marked), a new option entry with the option key, default value, and comment (if available) of this definition will be added as the last entry in the left pane editor. When there is a selection on a cell or a row the shortcut Return delivers the same behavior.
    - In case this definition has already been added/inserted (a checkbox in front of the entry is marked), by default the studio option editor will ask for overriding existing option if there is an option from the same definition that has already been added/inserted into the left pane editor. A pop-up message box appears and offers three alternatives: either to replace existing entry, or to add new entry, or to abort. Replace existing entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition. Add new entry will add a new option entry with the option key and default value of this definition into the left pane editor. Abort will cancel the action. See section **override existing option** on how to suppress this default behavior.

When double clicking an enumerated value entry of the definition a new option entry will be added with the option key of the parent entry and the selected enumerated value.

  - drag a definition entry from the right pane browser and drop in the left pane editor.
    - In case this definition has not yet been added/inserted (a checkbox in front of the entry is not marked), a new option entry with the option key, default value, and comment (if available) of this definition will be dropped before the position of selected entry in the left pane editor.
    - In case this definition has already been added/inserted (a checkbox in front of the entry is marked), by default the studio option editor will ask for overriding existing option if there is an option from the same definition that has already been added/inserted into the left pane editor. A pop-up message box appears and offers three alternatives: either to replace existing entry, or to add new entry, or to abort. Replace existing entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition. Add new entry will insert a new option entry with the option key and value of this definition before the position of selected entry in the left pane editor. Abort will cancel the action. See section **override existing option** on how to suppress this default behavior.

See also section **Settings** on how to insert a new option together with a comment from the definition.

• **Toggle comment/option**: This action performs in the left pane editor, turning an option entry into a comment entry and turning a comment entry into an option entry.

  - select the option entry and right click on the selection, then choose **toggle comment/option selection** from the context menu. In case of an option entry this action turns the entry into a comment entry (shown in grey color). In case of a comment entry this action turns the entry into an option entry entry (shown in either green or red color depending on whether or not
there is an error). When a cell or a row is already selected the shortcut Ctrl - * delivers the same behavior. Clicking on the color box in front of the entry row also delivers the same behavior, even without a selection.

- **Move up and down**: These two actions perform in the left pane editor, changing the order of the option and comment entries.

  - to move an entry up in the left pane editor: select the option entry and right click on the selection, then choose **move up** from the context menu. The selected option entry will be moved one position up the option entry table. When a cell or a row is already selected the shortcut Ctrl - Up delivers the same behavior.

  - to move an entry up in the left pane editor: select the option entry and right click on the selection, then choose **move down** from the context menu. The selected option entry will be moved one position down the option entry table. When a cell or a row is already selected the shortcut Ctrl - Down delivers the same behavior.

- **Deleted option**: It is possible to perform this action from the left pane editor and from the the right pane browser.

  - from the left pane editor, select the option entry and right click on the selected, then choose **delete selection**. The selected option entry will be deleted from the option entry table. When there is a selection on a cell or a row the shortcut Ctrl - Delete delivers the same behavior.

  - from the right pane browser, select the definition entry that has already been add/inserted into the left pane editor (a checkbox in front of the entry is marked) and right click on the selection then choose **remove this option**. All entries in the left pane editor defined by this definition will be deleted from the option entry table. When there is already a selection on a definition row the shortcut **Delete** delivers the same behavior.

- **Show option definition**: This action performs in the left pane editor. Right click on the left pane of the option editor and choose **Show option definition**. The option definition entry on the right pane will be highlighted. The shortcut Ctrl - F1 delivers the same behavior.

- **Show all options of the same definition**: This action performs in the left pane editor. Right click on the left pane of the extended editor and choose **Show all options of the same definition**. All option entries on the left pane will be highlighted. The shortcut Shift - F1 delivers the same behavior.

![Figure 6.19 All entries of the same option are highlighted](image_url)
6.14.2.6.4 Compact View  Compact View of the solver option editor allows to view and edit solver option without comments. Comments in a solver option file are not interpreted by either GAMS or the solver but used for documentation purpose. As the contents of the solver option file grows larger with several comment lines, it can be difficult to see which options eventually will be interpreted. To this end, the compact view becomes useful to hide all comments and show only non-comment lines. In the right pane editor, mark Compact View checkbox to activate the compact view and unmark the checkbox to deactivate the compact view. The comment entry is shown again once the compact view is deactivated.

Note that the result of some actions are not visible when in compact view. For example, action toggle comment/option selection when performed on an option row entry, turning the entry into a comment entry and therefore hidden from the compact view. Action delete selection when performed on an option row entry, removing the content entry and therefore no longer visible hidden from the compact view.

Some editing actions that can change the order of the contents are suppressed. These actions are insert new option, insert new comment, move up, and move down. Nevertheless adding or inserting option from the right pane are allowed, but a comment that has been inserted with the option (if set) are not visible in compact view. See also section Settings on how to insert a new option together with a comment from the definition.

6.14.2.6.5 Settings  The setting tab allows to configure the behavior when inserting new option from definition and deleting option. The setting can be accessed by opening the Settings dialog (File > Settings) and switching to the Misc. tab. These configurations are:

- **Override existing option.** This behavior allows Studio to override existing option when an option entry has been added or inserted from the right pane browser. In case there are more than one entry of the same option, Studio will pop-up a message box to offer three alternatives: either to replace existing entry, or to add new entry, or to abort.
  - Replace existing entry will remove all other entries of this definition key but the first entry from the left pane editor and replace the option value of the entry by the default value defined by the definition.
  - Add new entry will add or insert a new option entry with the option key and default value of this definition into the left pane editor.
  - Abort will cancel the action.

By default this behavior has been set. In the Settings dialog, unmark the checkbox in front of the text overriding existing option to suppress the behavior and mark to enable the behavior.

- **Add option description as comment above.** This behavior allows Studio to add option description as additional comment entry above an option entry that has been added or inserted from the right pane browser. The description has been taken from the option definition in the right pane browser. By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text add option description as comment above to enable the behavior and unmark the checkbox to suppress the behavior.

- **add option description as end of line comment** This behavior allows Studio to add option description as additional end-of-line comment of an option entry that has been added or inserted from the right pane browser. The end of line comment is only available when the solver defines valid end of line characters. The end-of-line comment column will be shown in the solver option editor only when available (there is definition of end-of-line comment characters for a solver option file). By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text add option description as end of line comment to enable this behavior and unmark the checkbox to suppress the behavior.

- **delete all immediate comments above** This behavior allows Studio to delete all immediate comments (if there is any) above when deleting an option. By default this behavior has not been set. In the Settings dialog, mark the checkbox in front of the text delete all immediate comments above to enable this behavior and unmark the checkbox to suppress the behavior.
### 6.14.2.6.6 Summary of Actions and Shortcuts

Actions and their shortcuts that can be performed via the left pane of solver option editor are:

<table>
<thead>
<tr>
<th>Action</th>
<th>Shortcut</th>
<th>macOS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Toggle option/comment selection</td>
<td>Ctrl - *</td>
<td>Command - *</td>
<td>Toggle between option and comment</td>
</tr>
<tr>
<td>Insert new option</td>
<td>Ctrl - Return</td>
<td>Command - Return</td>
<td>Insert a new option</td>
</tr>
<tr>
<td>Insert new comment</td>
<td>Ctrl - Shift - Return</td>
<td>Ctrl - Shift - Return</td>
<td>Insert a new comment</td>
</tr>
<tr>
<td>Delete selection</td>
<td>Ctrl - Delete</td>
<td></td>
<td>Delete the selected option/comment</td>
</tr>
<tr>
<td>Move up</td>
<td>Ctrl - Up</td>
<td>Command - Up</td>
<td>Move the selected option/comment up for 1 row</td>
</tr>
<tr>
<td>Move down</td>
<td>Ctrl - Down</td>
<td>Command - Down</td>
<td>Move the selected option/comment down for 1 row</td>
</tr>
<tr>
<td>Select all</td>
<td>Ctrl - A</td>
<td>Command - A</td>
<td>Select all options</td>

<tr>
<td>Resize columns to contents</td>
<td>Ctrl - R</td>
<td>Command - R</td>
<td>Resize the columns in the right pane to contents</td>
</tr>
</tbody>
</table>

### 6.14.2.7 GAMS Configuration Editor

The GAMS Configuration Editor is used to view and edit a GAMS Configuration File in YAML Format. The editor shows the two configuration sections: command line parameters (commandLineParameters), and operating system environment variables (environmentVariables), in different tabs of the editor.
Note that GAMS Configuration editor does not show the contents of the third section: external solver configuration (solverConfig) if exists. However, the contents in this section will be written out to the file when saving the file via the editor. It is possible to use Reopen File as Text from Project Explorer context menu to reopen and edit the file contents in text editor when the file is already opened in the GAMS Configuration Editor and use Open File as Text from Project Explorer context menu to open the file in text editor when the file is not yet opened in any editor. See the syntax of gamsconfig.yaml file from GAMS Configuration File in YAML Format.

GAMS will process a sequence of gamsconfig.yaml files from different locations (see the location of GAMS Configuration file from The GAMS Configuration in YAML Format and the order of precedence for command line parameters from Order of Precedence for Options). Studio can create a new gamsconfig.yaml file at the default user-specific location and open the file in the editor when the file at the location does not exist. This can be done by choosing GAMS > Default GAMS Configuration. In case the file already exists at the default location, choosing GAMS > Default GAMS Configuration will not override the gamsconfig.yaml in the default user-specific location but open the file in the editor.
It is possible to save the `gamsconfig.yaml` file into different location using File > Save As....

### 6.14.2.8 Tab Browser

The Tab Browser is accessible with a button next to the main tab bar or via the shortcut Ctrl - 4. It opens a list of all open files and features a search input field. When opening the tab browser, the search field is already focused. Typing updates the list in real time. The Enter key selects the first item in the list and opens it. It is also possible to use arrow up/down to navigate the list and select an item with Enter. The filter supports wildcard syntax.

### 6.14.2.9 Navigation History

The Navigation History records a navigation history event each time the cursor is moved in some kind of text file opened in the Studio central widget. This allows the user to quickly jump back (and forward again) to text passages that were recently edited. To reduce clutter some events are set to overwrite the previous event. This happens when the cursor is moved by only a single position in either direction, so that when a user jumps through text or types something only the latest position will be put into the history. The idea behind this is to make it easier and more convenient to jump to positions that actually matter. Using the navigation history is not limited to a single file. It is easy to jump between two or more files to go back and review recent changes. If a file was closed in the meantime it will be reopened when navigating through the history. This includes even files that were completely removed from Studio. When such a file is reopened through the Navigation History feature, due to technical limitations, the affiliation of the file to its previous group is lost. Please note that after navigating back in the history all "future" history events will be deleted and overwritten if the user creates new history events.

</tr>
</tbody>
</table>

### 6.14.3 Further Studio Widgets

#### 6.14.3.1 Project Explorer

The Project Explorer provides a group organization of files opened in Studio. The Project Explorer lists all files and their corresponding group in a flat hierarchical tree structure with Project Explorer as its root. A group entry is listed with the folder icon and its tooltip tells the location of the group in the file system. To support faster detection there are several icons for different file types:
• The runnable GAMS files (currently supported .gms and .inc) are listed with GAMS icon,
• the main GAMS file assigned to the group additionally contains a green play symbol,
• GDX files (.gdx) have an database icon,
• Reference files (.ref) are shown with a reference nodes on a sheet,
• editable files (e.g. .txt) contain a pen on a sheet,
• read-only files (e.g. .log) contain lines on a sheet.

The tooltip of a file entry tells the location of the file in the file system. The file location and the group location can be explored using the default file system explorer via the context menu "Open location". Selecting "Open terminal" opens the systems terminal in the location of the selected file or group. The context menu of a .gdx file provides a special entry "Open in GDX Diff" that opens the specific GDX Diff Dialog.

A group entry is created automatically when opening a file, the groups name is determined by the name of the opening file. One group may contain multiple runnable GAMS files but only one runnable GAMS file is set as the main file, marked with a green arrow over its GAMS icon. By default the first runnable GAMS file in a group is considered the main file. The tooltip of a group also tells the location of the folder and the name of the current main file. Additionally the name of the recently created output file
(.lst) is shown after the first run. The main file can be changed to other runnable GAMS file in a group via the context menu "Set as main file".

The main file will be executed when pressing F9 or clicking the execute button (see how to set GAMS parameters and execute the main file in Quick Access Toolbar and GAMS Parameter Editor). After executing the main file, the generated listing file (.lst) is added to its group and the output view (see Process Log) is opened. A clickable log line in the process log may add the corresponding file into the group and open the file in the Central Widgets area. Users can manually add more files to a group by right-clicking and choosing either "Add existing file" or "Add new file" from the context menu.

Files can also be removed from a group and group can be removed from Project Explorer via the two actions "Close group" and "Close file" from the context menu. The action "Close group" closes all files in the group if opened as well as removes all file entries and the group entry from the Project Explorer without actually touching the file on the file system. The action "Close file" closes the file if opened and removes the file entry from the group. In case the closed file is the only entry in the group, the group is also closed accordingly. In case there are unsaved changes a message popup will appear, asking the user how to proceed.

It is possible to select multiple items in the project explorer. A selection always contains items of one kind, files or groups never both depending on the first selected item. The context menu then addresses all selected items.

Selected files can be dragged to another group. By dropping them they are moved to the destination group. Pressing the Ctrl key creates a copy of the file-reference in that group (no file copy). If the group already contains a specific file it is just ignored.

Actions like rename, move, or delete from file system are currently not supported but will be added in the future.

Note

For long-time users of the classic GAMS IDE the section about the differences between IDE projects and Studio groups might be of particular interest.

6.14.3.2 Process Log

After starting a GAMS process the LogViewer is opened to view the process Log. Usually the Log stays at the bottom to keep tracking the latest log lines. The tracking can be paused by clicking on the up arrow of the vertical scrollbar. To continue tracking drag the scrollbar to the bottom.

The Log usually contains links of different kinds:

- compilation errors (red): Links to the gms file where the error occurred. Additionally contains a link to the listing file (.lst) at the beginning of the line (blue).
- listing links: Links to a specific line in the listing file
- file link (green): Links to a file without line numbers such as .gdx or .ref

Clicking on a link takes the focus to that file (and line). Double-clicking in the Log looks for the nearest link to the listing file and takes the focus there. Files that were not part of the current project are added when they are opened by link.

For general messages there is the System Log stacked together with all Process Logs. It keeps track of Studio related messages not originated from a specific GAMS run.
6.14.3.3 Quick Access Toolbar and GAMS Parameter Editor

The toolbar contains two parts: a quick access section and GAMS Parameter editor to customize how GAMS is executed the model (see The GAMS Call and Command Line Parameters).

The quick access section contains icons for performing common File actions like New, Open, and Save, as well as accessing Settings dialog, Model Library Explorer dialog, Project Explorer view, Process Log, and Help view.

The GAMS Parameter Editor provides a way to control and customize the execution of a GAMS model. The editor displays the parameters of the group of the file that is currently opened in Central Widgets (see also Project Explorer for group and its runnable files). The parameters can be typed into a combobox and the execution of a GAMS model can be carried out using the following pre-customized execution commands:

- **Run**: Choose Run or press F9 to compile and execute GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the default parameter action=CE (Compile and Execution).

- **Run with GDX Creation**: Choose Run with GDX Creation or press F10 to compile and execute GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two parameters action=CE and gdx=default.

- **Compile**: Choose Compile or press Shift - F9 to compile GAMS statements in the main runnable file. This execution command is equivalent to running GAMS with the parameter action=C (CompileOnly).

- **Compile with GDX Creation**: Choose Compile with GDX Creation or press Shift - F10 to compile GAMS statements in the main runnable file and create a GDX file with the name of the main runnable file and a gdx extension. This execution command is equivalent to running GAMS with the combination of the two parameters action=C and gdx=default.

- **Run NEOS**: Choose Run NEOS to compile GAMS statements in the main runnable file locally and pass the execution to the NEOS server.

- **Run GAMS Engine**: Choose Run GAMS Engine to compile GAMS statements in the main runnable file locally and pass the execution to the GAMS Engine server.
The pre-customized execution command will operate on the main file (marked with a little green arrow over the regular icon) of the active group (see how to manage the main file in section Project Explorer). In case GAMS parameters have been set they will be appended to the pre-customized commands. Just like the GAMS Terminal, when there are identical parameters with different values the last one "wins" and overwrites the previous ones. Thus it is possible for a user to change and override GAMS Studio default parameters, which can possibly lead to problems if done incorrectly. In this case Studio prints out a warning message, informing users about potential problems. To debug what Studio does the full GAMS call parameters will be printed to the system log. After execution, the parameters will be added into the group history. All files in a group share one parameter history. The previous GAMS parameters can be recalled from the group history via the drop-down menu of the combobox. Switching the file opened in Central Widgets will activate the different group history only when the group of the newly opened file is different from the group of the file before switch.

The parameters curDir and workDir behave slightly differently in Studio compared to the terminal. When using one of these parameters on the command line GAMS expects the gms file to be in the given folder. In Studio the path to the input file is always given as an absolute one. Therefore, there is no need to use the inputDir parameter to make the gms file accessible to GAMS if it is not in the specified working directory.

The GAMS Parameter Editor provides a way to either interrupt or stop the currently running job when an execution of a GAMS model is in progress (indicating with animated icon over the project folder icon in Project Explorer):

- **Interrupt**: Click the Interrupt button or press F12 to send an interrupt request to the running job in order to perform a graceful stop and collect an incumbent result back from the execution if the solver supports this feature. The command is enabled when there is a job that is currently running in the group and disabled when there is no currently running job in the group.

- **Stop**: Click the Stop button or press Shift - F12 to send a request to stop the running job immediately. The command is enabled when there is a job that is currently running in the group and disabled when there is no currently running job in the group.

The Extended GAMS Parameter Editor allows to configure the GAMS parameters. The extended parameter editor is shown when the Show button next the parameter combobox is clicked or with the shortcut Ctrl - Alt - 3. The editor can be hidden when the button is clicked again. When shown, the GAMS parameters from the parameter combobox will appear as a list of entries in the left pane of the extended parameter editor, each entry contains the Key and Value.

Note that the GAMS parameter combobox will be disabled when the extended parameter editor is shown and all editing has to be done in the extended parameter editor.
Figure 6.23 Extended GAMS Parameter Editor is shown when the button next to parameter combobox is clicked

The right pane of the extended editor displays the list of all valid parameter definitions, each contains Parameter Name, Synonym, Default Value, Type, and Description. The parameter definition entry with enumeration type (EnumStr or EnumInt) can be expanded to show all enumerated values of the parameter by clicking the bullet in front of the parameter entry, clicking the bullet again will hide all enumerated values of the parameter. Above the list of all valid parameter definitions is a search box (with placeholder text Search Parameter...) to allow a simple search through all parameter definitions. As a search keyword has been typed into the search box the results will be displayed in the list below. The search will perform on all fields of parameter definitions including enumerated values.

The parameter editor displays potential parameter errors in red color both in the combobox and in the left pane of the extended editor. When hovering a mouse over the error key or value, a tooltip with more detailed explanation of the error appears.

Figure 6.24 Parameter key turns red with pop-up tooltip when there is a potential error
When there are several entries of the same parameter, all other entries except the last entry will be ignored when gams executes the model. In such case, the combobox of parameter editor displays a warning in yellow and the icon in front of the parameter in the extended editor turns half-yellow in combination of another color, red or green, depending of whether or not there is a potential error.
6.14 GAMS Studio

Figure 6.26 Parameter key turns yellow and the pop-up tooltip indicating a warning

See edit parameter key and value on how to edit parameter key and value that contains an error or a warning. See show all parameters of the same definition on how to locate all entries of the same parameter.

The followings describes all editing actions that can be performed via the extended parameter editor:

- **Edit parameter key and value**: double click on key cell to edit Key and on value cell to edit Value of the entry. A drop-down list will suggest possible keys and values when possible. Press Enter to confirm the edit and press Esc to cancel the edit.
• **Add new parameter:** there are several ways to add a new parameter via extended parameter editor.

  - right click on the left pane of the parameter editor and choose **add new parameter** from the pop-up context menu
  - right click on the selected parameter entry of the parameter table and choose **add new parameter** from the pop-up context menu
  - click on the add new parameter button next to **Key** table header in the left pane

A new entry will be added at the end of parameter entry table with dummy parameter key \([\text{KEY}]\) and dummy parameter value \([\text{VALUE}]\). See **edit parameter key and value** on how to edit parameter key and Value.

It is also possible to add a new parameter from the right pane of the parameter editor by double clicking at the definition entry in the right pane. The selected definition entry will be added as a new parameter entry at the end of table in the left pane. In case of double clicking an enumerated value entry of a parameter definition the definition entry will be added as a new parameter with the selected enumerated value. Otherwise the default value of the entry will be added.
• **Insert new parameter**: right click on the selected entry and choose *insert new parameter*. A new entry will be inserted before the selected entry with dummy parameter key [KEY] and dummy parameter value [VALUE]. See *edit parameter key and value* on how to edit parameter key and value.

• **Move up**: right click on the selected entry and choose *Move Up*. The selected entry will be moved one position up the table. This action will change the order of parameters.

• **Move down**: right click on the selected entry and choose *Move Down*. The selected entry will be moved one position down the table. This action will change the order of parameters.

• **Delete selection**: right click on the selected entry and choose *Delete Selection*. The selected entry will be deleted from the table.

• **Delete all parameters**: right click on the left pane of the extended editor and choose *Delete all Parameters*. All entries will be deleted from the table.

• **Show parameter definition**: right click on the left pane of the extended editor and choose *Show parameter definition*. The parameter definition entry on the right pane will be highlighted.

• **Show all parameters of the same definition**: right click on the left pane of the extended editor and choose *Show all parameters of the same definition*. All parameter entries on the left pane will be highlighted.
• **Resize columns to contents:** right click on the left or right pane of the extended editor and choose **Resize columns to contents.** All columns will be resized according to their contents.

• **Add this parameter:** right click on the right pane of the extended editor and choose **Add this parameter.** The parameter with default value (if defined) of the selected definition will be added as the last entry on the left pane of the extended parameter editor. This action in the context menu is enabled only when there is no entry of this parameter on the left pane. Note that a double click on the definition will also perform add this parameter action. Performing the action on the parameter definition that has already been added will pop-up a dialog indicating that the parameter exists on the left pane and prompting for one of the followings:
  - replace existing entry If there is only one entry or replace the first entry and delete other entries if there is more than one entry, or
  - add new entry of the same definition, or
  - show details of all entries of the same parameter, or
  - abort the action

• **Remove this parameter:** right click on the right pane of the extended editor and choose **Remove this parameter.** The parameter of the selected definition will be deleted from the left pane of the extended parameter editor. This action in the context menu is enabled only when there is an entry of this parameter definition on the left pane. In case there are multiple entries of the same parameter, all entries on the left pane will be deleted.

Press F1 on a parameter entry in the extended parameter editor will activate the The GAMS Call and Command Line Parameters help page containing the detailed description of the GAMS parameter.

6.14.3.3.1 **Summary of Actions and Shortcuts** Actions and their shortcuts that can be performed via Toolbar and GAMS parameter editor are:
<table>
<thead>
<tr>
<th>Action</th>
<th>Shortcut</th>
<th>macOS</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</table>

6.14.3.4 Integrated Help

The Help View is designed to integrate the navigation of the GAMS documentation into GAMS Studio. Press F1 or choose Help > GAMS Documentation or check View > Help to start the Help View and browse the documentation. The start page of the Help View is the main document page available in the GAMS distribution that has been used to run GAMS Studio. See Home on how to always navigate back to the start page of the document. Alternatively, choose Help > Studio Documentation to directly jump to the to start of the GAMS Studio documentation. Click Close button or uncheck View > Help to dismiss the Help View. GAMS Studio will remember the last viewed page along with its browsing history until GAMS Studio is restarted.

The Help View starts in docking state for the first time and can be docked around the editor in the central widgets area by either dragging the view to the desired location. Studio will remember last state of the Help View before it was closed.

The Help View can also be floated by double clicking the title part of the Help View. Dragging or double clicking the title of the Help View again will dock the Help View.
Note that the Help View does not offer the full browsing features of a web browser. Though the help view offers a Open this page in Default Web Browser button to use the full features of a web browser.

An overview of Help features:

- **Home**: Start the start help page [GAMSDir]/docs/index.html
- **Back**: Back to previous page
- **Forward**: Go to next page
- **Reload**: Reload the content of this page
- **Stop**: Stop loading the content of this page
- **Bookmarks**:
  - **Bookmark this page**: Store the title of the page as the name of bookmark together with its location. The entry of the bookmark will appear below the Organize Bookmarks section. Click on an entry to jump to the page that has been bookmarked.
Organize Bookmarks: Open the bookmark dialog to edit or delete a bookmark entry. Right click on the selected entry in the bookmark table, then either load the selected bookmark in the Help View, or delete the selected bookmark. The selected bookmark Name and Location can be edited from the lower part of the bookmark dialog and press Enter. Press Esc to cancel the edit. Click close button to dismiss the bookmark dialog.

- **Zoom In**: Zoom in the page to increase the font size. Press Ctrl - +, or Ctrl - Mousewheel Up or choose View > Zoom In menu to zoom in the page.

- **Zoom Out**: Zoom out the page to reduce the font size. Press Ctrl - -, or Ctrl - Mousewheel Down or choose View > Zoom Out menu to zoom out the page.

- **Reset Zoom**: Reset the font size of the page to its original size. Press Ctrl - 0 or choose View > Reset Zoom menu to reset zoom in the page.

- **Help Option**:  
  - **View This Page Online**: Browse the same documentation on GAMS website. This, for example, allows to use more sophisticated search functionalities across all GAMS documentation of version 35.2 or to browse different version of documentation, or to browse the GAMS website from the Help View.
- **Open in Default Web Browser**: Browse the same document in default web browser. As the help view does not offer the full features of a web browser, this allows to browse the documentation using the full web browser features in default web browser.

- **Copy page URL to Clipboard**: Copy of the current page's URL to the clipboard. This, for example, help to see the URL of the currently viewed page of the document.

---

**The GAMS Call and Command Line Parameters**

There are multiple ways to trigger the run of a GAMS model: Running a model via F9 from GAMS Studio, executing GAMSJob. Run method in the object oriented APIs or calling the gams executable from a command line. In all cases the same GAMS engine runs the user's model. Several options are available to customize the GAMS run. Depending on the particular way GAMS is triggered these options are supplied in different ways. For example, in Studio via the parameter editor in the toolbar, in the object oriented API through the GAMSOptions class, and from the command line via command line arguments. In order to avoid confusion with the often used word option we refer to these entities as command line parameters and demonstrate its with the gams executable from the command line. Although details will vary with the type of computer and operating system used, the general operating principles are the same on all machines.

In this chapter we will introduce how GAMS is called from the command line and how parameters may be specified on the command line or in other ways. In addition, we will discuss user-defined command line parameters, compile-time variables and compile-time constants, which are GAMS specialties, and environment variables in GAMS.

---

- **Find in page...** : Press Ctrl - F or choose Edit > Search menu to activate a search at the bottom area of the Help View. Type in a word to be found in the page. The word found in the page will be highlighted as it has been typed in and the number of found occurrences will be highlighted in the scrollbar of the Help View. Click previous button to find the previous occurrence, and click next button or press Enter to find the next occurrence. Check Case Sensitivity box to find a word case sensitively. Highlighting the word stays as the document is navigated from page to page until the keyword is clear or the search is dismissed or the Help View is closed or invisible. Click the close button or press Esc to dismiss the search.
Help on Specific widgets

It is possible to jump directly from directly from different widgets (Welcome Page, Code Editor, Listing Viewer, GDX Viewer, Reference File Viewer, and Solver Option Editor) to the related part of the document.

From Welcome Page, Listing Viewer, GDX Viewer, and Reference File Viewer, press F1 will activate the GAMS Studio page and jump to the section corresponding to the widget. From GAMS Parameter Editor, press F1 on a parameter entry in the extended parameter editor will activate the The GAMS Call and Command Line Parameters help page containing the detailed description of the GAMS parameter. From Solver Option Editor, press F1 on an option entry in the editor will activate the related solver page containing the detailed description of the option.

From Code Editor, it is possible to jump to the document page that describes Dollar Control Options or to the index page that lists entries related to Data Types and Definitions and Language Items in Code Editor, as well as from the parameter editor to the GAMS parameter described in The GAMS Call and Command Line Parameters:

- Press F1 on a Dollar Control Option within the editor will activate the page Dollar Control Options in the Help View and jump to the corresponding dollar control option described in Dollar Control Options chapter.
• Press F1 on a keyword in Data Types and Definitions or in Language Items within the editor to activate the Index Page in the Help View that lists the index entries related to the keyword.

• Press F1 on a parameter entry within the extended parameter editor to activate the help page displaying the detailed description of the GAMS parameters in The GAMS Call and Command Line Parameters.
### Action | Shortcut | macOS | Description
--- | --- | --- | ---
Zoom In | Ctrl- + or Ctrl - Wheel Up | Command - + or Command - Wheel Up | Zoom in the page to increase the font size
Zoom Out | Ctrl- - or Ctrl - Wheel Down | Command - - or Command - Wheel Down | Zoom out the page to reduce the font size
Reset Zoom | Ctrl - 0 | Command - 0 | Reset the font size of the page to its original size

6.14.3.4.1 Summary of Actions and Shortcuts

6.14.4 MIRO

GAMS Studio can be used to develop models for GAMS MIRO. Please go to the GAMS MIRO documentation to learn more about the features and workflow of the MIRO integration.

6.14.4.1 GAMS MIRO Shortcuts

<table>
<thead>
<tr>
<th>Action</th>

</tbody>
</table>

6.14.5 NEOS

GAMS Studio can remotely execute models on the NEOS server. The model is compiled locally before the compilation object is send to NEOS. Note that a GDX file can be created but always has the name out.gdx. On running a dialog pops up to enable further setup:

- "Email" - The email to submit a job. It can be predefined by setting NEOS_EMAIL in the GAMS User Configuration or by defining the environment variable NEOS_EMAIL.
- "Create a GDX file" - Create a GDX file even if the Command line parameter is not set.
- "Short priority" - The execution may start earlier and provides intermediate log output, but it is limited to an execution time of five minutes.
- "Long priority" - The execution may start later and provides no intermediate log output, but it is not limited in execution time.

The selections of the dialog are stored to the settings. To reveal the Terms of Use after checked Don't show Terms of Use again there is a checkbox in Settings > Misc.

The results of the remotely executed model are placed into a sub-folder named by the base name of the model. Links in the log output are replaced by their local counterpart.
6.14.6 GAMS Engine

GAMS Studio can remotely execute models on your own the **GAMS Engine server**. The model is compiled locally before the compilation object is send to GAMS Engine. On running a dialog pops up to enable further setup:

- "Create a GDX file" - Create a GDX file even if the Command line parameter is not set.
- "Url" - The **URL** to your GAMS Engine server
- "Namespace" - The **namespace** to use on the server
- "User" - The username to login
- "Password" - The password to login

On changing the URL, Studio tries directly to reach the server and request version information. On success it gets the GAMS Engine version placed to the right and the version of the GAMS installation on the server. If the local GAM version is newer the Command line Parameter "previousWork=1" will be added automatically if no "previousWork" is already present. The entries of the dialog (excluding the password) are stored to the settings.

The results of the remotely executed model are placed into a sub-folder named by the base name of the model. Links in the log output are replaced by their local counterpart.

6.14.7 Dialogs and Actions

6.14.7.1 GAMS Licensing

The GAMS Licensing dialog is part of the GAMS Studio Help menu. It provides information about the used GAMS as well as available solvers, which lists the solver licenses and their capabilities. Furthermore, the dialog can be used to install a GAMS license. To do so the steps below have to be applied.

1. Copy the GAMS license to the clipboard
2. Open GAMS Studio and click on Help > GAMS Licensing
3. A messages box shows up if a GAMS license has been found on the clipboard. If 'Yes' is clicked the new license will be installed and presented via the GAMS Licensing dialog; otherwise the old license is shown.

Studio will also detect a license on the clipboard when it starts. If a license is detected the same message box will show up like if the GAMS Licensing dialog is used.

6.14.7.2 Check for Update

Check if a more recent version of GAMS or GAMS Studio is available for download (and can be used with the present license) and report the results. The information shown uses the current license file for this.

6.14.7.3 Search and Replace
### 6.14 GAMS Studio

<table>
<thead>
<tr>
<th>Action</th>
<th>Shortcut</th>
<th>macOS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open/Focus Search Dialog</td>
<td>Ctrl - F</td>
<td>Command - F</td>
<td>Opens the search dialog or focusses it if it is already open, if Text is selected it will automatically be entered as a search term</td>
</tr>
<tr>
<td>Find next</td>
<td>F3 or Enter</td>
<td>F3 or Enter</td>
<td>Jumps to the next match that fits all search criteria</td>
</tr>
<tr>
<td>Find previous</td>
<td>Shift - F3</td>
<td>Shift - F3</td>
<td>Jumps to the previous match</td>
</tr>
<tr>
<td>Find All</td>
<td>Shift - Enter</td>
<td>Shift - Enter</td>
<td>Starts a search, opens the page of search results and jumps to the first hit</td>
</tr>
<tr>
<td>Close Dialog</td>
<td>Esc</td>
<td>Esc</td>
<td>Closes the search dialog. On second press any highlights of results will be removed</td>
</tr>
</tbody>
</table>

Pressing the Ctrl - F opens the Search and Replace window. If text is selected it will be pasted into the search field. Users can search specific files with it and do text replacement operations. Depending on which file type is opened in the editor, the search widget changes to visualize which actions are available. Due to technical limitations .gdx files cannot be searched, also replacing in read-only file types (e.g. lst or ref) is deactivated. For reasons of performance the search stops when reaching 50000 search results. This is visualized in all places where the number of matches is shown by showing ”50000+” as the results number, indicating that there might be more results.

![Image](search_window.png)

**Figure 6.37 Search window in its default configuration**

In the first row of the search widget from left to right the following items are located: Search field, which takes the search term and saves a list of recent searches. Next to it there is a ”Find All” button which starts a search in a user defined scope. In the output pane of studio a table containing all matches will open. Items can be double clicked to perform a jump to the result. Information about the file, the location of the match, plus some context information are also shown. Right of ”Find All” there are the find previous occurrence and find next occurrence buttons located, labeled ”<” and ”>” respectively. These will find and highlight the next word matching the search criteria either before or after the current text cursor position.

The next row houses items related to the replace functionality. Most of these are deactivated for files that are opened in read-only mode (e.g. .lst). First comes the replace input field where users can input the text which replaces the search term. ”Replace All” replaces all matches in the currently selected scope after a pop-up is shown asking the user whether the replacement of n occurrences of X with Y is intended. In this pop-up the user can also decide to start a search instead, opening the results page showing all occurrences of the would-be replace action. The next button is ”Replace” and works similarly to Find Next. On the very first click it selects the next match, without replacing anything. On the next click it replaces the current selection with the replacement term and jumps to the next match in the same file, selecting it. Users can use this to click through a file, replacing words while keeping an overview over what is actually changed. Both replacement actions can be undone by pressing either the undo button or hotkey Ctrl - Z. The button ”Clear” on the far right clears all highlighted results and both text fields. A shortcut to clear all results is to press the Esc key in the Code Editor.
The last row contains options to narrow down a search. "Whole Words" excludes partial hits from matches. For example, when searching for "in" with the option checked only the word "in" is found but no occurrences in "information". "Case Sensitivity" sets if the case of letters in the search term matters. Reminder: The GAMS language is case insensitive, so this option can actually lead to incomplete results, depending on what it is used. "Use Regex" activates an advanced search term interpretation mode and stands for Regular Expressions. When activated, instead of a single search term users can specify a pattern that matches an array of different words. Click here for further information about regular expressions.

The "File Pattern" drop-down menu can be used to filter the files to be searched. Using a wildcard syntax patterns of filenames can be specified. The drop-down menu comes with a few default options for GAMS specific file types but can also be used to enter own patterns. Comma-separated lists of patterns are also supported. Right next to it is another, non-editable drop down menu which works like a simpler filter. The scope of the search can be set here with four options available:

- "This File" limits the search to the currently active file and is the default. File patterns are ignored for this option.
- "This Group" searches all files that belong to the same group as the currently opened file. A group of files are all children of the same node in the Project Explorer.
- "Open Tabs" searches all files currently opened in Studio (except GDX files).
- "All Files" searches all files that appear in the Project Explorer and are searchable.

Tooltips are available for most items in the search window and contain further information like keyboard shortcuts.

6.14.7.3.1 Workflow Tips

- Edit a file, hit Ctrl - F to open the search widget. The search field is focused automatically so you can start typing your search term. Pressing the Enter key is a shortcut for Find Next. Press Enter again or F3 to step through all matches. Press Shift - F3 to step backwards. Make changes to your document, press Ctrl - F again to re-focus the search widget without having to pick up the mouse.
- Enter a search term, and then Shift - Enter to trigger "Find All". This will open a list of results.
- The Esc key will close the search widget. Pressing Esc again will clear all highlighted search results.
- Use groups or file prefixes when working with projects with many files. Use search filters to only search relevant files.

6.14.7.4 Model Library Explorer

The Model Library Explorer is used to search the different model libraries provided by GAMS and to retrieve their models in a convenient way. It can be opened either by choosing GAMS > Model Library Explorer from the menu, by using the shortcut F6 or by clicking the corresponding icon in the Quick Access Toolbar.

Every library is presented in a separate tab. The search facility in the upper part of the Model Library Explorer allows for dynamic filtering of all model libraries simultaneously using a wildcard syntax. As the search string is entered, the results are applied to the tabs representing the different libraries. If there are no more results on the selected model library tab, the first non-empty tab is automatically selected. This is undone as soon as the originally selected model library contains results again. The parenthesis enclosed
numbers indicate the number of models found for the specific library and the current search input. For a more sophisticated search syntax select the Regular Expression checkbox next to the search input.

![Model Library Explorer](image)

**Figure 6.38 Searching for trns in the Model Library Explorer**

Beside a short description, several models have a longer and more detailed description available. Selecting a model and clicking on the Description button in the lower right corner opens a pop-up dialog showing further information about the model. A model can be opened either by clicking on the Load button, by double clicking or by selecting the model and pressing the Enter key.

### 6.14.7.4.1 User Libraries

Additionally to the model libraries distributed by GAMS, it is possible to access user defined model libraries by providing a GLB file along with the corresponding files belonging to the models in the library. The Model Library Explorer looks into a specific location for user defined model libraries. This location can be accessed by opening the Settings dialog (File > Settings) and switching to the Misc. tab. The Open Location button will show the location where the Model Library Explorer tries to find user defined model libraries. Adding a new library is done by copying the required files into a subdirectory in this location. See Creating a User Library on how to create a custom model library. Newly added libraries require a restart of the Model Library Explorer to become visible.

### 6.14.7.5 Settings

The GAMS Studio settings dialog can be accessed via the File > Settings menu entry or with the hotkey F7. Users can change certain aspects of Studio like behavior or appearance. Settings are categorized loosely on five tab pages.

#### 6.14.7.5.1 General page

On the "General" tab users control general settings of Studio. Some additional hints:

- "Default GAMS Studio workspace". This path is used as a default location for models imported from the Model Library Explorer.
• "Automatically save modified files before running GAMS" is an option that saves all modified files when the user starts a GAMS run. Thereby, previously unsaved changes will be incorporated into that GAMS execution without the need to go through all files and make sure that changes were saved manually.

• "Open .lst file after running GAMS" automatically puts the generated lst file into the foreground after each GAMS run.

• "Jump to first compilation error" is an automatism that aims to make working with Studio a little easier. When compilation errors occur, the editor and the log both jump to the first error detected if this option is activated. This also applies when the option Open .lst file after running GAMS is activated. Studio then opens the lst file generated and jumps to the first error in it. If you navigate back to the gms file, the view has also moved to the first error found.

• "Open file in current group by default" switches the menu File > Open (Ctrl-O) to always open a file in the current group, even if it exists in another group. The alternative open (Ctrl-Shift-O) is changed to File > Open in new group.

• "Open file finds or creates new group" switches the menu File > Open (Ctrl-O) to find the file in any group and open it. If not found, a new group is created. The alternative open (Ctrl-Shift-O) is changed to File > Open in current group.

• At the bottom of this tab there is a section to backup all settings. When pressing the Export button a dialog pops up, asking for a filename. This name can be chosen freely and the file can than be copied to a USB stick for sharing, or just be saved for later. This is handy if you are planning a fresh install or want to copy your personal settings to a different machine. The button Import is used to load a saved settings file. These settings are applied immediately and the settings dialog will be closed automatically.

6.14.7.5.2 Editor & Log page  The "Editor & Log" tab contains many self explanatory appearance options. Most notably font settings which are shared between editor and log.

• "Enable auto-indentation" activates smart line break behavior. When pressing the Enter key a line break is inserted and the indentation of the line of origin is copied instead of moving the cursor to the first column.

• "Highlight word under cursor without selection" changes the highlighting behavior of word occurrences. While the default behavior highlights other occurrences of the same word when double clicking or selecting a word, activating this option changes the behavior so that every time there is a word under the text cursor, all of its occurrences will be highlighted. Only full words and no partial matches are highlighted.

• "Tab stop size" lets the user decide how many tabs will be inserted when pressing the Tab-key. GAMS Studio always replaces inserted tabs with spaces.

• "Clear process log before GAMS execution" empties the log before running a gms file. If deactivated old log output is kept but colored in a lighter gray so users are still able to identify that they are looking at an old run instead of the most current one. One can also decide if the log should be written to disk as well and if so, how many old versions of the same log should be kept on disk as backup. Note, that in addition to this log file written by Studio, one can instruct GAMS itself to write a log file using the GAMS parameter logOption, which could cause a file naming clash.

6.14.7.5.3 Colors page  The "Colors" tab enables you to configure several colors. Studio provides two fixed themes: the "dark" theme and the "light" theme. Depending on the your operating system, this can be selected by the system and/or manually. You can use this to set Studio to use a darker color palette for when you like to work in the dark and don't like to get blinded by bright windows.
The fixed themes can't be modified, modifying a value implicitly creates a copy of the theme where the changed value is applied. After copying a theme, the new user theme can be adapted to your needs. Additionally these user themes can be exported and imported to a file each.
The colors are listed in two sections:

- On the "Syntax colors" page you can define a text color and the attributes bold and italic.
- The "Editor colors" page allows to change the colors of text, background, and second background (for blinking). The very first entry on this page, the "Default Text", is the base of the syntax colors.

6.14.7.5.4 Miro page The "MIRO" tab is used to set the location of your local MIRO installation. This page might host more options in the future.

6.14.7.5.5 Misc page The "Misc" tab contains some lesser common settings.

- "GAMS source file extensions" allows to add own file extensions that Studio counts as runnable GAMS. File types added here can be executed, set as main file, and are assigned to the GAMS Syntax Highlighter. The field accepts a comma separated list of file extensions.
6.14.7.6 Delete scratch directories

GAMS creates working folders for running processes in your working directory. Normally these are automatically removed when a run finishes. However, if a run was interrupted sometimes these working directories remain. That in itself is not a problem as GAMS will pick a new name for the next run if the default name for the working directory is already taken. To automatically clean up the user workspace, Studio offers an action to do this. In the menu under GAMS > Delete scratch directories the user has the possibility to remove unwanted, autogenerated directories. Before deleting anything, there will be a popup asking the user for confirmation and also showing the path of the directory that will be cleaned. If the user chooses “Yes”, all directories that start with 225 followed by one or two letters will be deleted in the given path, which is usually the default workspace. This action is automatically triggered when GAMS has exhausted the pool of possible scratch directory names, but not without asking the user for confirmation first. To avoid any potential errors this action should only be triggered if there are no running GAMS jobs at the moment.

6.14.7.7 Full Screen & Distraction Free Mode

Especially small devices suffer from sparse screen real estate. Studio comes with a few features to make the most of the space that is available on your machine.

The Full Screen mode is activated by pressing Alt-Enter on Windows and Linux systems, while on macOS the shortcut is Command-Control-F. This enlarges Studio over the whole screen, covering the taskbar and other operating system specific items. The same shortcuts also exit Full Screen mode.

As an alternative, there is also the Distraction Free mode. Some users want to keep their taskbar so with the shortcuts Ctrl-Alt-Enter on Windows and Linux or Cmd-Option-Enter on macOS hide all Studio widgets and enlarge the central widget to the size of the studio window. You can use this to get the log-, file- and help view out of the way and concentrate writing. Pressing the shortcut again brings everything back. Running your GAMS model in the Distraction Free mode will also open the log, so you are not missing out on anything.

<table>
<thead>
<tr>

<td>Ctrl - Alt - Enter</td>
<td>Command - Option - Enter</td>
</tr>
</tbody>
</table>

6.14.7.8 GDX Diff

The GDX Diff dialog serves as a graphical interface to the command line tool GDXDIFF. It compares the data of two GDX files and writes the differences to a third GDX file. The dialog can be opened by choosing Tools > GDX Diff from the menu.
The dialog consists of two parts. The upper part is used to specify the two GDX files for the comparison. The resulting GDX difference file is determined automatically as long as no manual changes have been applied. The default schema for the resulting GDX difference file is the location of the first input GDX file and the file name `diff.gdx`. The difference file will be updated whenever the first input is modified to an existing file. If the GDX Diff dialog gets opened and does not contain a valid first input file, the most recently used directory is used as the location for the resulting difference file instead.

The lower part of the dialog contains different options that can be used in order to control the behavior of the comparison:

- **Eps**: Absolute difference for comparisons. If the difference between two values exceeds Eps, a difference will be reported. Default is $0.0$.
- **RelEps**: Relative difference for comparisons. If the value of RelEps is exceeded, a difference will be reported. Default is $0.0$.
- **Field To Compare**: The specified subfield is the only field used for deciding if a variable or equation is different. List of possible values:
  - All: All fields
  - L: Level
  - M: Marginal
  - Lo: Lower Bound
  - Up: Upper Bound
  - Prior
  - Scale
- **Ignore Set Text**: Allows to ignore explanatory text of set elements.
- **Diff Only**: Differences for variables and equations will be written as parameters. Each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option can not be used in combination with **Field Only**.
• **Field Only**: Used in combination with **Field To Compare**. The variables and equations will be written as parameters for the selected subfield. This option can not be used in combination with **Diff Only** and it requires a value for **Field To Compare** other than **All**.

As soon as the **OK** button is clicked, a validation check on the given input is performed and the two input files are compared. If the specified difference file is already open in a **GDX Viewer**, the corresponding tab remains open while the underlying GDX file is detached. As soon as the file was updated, the GDX Viewer is reinitialized. In case the GDX file was not open already it gets opened in a new tab. The **Cancel** button closes the dialog and stops a process that has not been finished yet. The dialog needs to be kept open for longer running comparisons of large input files. The **Reset** button can be used to reset the whole dialog to its default state which also enables the automatic pre-population of the difference file path in case it has been disabled before due to a manual change.

The GDX Diff dialog also has an integration in the context menu of the **Project Explorer**. As soon as either exactly one or two GDX files are selected, the context menu contains an entry for opening the GDX Diff dialog with the file(s). If only one file is selected, the input field that is empty is populated with the corresponding file path. If both fields are filled, the first input file path gets overwritten. In case of two selected GDX files, both input fields get overwritten.

### 6.14.8 Terminal

GAMS Studio is able to open a native terminal via the main menu **Tools > Terminal** or the shortcut **CTRL - T**. Alternatively, a terminal can be opened by right clicking on any entry of the "Project Explorer" and selecting **Open terminal**. The terminal points to the workspace of the current project group. On macOS the terminal location is always the user's home directory.

### 6.14.9 Command Line Options

GAMS Studio can be started with additional command line options that change the behavior or trigger certain functionality at start up time. The syntax for starting GAMS Studio from the command line is:

```
studio [options] [files]
```

While **files** is one or more files to be opened by GAMS Studio, the following **options** can be supplied:

- `-?, -h, --help` : Displays the help.
- `-v, --version` : Displays version information.
- `--ignore-settings` : Ignore settings files. Studio will load with default settings without writing them.
- `--reset-settings` : Reset all settings to default. Studio will load with default settings and save them.
- `--reset-view` : Reset studio visually without resetting settings. Useful when a widget got lost or studio started on a disconnected monitor.
- `--gams-dir path_to_gams` : Point Studio to a specific GAMS installation.

### 6.14.10 General Shortcuts

This section lists any shortcuts that are global to Studio. Shortcuts for more specific areas are mentioned in their corresponding section.

#### 6.14.10.1 Studio Workflow Shortcuts
### 6.14.10.2 Studio Dialogs

### 6.14.11 System Requirements

Compared to most of the GAMS system, GAMS Studio has some additional system requirements, which depend on the platform used. Also, additional information about technical requirements are listed at the [GAMS Studio GitHub Wiki](https://github.com/gams/GAMS/wiki).

#### 6.14.11.1 Linux

The Linux version of GAMS Studio is distributed as **AppImage** and requires glibc 2.14 as well as **FUSE** to be installed.

The GAMS Studio AppImage was tested and it was verified that it worked for the following Linux distributions (which are all under maintenance). All Linux distributions are under constant development and updates may change the behavior of the AppImage. Please check the [Studio issue page](https://github.com/gams/GAMS/issues) if you encounter any issue.

- Arch
- CentOS 8
- Debian 9
- Debian 10
- Fedora 33
- openSUSE Leap
- openSUSE Tumbleweed
- Ubuntu 16.04 LTS
- Ubuntu 18.04 LTS
- Ubuntu 20.04 LTS

Other flavors might work as well, but were not tested. If you experience problems with a particular Linux distribution, please let us know.

#### 6.14.11.2 macOS

macOS has some special platform requirements related to finding GAMS. Below the steps are listed which are used to link GAMS Studio to GAMS.

- GAMS Studio is going to find GAMS in `/Applications/**` and `/Users/username/Applications/**` if it is part of a GAMS folder. It is required that GAMS Studio gets copied via Finder to its target location. This is the case if the GAMS installer is used or if the GAMS Studio DMG is open and GAMS Studio gets copied from there.

- If GAMS Studio could not find GAMS like described previously then it will search `/Applications/**` for a valid GAMS installation, i.e. a GAMS installation which has the minimum required GAMS version or higher.

- GAMS Studio will check the `$PATH` to find GAMS. In almost all cases this will not work on macOS.

- In case of special needs the path to GAMS can be set explicitly by starting GAMS Studio with the command line argument `--gams-dir`.

</tr>
</thead>
</table>
| Ctrl - F2 | Command - F2 | Reset Studio to default visual settings (window position and -size, widget position and -visibility)  
Useful when a widget got lost or studio started on a disconnected monitor. |
6.14.11.3 Windows

There are dependencies on certain Visual C++ libraries. These are present on most Windows systems but are missing on some. If you get a complaint about missing libraries on startup of GAMS Studio, please run the appropriate installer for these libraries, which can be found in the GAMS installation folder:

- Run \`vcredist_x64.exe\`, found in \`[GAMS system]\apifiles\C++\lib\vs2017\`.

6.14.12 Comparing GAMS Studio and GAMSIDE

As mentioned above, the classic GAMS IDE has been shipped with the GAMS system for many years and is still the workhorse for many GAMS programmers. So it is still around and an alternative to GAMS Studio, especially since it has features, which are not available in GAMS Studio (yet), but it also lacks some features which are available in GAMS Studio. The following table gives a compact overview about most of the differences.

<table>
<thead>

</tbody>
</table>

### 6.14.12.1 GAMSIDE Projects vs. GAMS Studio Groups

With the GAMSIDE one always started with creating a "Project". This mainly defined a directory used to execute the models added to it (so, it is used to implicitly define the `workDir` when starting GAMS). When starting the IDE for the first time, one is asked to create a new project. For example, one creates this in directory `a`. After adding models `a/a.gms` and `b/b.gms` both get executed in the project directory `a`, meaning that data sources are expected in `a` (or relative to it) and also output files are generated in `a`, and not necessarily at the location of the `gms` file.

When starting GAMS Studio for the first time, it starts with an empty Project Explorer. Opening a new file creates a new "Group" per default. Groups do not know about a specific folder (meaning, in contrast to the GAMSIDE, Studio does **not** set the `workDir` implicitly). If a model gets executed, it gets executed at its location. So, if ones opens `a/a.gms` and `b/b.gms`, by default, Studio will create two groups: `a` and `b`. When `a` is started input files are expected in directory `a` and output files get generated in `a`. When `b` is started input files are expected in directory `b` and output files get generated in `b`. If one has structured the models so that they rely on the "GAMSIDE way" to execute a model, one can just set `workDir` explicitly when starting the model.

It is also possible to have multiple files in one group. For example, one could add `b.gms` to group `a` by drag’n’drop in the Project Explorer. Now, the concept of the "main file" of a groups becomes important: While the GAMSIDE always executed the currently active `.gms` file, GAMS Studio always executes the main file of the currently active group. So, in our example, you can look at `a.lst` and press F9 to rerun `a.gms` (the GAMSIDE would not run anything in this case). After adding `b.gms` to group `a`, one would also execute `a.gms` by pressing F9 while looking at `b.gms`. If you want to execute `b.gms` instead, you can make it the main file of the group. For this, right-click in the Project Explorer at `b.gms` and select "Set as main file". Note that the green arrow indicating the main file of a group in the Project Explorer switches from `a.gms` to `b.gms`. As a reminder: Groups do not know a particular working directory. Pressing F9 after switching the main file will execute `b.gms` in folder `b`. 
6.15 GDX2ACCESS

6.15.1 Overview

GDX2ACCESS is a tool to dump the contents of a GDX file to an MS Access file (MDB or ACCDB format). Every identifier gets its own table in the database.

6.15.2 Usage

```
gdx2access inputFile {options}
```

The .gdx file extension of the inputfile can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

6.15.3 Options

Options are specified in an INI file and not directly on the command line. By default, the file gdx2access.ini located in the same directory as gdx2access.exe is consulted. If this file is not available, the program will continue using default settings (listed in the tables below).

It is also possible to tell the program to use a different INI file. This is done by using an extra argument of the form @iniFile. If you want to dump the contents of myFile.gdx to an MS Access file according to the options specified in a file called myIniFile.ini, run the following code:

```
gdx2access myFile.gdx @myIniFile.ini
```

In this case, the program will not read gdx2access.ini located in the same directory as gdx2access.exe, but rather myIniFile.ini in the current directory.

The INI file can contain two sections: [settings] and [debug]. A complete INI file with all possible settings looks like:
Note that the values above are not the default values for some options!

Section [settings]

Below some short descriptions for the options in the [settings] section:

<table>

</tr>
</tbody>
</table>

Section [debug]

Below some short descriptions for the options in the [debug] section:
### 6.15.4 Examples

#### 6.15.4.1 Intro

Suppose we want to write the data of the [trnspor\textit{t}] model from the GAMS model library after solving to an MS Access data file. First of all, we solve the model by running the following command. Note that we will save the complete symbol table to a GDX file called trnspor\textit{t}.gdx by adding the command line option \texttt{gdx=trnspor\textit{t}}.

\begin{verbatim}
gams trnspor\textit{t} gdx=trnspor\textit{t} lo=2
\end{verbatim}

The option \texttt{lo=2} causes GAMS to save the log to an external file (in this case trnspor\textit{t}.log), instead of writing it to the screen. In order to get an idea about the data at this point, we use the \texttt{GDXDUMP} tool to display the contents of the GDX file by running the following command:

\begin{verbatim}
gdxdump trnspor\textit{t}.gdx symbols
\end{verbatim}

By adding the \texttt{GDXDUMP} option \texttt{symbols}, we will only display the table of contents (shown below) rather than all data stored in trnspor\textit{t}.gdx.

---

  * Compression : 0
  * Symbols : 12
  * Unique Elements: 5
  Symbol Dim Type Explanatory text
6.15 GDX2ACCESS

1 a  1 Par capacity of plant i in cases
2 b  1 Par demand at market j in cases
3 c  2 Par transport cost in thousands of dollars per case
4 cost 0 Equ define objective function
5 d  2 Par distance in thousands of miles
6 demand 1 Equ satisfy demand at market j
7 f  0 Par freight in dollars per case per thousand miles
8 i  1 Set canning plants
9 j  1 Set markets
10 supply 1 Equ observe supply limit at plant i
11 x  2 Var shipment quantities in cases
12 z  0 Var total transportation costs in thousands of dollars

Once we have a GDX file, we can use GDX2ACCESS to create a MDB or an ACCDB file. Versions of MicroSoft Office prior to version 2007 use the file extension .mdb, while version 2007 and later versions use the file extension .accdb. We write all the data stored in the GDX file transport.gdx to transport.mdb resp. transport.accdb by running the following code:

gdx2access transport.gdx

Note that we do not referenced an INI file in the previous command in order to specify the options, i.e. GDX2ACCESS will consult the file gdx2access.ini located in the same directory as gdx2access.exe or, if the file does not exist, the tool will continue using the default settings (see Options). The information written to the log is shown below, including the identifiers of the symbols which are written to transport.accdb and the elapsed time per symbol and in total.

GDX Access ALFA 23Mar10 23.4.0 WIN 16693.16738 VS8 x86/MS Windows
Creating C:\GAMS support\settext\temp1.accdb with Access: 0.48 seconds
Using temp directory C:\Users\Paul\AppData\Local\Temp\i. Insert: 0.00 seconds
j. Insert: 0.00 seconds
a. Insert: 0.00 seconds
b. Insert: 0.00 seconds
d. Dump: 0.00 seconds Load: 0.05 seconds
f. Insert: 0.00 seconds
c. Dump: 0.00 seconds Load: 0.05 seconds
x. Dump: 0.00 seconds Load: 0.03 seconds
z. Insert: 0.00 seconds
cost. Insert: 0.00 seconds
supply. Insert: 0.02 seconds
demand. Insert: 0.02 seconds
Renaming C:\GAMS support\settext\temp1.accdb -> trnsport.accdb
Total elapsed time: 0.92 seconds

The resulting ACCBD, opened with MS Access, is shown in Figure 1 (limited to the parameter c on the left and the variable x on the right).

As can be seen, every identifier is stored in its own table. For parameters like c, the value is stored in a column named value, while variables like x and equations have the columns level, marginal, lowerbound and upperbound. A possible additional field (scale for NLP’s, priority for MIP’s, stage for stochastic problems) is not exported. If needed, you can assign such a quantity to a parameter in GAMS before writing the GDX file. The complete process shown here can be automated as demonstrated in Example 1.

If no domain information is available for a symbol (like B in the code below), each index position gets a column and will be labeled automatically with dim1, dim2, etc. If domain information is available, the columns will use that information but keeping the names unique (like A in the code below). The small example below shows how the index positions are made unique using the (relaxed) domain information by adding an ascending number to the identifier.
Set i / i1*i5 /;
Alias (i,j,k);

Parameter A(i,i,i) 'domain informations, but the column name would not be unique';
A(i,j,k) = uniform(0,1);

Parameter B 'no domain information' / i1.i1 1, i1.i2 2, i2.i1 3, i2.i2 4 /;
execute_unload 'AB.gdx', A, B;
execute '=gdx2access AB.gdx';

The resulting database file, opened with MicroSoft Access, is shown in Figure 2 (parameter A on the left, parameter B on the right).

6.15.4.2 Example 1 - Dumping the Contents of trnsport.gdx

This example will solve the [trnsport] model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Access and MS Access is launched to inspect the results. This is a small example that should run very quickly.

execute '=gamslib trnsport';
execute '=gams trnsport lo=3 gdx=trnsport';
execute '=gdx2access trnsport.gdx';
execute '=ShellExecute trnsport.mdb';

Note: the equal signs in front of the external programs indicate we don't go through a shell (e.g. command.com or cmd.exe). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=' sign, such errors go undetected and the GAMS model will continue.

The command ShellExecute will launch Access to view the MDB file. This assumes that the version of Access installed is a version prior to version 2007. Later versions will generate a database with the extension .accdb and the ShellExecute command needs to be changed as follows:

* view generated file create
execute '=ShellExecute trnsport.accdb';

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample1] for reference.
6.15.4.3 Example 2 - Writing Explanatory Text to Database

In this example, we write a few sets to a GDX file; two of the sets written have explanatory text for set elements. We use the option etFlag to get this text saved in the Access database file along with the corresponding set elements. Without using the option, only the set tuples are saved in the database.

Running this example on a machine with Access 2007 or a later version installed will create a database with the .accdb file extension that cannot be read by an older version of Access. We use the dbVersion option to save the database in the MDB format. Both options must be specified in an user defined INI file within the settings section, see howToWrite.ini in the code below.

Set
  i  /  i1 'one', i2 'two', i3 'three', i4 'four' /
  j  /  j1*j4 /
  ij(i,j) /  i1.j1 'red', i2.(j2,j3) 'green', i3.(j1,j2) 'blue' /

$gdxOut example2.gdx
$unload i j ij
$gdxOut

$onEcho > howToWrite.ini
[settings]
etFlag=1
dbVersion=10
$offEcho

$call =gdx2access example2.gdx @howToWrite.ini%

When we open the database and inspect the table created from the set ij, we see the explanatory texts stored along with the corresponding set elements. The column containing the explanatory text will be labeled with SetText automatically. The column headers can be renamed as demonstrated in Example 5 - Renaming Fields.

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample2] for reference.

6.15.4.4 Example 3 - Dumping a large Table to Database

This is an artificial example where we generate a large identifier in GAMS: a parameter with a million elements. This parameter will be dumped to an MS Access Database afterwards. Note that the GDX2ACCESS execution will last several seconds. The resulting database file has approximately 36MB of size.

Set i /  i1*i1000 /
Alias (i,j);
Parameter p(i,j);
p(i,j) = uniform(-100,100);
execute_unload 'example3.gdx', p;
execute '=gdx2access example3.gdx';

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample3] for reference.
6.15.4.5 Example 4 - Special Value Mapping

To store special values like +INF, -INF, EPS, NA and UNDF in a numeric field in the database, GDX2ACCESS uses a mapping. This mapping can be changed by using an INI file (for the default values, see Options resp. the comments in the second code below). We will define a scalar for each special value in GAMS in order to demonstrate the scalarTable option in addition. By default, every scalar will be written to a new table. By activating the scalarTable option in the INI file, all scalars will be stored together in a single table.

$onEcho > howToWrite.ini
[settings]
inf=1
mininf=2
eps=3
na=4
undf=5
scalarTable=1
$offEcho

The usage of our previously customized INI file howToWrite.ini is indicated by the argument @howToWrite.ini within the execute statement.

$onUndf
Scalar
    pInf / inf /
    mInf / -inf /
    epsilon / eps /
    notAvail / na /
    undefined / undf /;

* save scalars in scalars.mdb in a single table named ScalarParameter using
* the scalarTable option
* special values are translated to default values:
*  INF -> 1.0e100
*  -INF -> -1.0e100
*  EPS,NA,UNDF -> 0
execute_unload 'scalars.gdx', pInf, mInf, epsilon, notAvail, undefined;
execute 'gdx2access scalars.gdx @howToWrite.ini';

Note the $onUndf command in order to enter Undf values directly within the definition of the scalars. When we view the generated GDX file in the GAMS IDE or GAMS Studio, the special values are shown (note that the figure shows a parameter actually instead of five single scalars for a more compact presentation):

Viewing the resulting table in Access shows how the mapping for special values was applied (i.e. the GAMS special values have been substituted by our customized values defined in the INI file):

Note that the table will be named ScalarParameter automatically.

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample4] for reference.
6.15.4.6 Example 5 - Renaming Fields

GDX2ACCESS will use names like \( i, j, \text{dim1}, \text{dim2}, \text{value} \) etc. for the column headers in the resulting database file. In some cases, this may not be convenient, e.g. when more descriptive field names are required. In the following model, we will show how a small script in VBScript\([1]\) can handle this task. The script will rename the columns \( i, j \), and Value in table \( c \) to \( \text{ifrom}, \text{jto}, \) and \( \text{transportcost} \). At first, the data is defined and dumped to an MicroSoft Access database. The VBscript named access.vbs is written at compile time and later executed at execution time in order to rename the column headers.

```vb
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /

Parameter
  a(i) 'capacity of plant \( i \) in cases'
    / seattle 350
    san-diego 600 /

  b(j) 'demand at market \( j \) in cases'
    / new-york 325
    chicago 300
    topeka 275 /

Table d(i,j) 'distance in thousands of miles'
  new-york 2.5 1.7 1.8
  seattle  2.5 1.8 1.4
  san-diego

Scalar f 'freight in dollars per case per thousand miles' / 90 /

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

* export to gdx file.
execute_unload 'c.gdx', c;

* move to access database
* column names are i and j
execute '=gdx2access c.gdx';

* rename columns
execute '=cscript access.vbs';

* view results
execute '=shellexecute c.accdb';
```

$onEcho > access.vbs
'this is a VBscript script
WScript.Echo "Running script: access.vbs"
set oa = CreateObject("Access.Application")
set DAO = oa.DBEngine
Wscript.Echo "DAO Version: " & DAO.version
Set DB = DAO.openDatabase("%system.fp%\c.accdb")
Wscript.Echo "Opened : " & DB.name
Set Table = DB.TableDefs.Item("c")
Wscript.Echo "Table : " & Table.name
'rename fields
```

```
oTable.Fields.Item("i").name = "ifrom"
oTable.Fields.Item("j").name = "jto"
oTable.Fields.Item("Value").name = "transportcost"
Wscript.Echo "Renamed fields"
oDB.Close
Wscript.Echo "Done"
$offEcho

The resulting ACCBD, opened with MS Access, is shown in Figure 6 (parameter c before executing the VBScript on the left, parameter c after renaming the column headers on the right).

The complete example is also part of the GAMS Data Utilities Library, see model [GDX2ACCESSExample5] for reference.

6.16 GDX2HAR and HAR2GDX

GDX2HAR and HAR2DX are translation Tools for GDX and HAR Files.

Author

Mark Horridge, Centre of Policy Studies and the Impact Project, Monash University
Thomas F. Rutherford, Department of Economics, University of Colorado

Date
August, 2003 (revised July, 2007)

Source of this document: http://www.mpsge.org/gdxhar/index.html

The purpose of this document is to provide an overview of GDX2HAR and HAR2GDX translation tools. The GDX2HAR and HAR2GDX programs efficiently translate between HAR and GDX file formats, and their operation is straightforward. The examples covered in this document have been designed to illustrate potential difficulties which may arise and how these issues can be addressed.
6.16 GDX2HAR and HAR2GDX

6.16.1 Syntax

6.16.1.1 Syntax for GDX2HAR

gdx2har GDX_file_prefix [.gdx] [HAR_file_prefix [.har]] [/s]

Comments:

- \texttt{gdx2har.exe} is a Windows console application which runs on 32-bit versions of MSWindows (Win95 or later).
- The program requires \texttt{gdxiomh.dll} to be located in the same folder as \texttt{gdx2har.exe}.
- When only a single file is specified, the output file is \texttt{GDX_file_prefix.HAR}.
- Any (and all) single dimensional sets and all parameters in the GDX file are written to the HAR file. Variables, equations and multi-dimensional sets (tuples) in the GDX file are ignored.
- Sets in the GDX file are written as sets in the HAR file. Parameters from the GDX file are written as coefficients in the HAR file.
- The /s switch invokes strict enforcement of translation syntax. When this switch is specified, warning messages result in program termination without generation of any output.
- Warning messages are generated when incompatible features are encountered in the translation process, including names or set labels with more than 12 characters or other non-conforming syntax. (Set labels in GEMPACK may not begin with a numeric symbol).

Making sense of \texttt{gdx2har} requires some understanding of the underlying file formats. GAMS stores values for parameter matrices in GDX files using a sparse matrix format, so that a table like

<table>
<thead>
<tr>
<th></th>
<th>USA</th>
<th>France</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agriculture</td>
<td>411</td>
<td>87</td>
</tr>
<tr>
<td>Services</td>
<td>2831</td>
<td>365</td>
</tr>
<tr>
<td>SweetCorn</td>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>Truffles</td>
<td>0</td>
<td>68</td>
</tr>
<tr>
<td>Durian</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

is stored in a GDX file in a binary format corresponding to the following list:

"Agriculture" "USA" 411
"Agriculture" "France" 87
"Services" "USA" 2831
"Services" "France" 365
"SweetCorn" "USA" 11
"Truffles" "France" 68

The key point is that zero elements are not stored in the GDX format, and nor is explicit information about the domain of parameters as declared in the GAMS program which produced the GDX file. To work around this problem, GDX2HAR uses two strategies to infer the domain of a parameter:

1. GDX2HAR scans the descriptive text of parameters in the GDX file to see if an \emph{explicit} header and domain have been provided. This information is identified by its enclosure in double square brackets, e.g.
PARAMETER OUTPUT(i,r) Base year production [[Y:I*R]]

The HAR information enclosed in double square brackets consists of the header key ("Y" in this example) and the domain defined with dimension sets separated by 's. The maximum length of a header key is 4 characters.

2. In the absence of explicit declaration in the descriptive text, GDX2HAR examines the labels of nonzero array elements which are stored in a GDX file to see if they correspond to a declared set. If the row or column set does not correspond to a set stored in the GDX file, a new set is created to define the coefficient domain in the HAR file. In the above example, if the GDX file contained sets defined as

GOODS = [Agriculture, Services, SweetCorn, Truffles, Durian]

and

REGIONS = [USA, France]

The GDX2HAR program would then correctly infer that the column set is REGIONS, but it would not conclude that the row set is GOODS. It would instead declare a new set

SET1 = [Agriculture, Services, SweetCorn, Truffles]

with which to dimension the data table in the HAR file. As illustrated in this example, the translation process can be problematic which parameters in the GDX file are not explicitly declared.

6.16.1.2 Syntax for HAR2GDX

har2gdx HAR_file_prefix [.har] [GDX_file_prefix [.gdx]] [/s]

Comments:

- har2gdx.exe is a Windows console application which run on 32-bit versions of MSWindows (Win95 or later).
- The program requires gdxiomh.dll to be located in the same folder as gdx2har.exe.
- When only a single file is specified, the output file is HAR_file_prefix.GDX.
- All sets and coefficients in the HAR file are written to the GDX file as sets and parameters, respectively.
- The /s switch invokes strict enforcement of translation syntax. When this switch is specified, warning messages result in program termination without generation of any output.

6.16.2 GDX2HAR Examples

6.16.2.1 Example 1: Default operation

This example shows how a GDX file can be written by a GAMS program and the results then transferred into a HAR file. In the small GAMS example two sets and three parameters are defined. The program output is then written to the GDX file. Set and parameter names are shorter than 12 characters and conform to GEMPACK syntax rules, so the translator retains all same names in the HAR file. In this case, set and parameter names have fewer than 4 characters, so the HEADER identifiers in the HAR file are identical to the GAMS names.

GDX2HAR infers domains of the parameters from the array elements, which are all non-zero in this case.
Set

\[ i / a, b, c / \]
\[ j / \text{red, green, blue} /; \]

Parameter

\[ x '\text{Scalar value}' / 1.5 / \]
\[ y(i) '\text{Vector of values}' / a \text{ 10.2, b 1.3, c 1.5} / \]
\[ z(i,j) '\text{Matrix of random values}'; \]

\[ z(i,j) = \text{uniform}(0,1); \]

This program may be stored as `ex1.gms` and then run from the command line as

```plaintext
gams ex1 gdx=ex1
```

If the program is executed from the GAMS IDE a GDX file can be generated by adding `gdx=ex1` to the Additional Parameters box in the File/Options/Execute dialogue. The resulting GDX file can be opened in the GAMS IDE and appears as follows:

The GDX file can be translated into HAR format with the command:

```plaintext
gdx2har ex1 >ex1.log
```

As specified here, GDX2HAR program output (including warning messages) is written to `ex1.log`:

Running program: C:\GAMS21.0\GDX2HAR.EXE
Input file: H:\gdxhar\examples\ex1.gdx
Output file: H:\gdxhar\examples\ex1.har
Deleted existing file: H:\gdxhar\examples\ex1.har
Loaded GDX library: C:\GAMS21.0\gdxiomh.dll
Above is DLL version: _GAMS_GDX_V228_2003-05-07
GDX file was produced by:
  GAMS Rev 134 May 1, 2003 WIN.00.NA 21.0 134.000.041.VIS P3PC
  Using GDX library: _GAMS_GDX_V228_2003-05-07
GDX file contains 5 symbols and 6 set elements.
Reading GDX set "i".
Reading GDX set "j".
Reading GDX array "x".
Reading GDX array "y".
Reading GDX array "z".
Finished OK; created file: H:\gdxhar\examples\ex1.har

The resulting HAR file can be examined using the `VIEWHAR` utility:

Note that the HAR file contains the five items from the source GDX file as well as two additional sets named `OGEL` and `NGEL`. These sets are always provided to provide a consistent report in the event that set labels may have been translated.
6.16.2.2 Example 2: Missing sets are constructed.

In this example, sets are not written to the GDX file. GDX2HAR then generates the sets based on the nonzero patterns of the parameters. This example illustrates how a GDX file can be written and translated into HAR format within a GAMS program.

Set
  i / a, b, c /
  j / red, green, blue /;

Parameter
  x 'Scalar value' / 1.5 / 
  y(i) 'Vector of values' / a 10.2, b 1.3, c 1.5 / 
  z(i,j) 'Matrix of random values';

z(i,j) = uniform(0,1);

execute_unload 'ex2.gdx', x, y, z;
execute 'gdx2har ex2 > ex2.log';

The resulting HAR file appears as follows:

The sets titled Set1 and Set2 have been introduced by GDX2HAR and are stored in the HAR file under headers S1 and S2. GDX2HAR has inferred that y and z share the common dimension set1, but does not know that set1 was called "i" in the GAMS program.

6.16.2.3 Example 3: Zeros can create problems.

If one element of the w vector is zero, GDX2HAR does not assume that the coefficient is defined over set "i". Instead GDXHAR introduces a new set to define the domain.

Set i / a, b, c /;

Parameter w(i) 'Vector of values' / a 10.2, c 1.5 /;

execute_unload 'ex3.gdx', i, w;
execute 'gdx2har ex3 > ex3.log';

Above, the set Set1 contains only 2 members, a and c, corresponding to non-zero elements of w.

6.16.2.4 Example 4: EPS can be used to define a domain.

The GAMS language includes a special value EPS, standing for "epsilon," a infinitesimally small but nonzero number. When EPS is added to every element of an array over a given domain, then when that array is written to the GDX file the zeros become visible. The EPS values which are stored in the GDX file appear as a true zero in the translated HAR output file.
Set i / a, b, c /;
Parameter w(i) 'Vector of values' / a 10.2, c 1.5 /;
execute_unload 'ex3.gdx', i, w;
execute 'gdx2har ex3 > ex3.log';

* Add eps to create zeros which are "visible" in the
* GDX file:
w(i) = w(i) + eps;
execute_unload 'ex4.gdx', i, w;
execute 'gdx2har ex4 > ex4.log';

6.16.2.5 Example 5: Explicit declaration of HAR coefficients.

As an alternative to adding EPS to all parameter values, the header and coefficient domain may be
specified in the GAMS declaration of a parameter. The HAR declaration is provided within double square
quotes, \[[]\].

In this example the GAMS parameter is 12 characters in length. This name may be used in the HAR file
to define the coefficient, but it may not be used as the header. (Headers are limited to four characters.) It
is possible to define a specific header and domain within the descriptor text of the GAMS parameter.

Set
  i / a, b, c /
  j / red, green, blue /;
Parameter zs_long_name(i,j) 'Param with header and domain \[[z:i*j]\]';

* Note that missing rows are not a problem when the domain is explicitly
* specified:
zs_long_name(i,j) = uniform(0,1);
zs_long_name("b",j) = 0;
display zs_long_name;
execute_unload 'ex5.gdx', i, j, zs_long_name;
execute 'gdx2har ex5 > ex5.log';

6.16.2.6 Example 6: Long names are truncated

In GAMS, a set or parameter may have as many as 31 characters. GDX2HAR truncates such names to 12
characters.

Parameter GAMS_name_with_31_characters_OK 'A long GAMS identifier' / 1.5 /;
execute_unload 'ex6.gdx', GAMS_name_with_31_characters_OK;
execute 'gdx2har ex6 > ex6.log';

In this example GDX2HAR generates the following HAR file:

But issues the following warning message:

**** Warning: To conform with GEMPACK rules, GDX symbol
  GAMS_name_with_31_characters_OK was converted to GAMS_name_wi
6.16.2.7 Example 7: The GAMS symbol table controls set sequencing

Attention to the GAMS symbol table is needed if set sequences in the HAR file are to be in a particular order. Consider the following GAMS program:

Set
   r 'Selected South American countries' / ARG, BRA, COL, PER, BOL, URG /
   e 'Selected energy goods' / OIL, COL, GAS, ELE /

display e;

Parameter d(e,r) 'Energy demands';
d(e,r) = uniform(0,1);

execute_unload 'ex7.gdx', r, e, d;
execute 'gdx2har ex7 > ex7.log';

Note that the listing file output of this program presents set e is ordered in a sequence which differs from the declared sequence:

---- 5 SET e Selected energy goods

COL, OIL, GAS, ELE

The point is that GAMS orders all output rows and columns in accordance with the sequencing of the *global symbol table*. This aspect of GAMS carries over into HAR file generation. In this example, the order in which set e is displayed in the listing file is the same as the order in which the rows are sorted in the GDX and HAR files:

One way to control the global symbol table in a GAMS program is to declare a *fictive* set at the top of a program in which set elements are defined in the preferred sequence. For example, in the case of the previous program, the following declaration would produce the desired sequence of both sets R and E in the HAR file:

Set
   symbols / ARG, BRA, OIL, COL /
   r 'Selected South American countries' / ARG, BRA, COL, PER, BOL, URG /
   e 'Selected energy goods' / OIL, COL, GAS, ELE /

This produces a consistent ordering of both sets r and e, but this type of work-around may not always be possible. (See example 9 below.)

6.16.2.8 Example 8: Set elements may be truncated or revised.

Restrictions in GEMPACK on the length of set elements and the use of embedded blanks enforced by GDX2HAR. Also, GEMPACK does not allow for set elements to begin with a digit.

Set
   c / 'New York', 'San Francisco', 'Los Angeles' /
   t / 2000*2010 /;

execute_unload 'ex8.gdx', c, t;
execute 'gdx2har ex8 > ex8.log';
With this example GDX2HAR produces the following warning message:

**** Warning: To conform with GEMPACK requirements,
   the following GDX set elements were changed:

New York became NewYork
San Francisco became SanFrancisco
Los Angeles became LosAngeles
2000 became A2000
2001 became A2001
2002 became A2002
2003 became A2003
2004 became A2004
2005 became A2005
2006 became A2006
2007 became A2007
2008 became A2008
2009 became A2009
2010 became A2010
Reading GDX set "c".
Reading GDX set "t".
**** Warning: Some GDX set elements were changed.
There were 2 warnings.

GDX2HAR also alters identifiers to assure that they remain unique, for example, after truncation to 12 letters.

6.16.3 HAR2GDX Examples

6.16.3.1 Example 9: GlobalSet is provided by HAR2GDX to sequence the GAMS symbol table.

HAR2GDX constructs a symbol table which, where possible, provides properly sequenced arrays in
the resulting GDX file. A simple example illustrates how this works. In the source HAR file there
are two sets, COM and HAR. COM consists of [Cereals, OtherCrops, Power, Services], and IND
contains [Agriculture, Nuclear, CoalFired, Services]. The HAR file contains a single numeric
matrix, MAKE, which appears in VIEWHAR as follows:

When the HAR file ex9.har (from href="examples.zip">examples.zip) is translated by HAR2GDX, the
resulting GDX file contains three sets and one parameter array. The sets include COM and IND, as well
as a GlobalSet which is inserted to provide a means of sorting the ata arrays into proper sequence. By
virtue of the HAR2GDX global symbol table, the translated MAKE array appears in the GDXVIEWer as
follows:

If, however, the global symbol table is ignored when the data is read into a GAMS program, as in the
example:

Set
   COM(*) 'Set of commodities'
   IND(*) 'Set of industries';
$gdxIn make.gdx
$load com ind
Parameter make(com,ind) 'Make matrix';
$load make
display make;
Then the program develops a global symbol table in which set IND is ordered differently than in the source HAR file. The reason is that GAMS constructs a symbol table sequentially, so if COM is read before IND, then Services is introduced prior to Agriculture, Nuclear, and CoalFired:

```
--- 11 PARAMETER make Make matrix

<table>
<thead>
<tr>
<th></th>
<th>Services</th>
<th>Agriculture</th>
<th>Nuclear</th>
<th>CoalFired</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cereals</td>
<td>7.000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>OtherCrops</td>
<td>4.000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Power</td>
<td>2.000</td>
<td>14.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Services</td>
<td>29.000</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

On the other hand, if GlobalSet is read first, then the GAMS set order (in this example) is identical to the HAR file order:

```
Set
  GlobalSet(*) 'Set provided by GDX2HAR to order symbol table'
  COM(*) 'Set of commodities'
  IND(*) 'Set of industries';

$gdxIn make.gdx
$load globalset com ind
Parameter make(com,ind) 'Make matrix';
$load make
display make;
```

```
--- 12 PARAMETER make Make matrix

<table>
<thead>
<tr>
<th></th>
<th>Agriculture</th>
<th>Nuclear</th>
<th>CoalFired</th>
<th>Services</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cereals</td>
<td>7.000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>OtherCrops</td>
<td>4.000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Power</td>
<td>2.000</td>
<td>14.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Services</td>
<td>29.000</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

6.16.3.2 Example 10: Some GEMPACK datasets cannot be represented in GAMS without reordering sets.

The following is an example of a HAR file which cannot be translated to GAMS without reordering sets. Within ex10.har the sets IND and COM in this example are, respectively, [A,B,C,D] and [D,C,B,A]:

```
The HAR file can be translated to GDX, but this produces the following error message:

**** Warning: Inconsistent order: elements "D" and "C" in set COM
**** Warning: Inconsistent order: elements "C" and "B" in set COM
**** Warning: Inconsistent order: elements "B" and "A" in set COM
```

This message means that HAR2GDX was unable to construct a global symbol table which is ordered consistently with both HAR sets COM and IND. The translated data appears as:

Within the GDX file both COM and IND will be ordered [A,B,C,D], and the elements of X are displayed in that order. Notice that values for particular array elements are translated correctly, e.g. \( X("A","B") = 14 \) in both HAR and GDX files.
6.16.4 Concluding Remarks

GDX2HAR and HAR2GDX efficiently translate between HAR and GDX file formats. Although the examples above concentrate on potential problems, in practice both programs are generally easy to use. To avoid problems:

- if you are using GAMS to prepare a GDX file for translation to HAR, remember that GDX files do not naturally contain information about array domains — the sets over which the array is defined. To assist GDX2HAR, you should store associated sets in the GDX file and include domain information and a suggested header key in the "explicit text" description of each GAMS array declaration, as in example 5 above.

- if you are using GEMPACK to prepare a HAR file for translation to GDX, avoid creating sets which share common elements that are ordered differently. If you follow this rule, the GAMS user can use GlobalSet (prepared by HAR2GDX) to ensure that GAMS orders set elements in the same way as GEMPACK. See example 9 above.

- Try to use names (for arrays, sets and set elements) which are legal in both GEMPACK and GAMS. Identifiers of maximum length 10 with first character one of [A..Z,a..z] and remaining characters in [A..Z,a..z,0..9] will translate most smoothly.

6.17 GDX2SQLITE

A Tool to dump GDX contents into SQLite database file

Author

Erwin Kalvelagen

Date

November 30, 2015

6.17.1 Introduction

GDX2SQLITE.EXE is a tool to dump the complete contents of a GAMS GDX file (see GAMS Data eXchange (GDX)) into a SQLite database file (the website http://www.sqlite.org/ contains a wealth of information on SQLite).

A SQLite database is stored in a single file so it can be easily e-mailed or otherwise transmitted. The main advantages of using SQLite over other single file database systems such as MS Access is that SQLite is free and in the public domain and that it does not impose a 2 GB file size limit. For some large data sets this size limit present in MS Access and DBF database files causes problems. Another useful format is CSV files, but typically several CSV files are needed to store a data set stored in a GDX file. Many programs support reading SQLite database files, either through a native database access driver or via a standard ODBC interface. In summary: SQLite is a useful export format for GAMS solution data sets.

6.17.2 Usage

'GDX2SQLITE' is a command line tool that is best called from within a GAMS program using the $call or Execute statement, e.g.:

execute_unload "results.gdx", yield, price;
execute "gdx2sqlite -i results.gdx -o results.db";

The following options are available:
<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i gdxinputfile</td>
<td>Specifies the input GDX file. Typically this is a file with a .gdx extension</td>
</tr>
<tr>
<td>-o sqloutputfile</td>
<td>Specifies the output SQLite database. Typically this file has a .db extension.</td>
</tr>
<tr>
<td>-debug</td>
<td>This is an optional flag that will cause gdx2sqlite to print additional debugging information.</td>
</tr>
<tr>
<td>-expltext</td>
<td>This optional flag will export explanatory text for set elements.</td>
</tr>
<tr>
<td>-append</td>
<td>Don’t delete the database file before processing. This will allow adding new symbols in new tables. We will not allow adding data to existing tables.</td>
</tr>
<tr>
<td>-small</td>
<td>Write data strings in a separate table. A user-friendly SQL VIEW is created to hide the complexities of the joins.</td>
</tr>
<tr>
<td>-fast</td>
<td>Try to speed up writing the data using some non-standard pragmas. Using both -small -fast will write the data most efficiently.</td>
</tr>
<tr>
<td>-varchar</td>
<td>String columns will have the type VARCHAR(255) instead of TEXT.</td>
</tr>
</tbody>
</table>

An example of explanatory text is:

```
Set cty / AFG 'Afghanistan'
        AGO 'Angola'
        ALB 'Albania' /;
```

In GAMS set elements have a maximum length of 63 characters. Explanatory text has a maximum length of 255 characters.

### 6.17.3 How data is stored

#### 6.17.3.1 Gams issues

GAMS does not store zero values (or default records for variables and equations). Such non-existing records will not be exported to the GDX file and to the database either. To force a zero to be exported, set it to EPS in GAMS. E.g.:

```
  p(i)$(p(i)=0) = EPS;
```

In case of doubt you are encouraged to inspect the GDX file.

#### 6.17.3.2 Sets

n-dimensional sets are stored as tables with n text columns. In case the option -expltext is used, another column may be added with explanatory text.
### 6.17.3.3 Parameters

n-dimensional parameters will have n index columns plus a value column. Scalars are collected in a separate table.

<table>
<thead>
<tr>
<th>GAMS</th>
<th>SQLite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set month / jan, feb, mar / year / 2013, 2014 / date(year,month) / (2013,2014).(jan,feb,mar) /;</td>
<td>sqlite&gt;select * from month; month --------- jan feb mar</td>
</tr>
<tr>
<td>execute_unload &quot;sets.gdx&quot;; execute &quot;gdx2sqlite -i sets.gdx -o sets.db&quot;;</td>
<td>sqlite&gt;select * from year; year --------- 2013 2014</td>
</tr>
<tr>
<td>Set month / jan 'january' feb 'fabruary' mar 'march' /;</td>
<td>sqlite&gt;select * from date; year month --------- --------- 2013 jan 2013 feb 2013 mar 2014 jan 2014 feb 2014 mar</td>
</tr>
<tr>
<td>execute_unload &quot;sets.gdx&quot;; execute &quot;gdx2sqlite -i sets.gdx -o sets.db -expltext&quot;;</td>
<td>sqlite&gt;select * from month; month expltext --------- --------- jan january feb f fabruary mar march</td>
</tr>
</tbody>
</table>

n-dimensional variables and equations have besides n index columns also columns for the level, the lower and upper-bound and the marginal. Scalars are collected in the tables scalarvariables and scalarequations. Note that INF and -INF are mapped to 1.0e100 and -1.0e100. The special value EPS is exported as zero. To be complete: UNDEF, NA and acronyms are exported as NULLs.

<table>
<thead>

6.17.3.5 Fixing up names

A database table is not allowed to have columns with the same name. If a name clash is detected new names may be invented.

6.17.3.6 Speeding up writing data

With the -small option we write data in a slightly different format. Instead of using strings for the GAMS indices we write integers. The integers can be looked up in a separate table $UEL$ were the GAMS UELS (Unique Elements) are stored. We export an SQL view for each symbol to hide the complexities of the joins needed to replace the integers by strings.

For more information see: http://yetanothermathprogrammingconsultant.blogspot.com/2014/06/big-data-cubes.html.

The -fast option will set some SQLite pragmas that can speed up the inserts. Basically they will give up some consistency in case the program crashes, in which case the created database may be invalid.

For more information see: http://yetanothermathprogrammingconsultant.blogspot.com/2014/07/a-little-bit-extra-fine-tuning.html.

6.17.4 SQLite Browsers and compatible software

6.17.4.1 SQLite3.exe

From the distribution on http://www.sqlite.org/download.html a command line tool is available that functions as shell for SQLite. An example session can look like:
6.17 GDX2SQLITE

C:\projects\impact3\sqlite>sqlite3.exe data.db
SQLite version 3.8.0.2 2013-09-03 17:11:13
Enter ".help" for instructions
Enter SQL statements terminated with a ";
sqlite> .schema
CREATE TABLE [i]( [i] TEXT);
CREATE TABLE [p]( [i] TEXT,[i2] TEXT,[value] REAL);
sqlite> select * from p;
i1|i1|1.0
i2|i2|1.0
i3|i3|1.0
i4|i4|1.0
sqlite> .quit
C:\projects\impact3\sqlite>

6.17.4.2 SQLite Studio

A visual front-end can be downloaded from http://sqlitestudio.pl/.

6.17.4.3 SQLite Database Browser

Another visual browser is available from http://sqlitebrowser.sourceforge.net/.

6.17.4.4 SQLite and R

The statistical software R can conveniently use SQLite data, and can be called from a GAMS environment as follows:

$onText
Get data from GAMS into R via SQLite
$offText

$set IMPACTPATH  c:\projects\impact3\impact_3\IMPACTv3.0
$set SCRIPT     script.R
$set RPATH      "C:\Program Files\R\R-3.0.2\bin\R.exe"
$set DB         mapdata.db
Set cty;
$gdxIn %IMPACTPATH%\GDXs\Sets.gdx
$load cty
display cty;
Set maps / data1 'uniform random data between 0 and 1'
        data2 'uniform random data between 0 and 2' /
Parameter mapdata(cty,maps);
mapdata(cty,"data1") = uniform(0,1);
mapdata(cty,"data2") = uniform(0,2);
execute_unload "mapdata.gdx"
execute "gdx2sqlite -i mapdata.gdx -o %DB% -expltext";
execute '"%RPATH%" --vanilla < %SCRIPT%';

$onEcho > %SCRIPT%
if (!require(RSQLite)) {
   install.packages("RSQLite", repos="http://cran.r-project.org")
   library(RSQLite)
}

sqlite<-dbDriver("SQLite")
db <- dbConnect(sqlite,"%DB%")
dbListTables(db)

maps<-dbGetQuery(db,"select * from maps")
maps

mapdata<-dbGetQuery(db,"select * from mapdata")
mapdata
$offEcho

6.17.4.5 SQLite and Python

Python has built-in support for SQLite:

import sqlite3
db = sqlite3.connect("turkey.db")
c = db.execute("select * from yieldl")
for row in c:
    print row
db.close()

6.17.4.6 SQLite ODBC Driver

ODBC is a database access layer for Windows. It allows many Windows programs that need to talk to databases to do this in a database independent manner. The SQLite ODBC driver can be downloaded from:  http://www.ch-werner.de/sqliteodbc/.

6.17.4.7 SQLite and Excel

Excel can read SQLite database files through ODBC.

6.17.4.7.1 Import as Table  To import a table from a SQLite database perform the following steps:

1. Select the Data tab and choose Get External Data From Other Sources
2. Choose the Data Connection Wizard
3. Choose ODBC DSN
4. Select SQLite3 Datasource
5. Enter the name and path of the database file and press OK.
6. Choose a table from the database.
7. Give this selection a name.
8. Choose Import as Table

The result is a table:

6.17.4.7.2 Import as Pivot Table  The same steps can be used to import as Pivot Table. This way we can easily create summary reports, such as:

6.18  GDX2VEDA

Translates a GDX file into the VEDA format.

6.18.1  Usage

gdx2veda gdx vdd [run]

gdx
    GAMS GDX file
vdd
    VEDA Data Definition file
run
    VEDA Run identifier (optional)

The VEDA data file name and run identifier are either taken from the gdx file name or specified with the run name. Use "token with blanks" if needed.

6.18.2  Examples

This example dumps the gdx symbols:

gdx2veda mygdx

This example prints usage and example:

gdx2veda

To print more detailed help message:

gdx2veda --help

Add .csv to the run name to write in csv format
6.18.3 Detailed Help Message

6.18.3.1 VDD file Summary

[DataBaseName]
myveda

[Dimensions] cube dimensions
long_name tuple_element1 tuple_element2 ...

[DataEntries] data for the cube
long_name gams_name tuple_element1 tuple_element2 ...

[DimensionText] for generating .vde file (only for data in [DataEntries])
gams_set tuple_element1 tuple_element2 ...

[DimensionTextAll] for generating .vde file (also for data not in [DataEntries])
gams_set tuple_element1 tuple_element2 ...

[SubSets] for generating .vds file
sub_name gams_name tuple_element1 tuple_element2 ...

[ParentDimension] defines parent-child structure
parent_tab child_tab1 child_tab2 ...

[ParentDimensionTextAll] .vde file definitions with parent-child structure
2d_gams_set parent_tab child_tab
2d_gams_set child_tab parent_tab

[ParentSubSets] .vds file definitions with parent-child structure
sub_name 2d_gams_set parent_tab child_tab
sub_name 2d_gams_set child_tab parent_tab

[Options]
TupleSeparator "string" use a different separator symbol between tuple elements
ShowAllSeparators don't squeeze unnecessary separators
RelaxDimensionAll relax strict dimensionality checks in DimensionText(All) sections.
ValueDim n if n=2 write PV/DV value pairs for VEDA
SetsAllowed dim1 dim2 .. write SetsAllowed specification line to VEDA .vd file
Scenario scenarioSet specify the scenario set; a record with expl text goes to .vde
Format veda/csv specify the format of the data files
Not-0 attribute ... don't write records with zero values for these attributes

[SpecialValues]
EPS "string" value to be used for EPS
INF "string" value to be used for +INF
MINF "string" value to be used for -INF
NA "string" value to be used for NA
UNDEF "string" value to be used for UNDEF

<myveda>

is usually the application name which will be displayed on the top of the VEDA splash screen. When a new VEDA database is created, a new folder with this name will appear:

...veda\database\mayveda_date_time.
Where data and time are the creation time stamp.

\(<\text{tab\_name}>\)

corresponds to the tabs of your VEDA screen.

Lines starting with * and empty lines are ignored. Blanks, commas and tabs are delimiters, blanks before and after delimiters are ignored. Quotes around data items are optional. The input data is NOT case sensitive.

### 6.18.3.2 Veda Data Definition file

Example of a Veda Data Definition file:

* Transport model

\([\text{DataBaseName}]\)

myveda

\([\text{Dimensions}]\)

* tab-name indices
Plants i
Warehouses j
Links ii jj

\([\text{DataEntries}]\)

* veda\_attribute gams\_name tab1 tab2 ... for gams index 1, 2, ...
"x(i,j) duals" x.m i Warehouses
Shipments x.l i j
SupplyPrice supply.m i
DemandPrice demand.m j
TransportCost c i j
Distance d ii jj
Supply a i
Demand b j
TotalCost z.l
SupplyNodes i i
DemandNodes j j
Rate f

\([\text{DimensionText}]\)

* gams\_set tab
i i

\([\text{DimensionTextAll}]\)

* gams\_set tab
j j

\([\text{SubSets}]\)

* sub\_name gams\_name tab
ii ic Plants
i id i

Notes:

The long name from the [Dimensions] section can be used as a macro that expands to the tuples it defines. E.g. "Links" is identical to "ii jj".

In the [DataEntries] section a literal tuple element can be defined as /element/.

When ValueDim=2, the [DataEntries] section can contain X.LM entries, indicating both .L and .M needs to written as a pair.
6.19 GDX2XLS

A Tool to convert GDX data to MS Excel spreadsheets

Author

Erwin Kalvelagen

Date

June 10, 2005; December 6, 2006

This document describes the GDX2XLS utility which allows to convert data stored in a GDX file into Excel spreadsheets.

6.19.1 Overview

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only GDXXRW is under active development. Therefore, we strongly recommend using GDXXRW for data exchange with Excel.

GDX2XLS is a tool to dump the complete contents of a GDX file to an MS Excel spreadsheet file (.xlsx or .xls file). Every identifier gets its own sheet in the .XLSX file. Excel 2007 or more recent versions will default to an .xlsx file; versions before that default to the .xls file format. For instance when we save the results of the trnsporth model from the model library:

```
C:\tmp>gamslib trnsporth
Model trnsporth.gms retrieved
C:\tmp>gams trnsporth gdx=trnsporth lo=2
C:\tmp>gdxdump trnsporth.gdx symbols
C:\tmp>gdxdump trnsporth.gdx symbols
  Symbol Dim Type Records  Explanatory text
    1  a  1  Par     2  capacity of plant i in cases
    2  b  1  Par     3  demand at market j in cases
    3  c  2  Par     6  transport cost in thousands of dollars per case
    4  cost 0  Equ     1  define objective function
    5  d  2  Par     6  distance in thousands of miles
    6  demand 1  Equ     3  satisfy demand at market j
    7  f  0  Par     1  freight in dollars per case per thousand miles
    8  i  1  Set     2  canning plants
    9  j  1  Set     3  markets
  10  supply 1  Equ     2  observe supply limit at plant i
  11  x  2  Var     6  shipment quantities in cases
  12  z  0  Var     1  total transportation costs in thousands of dollars
C:\tmp>
```
The example shows how we copy the transport.gms model from the model library, and then solve it. The option gdx=filename will save the complete symbol table to a GDX file. The option lo=2 tells GAMS to save the log to a file (in this case transport.log) instead of writing it to the screen. The gdxdump will display the contents of the GDX file (the option symbols will only display the table of contents, rather than all data)

Once we have a GDX file we can use GDX2XLS to create an .XLSX file:

C:\tmp>gdx2xls trnspor.gdx
GDX2XLS 34.1.0 r644dbd9 Released Jan 29, 2021 WEI x86 64bit/MS Window
Output file: C:\tmp\trnspor.xlsx
C:\tmp>

The resulting XLSX file, opened with MS Excel is shown in Figure 1. The first page is the Table of Contents page with all identifiers sorted alphabetically. When clicking on variable x, the sheet shown in Figure 2 is displayed.

The table of contents can be reached again by clicking on the TOC link in the top left corner. The complete process shown here can be automated as is shown in section Model gdx2xls1: import trnspor.gdx. As can be seen, every identifier is stored in its own sheet. Index positions get a column with labels showing their domains, or dim1, dim2, etc. if domain information is not available. By default scalar quantities are collected in a single sheet called scalar.

6.19.2 AutoFilter

By default the exported tables are organized in AutoFilter tables. This will allow you to easily make selections and sort the results.

It is possible to set filters for different columns. Only the rows that meet the criteria will be shown. The columns used in the filter can be recognized by having a blue arrow instead of a black one in the drop down menu header.

Sorting can also be performed on multiple columns: e.g. first sort on one column, then sort on a second column.

The autofilter generation can be turned off using an option in the .ini file.

6.19.3 Options

6.19.3.1 Default ini file

Options are specified in an .INI file. By default, the file gdx2xls.ini located in the same directory as gdx2xls.exe is consulted. If this file is not available, the program will continue using default settings.
6.19.3.2 Custom ini file

It is also possible to tell the program to use a different .ini file. This is done by using an extra argument of the form @inifile. An example would be:

C:\\TMP> gdx2xls myfile.gdx @myinifile.ini

In this case the program will not read gdx2xls.ini located in the same directory as gdx2xls.exe but rather myinifile.ini in the current directory.

The ini file can contain two sections: [settings] and [colors]. A complete ini file with all possible settings looks like:

```
[settings]
inf=INF
mininf=-INF
eps=EPS
na=NA
undf=INDF
scalarsheet=1
tableformatting=1
toc=1
sorttoc=1
autofilter=1
freezeheader=1
indexformat=
valueformat=

[colors]
header=17
body=19
italics=48

[xmlcolors]
link=#0000FF
header=#9999FF
body=#FFFFCC
italics=#969696
```

6.19.3.3 Settings section

A complete description for the [settings] section is:

<table>
<thead>
<tr>
<th>[settings]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inf</td>
<td>Special values may need to be mapped to numeric values so the values can be used in formula's etc. This setting will specify the value for the GAMS INF quantity. The default is the string INF.</td>
</tr>
<tr>
<td>mininf</td>
<td>This is the mapped value for -INF. The default is -INF.</td>
</tr>
<tr>
<td>eps</td>
<td>This is the mapped value to be used for EPS. The default is EPS.</td>
</tr>
<tr>
<td>na</td>
<td>This is the mapped value to be used for NA. The default is NA.</td>
</tr>
<tr>
<td>undf</td>
<td>This is the mapped value to be used for UNDF. The default is UNDF.</td>
</tr>
</tbody>
</table>
An example of setting special values can be found in section Model gdx2xls4: special value mapping.

### 6.19.3.4 Colors section

A complete description for the `[colors]` section is:

<table>
<thead>
<tr>
<th>[colors]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>The colorindex to be used as background for table headers. Default is 17.</td>
</tr>
<tr>
<td>body</td>
<td>The colorindex to be used as background for table bodies. Default is 19.</td>
</tr>
<tr>
<td>italics</td>
<td>The colorindex to be used for the font when writing explanatory text. The default is light grey (color index 48).</td>
</tr>
</tbody>
</table>

The `[xmlcolors]` section is used to specify colors in the XML file to be generated.

### 6.19.3.5 Custom formats

The format strings consists of four pieces:

```
[format for $x>0$];[format for $x<0$];[format for $x=0$];[format for strings]
```

An example given in the Excel help is:

```
#,###.00_;[Red](#,###.00);0.00;"sales ";
```

The codes used here have the following meaning:

<table>
<thead>
<tr>
<th>Formatting Characters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td># (number sign)</td>
<td>displays only significant digits and does not display insignificant zeros.</td>
</tr>
</tbody>
</table>
To display a comma as a thousands separator or to scale a number by a multiple of one thousand, include a comma in the number format. A comma (,) displays insignificant zeros if a number has fewer digits than there are zeros in the format. An underscore (_) creates a space the width of a character in a number format, included by an underscore, followed by the character. For example, when you follow an underscore with a right parenthesis, such as ), positive numbers line up correctly with negative numbers that are enclosed in parentheses.

<table>
<thead>
<tr>
<th>Formatting Characters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>, (comma)</td>
<td>To display a comma as a thousands separator or to scale a number by a multiple of one thousand, include a comma in the number format.</td>
</tr>
<tr>
<td>0 (zero)</td>
<td>Displays insignificant zeros if a number has fewer digits than there are zeros in the format.</td>
</tr>
<tr>
<td>_ (underscore)</td>
<td>To create a space the width of a character in a number format, include an underscore, followed by the character. For example, when you follow an underscore with a right parenthesis, such as ), positive numbers line up correctly with negative numbers that are enclosed in parentheses.</td>
</tr>
<tr>
<td>[color]</td>
<td>One of [Black], [Blue], [Cyan], [Green], [Magenta], [Red], [White], [Yellow].</td>
</tr>
<tr>
<td>@ (at sign)</td>
<td>Include an at sign (@) in the section where you want to display any text entered in the cell.</td>
</tr>
</tbody>
</table>

Additional formatting characters include:

<table>
<thead>
<tr>
<th>Formatting Characters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>? (question mark)</td>
<td>Adds spaces for insignificant zeros on either side of the decimal point so that decimal points align when formatted with a fixed-width font, such as Courier New. You can also use ? for fractions that have varying numbers of digits.</td>
</tr>
<tr>
<td>condition</td>
<td>Conditions can be specified as follows: [Red] &lt;=100; [Blue] &gt;=100.</td>
</tr>
<tr>
<td>exponent</td>
<td>To display numbers in scientific format, use exponent codes in a section, for example, E-, E+, e-, or e+.</td>
</tr>
</tbody>
</table>

A useful format is:

```
[settings]
valueformat=#.?????
```

which aligns numbers on the decimal point and depicts zero's as dots just as the listing file is doing.

### 6.19.4 Examples

#### 6.19.4.1 Model gdx2xls1: import transpport.gdx

This example will solve the `transpport.gms` model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a small example that should run very quickly.

```
$onText
Test of GDX2XLS. Dumps all symbols of transpport.gms to transpport.xlsx.
$offText
execute '=gamslib transpport';
execute '=gams transpport lo=3 gdx=transpport';
execute '=gdx2xls transpport.gdx';
execute '=shellExecute transpport.xlsx';
```

Notes: the equal signs in from of the external programs indicate we don't go through a shell (e.g. `command.com` or `cmd.exe`). This will improve reliability in case the external program is not found. In such a case a proper error will be triggered. Without the '=' such errors go undetected and the GAMS model will continue.

The command `ShellExecute` will launch Excel to view the `.XLSX` file.
6.19.4.2 Model gdx2xls2: import indus89.gdx

This example will solve the indus89.gms model from the model library and generate a GDX file containing the complete symbol table. This GDX file is exported to Excel and MS Excel is launched to inspect the results. This is a fairly large GDX file, with many identifiers, resulting in many sheets in the workbook.

$onText
Test of GDX2XLS. Dumps all symbols of indus89.gms to indus89.xlsx. This takes longer as there is a large number of symbols.
$offText

execute '=gamslib indus89';
execute '=gams indus89 lo=3 gdx=indus89';
execute '=gdx2xls indus89.gdx';
execute '=shellExecute indus89.xlsx';

6.19.4.3 Model gdx2xls3: a large table

This is an artificial example where we generate a large identifier in GAMS: a parameter with as many elements as the number of rows that Excel can handle.

$onText
Test of GDX2XLS. Single symbol with 65536-3=65533 records.
Maximum rows that XLS can handle is 65536; an XLSX file allows for slightly more than a million rows.
$offText

Set i / i1*i65533 /;

Parameter p(i);
p(i) = uniform(-100,100);
execute_unload 'test.gdx', p;
execute '=gdx2xls test.gdx';
execute '=shellExecute test.xlsx';

If you create a spreadsheet with too many rows, the XLSX file writer will return OLE error 800A03EC. When generating an XML file, an error will occur when Excel loads the file.

6.19.4.4 Model gdx2xls4: special value mapping

To store special values like INF, EPS, NA in a numeric field in the database, GDX2XLS uses a mapping. This mapping can be changed using an INI file.

$onText
Test of GDX2XLS.
Check special value mapping.
$offText

$onEcho > m.ini
[settings]
inf=1.0e100
$offEcho
mininf=-1.0e100
eps=0.0
na=#NA!
undf=#UNDF!
$offEcho

Parameter p(*) / i1 inf, i2 -inf, i3 eps, i4 na /;
p('i5') = 1/0;
display p;

* save parameter p in p.xlsx
* special values are translated to default values:
execute_unload "p.gdx", p;
execute '=gdx2xls p.gdx';
execute '=shellExecute p.xlsx';

* save parameter p in q.xls using new mapping
* INF -> 1.0e100 (numeric)
* -INF -> -1.0e100 (numeric)
* EPS -> 0.0 (numeric)
* NA -> #NA! (string)
* UNDF -> #UNDF! (string)
*
execute_unload "q.gdx", p;
execute '=gdx2xls q.gdx @m.ini';
execute '=shellExecute q.xlsx';

Numeric values are important if you want Excel being able to operate on these numbers.

6.19.4.5 Model gdx2xls8: custom format

We use a custom value format to color the different values \(x<0, x=0, x>0\) differently. Also align on the decimal point.

$onText
GDX2XLS example: use of custom format
$offText

$onEcho > mexls.ini
[settings]
valueformat=[Blue]#.????;[Red]-#.????;[Green]0.????;[Magenta]
$offEcho
execute '=gamslib mexls';
execute '=gams mexls lo=3 gdx=mexls';
execute '=gdx2xls mexls.gdx @mexls.ini';
execute '=shellExecute mexls.xlsx';

6.19.4.6 Model gdx2xls9: custom format 2

This uses the more useful custom format valueformat=#.???? (see Figure 7).
6.20 GDXCOPY

GDX files from different GAMS version can possibly be incompatible. A current GAMS system can read all older GDX file formats. The GDXCOPY utility provides a mechanism to convert GDX files to a format that different GAMS systems can read.

6.20.1 Usage

gdxcopy option inFile outDir

or

gdxcopy option -Replace inFile

The first form copies the converted files to a directory; the second form replaces the original file(s).

inFile

Single file or a file pattern with .gdx file extension.

outDir

The output directory.

Instead of converting the files explicitly using the GDXCOPY utility, files can also be converted by using the environment variable GDXCONVERT with values V5, V6 or V7. The values specified will be used together with the value of the environment variable GDXCOMPRESS to call GDXCOPY as soon as a GDX file is created.

The values of the environment variables can also be set using the GAMS parameters GDXCONVERT and GDXCOMPRESS.

Option:
<table>
<thead>
<tr>
<th>Option</th>
<th>Target format</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V5</td>
<td>Version 5</td>
</tr>
<tr>
<td>-V6U</td>
<td>Version 6 uncompressed</td>
</tr>
<tr>
<td>-V6C</td>
<td>Version 6 compressed</td>
</tr>
<tr>
<td>-V7U</td>
<td>Version 7 uncompressed</td>
</tr>
<tr>
<td>-V7C</td>
<td>Version 7 compressed</td>
</tr>
</tbody>
</table>

A current GAMS system can always handle older GDX file formats. The **gdxcopy** utility provides a mechanism to convert GDX files to a prior format, so an older GAMS system can read these files.

**Notes:**

- Version 7 formatted files were introduced with version 22.6 of GAMS; version 6 formatted files were introduced with version 22.3 of GAMS. Prior versions used version 5.
- Some features introduced in version 7 of the GDX file format cannot be represented in older formats.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Action taken</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimension &gt; 10</td>
<td>Symbol is ignored</td>
</tr>
<tr>
<td>Identifier longer than 31 characters</td>
<td>Truncated to 31 characters</td>
</tr>
<tr>
<td>Unique element longer than 31 characters</td>
<td>Truncated to 31 characters</td>
</tr>
<tr>
<td>Domain of a symbol</td>
<td>Domain is ignored</td>
</tr>
<tr>
<td>Aliased symbol</td>
<td>Symbol is entered as a set</td>
</tr>
<tr>
<td>Additional text for symbol</td>
<td>Additional text is ignored</td>
</tr>
</tbody>
</table>

- The Macintosh Intel-based system (DII) which was introduced with GAMS 22.6 does not support GDX conversion into formats version 6 and version 5.

### 6.20.2 Example

In the example below we convert all GDX files to a compressed format for version 6.

```plaintext
dir 1,219 t1.gdx 1,740 t0.gdx 889,973 i.gdx 1,740 pv.gdx 894,672 bytes
gdxcopy -v6c *.gdx newdir
dir newdir 1,219 t1.gdx 1,219 t0.gdx 203,316 i.gdx 1,219 pv.gdx 206,973 bytes
```
6.21 GDXDIFF

The GDXDIFF tool compares the data of symbols with identical name, type and dimension in two GDX files and writes the differences to a third GDX file. A summary report will be written to standard output.

6.21.1 Usage

```
gdxdiff file1 file2 {diffile} {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. GDXDIFF requires two parameters, the file names of two GDX files. An optional third parameter is the name of the GDX difference file. Without the third parameter, the difference file will be diffile.gdx in the current directory.

diffile = fileName (default = diffile.gdx)

An optional name of the GDX difference file.

6.21.2 Options

The following options can be used when calling GDXDIFF:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eps</td>
<td>0.0</td>
<td>Epsilon for comparison (absolute).</td>
</tr>

<td>Y</td>
<td>Control if associated text of matching set elements is compared.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the options:

**Eps = value (default = 0.0)**

Absolute difference for comparisons; see also Comparing numeric values. If the difference between two values exceeds Eps, a difference will be reported. The valid range is
\( \textbf{RelEps} = \textit{value} \) (default = 0.0)

Relative difference for comparisons; see also Comparing numeric values. If the value of \( \textbf{RelEps} \) is exceeded, a difference will be reported.

\( \textbf{field} = \textit{fieldName} \) (default = all)

The specified subfield is the only field used for deciding if a variable or equation is different. FieldName is one of the following: \( l, m, up, lo, prior, scale \) or \( all \).

\( \textbf{fldOnly} \) (disabled by default)

Used in combination with the \( \textbf{field} \) option; The variables and equations will be written as parameters for the selected subfield. This option cannot be used in combination with \( \textbf{diffOnly} \) and requires \( \textbf{field} \) being set to an actual field name but not to \( all \).

\( \textbf{id} = \textit{identifier} \) (default = all)

Limits the comparison to one or more symbols; symbols not specified will be ignored. Multiple identifiers can be specified as: \( \textbf{id}=\textit{id1} \ \textbf{id}=\textit{id2} \) or as \( \textit{id}="\textit{id1} \ \textit{id2}" \). When using \texttt{GDXDIFF} from the menu bar in the GAMS IDE (Utilities), this option is not available.

\( \textbf{diffOnly} \) (disabled by default)

Differences for variables and equations will be written as parameters; each parameter will have an additional index which is used to store the field name. Only fields that are different will be written. This option cannot be used in combination with \( \textbf{fldOnly} \).

\( \textbf{cmpDefaults} \)

Enables the comparison of default values. When using \texttt{GDXDIFF} from the menu bar in the GAMS IDE (Utilities), this option is not available.

\( \textbf{cmpDomains} \) (disabled by default)

Enable the comparison of symbol domains. Note that the difference are not listed in particular in the diffile. When using \texttt{GDXDIFF} from the menu bar in the GAMS IDE (Utilities), this option is not available.

\( \textbf{matrixFile} \)

This activates a special mode to compare GAMS matrix files in GDX format. This is mostly done for internal use. When using \texttt{GDXDIFF} from the menu bar in the GAMS IDE (Utilities), this option is not available.

\( \textbf{setDesc} = \textit{boolean} \) (default = \( Y \))

Enable or disable the comparison of associated texts for set elements.

\textbf{Criterion for comparing numeric Values}

The use of \( Eps \) and \( \textbf{RelEps} \) is best described by the code fragment below.
AbsDiff := Abs(V1 - V2);
if AbsDiff <= EpsAbsolute
  then
    Result := true
  else
    if EpsRelative > 0.0
      then
        Result := AbsDiff / (1.0 + DMin(Abs(V1), Abs(V2))) <= EpsRelative
      else
        Result := false;

Interpreting the Labels in the diffile
Only symbols with the same name, type and dimension will be compared. Tuples with different values are written to the GDX difference file, and a dimension is added to describe the difference using the following labels:

- **ins1** indicates that the tuple only occurs in the first file.
- **ins2** indicates that the tuple only occurs in the second file.
- **dif1** indicates that the tuple occurs in both files; contains the value from the first file.
- **dif2** indicates that the tuple occurs in both files; contains the value from the second file.

6.21.3 Examples

6.21.3.1 Compares two GDX Files and writes the Differences to a third GDX File

In the following example, the **transport** model is solved twice with different capacity data. GDX files are saved for each run, and compared afterwards using GDXDIFF. The shipments variable is loaded into a new variable used for a display statement. We introduce four new unique elements that are used in the difference file.

* solve and write to unmodified.gdx before manipulating the data
  solve transport using lp minimizing z;
  execute_unload 'unmodified.gdx', a, x;

* manipulate the data and solve again, write to modified.gdx
  a('seattle') = 1.2*a('seattle');
  solve transport using lp minimizing z;
  execute_unload 'modified.gdx', a, x;

  execute 'gdxdiff unmodified modified diffile > %system.nullfile%';

* Declare symbols to hold the data for differences
  Set difftags / dif1, dif2, ins1, ins2 /;
  Variable xdif(i,j,difftags);
  Parameter adif(i,difftags);

  execute_load 'diffile' adif=a, xdif=x;
  display a, xdif.l;
The display statement generates the following output in the listing file:

```plaintext
---- 101 PARAMETER a capacity of plant i in cases
      seattle 420.000, san-diego 600.000

---- 101 VARIABLE xdif.L
      dif1    dif2
      seattle .new-york 50.000 120.000
      san-diego.new-york 275.000 205.000
```

Alternatively, one can open the diff file in the GAMS IDE or GAMS Studio to display the differences.

This example is also part of the GAMS Data Utilities Library, see model [GDXDIFFExample16] for reference.

### 6.22 GDXDUMP

GDXDUMP is a tool to write scalars, sets, parameters (tables), variables and equations from a GDX file formatted as a GAMS program with data statements to standard output, GMS or CSV files. To write to a file, use the output redirection ‘>’ provided by the operating system or the output option of GDXDUMP.

#### 6.22.1 Usage

```
gdxdump filename {options}
```

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

#### 6.22.2 Options

The table summarizes the options of GDXDUMP. Running GDXDUMP without any arguments will write the sets, parameters, scalars etc. to standard output formatted as a GAMS program with data statements.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output</td>
<td>none</td>
<td>Specify the output filename.</td>
</tr>
<tr>
<td>version</td>
<td>disabled</td>
<td>Writing version information only.</td>
</tr>
<tr>
<td>symb</td>
<td>none</td>
<td>Specify a single identifier to be written from the GDX.</td>
</tr>
<tr>
<td>UelTable</td>
<td>none</td>
<td>Write all unique elements in the GDX to a single set.</td>
</tr>
<tr>
<td>delim</td>
<td>if format=normal: period if format=csv: comma</td>
<td>Specify a delimiter to separate elements in the output.</td>

</tr>
<tr>
<td>UndfOut</td>
<td>Undf</td>
<td>String to be used when writing the value for 'Undefined'.</td>
</tr>
<tr>
<td>ZeroOut</td>
<td>0</td>
<td>String to be used when writing the value for 'Zero'.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the options:

**output = fileName** (default=none)

Write the output to a file. The .gms resp. the .csv file extension must be added when writing to GMS resp. CSV.

This option is demonstrated in **Writing GDX to CSV**.

**-version** (disabled by default)

Synonym: -v

Write version information only and terminate; all other options will be ignored.

**symb = identifier** (default=none)

Specify a single identifier in the GDX file to be written to standard output, GMS or CSV. When writing to CSV, one must specify the **symb** option.

This option is demonstrated in **Writing GDX to standard output and to GMS**.

**UelTable = identifier** (default=none)
Write all unique elements found in the GDX file to a set using the identifier specified as the name for the set.

This option is demonstrated in Writing GDX to standard output and to GMS.

delim = [period, comma, tab, blank, semiColon] (if format=normal: default=period, if format=csv: default=comma)

Selects a different delimiter to separate unique elements; period is the default when writing to standard output or GMS, while comma is the default when writing to CSV.

This option is demonstrated in Writing GDX to CSV.

decimalSep = [period, comma] (default=period)

Specify a decimal separator.

This option is demonstrated in Writing GDX to CSV.

noHeader (disabled by default)

Suppress the header information when writing a single symbol; only the data for the symbol will be written, not its declaration. The option is ignored when writing all symbols. When writing to CSV, the header row can be suppressed by enabling noHeader.

This option is demonstrated in Adding double Quotes to an user defined Header when writing to CSV.

header = string (default=None)

The string supplied replaces the default header written by the program to a CSV file. If an empty header is desired, the string can be empty; such a string can be written using two single quotes (header=""), while in general it is best to enclose the string with double quotes.

This option is demonstrated in Writing GDX to CSV and Adding double Quotes to an user defined Header when writing to CSV.

noData (disabled by default)

Only write the headers for the symbols; no data is written. The option is ignored when writing to CSV.

CSVAllFields (disabled by default)

When writing a variable or equation to CSV, all fields (level, marginal, lower, upper, and scale) will be written. Without this option, only the level will be written. When writing a set the option control the writing of the element text.

This option is demonstrated in Writing GDX to CSV.

CSVSetText (disabled by default)

When writing a set to CSV, the set element text will be written as the last column in the CSV file in addition to the set elements. Without this option, only the set elements will be written.

This option is demonstrated in Writing GDX to CSV.
symbols (disabled by default)

Generate an alphabetical list of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in Writing GDX to standard output and to GMS.

symbolsAsSet (disabled by default)

Generate a set declaration where the data represents basic information (symbol identifier, dimension, type, explanatory text) of all symbols in the GDX file (not valid when writing to CSV).

This option is demonstrated in Writing GDX to standard output and to GMS.

domainInfo (disabled by default)

Generate an alphabetical list of all symbols in the GDX file that includes domain information (not valid when writing to CSV). The column DomInf can have the following values:

N/A - The function to get the type of domain information is not available
None - No domain was specified (domain is the universe)
Relaxed - The domain is relaxed, i.e. the identifiers shown do not necessarily represent one dimensional sets
Regular - Regular domain; the identifiers shown are one dimensional sets

This option is demonstrated in Writing GDX to standard output and to GMS.

setText (disabled by default)

Show the set text (aka the associated set text or the set element text) in the GDX file (not valid when writing to CSV).

GDX allows a string of text to be associated with each element of a set. The universe of such strings stored for use in any particular GDX file (i.e. the set text list) can be shown with this option.

format = [normal, gamsbas, CSV] (default=normal)

Change the output format and the symbols written.

When using the gamsbas format, the program will not write the declarations for the symbols and only write the Level and Marginal assignment statements for the variables, and the Marginal assignment statements for equations.

The CSV format adds column headers to the output. By enabling the cDim option the unique elements of the last dimension of the symbol will be used as column headers for the values. If domain information is available, the column headers will be made unique if overlapping names have been used for the names of the index positions. If no domain information is available, the index names used will be of the form dim1, dim2, ...

In order to run GDXDUMP, one must specify a single symbol using the symb option when writing to CSV.

The gamsbas and CSV format is demonstrated in Writing GDX to standard output and to GMS resp. Writing GDX to CSV.
\textbf{dFormat} = [normal, exponential, hexBytes] (default=normal)

Specify the numerical format in the output file.

\textbf{cDim} = [\texttt{Y}, \texttt{N}] (default = \texttt{N})

Can be used when writing a CSV file; when enabled, the unique elements of the last dimension will be used as column headers for the values.

This option is demonstrated in Writing GDX to CSV.

\textbf{filterDef} = [\texttt{Y}, \texttt{N}] (default = \texttt{Y})

When enabled, default values will be filtered and not written. This option is enabled by default. For example, if the Level field (.L) of a variable is zero, the value will not be written.

\textbf{EpsOut} = \textit{string} (default = \texttt{EPS})

String to be used when writing the value for 'Epsilon'.

\textbf{NaOut} = \textit{string} (default = \texttt{NA})

String to be used when writing the value for 'Not Available'.

\textbf{pInfOut} = \textit{string} (default = +\texttt{Inf})

String to be used when writing the value for 'Positive Infinity'.

This option is demonstrated in Writing GDX to CSV.

\textbf{mInfOut} = \textit{string} (default = -\texttt{Inf})

String to be used when writing the value for 'Negative Infinity'.

\textbf{UndfOut} = \textit{string} (default = \texttt{Undf})

String to be used when writing the value for 'Undefined'.

\textbf{zeroOut} = \textit{string} (default = 0)

String to be used when writing the value for 'Zero'.

Note that GDX files can also be viewed using the GAMS IDE or GAMS Studio.

\textbf{6.22.3 Examples}

To demonstrate the features of \texttt{GDXDUMP} in the Writing GDX to standard output and to GMS and Writing GDX to CSV examples, we execute the model \texttt{transport.gms} (\texttt{TRANSPORT} from GAMS Model Library) initially to create the GDX file \texttt{transport.gdx} by using the GDX command line option. Afterwards, some important features of \texttt{GDXDUMP} are demonstrated.

\texttt{gams transport gdx=transport}

The figure shows the symbol listing of the GDX file in total and the variable \texttt{x} in particular, since those data is used quite often in the following examples:

All subfields of the variable \texttt{x} are shown in the next figure:
6.22 GDXDUMP

6.22.3.1 Writing GDX to standard output and to GMS

In this example, we will demonstrate the effect of some basic features of GDXDUMP.

While we write to standard output in the most sections of this example, one can also write the GDX file contents into a GAMS file using the following command to redirect the output:

gxdump trnsport.gdx > GDXContents.gms

Alternatively, the output option can be used to specify an output filename.

**Option symbols**

This listing shown above can also be written to standard output by using the symbols option of GDXDUMP:

gxdump trnsport symbols

The GDXDUMP program writes the following output (except for the numbering and the records column, the content is identical compared to the figure):

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Dim</th>
<th>Type</th>
<th>Records</th>
<th>Explanatory text</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>Par</td>
<td>2</td>
<td>capacity of plant i in cases</td>
</tr>
<tr>
<td>b</td>
<td>1</td>
<td>Par</td>
<td>3</td>
<td>demand at market j in cases</td>
</tr>
<tr>
<td>c</td>
<td>2</td>
<td>Par</td>
<td>6</td>
<td>transport cost in thousands of dollars per case</td>
</tr>
<tr>
<td>cost</td>
<td>0</td>
<td>Equ</td>
<td>1</td>
<td>define objective function</td>
</tr>
<tr>
<td>d</td>
<td>2</td>
<td>Par</td>
<td>6</td>
<td>distance in thousands of miles</td>
</tr>
<tr>
<td>demand</td>
<td>1</td>
<td>Equ</td>
<td>3</td>
<td>satisfy demand at market j</td>
</tr>
<tr>
<td>f</td>
<td>0</td>
<td>Par</td>
<td>1</td>
<td>freight in dollars per case per thousand miles</td>
</tr>
<tr>
<td>i</td>
<td>1</td>
<td>Set</td>
<td>2</td>
<td>canning plants</td>
</tr>
<tr>
<td>j</td>
<td>1</td>
<td>Set</td>
<td>3</td>
<td>markets</td>
</tr>
<tr>
<td>supply</td>
<td>1</td>
<td>Equ</td>
<td>2</td>
<td>observe supply limit at plant i</td>
</tr>
<tr>
<td>x</td>
<td>2</td>
<td>Var</td>
<td>6</td>
<td>shipment quantities in cases</td>
</tr>
<tr>
<td>z</td>
<td>0</td>
<td>Var</td>
<td>1</td>
<td>total transportation costs in thousands of dollars</td>
</tr>
</tbody>
</table>

**Option domainInfo**

We use the domainInfo option to write some basic information including domain information (column DomInf) to standard output:

gxdump trnsport domainInfo

The GDXDUMP program writes the following output:

<table>
<thead>
<tr>
<th>SyNr</th>
<th>Type</th>
<th>DomInf</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Par</td>
<td>Regular</td>
<td>a(i)</td>
</tr>
<tr>
<td>4</td>
<td>Par</td>
<td>Regular</td>
<td>b(j)</td>
</tr>
<tr>
<td>7</td>
<td>Par</td>
<td>Regular</td>
<td>c(i, j)</td>
</tr>
<tr>
<td>10</td>
<td>Equ</td>
<td>None</td>
<td>cost</td>
</tr>
<tr>
<td>5</td>
<td>Par</td>
<td>Regular</td>
<td>d(i, j)</td>
</tr>
<tr>
<td>12</td>
<td>Equ</td>
<td>Regular</td>
<td>demand(j)</td>
</tr>
<tr>
<td>6</td>
<td>Par</td>
<td>None</td>
<td>f</td>
</tr>
<tr>
<td>1</td>
<td>Set</td>
<td>None</td>
<td>i(*)</td>
</tr>
<tr>
<td>2</td>
<td>Set</td>
<td>None</td>
<td>j(*)</td>
</tr>
<tr>
<td>11</td>
<td>Equ</td>
<td>Regular</td>
<td>supply(i)</td>
</tr>
<tr>
<td>8</td>
<td>Var</td>
<td>Regular</td>
<td>x(i, j)</td>
</tr>
<tr>
<td>9</td>
<td>Var</td>
<td>None</td>
<td>z</td>
</tr>
</tbody>
</table>
Check the **domainInfo** option explanation linked above to get a full list of possible values for **DomInf** and their interpretation. In this example, the symbol dimensions were not specified (none) or they are defined on the one dimensional sets i and j (regular).

**Option symbolsAsSet**

Using the **symbolsAsSet** option one can write the information displayed by enabling the **symbols** option to a set declaration:

```
gxdump transport symbolsAsSet
```

The **GDXDUMP** program writes the following:

```
alias (Symbol, Dim, Type, *)
set gdxitems(Symbol,Dim,Type) Items in the GDX file /
  "i".1."Set" "canning plants",
  "j".1."Set" "markets",
  "a".1."Par" "capacity of plant i in cases",
  "b".1."Par" "demand at market j in cases",
  "d".2."Par" "distance in thousands of miles",
  "f".0."Par" "freight in dollars per case per thousand miles",
  "c".2."Par" "transport cost in thousands of dollars per case",
  "x".2."Var" "shipment quantities in cases",
  "z".0."Var" "total transportation costs in thousands of dollars",
  "cost".0."Equ" "define objective function",
  "supply".1."Equ" "observe supply limit at plant i",
  "demand".1."Equ" "satisfy demand at market j"
/;
```

**Option symb**

One can write a single identifier from the GDX using the **symb** option:

```
gxdump transport.gdx symb=x
```

The default output includes the declaration header and a data statement when writing a set or parameter. When writing a variable, the output includes the level and marginal subfields:

```
positive Variable x(i,j) shipment quantities in cases /
  'seattle'.'new-york'.L 50,
  'seattle'.'chicago'.L 300,
  'seattle'.'topeka'.M 0.036,
  'san-diego'.'new-york'.L 275,
  'san-diego'.'chicago'.M 0.00900000000000001,
  'san-diego'.'topeka'.L 275 /;
```

Note the default values are not written (for instance, zero values of the level or lower bound subfields are missing).

**Option UelTable**

Using the **UelTable** option one can write a set (named **allUELs** in this example) containing all unique elements of the GDX file:

```
gxdump transport output=allUELs.gms UelTable=allUELs
```
The following set declaration will be part of the output file allUELs.gms:

\[
\text{Set allUELs /}
\text{ 'seattle' ,}
\text{ 'san-diego' ,}
\text{ 'new-york' ,}
\text{ 'chicago' ,}
\text{ 'topeka' /};
\]

**Format gamsbas**

Using the `format` option one can write a variable or equation in the gamsbas format, i.e. there will be no declaration of the symbol and the level and marginal subfields will be written as assignments.

```
gdxdump transport format=gamsbas
```

**GDXDUMP** writes the following to standard output:

\[
x.L ('seattle'.'new-york') = 50 ;
x.L ('seattle'.'chicago') = 300 ;
x.M ('seattle'.'topeka') = 0.036 ;
x.L ('san-diego'.'new-york') = 275 ;
x.M ('san-diego'.'chicago') = 0.00900000000000001 ;
x.L ('san-diego'.'topeka') = 275 ;
z.L = 153.675 ;
cost.M = 1 ;
supply.M ('seattle') = Eps ;
demand.M ('new-york') = 0.225 ;
demand.M ('chicago') = 0.153 ;
demand.M ('topeka') = 0.126 ;
\]

### 6.22.3.2 Writing GDX to CSV

Next we specify CSV as the output `format` and demonstrate some simple features available when writing to CSV.

**Writing to CSV**

One can write to a CSV file by running the following command:

```
gdxdump transport.gdx output=varX.csv symb=x format=csv
```

By doing this, the level subfield of the variable \( x \) is written as a list to the file `varX.csv` specified in the `output` statement. The header row contains the domain set identifiers \( i \) and \( j \) of \( x \) and the field "Val":

```
seattle, new-york 50
seattle, chicago 300
topeka, seattle 0.036
```
"i","j","Val"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275

Option cDim
Using the cDim option one can write the data as a table since the right most dimension is used as the
column header:

gdxdump transport.gdx symb=x format=csv cDim=y

We did not specify an output file in this case, so the data will be written to standard output formatted as
CSV:

The GDXDUMP program writes the following:

"i","new-york","chicago","topeka"
"seattle",50,300,0
"san-diego",275,0,275

Note the elements new-york, chicago and topeka are written to the header row, since they are elements of
the most right dimension j.

Customizing the output: CSVAllFields, header, decimalSep, delim, pInfOut etc.
In this section, all subfields of the variable x are written to CSV and the representation is customized.
The writing of subfields is enabled by CSVAllFields. In addition, the header option is used to overwrite
the default header (as seen in the two previous paragraphs). For instance, we want to replace i with the
term 'canning plants', j with the term 'markets' and "Val" with the term 'shipment quantities in cases',
while we are fine with the default column labels for the level, marginal etc. subfields, but they will be
overwritten, too. Therefore, we must specify them again manually in the header option. For some reason,
the field separator is changed from comma (default) to semicolon and the decimal separator from period
(default) to comma using the delim and decimalSep options. One can define the string written to CSV for
special values of GAMS like +INF by using the corresponding option pInfOut, which might be useful for
further processing of the CSV file.

gdxdump transport format=csv output=varX.csv symb=x CSVAllFields header="canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale" delim=semiColon decimalSep=comma pInfOut=1E+100

GDXDUMP creates the following output:

canning plants;markets;shipment quantities in cases;Level;Marginal;Lower;Upper;Scale
"seattle";"new-york";50;0;0;1E+100;1
"seattle";"chicago";300;0;0;1E+100;1
"seattle";"topeka";0;0,036;0;1E+100;1
"san-diego";"new-york";275;0;0;1E+100;1
"san-diego";"chicago";0;0,00900000000000001;0;1E+100;1
"san-diego";"topeka";275;0;0;1E+100;1
Note that the fields in the header are not enclosed by double quotes. This problem is addressed in the next section Adding double Quotes to an user defined Header when writing to CSV.

**Customizing the output: CSVSetText**

The set element text is the *value* of a set element. Often this is left out when defining sets, but for descriptive models often set element text is provided. When dumping a set to a CSV file the set element text is not written to the CSV file by default. The option `CSVSetText` enables the writing of the text. The model `mexss.gms` ([MEXSS] from GAMS Model Library) has a set `i` of steel plants with set element text.

```
Set i 'steel plants' / ahmsa 'altos hornos - monclova'
    fundidora 'monterrey'
    sicartsa 'lazaro cardenas'
    hylsa  'monterrey'
    hylsap 'puebla' /;
```

When we create a GDX file and dump set `i` as CSV with defaults via the following commands

```plaintext
gamslib mexss
export mexss gdx=mexss
gdxdump mexss format=csv output=setI.csv symb=i header="steel_plants"
```

`GDXDUMP` creates the following output:

```
steel_plants
"ahmsa"
"fundidora"
"sicartsa"
"hylsa"
"hylsap"
```

If we add `CSVSetText`

```plaintext
gamslib mexss
export mexss gdx=mexss
gdxdump mexss format=csv output=setI.csv symb=i CSVSetText header="steel_plants,real_name"
```

`GDXDUMP` creates the following output:

```
steel_plants,real_name
"ahmsa","altos hornos - monclova"
"fundidora","monterrey"
"sicartsa","lazaro cardenas"
"hylsa","monterrey"
"hylsap","puebla"
```
6.22.4 Adding double Quotes to an user defined Header when writing to CSV

This sections describes a possible workaround for the following problem: Suppose one wish to write a parameter or variable from GDX to CSV, but with a non default header containing double quotes. For this purpose, one might try to use the header option of GDXDUMP to specify an user defined header. Though, there is no way to add double quotes enclosing the single fields using the header option, but this is a quite common standard in CSV files (for instance, if the fields contain reserved characters).

Initially, define the header you want to write to the CSV file and redirect the line to your final CSV file (which will be created at this point, an already existing file will be overwritten!). Note the double quotes enclosing the field content. Adding the single quotes is necessary in order to run the following statement from GAMS IDE (however, they will not be written to the file), while they must be omitted when using the command prompt.

$echo '"canning plants","markets","shipment quantities in cases"' > quotedHeader.csv

Afterwards, call GDXDUMP by specifying the GDX file, the single symbol x we want to write, the output format CSV and redirect the output to the file quotedHeader.csv:

$call gdxdump trnsport.gdx symb=x format=csv noHeader >> quotedHeader.csv

Appending the output of the recent GDXDUMP call to the already existing file quotedHeader.csv adds the data of x to the file and creates the following CSV file (note that one must prevent GDXDUMP to write the default header by using the command noHeader):

"canning plants","markets","shipment quantities in cases"
"seattle","new-york",50
"seattle","chicago",300
"seattle","topeka",0
"san-diego","new-york",275
"san-diego","chicago",0
"san-diego","topeka",275

6.23 GDXMERGE

The program GDXMERGE combines multiple GDX files into a single GDX file. Symbols with the same name, dimension and type are combined into a single symbol of a higher dimension. The added dimension has the file name of the combined file as its unique element.

6.23.1 Usage

gdxmerge filepattern1 filepattern2 .... filepatternN {options}

Each file pattern represents a file name or a wildcard representation using ? and *. A parameter of the form @filename will process the commands from the text file specified. The result of the GDXMERGE execution will be written to a file called merged.gdx, unless this default is overwritten by the output option.

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.
6.23 GDXMERGE

6.23.2 Options

The following options can be specified:

\[ \text{id} = \langle\text{id1}\rangle, \langle\text{id2}\rangle... \text{ (default = none)} \]

Only merge the symbols \text{id1, id2, ...}

\[ \text{exclude} = \langle\text{id1}\rangle, \langle\text{id2}\rangle... \text{ (default = none)} \]

Merge all symbols except for \text{id1, id2}, ...

\[ \text{big} = <\text{integer}> \]

The size for big symbols.

\[ \text{strict} = \text{true|false} \text{ (default = false)} \]

The program terminates with an error (non-zero return code) if input files specified cannot be found or a file pattern results in no files. An already existing output file also triggers an error if strict is set to true.

\[ \text{output} = \text{fileName} \text{ (default = merged.gdx)} \]

The optional output file name.

All symbols with matching type and dimension will be merged. By specifying the parameter \text{id=ident1} the merge process will only be performed for the identifier(s) specified, while \text{exclude=ident1} indicates that all symbols should be merged except for the ones specified in the \text{exclude} list. Note that the two options \text{id} and \text{exclude} are mutually exclusive.

By default, the program reads all GDX once and stores all data in memory before writing the merged.gdx file. The \text{big} parameter is used to specify a cutoff for symbols that will be written one at a time. Each symbol that exceeds the size will be processed by reading each GDX file and only process the data for that symbol. This can lead to reading the same GDX file many times, but it allows the merging of large data sets. The formula used to calculate the cutoff is:

\[ \text{dimension} \ast \text{totalNumberOfElements}. \]

The calculated value is doubled for variables and equations.

In addition to the symbols written, a set is added to the GDX file representing all the files processed during the merge operation. The name of the set is \text{Merged_set_1}, and is made unique by changing the number. The explanatory text for each set element contains the date and time of the GDX file processed.

Note

- The file merged.gdx, or the file specified with the output parameter, will never be used in a merge operation even if the name matches a file pattern.
- Symbols with dimension 20 cannot be merged, because the resulting symbol will have dimension 21 which exceeds the maximum dimension allowed by GAMS.
6.23.3 Examples

6.23.3.1 Merging several GDX Files

In this example, we solve the [transport] model from the GAMS Model Library using different LP solvers. After each run, we write all symbols to a GDX file and merge the files into one file. The variable X is read from the merged file and displayed.

```gams
$call gamslib trnsport
$call gams trnsport lp=cplex gdx=cplex
$call gams trnsport lp=xpress gdx=xpress
$call gams trnsport lp=conopt gdx=conopt
$call gams trnsport lp=minos gdx=minos
$call gams trnsport lp=snopt gdx=snopt
$call gdxmerge *.gdx

Variable AllX(*,*,*);
$gdxIn merged.gdx
$idxAllX=X
$gdxIn

option AllX:5:1:2;
display AllX.L;
```

The display statement generates the following output in the listing file:

```
---- 22 VARIABLE AllX.L shipment quantities in cases
          seattle   seattle   san-diego   san-diego
             new-york  chicago   new-york   topeka
  conopt         300.0000   325.0000   275.0000
  cplex          50.0000    300.0000   275.0000   275.0000
  minos          50.0000    300.0000   275.0000   275.0000
  snopt          50.0000    300.0000   275.0000   275.0000
  xpress         300.0000   325.0000   275.0000
```

Note that the different solutions are combined into a single symbol of a higher dimension. The filenames (resp. the solver used) are added as unique elements.

Instead of using the display statement, we can also use the GAMS IDE or GAMS Studio to display the merged.gdx file. The following figure shows the contents of merged.gdx after selecting the level subfield of the variable to be displayed and arranging the display:

This example is also part of the GAMS Data Utilities Library, see model [GDXMERGEEExample17] for reference.

6.23.3.2 Recursively Merging GDX Files

Some users generate data scenarios for a model in a hierarchical way and store the results in a directory tree: The following example demonstrates how to use three independent scenario scalars a, b, and c with values low, medium, and high to generate 3*3*3=27 scenarios, store these in a directory tree, and merge them recursively. The resulting GDX file has for each scenario scalar a new dimension which makes this data especially suitable for viewing in a pivot table:
6.23 GDXMERGE

The GAMS program that creates the directory structure and runs the model for all 27 scenarios looks as
follows:
set a,b,c;
parameter
ascen(a<) / a_low 0.9, a_med 1.0, a_high 1.1 /
bscen(b<) / b_low 0.9, b_med 1.0, b_high 1.1 /
cscen(c<) / c_low 0.9, c_med 1.0, c_high 1.1 /;
loop((a,b,c),
put_utility ’shell’ / ’mkdir ’ a.tl:0 ’\’ b.tl:0 ’\’ c.tl:0
put_utility ’exec’ / ’gams t.gms lo=2 -idir "%gams.wdir%" -curdir ’ a.tl:0 ’/’ b.tl:0 ’/’ c.tl:0
);
The program creates the directory tree (by creating the leave nodes of the tree), changes into the leave
directory (curDir) and calls GAMS (using iDir to point to the starting location). The program t.gms is
almost an identical copy of the [trnsport] model with the last few lines changed:
* ...
a(i) = %a%*a(i);
b(j) = %b%*b(j);
c(i,j) = %c%*c(i,j);
solve transport using lp minimizing z;
scalar tmodelstat;
tmodelstat = transport.modelstat;
parameter p(j) ’commodity price’;
p(j) = demand.m(j);
execute ’test -d results || mkdir results’;
execute_unload ’results/input’, a, b, c;
execute_unload ’results/report’, x, z, p, tmodelstat;
This code saves the results of a run in to GDX files input.gdx and report.gdx in a results subdirectory.
After the program has executed the 27 runs of t.gms it executes some Python code that walks recursively
through the directory tree and merges GDX files it finds in a results folder in the leaf nodes percolates
the results up in the tree by calling gdxmerge on each high node level. The Python function os.walk
with argument topdown=False ensure the walking of the tree in the correct order. The complete example
can be found in the GAMS Model Library in model [scenmerge]:


6.24 GDXMRW

Interfacing GAMS and MATLAB. This document briefly describes GDXMRW (GDX-Matlab Read/Write), a suite of utilities to exchange data between GAMS and MATLAB. The software gives MATLAB users the ability to use all the optimization capabilities of GAMS, and allows visualization of GAMS models directly within MATLAB. The most recent version of GDXMRW is included as part of the current GAMS Distribution.

6.24.1 Introduction

Optimization is becoming widely used in many application areas as can be evidenced by its appearance in software packages such as Excel and MATLAB. While the optimization tools in these packages are useful for small-scale nonlinear models (and to some extent for large linear models), the lack of a capability to
compute automatic derivatives makes them impractical for large scale nonlinear optimization. In sharp contrast, modeling languages such as GAMS and AMPL have had such a capability for many years, and have been used in many practical large scale nonlinear applications.

On the other hand, while modeling languages have some capabilities for data manipulation and visualization (e.g., Rutherford’s GNUPLOT), specialized software tools like Excel and MATLAB are much better at these tasks.

This paper describes a link between GAMS and MATLAB. The aim of this link is two-fold. Firstly, it is intended to provide MATLAB users with a sophisticated nonlinear optimization capability. Secondly, the visualization tools of MATLAB are made available to a GAMS modeler in an easy and extendable manner so that optimization results can be viewed using any of the wide variety of plots and imaging capabilities that exist in MATLAB.

In order to enable this link between GAMS and MATLAB, we have implemented MATLAB callable functions that can efficiently import and export data to and from GAMS through GDX files. The simplest read and write functions, *irgdx* and *iwgdx*, deal with indexed parameters. Without getting into their precise meaning, these parameters are essentially indexed in each dimension by the sequence of integers from 1 to the size of that dimension. As an example of the read function, the following command in MATLAB will store the matrices A and B into the caller workspace after reading from the file *foo1.gdx*:

```matlab
>> irgdx('foo1','A','B');
```

Similarly, the call

```matlab
>> iwgdx('foo2','C','D');
```

would write the matrices C and D (located in the MATLAB workspace) as indexed parameters into a file named *foo2.gdx*. Note that, many of the examples found in this manual are also part of the GAMS data utilities models library, referred to here as *datalib*. The statements above can be found in datalib example *gdxmrw_intro02_init*. For reading and writing more complex data such as sets, variables, equations, and non-indexed parameters, we can use the more sophisticated functions *rgdx* and *wgdx*. Further descriptions of these functions together with advanced use of *irgdx* and *iwgdx* are detailed in the rest of this paper.

In Section Data Transfer, we discuss the data transfer utilities that allow importing and exporting data between MATLAB and GDX files: *irgdx*, *iwgdx*, *rgdx*, *wgdx*. In Section Extended use, we give a few examples of the MATLAB and GAMS interface. In APPENDIX A - Configuring GDXMRW, we provide information about configuring GDXMRW and testing the utilities. In APPENDIX B - Utility functions: gdxWho and gdxInfo, we describe additional utility functions, *gdxWho* and *gdxInfo*, that allow viewing contents of GDX files in the MATLAB console. Finally, in APPENDIX C - Calling GAMS model from MATLAB, we discuss the *gams* function that with a single call initializes a GAMS model with MATLAB data, executes GAMS on the model, and returns results back into MATLAB.

### 6.24.2 Data Transfer

This paper describes a suite of tools for exchanging data between GAMS and MATLAB. This data exchange is accomplished via the GDX (i.e. the GAMS Data eXchange) interface and API. There are many advantages to using GDX, including platform independence, space and time efficiency in storing and accessing data, and a guarantee that all GDX data contains no duplicates and is free from any logical or syntax errors that might prevent it from being read into GAMS. The GDX interface is well tested, available to the public, and is the basis for most if not all of the GAMS data utilities.

In this section we discuss four MATLAB routines. The first two, *irgdx* and *iwgdx*, are the subject of sections *irgdx* and *iwgdx* and are used to quickly and simply read indexed parameters from a GDX file into MATLAB and vice versa. For an example use of these functions, a generic quadratic program function that mimics MATLAB’s *quadprog* function is provided in datalib example *gdxmrw_qp3*. The *rgdx* and *wgdx* routines (sections *rgdx* and *wgdx*) are more sophisticated versions of the first two that can read and write more general GDX data, e.g. sets, variables, equations, and non-indexed parameters. To understand the structure of this GDX data, the material in section Indexing with labels (UELS) is essential.
6.24.2.1 irgdx

irgdx is a specialized MATLAB function to do an efficient import of an indexed parameter from a GDX file. The irgdx call will not read non-indexed parameters; it can only read data recognized as an indexed data type. If a GDX file consists of both indexed and non-indexed data, irgdx can still read the indexed data. To see whether particular parameters in a GDX file are indexed, the gdxWhos function described in APPENDIX B - Utility functions: gdxWhos and gdxInfo can be used.

The syntax and functionality of irgdx closely resembles that of the MATLAB load function to import MATLAB formatted data, i.e. data stored in MAT files. In Basic syntax and Load symbols into output structure we describe the basic modes of operation where the data read from GDX are either stored in the caller workspace or into a MATLAB structure on the left-hand side of an assignment. In MATLAB sparse form, we describe an optional specification that allows read results to be stored in MATLAB sparse form. Finally, in Subsection Renaming, we describe a simple syntax that allows the renaming of variables/parameters without the need to make expensive copies.

6.24.2.1.1 Basic syntax  The basic syntax for irgdx is

\[
\text{irgdx(} \text{'gdxFileName'}, \text{'sym1'}, \text{'sym2'}, ..., \text{)};
\]

The above call will read the indexed parameters named sym1, sym2, and so on from the GDX file whose name is specified in the first argument and store the results in the MATLAB caller workspace. Only the GDX name argument is mandatory. If only this argument is specified (i.e. no symbol names are provided) then all of the indexed parameters stored in the GDX file will be loaded into the workspace. The GDX name can be specified with or without the '.gdx' extension. Note that all of the input arguments must be specified in string form.

As an example of the above syntax, we can read the scalar a0, the vector a1, and the matrix a2 from the file idx1_.gdx with the following command:

\[
\text{>> irgdx(} \text{'idx1_'}, \text{'a0'}, \text{'a1'}, \text{'a2'});\]

The three symbols are stored as MATLAB variables a0, a1, and a2 in the caller workspace. If we want to read all the symbols from the file idx1_.gdx, we simply call irgdx with only the file name:

\[
\text{>> irgdx(} \text{'idx1_'});\]

6.24.2.1.2 Load symbols into output structure  An alternative to storing the results in the MATLAB caller workspace is to return the results in a MATLAB structure. Here, the syntax is:

\[
s = \text{irgdx(} \text{'gdxFileName'}, \text{'sym1'}, \text{'sym2'}, ..., \text{)};
\]

This call will return the indexed parameters named sym1, sym2, and so on in the structure s, with fields s.sym1, s.sym2, and so on containing the values of the respective indexed parameters. The input arguments must all be in string form. Only the GDX name is mandatory; if only this argument is specified, all of the indexed parameters stored in the GDX file will be returned in the output structure. The GDX name can be specified with or without the .gdx extension.

For example, the following call returns the values of parameter a2 in the structure s:

\[
\text{>> irgdx(} \text{'idx1_'}, \text{'a2'});
\]
>> s = irgdx('idx1_','a2');
>> s.a2

ans =
  50  50
  50  50

To return all the indexed parameters in the fields of the structure s, we would simply call \texttt{irgdx} with only the GDX name:

>> s = irgdx('idx1_');

See datalib example \texttt{gdxmrw_irgdx01_init}.

6.24.2.1.3 MATLAB sparse form  By default, \texttt{irgdx} will store results in MATLAB dense form. However, it is possible to use MATLAB sparse form for parameters with dimension less than or equal to 2; MATLAB's sparse storage scheme cannot handle matrices with more than 2 dimensions. Using sparse storage will allow for efficient import of especially large sparse indexed parameters. Note that in this context \texttt{sparse} does not refer to data represented in the form \([i,j,...,val]\) but rather to MATLAB's internal sparse storage scheme. To store a particular symbol in MATLAB sparse form, one can simply append \texttt{'s'} to that symbol's name in the \texttt{irgdx} call. For example, the following call will store the parameter \texttt{a2} into the caller's workspace in sparse form:

>> irgdx('idx1_','a2:s');

Note that if we want to store \texttt{all} the indexed parameters from a specified file in MATLAB sparse form, we would need to specify each symbol individually in order to append the \texttt{'s'} to each symbol's name.

6.24.2.1.4 Renaming  The details of this section are rather involved; it can be skipped without loss of continuity.

While an \texttt{irgdx} call will typically store results in the caller workspace or create field names in the output structure using the symbol names from the GDX file, it is possible to rename the outputs in MATLAB without making potentially expensive copies. To rename a symbol, we can take advantage of MATLAB's default copy-on-write mechanism: when an assignment occurs, the values assigned are not actually copied until one of the values (the original or the copy) is actually changed. For example, after executing the following two lines of code, the variable \texttt{a2\_new} points to the same memory location as \texttt{a2} and is not a separate copy of \texttt{a2}:

```matlab
>> irgdx('idx1_','a2');
>> a2\_new = a2;
```

If however the value of \texttt{a2\_new} were changed after executing the above lines, MATLAB would then need to make a separate copy, at the cost of memory and time. Now, the command

```matlab
>> clear a2;
```

immediately following the above code would complete the rename of \texttt{a2} to \texttt{a2\_new} as desired. Once \texttt{a2} is cleared, we can change \texttt{a2\_new} without needing to make a copy. Similarly, we can do a rename when we have an output structure:
To convince ourselves that this code indeed does not require a copy, we can run the commands in the debug output format. That is, immediately after the assignment of \( s.a2 \) to \( s.a2\_new \) in the above code (before using the rmfield function), we can run the following commands:

```matlab
>> format debug;
>> s.a2

Structure address = 8c1eda0
m = 2
n = 2
pr = 75fa88a0
pi = 0
  50  50
  50  50
```

```matlab
>> s.a2\_new

Structure address = 8c1eda0
m = 2
n = 2
pr = 75fa88a0
pi = 0
  50  50
  50  50
```

Note that the pointer pr is the same for both outputs, implying that MATLAB does not make a separate copy prior to a write. A similar test can also be done when parameters are stored in workspace variables rather than a structure.

### 6.24.2.2 iwgdx

`iwgdx` is a function that creates a GDX file of indexed parameters from MATLAB data. Since `iwgdx` writes only indexed parameters to GDX, the input MATLAB data is simplified: no labels are required or implied. The input matrices can be stored in the usual (dense) scheme or using the MATLAB sparse scheme: `iwgdx` detects and handles the two cases automatically. Note that matrices represented in \([i,j,...,val]\) form are not acceptable as `iwgdx` input.

While the `iwgdx` function is patterned after the `save` function in MATLAB, there are important differences. Firstly, if only the file name is specified, the `save` function stores all variables in the caller workspace, while `iwgdx` creates an empty GDX file. The behavior of `iwgdx` in this case also differs from that of `irgdx`, which reads all parameters when only the file name is specified. Secondly, `iwgdx` has an additional pass by reference and renaming syntax, in which the parameter string name and values are passed as two consecutive arguments. In Subsection Basic syntax, we describe the basic syntax for `iwgdx`. In Subsection Pass by reference syntax, we introduce the pass by reference and renaming syntax. Finally, in Subsection Dimensionality specification, we describe an optional dimensionality specification that allows symbols to be written with a larger dimensionality than the default.
6.24.2.2.1 Basic syntax The basic syntax for *iwgdx* is:

```
iwgdx('fileName','sym1','sym2',...);
```

The above call will write the values of the variables *sym1*, *sym2*, and so on in the MATLAB caller workspace into a GDX file with the name given by the first input argument. The file name can be specified with or without the '.gdx' extension. If a GDX file with the same name already exists, it will be overwritten. Note that a call with a single input argument (the GDX name) will raise a warning and will create an empty GDX file. This contrasts to the MATLAB save function, which writes all of the workspace variables when none are specified. In the basic form described here, all of the *iwgdx* input arguments are strings.

To illustrate, suppose the matrices *a2* and *a3* exist in the MATLAB caller workspace. We can write the results of these matrices into a file test.gdx with the following call:

```
>> iwgdx('test','a2','a3');
```

If the file test.gdx already exists, it will be overwritten. Specifying only the file name will create an empty GDX file:

```
>> iwgdx('test');
Warning: an empty gdx file was created.
```

6.24.2.2.2 Pass by reference syntax When using the basic *iwgdx* syntax, a copy of the workspace variable to be written to GDX is made as part of the call. This is unavoidable: the MATLAB executable (MEX) interface only provides functions that return copies of workspace variables, most likely to avoid overwriting or corrupting data. However, an alternative, more efficient approach is possible by passing the numeric data as an argument. Essentially, the pointer to the data values are passed by reference and no copy is made. This could be especially useful when writing a large amount of data. An additional benefit of this syntax is the ability to write GDX parameters with different names than used in the MATLAB caller workspace. For example:

```
>> iwgdx('test','s1',s1Mat,'s2',s2Mat);
```

In the above command, *s1* and *s2* are strings holding the GDX parameter names, while *s1Mat* and *s2Mat* are matrices containing the values to store. We can also use a mix of the basic syntax with the pass by reference syntax. For example:

```
>> iwgdx('test','anew',a,'b','c',c);
```

This call would save matrix *a* as anew in GDX without making a copy, would internally make a copy of *b* while saving *b* to GDX, and would save *c* to GDX without renaming or making a copy.

We can do a timing test to see the performance difference between the basic syntax and the pass by reference syntax. The following commands create a 5000x5000 dense matrix consisting of random values in the workspace.

```
>> clear;
>> randMat = rand(5000);
```

First, we do a timing test using the basic syntax:
Now, we do a timing test using the pass by reference syntax:

```matlab
>> delete test.gdx; % delete file if it exists
>> tic;
>> iwgdx('test','randMat');
>> t1 = toc
```

```
t1 = 
5.3346
```

For the above example, the improvement in time performance is about 3%. Of course, the pass by reference call will also use only the half the memory compared to the basic call. We can expect further improvement in performance time and memory use for even larger data.

### 6.24.2.2.3 Dimensionality specification
It is possible to specify the number of dimensions (i.e. dimensionality) for the symbol written to GDX by appending :n to the variable/symbol name, where n is the desired dimensionality of the GDX symbol. This feature is motivated by two quirks of the MATLAB environment. Firstly, all scalars and vectors are stored in MATLAB as 2-dimensional matrices. For example:

```matlab
>> s0 = 100
>> s1 = [ 100 ]
```

results in two variables with identical storage schemes: 1x1 matrices. In the MATLAB environment this isn't a problem: things behave as you would expect them to, and the `isscalar`, `isvector`, and `ismatrix` calls are available to interrogate MATLAB about how it views variables. However, in GDX there is a distinction between a scalar (something with 0 dimensions), a parameter with 1 dimension and length 1, and a 1x1 parameter. We need to be able to create GDX files containing any or all of these.

Secondly, MATLAB "flattens" all variables by removing trailing dimensions whose size is 1. For example, after executing

```matlab
>> B = ones(2,2,2)
>> C = ones(2,2,2,1,1)
```

B and C will be identical 3-dimensional MATLAB arrays, yet we need to be able to create a 2x2x2x1x1 indexed parameter in GDX.

By default, `iwgdx` creates GDX parameters that are consistent with the MATLAB view of the data passed in. For example, executing
results in indexed parameters with 0, 1, and 2 dimensions, respectively, being written to GDX. However, if we want to write d0 as a vector or matrix or higher-dimensional array, we need to use the optional syntax to specify the dimensionality of the resulting symbol in GDX. For example:

```matlab
>> d0 = pi;
>> p1 = d0;
>> d1 = pi*ones(3,1);
>> p2 = d1;
>> d2 = pi*ones(3,3,1)
>> iwgdx('pp','d0','p1:1','d1','p2:2','d2','p3:3',d2)
```

will write the following symbols to GDX:

- The 0-dimensional symbol d0. This is the default behavior, consistent with the MATLAB view that d0 is a scalar.
- The 1-dimensional symbol p1. The scalar variable p1 was promoted to a 1-dimensional symbol by adding an additional singleton dimension.
- The 1-dimensional symbol d1. This is the default behavior, consistent with the MATLAB view that d1 is a vector.
- The 2-dimensional symbol p2. The vector variable p2 was promoted to a 2-dimensional symbol by adding an additional singleton dimension.
- The 2-dimensional symbol d2. This is the default behavior, consistent with the MATLAB view that d2 is a matrix, i.e. the final singleton dimension is just removed.
- The 3-dimensional symbol p3. The matrix variable d2 was promoted to a 3-dimensional symbol by adding an additional singleton dimension. Independently, call-by-reference was used to rename d2 to p3.

Note that the dimensionality specified must always be a promotion, i.e. the dimensionality of the resulting GDX symbol is only increased from what it would be by default.

See datalib example `gdxmrw_iwgdx01_init`.

### 6.24.2.3 Indexing with labels (UELs)

To this point we have been looking at functions to read (`irgdx`, Section `irgdx`) and write (`iwgdx`, Section `iwgdx`) indexed parameters from and to GDX. Indexed parameters are convenient since their structure is essentially identical to that of MATLAB matrices. This structure can be encapsulated very simply as the number of dimensions and the size or extent of each dimension. Using indexed parameters, we do not need to be very concerned with the structure of the data since little structure exists. However, there is much more to GDX data than indexed parameters. If we want to read and write GDX data in more generality we will need to understand how labels or strings are used to reference GDX data and how these labels are organized within GDX.

In general, GAMS data is referenced with labels instead of with numbers, so that one references `demand('chicago')` instead of `demand(2)` in a GAMS model. These labels are also called Unique Element Labels, or UELs. The collection of UELs used in a model or in a GDX file is ordered internally...
and often referred to as the universe of UELs. For efficiency, it is not necessary to use labels internally in GDX or when using the GDX API. Instead, a correspondence or mapping between integers and labels is established initially and/or built up as labels are introduced, so that integers can be used in place of the UELs that reference the data. It is important to keep in mind that the labels are the key thing in referencing GDX data: when integer maps are used the integers are only used to efficiently represent the labels.

A similar scheme mapping integers to labels is used in the rgdx and wgdx routines for reading and writing general GDX data. In addition to the actual data values being stored, there will be a mapping passed to allow integers to be mapped to labels and vice versa. In some cases, where no mapping is passed and data are written to GDX, a default mapping (1 to '1', 2 to '2', etc.) may be used. When reading, the default mapping to use when passing back data is the universe mapping from the GDX, but it is possible to apply a filter. A filter can reduce the amount of data returned and also change the order of that data.

6.24.2.4 rgdx

rgdx is a MATLAB utility to import data from a GDX file. It takes structural input and returns data back in the form of a structure. This is a very flexible routine as it gives user control over the output data structure. rgdx can read a set/parameter/equation/variable from a GDX file and display results in either full/dense or sparse form. A user can also perform a filtered read to read only certain specific elements of a symbol. It can also perform compression to remove extra zeros.

This routine can take up to two arguments. The first argument is a string input containing the GDX file name. It can be with or without the '.gdx' file extension. If you call this routine with only the GDX file name as an argument then the 'uels' field of output structure will be the global UEL of the GDX file and the rest of the fields of the output structure will be NULL. The second argument is a structure input containing information regarding the desired symbol. The syntax for this call looks like this:

```matlab
x = rgdx('fileName', structure);
```

As an example, we read a 3D parameter, 'test3' from 'sample.gdx'. Here we display this parameter in full format but without redundant zeros:

```matlab
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)
```

```matlab
x =

    name: 'test3'
    type: 'parameter'
    dim: 3
    val: [4x2x2 double]
    form: 'full'
    uels: {{1x4 cell} {1x2 cell} {1x2 cell}}

>> x.val
```

```matlab
ans(:,:,1) =
     3     4
     4     5
     5     6
     6     7
```
In the following subsections we will explain the input and output structures. Please note that except for the 'name' and 'uels' fields, all other string fields take case insensitive input. All boolean fields can also be entered as string values as well.

6.24.2.4.1 Input structure
To read a symbol from a GDX file we just need to know its name in string format. Thus, the only mandatory field of the input structure is 'name'. e.g.

```matlab
>> s.name = 'test3';
```

There are several other optional fields of the input structure that give user more control over the output structure. These optional fields are as follows:

1. form
   This field represents the form of the output data. Output data can be either in 'full' or 'dense' form or it can be in [i, j, ... , val] sparse form. We will label [i, j, ... , val] as 'sparse'. A user can enter it as string input with value 'full' or 'sparse'. e.g.
   ```matlab
   >> s.form = 'full';
   ```

   By default the data will be in 'sparse' format. Note that this sparse format differs from MATLAB's internal sparse storage scheme that we referred to in prior sections for the irgdx and iwgdx functions.

2. compress
   By default the uels in the output structure will be a global UEL of the GDX file and the 'val' field data will be indexed to this UEL. The rgdx routine allows a user to remove rows and columns with all zeros from the 'val' data matrix and re-indexes the uels accordingly. This is called compression of the data. This can be achieved by setting compress as true in the input structure. Valid values for this field are true and false, either in logical form or in string form. e.g.
However, we note that compressing the data can be dangerous because the size of the matrix that is read can be incorrect. Essentially, all zero rows and columns are removed, including those that might actually be part of the data values in the symbol matrix.

3. uels

This input field is used to perform a filtered read, i.e. output data matrix will contain values only corresponding to the entered uels. Filtered read is very useful if user just wants certain specific set of data. Uels should be entered in cell array form. It has to be in 1xN form with each column being a cell array representing the uels for that dimension. Each column can have strings, doubles or combinations of both. It also allows a user to enter double data in shorthand notation or a 1 x N matrix. For example, in the previous example we can perform a filtered read to get data corresponding to only the '1&prime,' '3' elements of the first index of the parameter 'test3'. The following function is handy when one needs to generate a UEL listing for the input structure:

```matlab
>> guel = @(s,v) strcat(s,strsplit(num2str(v)));
```

Using the above function, we can create a listing of strings consisting of the string s appended to each number in the array v. Thus, instead of using the command

```matlab
>> s.uels = {{'1', '3'}, {'j1', 'j2'}, {'k1', 'k2'}};
```

we can conveniently use the command

```matlab
>> s.uels = {guel('', [1, 3]), guel('j', 1:2), guel('k', 1:2)};
```

The benefit of using the latter command will be more apparent when creating many elements in the listing. Now, as an example, suppose we would like to do a filtered read on the parameter called test2 in sample.gdx. We could use the following commands:

```matlab
>> s.name = 'test3';
>> s.form = 'full';
>> s.compress = false;
>> s.uels = {guel(' ', [1, 3]), guel('j', 1:2), guel('k', 1:2)};
>> x = rgdx('sample', s)
```

```matlab
x =

    name: 'test3'
    type: 'parameter'
    dim: 3
    val: [2x2x2 double]
    form: 'full'
    uels: {{1x2 cell} {1x2 cell} {1x2 cell}}
```

```matlab
>> x.val
```

```matlab
ans(:,:,1) =
    3   4
    5   6
```

```matlab
ans(:,:,2) =
    4   5
    6   7
```
Here it should be noted that we turned off compression while performing the filtered read. This is necessary because the filtered read will give data in accordance with the entered uels and the output uels will be the same as the input uels; thus compression is not possible.

4. field
This field is required when variables or equations are to be read from a GDX file. Sets and parameters in the GDX file do not have any field value but variables and equations have 5 fields namely, level, marginal, lower, upper, and scale. Thus, it may be useful to enter field as an input when reading an equation or a variable. A user can enter it as a string with valid values being 'l/m/up/lo/s'. e.g.

```
>> s.field = 'm';
```

By default, the output will be the level value of a variable or an equation.

5. ts
This represents the text string associated with the symbol in the GDX file. If a user sets this field to be 'true', then the output structure will have one more string field 'ts' that contains the text string of the symbol. e.g.

```
>> s.ts = true;
```

6. te
GAMS allows a modeler to enter text elements for a set. Similarly to the 'ts' field, if a user sets 'te' to be true in the input structure, then the output structure will contain one more field representing the text elements for that symbol. Please note that text elements only exist for 'sets'. e.g.

```
>> s.te = true;
```

6.24.2.4.2 Output Structure
As mentioned earlier, output of the rgdx routine will be in structure form. This structure is very similar to the input structure. To get information regarding any symbol, we always need to display its basic characteristics, such as its name, type, value, uels, form, etc. An output structure will always have these fields:

1. name
   It is same as that entered in the input structure name field, i.e., the symbol name in the GDX file.

2. val
   It represents the the value matrix of the symbol. To save MATLAB memory by default it will be in 'sparse' format. e.g.

```
>> s = rmfield(s, 'form');
>> s

s =
    name: 'test3'
    compress: 0

>> x = rgdx('sample', s)

x =

    name: 'test3'
    type: 'parameter'
    dim: 3
    val: [16x4 double]
    form: 'sparse'
    uels: {{ix8 cell} {ix8 cell} {ix8 cell}}
Here \texttt{val} is a 16x4 double matrix. As it is a parameter; thus the last column of the sparse matrix will represent the value and the rest (i.e. the first three columns) will represent its index. Please note that in the case of a 'set', the number of columns in the sparse matrix will be equal to its dimension, i.e., it will not have a column representing its value. Here, the presence of each row in the output '\texttt{val}' field corresponds to the existence of a set element at that index. When a 'full' matrix output is specified, a 1 represents existence of a set element and a 0 otherwise.

3. form
   It represents the format in which the '\texttt{val}' field is being displayed. As mentioned earlier it can be either in 'full' or 'sparse' form.

4. type
   While reading a symbol from a GDX file it is often very useful to know its type. The \texttt{rgdx} routine is designed to read set, parameter, variable and equation. This field will store this information as a string.

5. uels
   This represents the unique element listing of the requested symbol in the form of a cell array. It is a 1 x N cell array, where N is the dimension of the symbol. Each column of this array consists of string elements. By default, the output uels will be the same as the global uel of the GDX file, but it can be reduced to element specific local uels if compress is set to be true in the input structure. If a user is using a filtered read, i.e. calling \texttt{rgdx} with input uels, then the output uels will be essentially the same as the input uels.

6. dim
   It is a scalar value representing the dimension of the symbol.
   Apart from these necessary fields there are a few additional fields as well. They are as follows:

7. field
   If we are reading variables or equations, then it becomes useful to know which field we have read, i.e., \texttt{l/m/up/lo/s}. This information is displayed via this field in the form of a string.

8. ts
   It displays the explanatory text string associated with the symbol. This field only exists in the output structure if the 'ts' field is set as 'true' in the input structure.

9. te
   It is an N dimensional cell array representing the text elements associated with each index of the set. This field only exists in the output structure if the 'te' field is set as true in the input structure and the symbol is a set.

See datalib example \texttt{gdmxrws\_rgdx01\_init}.

### 6.24.2.5 \texttt{wgdx}

\texttt{wgdx} is a MATLAB routine to create a GDX file containing data from MATLAB. Similar to the \texttt{rgdx} routine, it takes a structure input and can write multiple symbols into a single GDX file with one call. The first argument is the file name of the GDX file to be created in string format; it can be with or without the '.gdx' file extension. The rest of the arguments are structures, each containing data for different symbols to be written into the GDX file. The syntax for the call is:

```
>> wgdx('fileName', s1, s2 ...);
```

If the GDX file already exists in the MATLAB current directory, \texttt{wgdx} will overwrite it; otherwise a new file will be created. After a successful run, it doesn't return anything back into MATLAB. Most of the fields of its input structures are the same as those of the \texttt{rgdx} output structure. In the example below, we use the \texttt{wgdx} routine to create \texttt{foo.gdx} containing a set 'l' and a parameter 'par'.

---

---
The equivalent code in GAMS to create the above set \( l \) is:

```gams
Set
   a / i1*i3 /
   b / j1*j2 /
   l(a,b);

l(a,b) = yes;
```

In the next subsection we will explain the input fields in detail.

### 6.24.2.5.1 Input Structure

The necessary fields in an input structure to represent a symbol are given below:

1. **name**
   - It is a string representing the name of the symbol.

2. **val**
   - It represents the value matrix of the parameter or set. It can be entered in either full or sparse format, whichever is convenient to the user; the corresponding format must be specified in the \( \text{form} \) field. By default the value matrix is assumed to be in sparse format.

3. **type**
   - It is a string input to specify the type of the symbol. The \text{wgdx} routine can write a set or parameter into the GDX file. In the previous example, we didn’t specify the type for structure \( s \) because by default it is assumed to be a set.

4. **form**
   - This is a string input representing the format in which the val matrix has been entered. By default it is assumed that the data is specified in sparse format.

5. **uels**
   - Similar to the \text{rgdx} uels field, this represents the local unique element listing of the symbol in an \( 1 \times N \) cell array form. Each column of this cell array can contain string or double or both. Again we can make use of a handy function to create a UEL listing as mentioned previously in the section about \text{rgdx}:

   ```gams
   >> guel = @(s,v) strcat(s,strsplit(num2str(v)));
   >> s.name = 'l';
   >> s.uels = {guel('i',1:20),guel('j',1:40)};
   >> wgdx('foo',s);
   ```

   As an example, we create a set using this function and the \text{wgdx} routine:

   ```gams
   >> s.name = 'l';
   >> s.uels = {guel('i',1:20),guel('j',1:40)};
   >> wgdx('foo',s);
   ```

   The above code will create \texttt{foo.gdx} that contains a 2 dimensional set \( l \) with set elements for each of the specified uels. If a user would like to create a set with set elements only at specified indices, one could do so by entering the indices in the val field. e.g.
Now the above would result in a set with only elements existing in the indices specified in the `val` field. If a user enters a structure with only two fields, name and uels, as in the example given in the introduction of this section (structure s), then `wgdx` will create a full set corresponding to the global uels.

The optional fields are:

6. **dim**
   This field is useful when a user wants to write a zero dimensional or 1 dimensional data in full format. As every data matrix in MATLAB is at least 2D, it becomes necessary to indicate its dimension for writing purposes.

7. **ts**
   This is the text string that goes with the symbol. If nothing is entered then 'MATLAB data from GDXMRW' will be written in the GDX file.

See datalib example `gdxmrw_wgdx01_init`.

### 6.24.3 Extended use

In this section, we will discuss a few examples of the MATLAB and GAMS interface. We will give a simple example of a nonlinear optimization problem that would benefit from this capability and describe the steps that are needed in order to use our interface in this application.

- **Special values**
  Following example shows how special values are handled by this interface. It can be seen that `rgdx` can retrieve all these values from GDX file and display them appropriately in MATLAB.

```matlab
>> s.name = 'special';
>> s.form = 'full';
>> s.compress = true;
>> x = rgdx('sample', s)

x =

    name: 'special'
    type: 'parameter'
    dim: 1
    val: [4x1 double]
    form: 'full'
    uels: {{1x4 cell}}

>> x.val

ans =

    -Inf        NaN      3.141592653589793         Inf
```
• Variables and Equations
In an optimization problem, we are not only interested in level value of variables and equations but also in their marginal values, lower and upper bounds. This interface gives its user ability to read any of these values into MATLAB. By default rgdx and gams routines will read the level value of equations and variables but this can be changed very easily by using 'field' in input structure. In gams call user can also specify this in "$set matout" statement. e.g.

$set matout "'matsol.gdx', x.m, dual.lo=dl ";

In this case the marginal value of variable 'x' will be read and lower bound of dual variable will be read and stored in 'dl'.

• Text string and Text elements
GAMS allows its user to enter text string and explanatory text elements and all GDX file contain this information as well. Following example shows how to get these text elements in MATLAB.

```matlab
>> s1.name = 'el';
>> s1.te = true;
>> s1.ts = true;
>> s1.compress = true

s1 =
    name: 'el'
    te: 1
    ts: 1
    compress: 1

>> z = rgdx('sample', s1)

z =
    name: 'el'
    type: 'set'
    dim: 2
    val: [3x2 double]
    form: 'sparse'
    uels: {{1x2 cell} {1x2 cell}}
    ts: 'This is 2D set with text elements'
    te: {2x2 cell}

>> z.te

ans =

    'element1' 'element2'
    '2.j1' []

>> z.val

ans =

    1 1
    1 2
    2 1
```

• String elements
One piece of information that may be needed within MATLAB is the modelstat and solvestat values generated by GAMS for the solves that it performed. This is easy to generate, and an example is
given in do_status.m. This example is generated by taking the standard gamslib transport example, and adding the following lines to the end:

```gams
set matout 'matsol.gdx', returnStat, str ;
set stat / modelstat, solvestat /;
str / 'grunt', '%system.title%' /;
parameter returnStat(stat);
returnStat('modelstat') = transport.modelstat;
returnStat('solvestat') = transport.solvestat;
execute_unload %matout%;
```

Note that the relevant status numbers are stored in GAMS into the parameter returnStat which is then written to matsol.gdx and read back into MATLAB using the rgdx call.

```matlab
>> gamso.output = 'std';
>> gamso.form = 'full';
>> gamso.compress = true;
>> s = gams('trnsport')
```

See datalib example gdxmrw_ext01.init.

- Advanced Use: Plotting

One of the key features of the GAMS/MATLAB interface is the ability to visualize optimization results obtained via GAMS within MATLAB. Some simple examples are contained with the program distribution. For example, a simple two dimensional plot with four lines can be carried out as follows. First create the data in GAMS and export it to MATLAB using the gams routine (see APPENDIX C - Calling GAMS model from MATLAB for a detailed description of this routine).

We make an assumption that the user will write the plotting routines in the MATLAB environment. To create the plot in MATLAB, the following sequence of MATLAB commands should be input (saved as do_plot.m).

```matlab
gamso.output = 'std';
gamso.compress = true;
gamso.form = 'full';
[a,xlabels,legendset,titlestr] = gams('simple');
figure(1)
% Plot out the four lines contained in a;
% format using the third argument
plot(a,'+-');
% only put labels on x axis at 5 year intervals
xtick = 1:5:length(xlabels);
xlabels{1} = xlabels{1}(xtick);
set(gca,'XTick',xtick);
set(gca,'XTickLabel',xlabels{1});
% Add title, labels to axes
title(titlestr{1});
xlabel('Year -- time step annual');
ylabel('Value');
% Add a legend, letting MATLAB choose positioning
legend(legendset{1},0);
% match axes to data, add grid lines to plot
axis tight
grid
```

The data is created using the following gams code.
$title Examples for plotting routines via MATLAB

$set matout "'matsol.gdx', a, t, j, sys ";

Set
   sys / '%system.title%' /
   t / 1990*2030 /
   j / a, b, c, d /
;
Parameter a(t,j);
a("1990",j) = 1;
loop(t, a(t+1,j) = a(t,j)*(1 + 0.04*uniform(0.2,1.8))););

Parameter year(*);
year(t) = 1989 + ord(t);

* Omit some data in the middle of the graph:
a(t,j)$((year(t) > 1995)*(year(t) <= 2002)) = na;

execute_unload %matout%;

The following figure is an example created using this utility (and the MATLAB command print -djpeg simple).

See datalib example GDXMLRPlotting01.

MATLAB supports extensive hard copy output or formats to transfer data to another application. For example, the clipboard can be used to transfer meta files in the PC environment, or encapsulated postscript files can be generated. The help print command in MATLAB details the possibilities on the current computing platform.

Scaling of pictures is also most effectively carried out in the MATLAB environment. The following code is an example of rescaling printed out. Note that the output of this routine is saved as a jpeg file "rescale.jpg".

do.plot;
    fpunits = get(gcf,'PaperUnits');
    set(gcf,'PaperUnits','inches');
    figpos = get(gcf,'Position');
    pappos = get(gcf,'PaperPosition');
    newpappos(1) = 0.25;
    newpappos(2) = 0.25;
    newpappos(3) = 4.0;
    % get the aspect ratio same on the print out
    newpappos(4) = newpappos(3)*figpos(4)/figpos(3);
    set(gcf,'PaperPosition',newpappos),
    print -djpeg100 rescale.jpg
    set(gcf,'PaperPosition',pappos);
    set(gcf,'PaperUnits',fpunits);

Other examples of uses of the utility outlined in this paper can be found in the "m" files:
do,ecl
plot,gon

that are contained in the distribution.
6.24.4 Acknowledgements

The authors would like to thank Alexander Meeraus and Michael R. Bussieck of GAMS corporation for constructive comments on the design and improvement of this tool. Thanks to Rishabh Jain for work on an earlier version.

6.24.5 APPENDIX A - Configuring GDXMRW

6.24.5.1 Installation

This section describes the installation procedure for all types of machines. The following section describes the testing procedure for verifying a correct installation.

First of all, you need to install both MATLAB and GAMS on your machine. For brevity, we will assume that the GAMS system (installation) directory is (for Windows)

\[ C:\GAMS \]

and for non-Windows systems:

\[ /usr/local/gams \]

All of the utilities come as a part of the GAMS distribution, so to use them you have only to add the GAMS directory to the MATLAB path. One way to do this is from the MATLAB command prompt, as follows:

\[ >> \text{addpath } 'C:\GAMS'; \text{savepath}; \]

OR this can be done by following these steps:

1. Start MATLAB
2. Click on 'File' tab.
3. Now click on 'Set Path'
4. Click on 'Add Folder'
5. Select GAMS directory and click 'OK'.
6. Save it and then close it.
6.24.5.2 Testing

The GAMS system comes with some tests that you should run to verify the correct configuration and operation of the GDXMRW utilities. In addition, these tests create a log file that can be useful when things don't work as expected. To run the tests, carry out the following steps.

1. Create a directory to run the tests in, e.g.
   
   ```
   % mkdir \tmp
   ```

2. Extract the test models and supporting files from the GAMS test library into the test directory.
   
   ```
   % cd \tmp
   % testlib gdxmrw03
   % testlib gdxmrw04
   % testlib gdxmrw05
   % testlib gdxmrw06
   ```

3. Execute the GAMS files `gdxmrw03`, `gdxmrw04`, and `gdxmrw06`. The files `gdxmrw03` and `gdxmrw04` test that the `rgdx` and `wgdx` routines are working properly, and `gdxmrw06` test `irgdx` and `iwgdx`. In addition to calling MATLAB in batch mode, they verify that the data are read and written as expected and give a clear indication of success or failure.

4. The GAMS file `gdxmrw05` tests the `gams` MATLAB routine. Like the other tests, it can be run in batch mode. You can also run it interactively by starting MATLAB, making `tmp` the current directory, and running the script `'testinst.m'`.

   ```
   >> testinst
   ```

   In addition to messages indicating success or failure, this test produces a log file `testinstlog.txt` that will be useful in troubleshooting a failed test.

6.24.6 APPENDIX B - Utility functions: gdxWhos and gdxInfo

In this section, we'll describe two utilities, `gdxWhos` and `gdxInfo`, provided with GDXMRW that can be called from the MATLAB command prompt. The `gdxWhos` function is patterned loosely after the MATLAB function `whos` used to query `.mat` files. It provides information about symbols in a specified GDX file. The only input argument is the name of a GDX file, which can be with or without the `.gdx` extension. With no output argument, `gdxWhos` lists the symbols in the specified GDX file in the MATLAB command prompt. When used with an output argument, `gdxWhos` lists the symbols in the specified GDX file in the MATLAB command prompt. When used with an output argument, information about the symbols in the GDX file is returned as an array of structures. This meta-data can be used in a variety of ways and is especially useful when programming.

An example GDXWhos call without an output argument is shown below:

```
>> gdxWhos('idx1_.gdx');
Symbol info of GDX idx1_.gdx
   Index Type  Dim  NRecs  Name
    1 Parameter 0  1  a0
    2 Parameter 1  3  a1(5)
    3 Parameter 2  4  a2(2,2)
    4 Parameter 3  6  a3(3,5,2)
    5 Parameter 10 256  a10(3,5,2,2,2,2,2,2,2,2)
```
The above output indicates that there are five indexed parameters in the file 'idx1.gdx'. The way we can recognize an indexed parameter is by noticing numbered arguments of the parameters under the 'Name' column. For non-indexed data, the arguments will appear either as the name of a set or by a '*'. For example, the first three symbols are non-indexed and the last symbol is indexed in the output from this call:

```matlab
>> gdxWhos('fake.gdx');
Symbol info of GDX fake.gdx

<table>
<thead>
<tr>
<th>Index</th>
<th>Type</th>
<th>Dim</th>
<th>NRecs</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set</td>
<td>1</td>
<td>3</td>
<td>i(*)</td>
</tr>
<tr>
<td>2</td>
<td>Parameter</td>
<td>1</td>
<td>3</td>
<td>a(i)</td>
</tr>
<tr>
<td>3</td>
<td>Set</td>
<td>1</td>
<td>3</td>
<td>d_i_m__3(*)</td>
</tr>
<tr>
<td>4</td>
<td>Parameter</td>
<td>1</td>
<td>3</td>
<td>aa(3)</td>
</tr>
</tbody>
</table>
```

The GDXInfo function is patterned after the `gdxdump` utility in GAMS. It lists and dumps all of the data values for each symbol in the specified GDX file to the MATLAB console. The only input argument is the name of a GDX file, which can be with or without the '.gdx' extension. It accepts no output arguments. It is especially useful to see the entire contents of smaller GDX files. To use the function, we could simply enter a command such as `gdxInfo('idx1')` in the MATLAB command prompt, and the entire data contents would be displayed in the console. Further information about what is displayed can be found in the GAMS documentation of the `gdxdump` utility.

## 6.24.7 APPENDIX C - Calling GAMS model from MATLAB

Until now we have discussed the data Import/Export utility between MATLAB and GAMS. In this section, we will discuss a new MATLAB utility 'gams' that initializes a GAMS model with MATLAB data then executes GAMS on that model and bring the results back into MATLAB. This 'gams' routine is based on the same design as `rgdx` and `wgdx` but instead it does everything in one call. This routine can take multiple input arguments and can return multiple output arguments. Its standard syntax is as follows:

```matlab
>> [x1, x2, x3] = gams('model', s1, s2.., c1, c2..);
```

Here note that the first argument of `gams` is the GAMS model name plus any user specific command line settings. If a user wants to solve the given model (in this case found in `qp.gms`) using a different solver then it can be done by adding that solver to the GAMS model name as "qp nlp=baron". This feature allows a user to change the execution time behavior of the model.

The rest of the input arguments of GAMS are structures. Their positioning is not important. These structures are of two kinds; one is similar to the input structure of `wgdx` and the other structure has just two string fields, name and val. This latter structure is used to set or overwrite values in the model using the "$set" variables syntax of GAMS. We will explain it in detail a later section.

The first step is to generate a working GAMS model. For example, we can set up a simple model file to solve a quadratic program that minimizes $\frac{1}{2} x^T Q x + c^T x$ subject to $A x \geq b$ and $x \geq 0$.

The GAMS model for this quadratic problem is as given in the following code.

```gams
$set matout "'matsol.gdx', x, dual, obj, returnStat ";
Set
   i / 1*2 /
   j / 1*3 /;
```
Alias (j1,j);

Parameter
  Q(j,j1) / 1 .1 1.0
         2 .2 1.0
         3 .3 1.0 /
  A(i,j) / 1 .1 1.0
         1 .2 1.0
         1 .3 1.0
         2 .1 -1.0
         2 .3 1.0 /
  b(i) / 1 1.0
        2 1.0 /
  c(j) / 1 2.0 /;

Variable obj;
Positive Variable x(j);

Equation cost, dual(i);

cost.. obj =e= 0.5*sum(j, x(j)*sum(j1, Q(j,j1)*x(j1))) + sum(j, c(j)*x(j));
dual(i).. sum(j, A(i,j)*x(j)) =g= b(i);

Model qp / cost, dual /;

$if exist matdata.gms $include matdata.gms
solve qp using nlp minimizing obj;
Set stat / modelStat, solveStat /;
Parameter returnStat(stat);
returnStat('modelStat') = qp.modelstat;
returnStat('solveStat') = qp.solvestat;
execute_unload %matout%;

This GAMS qp model can be executed directly at the command prompt using the following command

   gams qp (for Unix/Linux)

or

   gams.exe qp (for Windows)

or the user can simply hit the run button in the GAMSIDE. The optimal value is 0.5. In order to run the same model within MATLAB and return the solution vector x back into the MATLAB workspace, no change is required to the GAMS file. In MATLAB, all you have to do is to execute the following command:

   >> x = gams('qp');
This command will first collect the input structure data and create ‘matdata.gdx’ and ‘matdata.gms’ that contains include statements for the symbols written in a file matdata.gdx. In the previous example there is no structural input, so an empty ‘matdata.gdx’ file will be created and ‘matdata.gms’ will have just have a load statement for the GDX file but no load statements for any symbol. This is done to prevent any undesirable loading of data in the main model if there had already existed a ‘matdata.gdx’ or ‘matdata.gms’ file. After creating these two files then the ‘gams’ routine will execute “gams qp” using a system call. When this model is executed, another file ‘matsol.gdx’ will be created because of the execute_unload statement in the last line of the model. Here it should be noted that any model that you want to execute using the MATLAB gams routine should contain something like

```matlab
$set matout "'matsol.gdx', x, dual, obj, returnStat ";
```

either as the first line, or somewhere near the start of the model file. This is a standard gams $set statement, setting the value of the local variable ‘matout’. The reason to have this statement near the start of the gms file is that the gams routine searches the file from the beginning for "$set matout" in the gms file. As these files can be very large, it is wise to have this statement near the start of the file. In this statement ‘fileName’ is the gdx file name that will be created containing symbols ‘x1’, ‘x2’, etc. These symbols can then be exported to MATLAB. The last line of the model should always be

```matlab
execute_unload %matout%;
```

The purpose of setting the first and last line of the model in this manner is to specify what data the user wants to export to MATLAB in a "header" of the model. As MATLAB does not give any information about the output arguments except the number of expected arguments, we have to specify what data to export to MATLAB in the GAMS model with minimum modification to the existing model. In the previous example, there is only one output argument, thus the gams routine will get data for its first element from the output gdx file and store it in the MATLAB output argument.

If there is more than one output argument, e.g.,

```matlab
>> [x, u] = gams('qp');
```

then the gams routine will read the output gdx file and store its first element information of the GDX file as the first output argument of MATLAB, i.e. ‘x,’ and the second element information of the GDX file in the second output argument of MATLAB, i.e. ‘u’ and so on. If the number of MATLAB output arguments is greater than the number of elements in the GDX file then gams will throw an error.

See datalib example gdxmrw_qp4.

### 6.24.7.1 Input Structure

As mentioned earlier, the gams routine takes input arguments in structured form. It allows two different types of structure input. One contains the symbol data similar to the wgdx input structure, to be exported to the GDX file. The other structure will just have two string fields ‘name’ and ‘value’. Example use:

```matlab
>> s.name = 'Q';
>> s.val = eye(3);
>> s.form = 'full';
>> m = struct('name','m','val','2');
>> [x] = gams('qpmcp',s, m);
```
In this example both 's' and 'm' are structures but 'm' has only two fields and both are strings. The gams routine will use the 's' structure to create a 'matdata.gdx1 file and 'm' to modify the execution command line to include "--m=2" at the end i.e. a command that will executed will be "gams qpmcp --m=2"

The structure 's' is the same as the input structure for wgdx but with two important differences. Firstly, it can be seen in the above example that 's' doesn't have a 'type' field. In wgdx we assume the type to be 'set' by default, but in the gams routine the type is assumed to be 'parameter' by default. The second change is an optional additional input field (in addition to those given in Section Input Structure) called "load".

- load
  It is a string input representing how the corresponding data will be loaded into the GAMS program. Depending on the value of the global option "gamso.input" (see next section) the input data will be read into GAMS in different ways. Suppose the input structure 's' has a 'name' field called 'foo'. By default (where gamso.input = 'compile'), the file matdata.gms will $loadR foo

  The GAMS parameter (or set) foo will be replaced by the data that is in the 'matdata.gdx' container called 'foo'. If the data has been initialized before in the model, this will replace that initial data with the new data from 'matdata.gdx'. The option can also be explicitly set using

  s.load = 'replace'

  There are two other compile time load options, namely 'initialize' and 'merge'. The first is only valid if the parameter values have not been initialized in the GAMS file, otherwise an error is thrown. It uses the GAMS syntax

  $load foo

  The merge option is valid when the GAMS file being run has already initialized the parameter values. The new values in the MATLAB structure 's' are merged into the parameter simply overwriting existing values with the new values given. Explicitly, the 'matdata.gms' file contains the statement

  $loadM foo

  to direct GAMS accordingly.

  Finally, if gamso.input = 'exec', the loading will occur at execution time. In this case, s.load = 'initialize' is not a valid input, the default setting is s.load = 'replace' which carries out

  execute_load "matdata.gdx" foo

  and the alternative setting s.load = 'merge' carries out

  execute_loadpoint "matdata.gdx" foo

  In this way, the data is loaded at execution time and performs an appropriate replace or merge.

6.24.7.2 Global input to change default behavior

Until now we have seen how to specify different input to the gams routine and in this section we will see how to change the default behavior of a gams call. This can be done by creating a structure 'gamso' in the current workspace and adding different fields to that structure. There are currently nine fields that can be set in that structure that affect the behavior of the program. Except the uels field, all other string fields take case insensitive data. These are as follows:
• gamso.output
By default, output of the gams routine will be in structure form but it might be the case that a user is only interested in the data matrix, i.e., the val field of that structure. This can be done by setting gamso.output as 'std'. This will give only the value matrix as output. If this is not set to 'std' then output will be in the structure form described in the wgdx section.

```matlab
>> gamso.output = 'Std';
>> x = gams('qp nlp=baron')
```

```matlab
x =
  0.5000
```

• gamso.input
By default, the interface updates data at compile time. Thus, if execution time updates are made to the parameters before the line '$include matdata.gms$' these may override the data that is provided in 'matdata.gms' (i.e. from the command line). This may not be desirable. If you wish to perform execution time updates to the data, you should set gamso.input to 'exec'.

• gamso.write_data
If this is set to 'no', then all parameters on the call to gams are ignored, except the program name. This is useful for dealing with large datasets. Consider the following invocation:

```matlab
x = gams('largedata','A');
y = gams('resolve','A');
```

The first call generates a file 'matdata.gms' containing the elements of the matrix A for use in the largedata.gms program. The second call rewrites a new 'matdata.gms' file that again contains A. If we wish to save writing out A the second time we can use the following invocation:

```matlab
x = gams('largedata','A');
gamso.write_data = 'no';
y = gams('resolve','A');
clear gamso;
```

or the equivalent invocation:

```matlab
x = gams('largedata','A');
gamso.write_data = 'no';
y = gams('resolve');
clear gamso;
```

• gamso.show
This is only relevant on a Windows platform. This controls how the 'command box' that runs GAMS appears on the desktop. The three possible values are:

- 'minimized' (default): The command prompt appears iconified on the taskbar.
- 'invisible': No command prompt is seen.
- 'normal': The command prompt appears on the desktop and focus is shifted to this box.

• gamso.path
This option is used to specify fully qualified path for the gams executable. This is very useful if you have multiple versions of GAMS installed on your system and want to make sure which version you are running for the gams call. e.g.

```matlab
>> gamso.path = 'C:\Program Files\GAMS23.4GAMS.exe';
```

The output of gams is similar to rgdx but unlike the rgdx gams routine it doesn't take input specific to a particular symbol. Thus it becomes important to implement a way to change the default behavior of the output. This can be achieved by adding following field to the global structure 'gamso'. All these fields behave similar to that described in rgdx and take the same input as of rgdx.
6.25 GDXRANK

A GAMS Utility for Ranking One-Dimensional Numeric Data.

Author

- Thomas F. Rutherford, Department of Economics, University of Colorado
- Paul van der Eijk, GAMS Development Corporation

Date

July, 2003

Source of this document: http://www.mpsge.org/gdxrank/index.html

This utility consists of an executable file, gdxrank.exe, and a GAMS libinclude file, rank.gms. The former resides in the GAMS system directory, and the latter resides in the inclib/ subdirectory of GAMS system.

6.25.1 Usage

6.25.1.1 Usage for GDXRANK

GDXRANK reads one or more one dimensional parameters from a GDX file, sorts each parameter and writes the sorted indices as a one dimensional parameters to the output GDX file.

Usage:

gdxrank inputfile outputfile

Each one dimensional parameter is read from the input file, sorted and the corresponding integer permutation index written to the output file using the same name for the symbol. GAMS special values such as Eps, +Inf and -Inf are recognized.

6.25.1.2 Usage for RANK

$libInclude rank v s r [p]

The first three arguments are required. The last is optional. These are defined as following:
### 6.25.2 General Comments

- RANK only works for numeric data. You cannot sort sets.
- The first invocation must be outside of a loop or if block. This routine may be used within a loop or if block only if it is first initialized with blank invocations ("$libInclude rank" in a context where set and parameter declarations are permitted (See Example 3).
- The following names are used within these routines and may not be used in the calling program:
  
  ```
  rank_tmp    rank_u    rank_p
  ```

- This routine returns rank values and does not return sorted vectors, however rank values are easily used to produce a sorted array. This can be done using computed "leads" and "lags" in GAMS' ordered set syntax, as illustrated in examples 1 and 3 below.

### 6.25.3 GDXRANK Example

In this example we sort a parameter, create a sorted version and verify that the sort worked correctly:

```gams
Set I / i1*i6 /;
Parameter A(I) / i1 +Inf, i2 -Inf, i3 Eps, i4 10, i5 30, i6 20 /;
display A;

* write symbol A to gdx file
execute_unload "rank_in.gdx", A;

* sort symbol; permutation index will be named A also
execute 'gdxrank rank_in.gdx rank_out.gdx';

* load the permutation index
Parameter AIndex(i);
execute_load "rank_out.gdx", AIndex=A;
display AIndex;

* create a sorted version
Parameter ASorted(i);
ASorted(i + (AIndex(i) - ord(i))) = A(i);
display ASorted;
```
* check that the result is sorted
Set C(i);
C(i)=yes$(ord(i) < card(i)) and (ASorted(i) > ASorted(i+1));
display C;
abort$(card(C) <> 0) 'sort failed';

6.25.4 RANK Example

6.25.4.1 Example 1: Rank a vector, and display the data in sorted order

Set
i 'Set on which random data are defined' / a, b, d, c, e, f /
k 'Ordered set for displaying sorted data' / 1*6 /;
Parameter
  x(i) 'Random data to be sorted'
  r(i) 'Rank values'
  s(k,i) 'Sorted data';
x(i) = uniform(0,1);
$libInclude rank x i r
display x;

* Generate a sorted list using the ordered set k.
* This assignment statement illustrates how the rank orders
* can be used to sort output for display in proper order. This
* statement uses GAMS support for computed "leads" and "lags"
* on the ordered set k. The loop is used to improve execution
* speed for larger dimensional sets:

loop(k$sameas(k,"1"),
  s(k+(r(i)-1),i) = x(i);
); option s:3:0:1;
display s;

This example is also part of the GAMS Data Utilities Library, see model [rank01] for reference. It writes the following lines to ex1.lst:

---- 11 PARAMETER x Random data to be sorted
  a 0.172,  b 0.843,  d 0.550,  c 0.301,  e 0.292,  f 0.224

---- 75 PARAMETER s Sorted data
  1.a 0.172
  2.f 0.224
  3.e 0.292
  4.c 0.301
  5.d 0.550
  6.b 0.843
The RANK libinclude can be used to also sort variable levels as the following example shows:

Set
   i 'Set on which random data are defined' / a, b, d, c, e, f /
   k 'Ordered set for displaying sorted data' / 1*6 /;

Variable
  x(i) 'Random data to be sorted'

Parameter
  r(i) 'Rank values'
  s(k,i) 'Sorted data';

x.l(i) = uniform(0,1);

$onDotL
$libInclude rank x i r
display x.l;

loop(k$sameas(k,"1"),
   s(k+(r(i)-1),i) = x(i);
);

option s:3:0:1;
display s;

Before the "$libInclude rank" the dollar control option $onDotL needs to be activated.

6.25.4.2 Example 2: Generate percentiles for a random vector

Set
   i 'Set on which random data are defined' / a, b, d, c, e /
   p 'Percentiles (all of them)' / 0*100 /;

Parameter x(i) 'Random data to be sorted';

* Generate the random data on set i:
  x(i) = uniform(0,1);
display x;

Parameter
  r(i) 'Rank values'
  pct(*) 'Percentiles to be computed' / 20 20.0, median 50.0, 75 75.0 /;

* Generate ranks and compute the specified percentiles (Note that
* the rank array, r, is required, even if the values are not used.)

$libInclude rank x i r pct

* Display three percentiles:
  display pct;

This example is also part of the GAMS Data Utilities Library, see model [rank02] for reference. The random data are displayed as follows in the listing file:
6.25 GDXRANK

----  11 PARAMETER x  Random data to be sorted

a 0.172,  b 0.843,  d 0.550,  c 0.301,  e 0.292

The interpolated percentiles are computed as follows:

----  103 PARAMETER pct  Percentiles

20 0.268,  75 0.550,  median 0.301

The following code evaluates a full set of percentiles, from 1 to 100. The GAMS special value of EPS is used to represent zero in the percentile calculation. (Percentiles between zero and one are not permitted to avoid misunderstandings about how percentiles are scaled.) The code makes use of Tom Rutherfords plot libInclude available at http://www.mpsge.org/gnuplot/index.html

pct(p) = (ord(p) - 1) + eps;
pct("median") = 0;
display pct;

$libInclude rank x i r pct
display pct;

* Plot the results using GNUPLOT:

Set pl(p) / 20, 40, 60, 80, 100 /;
$setGlobal domain p
$setGlobal labels pl
$libInclude plot pct

This is the generated plot:

6.25.4.3 Example 3: Use GDXRANK to report multisectoral Monte Carlo results

One of the most perplexing challenges in economic modeling with GAMS is to present multisectoral results in an easily interpreted format. One simple idea is to present sectoral results in a sorted sequence to make it easier to identify the most seriously affected sectors. The presentation of results in a multisectoral model is made even more challenging when model results are generated for a randomized set of scenarios. A summary of Monte Carlo results involves reporting both mean results and their sensitivity. One means of characterizing the sensitivity of model results is to report functions of the sample distribution such as the upper and lower quartiles.

In this example, I illustrate how gdxrank can be used to help report results from the Monte Carlo analysis of a multisectoral model.

The complete model used as example here is part of the GAMS Data Utilities Library, see model [rank03] for reference. The following extract of that model generates the result we want to look at.
* Determine ranking of sectors by mean impact:
  mean(i) = qvalue(i,"mean");
$libInclude rank mean i meanrank

* The following statement creates a tuple matching the ordered
* set, ki, to the set of sectors, i. In this tuple, the sequence of
* assignments corresponds to increasing mean impacts:
  imap(ki+(meanrank(i)-ord(ki)),i) = yes;

* Evaluate quartiles of sectoral impacts for each sector:
  loop(i,
      x(s) = v(s,i);
  * Load quartile with the perctiles to be
  * evaluated (25th, 50th and 75th):
    quartile(qtl) = qv(qtl);
$ libInclude rank x s r quartile

* Save the quartile values:
  qvalue(i,qtl) = quartile(qtl);
); display qvalue;

Parameter results(ki,i,*) 'Summary of impacts (sorted)';
results(ki,i,"mean")$imap(ki,i) = mean(i);
results(ki,i,qtl)$imap(ki,i) = qvalue(i,qtl);
display results;

The program produces the following display output:

<table>
<thead>
<tr>
<th></th>
<th>q25</th>

### Example 4: Repeated computation of percentiles within a loop

The following code extract shows how to do repeated computation of percentiles within a loop while the data is changing. This is an extract of the model [rank04] from the GAMS Data Utilities Library.
* Do several iterations, computing percentiles in each step:

```
loop(iter,  
  * Substitute a call to the NLP solver by a call to the random  
  * number generator. In many applications, this substitution  
  * produces profoundly more sensible results.  
  *  
  * solve catchment using nlp maximizing max;
```

```
z(week) = uniform(0,1);
```

```
* If you want to retrieve percentile values, you need to reassign  
the percentiles that you wish to retrieve at this point in the  
program. If pct() were not reassigned at this point, the INPUT  
values would correspond to the OUTPUTs from the previous call.  

```
pct(pctl) = pct0(pctl);
```

```
$p  libInclude rank z week rnk pct
```

```
pctval(iter,pctl) = pct(pctl);
```

```
); display pctval;
```

Output:

```
---- 58 Here are the INPUT values of PCT0 and PCT prior to the call to rank:
```

```
---- 58 PARAMETER pct0  Percentiles to be computed
50 50.000,  75 75.000,  80 80.000,  95 95.000
```

```
---- 58 PARAMETER pct  Percentiles to be computed (input) and those values (output)
50 50.000,  75 75.000,  80 80.000,  95 95.000
```

```
---- 153 Here are the values of PCT0 and PCT after the call to rank:
```

```
---- 153 PARAMETER pct0  Percentiles to be computed
50 50.000,  75 75.000,  80 80.000,  95 95.000
```

```
---- 153 Note that rank has changed the OUTPUT value of pct
```

```
---- 153 PARAMETER pct  Percentiles to be computed (input) and those values (output)
50 0.424,  75 0.662,  80 0.712,  95 0.864
```

```
---- 273 PARAMETER pctval  Percentile values in successive iterations
```

```
  50  75  80  95
```
6.25.4.5 Example 5: Use GDXRANK generating percentiles for heterogenous households.

$title Percentile ranking of household expenditure data with heterogenous household size

Set h / 0*100 /;

Parameter
  y(h)  'Aggregate expenditure associated with household type h'
  n(h)  'Number of persons associated with household type h'
  ypc(h)  'Per-capita expenditure of household type h'
  rank(h)  'Rank of household in per-capita expenditure';

* Assign some random values:
  y(h) = uniform(0.2,1.2);
  n(h) = uniform(1,6);
  ypc(h) = y(h)/n(h);

* Assign ranks to household based on per-capita expenditures:
$libInclude rank ypc h rank

* Now determine percentile ranking of the households taking into account
  * differences in numbers of members and household representation:
      Set r 'Temporary set used for ranking' / r0*r100 /;

Parameter
  pcttmp(r)  'Temporary array for computing percentiles'
  pct(h)  'Percentile rankings for households';

Set r0(r) / r0 /;

* First, create an array with households assigned
  loop((r0(r),h), pcttmp(r+(rank(h)-1)) = n(h););
  loop(r,  pcttmp(r) = pcttmp(r) + pcttmp(r-1););
  pcttmp(r) = pcttmp(r)/sum(h, n(h));

loop((r0(r),h), pct(h) = pcttmp(r+(rank(h)-1)););

Parameter ranking 'Ranking of households and expenditures';

  loop((r0(r),h),
      ranking(r+(rank(h)-1),h,"n") = n(h);
      ranking(r+(rank(h)-1),h,"ypc") = ypc(h);
      ranking(r+(rank(h)-1),h,"pct") = pct(h);
  );

display ranking;
This example is also part of the GAMS Data Utilities Library, see model [rank05] for reference. It produces the following output:

<table>
<thead>
<tr>
<th></th>
<th>n</th>
<th>ypc</th>
<th>pct</th>
</tr>
</thead>
<tbody>
<tr>
<td>r0</td>
<td>.43</td>
<td>5.662</td>

</tr>
<tr>
<td>r100</td>
<td>.73</td>
<td>1.053</td>
<td>1.076</td>
</tr>
</tbody>
</table>

### 6.26 GDXRENAME

The GDXRENAME program renames the unique elements in a GDX file using the unique elements from a second GDX file.

#### 6.26.1 Usage

`gdxrename data-file map-file {options}`

The .gdx file extension can be omitted. Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory.

The GDXRENAME utility renames the unique elements in the `data-file` using a two dimensional set called `map` in the `map-file`. The renaming of the unique elements only affects the string stored for each element, and does not change the data order for the symbols in the data-file. Because no data is changing in the data-file, only the strings for the unique elements, these changes are applied to the data-file directly and no new data-file is created.

**data-file = fileName** (default = none)

Name of the file where the renaming is to be applied.

**map-file = fileName** (default = none)

Name of the file where the map set appears containing the renaming tuples.
6.26.2 Options

-reverse (disabled by default)

Synonym: -r

Reverse the direction of the rename operation; see below

6.26.3 Example

A simple example, where the labels of the parameter A are renamed according to the map specified.

Set c / r, g, b, y /;
Parameter A(c);
A(c) = ord(c);

execute_unload 'data.gdx', A;
execute 'gdxdump data.gdx';

Set map(*,*) / r.red, g.green, b.blue, y.yellow /;
execute_unload 'map.gdx' map;

execute 'gdxrename data map';

Scalar rc;
rc = errorLevel;
abort$(rc < 0) 'GDXRENAME execution error';
execute 'gdxdump data.gdx';

Symbol A before the rename:

Parameter A(*) /
'r' 1,
'g' 2,
'b' 3,
'y' 4 /;

Symbol A after the rename:

Parameter A(*) /
'red' 1,
'green' 2,
'blue' 3,
'yellow' 4 /;
6.27 GDXRRW

Interfacing GAMS and R

Author

Michael C. Ferris (ferris@cs.wisc.edu), Computer Sciences Department, University of Wisconsin - Madison, 1210 West Dayton Street, Madison, Wisconsin 53706
Steven Dirkse (sdirkse@gams.com) GAMS Development Corp.

GDXRRW is a suite of utilities to import/export data between GAMS and R (both of which the user is assumed to have already) and to call GAMS conveniently from R. The software gives R users the ability to use all the optimization capabilities of GAMS, and allows visualization and other operations on GAMS data directly within R.

The GDXRRW tool is unique among the GDX interface utilities in that it is an R extension made available as an R package. As such, it is run as part of an R session or script, not as part of a GAMS run, and it follows the usual R package conventions.

1. **Installation**: The R software is designed to be easily extended. Thousands of extension packages are freely and conveniently available online and can be installed easily using a simple, standard procedure. The GDXRRW package is one of these. The latest version is available from the GDXRRW Wiki in both source and binary form, along with a FAQ list, some hints and tips on common problems and solutions, and other helpful content. For convenience, the source and binary packages are also available in the gdxrrw directory of the GAMS distribution.

2. **Documentation**: The GDXRRW documentation is installed as part of the GDXRRW package and is available from within R in the usual way. See the GDXRRW Wiki for details and hints.

3. **Examples, tests, and data**: Like many R packages, GDXRRW comes with examples and data that help a user get started using the package. The R help system and the GDXRRW Wiki provide pointers to these. The Wiki also provides hints on finding and running the thousands of lines of tests that come with the GDXRRW package.

6.28 GDXTROLL

gdxtroll reads TROLL data files into a GDX container.

6.28.1 Usage

gdxtroll in [out]

where

in

TROLL data text file (default extension is .txt)

out

GDX container file name (default in.gdx)

Accepts SPECS:NUMeric and the following periodicities scalar NA, annual yyyyA, quartely yyyyQq, monthly yyyyMm weekly yyyyWwww (ISO 8601)
6.29 GDXVIEWER

6.29.1 Overview

GDXVIEWER is a tool to view and convert data contained in GDX files.

Besides inspecting a GDX file, gdxviewer allows you to export to a large number of data formats, including ASCII text, CSV, HTML, XML, database, and spreadsheet formats.

This tool is designed as an interactive Windows program, but it can also be operated through command line parameters.

6.29.2 Requirements

GDXVIEWER runs only on PC’s running Windows (95/98/NT/XP). The DLL GDXDCLIB.DLL needs to be in the same location as GDXVIEWER.EXE. If XLS files are saved, MS Excel needs to be present. If MDB database files are saved, MS Access needs to be present.

If GDXDCLIB.DLL is not found in the same directory as the executable gdxviewer.exe, the following window will be shown:

A simple way to make sure that GDXVIEWER has access to the GDXDCLIB.DLL dynamic load library is to place gdxviewer.exe in the GAMS system directory, e.g. c:\program files\GAMS21.3.

6.29.3 Creating GDX files

GDX files are binary data files. They can contain sets, parameters (including scalars), equations and variables. These files can be generated by a number of tools: by GAMS itself, by utilities such as MDB2GMS, SQL2GMS, GDXXRW.

To save all data from a GAMS model into a GDX file you can use the GDX=fln command line parameter:

C:\> gams transport.gms GDX=transport.gdx

From the IDE you can specify the command line parameter GDX=transport.gdx in the parameter edit box:
To selectively place identifiers in a GDX file you can use the \texttt{execute_unload} statement:

```
Model transport / all /;
solve transport using lp minimizing z;
display x.l, x.m;
execute_unload 'results.gdx', i, j, x;
```

In this example the sets \textit{i} and \textit{j} and the variable \textit{x} are saved to the GDX file \texttt{results.gdx}.

Other ways to create GDX files include:

- The \texttt{MDB2GMS} tool can be used to convert data stored in MS Access tables to GDX files.
- The \texttt{SQL2GMS} tool can read data from virtually any SQL database (including any ODBC accessible database) and can create GDX files.
- The tool \texttt{GDXXRW} allows data from an Excel spreadsheet to be stored in a GDX file.
- \texttt{GDXOUT} allows you to write data to a GDX file during GAMS compile time. This is not as useful as \texttt{execute_unload} but may have its use in special cases.
- You can write your own program to write a GDX file. There is an API and bindings for different languages such as Delphi, Kylix, VB6, VBA, VB.NET, C/C++, C#, Java, Fortran.
6.29 GDXVIEWER

6.29.4 Viewing GDX files

After loading a GDX file in gdxviewer the content of the file is displayed in list view. The left-hand side of the window shows the index of the GDX file organized in a tree structure. When clicking on an identifier, the right-hand-side will display the actual data for the identifier.

When variables are shown, more information is available, such as bounds (lower and upper bounds) and marginals.

The GDX file can be loaded interactively using the File|Open menu, or it can be launched from the command line:

```bash
C:\> gdxviewer e:\models\trnsport.gdx
```

The command line specification can also be used to launch gdxviewer from within a GAMS model as in:

```gams
Model transport / all /;
solve transport using lp minimizing z;
display x.l, x.m;
execute_unload 'results.gdx', i, j, x;
execute '=gdxviewer results.gdx';
```

In this case `gdxviewer.exe` was located in the GAMS system directory, such that `execute` had no problems in finding it.

Note: there are alternative tools to view GDX files. The GAMS IDE has a built-in GDX file viewer (use File|Open) and there is a command line utility called GDXDUMP.
6.29.5 Exporting an identifier

When the right mouse button is clicked on an identifier a pop-up menu is presented that allows you to export an identifier to a number of target formats.

The same operation can be invoked from the File|Export menu:
6.29.6 Exporting to a Text File

The text file export facility (File|Export|Text File) will write a GAMS identifier to a standard ASCII text file. Such a text file can look like:

```
seattle new-york 2.5
seattle chicago 1.7
seattle topeka 1.8
san-diego new-york 2.5
san-diego chicago 1.8
san-diego topeka 1.4
```

The separator symbol can be set using the menu Options|Configuration|Text File:

Other options that involve the format of the text file being written are: Options|Configuration|Export and Options|Configuration|Special Values. Currently there are no facilities to write fixed format text files. If you need to write fixed format text files you can use the GAMS PUT statement.
6.29.7 Exporting to a CSV files

Comma-separated Values (File|Export|CSV File) is a popular format to exchange data between applications. An example of such a file is:

'new-york',325
'chicago',300
'topeka',275

Strings are surrounded by quotes and each field is separated by a comma. The precise format can be specified using the menu Options|Configuration|CSV File:

![CSV File Configuration Options]

Other options that involve the format of the CSV file being written are: Options|Configuration|Export and Options|Configuration|Special Values.

6.29.8 Exporting to an XLS file

A GAMS identifier can be exported directly to an MS Excel spreadsheet using File|Export|Excel XLS File:
There are a few options available for this operation. Under Options|Configuration|Excel the following settings can be changed:

Other options that involve the format of the CSV file being written are: Options|Configuration|Export and Options|Configuration|Special Values. Exporting to Excel is only available if you have Microsoft Excel installed on your machine.

Note: We can write all symbols in the gdx file to Excel by specifying ID=* on the command line.
6.29.9 Exporting to an XLS Pivot Table

We can export to an XLS file and create a Pivot Table automatically (File|Export|Excel Pivot Table):

![GDXViewer and Excel images]

Pivot tables are a very convenient way to analyze multi-dimensional data.

The following options are available: Options|Configuration|Excel, Options|Configuration|Export and Options|Configuration|Special Values.

6.29.10 Exporting to a GAMS Include Files

The option File|Export|GAMS Include file will export an identifier to a GAMS include file format. An example of such an exported include file can look like:

```
Parameter d 'distance in thousands of miles'
  / seattle.new-york 2.5, san-diego.new-york 2.5,
  seattle.chicago 1.7, san-diego.chicago 1.8,
  seattle.topeka 1.8, san-diego.topeka 1.4 /;
```
6.29.11 Exporting to an Access Tables

GDXVIEWER can export data directly to a table in an Access database using File|Export|Access (MDB or ACCDB) File. The name of the table will be the name of the parameter. If the table already exists, GDXVIEWER will try to create a new table with a slightly different name (e.g. d2, d3,...).

An option Options|Configuration|Access allows you to set the length of the text fields where the GAMS indices are stored. This length is used when creating the table.
A feature added in version 2.9 is the possibility to use intermediate CSV (comma separated value) files instead of using direct SQL INSERT statements. The CSV files can be read into Access using a bulk operation and is therefore faster for large datasets. When using CSV files make sure double quotes are used (if single quotes are used they will become part of the data). The temporary CSV files will be written to the Windows TEMP directory (e.g. `C:\WINDOWS\TEMP`). When the import is done, these scratch files will be removed automatically. If you want to look at the CSV files that are being fed into Access, export the data to a CSV file.

### 6.29.12 Exporting to an SQL Table

It is possible to export data to SQL databases through ADO which includes all databases accessible through ODBC. The configuration information can be specified in `Options|Configuration|SQL Database`.
The **Test Connection** button will allow you to check the configuration and see if the database can be connected to.

The SQL data for double precision number is no always the same for each database. E.g. for MS Access you can use **double** while for MS SQL server you can use **float**.

When exporting data a new table is created with the name of the identifier. If such a table already exists, names like **name2**, **name3**, are tried.

### 6.29.13 Exporting to MS SQL Server

We can export to Microsoft SQL Server through the standard SQL export facility. However a special facility called BULK INSERT is only available through the specialized SQL Server export tool. BULK INSERT writes a TAB delimited text file to the Windows TEMP directory and subsequently calls BULK INSERT to load that file. This way is often much faster that using individual INSERT statements for each record.

### 6.29.14 Exporting to SQL Insert script

An SQL script with INSERT statements like:

```sql
```

can be generated with **File|Export|SQL Insert script**. The following settings in **Options|Configuration|SQL Insert** were used:

<table>
<thead>
<tr>
<th>DB Column</th>
<th>GDK column:</th>
<th>Quote:</th>
<th>Table name:</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>city1</td>
<td>dim1</td>
<td>✔</td>
<td>dis1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>city2</td>
<td>dim2</td>
<td>✔</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>distance</td>
<td>level</td>
<td>✔</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SQL INSERT statements will be generated of the form:**

```
INSERT INTO
tablename(dbcol1, dbcol2, ...)
VALUES (gdxcol1, gdxcol2, ...).
```

Column values can be quotes and INSERT statements are often terminated with a semicolon.
6.29.15 Exporting to SQL Update script

An SQL script with UPDATE statements like:

can be generated with File|Export|SQL Update script. The following settings in Options|Configuration|SQL Update were used:

<table>
<thead>
<tr>
<th>DB Columns</th>
<th>GDX column:</th>
<th>Quote:</th>
</tr>
</thead>
<tbody>
<tr>
<td>city1</td>
<td>dim1</td>
<td></td>
</tr>
<tr>
<td>city2</td>
<td>dim2</td>
<td></td>
</tr>
<tr>
<td>distance</td>
<td>level</td>
<td></td>
</tr>
</tbody>
</table>

Table name:

dist

☑ Semicolon separator

SQL UPDATE statements will be generated of the form: UPDATE tablename SET dcol1=gdxval1, dcol2=gdxval2 WHERE dcol3=gdxdim1 and dcol4=gdxdim2. Column values can be quotes and UPDATE statements are often terminated with a semicolon.

6.29.16 Exporting HTML

GDXVIEWER can write an identifier to an HTML file using File|Export|HTML File.
6.29.17 Exporting XML

GDXVIEWER can write an identifier to an XML file using File|Export|XML File.
The XML tags can be specified in Options|Configuration|XML.
6.29.18 Exporting fields

The menu Options|Configuration|Export allows you to set which fields are exported.

![Figure 6.43 400px](image)

The following table gives the possibilities for exports:

<table>
<thead>
<tr>
<th></th>
<th>set</th>
<th>scalar</th>
<th>parameter</th>
<th>variable</th>
<th>equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indices</td>
<td>+</td>
<td></td>
<td>+</td>
<td>+</td>
<td>+</td>
</tr>
<tr>
<td>Lower bound</td>
<td></td>
<td>+</td>
<td></td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>Level/Value</td>
<td></td>
<td>+</td>
<td></td>
<td>+</td>
<td></td>
</tr>
<tr>
<td>Upper bound</td>
<td></td>
<td>+</td>
<td></td>
<td></td>
<td>+</td>
</tr>
<tr>
<td>Marginal</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>+</td>
</tr>
</tbody>
</table>

6.29.19 Special Values

GAMS data can assume so called special values: -INF, +INF, EPS, NA, and UNDF. The meaning of these special values is as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-INF</td>
<td>Minus infinity. Mostly used for non-binding lowerbounds.</td>
</tr>
<tr>
<td>+INF</td>
<td>Plus infinity. Mostly used for non-binding upperbounds.</td>
</tr>
<tr>
<td>EPS</td>
<td>Mostly used for marginals where it can indicate non-basic but numerically zero.</td>
</tr>
<tr>
<td>NA</td>
<td>Not available. Not often used.</td>
</tr>
<tr>
<td>UNDF</td>
<td>Undefined. Not often used.</td>
</tr>
</tbody>
</table>

When exporting GAMS identifiers we need to map such values to strings that the receiving program can understand. E.g. we could map -INF to -1.0e10 and +INF to +1.0e10. A good choice for EPS would be 0.0.

The mapping can be specified in Options|Configuration|Special Values:
When we export to a GAMS include file all special values are understood, so the mapping is not used. The defaults button will reset the mapping to their default values.

6.29.20 Plotting Data

GDXVIEWER has a built-in facility to quickly plot data. It includes LINE, BAR and PIE charts, examples are shown below. The plots can be made through the menu File|Plot.
For multi-dimensional data it may be needed to take a “slice” of the data to make meaningful graphs. In the example above we plotted a two dimensional quantity $vf$ which looks like:
In this case we want to plot a pie graph of \( \text{vf}(*, 'mexico-df') \) which can be specified in the index-selection tab:
6.29.21 Cube View

GDXVIEWER has a Cube View which allows to select rows and columns in a flexible way. In the example below we show a six dimensional variable where three dimensions are fixed, one dimension is chosen for the rows and two dimensions are chosen for the columns.

Below are some of the possibilities using parameter \(d(i,j)\) from the `transp.gms` model:

6.29.22 Exporting cubes

After creating a cube view, we can export that configuration by a right mouse click:
Exporting a cube will only export the selected slice (if certain dimensions are held fixed) and depending on the target format it will preserve the layout, e.g. an exported aligned text file can look like:

```
new-york  chicago  topeka
seattle    2.5  1.7  1.8
san-diego   2.5  1.8  1.4
```

Similarly, the XLS file can look like:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>new-york</td>
<td>chicago</td>
<td>topeka</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>seattle</td>
<td>2.5</td>
<td>1.7</td>
</tr>
<tr>
<td>3</td>
<td>san-diego</td>
<td>2.5</td>
<td>1.8</td>
</tr>
</tbody>
</table>

### 6.29.23 Commandline operation

The GDXViewer utility from version 2.3 accepts several command line parameters, so it can be used in a batch environment. When running in batch mode, the same configuration and option settings are used as for the interactive system and they can be changed by running GDXviewer interactively using the Options menu (the settings are saved in an INI file). It is advised to first run the program interactively until the results are as intended.

- **Single parameter** A single parameter is the filename of the GDX file. GDXViewer will load this file, and will continue to run interactively. Example: .

  `Gdxviewer.exe test.gdx`

- **XLS writing** To write an XLS file, one can use the syntax `i=inputfile.gdx xls=outputfile.xls id=x`. If a path or filename contains blanks, the name can be surrounded by quotes ("`). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx xls=d:\tmp\result.xls id=x';
  ```

- **Text file writing** To write a text file, one can use the syntax `i=inputfile.gdx txt=outputfile.txt id=x`. If a path or filename contains blanks, the name can be surrounded by quotes ("`). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx txt=d:\tmp\result.txt id=x';
  ```

- **CSV file writing** To write a CSV file, one can use the syntax `i=inputfile.gdx csv=outputfile.csv id=x`. If a path or filename contains blanks, the name can be surrounded by quotes ("`). The 'id' parameter indicates the variable or parameter to export from the GDX file. A complete example is:

  ```
  execute_unload 'd:\tmp\result.gdx',x;
  execute 'gdxviewer.exe i=d:\tmp\result.gdx csv=d:\tmp\result.csv id=x';
  ```
2746

Tools Manuals

• HTML file writing To write an HTML file, one can use the syntax i=inputfile.gdx
html=outputfile.html id=x. If a path or filename contains blanks, the name can be surrounded
by quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file.
A complete example is:
execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx html=d:\tmp\result.html id=x’;
• XML file writing To write an XML file, one can use the syntax i=inputfile.gdx
xml=outputfile.xml id=x. If a path or filename contains blanks, the name can be surrounded by
quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file. A
complete example is:
execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx xml=d:\tmp\result.xml id=x’;
• GAMS include file writing To write a GAMS include file, one can use the syntax
i=inputfile.gdx inc=outputfile.inc id=x. If a path or filename contains blanks, the name
can be surrounded by quotes (”). The 'id' parameter indicates the variable or parameter to export
from the GDX file. A complete example is:
execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx inc=d:\tmp\result.inc id=x’;
• Access MDB file writing To write a Access MDB file, one can use the syntax i=inputfile.gdx
mdb=outputfile.mdb id=x. If a path or filename contains blanks, the name can be surrounded by
quotes (”). The 'id' parameter indicates the variable or parameter to export from the GDX file. A
complete example is:
execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx mdb=d:\tmp\result.mdb id=x’;
• Excel Pivot Table writing To write a file containing a pivot table, one can use the syntax
i=inputfile.gdx pivot=outputfile.xls id=x. If a path or filename contains blanks, the name
can be surrounded by quotes (”). The 'id' parameter indicates the variable or parameter to export
from the GDX file. A complete example is:
execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x’;
• SQL Database Table writing To write a table to an SQL database, first interactively configure
the connection to the database. The Export SQL Database option allows you to see if a connection
succeeded and if the correct database was accessed. The configuration information is written to the
SQLVIEWER.INI configuration file. The information in this file is used also when performing a
batch command-line operation. The syntax is: i=inputfile.gdx sql id=x. A complete example
is:
execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx sql id=x’;

If you need to access several different databases, you can copy the file SQLVIEWER.INI (located in the
directory where SQLVIEWER.EXE is placed). To tell GDXVIEWER to read a different INI file, you can say:

execute_unload ’d:\tmp\result.gdx’,x;
execute ’gdxviewer.exe i=d:\tmp\result.gdx ini=copy.ini sql id=x’;


GDXVIEWER uses the MS Access and MS Excel applications as COM Object to write files in XLS (both XLS and PIVOT commands) or MDB format. Those applications may write to C: \My Documents in case no full path is specified. Other formats use the default GAMS working directory. In case when running under the IDE this is the location of the project file (*.GPR).

If a path or file name contains a blank, then it is possible to surround the name by double quotes as in:

execute_unload 'result.gdx',x;
execute 'gdxviewer.exe i=result.gdx csv="c:\my documents\result.csv" id=x';

Under windows 98 ME the call

execute 'gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';

will cause GAMS to continue while GDXVIEWER is executing. If we use:

execute '=gdxviewer.exe i=d:\tmp\result.gdx pivot=d:\tmp\result.xls id=x';

GAMS will wait until gdxviewer.exe is terminated before executing more statements. This situation is different under other operating systems such as XP and NT.

6.29.24 Notes

GDX

GDX stands for Gams Data Exchange. It is a binary file format to get data in and out of GAMS.

6.30 GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet.

6.30.1 Usage

gdxxrw inputFile {outputFile} {options} [symbols]

Options and symbol specifications can also be read from a text file; the use of an option file is indicated by preceding the file name with a @ (At sign). When reading from a text file, lines starting with an asterisk (*) will be ignored and act as a comment.

Options and symbol specifications can also be read from an area in a spreadsheet; see index below.

Files without a full path name are assumed to be in the current directory when using a command prompt. When using the GAMS IDE, these files are assumed to be in the current project directory. The use of file names with embedded blanks is allowed as long as the file name is enclosed in double-quotes (").

Note: A small utility program is available to see if Excel is installed, to close an Excel file etc. See XLSTALK for more details. To read data from an Excel file without Excel installed see XLS_DUMP.
6.30.2 Options

Describing the actions to be taken by GDXXRW requires passing a number of options and symbol specifications to the program. The ability of GDXXRW to process multiple actions in a single call makes the option passing and interpretation more complex.

There are four kinds of options:

1. **Immediate** Immediate options are recognized and processed before any other actions are taken and can only be specified once. Examples are:
   
   ```
   input= output= trace=
   ```

2. **Global** Global options are interpreted from left to right and affect every action that follows. The same option can be used multiple times to affect the actions that follow. Examples are:
   
   ```
   skipEmpty= epsOut=
   ```

3. **Symbol** A symbol definition introduces a new action for reading or writing a symbol. Examples are:
   
   ```
   par= set= dSet=
   ```

4. **Symbol attributes** Attributes specify additional information for the last symbol defined. Examples are:
   
   ```
   dim= cDim= merge clear
   ```

6.30.2.1 Immediate Options

Immediate options are recognized independent of their position on the command line. They are global and they can only be specified once.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>none</td>
<td>Specify the input filename (required).</td>
</tr>
<tr>
<td>output</td>
<td>inputFileName</td>
<td>Specify the output filename.</td>
</tr>
<tr>
<td>log</td>
<td>none</td>
<td>Specify the log filename.</td>
</tr>
<tr>
<td>logAppend</td>
<td>none</td>
<td>Appending the log information to the file specified.</td>
</tr>
<tr>
<td>index</td>
<td>none</td>
<td>Indicates reading the options and symbols directly from the spreadsheet.</td>
</tr>
<tr>
<td>password</td>
<td>none</td>
<td>Password for an encrypted input file.</td>
</tr>
<tr>
<td>rWait</td>
<td>0</td>
<td>Delay after opening a spreadsheet.</td>
</tr>
<tr>
<td>checkDate</td>
<td>disabled</td>
<td>Write GDX file only if the input file is more recent than the GDX file.</td>
</tr>
<tr>
<td>useRC</td>
<td>disabled</td>
<td>Use Row-Column notation to specify cells and ranges.</td>
</tr>
<tr>
<td>reCalc</td>
<td>N</td>
<td>Controls if recalculations of cells inside Excel are executed after writing to the spreadsheet.</td>
</tr>
<tr>
<td>trace</td>
<td>1</td>
<td>Controls the amount of information written to the log.</td>
</tr>
<tr>
<td>maxDupeErrors</td>
<td>0</td>
<td>Maximum number of duplicate records allowed for a symbol.</td>
</tr>
<tr>
<td>updLinks</td>
<td>0</td>
<td>Updating of cells that refer to other spreadsheets.</td>
</tr>
<tr>
<td>runMarcos</td>
<td>0</td>
<td>Execution of Excel Auto macros.</td>
</tr>
</tbody>
</table>
Some more detailed remarks on the immediate options:

**input = fileName** (required, default = none)

Synonym: i

Either use the keywords **input** or **i** to specify the input file name anywhere on the command line or just specify the input file name without keyword at the first position behind **GDXXRW**. The file extension of the input file is required and determines the action taken by the program.

The extension .gdx for the input file will read data from a GDX file and write data to a spreadsheet. The extension .xls or .xlsx for the input file will read a spreadsheet and write the data to a .gdx file. In addition to the .xls and .xlsx input file extension, the following file extensions are also valid for spreadsheet input files: .wk1, .wk2, .wk3 and .dbf.

A file sharing conflict will arise when writing to a spreadsheet with the target file open in Excel. Either close the file in Excel before executing **GDXXRW**, or mark the spreadsheet as a shared workbook in Excel. To change the shared status of a workbook, use the Excel commands available under: **Tools|Share Workbook**.

Writing to a shared workbook can be painfully slow; simply closing the file and reopen the file after **GDXXRW** has finished is often a better option.

**output = fileName** (default = inputFileName)

Synonym: o

When an output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. The file type, i.e. the file extension, depends on the installed version of Excel. Versions prior to Excel 2007 use the .xls file extension, later version use .xlsx. Excel 2007 can write .xls files, but in that case the output file has to be specified with an .xls file extension.

**log = fileName** (default = none)

Specifies the filename of the log file. When omitted, log information will be written to standard output. When using **GDXXRW** in a GAMS model that is started from the GAMS IDE, the output will be written to the IDE process window.

**logAppend = fileName** (default = none)

Using **logAppend** will add the log information to the end of the file specified. If the file does not exist yet, a new one will be created.

**index = Excel Range**

The **index** option is used to obtain the global options, symbols and symbol attributes specified by reading them from the spreadsheet directly. The parameters are read using the specified range, and treated as if they were specified directly on the command line. The first three columns of the range have a fixed interpretation: dataType, Symbol identifier and dataRange. The fourth and following columns can be used for additional parameters. The column header contains the keyword when necessary, and the cell content is used as the parameter value. See Reading Spreadsheet using the Index Option for instance.
password = string (default = none)

Specifies a password for a protected spreadsheet file.

rWait = integer (default = 0)

Introduce a delay (in milliseconds) after opening a spreadsheet before accessing the data. This parameter can be used to work around an issue we encountered that Excel indicated it was not ready.

ccheckDate (disabled by default)

When specified, no data will be written if the output file already exists and the file date for the output file is more recent than the file date for the input file. Provides a simple check to update the output file only if the input file has changed to save resources.

useRC (disabled by default)

Specify that all cell and range references use RC notation. So, instead of specifying the range Sheet1!A1:D6, one specifies Sheet1!R1C1:R6C4. When tracing is enabled, ranges will be reported in RC notation. This is a global option and applies to all cell references.

reCalc = flag (default = N)

Enable or disable the recalculation of cells inside Excel after writing to the spreadsheet. If there are many formulas in the spreadsheet the recalculation of cells can become very expensive and slowing down the writing process. By default, the recalculation is disabled and can be enabled via this option.

trace = integer (default = 1)

Sets the amount of information written to the log (for a better debugging). Higher values will generate more output. Valid range is 0..4.

0 Minimal information is included in the output
1 Message appears telling about each GDXXRW call indicating input file, output file and execution time
2 Message appears giving the level 1 output plus a listing for each symbol specified, indicating the type, sheet name, dimension, data range and the range of the row and column headers
3 Message appears giving the level 2 output plus cell ranges affected by reading, writing and clearing
4 Message appears giving the level 3 output plus cell addresses, and numerical or string values for every cell worked with

maxDupeErrors = integer (default = 0)

Sets the maximum number of duplicate records that is allowed when reading a spreadsheet and writing to a GDX file. The duplicate records for each symbol will be reported in the log file, and if their accumulated number does not exceed the maximum specified using this option, the GDX file will not be deleted. This is a global option and applies to each symbol read from the spreadsheet.

The option is demonstrated in Reading Set from Lists with Duplication.

updLinks = integer (default = 0)
Specifies how links in a spreadsheet should be updated. The valid range is 0..3.

0 Doesn't update any references
1 Updates external references but not remote references
2 Updates remote references but not external references
3 Updates both remote and external references

\textbf{runMacros} = \textit{integer} (default = 0)

This option controls the execution of the 'Auto\_open' and the 'Auto\_close' macros when opening or closing a spreadsheet. Valid range is 0..3.

0 Doesn't execute any macros
1 Executes Auto\_open macro
2 Executes Auto\_close macro
3 Executes Auto\_open and Auto\_close macro

\subsection*{6.30.2.2 Global Options}

The following options affect the symbols that follow the option. They remain in effect unless they are redefined and used again for another symbol.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acronyms</td>
<td>0</td>
<td>Controls the handling of acronyms.</td>
</tr>
<tr>
<td>cMerge</td>
<td>0</td>
<td>Controls the handling of merged Excel ranges.</td>
</tr>
<tr>
<td>dSetText</td>
<td>N</td>
<td>Read explanatory text for set elements of domain sets.</td>
</tr>
<tr>
<td>epsOut</td>
<td>Eps</td>
<td>String to be used when writing the value for 'Epsilon'.</td>
</tr>
<tr>
<td>filter</td>
<td>0</td>
<td>Set the Excel filter for symbols written to Excel.</td>
</tr>
<tr>
<td>incRC</td>
<td>N</td>
<td>Include Excel row and column indices when a symbol is written to the GDX file.</td>
</tr>
<tr>
<td>mInfOut</td>
<td>-Inf</td>
<td>String to be used when writing the value for 'Negative infinity'.</td>
</tr>
<tr>
<td>NIn</td>
<td>none</td>
<td>String to be used when reading a value for 'Not available'.</td>
</tr>
<tr>
<td>nameConv</td>
<td>N</td>
<td>Controls the interpretation of an Excel range.</td>
</tr>
<tr>
<td>NaOut</td>
<td>\textsl{NA}</td>
<td>String to be used when writing the value for 'Not available'.</td>
</tr>
<tr>
<td>pInfOut</td>
<td>+Inf</td>
<td>String to be used when writing the value for 'Positive infinity'.</td>
</tr>
<tr>
<td>resetOut</td>
<td>disabled</td>
<td>Reset the output strings for special values to their defaults.</td>
</tr>
<tr>
<td>squeeze</td>
<td>Y</td>
<td>Controls writing of default values of sub-fields of variables and equations resp. the handling of zero values within parameters when reading from spreadsheet.</td>
</tr>
<tr>
<td>skipEmpty</td>
<td>1</td>
<td>Number of empty rows or columns indicating the end of a block when reading from spreadsheet using the top left cell specification.</td>
</tr>
<tr>
<td>UndfOut</td>
<td>Undf</td>
<td>String to be used when writing the value for 'Undefined'.</td>
</tr>
<tr>
<td>allUELs</td>
<td>Y</td>
<td>Controls the handling of UELs without associated values in the data range.</td>
</tr>
<tr>
<td>zeroOut</td>
<td>0</td>
<td>String to be used when writing the value for 'Zero'.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the global options:
acronyms = integer (default = 0)

A non-zero value indicates that acronyms can be expected and should be processed.

If no acronym processing takes place, reading an identifier in the data section of a sheet will generate an error. Writing an acronym to a sheet will write the internal numerical representation of the acronym.

Processing acronyms:

When reading a spreadsheet, an identifier in the data section of the sheet will be interpreted as an acronym and will be written to the GDX file.

When writing to a spreadsheet, a data tuple containing an acronym will be stored using the corresponding identifier of the acronym.

cMerge = integer (default = 0)

Option indicating how to read an empty cell that is part of a merged Excel range. See Reading merged Excel Ranges with cMerge. Possible values and their interpretation are:

0 Leave the cell empty
1 Use merged value in row and column headers only
2 Use merged value in all cells

dSetText = flag (default = N)

Valid only when reading a spreadsheet.

This controls the reading of explanatory text for set elements of domain sets. By default, no text is read for domain sets. If this option is activated this is changed. If an element appears more than once, the first one defines the explanatory text read.

epsOut = string (default = Eps)

String to be used when writing the value for 'Epsilon'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet and Writing Parameter to Spreadsheet including Zero Values.

filter = integer (default = 0)

Adds basic Excel filter to the columns of the spreadsheet to display only those values matching some conditions. Using this option when reading an Excel file will result in an error. Specifying filter=1 will set an Excel filter for the row of labels that are closest to the data values. When there are multiple rows in a column header (cDim > 1) we can specify filter=x where x is a number of the range 2..cDim, indicating to use a row farther away from the data values. See also Writing to Spreadsheet using a Filter.

incRC = flag (default = N)

Valid only when reading a spreadsheet.

Include Excel row and column indices when a symbol is written to the GDX file. For example, when we write a parameter P with indices I and J, without this option it will be written as P(I, J). When incRC is enabled, the parameter will be written as P(Excel_Rows, I, Excel_Columns, J). Note that the sets Excel_Rows and Excel_Columns will be added to the GDX file automatically.
mInfOut = string (default = -Inf)

String to be used when writing the value for 'Negative infinity'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

NaIn = string (default = none)

String to be used when reading a value for 'Not available'; this string is recognized in addition to the string 'NA' and is not case-sensitive. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

nameConv = flag (default = N)

Synonym: nC

The naming convention parameter is used to change the interpretation of an Excel range that does not contain an '!' (exclamation mark). For details see Excel Ranges below.

NaOut = string (default = NA)

String to be used when writing the value for 'Not available'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

pInfOut = string (default = +Inf)

String to be used when writing the value for 'Positive infinity'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

resetOut (disabled by default)

Reset the output strings for special values to their defaults. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

squeeze = flag (default = Y)

Synonym: sq

Writing to a spreadsheet:

The squeeze option affects the writing of sub-fields of variables and equations. A value for the field that is the default value for that type of variable or equation will not be written to the spreadsheet. For example, the default for .l (level value) is 0.0, and therefore zero will not be written to the spreadsheet. When we set squeeze=n, all values will be written to the spreadsheet.

The squeeze option for writing data is demonstrated in Reading Data from Spreadsheet and writing Data to Spreadsheet and Writing Parameter to Spreadsheet including Zero Values.

Reading a spreadsheet:

When the squeeze option is enabled, zero values for parameters will not be written to the GDX file. When the squeeze option is disabled, zero values will be written to the GDX file. In either case, empty cells, or cells containing blanks only, will never be written to the GDX file.

The squeeze option for reading data is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.
skipEmpty = integer (default = 1)

Synonym: sE

The skipEmpty option can be used when reading a spreadsheet and the range is specified using the top left corner instead of a block range. The value defines the number of empty row or column cells signal the end of a block. Valid values are 0..n. If the range is specified using a block range, skipEmpty will be ignored. Blank rows or columns will be skipped automatically.

Note that skipEmpty is also valid when using the merge resp. clear options in order to write data to spreadsheet (in a specific order determined by matching row and column labels already stored in the spreadsheet).

See Skipping Empty Rows and Columns or Reading Multi-dimensional Parameter from Spreadsheet for instance.

UndfOut = string (default = Undf)

String to be used when writing the value for 'Undefined'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

eallUELs = flag (default = Y)

Valid only when reading a spreadsheet.

When enabled, all unique elements found in a range will be entered in the GDX file. When disabled, only those unique elements that are used in conjunction with a value will be entered in the GDX file.

zeroOut = string (default = 0)

String to be used when writing the value for 'Zero'; by default this is '0'. This option is demonstrated in Reading Special Values from Spreadsheet and writing to Spreadsheet.

### 6.30.2.3 Symbols

To write data to a spreadsheet or to a GDX file, one or more symbols and their associated Excel range need to be specified. See also Excel Ranges.

The general syntax for a symbol specification is:

    dataType=symbolName {symbolAttributes}

Among the symbolAttributes, one specifies the dataRange, the dimensions of the symbol and some additional symbolOptions in general.

dataType

<table>
<thead>
<tr>
<th>dataType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>par</td>
<td>Declare the symbol as parameter and define a individual name when reading from spreadsheet, or specify a parameter from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>equ</td>
<td>Specify a sub-field of a equation from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>var</td>
<td>Specify a sub-field of a variable from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>set</td>
<td>Declare the symbol as set and define a individual name when reading from spreadsheet, or specify a set from a GDX file when writing to spreadsheet.</td>
</tr>
<tr>
<td>dSet</td>
<td>Declare the symbol as domain set and define a individual name when reading from spreadsheet, or specify a domain set from a GDX file when writing to spreadsheet.</td>
</tr>
</tbody>
</table>
par = *GAMS_Parameter*

Specify a GAMS parameter to be read from a GDX file and written to spreadsheet, or to be read from a spreadsheet and written to a GDX file.

When writing to a spreadsheet, special values such as `Eps`, `NA` and `Inf` will be written in ASCII. When reading data from a spreadsheet, the ASCII strings will be used to write the corresponding special values to the GDX file.

This datatype is used in the most examples. Reading parameters is demonstrated in `Reading Parameter from Spreadsheet` or `Reading Multi-dimensional Parameter from Spreadsheet`. Writing parameters from GDX to spreadsheet is demonstrated in `Writing Parameter to Spreadsheet`.

equ = *GAMS_Equation*

var = *GAMS_Variable*

A sub-field of a variable or equation can be written to a spreadsheet and should be specified as part of the symbolName. The fields recognized are `.l` (level), `.m` (marginal), `.lo` (lower bound), `.up` (upper bound), `.prior` (priority), and `.scale` (scale). The sub-field names are not case-sensitive. See also `Reading Data from Spreadsheet` and `writing Data to Spreadsheet after Solve`.

A sub-field of a variable or equation cannot be read from a spreadsheet and written to a GDX file.

set = *GAMS_Set* [values = `valueType`]

In GAMS we can define a set by specifying all its elements. In addition, each tuple can have an associated text. To read a set from a spreadsheet, the values option is used to indicate if there is any data, and if there is, if the data should be interpreted as associated text or as an indicator whether the tuple should be included in the set or not.

Reading sets is demonstrated in `Reading Set from Spreadsheet` or `Reading Set Elements associated with Data or Text using the values Option` (focusing on the values option) for instance. Writing sets from GDX to spreadsheet is demonstrated in `Writing Set to Spreadsheet`.

<table>
<thead>
<tr>
<th>valueType</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Based on the range, row and column dimensions for the set, the program decides on the valueType to be used. This is the default for values.</td>
</tr>
<tr>
<td>noData</td>
<td>There is no data range for the set; all tuples will be included.</td>
</tr>
<tr>
<td>YN</td>
<td>Only those tuples will be included that have a data cell that is not empty and does not contain '0', 'N' or 'No'.</td>
</tr>
<tr>
<td>sparse</td>
<td>Only those tuples will be included that have a data cell that is not empty. The string in the data cell will be used as the associated text for the tuple.</td>
</tr>
<tr>
<td>dense</td>
<td>All tuples will be included. A string in the data cell will be used as the associated text for the tuple.</td>
</tr>
</tbody>
</table>

Due to backward compatibility, `valueType=string` or `all` are also recognized and are synonyms for `valueType=dense`. The following table summarizes which valueType will be used when reading a set, if a valueType was not specified:
When writing to a spreadsheet, the entire set is written to the spreadsheet and the writing of the associated text is governed by the values option:

<table>
<thead>
<tr>
<th>valueType</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>If rDim=0 or cDim=0, auto means string, otherwise auto means YN.</td>
</tr>
<tr>
<td>noData</td>
<td>Neither associated text nor 'Y' is written for a set element.</td>
</tr>
<tr>
<td>YN</td>
<td>A 'Y' is written for a set element.</td>
</tr>
<tr>
<td>string</td>
<td>The associated text is written for a set element. If no text is stored with set element the cell will be empty.</td>
</tr>
</tbody>
</table>

Due to backward compatibility, valueType=dense, sparse or all are also recognized and are synonyms for valueType=string.

dSet = GAMS_Set

A domain set is used to read the domain of a set from a spreadsheet row or column. Either the row or the column dimension (rDim or cDim) should be set to '1' to specify a row or column for the set, resulting in a one-dimensional set. Duplicate labels in the range specified do not generate an error message. For instance, see also Reading Set from Lists with Duplication.

Note that reading explanatory text of set elements is not supported by dSet. In order to read explanatory text, use set instead. If there are duplicate set element labels in your data, use the set symbol specification while increasing the value of the immediate option maxDupeErrors to oppress an error message when reading duplicates.

text = "String of characters" {dataRange}
textID = Identifier {dataRange}

Write the text to the cell specified in the DataRange. In addition, textID will write the explanatory text of the Identifier in the cell to the right of the dataRange.

A Text directive can be followed by a link=Address or linkID=identifier directive. Using link will create a hyperlink to an external page or to a cell in the spreadsheet, while linkID will create a hyperlink to the top left corner of the symbol specified. See Writing to Spreadsheet adding Text and Hyperlinks for instance.

hText = "String of characters" {dataRange}
vText = "String of characters" {dataRange}

Write a string of characters in the horizontal direction for hText or vertical direction for vText. Text for the next cell is indicated by a comma. In order to write a comma as part of the text, the comma needs to be preceded by a backslash. See Writing Set to Spreadsheet for instance.

6.30.2.3.1 Symbol Attributes  The following options apply to the symbol preceding the option, and only affect that symbol:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataRange</td>
<td>Cell A1 of the first sheet</td>
<td>Specify the Excel range of the symbol for reading from spreadsheet or for writing to spreadsheet.</td>
</tr>
<tr>
<td>dim</td>
<td>2 when reading from spreadsheet Defined by the symbol dimension stored in the GDX file when writing to spreadsheet</td>
<td>Total dimension of the symbol.</td>
</tr>
<tr>
<td>cDim</td>
<td>1</td>
<td>Column dimension of the symbol.</td>
</tr>
<tr>
<td>rDim</td>
<td>dim-1</td>
<td>Row dimension of the symbol.</td>
</tr>
<tr>
<td>merge</td>
<td>disabled</td>
<td>When enabled, the data will be written in a specific order determined by matching row and column labels already stored in the spreadsheet.</td>
</tr>
<tr>
<td>clear</td>
<td>disabled</td>
<td>In addition to the effect of merge, already existing values in the data range of the spreadsheet are removed before writing.</td>
</tr>
<tr>
<td>colMerge</td>
<td>0</td>
<td>Determines the columns for which non-empty content of the previous cell will be used as content for the empty cell of a column.</td>
</tr>
<tr>
<td>intAsText</td>
<td>Y</td>
<td>Determines the cell format when writing unique elements that are a proper integers to spreadsheet.</td>
</tr>
<tr>
<td>ignoreRows/Cols</td>
<td>none</td>
<td>Specify rows and columns to be ignored when reading from spreadsheet.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the symbol attributes:

**dataRange**

\[ \text{rng} = \text{Excel Range} \]

The **Excel Range** for the data for the symbol. Note that an empty range is equivalent to the first cell of the first sheet.

**dimensions**

\[ \text{dim} = \text{integer} \]

The total dimension for the symbol.

\[ \text{cDim} = \text{integer} \]

Column dimension: the number of rows in the data range that will be used to define the labels for the columns. The first cDim rows of the data range will be used for labels.

\[ \text{rDim} = \text{integer} \]
Row dimension: the number of columns in the data range that will be used to define the labels for the rows. The first $\text{rDim}$ columns of the data range will be used for the labels.

More about dimensions:

When reading data from a GDX file and writing to a spreadsheet, the dimension of the symbol is known. When reading a spreadsheet and writing to a GDX file, the dimension is not known.

The sum of $\text{cDim}$ and $\text{rDim}$ determine the dimension of the symbol. This dimension is used when writing data to a GDX file, and is used to verify the dimension of a symbol when reading from a GDX file.

When reading a GDX file, the dimension of a symbol is known, and therefore the $\text{cDim}$ or $\text{rDim}$ parameter can be omitted. If both $\text{cDim}$ and $\text{rDim}$ are omitted, the program assumes that $\text{cDim}=1$ and $\text{rDim}=\text{dim}-1$.

symbolOptions

The options below are only valid when reading a GDX file and writing to a spreadsheet.

By default, writing data to a spreadsheet will include the row and column labels in addition to the data. The row and column labels will appear in the same order as they appear in the GDX file.

merge (disabled by default)

Using the merge option assumes that the row and column labels are in the spreadsheet already. For each value read from the GDX file, the location of the row and column labels is used to update the spreadsheet. Using the merge option will force the data to be presented in a given order using the row and column labels. Spreadsheet cells for which there is no matching row/column pair will not be changed. The matching of labels is not case-sensitive. See also Writing to Spreadsheet with merge Option Example.

Note that the skipEmpty option value affects the reading of the row and column labels from spreadsheet in case of top left range specification (while skipEmpty is ignored in case of block range specification).

Warning: The merge or clear option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.

clear (disabled by default)

The clear option is similar as the merge option, except that the data range will be cleared before any data is written. See also Writing to Spreadsheet with clear Option Example.

colMerge = integer (default = 0)

The number of columns that will use a previous value in that column if the cell is empty. Can only be used when reading from a spreadsheet. See Reading empty Cells with colMerge.

intAsText = flag (default = Y)
Unique elements that are a proper integer can be written as text or as an integer value. The default is Y, which will write the unique element as a string. Note that this impacts the sorting order and can be used when using an Excel filter on a data range.

Ignoring Rows and Columns when reading from a spreadsheet

ignoreRows = rownr, rownr, rownr:rownr
ignoreColumns = colnr, colnr, colnr:colnr

Row numbers are represented by integers. Column numbers are represented by Excel column numbers, like A, CD, IV etc, or by integers.

Note

- Ignoring rows or columns is only allowed when reading a spreadsheet.
- The specification of ignored rows or columns follows the symbol specification and only applies to that symbol.
- When ignoring a column that would be part of an index if the column was not ignored, the range for the index will be extended for each column that is ignored. The same holds for ignored rows that are part of an index.

See also Ignoring Rows and Columns.

6.30.2.4 Syntax Elements

The most options are specified by using an integer, a string or a flag. Note that the options useRC, resetOut, checkDate, merge and clear are enabled or disabled by simply adding the keyword to your GDXXRW statement.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>An unsigned integer</td>
</tr>
<tr>
<td>string</td>
<td>A string of characters; a string can be quoted with single or double quotation marks.</td>
</tr>
</tbody>
</table>
| flag    | True values: 1, Y or Yes  
False values: 0, N or No  
(not case-sensitive) |

6.30.2.5 Excel Ranges

An Excel Range is specified using the standard Excel notation: SheetName!CellRange.

When the SheetName! is omitted, the first sheet will be used. A CellRange is specified by using the TopLeft:BottomRight cell notation like A1:C12. When :BottomRight is omitted, the program will extend the range as far down and to the right as possible. (Using '..' in stead of '!' is supported.)

Excel also allows for named ranges; a named range includes a sheet name and a cell range. Before interpreting a range parameter, the string will be used to search for a pre-defined Excel range with that name. See Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges for instance.
When writing to a spreadsheet and a sheet name has been specified that does not exist, a new sheet will be added to the workbook with that name. Reading a spreadsheet and using an unknown range or sheet name will result in an error.

The following table summarizes all possible input combinations and their interpretation:

<table>
<thead>
<tr>
<th>Input</th>
<th>Sheet used</th>
<th>Cell(s) used</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>First sheet</td>
<td>A1</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>First sheet</td>
<td>Name</td>
<td>When nc=0</td>
</tr>
<tr>
<td>Name!</td>
<td>Name</td>
<td>A1</td>
<td>When nc=1</td>
</tr>
<tr>
<td>!Name</td>
<td>First sheet</td>
<td>Name</td>
<td></td>
</tr>
<tr>
<td>Name1!Name2</td>
<td>Name1</td>
<td>Name2</td>
<td></td>
</tr>
</tbody>
</table>

The term \( nc \) refers to the \texttt{nameConv} option.

### 6.30.3 Return Codes

On success, \texttt{GDXXRW} will return 0 as error code. However, there might be an error which will be signaled with a specific return code in addition to an error message.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error</td>
</tr>
<tr>
<td>1</td>
<td>Cannot write log</td>
</tr>
<tr>
<td>2</td>
<td>GDX error</td>
</tr>
<tr>
<td>3</td>
<td>No input file</td>
</tr>
<tr>
<td>4</td>
<td>Input file not found</td>
</tr>
<tr>
<td>5</td>
<td>Bad parameter</td>
</tr>
<tr>
<td>6</td>
<td>Read error</td>
</tr>
<tr>
<td>7</td>
<td>Problem loading GDX DLL</td>

</tr>
<tr>
<td>22</td>
<td>Deprecated</td>
</tr>
</tbody>
</table>
### 6.30 GDXXRW

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>Program aborted</td>
</tr>
<tr>
<td>24</td>
<td>Merge range empty</td>
</tr>
<tr>
<td>25</td>
<td>Too many columns skipped</td>
</tr>
<tr>
<td>26</td>
<td>Too many rows skipped</td>
</tr>
</tbody>
</table>

#### 6.30.4 Warning

When executing GDXXRW twice and redirecting output to the same log file may result in a fatal error. For example:

```bash
gdxxrw step1 parameters > logfile
gdxxrw step2 parameters > logfile
```

The execution of step2 may fail, because Excel will close the logfile in step1 in a delayed fashion, but return control to GDXXRW immediately. Using the `log` or `logAppend` parameter will avoid this problem.

#### 6.30.5 Reading from Spreadsheet - Examples:

##### 6.30.5.1 Reading Set from Spreadsheet

Assuming we want to read set elements from the first sheet of the spreadsheet file test.xls and write the data to test.gdx.

Either of the following two statements below reads the second row of set elements from the spreadsheet above:

```bash
gdxxrw exampleData.xlsx set=i1 rng=readingSets!A2:C2 cDim=1
gdxxrw exampleData.xlsx dSet=i1a rng=readingSets!A2:C2 cDim=1
```

When the output file is not specified, the output file will be derived from the input file by changing the file extension of the input file and removing any path information. Since all elements in the second row are unique, there is no need of increasing the `maxDupeErrors` parameter to avoid an error message when defining the symbol as set. By specifying the symbol directly as a dSet (domain set) in the second statement, duplicate labels would be removed without throwing an error. We set `cDim` to one so that the first row of the range is used for the labels of the set.

On the other hand if we want to read set elements listed in a column:

Either of the following two statements reads column A of set elements from the spreadsheet above:

```bash
gdxxrw exampleData.xlsx set=j1 rng=readingSets!A35:A37 rDim=1
gdxxrw exampleData.xlsx dSet=j1a rng=readingSets!A35:A37 rDim=1
```

Besides the range we also had to change the parameter `rDim` to indicate that the first column of the range is to be used for the labels.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.
6.30.5.2 Reading Set and Explanatory Text

Suppose we want to read the set elements in the ninth row and their associated text in the tenth row of the following spreadsheet:

We can read the set elements and their explanatory text by executing the command:

```
gdxr exampleData.xlsx set=i3 rng=readingSets!A9:E10 cDim=1
```

To read the explanatory text, we simply include the tenth row within the range of the symbol i3 and specify cDim=1. By doing this, the first row of the range, i.e., the elements of the ninth row, will be used as the set elements, while the tenth row will be interpreted as their associated text (depending on the values option specified. By default, the values option is set to dense in this example, i.e., all elements will be included and the string in the associated data cell will be used as explanatory text. See also Reading set elements associated with Data or Text for instance.).

Note here the explanatory text of the set element skipme2 is just a Y as it has a blank entry for the explanatory text.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.

6.30.5.3 Reading Set Elements associated with Data or Text using the values Option

When reading set elements from spreadsheet, the values option can be used to control whether elements and associated text are included in the set or not. We use the data displayed in the spreadsheet below to demonstrate the \texttt{yn}, \texttt{dense}, \texttt{sparse} and \texttt{noData} specifications:

The set element names are stored in the first row, the associated data cells in the second row.

1. \textbf{values=yn}
   Run the following command to load those element names associated with nonzero data or yes without storing the data as explanatory text:

   ```
gdxr exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=yn
```

   The set \texttt{A} will contain the elements \texttt{a}, \texttt{b}, \texttt{e}, \texttt{f}, \texttt{h}, \texttt{i}, \texttt{k} and \texttt{m}, since the elements \texttt{c}, \texttt{d}, \texttt{g}, \texttt{j} and \texttt{l} are associated with a zero, a blank or a no resp. \texttt{N} (case insensitive).

2. \textbf{values=dense}
   This option must be specified, if we want to read all elements while using the strings in the data cells as explanatory text.

   ```
gdxr exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=dense
```

3. \textbf{values=sparse}
   To read in all elements having a non-empty data cell while interpreting the string in the data cell as explanatory text, run the following command:
gdxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1 values=sparse

The set A will contain all elements except for j, since the associated data cell is empty.

4. values=noData
This option must be used, if we want to read all set elements while ignoring the data range. Especially, the data cells will not be interpreted as explanatory text. To read the elements from the range A1:M1, one could run the following command:

```
gdxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1
```

While all elements a - m will be included this way, the second row will be automatically interpreted as explanatory text (even though we specified only the first row within the `rng` statement). This might be not desirable at all in some situations, e.g. when reading the city names in the next example Reading Set from Data Tables, we do not want to have the numbers 5000, 6000 and 0 to be explanatory text for the city names. Run the following command to include all elements in your set without interpreting the cells in the second row as explanatory text:

```
gdxrw exampleData.xlsx set=A rng=readingWithValues!A1:M1 cDim=1 values=noData
```

5. values=auto (default)
The second table within the description of the values options indicates which value type will be used by default based on the `rng`, `cDim` and `rDim` specifications for the set. For instance, when running the following command:

```
gdxrw exampleData.xlsx set=A rng=readingWithValues!A1:M2 cDim=1
```

the value type used is `dense`, since we specified a block range with a data row and `rDim` equals zero.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample9] for reference.

6.30.5.4  Reading Set from Data Tables

One may wish to load set elements from a data table. Given a spreadsheet segment like the following:

```
We can take the set across the top containing the elements cleveland, chicago and dallas with any of the following commands:
```

```
gdxrw exampleData.xlsx set=i6  rng=readingSets!B20:D20  cDim=1  values=noData
```
```
gdxrw exampleData.xlsx set=i6a rng=readingSets!B20:D20  cDim=1
```
```
gdxrw exampleData.xlsx set=i6c rng=readingSets!B20:D21  cDim=1  values=noData
```

Note the usage of the values option in order to avoid reading the numbers as explanatory text. See also Reading set elements associated with Data or Text. However, this can also be avoided by declaring the symbol as a domain set using the symbol declaration `dSet`.

We can also take a set vertically from column A as follows:

```
gdxrw exampleData.xlsx dSet=j4  rng=readingSets!A21:A23  rDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample18] for reference.
6.30.5.5 Reading Set from Lists with Duplication

One may wish to extract set elements from a spreadsheet where there is no unique list of elements that can be read but rather a list where some names are repeated. In the example below note that in rows 26 and 27 there are set element names but they are duplicated:

One can read this using dSet as follows:

\[
gdxxrw\text{ exampleData.xlsx }\text{ dSet=i7 }\text{ rng=readingSets!B26:E26 }\text{ cDim=1 }\text{ dSet=i8 }\text{ rng=readingSets!B27:E27 }\text{ cDim=1}
\]

Both domain sets will be read within a single GDXXRW call. The \text{ rng} and \text{ cDim} specifications affect only the symbol that they are following directly.

It may be favored in some situation to use the set symbol instead (e.g. for reading explanatory text). To oppress an error message when reading sets with duplication, one must specify a sufficient large number within the maxDupeErrors option.

\[
gdxxrw\text{ exampleData.xlsx maxDupeErrors=4 set=i7 rng=readingSets!B26:E26 cDim=1 values=noData set=i8 rng=readingSets!B27:E27 cDim=1 values=noData}
\]

For the data in this example, four is a sufficient large number since there are two duplicates for the first and two duplicates for the second set within each range. Note the usage of the \text{ values} option in order to avoid reading 'cleveland' as explanatory text for the elements of set \text{i7} and to avoid reading the numbers as explanatory text for the elements of \text{i8}. See also Reading set elements associated with Data or Text for more informations about the \text{ values} option.

This example is also part of the GAMS Data Utilities Library, see model \text{ [GDXXRWExample18]} for reference.

6.30.5.6 Reading Parameter from Spreadsheet

Assuming we want to read parameter data1 from the file Test1.xls and write the data to Test1.gdx.

The following statement reads parameter data1 from the spreadsheet above (using the par data type):

\[
gdxxrw\text{ Test1.xls par=data1 rng=A1:D3 cDim=1 rDim=1}
\]

The sheet name in a range can be omitted when it refers to the first sheet. The elements in the first row and first column of the data range will be used as labels for the two dimensional parameter data1 by defining \text{ cDim=1} and \text{ rDim=1} (see also \text{ cDim} resp. \text{ rDim}).

This example is also part of the GAMS Data Utilities Library, see model \text{ [GDXXRWExample5]} for reference.
6.30.5.7 Reading Parameter from Spreadsheet with Duplication

The same data as in the previous example, but organized differently. We use the dSet symbol specification instead of set to read set I (in column A) and set A (in column B), since there are duplicate entries in column A resp. column B.

The following statement reads parameter data2 from the spreadsheet above:

```
gdxxrw Test1.xls par=data2 rng=EX2!A1 rDim=2 dSet=I rng=EX2!A1 rDim=1 dSet=A rng=EX2!B1 rDim=1
```

By setting rDim=2 for the parameter data2 we indicate to use the first two columns of the data range as the labels for the parameter values. Since the sheet does not contain further data, one can specify the ranges using the top left cell notation without hesitation.

When using a few symbols, the command line can become too long to be practical. In such case, use a text file to hold the parameters. A parameter file can contain multiple lines to increase readability and a line starting with a ‘#’ will be ignored.

```
* file example6.txt
par =data2 rng=EX2!A1 rDim=2
dSet=I     rng=EX2!A1 rDim=1
dSet=A     rng=EX2!B1 rDim=1
```

An option file is indicated by preceding the file name with a @ (At sign.).

```
gdxxrw Test1.xls @example6.txt
```

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample6] for reference.

Note

- An option file can contain multiple lines to increase readability.
- When reading parameters from a text file, lines starting with an asterisk (*) will be ignored and act as a comment.
- An option file can also be written during the execution of a GAMS model using the GAMS Put Facility and the subsequent GDXXRW commands must use execute command so the put file is written before it is to be read (this would happen when using the compile time command $call to run GDXXRW).
6.30.5.8 Reading Multi-dimensional Parameter from Spreadsheet

This example illustrates how to read a four-dimensional parameter from spreadsheet:

The strings in the first two columns and the first two rows of the data range A1:F6 shall be used as labels for the parameter values. Therefore, we define \texttt{rDim}=2 and \texttt{cDim}=2 (see also \texttt{rDim} and \texttt{cDim}). The parameter will be named \texttt{data3} (within the \texttt{par} declaration). Run the following command to read the data with GDXXRW:

\begin{verbatim}
gdxrw Test1.xls par=data3 rng=EX3!A1:F6 rDim=2 cDim=2
\end{verbatim}

Note that the data range was specified using the block range notation. However, it might be more comfortable to specify only the top left corner sometimes, but empty rows or columns may affect the reading process, i.e. GDXXRW might stop too early when encountering empty rows or columns or it will try to read data separated by empty rows or columns not being part of the data you wish to read. When we specify the range as a block, an empty row or column will always be ignored. When we specify the top left cell only, the \texttt{skipEmpty} option can be used to ignore one or more empty rows or columns. However, for the data in this example, we do not need to ignore empty rows or columns within the data range, but suppose there is non-relevant data starting in column H. By default (\texttt{skipEmpty}=1), GDXXRW would try to read the data starting in H. When we specify \texttt{skipEmpty}=0 and cells A7, B7, G1 and G2 are empty, the range can be specified with the top left cell only in this example:

\begin{verbatim}
gdxrw Test1.xls skipEmpty=0 par=data3 rng=EX3!A1 rDim=2 cDim=2
\end{verbatim}

Since \texttt{skipEmpty} is a global option, affecting every symbol that follows, we define it before declaring the parameter \texttt{data3}.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample7] for reference.

6.30.5.9 Reading Spreadsheet using the Index Option

The \texttt{index} option is used to read a number of parameters and sets based on information stored in the spreadsheet itself. By doing this, the GDXXRW command becomes quit short and the informations on how to read the data can be written directly within the spreadsheet to increase readability. The first row of the range is used for column headings indicating additional parameters. We will discuss the results only briefly, because all other options used in this example were demonstrated before.

Suppose we want to read the parameters and sets from the following spreadsheet:

The informations about all parameters and sets are stored within the sheet index in the same spreadsheet file exampleData.xlsx as testIndex above:

The following statement reads parameters and sets from the spreadsheets using the \texttt{index} option:

\begin{verbatim}
gdxrw exampleData.xlsx output=gdxAll.gdx index=index!A1
\end{verbatim}

We use the \texttt{output} option to write the data to gdxAll.gdx for demonstration here. By default, GDXXRW would write to testIndex.gdx. Some brief remarks on the results:
- Elements of set $i1$ and $i1a$: trains, cars and planes. There is no explanatory text, since the data range (third row) is empty. We can use $\text{dim}=1$ equivalently to $\text{cDim}=1$ in this example, because by default, $\text{cDim}=1$ and $\text{rDim}=\text{dim}-1$. See also dimensions.

- When reading the sets $i2$ and $i3$, we are defining which elements and explanatory text will be stored by specifying the $\text{values}$ option.

- The set $i4$ will contain all elements of the thirteenth row. Afterwards, $\text{skipEmpty}$ is set to zero, affecting the reading of $i4a$ and $i5$. Unlike $i4$, the sets $i4a$ and $i5$ will not contain the element houston, since $\text{skipEmpty}=0$ and the empty column signals GDXXRW to stop reading (note that the range is not defined using the block range specification). Since there is a data range for $i5$, the strings $\text{city1} - \text{city5}$ will be used as explanatory text by default. After reading $i4a$ and $i5$, $\text{skipEmpty}$ is reset to zero (default).

- Each of the sets $i6$, $i6a$ and $i6b$ will contain the elements cleveland, chicago and dallas. There is no explanatory text for any of the sets in the GDX file, however, one must enforce this for the set $i6$ with $\text{values}=\text{noData}$.

There are no interesting details for the remaining sets and parameters to discuss here. The complete example and the results displayed within GAMS can be found in the GAMS Data Utilities Library, see model [GDXXRWExample10] for reference.

Note

- The parameters and sets are read using the specifications within the myIndex sheet. They are treated as if they appeared directly on the command line.

- In the spreadsheet, the first three columns of the range have a fixed interpretation: DataType (par, set, dSet, equ, or var), Item name identifier and spreadsheet data range. The fourth and following columns can be used for additional parameters like $\text{dim}$, $\text{rDim}$, $\text{cDim}$, $\text{merge}$, $\text{clear}$ and $\text{skipEmpty}$. The column header contains the keyword when necessary, and the cell content is used as the option value.

- When an entry appears in a column without a heading then it is directly copied into the GDXXRW option file. Thus in the example above the items in column G are directly copied into the file.

- Rows do not need to have entries in the first three columns if one just wants to enter persistent options such as $\text{skipEmpty}$ or some of the special character string re-definitions (as in row seven and ten from the spreadsheet above).

### 6.30.5.10 Reading Data from Spreadsheet and Loading into GAMS

One can use $\text{call}$ to execute the GDXXRW command in the GAMS code to read from spreadsheet at compilation time (the data is taken from the previous example):

$\text{call gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData}$

Getting a set from the spreadsheet into a GDX file is only half the battle. One must also use commands in GAMS to load the data as discussed in the chapter Using GAMS Data Exchange or GDX Files. At compile time this is done using:
Set i9;
* read/load set from data at compile time
$call gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData
$gdxIn testIndex.gdx
$load i9

where the set must be declared in a set statement then one can if needed create the GDX file using GDXXRW, then one uses a $gdxIn to identify the source file and a $load to bring in the data.

Some users may wish to load sets at execution time. However, this is limited to subsets that are dynamic sets and cannot be used in domains. To do this one simply uses the statements as above, but substitutes execute in place of $call as follows:

Set i9(i6a);
* read/load set from data at execution time
execute 'gdxxrw testIndex.xlsx set=i9 rng=Sheet1!B20:C20 cDim=1 values=noData'
execute_load 'testIndex' i9;

where the set i9 must be declared as a subset in a set statement (of i6a in this case), then one can if needed create the GDX file using execution time GDXXRW, and an execute_load to bring in the data with an identification of the GDX source file name. Note that we used the set i6a as superset, fitting best to the data from the previous example. However, one could also use the statement Set i9(*);

One can load the universe of labels from a GDX file into a set at run-time using the syntax:

execute_load 'someFile', someSet=*

Note
In doing this, only labels known to the GAMS program will be loaded.

6.30.5.11 Reading empty Cells with colMerge

Suppose we want to read the four dimensional parameter from the following spreadsheet:

The cells B4, B5, C4 and D5 might be empty to avoid duplication, i.e., the non-empty content of the previous cell in the same column shall be used as content for the empty cell. In particular: the content of B3 shall be used for the content of B4 and B5, the content of C3 for C4 and the content of D4 for cell D5.

Reading the above spreadsheet using the following GAMS statement:

gdxxrw exampleData.xlsx par=A_d rng=colMerge!B2 rDim=3 cDim=1

results in empty cells B4, B5, C4 and D5, causing troubles if you want to declare the parameter as A(number,number,number,color) certainly:

Adding the symbol attribute colMerge, we use the non-empty content of the previous cell in the same column as the content for the empty cell. Specifying colMerge=2 will do this for the first two columns for instance.

gdxxrw exampleData.xlsx par=A_2 rng=colMerge!B2 rDim=3 cDim=1 colMerge=2

Only the two entries corresponding to the cell D5 are still empty, since we do not specify all three columns within colMerge:
6.30 GDXXRW

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an `<empty>` entry instead.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample20] for reference.

6.30.5.12 Reading merged Excel Ranges with cMerge

Suppose we want to read the three dimensional parameter from the following spreadsheet:

Note that the label 'red' is centered over the merged cells B1, C1 and D1 and label 'green' over the merged cells E1 and F1. Additionally, in the data range, the cells B3:C3 and B4:C4 are merged, too. The option cMerge can be used to control the way merged cells are handled. We will discuss the effect of the possible values for cMerge on the data presented above by running the following commands (an option file is used to increase readability):

```gams
$onEcho > howToRead.txt
cMerge=0 par=B_d rng=cMerge!A1 rDim=1 cDim=2
cMerge=1 par=B_1 rng=cMerge!A1 rDim=1 cDim=2
cMerge=2 par=B_2 rng=cMerge!A1 rDim=1 cDim=2
$offEcho

call gdxxrw exampleData.xlsx output=cMerge.gdx @howToRead.txt
```

We specify cMerge in advance, since it is a global option affecting every symbol that follows. Executing the three statements will create three different output files, all displayed in GAMS Studio:

Note

A blank field displayed in GAMS Studio indicates an empty UEL. In the GAMS IDE, there would be an `<empty>` entry instead.

Some remarks on the results:

**cMerge=0** (default)
Empty cells being part of a merged Excel range will remain empty. Thus, the cells C1, D1, F1, C3 and C4 from the spreadsheet above will remain empty when reading with GDXXRW. Since C3 and C4 are empty while being part of the data range, they won't show up in the GDX file. The values in the last column of the GDX file are useful to compare the results with the spreadsheet. For instance, the UELs of the value 5 are a, `<empty>` and two, since the cell F1 is empty, while A3 contains the string a and F2 the string two.

**cMerge=1**
The value of a merged range within a row or column header will be used for all cells being part of the merged range. Thus, the string 'red' will be used for the cells in the column header C1 and D1 and the string 'green' for the cell F1. Since C3 and C4 are part of the data range, they will remain empty and are not displayed in the GDX file. As you can see, there is no longer an empty UEL.
cMerge=2
The value of a merged range will be used for all cells being part of the merged range, i.e. cMerge=1 is extended to the data range. Therefore, the value 1 resp. 11 will be also used for the cell C3 resp. C4, appearing in the GDX file for the first time. Since there is no change in handling merged cells within the row or column header, all values have non-empty labels.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample20] for reference.

6.30.5.13 Skipping Empty Rows and Columns

By using the skipEmpty option, we can control the way blank rows or columns are handled and causes GDXXRW to either stop or skip over if a blank row or column is encountered when using the top left corner range specification instead of a block range. If the range is specified using the TopLeft:BottomRight cell notation (often referred as block range notation), empty rows or columns will be skipped automatically. Suppose the data is stored in the following spreadsheet:

We can read this spreadsheet and skip blank rows and columns with the following command:

gdxxrw exampleData.xlsx par=A_d rng=skippingRC!A2 rDim=2 cDim=1

or

gdxxrw exampleData.xlsx se=1 par=A_1 rng=skippingRC!A2 rDim=2 cDim=1

Note that there will be no difference concerning the generated GDX files, since skipEmpty is set to one by default. On the other hand, if skipEmpty is set to zero

gdxxrw exampleData.xlsx se=0 par=A_0 rng=skippingRC!A2 rDim=2 cDim=1

the blanks terminate the read not reading the rail column and the san francisco.chicago row. After loading into GAMS the data become:

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample21] for reference.

Note
The skipEmpty option must appear before any par, set, dSet etc statements that use it and will persist for the rest of the statements in a command unless it is set to another value.
6.30.5.14 Ignoring Rows and Columns

We can use the options ignoreColumns and ignoreRows to ignore columns and rows when reading data for a symbol. Suppose we want to ignore the red colored rows and columns of the following spreadsheet, when reading the four dimensional parameter:

We can read this spreadsheet and ignore the red colored columns and rows with GDXXRW by running the following command:

```
gdxxrw exampleData.xlsx par=A rng=ignoringRCC1 cDim=2 rDim=2 ignoreRows=2,6 ignoreColumns=D,G
```

The options ignoreRows and ignoreColumns are symbol options and therefore must appear after the symbol specification, affecting only this particular symbol.

In the example above we ignored column D which would have been part of the index for the rows. So the range for the row index was extended with column E. The E column is no longer part of the data range. The treatment of the column index is similar. The second row would have been part of the column index, and now that the row is ignored, the next row becomes part of the column index and the third row is no longer part of the data range.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample21] for reference.

Note

The ignoreColumns and ignoreRows options appear after any par, set, dSet etc GDXXRW command instruction and only affect reading of that item.

6.30.5.15 Reading Parameter from Spreadsheet using pre-defined Excel Named Ranges

As mentioned in section Excel Ranges, the range of a symbol to be read can be defined by using named ranges. To name a cell range within Excel, simply select the cell range and type in the name you want to assign to this particular range by using the name-box next to the top left corner of your spreadsheet. Suppose we want to read the data in the range A1:D3 taken from the example Reading Parameter from Spreadsheet:

Instead of specifying the range explicitly by rng=A1:D3, we use the pre-defined named range 'parRange', i.e. rng=parRange. GDXXRW uses the string specified to search for a matching pre-defined named range first. In summary, run the following command to read the parameter data4 from the file Test1.xls:

```
gdxxrw Test1.xls par=data4 rng=parRange rDim=1 cDim=1
```

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample5] for reference.

Note

In Excel, one can assign a single name to several separated block ranges, e.g. assign the name 'disconnected' to the block ranges A1:D3 and F4:H5 (by holding 'Strg' while selecting the second block range and using the name-box to assign the name). However, such disconnected data cannot be read using the named-range specification.
6.30.6 Writing to Spreadsheet - Examples:

6.30.6.1 Unloading Data from GAMS before Writing to Spreadsheet

When writing to spreadsheet with GDXXRW, one must use commands in GAMS to place the data into the GDX file at first (see also Using GAMS Data Exchange or GDX files). When reading data, it is often desirable to use a $call command to run GDXXRW and the statements $gdxIn and $load afterwards to load the data, allowing also domain definitions (at compile time) for instance. This is hardly ever desirable or realizable when unloading and writing to a spreadsheet, for example, if one wish to write the solution after solving a model to spreadsheet. This should generally not be done at compile time so one should only use the execute and execute_unload commands at execution time as follows:

```
execute_unload 'test.gdx' someParameter;
execute 'gdxxrw test.gdx par=someParameter rng=A1'
```

where the execute_unload tells what data to place in the GDX file and determines the GDX source file name. The matching GDXXRW execution tells the name of the GDX file, the name of the spreadsheet (optional) and identifies the data to write.

See also Writing Set to Spreadsheet and Writing Parameter to Spreadsheet for demonstration.

Note

- One must be careful when using GDXXRW as each time the command is executed the GDX file is erased and only has the current contents and thus should be written just before if reusing the name.
- One also obtains output of sets using the command execute_unloaddi where the GDX file automatically includes all sets associated with unloaded parameters, variables and equations without need to list the set element names.

6.30.6.2 Writing Set to Spreadsheet

At first, we will create a GDX file containing a simple set using the execute and execute_unloading directives. Most of the elements have an explanatory text:

```
Set x / element1 'explanatory text'
    element2
    element3 'previous element does not have explanatory text' /;
execute_unload 'writingSet.gdx' x;
```

Of course, in this particular code section above, one could also use $gdxOut and $unload. The values option can be used to control whether explanatory text is written to the spreadsheet. We'll demonstrate all three possible values explicitly within a single GDXXRW execution:
Before executing this example, check if the Excel file (writingSet.xlsx) is open. If you run GDXXRW for writing a file sharing conflict will arise. To avoid this problem, either close the Excel file or use the Excel Tools menu to make this a shared notebook. After writing to the spreadsheet (still opened), use the Excel "File Save" command to verify the changes made.

By adding two additional commas within the hText statement, the cells B1, C1 and E1, F1 will be skipped when writing the text to the first row of the spreadsheet. If values=noData, neither explanatory text nor a Y are written to spreadsheet for the set elements. If values=yn, GDXXRW writes a Y for each set element to spreadsheet. To write the explanatory text, specify values=string.

Since cDim=0, the default option is string (see values). Imagine a two dimensional set, one could write the set in a table format, i.e. cDim=1 and rDim=1. By default, GDXXRW would write this set using the values=yn format.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample11b] for reference.

Note

- A workbook cannot in general be open unless you have made special provisions with an error signaled indicating a file sharing conflict will arise when the target file is open in Excel.
- To avoid the sharing conflict error the user must either close the file or indicate that the spreadsheet is a shared Excel workbook by using the Excel Tools Share Workbook dialogue.
- In an open shared workbook the contents are not updated until you have done a file save in Excel.
- Writing to a shared workbook can be painfully slow.
- In general, it is best to close the workbook.

6.30.6.3 Writing Parameter to Spreadsheet

At first, we create a GDX file, containing some random data:

* file makeData.gms
Set
  i / i1*i4 /
  j / j1*j4 /
  k / k1*k4 /;
Parameter V(i,j,k);
V(i,j,k)$((uniform(0,1) < 0.30) = uniform(0,1);
When we run this GAMS model from the command prompt using the following statement, the file `writingPar.gdx` will be created at the end of the run.

```
GAMS makeData gdx=writingPar
```

Using the file `writingPar.gdx`, we can write to a spreadsheet:

```
Write parameter V to the first cell in the first sheet; because we only specify the top left corner of the sheet, the complete sheet can be used to store the data. We do not specify the row and column dimension, so they will be set to \texttt{rDim=2} and \texttt{cDim=1} by default. (See also \texttt{dimensions})
```

By using the following command (remember to close an already existing file `writingPar.xlsx` in advance or make it a shared notebook as discussed in the previous example):

```
gdxxrw writingPar.gdx output=writingPar.xlsx par=V rng=A1
```

The steps above can be combined in a single GAMS model using the `execute_unload` and `execute` statements as follows:

```
Set
i / i1*i4 /
j / j1*j4 /
k / k1*k4 /;
Parameter V(i,j,k);
V(i,j,k)$\text{uniform}(0,1) < 0.30) = \text{uniform}(0,1);
execute_unload 'writingPar.gdx', i, j, k, V;
execute 'gdxxrw writingPar.gdx par=V rng=A1';
```

The resultant spreadsheet looks like:

Note that if we only want to write the parameter \texttt{V}, there is no need to unload the sets \texttt{i}, \texttt{j} and \texttt{k} explicitly. The labels written to the columns A and B and to the first row are stored directly together with \texttt{V} in the GDX file.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample11b] for reference.
6.30.6.4 Writing to Spreadsheet with merge Option

When writing to a spreadsheet one can control data handling and matching using the merge command line option. When merge is active, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already. Also under merge, spreadsheet cells for which there is no matching row/column pair will not be changed. This option might be very useful, e.g., if there is a fixed report layout/framework already in your spreadsheet file which should not be changed when writing the data from GAMS.

Suppose we want to write the parameter \( A \), already stored in data.gdx, to an existing spreadsheet:

In the following spreadsheet, there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non-existing row labels 'san francisco.chicago':

Use the following commands to write the data from GDX to spreadsheet twice to different ranges for comparison:

```plaintext
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B1:G4 rDim=2 cDim=1 merge
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!B8 rDim=2 cDim=1
```

Note that merge is a symbol option affecting only the symbol \( A \). The resultant spreadsheet looks like:

The parameter is written to the range B8-F12 without merge enabled, while the option is enabled when writing to the range B1:G4, respecting the data arrangement already existing. Note that the column and row orders vary and the san francisco - chicago row is missing since it is not mentioned in the labels within the spreadsheet before the merge operation, while the horse column is still present with it's data left alone, not being overwritten by the parameter.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample12] for reference.

Note

- Using the merge option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a merge option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements at all.
- The matching of labels is not case-sensitive.
- Warning: Enabling the merge option will clear the Excel formulas in the rectangle used, even if the cells do not have matching row/column headings in the GDX file. Cells containing strings or numbers are not affected.
### 6.30.6.5 Writing to Spreadsheet with clear Option

When writing to a spreadsheet one can also use the clear option to control data handling and matching. When clear is enabled, the only data that will be written to the spreadsheet are those data for which the element names match row and column labels that are in the spreadsheet already but all data and formulas in the target range will be removed.

Suppose the parameter $A$ from the previous example is stored in data.gdx and there are row and column labels matching most of the data in the GDX file, except for the additional column header 'horse' and the non-existing row labels 'san francisco.chicago':

Use the following command to write to exampleData.xlsx with clear enabled:

```
gdxxrw data.gdx output=exampleData.xlsx par=A rng=merge_clear!I1 rDim=2 cDim=1 clear
```

then the result is

The results are similar to those under merge but the old data in the column labeled 'horse' has been removed.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample12] for reference.

Note

- Using the clear option will force the data to be presented in the order in which the row and column labels are entered already.
- GDX file contents that do not have matching row/column pair of named elements in the spreadsheet will be overlooked.
- A write under a clear option addressing a blank area of a spreadsheet will always be blank as there will not be matching set elements.
- The matching of labels is not case-sensitive.
- Warning: The clear option will clear all Excel formulas and values in the rectangle used, even if the cells do not have matching row/column labels in the GDX file.

### 6.30.6.6 Writing to Spreadsheet using a Filter

In Excel, you can filter the data by some specified conditions so that only the data matching the conditions is displayed. This might be useful in some cases, e.g. it helps you to focus on the most relevant data within a large table of data. With GDXXRW you can add some basic filter to your spreadsheet when writing data from a GDX file.

The following example creates a small GDX file with some random data, which is used to write the symbol $A$ to a spreadsheet later on with the filter option enabled.

Set

```
  i / i1*i2 /
  j / j1*j2 /
  k / k1*k2 /
```

Parameter $A(i,j,k)$;

```
A(i,j,k) = uniform(0,1);
```

execute_unload 'test.gdx', A;

execute 'gdxxrw test.gdx filter=1 par=A rDim=1 cDim=2 rng=Sheet1!A1';
Since \texttt{filter} is a global option, it must be specified in advance of the symbols for which you want to add a filter. The default value is zero, i.e. no filter will be added. If there are multiple rows in the column header, i.e. \texttt{cDim} is greater than zero, the valid range for the filter option is 1..\texttt{cDim}.

The screenshot above shows the filter in Excel. When we specify \texttt{filter=2} in this example with two dimensions for the column header, the row with the filter moves away from the data range as illustrated below:

One could now filter the data, e.g. displaying only the values where the label of the first dimension is \texttt{i1} by selecting this value exclusively within the drop down menu of column A.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample15] for reference.

6.30.6.7 Writing to Spreadsheet adding Text and Hyperlinks

The following example illustrates the use of the \texttt{text} directive. Adding text and hyperlinks to your spreadsheet is useful to customize the output and to navigate more quickly through the data.

First, we write some data to a GDX file and we use the text directive to write text to various cells in the spreadsheet; some of the cells are hyperlinks to other locations. To increase readability, we'll use a parameter file \texttt{howToWrite.txt} to shorten the \texttt{GDXXRW} statement.

```plaintext
Set
  i / i1*i9 /
  j / j1*j9 /;

Parameter A(i,j);
A(i,j) = 10*ord(i) + ord(j);
execute_unload 'pv.gdx' A;

$onEcho > howToWrite.txt
  text="Link to data" rng=Index!A2 linkID=A
  text="Below the data for symbol A" rng=data!C2
  par=A rng=data!C4
  text="Back to index" rng=data!A1 link=Index!A1
  text="For more information visit GAMS" rng=data!C1 link=http://www.gams.com
$offEcho

execute 'gdxxrw pv.gdx output=pv.xls @howToWrite.txt'
```

We will write the text "Link to data" to the cell A2 of sheet Index. The option \texttt{linkID} is used to add a hyperlink to the range of the symbol \texttt{A}. In addition, we create a hyperlink "Back to index" in the cell A1 of sheet data using the \texttt{link} option pointing to the cell A1 of sheet Index. One can also specify links to external sources. For demonstration, we add a link to the GAMS homepage.

Below a screen shot showing both sheets data and Index created by the commands above:

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample16] for reference.
6.30.7  Reading and Writing, Extended Use - Examples:

6.30.7.1  Reads a Table from Spreadsheet, manipulates the Data and writes back to Spreadsheet

In the following example, we read data from a spreadsheet and save the data in a GDX file. Using the \$gdxIn and \$load GAMS directives, we load the data from the GDX file into GAMS afterwards. The GAMS program modifies the data and at the end of the run the data is saved in a new GDX file (tmp.gdx). The last step updates the spreadsheet with the modified parameter.

We read the spreadsheet and load the data from the resultant GDX file at compile time. The data modification and the unloading and writing process are done at execution time, using the execute_unload and execute directives:

```gams
$call gdxrw test1.xls dSet=I rng=A2:A3 rDim=1 dSet=A rng=B1:D1 cDim=1 par=X rng=A1:D3 rDim=1 cDim=1
$gdxIn test1.gdx
Set I(*), A(*);
$load I A
Parameter X(I,A);
$load X
display I, A, X;
$gdxIn
X(I,A) = - X(I,A);
execute_unload 'tmp.gdx', I, A, X;
execute 'gdxrw tmp.gdx output=test1.xls par=X rng=EX6!A1:D3 rDim=1 cDim=1';
```

The parameter is written to the sheet EX6. However, since we only write the parameter X, we do not necessarily have to unload the set I and A.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample13] for reference.

6.30.7.2  Reading Data from Spreadsheet and writing Data to Spreadsheet after Solve

In this example, we use a modified version of the [trnsport] model from the GAMS model library to demonstrate the process of reading data, defining and solving the model and writing a solution report to spreadsheet altogether. This example illustrates in particular:

- Compilation phase
- Read data from a spreadsheet and create a GDX file
- Loading sets from the GDX file
- Using the sets as a domain for additional declarations
- Reading additional data elements
• Execution phase
• Solve the model
• Write solution to a GDX file
• Use GDX file to update spreadsheet

A parameter file howToRead.txt is used to increase the readability of the GDXXRW call. Note that the dimension of the scalar we want to read is set to zero. The range of each parameter can be specified by using the top left corner only, since there are two empty rows separating the data blocks from each other and the default value of skipEmpty signals to stop reading if two empty rows occur.

```plaintext
$onEcho > howToRead.txt
dSet=i rng=A3:A4  rDim=1
dSet=j rng=B2:D2   cDim=1
par =d rng=A2     rDim=1  cDim=1
par =a rng=A8     rDim=1
par =b rng=A13    rDim=1
par =f rng=A19    dim=0
$offEcho
$call gdxxrw TrnsportData.xls @howToRead.txt
$gdxIn TransportData.gdx

Set
  i(*) 'canning plants'
  j(*) 'markets';

$load i j

display i, j;

Parameter
  a(i) 'capacity of plant i in cases'
  b(j) 'demand at market j in cases'
  d(i,j) 'distance in thousands of miles';

Scalar f 'freight in dollars per case per thousand miles';
$load d a b f
$gdxIn

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*d(i,j)/1000;

Variable
  x(i,j) 'shipment quantities in cases'
  z 'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
  cost   'define objective function'
  supply(i) 'observe supply limit at plant i'
  demand(j) 'satisfy demand at market j';

cost..   z =e= sum((i,j), c(i,j)*x(i,j));
supply(i).. sum(j, x(i,j)) =l= a(i);
demand(j).. sum(i, x(i,j)) =g= b(j);
```

---

6.30 GDXXRW

---
Model transport / all /;

solve transport using lp minimizing z;

display x.l, x.m;

execute_unload 'TrnsportData.gdx', x;
execute 'gdxxrw TrnsportData.gdx output=TrnsportData.xls squeeze=n var=x.l rng=Sheet2!A1';

The solution is written to Sheet2 of the input file TrnsportData.xls by executing GDXXRW at execution time. The var statement is used in the symbol specification to write out the level of variable x. In order to write zero values, the squeeze option is disabled. Otherwise, the cells C4 and D3 remain blank.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample14] for reference.

6.30.7.3 Reading Special Values from Spreadsheet and writing to Spreadsheet

This example demonstrates the reading and writing of special values with GDXXRW.

**Reading Special Values**

Assuming we want to read the special values stored in the spreadsheet below:

The following statement reads parameter vIN from the spreadsheet above:

```
gdxxrw exampleData.xlsx output=specialValues.gdx NaIn=N/A squeeze=n par=vIN cDim=1 rng=specialValues!A1:S2
```

To affect the parameter vIN, the global options NaIn and squeeze (to display zero values in the GDX file) must be specified in advance.

The cells containing the strings Eps, +Inf, -Inf, Inf, NA and Undf are read in correctly. The division by zero error in the spreadsheet will be written as Undf. We defined a new string - 'N/A' - within the option NaIn to be recognized as NA additionally. Within GAMS, there is no directly comparable data type for 'None' and 'Null', so these strings will be interpreted as Undf. Note the importance of the cell format specified within Excel. For instance, the values for v13 and v14 are different, although both fields contain a Dollar sign, since the cell format of M2 is 'General', while the cell format of N2 is 'Currency'.

The boolean 'False' turns into zero after reading, while 'True' turns into -1. Note here, that this is independent whether the booleans are written as plain text within Excel or by using the formulas '='True()' resp. '='False()'. We disabled squeeze in order to display the zero values for the elements v16, v18 and v19 in the GDX file.

**Writing Special Values**

Initially, we declare a parameter with special values and generate a GDX file from it:

```
$onUndf
Set v / v1*v7 /;
Parameter vOUT(v) / v1 Eps, v2 +Inf, v3 -Inf, v4 Inf, v5 Undf, v6 0.0, v7 NA /;
Scalar S / 0 /;

execute_unload 'specialValues.gdx', v, vOUT, S;
```

We will write the parameter \texttt{vOUT} to spreadsheet twice. At first to demonstrate the usage of \texttt{EpsOut}, \texttt{pInfOut}, \texttt{mInfOut}, \texttt{UndfOut}, \texttt{zeroOut} and \texttt{NaOut}, the second time to show the default settings when writing. Those output string options may be useful, if the GAMS default settings are not appropriate for your Excel calculations later on or to customize the representation of the values in Excel in general. Note that there is also a scalar declaration in order to demonstrate the different behavior when writing scalars and parameter with zero values to Excel while using the \texttt{zeroOut} option.

```gams
$onEcho > howToWrite.txt
* defining new strings to be used when writing special values:
EpsOut=0 pInfOut=+1E+100 mInfOut=-1E+100 UndfOut=undefined zeroOut=zero NaOut=notAvailable

* now write parameter \texttt{vOUT} with merge to force the column F containing set element "v6" and \texttt{vOUT("v6")}
set=v  rng=specialValues!A6:G6  cDim=1
par=vOUT  rng=specialValues!A6:G7  cDim=1  merge
text="Special values of Parameter \texttt{vOUT} written with user defined output strings:"  rng=specialValues!A5
text="Scalar S / 0 /:"  rng=specialValues!I6
par=S  rng=specialValues!I7

* reset the strings for special values back to default und write \texttt{vOUT} again
resetOut
set=v  rng=specialValues!A10:G10  cDim=1
par=vOUT  rng=specialValues!A10:G11  cDim=1  merge
text="Special values of Parameter \texttt{vOUT} written with default output strings:"  rng=specialValues!A9
text="Scalar S / 0 /:"  rng=specialValues!I10
par=S  rng=specialValues!I11
$offEcho

execute 'gdxxrw specialValues.gdx output=exampleData.xlsx @howToWrite.txt';
```

In order to increase readability when executing \texttt{GDXXRW}, we use a parameter file named \texttt{howToWrite.txt} and additionally, we write some text out to structure the Excel file. The range for the non-default values is A6:G7. We define the new strings to be used for the special values first, affecting the following symbols. To write the default values to the range A10:G11, we use the \texttt{resetOut} option to reset the output strings to default, otherwise, the new strings remain in effect, since they are global options.

As mentioned briefly above, the \texttt{zeroOut} option affects the scalar \texttt{S} and the parameter \texttt{vOUT} differently. While we get the expected result - 'zero' - for the scalar \texttt{S}, the cell F7 for the zero value of \texttt{vOUT} remains empty, since zero values of parameters are not even part of the GDX file in general (and cannot be added from your GAMS model; Note here, that the \texttt{squeeze} options only affects the writing of sub-fields of variables and equations). Therefore, cell F11 has no value, too. Though scalars with zero values are stored in the GDX file. We'll present a workaround for writing zero values of a parameter to spreadsheet in the next example Writing Parameter to Spreadsheet including Zero Values.

The complete example is also part of the GAMS Data Utilities Library, see model \[GDXXRWExample8\] for reference.

**Note**

- When writing to a spreadsheet, special values such as \texttt{Eps}, \texttt{NA}, \texttt{Undf} and \texttt{Inf} will be written but this can be changed. When reading data from a spreadsheet, the ASCII strings for these special character strings will be used to write corresponding special values to the GDX file.
- Cells that are empty or zero will not be written to the GDX file.
6.30.7.4 Writing Parameter to Spreadsheet including Zero Values

There is no straight way to write zero values of a GAMS parameter to spreadsheet from your model using GDXXRW, since zero values of a parameter are not stored in the GDX file (see also the previous example Reading Special Values from Spreadsheet and writing to Spreadsheet). However, instead of the zero values one can store an EPS in the GDX file and instruct GDXXRW to use a zero when writing the value for EPS using the epsOut option afterwards as demonstrated below:

```gams
Set i / i1*i9 /;
Parameter A(i), Amod(i);
A(i) = uniformInt(0,1);
* Amod(i) = A(i) if A(i) <> 0 and Amod(i) = EPS if A(i) = 0
Amod(i) = EPS$(not A(i)) + A(i);

* Unload the unmodified and modified parameter and write to spreadsheet using an option file
execute_unload 'zeroPar1.gdx' A Amod;
```

This approach is impracticable in the unlikely event that there are already EPS values in your parameter and you want to write these as EPS to your spreadsheet.

An alternate approach regarding variables while exploiting the squeeze option is demonstrated below (parameter A and set i refer to the data above):

```gams
Variable dummyPar(i);
dummyPar.l(i) = A(i);
* In order to write every entry of dummyPar in the spreadsheet, one must allocate
* a non-zero value to one of the variable attributes .m, .lo or .up
dummyPar.up(i) = 1;

* Unload the dummy variable and write the .l subfield to spreadsheet while disabling squeeze
execute_unload 'zeroPar2.gdx' dummyPar;
```

Creating the additional variable and the allocation of a non-zero value to one of the other variable attributes are the drawbacks of this approach. Note that we only declared the parameter Amod to keep the original data of A untouched in order to run the code in a single model and to write A to spreadsheet, too.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample19] for reference.
6.30.7.5 Reading several Scalars from Spreadsheet

Suppose you want to read a large number of scalars (i.e. scalar names and their associated values) for your model from a spreadsheet file as shown below. Originally, the data was taken from the model [indus89] of the GAMS Model Library.

Natively, one could declare all scalars directly inside the model and read every single one of them with GDXXRW afterwards (the following code is shortened for representation):

Scalar baseyear, repco;
$call gdxxrw exampleData.xlsx output=indus89Scalars.gdx par=baseyear rng=indus89Scalars!B2 dim=0 par repco rng=indus89Scalars!B3 dim=0 trace=0
$gdxIn indus89Scalars.gdx
$load baseyear repco

However, the code would become quit long and circumstantially for this example, especially the GDXXRW statement, because every scalar must be specified individually. Therefore, we present a more sneaky way to tackle the problem. At first, the file mkScalar.gms is written. We declare a set and a parameter to hold the scalar names and their values. A simple GDXXRW call is used to read the names and values from the file indus89Scalars.xls. Afterwards, we load the data using $gdxIn and $load. The result of this is a single parameter containing the scalar values defined over a set containing the scalar names. However, this is not exactly what we are looking for. To transform this representation into several single scalar definitions, we use a simple loop over the set scalarNames and the Put Writing Facility to generate a file scalars.gms, containing those single scalar statements.

$onEchoV > mkScalar.gms
Set scalarNames;
Parameter scalarValues(scalarNames);
$call gdxxrw exampleData.xlsx output=indus89Scalars.gdx set=scalarNames rng=indus89Scalars!A2:A22 rDim=1 par=scalarValues rng=indus89Scalars!A2:B22 rDim=1
$ifE errorLevel<>0 $abort Problems reading sheet indus89Scalars with GDXXRW
$gdxIn indus89Scalars.gdx
$load scalarNames scalarValues
File fs / 'scalars.gms' /;
put fs;
loop(scalarNames, put / 'Scalar ' scalarNames.tl ' / ' scalarValues(scalarNames):>20:10 ' /;');
$offEcho
$call gams mkScalar
$include scalars.gms

Calling the file mkScalar.gms will create the file scalars.gms, containing all those scalar statements (shortened for representation):

Scalar baseyear / 1988.0000000000 /;
Scalar repco / 2.5000000000 /;

Finally, the file scalars.gms is included to your model.

This example is also part of the GAMS Data Utilities Library, see model [GDXXRWExample17] for reference.
6.30.8 Changes in the Set Values Parameter

The following documents some changes that were made when reading a set using the \texttt{values=string} option. Reading a domain or a parameter was not affected by these changes.

To illustrate the various behaviors in different versions of GDXXRW, we are using the spreadsheet data as shown below, using the following call:

\begin{verbatim}
$call gdxxrw test.xlsx set=one rng=B2 rDim=1 values=string set=two rng=B1 rDim=1 cDim=1 values=string
\end{verbatim}

We read the one dimensional set in column B by specifying the top-left corner of the data (cell B2) or the full range (B2..B5). A two dimensional set is read using the top-left corner of the data (cell B1) or the full range (B1..E5). Variations are introduced by specifying options for \texttt{values} to be \texttt{string}, \texttt{yn}, or \texttt{noData}. The option value \texttt{all} is only available in later versions of GDXXRW and was used to introduce the same behavior as \texttt{strings} in earlier versions.

6.30.8.1 Chronological description of the changes made to the Values option:

- **GAMS versions prior to version 24.3:**
  \texttt{values=string} results in reading the data dense. The contents of a cell is used for the set associated text and an element is included even if the data cell is empty.

- **GAMS version 24.3.1**
  We changed the interpretation of \texttt{string} to mean that the set element was only to be included when the string data was not empty. Note below that element a4 is missing from the one-dimensional set and so are a1.b1, a2.b2 etc from the two-dimensional set. For the two-dimensional case this looked more or less how the GAMS compiler interprets a table statement. Unfortunately, the interpretation of empty data cells was also applied to one-dimensional sets leading to undesired results.

- **GAMS version 24.4.1**
  Recognizing that reading a set dense was no longer available, we introduced a new option \texttt{values=all}. This allowed us to read Excel data the same way as was possible before version 24.3.1 using the \texttt{values=string} i.e. reading the data dense and including all cells whether the data cell is empty or not and use the content of the data cell for the set associated texts.

- **GAMS version 24.4.6 (Current status)**
  We decided to remove some confusion with the interpretation of the \texttt{values} option by introducing the options \texttt{dense} and \texttt{sparse} and flagging the options \texttt{strings} and \texttt{all} as deprecated. Both \texttt{strings} and \texttt{all} are replaced with \texttt{dense}.

Backward compatibility issues.

With these changes we broke our in house rule not to introduce changes that break backward compatibility. Because of this, the user needs to change the parameters for the GDXXRW call or change the workbook data. The parameters for the call should be changed from \texttt{values=string} to \texttt{values=dense} for one-dimensional sets where we specify the top-left corner only. In case the data in the workbook needs to be changed, inserting a string to in the data cell will address the issue. In the example on the top of the page, inserting a 'Y' in cell C5.
6.31  INVERT

INVERT inverts a matrix.

6.31.1  Usage

invert gdxin i a gdxout inva

where

gdxin
    name of gdxfile with matrix

i
    name of set used in matrix

a
    name of 2 dimensional parameter inside gdxin

gdxout
    name of gdxfile for results (inverse matrix)

inva
    name of 2 dimensional parameter inside gdxout

Calculates the inverse of a matrix \( a(i,j) \), where \( i \) and \( j \) are aliased sets. The matrix \( \text{inva} \) in gdxout will contain the inverse.

6.31.2  Example

$onText
Finds the inverse of a matrix through an external program.

Erwin Kalvelagen, march 2005

Reference: model gauss.gms from the model library
http://www.gams.com/modlib/libhtml/gauss.htm
$offText

Set i /i1*i3 /;
Alias (i,j);

Table a(i,j) 'original matrix'
     i1   i2   i3
i1  1    2    3
i2  1    3    4
i3  1    4    3;

Parameter inva(i,j) 'inverse of a';

execute_unload 'a.gdx', i, a;
execute '=invert.exe a.gdx i a b.gdx inva';
execute_load 'b.gdx', inva;

display a, inva;

6.32 MCFILTER

MCFilter filters duplicate and dominated points from a solution set.

6.32.1 Usage

mcfiler InputFile

The input is a gdx file with the following data:

- parameter X(point, i)
  Points containing binary values; use EPS when all zero for a point
- parameter F(point, obj)
  Objectives for the points X; use EPS when all zero for a point
- parameter S(obj)
  Direction of each objective: 1=max, -1=min

The output will be a gdx file called InputFile.res.gdx with the same parameters but without duplicates and dominated points.

6.32.2 Example

* Generate random data to test MCFilter

Set

- Ri / R1*R65535 /
- Xi / X1*X16 /
- Fi / F1*F5 /

Parameter

- X(Ri,Xi) 'the binary variables'
- F(Ri,Fi) 'calculated F variables'
- S(Fi) 'sign on the F variables';

* The following points will be unique
  X(Ri,Xi) = mod(floor(Ri.ord/power(2, Xi.off)), 2);
  F(Ri,Fi) = uniform(1,2);
  S(Fi) = -1 + 2$(uniform(0,1) <= 0.5);

execute_unload 'testdata.gdx', X F S;
execute 'mcfiler testdata.gdx';

* The file testdata.res.gdx will contain the results

Below is the partial log after running the above model:

mcfiler v3.
Number of records = 65535
Number of X variables = 16
Number of F variables = 5
Loading GDX data = 156 ms
After X Filter, count = 65535
X Duplicate filter = 16 ms
After F Filter, count = 1070
F Dominance filter = 249 ms
Writing GDX data = 16 ms
6.33 MDB2GMS

Author
Erwin Kalvelagen

6.33.1 Overview

MDB2GMS is a tool to convert data from an Microsoft Access database into GAMS readable format. The source is an MS Access database file (.mdb or .accdb) and the target is a GAMS Include File (.inc) or a GAMS GDX File (.gdx).

When running the executable mdb2gms.exe without command-line arguments, the tool will run interactively with a built-in GUI interface. Alternatively MDB2GMS can be run in batch mode, which is useful when running it directly from a GAMS model without user intervention using the $call command at compile time or the execute command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL's should not be allowed to get into a GAMS data structure. The handling of NULL's can be specified in an option.

Besides parameters it is also possible to generate set data.

6.33.2 Requirements

MDB2GMS runs only on Windows PC's and with MS Access installed. MS Access comes with certain versions of MS Office, but some MS Office versions will not include Access. The actual retrieval of the database records is performed by DAO or Data Access Objects, an object layer for accessing the database. The actual database is the Jet engine, which performs the queries and retrieves the data. Also consider to use SQL2GMS instead of MDB2GMS, if MS Access is not installed on your system.

To use this tool effectively you will need to have a working knowledge of SQL in order to formulate proper database queries.

6.33.3 Batch Usage

MDB2GMS can be run in batch mode without user intervention from within the GAMS model by using the $call resp. execute statements or directly from command prompt while specifying all arguments in the command-line. A MDB2GMS batch call is of the following form:

mdb2gms inputFile outputFile queryString

A proper batch call will at least contain the following three command-line arguments:
1. The name of the MS Access database inputFile must be specified (.mdb or .accd format). Use the I argument to enter the file name, i.e. I=inputFile.

2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option O, i.e. O=outputFile.inc, while the use of a GDX file is indicated by the option X, i.e. X=outputFile.gdx.

3. The SQL queryString, containing the SQL statement to be executed on the database, must be specified within the option Q, i.e. Q=queryString.

See also Command-line Arguments below for a complete list of all possible command-line arguments. Consider that the $call or execute usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the interactive built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a @ (At sign).

Also consider to take a look at the section Strategies, mentioning some of the drawbacks of the batch usage and how to overcome them.

If you only specify I=inputFile then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command-line argument. Only if an input file, an output file and a query string is provided, the call will be considered as batch invocation.

**6.33.3.1 Command-line Arguments**

The following table summarizes the command-line arguments that can be specified when using MDB2GMS directly from the GAMS model or command prompt.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Interpretation</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>inputFile</td>
<td>none</td>
<td>Specify the name of the input file (required).</td>

<td>none</td>
<td>Maps database columns to GAMS index positions.</td>
</tr>
<tr>
<td>R</td>
<td>rowBatchSize</td>
<td>100</td>
<td>Row batch size; the default is 100 records.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the command-line arguments:

I = string (inputFile, default = none)

This option is required and specifies the name of the .mdb or .accbd file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. On a network UNC Names can be used, and files from another computer can be accessed, e.g.

"\hostname\c\my documents\a.mdb."

This option is required for batch processing. To specify a path equal to the location where the .gms file is located, you can use:

I=system.fpmydb.mdb

This option is demonstrated in most examples, see Example 1 - Reading a single valued Table for instance.
O = string (outputIncludeFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is writable. UNC Names can be used. An output file must be specified for batch operation: i.e. either O= or X= needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the $include command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in most examples, see Example 1 - Reading a single valued Table for instance.

On = string (outputIncludeFile, default = none)

When using multiple queries in a single MDB2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

Q1="SELECT a, b FROM table"
O1=ab.inc
Q2="SELECT c, d FROM table"
O2=cd.inc

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

X = string (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS GDX file. Make sure the directory is writable. UNC names can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either O= or X= needs to be specified (or both). This option is demonstrated in Example 5 - Reading Set with Explanatory Text or Example 7 - Multi-Query Batch Example for instance.

Q = string (Query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by Access we refer to the documentation that comes with MS Access. The query is passed on directly to the Jet database engine, so the complete power and expressiveness of Access SQL is available. For an exact description of allowed expressions consult a text on MS Access.

One notable syntax feature is that when field names or table names contain blanks, they can be specified in square brackets. Examples:

Q="SELECT * FROM mytable"
Q="SELECT year, production FROM [production table]"
Q="SELECT [GAMS City], value FROM [example table], CityMapper WHERE [Access City]=city"

This option is demonstrated in Example 1 - Reading a single valued Table for instance.

Qn = string (Query, default = none)
When using multiple queries in a single **MDB2GMS** call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

```
Q1="SELECT a, b FROM table"
Q1=ab.inc
Q2="SELECT c, d FROM table"
Q2=cd.inc
```

or (GDX output file format - where several sets and parameters can be stored in a single file):

```
Q1="SELECT a, b FROM table"
P1=abParameter
Q2="SELECT c FROM table"
S2=cSet
```

Note the usage of the arguments *Pn* resp. *Sn* in order to store the results as parameter resp. set and to specify the name of the symbols. See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

**S** = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in Example 4 - Reading a multi dimensional Set.

**Sn** = *string* (setName, default = none)

If multiple queries are used in a single **MDB2GMS** call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

```
Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet
```

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

**Y** = *string* (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in Example 5 - Reading Sets with Explanatory Text for instance.

**Yn** = *string* (setName, default = none)

If multiple queries are used in a single **MDB2GMS** call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.
The last column specified within the select clause in the SQL statements will be used as explanatory text.

\[\text{P} = \text{string \ (parameterName, default = none)}\]

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query).

\[\text{Pn} = \text{string \ (parameterName, default = none)}\]

If multiple queries are used in a single \texttt{MDB2GMS} call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

\[\begin{align*}
\text{Q1} &= \text{"SELECT i, j, value FROM table"} \\
\text{A1} &= \text{ijValue} \\
\text{Q2} &= \text{"SELECT n, m, value FROM table"} \\
\text{A2} &= \text{nmValue}
\end{align*}\]

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

\[\text{D} \ (\text{Debug, default = disabled})\]

This option can be used for debugging purposes. If specified the import filter will not run minimized but “restored”, i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of \texttt{MDB2GMS}.

\[\text{B} \ (\text{Quote Blanks, default = disabled})\]

If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off. For more information see subsection Quotes. This option only applies to an output include file.

\[\text{M} \ (\text{Mute, default = disabled})\]

Run in modest or mute mode: no additional information, such as version number, number of rows in the data, elapsed time, used query etc. is written to the log and include file.

\[\text{L} \ (\text{Listing, default = disabled})\]

Embed the data between the \texttt{$\text{offListing}$} and \texttt{$\text{onListing}$} dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

\[\text{@fileName} = \text{string \ (fileName, default = none)}\]
Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also Command Files for some further details.

**N** = *string* (fileName, default = mdb2gms.ini)

Use a different INI file than the standard mdb2gms.ini located in the same directory as the executable mdb2gms.exe.

**F** = *string* (formatString, default = none)

In special cases we can apply a format string on the include file output (not for GDX output). Each column in the result set is a string and can be represented by a `s` in the format string.

**W** = *string* (wiring, default = none)

By using the `W` option, one can map database columns to GAMS index positions. See model [Wiring] for reference.

**R** = *integer* (rowBatchSize, default = 100)

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of **MDB2GMS**.

### 6.33.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the **[transport]** model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.mdb).

The data can be queried with a simple SQL statement:
```sql
SELECT city1, city2, distance
FROM distances
```

By running the following **MDB2GMS** statement, the connection to the database Sample.mdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).

mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
The MS Access database file name is specified using the argument I. Note that the string is enclosed by
quotes, as the string contains blanks. The arguments Q and O are used to specify the query and the
output file name (and format).

The generated include file distances.inc looks like:

* -----------------------------------------------------
* MDB2GMS 24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* DAO version: 14.0
* Jet version: 4.0
* Database: F:\datalib\Sample.mdb
* Query: SELECT city1, city2, distance FROM distances
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------

The commented header section summarizes some information about the MDB2GMS resp. GAMS version
and about the executed database query. The standard export format is to consider the last column as
the value column (containing the distances) and the previous columns as the indices (containing the city
names). The indices are separated by a dot, allowing the generated include file to be used as part of a
parameter declaration statement in your GAMS model.

Retrieving the data using MDB2GMS from the database and including the queried data in your GAMS model
within the parameter declaration statement (at compile time) can be combined in the following way:

Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;
$call mdb2gms I=Sample.mdb Q="SELECT city1, city2, distance FROM distances" O=distances.inc
Parameter d(i,j) 'distance in thousands of miles' /
$include distances.inc
/;
display d;

Finally, the values of the parameter d are displayed:

<table>
<thead>
<tr>
<th></th>
<th>new-york</th>
<th>chicago</th>
<th>topeka</th>
</tr>
</thead>
<tbody>
<tr>
<td>seattle</td>
<td>2.500</td>
<td>1.700</td>
<td>1.800</td>
</tr>
<tr>
<td>san-diego</td>
<td>2.500</td>
<td>1.800</td>
<td>1.400</td>
</tr>
</tbody>
</table>

This example is also part of the GAMS Data Utilities Library, see model [Distances1] for reference.
Note that the query results are written to a GDX file in addition.
Example 2 - Reading a multi valued Table

In this scenario, we want to read the three index columns `year`, `loc`, `prod` and the value columns `sales` and `profit` from the database file Sample.mdb. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for `sales` resp. `profit`) and a UNION select.

Consider the table with two value columns `sales` and `profit`:

![Table: data (shortened for presentation)](image)

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```
SELECT year, loc, prod, sales
FROM data
SELECT year, loc, prod, profit
FROM data
```

We can generate a include file `sales.inc` by running the following command:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
```

Note that we specify the first query in order to select the sales and the relevant index columns within the `Q` argument. The query results are written to `sales.inc` using the `O` argument. Analogously we generate a include file `profit.inc` by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
```

Retrieving the data using `MDB2GMS` from the database Sample.mdb and including the queried data in your GAMS model within the parameter declaration statements of `sales` and `profit` (at compile time) can be combined in the following way:

```gams
Set
  year 'years' / 1997*1998 /
  loc 'locations' / nyc, was, la, sfo /
  prd 'products' / hardware, software /;
$call mdb2gms I=Sample.mdb Q="SELECT year, loc, prod, sales FROM data" O=sales.inc
Parameter sales(year,loc,prd) /
```

$include sales.inc
/

call mdb2gms I=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data" O=profit.inc
Parameter profit(year,loc,prd) /
$include profit.inc
/

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB1] for reference.

**Single Parameter with extra Index Position**

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index type to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

```sql
SELECT year, loc, prod, 'sales', sales FROM data
UNION
SELECT year, loc, prod, 'profit', profit FROM data
```

The data is accessed, queried and written to data.inc by running the following command:

```
mdb2gms @howToRead.txt
```

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

```plaintext
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
```

The generated include file data.inc looks like (shortened for presentation):

```plaintext
* -----------------------------------------------------
* MDB2GMS 24.8.5 r61358 Released May 10, 2017 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* DAO version: 14.0
* Jet version: 4.0
* Database: F:\datalib\Sample.mdb
* Query: SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
* -----------------------------------------------------
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110

1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
```
Retrieving the data using **MDB2GMS** from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index **type** in order to access the data type **sales** resp. **profit**):

```
$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
$offEcho

Set
  year 'years' / 1997*1998 /
  loc 'locations' / nyc, was, la, sfo /
  prd 'products' / hardware, software /
  type 'data type' / sales, profit /;

$call mdb2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
  $include data.inc
/;
```

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB2c](#) for reference.

### 6.33.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a MS Access database file. Suppose we want to read the column City1 (see table **distances**) in order to define the set `i` in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```
SELECT distinct(City1)
FROM distances
```

The include file `city1.inc` looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
SAN-DIEGO
SEATTLE
* -----------------------------------------------------
```

All steps (data access via **MDB2GMS**, set definition) can be combined:
$call mdb2gms I=Sample.mdb Q="SELECT distinct(city1) FROM distances" O=city_i.inc
Set i 'canning plants' /
$include city_i.inc
/

display i;

The display statement generates the following output in the listing file:

---- 56 SET i

seattle , san-diego

6.33.3.5 Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using
the O argument, one has to observe that the elements in the include file must have the correct format
in order to be interpreted as element of a multi dimensional set. For instance, a line containing a b c is
not recognized as a proper set element of a three dimensional set. In particular, one has to add periods
between the single elements, i.e. a.b.c will be interpreted correctly.

There are different ways to add these periods explicitly within the SQL statement. E.g. add a dummy
value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some
placeholders):

SELECT index1, index2, index3, ' ' FROM dataTable

or by adding the periods explicitly within the select clause (|| or & depending on DBMS):

SELECT index1'||index2'||index3 FROM dataTable
SELECT index1||'.'||index2||'.'||index3 FROM dataTable

For instance, suppose we want to define a two dimensional set

Set ij(i,j) 'canning plants - markets';

based on the data of the table distances stored in Sample.mdb. The following MDB2GMS statement connects
you to the database, queries the columns with the city names and adds an empty value field in order to
create periods between the set elements:

mdb2gms I=Sample.mdb Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc

The include file city_ij.inc looks like (header informations are removed in order to shorten the representation):
Without adding the empty value field, the resulting include file would look like (shortened):

```
* -----------------------------------------------------
SEATTLE NEW-YORK
SAN-DIEGO NEW-YORK
* -----------------------------------------------------
```

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

```
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;
$call mdb2gms I=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc
Set ij(i,j) 'two dimensional set' / $include city_ij.inc /
display ij;
```

The display statement generates the following output in the listing file:

```
-----    75 SET ij two dimensional set

         new-york    chicago    topeka
S A N - D I E G O     YES     YES     YES
S E A T T L E     YES     YES     YES
```

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the X and S resp. Y arguments, i.e. there is no need to modify the query:

```
SELECT index1, index2, index3 FROM datatable
```

when using MDB2GMS in the following way:

```
mdb2gms I=Sample.mdb Q="SELECT index1, index2, index3 FROM datatable" X=setData.gdx S=setName
```

which will generate the file setData.gdx with a three dimensional set named `setName` containing the results of the query.
6.33.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a MS Access database file using `MDB2GMS`. In the first place, we are going to write the query results to an include file, afterwards we use the `Y` argument in order to store the query results as a set with explanatory text in a GDX file.

![Figure 6.47 Table: setData](image)

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```sql
SELECT setElement, explText
FROM setData
```

Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument `B` in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file `setData.inc`:

```gams
$call mdb2gms I=Sample.mdb B Q="SELECT setElement, explText FROM setData" O=setData.inc
Set a /
$include setData.inc
/;
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

```gams
* -----------------------------------------------------
firstSetElement "Explanatory text for the first 'set element'"
secondSetElement "Explanatory text for the second "set element"
thirdSetElement "Explanatory text for the third 'set element'"
fourthSetElement "Explanatory text for the fourth set element"
* -----------------------------------------------------
```

Note the handling of the quotes according to the description in `B`.

Writing the Query Results in a GDX File

When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the `Y` argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file `setData.inc`:

```gams
$call mdb2gms I=Sample.mdb Q="SELECT setElement, explText FROM setData" X=setData.gdx Y=set_b
Set b;
.gdxIn setData.gdx
$load b = set_b
.gdxIn
```
Note that the name of the set in the GDX file is `set_b` (specified within the Y argument), while the name of the GDX file was specified within the X argument.

### 6.33.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

```
Set i / NY, DC, LA, SF /;
```

Now assume a data table looks like:

![Table: example table](image)

This means we have to map ‘new york’ to ‘NY’ etc. This mapping can be done in two places: either in GAMS or in the database.

#### 6.33.3.7.1 Index Mapping done in GAMS

When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
'new york' 100
'los angeles' 120
'san francisco' 105
'washington dc' 102
* -----------------------------------------------------
```

Note that the single quotes are added by activating the option B (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:
Set i / NY, DC, LA, SF /;
Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;

$call mdb2gms I=Sample.mdb B O="city1.inc" Q="SELECT city, value FROM [example table]"
Parameter dbdata(idb) /
$include city1.inc /
Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /;
Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;

The display statement generates the following output in the listing file:

----  47 PARAMETER data
   NY 100.000,   DC 102.000,   LA 120.000,   SF 105.000

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping1] for reference.

**6.33.3.7.2 Index mapping done in Database** The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

![CityMapper Table](image)

**Figure 6.49 Table: CityMapper**

This table can be used in a join to export the data in a format we can use by executing the query:

```sql
SELECT [GAMS City], value
FROM example_table, CityMapper
WHERE CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
  la 120
  ny 100
  sf 105
  dc 102
* -----------------------------------------------------
All steps can be combined in the GAMS model:

```gams
Set i / NY, DC, LA, SF /;
$onEcho > howToRead.txt
I=Sample.mdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_table.city
O=city2.inc
$offEcho
$call mdb2gms @howToRead.txt
$include city2.inc
Parameter data(i) /;
display data;
```

The display statement generates the following output in the listing file:

```
---- 38 PARAMETER data
 NY 100.000,  DC 102.000,  LA 120.000,  SF 105.000
```

**Note:** MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping2] for reference.

### 6.33.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual MDB2GMS execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single MDB2GMS call and write several GAMS include files containing the results of the queries, we can use the command-line arguments Qn and On. The structure of a multi-query call looks like:

```
I=sample.mdb
Q1=firstQuery
O1=outputFileName.inc
Q2=secondQuery
O2=outputFileName.inc
Q3=thirdQuery
O3=outputFileName.inc
```

The terms `firstQuery`, `secondQuery` etc. are placeholders for some SQL statements. We see that the argument Qn is matched by an argument On. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments Qn, SIn, Pn and Yn. The structure of a multi-query call when writing to a GDX file looks like:
I=sample.mdb
X=sample.gdx

Q1=firstQuery
S1=setName

Q2=secondQuery
S2=setName

Q3=thirdQuery
A3=parameterName

Q4=fourthQuery
A4=setName

Again, the terms firstQuery, secondQuery etc. are placeholders for some SQL statements. Here we see that a query Qn is matched by either a set name Sn or a parameter name Pn, i.e. the results of the first query will be stored as a set whose name is specified within the S1 argument, the results of the third query will be stored as a parameter whose name is specified within the P3 argument etc. The X argument is used to specify the name of the GDX file.

For a complete example see section Example 7 - Multi-Query Batch Example.

### 6.33.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file Sample.mdb):

![Table: data (shortened for presentation)](image)

We want to extract the following information:

- The set year
- The set loc
• The set `prd`
• The parameter `sales`
• The parameter `profit`

**Output: Several include Files**

This can be accomplished using the following GAMS code with multiple queries in a single `MDB2GMS` call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):

```gams
$onEcho > howToRead.txt
I=Sample.mdb
Q1=SELECT distinct(year) FROM data
O1=year.inc
Q2=SELECT distinct(loc) FROM data
O2=loc.inc
Q3=SELECT distinct(prod) FROM data
O3=prd.inc
Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc
Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
$offEcho
$call =mdb2gms @howToRead.txt

Set y 'years' /
$include year.inc
/;
Set loc 'locations' /
$include loc.inc
/;
Set prd 'products' /
$include prod.inc
/;
Parameter sales(prd,loc,y) /
$include sales.inc
/;
display sales;

Parameter profit(prd,loc,y) /
$include profit.inc
/;
display profit;
```

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB3] for reference.

**Output: A single GDX File**

The same example imported through a GDX file can look like:
The call of the GDXViewer will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB4] for reference.

### 6.33.5 Interactive Usage

When the tool is called without command-line parameters, it will startup interactively. Using it this way, one can specify the database file (.mdb or .accbd file), the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.
• **Input file (.mdb or .acbd)**. This is the combo box to specify the input file. See also `inputFile` for some more detailed remarks. The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation `\\machine\directory\file.mdb`.

• **Output GAMS Include file (*.inc)**. If you want to create a GAMS include file, then specify here the destination file. See also `outputIncludeFile` for some more detailed remarks.
• **Output GDX file (∗.gdx).** As an alternative to a GAMS include file, the tool can also generate a GDX file. One or both of the output files need to be specified. See also outputGDXFile for some more detailed notes.

![Output GDX file](image)

• **SQL Query.** The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also Q for some more detailed remarks. For an exact description of allowed expressions consult a text on MS Access.

![SQL query](image)

• **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

![Progress Memo](image)

• The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

• The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.
• The **Options button** will pop up a window where you can specify a number of options.

![Options button](image)

• Pressing the **Help button** will show this documentation.

![Help button](image)

• Pressing the **OK button** will execute the query and an include file or GDX file will be generated.

![OK button](image)

• Pressing the **Batch button** will give information on how the current query can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied to the clipboard. In the IDE press **Ctrl-C** or choose **Edit|Paste** to copy the contents of the clipboard to a GAMS text file.

![Batch button](image)

• Pressing **Close button** will exit the application. The current settings will be saved in an INI file so when you run **MDB2GMS** again all current settings will be restored.

![Close button](image)

### 6.33.5.1 Options

The **Options** window can be created by pressing the options button:
The following options are available in the options window:

- **Quote blanks**: Quote strings if they contain blanks or embedded quotes. See also B for some more detailed notes.
  
  ![Quote blanks box]

- **Mute**: Don't include the extra informational text (such as used query etc.) in the include file.
  
  ![Mute box]

- **No listing**: Surround the include file by $offListing and $onListing so that the data will not be echoed to the listing file. The equivalent command-line argument is L.
  
  ![No listing box]

- **Format SQL**: If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.
  
  ![Format SQL box]
The following options are only needed in special cases:

- **NULL**: This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.

- **Output Lines**: By default output lines are created as follows: all first n-1 fields are considered indices and the last n-th column is the value. The format corresponding to this situation is ‘%s.%s.%s %s’ (for a three dimensional parameter). In special cases you may want to tinker with the format string being used. The fields are all considered strings, so only use s as format placeholder. Make sure you specify exactly the same number of s’s as there are columns in the result set.

The buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made, and all option settings will revert to their previous values.
6.33.6 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.
- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.
- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

```
Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing
```

we can conveniently use the save/restart facility. The individual submodel are coded as:

- **Step 0: sr0.gms**

```
$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText

Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';
```

$onEcho > howtoRead.txt
I=transportation.mdb

Q1=select name from suppliers
O1=i.inc

Q2=select name from demandcenters
O2=j.inc

Q3=select name,demand from demandcenters
O3=demand.inc

Q4=select name, supply from suppliers
O4=supply.inc

Q5=select supplier, demandcenter, distance from distances
O5=dist.inc
$offEcho

$call =mdb2gms.exe @howtoRead.txt

Set i /
$include i.inc
/

Set j /
$include j.inc
/

Parameter demand /
$include demand.inc
/

Parameter supply /
$include supply.inc
/

Parameter dist /
$include dist.inc
/

display i, j, demand, supply, dist;

• Step 1: sr1.gms

$onText
step 1: data manipulation step
execute as: > gams sr1 restart=s0 save=s1
$offText

Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;

• Step 2: sr2.gms

$onText
step 2: model definition
execute as: > gams sr2 restart=s1 save=s2
$offText

Variable
x(i,j) 'shipment quantities in cases'
z 'total transportation costs in thousands of dollars';

Positive Variable x;

Equation
ecost 'define objective function'
esupply(i) 'observe supply limit at plant i'
edemand(j) 'satisfy demand at market j';

ecost.. z =e= sum((i,j), c(i,j)*x(i,j));
esupply(i).. sum(j, x(i,j)) =l= supply(i);
edemand(j).. sum(i, x(i,j)) =g= demand(j);

• Step 3: sr3.gms

$onText
step 3: model solution
execute as: > gams sr3 restart=s2 save=s3
$offText

option lp = cplex;

Model transport / all /;
solve transport using lp minimizing z;

• Step 4: sr4.gms

$onText
step 4: report writing
execute as: > gams sr4 restart=s3
$offText

abort$(transport.modelStat <> 1) "model not solved to optimality";

display x.l, z.l;

A model that executes all steps can be written as:

execute '=%gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute '=%gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute '=%gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute '=%gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute '=%gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";
If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [MDBSr5] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

**MDB2GDX1.gms**

execute '=gams.exe sr0 lo=3 gdx=trnsport.gdx';
abort$errorLevel "step 0 failed";
execute '=gdxviewer.exe trnsport.gdx';

The model [MDB2GDX1] is also part of the GAMS Data Utilities Library.

We can also let MDB2GMS create the GDX file:

**MDB2GDX2.gms**

This model demonstrates how to store data from Access database (file Transportation.mdb) into a GDX file.

$onEcho > howToRead.txt
I=Transportation.mdb
X=Transportation.gdx
Q1=SELECT name FROM suppliers
S1=i
Q2=SELECT name FROM demandcenters
S2=j
Q3=SELECT name, demand FROM demandcenters
P3=demand
Q4=SELECT name, supply FROM suppliers
P4=supply
Q5=SELECT supplier, demandcenter, distance FROM distances
P5=dist
$offEcho
$call =mdb2gms.exe @howToRead.txt

The first approach has the advantage that a complete audit record is available from the data moved from the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the database and how this was stored in the GDX file, that file gives the answer.

The model [MDB2GDX2] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

**GDXTRNSPORT.gms**

This model demonstrates how to load the transportation data from GDX file at compile time.
Set
  i 'suppliers'
  j 'demand centers';

Parameter
  demand(j)
  supply(i)
  dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist

display i, j, demand, supply, dist;

DBTimestamp1.gms

In one application I had to retrieve data from the database each morning, at the first run of the model. The rest of the day, the data extracted that morning could be used. The following logic can implement this:

$onText
Retrieve data from data base first run each morning.
$offText

$onEcho > getdate.txt
I=%system.fp%transportation.mdb
Q=select day(now())
O=dbtimestamp.inc
$offEcho

$if not exist dbtimestamp.inc $call "echo 0 > dbtimestamp.inc"

Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/;

Scalar currentday 'day of this run';
currentday = gday(jnow);
display "compare", dbtimestamp, currentday;

if(dbtimestamp <> currentday,
   execute('=gams.exe sr0 lo=3 gdx=transportation.gdx';
   abort$errorLevel "step 0 (database access) failed";
   execute '=mdb2gms.exe @getdate.txt';
);

The include file dbtimestamp.inc contains the day of the month (1,...,31) on which the data was extracted from the database. If this file does not exist, we initialize it with 0. We then compare this number with the current day of the month. If the numbers do not agree, we execute the database extraction step and rewrite the dbtimestamp.inc file. This last operation could be done using a PUT statement, but in this case we used an SQL statement.

The model [DBTimestamp1] is also part of the GAMS Data Utilities Library.
6.33.7 Command Files

Parameters can be specified in a command file. This is important if the length of the command-line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines. Instead of specifying a long command-line as in:

```bash
$call =mdb2gms I="c:\My Documents\test.mdb" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"
```

we can use a command-line like:

```bash
$call =mdb2gms @"c:\My Documents\options.txt"
```

The command file

```
c:\My Documents\options.txt
c\My Documents\test.mdb
0=c:\My Documents\data.inc
Q=SELECT * FROM mytable
```

It is possible to write the command file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```gams
$set cmdfile "c:\windows\temp\commands.txt"
$echo "I=E:\models\labordata.mdb" > "%cmdfile%"
$echo "O=E:\models\labor.INC" >> "%cmdfile%"
$echo "Q=SELECT * FROM labor" >> "%cmdfile%"
$call =mdb2gms @"%cmdfile%"
```

```
Parameter p /
$file "E:\models\labor.INC" /
display p;
```

Newer versions of GAMS allow the usage of the `$onEcho` and `$offEcho` commands:

```gams
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho > "%cmdfile%"
I=E:\models\labordata.mdb
O=E:\models\labor.INC
Q=SELECT * FROM labor
$offEcho
$call =mdb2gms @"%cmdfile%"
```

```
Parameter p /
$file "E:\models\labor.INC" /
display p;
```
Note that the quotes enclosing strings with blanks like `Q=SELECT * FROM labor` can be omitted when using an external parameter file.

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character `\` as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data \
UNION \
SELECT prod, loc, year, 'profit', profit FROM data
```

### 6.33.8 Notes

#### 6.33.8.1 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: `$gdxIn`, `$load`, `execute_load`, `execute_unload`. The `GDX=filename` command-line argument will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using `File|Open`.

#### 6.33.8.2 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\\<server>\\<share>\\<path>\\<file>
```

Examples:

```
\\athlon\c\My Documents\MDB2GMS.rtf
```

#### 6.33.8.3 Quotes

Examples of handling of indices when the option `B` for quoting strings containing blanks is used:
6.33.8.4 $CALL Command

The $call command in GAMS will execute an external program at compile time. There are two forms:

$call externalProgram

$call =externalProgram

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form $call externalProgram which uses the command processor.

2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call externalProgram.

3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalProgram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalProgram.

4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /w externalWindowsProgram. Otherwise, it is preferred to use: $call =externalWindowsProgram.

Attention
In general it is recommended to use the $call =externalProgram version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

$call ""external program" "parameter 1" "parameter 2"",
$call =""external program" "parameter 1" "parameter 2"

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes only if the = appears outside the double quotes.
6.33.8.5 Compile Time Commands

All $ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed before an execution time command, even if it is below. As an example consider:

File batchfile / x.bat /;
putClose batchfile "dir"/;
$call x.bat

This fragment does not work correctly as already during compilation, the $call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

$echo "dir" > x.bat
$call x.bat

or by moving the external program invocation to execution time:

File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;

Notice that all $ commands do not include a semi-colon but are terminated by the end-of-line.

6.34 MessageReceiverWindow

6.34.1 Introduction

MessageReceiverWindow is a graphical tool that receives and displays Windows messages. The tool can either be used with the put_utility feature or with an arbitrary client (e.g. a Python program) that sends messages to a previously spawned instance of MessageReceiverWindow.exe.

6.34.2 Usage

An instance of MessageReceiverWindow.exe can be started as follows:

MessageReceiverWindow <title>
The optional argument title specifies the title of the MessageReceiverWindow instance. If the argument is omitted, the instance gets the default title Form1. Windows messages of type WM_COPYDATA that are send to the spawned instance, appear in its message log. The Copy To Clipboard button allows to copy the content of the message log to the clipboard. The Save As ... button can be used to save the content to a file.

![MessageReceiverWindow during execution of Test Library model MRW01](image)

Figure 6.53 MessageReceiverWindow during the execution of Test Library model MRW01.

### 6.34.3 Special Commands

While arbitrary text messages are displayed in the message log, there are special commands for controlling special behavior of an instance of MessageReceiverWindow:

<table>
<thead>
<tr>
<th>Message</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>@CopyToClipboard</td>
<td>Copies the content of the message log to the clipboard</td>
</tr>
<tr>
<td>@SaveAs [file]</td>
<td>Writes the content of the message log to [file]</td>
</tr>
<tr>
<td>@Terminate</td>
<td>Terminates the MessageReceiverWindow executable</td>
</tr>
</tbody>
</table>

### 6.34.4 Usage With put_utility

The put_utility feature offers a convenient integration of MessageReceiverWindow. The example MRW01 shows how this works. First of all, an instance of MessageReceiverWindow needs to be spawned from within GAMS:

```
$set title Form1
Execute.Async "MessageReceiverWindow.exe %title%";
```
As soon as the window is ready, text messages or special commands can be sent by using put_utility with the command winMsg:

```gams
file f;
put_utility f 'WinMsg' / '%title%' / 'This is some Windows Message from GAMS';
```

By sending @Terminate, the instance can be terminated:

```gams
put_utility f 'WinMsg' / '%title%' / '@Terminate';
```

### 6.34.5 Usage With Python

The example MRW02 from the GAMS Test Library demonstrates the use of MessageReceiverWindow from within Python. While it uses the Python programming language from within an Embedded Code section, other programming languages can be used as long as they provide access to Windows messages.

First of all, a ctypes.Structure derived class is defined which is used for sending Windows message to a MessageReceiverWindow instance:

```python
class _CopyDataStruct(ctypes.Structure):
    _fields_ = [('dwData', ctypes.c_char),
                ('cbData', ctypes.c_ulong),
                ('lpData', ctypes.c_char)]
```

The function `sendMessage()` sends a message to the window with the title `windowName`. It makes use of functions `FindWindowA` and `SendMessageA` from `ctypes.windll.user32`:

```python
def sendMessage(windowName, message):
    cs = _CopyDataStruct()
    receiver = ctypes.windll.user32.FindWindowA(None, bytes(windowName, 'utf-8'))
    cmd = bytes(message, 'utf-8')
    cs.dwData = 1
    cs.cbData = len(cmd)+1
    cs.lpData = cmd
    ctypes.windll.user32.SendMessageA(receiver, WM_COPYDATA, 0, ctypes.byref(cs))
```

`Popen` from the `subprocess` module is used in order to start an instance of MessageReceiverWindow. The `system_directory` property of a GamsWorkspace instance from the GAMS Python API is used for finding a GAMS system directory:

```python
windowName = 'MRW Python'
p = Popen([os.path.join(GamsWorkspace().system_directory, 'MessageReceiverWindow.exe'), windowName])
```

As soon as the window is ready, text messages or special commands can be sent by using the previously defined `sendMessage` function:

```python
sendMessage(windowName, "This is some Windows Message from Python")
```

Sending @Terminate will terminate the running MessageReceiverWindow instance:

```python
sendMessage(windowName, @Terminate)
```

### 6.35 MODEL2TEX

A Tool to generate a documentation from GAMS source code in LaTeX format.

Author

Clemens Westphal

Special thanks to Ingmar Schlecht for supporting us and sharing his `gamsToLatex` implementation.
**6.35.1 Introduction**

MODEL2TEX is a tool to generate a documentation from GAMS source code in LaTeX format. This LaTeX output can then be further processed in order to generate pretty output files like PDF. The tool can be found in the root directory of GAMS. The tool allows to document one specific model symbol inside of a GAMS program. The resulting documentation contains two parts. The first part shows a list of symbols that are used by the model. The second part shows the actual algebra of the used equations and information about the types of used variables. An optional third part can contain additional notes.

**6.35.2 Usage**

MODEL2TEX is a command line tool. The general command line usage is as follows:

```bash
model2tex baseName [-h] [-m MODEL] [-f] [-o OUTPUT]
```

Since it operates on output files generated by GAMS, the first step is to generate the required files using the docfile option. In order to do that, execute the following command line:

```bash
gams myModel.gms docfile=myModel
```

The second step is to call MODEL2TEX: model2tex is distributed as Python source code (model2tex.py) and is executed via model2tex.cmd on Windows and model2tex.sh on all other platforms. For platforms other than Windows, Linux, or macOS, it is required to provide a Python 3 installation with access to the GAMS Python API.

Windows:

```bash
model2tex myModel [-m MODEL] [-f] [-o OUTPUT]
```

Linux/Mac OS X:

```bash
model2tex.sh myModel [-m MODEL] [-f] [-o OUTPUT]
```

The output file myModel.tex can be further processed for example by calling pdflatex in order to generate a PDF file.

```bash
pdflatex myModel.tex
```

**6.35.3 Options**

The following parameters can be used when calling MODEL2TEX:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-m model</code></td>
<td>Since MODEL2TEX generates documentation for one model symbol, the model name needs to be specified explicitly, if the GAMS file contains more than one model symbol.</td>
</tr>
<tr>
<td><code>-f</code></td>
<td>MODEL2TEX does not allow the occurrence of suffixes in equations. This option can be used in order to force the creation of the tex file by skipping the checks for suffixes.</td>
</tr>
<tr>
<td><code>-o output</code></td>
<td>Use this name for the generated TeX file instead of the base name.</td>
</tr>
</tbody>
</table>
6.35.4 Using a JSON style file

MODEL2TEX automatically creates a JSON file that can be modified in order to customize the output. If you want to get the default settings back, just delete the generated JSON file and let MODEL2TEX create it again. The following list shows the available options in the JSON file:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fontSize</td>
<td>11</td>
<td>The size of the used font</td>
</tr>
<tr>
<td>hrules</td>
<td>true</td>
<td>Horizontal rules are added between equations.</td>
</tr>
<tr>
<td>colors</td>
<td>black</td>
<td>Specifies the used colors in equations for variables, parameters, and sets.</td>
</tr>
<tr>
<td>landscape</td>
<td>false</td>
<td>Allows to change the page format to landscape.</td>
</tr>
<tr>
<td>noPowerFunc</td>
<td>false</td>
<td>Beside a power operator, GAMS offers several power functions. Setting this option to true will replace all power functions with the power operator.</td>
</tr>
<tr>
<td>reduceFrac</td>
<td>false</td>
<td>Try to resolve unbalanced fractions. This means that fractions with an unbalanced length of denominator and numerator will be changed in order to shrink the fraction.</td>
</tr>
<tr>
<td>reduceFracRatio</td>
<td>5.0</td>
<td>This number has only effect when reduceFrac is set to true. It specifies the ratio between denominator and numerator that is used as a threshold for reduceFrac.</td>
</tr>
<tr>
<td>latexDescription</td>
<td>false</td>
<td>Explanatory text for symbols is expected to be arbitrary text. In order to display the text correctly in LaTeX, some automatic adjustments are applied. If all explanatory text already contains valid LaTeX strings, this option can be enabled.</td>
</tr>
<tr>
<td>nameMap</td>
<td>the original names</td>
<td>This map allows to specify alternative names for symbols.</td>
</tr>
<tr>
<td>extraSymbols</td>
<td>empty list</td>
<td>On default, only the required symbols in a GAMS model symbol are contained in the generated LaTeX file. This list can be used in order to specify further symbols that should be included as well.</td>
</tr>
<tr>
<td>notes</td>
<td>empty list</td>
<td>Allows to specify additional notes for the documentation. Each list element will result in a new line.</td>
</tr>
</tbody>
</table>

6.35.5 Example

This example creates a PDF file for the pump model from the GAMS Model Library.

1. Retrieve model pump from GAMS Model Library
   ```
gamslib pump
   ```
2. Generate required doc files
   ```
gams pump.gms docfile=pump
   ```
3. Generate the LaTeX files
   ```
model2tex pump -m=pump
   ```
4. Generate PDF documentation
   ```
pdflatex pump.tex
   ```
5. Customizing the JSON style file  
In order to change the appearance of the PDF file, the generated JSON file `pump.json` can be modified. Changing the options in `pump.json` according to the picture and executing the commands from step 3 and 4 again will result in a customized PDF output.

```json
"fontSize": 10,
"brules": false,
"colors": {
    "variables": "red",
    "parameters": "blue",
    "sets": "black"
},
"landscape": false,
"noPowerFunc": true,
"reduceFrac": false,
"reduceFracRatio": 5.0,
"latexDescription": false,
"nameMap": {
    ...
    "vdot": "$\dot{v}\$",
    "sumx": "sumx",
    ...
},
"extraSymbols": [],
"notes": []
```
6.36 MPS2GMS

Translates an MPS file into an equivalent short generic GAMS program using a GDX file to store data. A number of solver specific extensions often used by CPLEX, MOSEK, OSL and XPRESS are recognized. Recently introduced QP extensions QMATRIX, QUADOBJ, QSECTION and NAME/QSECTION/ENDATA are recognized as well. Currently all Qsections are assumed to belong to the objective function only (quadratic constraints are added to the objective function). The Mosek CSECTION extensions for QUAD and RQUAD cones are recognized as well.

6.36.1 Usage

mps2gms mpsfile [ gdxfile gmsfile [key=value] ]

The MPS file is read in free format (no blanks in names). Row and column names can have up to 63 characters and are tested for case sensitivity because row and column names become GAMS set members.

GAMS Data Exchange (GDX) files, MPS files and matching GAMS source code can be written. Minimizing is the default.

If no optimization direction is given, minimization will be assumed.

MPS files may contain multiple section and objective functions. If none are specified the first one encountered will be used. Those keys are the same as the MPS type or section names: NAME, N, RHS, RANGES and BOUNDS.

Quick guide to parameters:
### 6.37 MSAPPAVAIL

Checks if a MS Office Application is available.

#### 6.37.1 Usage

```
msappavail [option]
```

Option:

```
?
```

List all known applications and their status. Check for specific application (ExitCode = 0 when available)

Access
Excel
Explorer
FrontPage
Outlook
PowerPoint
Project
Word

See how [eta] example from the GAMS model library uses this feature.

### 6.36.2 Examples

```
mps2gms old.mps MpsOut=new.mps
```

```
mps2gms old.mps old.gdx old.gms RHS=somerhs N=MYOBJ
```

```
mps2gms old.mps old.gdx old.gms Name=MYModel
```
6.38 GAMS Posix Utilities

Starting with distribution 20.6 the GAMS system for Windows includes a collection of Posix utilities which are usually available for the different Unix systems and therefore help to write platform independent scripts. The following utilities are available:

- awk - Pattern scanning and processing language (1)
- cat - Concatenate and print files
- cksum - Write file checksums and sizes
- cmp - Compare two files
- comm - Select or reject lines common to two files
- cp - Copy files
- cut - Cut out selected fields of each line of a file
- diff - Compare two files
- expr - Evaluate arguments as an expression
- fold - Fold lines
- gsort - Sort, merge, or sequence check text files (1)
- grep - File pattern searcher
- gdate - Write the date and time (1)
- head - Copy the first part of files
- join - Relational database operator
- mv - Move files
- od - Dump files in various formats
- paste - Merge corresponding or subsequent lines of files
- printf - Write formatted output
- rm - Remove directory entries
- sed - Stream editor (2)
- sleep - Suspend execution for an interval
- tail - Copy the last part of a file
- tee - Duplicate standard input
- test - Evaluate expression
- tr - Translate characters
- uniq - Report or filter out repeated lines in a file
- wc - Word, line, and byte count
- xargs - Construct argument list(s) and invoke utility
Please note that the utilities "date" and "sort" have been renamed to "gdate" and "gsort" to avoid conflicts with the Windows commands "date" and "sort". For compatibility reasons the GNU implementation of awk called "gawk" has been renamed to "awk".

Please note that sed might crash if it runs against the memory limit. This only happens if the input is very big. If you experience this problem please use sed from the 'gbin_new' directory. This version does not suffer the memory leak.

The collection consists of native Windows ports of GNU implementation of these utilities taken from the Sourceforge. Detailed descriptions of the utilities can be found at the GNU website.

The Posix tools and in particular the awk utility can be used to transform a variety of different text inputs into GAMS readable input files. Examples can be found in the GAMS Model Library (Subject "GAMS Tools").

6.39 SCENRED

6.39.1 Release Notes

- May, 2002: Level 001 (GAMS Distribution 20.6)
  - GAMS/SCENRED introduced.

6.39.2 Introduction

Stochastic programs with recourse employing a discrete distribution of the random parameters become a deterministic programming problem. They can be solved by an appropriate optimization algorithm, ignoring the stochastic nature of (some or all) parameters.

SCENRED is a tool for the reduction of scenarios modeling the random data processes. The scenario reduction algorithms provided by SCENRED determine a scenario subset (of prescribed cardinality or accuracy) and assign optimal probabilities to the preserved scenarios. The reduced problem is then solved by a deterministic optimization algorithm provided by GAMS.

6.39.3 Scenario Reduction Algorithms

Many solution methods for stochastic programs employ discrete approximations of the uncertain data processes by a set of scenarios (i.e., possible outcomes of the uncertain parameters) with corresponding probabilities.

For most practical problems the optimization problem that contains all possible scenarios (the so-called deterministic equivalent program) is too large. Due to computational complexity and to time limitations this program is often approximated by a model involving a (much) smaller number of scenarios.

The reduction algorithms developed in [1,2] determine a subset of the initial scenario set and assign new probabilities to the preserved scenarios. All deleted scenarios have probability zero.

SCENRED contains three reduction algorithms: The Fast Backward method, a mix of Fast Backward/Forward methods and a mix of Fast Backward/Backward methods. In general, the computational performance (accuracy, running time) of the methods differ. For huge scenario trees the Fast Backward method has the best expected performance with respect to running time. The results of the Forward and Backward methods are more accurate, but at the expense of higher computing time. The Forward
method is the best algorithm when comparing accuracy, but it can only be recommended if the number of preserved scenarios is small (strong reduction). The combined methods improve the result of the Fast Backward method if the Forward or Backward method, respectively, can be completed within the running time limit. If no reduction method is selected, the method with the best expected performance with respect to running time is chosen.

The reduction algorithms exploit a certain probability distance of the original and the reduced probability measure. The probability distance trades off scenario probabilities and distances of scenario values. Therefore, deletion will occur if scenarios are close or have small probabilities.

The reduction concept is general and universal. No requirements on the stochastic data processes (e.g., the dependency or correlation structure of the scenarios, the scenario probabilities or the dimension of the process) or on the structure of the scenarios (e.g., tree-structured or not) are imposed. The reduction algorithms can be tailored to the stochastic model if the user provides additional information (How many decision stages are involved? Where do the random parameters enter the model – in objective and/or right hand sides and/or technology matrices?) The information is used to choose the probability distances (cf. Remark 1 in [1]).

References:

6.39.4 Using GAMS/SCENRED

The reduction algorithms require additional data preparation and reformulation of the GAMS program for the stochastic programming model.

GAMS offers great flexibility with respect to the organization of data specification, model definition and solve statements. The most common way to organize GAMS/SCENRED programs is shown below. Since the initial scenarios and a number of input parameters have to be passed to SCENRED, the corresponding components of the GAMS program have to be defined before the SCENRED call. The reduced scenarios have to be defined before the equations of the (reduced) stochastic programming model are used in a solve statement. Therefore the SCENRED call can be placed anywhere between the definitions of the GAMS parameters and the solve statement of the reduced stochastic programming model.

When building or modifying a model for use with GAMS/SCENRED the following steps should be taken:

- Analyse the GAMS program of the stochastic programming model. Since the initial scenarios and a number of input parameters have to be passed to SCENRED (see Section The SCENRED Input File), one must identify the corresponding components of the GAMS model and create or calculate them if they do not already exist.

- Reformulate the GAMS program. Check if the model can handle varying scenario or node probabilities, and whether the equations are defined in terms of a (possibly reduced) tree. If the model doesn't already contain a scenario tree, one should be added. If it does, it is a simple task to rewrite the equation definitions (and possibly other statements too) in terms of a subset of the original nodes or tree.

- Add the statements for passing the initial set of scenarios to SCENRED, for the execution of SCENRED and for the import of the reduced scenarios from SCENRED.
A reduction of the initial scenarios makes sense only if we are able to generate that part of the model that corresponds to the preserved scenarios (i.e. the reduced subtree). This is done by declaring a subset of the nodes in the original tree. The parameters and equations are declared over the original node set, but are defined over only the subtree. This will be illustrated by an example later in the section.

Further, one should verify that the model can handle changing probabilities. Many practical models involve scenarios with equal probabilities. This property will not be maintained by the probabilities in the reduced subtree.

**ORGANIZATION OF GAMS/SCENRED PROGRAMS**

<table>
<thead>
<tr>

<td></td>
<td>* model definition &amp; solution</td>
</tr>
</tbody>
</table>

Prior to calling SCENRED, you should include the declaration of the SCENRED input and output parameters and the definition of the sets they are indexed by from the GAMS include library:

$libinclude scenred.gms

Once you have created all the inputs to SCENRED and assigned values to them, you are ready to write the SCENRED GDX data input file, write the SCENRED options file, call SCENRED, and read the reduced tree data from the SCENRED GDX data output file (see Section The SCENRED Input File, Section SCENRED Options and the Option File, and Section The SCENRED Output File). Assuming your model is formulated to use a subtree of the original, you can now continue with the solve and any subsequent reporting.

SCENRED is executed by issuing the statement

execute 'scenred optfilename';

where optfilename is the name of the SCENRED option file.

As an example, consider the srkandw model in the GAMS model library, and the kand model upon which it is based (get these from the modlib now!). To produce srkandw from kand, we first reformulate the original to allow for solution over a reduced tree. To do this, we introduce a subset of the node set: set sn(n) 'nodes in reduced tree'; For convenience and clarity, we introduce a second subset at the same time, the set of leaf nodes: set leaf(n) 'leaf nodes in original tree'; as well as some code to compute this set based on the existing time-node mapping. We also declare a new parameter, the probabilities for the reduced tree: parameter sprob(n) 'node probability in reduced tree'; Once these are declared, we can quickly edit the equation definitions so that they run only over the reduced subtree: we simply substitute the reduced probabilities sprob for the original prob, and the reduced node set sn for the original node set n. Note that the declaration of the equations does not change.

This example illustrates one other change that may be required: the stochastic data must be in parameters having the node set as their last index. This is not the case in the kand model, so we simply reversed the indices in the dem parameter to meet the requirement in srkandw. It is also possible to create a transposed copy of the original data and pass that the SCENRED if the original data cannot be changed conveniently.
6.39.5 The SCENRED Input File

The SCENRED input file contains the initial scenarios and their stochastic parameter data, as well as statistics describing this input and (possibly) options to control the SCENRED run. This input file has a special binary format; it is a GDX (GAMS Data Exchange) file. The name of the SCENRED input file is assigned in the option file (see Section SCENRED Options and the Option File).

The scalar inputs to SCENRED are collected in the one-dimensional parameter `ScenRedParms`, the first parameter stored in the SCENRED input file. Some of the elements of `ScenRedParms` are required (e.g., statistics for the input tree) while others are optional (e.g., the run time limit). SCENRED will stop if a required element is missing or out of range.

Table 1 Required `ScenRedParms` elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_leaves</td>
<td>the number of initial scenarios or leaves of the scenario tree (i.e., before the reduction)</td>
<td></td>
</tr>
<tr>
<td>num_nodes</td>
<td>number of nodes in the initial tree (the number of scenarios if not tree-structured)</td>
<td></td>
</tr>
<tr>
<td>num_random</td>
<td>Number of random variables assigned to a scenario or node, i.e., the dimension of the random data process</td>
<td></td>
</tr>
<tr>
<td>num_time_steps</td>
<td>Length of a path from the root node to a leaf of the scenario tree, i.e., the number of time steps involved</td>
<td></td>
</tr>
</tbody>
</table>

Table 2 Optional `ScenRedParms` elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>red_num_leaves</td>
<td>specifies the desired number of preserved scenarios or leaves</td>
<td>none</td>
</tr>
<tr>
<td>red_percentage</td>
<td>specifies the desired reduction in terms of the relative distance between the initial and reduced scenario trees (a real between 0.0 and 1.0)</td>
<td>none</td>
</tr>
<tr>
<td>num_stages</td>
<td>Set the number of branching levels of the scenario tree, i.e., the number of stages of the model -1. Hence num_stages=1 if no branching occurs, i.e., the values of the scenarios differ for all time steps</td>
<td>1</td>
</tr>
<tr>
<td>where_random</td>
<td>An integer indicating where the randomness enters the model. The value is interpreted as a digit map computed using the formula 100<em>inObj + 10</em>inRHS + inMatrix, where inObj is 1 if the objective contains random parameters and 0 otherwise, inRHS is 1 if the right-hand side contains random parameters and 0 otherwise, and inMatrix is 1 if the constraint matrix contains random coefficients and 0 otherwise.</td>
<td>10 (random right-hand side)</td>
</tr>
<tr>
<td>reduction_method</td>
<td>Select a reduction method: 0: automatic (best expected performance with respect to running time) 1: Fast Backward method 2: Mix of Fast Backward/Forward methods 3: Mix of Fast Backward/Backward methods</td>
<td>0</td>
</tr>
<tr>
<td>run_time_limit</td>
<td>Defines a limit on the running time in seconds</td>
<td>none</td>
</tr>
<tr>
<td>report_level</td>
<td>Control the content of the SCENRED log file: 0: Standard SCENRED log file 1: Additional information about the tree</td>
<td>0</td>
</tr>
</tbody>
</table>
A few comments on the parameters `red_percentage` and `red_num_leaves` are in order. At least one of these values must be set. The value of `red_percentage` will be ignored if the parameter `red_num_leaves` is non-zero. Otherwise, the tree will not be reduced if `red_percentage=0`, while the reduction of the tree will be maximal (i.e. only one scenario will be kept) if `red_percentage=1`. A numeric value of 0.5 means that the reduced tree maintains 50% of the information contained in the original tree. The reduction algorithms are skipped if `red_num_leaves=num_leaves` or if `red_num_leaves=0` and `red_percentage=0`. These values can be assigned if the user wishes to run the scenario tree diagnostic.

The second data element in the input file is the set of nodes making up the scenario tree. Note that the cardinality of this set is part of `ScenRedParms`.

The third data element is the ancestor mapping between the nodes. This mapping determines the scenario tree. Note that the mapping can be either an ancestor mapping (i.e. child-parent) or a successor mapping (parent-child). By default, SCENRED expects an ancestor mapping. If the check for this fails, it looks for a successor mapping.

The fourth data element is the parameter of probabilities for the nodes in the original tree. It is only required that probabilities for the scenarios (i.e. the leaf nodes) be provided, but the parameter can contain probabilities for the non-leaf nodes as well.

The remaining elements in the input data file specify the parameter(s) that comprise the random values assigned to the initial scenarios, or to the nodes of the scenario tree. There can be more than one such parameter, included in any order. The only requirement is that the node set be the final index in each of these parameters.

Table 3 summarizes the content of the SCENRED input file. Please keep in mind that the order of the entries must not be altered!

### Table 3 Content of the SCENRED Input File

<table>
<thead>
<tr>
<th>No.</th>
<th>Symbol</th>
<th>Type</th>
<th>Dimension</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>2</td>
<td>(any name)</td>
<td>Set</td>
<td>1</td>
<td>nodes in the scenario tree</td>
</tr>
<tr>
<td>3</td>
<td>(any name)</td>
<td>Set</td>
<td>2</td>
<td>the ancestor set</td>
</tr>
<tr>
<td>4</td>
<td>(any name)</td>
<td>Parameter</td>
<td>1</td>
<td>node probabilities; at least for the leaves</td>
</tr>
<tr>
<td>≥ 5</td>
<td>(any name)</td>
<td>Parameter</td>
<td>≥ 1</td>
<td>random values assigned to the nodes</td>
</tr>
</tbody>
</table>

To create the SCENRED data input file, the GAMS `execute_unload` statement is used. This statement is used to transfer GAMS data to a GDX file at execution time. As an example, to create a GDX file with the 4 required input parameters and one parameter `demand` containing the stochastic data, you might have the following statement:

```gams
eexecute_unload 'sr_input.gdx', ScenRedParms, node, ancestor, prob, demand;
```

### 6.39.6 SCENRED Options and the Option File

When the SCENRED executable is run, it takes only one argument on the command line: the name of the SCENRED option file. The option file is a plain text file. Typically, it is used to specify at least the names of the SCENRED data input and output files. The option file must be created by the SCENRED user (typically via the GAMS put facility during the GAMS run). The syntax for the SCENRED option file is

```gams
optname value or optname = value
```
with one option on each line. Comment lines start with an asterix and are ignored.

Some of the SCENRED options may be specified in two places: as elements of the `ScenRedParms` parameter of the SCENRED input file, or as entries in the options file. These parameters have been summarized in Table 2. If an option is set in both these places, the value in the option file takes precedence of over the value from `ScenRedParms`. In addition, the parameters in Table 4 can only be specified in the option file.

Table 4 Options - optfile only

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>input.gdx</td>
<td>Name of the SCENRED data input file</td>
<td>xllink.gdx</td>
</tr>
<tr>
<td>output.gdx</td>
<td>Name of the SCENRED data output file</td>
<td>scenred.gdx</td>
</tr>
<tr>
<td>log_file</td>
<td>Name of the SCENRED log file</td>
<td>scenred.log</td>
</tr>
</tbody>
</table>

6.39.7 The SCENRED Output File

The SCENRED output file contains the reduced scenario tree and the `ScenRedReport` parameter. Like the input file, the output file has a special binary format; it is a GDX (GAMS Data Exchange) file.

The first data element in the output file is the `ScenRedReport` parameter containing the scalar outputs and statistics from the SCENRED run. The elements of this parameter are summarized in Table 5. The second data element is the parameter containing the probabilities of the nodes in the reduced scenario tree. These node probabilities are required to construct the reduced tree. The third and final data element is the ancestor map for the reduced scenario tree. This map can be read from the GDX file, or the reduced tree can be built from the original one by using the reduced probabilities. The content of the data output file is summarized in Table 6.

Table 5 `ScenRedReport` elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScenRedWarnings</td>
<td>number of SCENRED warnings</td>

</tr>
<tr>
<td></td>
<td>1: Fast Backward method</td>
</tr>
<tr>
<td></td>
<td>2: Mix of Fast Backward/Forward methods</td>
</tr>
<tr>
<td></td>
<td>3: Mix of Fast Backward/Backward methods</td>
</tr>
</tbody>
</table>

Table 6 Content of the SCENRED Output File

<table>
<thead>
<tr>
<th>No.</th>
<th>Symbol</th>
<th>Type</th>
<th>Dimension</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ScenRedReport</td>
<td>Parameter</td>
<td>1</td>
<td>report of the SCENRED run</td>
</tr>
<tr>
<td>2</td>
<td>red_prob</td>
<td>Parameter</td>
<td>1</td>
<td>node probabilities for the reduced scenarios</td>
</tr>
<tr>
<td>3</td>
<td>red_ancestor</td>
<td>Set</td>
<td>2</td>
<td>the ancestor map for the reduced scenarios</td>
</tr>
</tbody>
</table>
To read the SCENRED data output file, the GAMS `execute_load` statement is used. This statement is used to transfer GDX data to GAMS at execution time. As an example, to read a GDX file named `sr_output.gdx` created by SCENRED, you might have the following statement:

```gams
eexecute_load 'sr_output.gdx', ScenRedReport, sprob=red_prob, sanc=red_ancestor;
```

In the statement above, the equal sign `=` is used to indicate that the data in the GDX parameter `red_prob` should be read into the GAMS parameter `sprob`, and the data in the GDX set `red_ancestor` should be read into the GAMS set `sanc`.

### 6.39.8 Diagnostic Check of Scenario Trees

When SCENRED reads its input data, it performs a number of checks to verify that the data is correct. The diagnostic checks of the input parameters include:

- consistency of the desired input parameters with the contents of the SCENRED input file (number of nodes, number of leaves, number of time steps, number of random values assigned to a node)
- range check of desired input parameters and options
- check of scenario and node probabilities
- check of the ancestor matrix (check the orientation of the graph, check if the graph contains a cycle, check if the graph contains incomplete forests or scenarios, check the consistency of the parameter `num_time_steps` with the ancestor matrix)

The following errors in the specification of the scenario tree cause SCENRED to skip the reduction algorithms:

- The input files cannot be opened.
- Not all required input parameters are given.
- The required input parameters are not consistent with the contents of the SCENRED input file.
- The required input parameters are out of range.
- Missing or negative scenario probabilities (probabilities of leaves).
- The ancestor set contains too many entries (more than `2*num_nodes`).
- SCENRED detects a cycle in the ancestor set.
- SCENRED detects incomplete scenarios in the ancestor set.
- Run time limit reached

### 6.39.9 SCENRED Errors and Error Numbers

When SCENRED encounters a serious error in the input files or in the scenario tree, it sends an error message to the screen and to the log file. These messages always start with

```
**** SCENRED run-time error . . .
```

The number of SCENRED errors are contained in the parameter `ScenRedReport` of the SCENRED output file (if it could be created). The occurrence of an error can also be detected from the last line that SCENRED sends to the screen:

```
**** SCENRED ErrCode= . . .
```

The numerical values of `ErrCode` and their meaning are given below.
<table>
<thead>
<tr>
<th>ErrCode</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(for internal use)</td>
</tr>
<tr>
<td>2</td>
<td>fatal error while reading from SCENRED input file</td>
</tr>
<tr>
<td>3</td>
<td>fatal error while writing to SCENRED output file</td>
</tr>
<tr>
<td>4</td>
<td>fatal error while reading from SCENRED option file</td>
</tr>
<tr>
<td>5</td>
<td>log file cannot be opened</td>
</tr>
<tr>
<td>6</td>
<td>a memory allocation error occurred</td>
</tr>
<tr>
<td>7</td>
<td>there are missing input parameters</td>
</tr>
<tr>
<td>8</td>
<td>could not access the GAMS names for the nodes</td>
</tr>
<tr>
<td>9</td>
<td>(for internal use)</td>
</tr>
<tr>
<td>10</td>
<td>ancestor set not given or contains too many entries</td>
</tr>
<tr>
<td>11</td>
<td>node probabilities cannot be not read or are wrong</td>
</tr>
<tr>
<td>12</td>
<td>random values for the nodes cannot be read</td>
</tr>
<tr>
<td>13</td>
<td>input parameters are out of range</td>
</tr>
<tr>
<td>14</td>
<td>ancestor set contains a cycle</td>
</tr>
<tr>
<td>15</td>
<td>incomplete scenarios or forests detected</td>
</tr>
<tr>
<td>16</td>
<td>fatal error in reduction algorithm (not enough memory)</td>
</tr>
<tr>
<td>17</td>
<td>running time limit reached</td>
</tr>
</tbody>
</table>

### 6.39.10 SCENRED Warnings

SCENRED warnings are caused by misspecification of the initial scenarios that can be possibly fixed. When SCENRED encounters such an error in the input files or in the scenario tree, it sends a message to the screen and to the log file. These messages always start with

```
**** SCENRED Warning . . .
```

The following list gives an overview of the cases that produce warnings, and the action taken by SCENRED in these cases.

- The user assigned an option value that is out of range.  
  **Action:** Assign the default value.

- Both parameters `red_num_leaves` and `red_percentage` are assigned nontrivial values.  
  **Action:** The value of `red_percentage` will be ignored.

- The scenario probabilities (probabilities of leaves) do not sum up to 1.  
  **Action:** The scenario probabilities are rescaled. Assign new probabilities to the remaining (inner) nodes that are consistent with the scenario probabilities.

- Missing probabilities of inner nodes.  
  **Action:** Assign node probabilities that are consistent with the scenario probabilities.

- The ancestor set contains more than one ancestor for a node.  
  **Action:** SCENRED assumes to be given a successor set instead of an ancestor set (i.e., the transpose of an ancestor matrix. This means that the graph corresponding to the ancestor set has the wrong orientation). SCENRED starts the tree diagnostic for the successor set. The reduced tree will be defined in terms of a successor set as well (if the successor set passes the tree diagnostic and if SCENRED locates no fatal error during the run).

- The fast backward method delivered a result, but the result cannot be improved by the forward or backward method (running time limit reached).  
  **Action:** Use the result of the fast backward method.
6.40 SCENRED2

6.40.1 Introduction

Scenred2 is a fundamental update of the well-known scenario reduction software Scenred. A lot of new features come along with the latest release version. Beside updates and extensions concerning the control of the scenario reduction action an all new device for scenario tree construction has been implemented in Scenred2. Moreover, a lot of visualization functions to plot scenario trees and scenario processes linked to the free Gnuplot plotting software are available with Scenred2 now.

Table: Summary of basic new functions in Scenred2

<table>
<thead>
<tr>
<th>Description</th>

<td>Command Line Interface</td>
</tr>
</tbody>
</table>

6.40.2 Using Gams/Scenred2

Successful applying Scenred or Scenred2 requires a special formulation of the stochastic programming model within the Gams program. Probabilistic information must be given by a set of nodes implying a certain ancestor structure including a well-defined root node. Note that the usage of Gams/Scenred2 is basically the same as the usage of Gams/Scenred. Hence, it is recommended for new users to look at the Scenred documentation first. All details about how to organize your Gams program, how to run Scenred from the Gams program by using the gdx interface, and, of course, examples can be found in that documentation.

The Gams/Scenred2 link provides the same gdx interface. But, due to new features some small changes in controlling the options are needed. Scenred2 supports now two types of option files. The first one is the SR-Command-File which must be passed to Scenred2 together with the Scenred2 call. The second one, the SR-Option-File includes more specific options to control the selected scenario reduction or scenario construction methods and can be declared in the SR-Command-File.

6.40.2.1 SR-Command-File

The command file includes the basic specifications. These are input/output gdx file names, the log file name, all other file names which are needed for diverse visualization and output options. It also includes the name of the SR-Option-File.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_file</td>
<td>specify a log file name</td>
<td>yes</td>
</tr>
<tr>
<td>input_gdx</td>
<td>specify the gdx input file for Scenred</td>
<td>yes</td>
</tr>
<tr>
<td>output_gdx</td>
<td>specify the gdx output file of Scenred</td>
<td>yes</td>
</tr>
<tr>
<td>sr_option</td>
<td>specify a SR-Option-File</td>
<td>no</td>
</tr>
<tr>
<td>visual_init</td>
<td>specify a name for visualization of input tree</td>
<td>no</td>
</tr>
<tr>
<td>visual_red</td>
<td>specify a name for visualization of reduced/constructed tree</td>
<td>no</td>
</tr>
<tr>
<td>plot_scen</td>
<td>specify a name for visualization of scenario processes</td>
<td>no</td>
</tr>
<tr>
<td>out_scen</td>
<td>specify a file for scenario data output in fan format</td>
<td>no</td>
</tr>
<tr>
<td>out_tree</td>
<td>specify a file for scenario data output in tree format</td>
<td>no</td>
</tr>
</tbody>
</table>
Example:

Scenred2 must be called together with a command file, which contains at least all required options. The data exchange via the gdx interface and the Scenred2 call from the Gams program is of the form (be careful with the meanings and right order of gdx symbols):

```plaintext
execute_unload 'srin.gdx', ScenRedParms, n, ancestor, prob, random;
execute 'scenred2 scenred.cmd';
execute_load 'srout.gdx', ScenRedReport, ancestor=red_ancestor, prob=red_prob;
```

For example, the command file could be the following (note the compatible gdx file names):

```plaintext
* scenred command file 'scenred.cmd'
log_file sr.log
input_gdx srin.gdx
output_gdx srout.gdx
sr_option scenred.opt
visual_red tree
out_scen raw.dat
```

### 6.40.2.2 ScenRedParms

With the symbol list of the parameter ScenRedParms and the SR-Option-File all necessary information regarding the Scenred2 run can be assigned. The Gams parameter ScenRedParms can easily included to the Gams program by the statement:

```
$libInclude scenred2
```

Of course, the include must be stated before calling Scenred2. After that statement all supported parameters can be assigned, but at least all required parameters regarding the input scenarios. By the symbols of the parameter ScenRedParms you make also the decision of what features you exactly want to use with Scenred2. Moreover, some other usefull parameters for the Scenred2 run are included in the symbol list of the parameter ScenRedParms.

**Table:** Supported Scenred2 parameters in ScenRedParms

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_time_steps</td>
<td>path length from root to leaf</td>
<td>yes</td>
</tr>
<tr>

<td>no</td>
</tr>
<tr>
<td>num_stages</td>
<td>number stages</td>
<td>no</td>
</tr>
<tr>
<td>run_time_limit</td>
<td>time limit in seconds</td>
<td>no</td>
</tr>
<tr>
<td>report_level</td>
<td>report level: more messages by higher values</td>
<td>no</td>
</tr>
<tr>
<td>scen_red</td>
<td>scenario reduction command</td>
<td>no</td>
</tr>
<tr>
<td>tree_con</td>
<td>tree construction command</td>
<td>no</td>
</tr>
<tr>
<td>visual_init</td>
<td>visualization initial tree</td>
<td>no</td>
</tr>
<tr>
<td>visual_red</td>
<td>visualization reduced (constructed) tree</td>
<td>no</td>
</tr>
<tr>
<td>plot_scen</td>
<td>visualization scenario processes</td>
<td>no</td>
</tr>
<tr>
<td>out_scen</td>
<td>output of scenario raw data</td>
<td>no</td>
</tr>
</tbody>
</table>
To enable some options assign a value to the parameter. A parameter value of zero (default) disables an option. Note that when running Scenred2 either scenario reduction or scenario tree construction can be performed. Hence, only `scen_red` or `tree_con` should be used at once.

Example:

The following statements describe a possible example setup for proceeding the scenario tree construction with visualization of the scenario tree and output of the scenarios to a raw data file afterwards. Note that for the visualization and the scenario output the name of output files must be specified in the SR-Command-File. Otherwise a warning will inform you about not selected file names.

```plaintext
* general parameters
ScenRedParms('num_leaves') = 100;
ScenRedParms('num_nodes') = 200;
ScenRedParms('num_time_steps') = 5;
ScenRedParms('num_random') = 2;
ScenRedParms('report_level') = 2;
ScenRedParms('run_time_limit') = 30;

* execution commands
ScenRedParms('tree_con') = 1;
ScenRedParms('visual_red') = 1;
ScenRedParms('out_scen') = 1;
```

Scenred2 can also be used for plotting tasks only. Disable both the `scen_red` and `tree_con` option and use one ore more visualization options only (see also Section Visualization for more details regarding visualizations).

6.40.2.3 SR-Option-File

The SR-Option-File is the more specific option file and will be passed to Scenred2 by the `sr_option` statement specified in the SR-Command-File. It serves as control unit for available methods provided by Scenred2. The supported options depend on what kind of method is called with Scenred2. A detailed list of all options together with examples are given below for both the scenario reduction and the scenario construction devices (see Sections Scenario Reduction and Scenario Tree Construction, respectively). Note that certain parameters can be assigned by using both ScenRedParms and the SR-Option-File. In case of having parameters defined twice a warning by Scenred2 will generated to inform you.

6.40.3 Scenario Reduction

The scenario reduction device consists of approved methods for reducing the model size by reducing the number of scenarios in an optimal way. Here it doesn't make any difference whether the input data is structured as scenario tree or not. But note, the classical scenario reduction approach is actually developed for two-stage models. Extensions for the multistage case are planed in the near future. To learn more about the mathematical theory see, for example,

With Scenred2 the most popular and accurate reduction algorithms of forward and backward type are maintained further on. New options make it possible to proceed with the scenario reduction more individual. The most important new parameter is given by the option *metric_type* which allows to control the reduction process by different type of probability distances. Altogether three distances can be selected (see Table below). All probability distances are associated with a special order specification which can be set by the new option *order*. Both options replace the old option *where_random* which is not used any longer.

**Table: SR Options - Scenario Reduction**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>red_num_leaves</td>
<td>desired number of scenarios (integer)</td>
</tr>
<tr>
<td>red_percentage</td>
<td>relative accuracy (number from 0.0 to 1.0)</td>
</tr>
<tr>
<td>reduction_method</td>
<td>1 - Forward, 2 - Backward, 0 - Default</td>
</tr>
<tr>
<td>metric_type</td>
<td>1 - Transport (default), 2 - Fortet-Mourier, 3 - Wasserstein</td>
</tr>
<tr>
<td>p_norm</td>
<td>choice of norm (example: 0 - max, 1 - sum, 2 - Euclidian)</td>
</tr>
<tr>
<td>scaling</td>
<td>0 - scaling off, 1 - scaling on (default)</td>
</tr>
<tr>
<td>order</td>
<td>metric order (integer, default is 1)</td>
</tr>
</tbody>
</table>

**Example:**

For example, a valid SR-Option-File is the following:

```
* scenred option file

reduction_method 1
red_percentage 0.3
metric_type 2
order 2
p_norm 1
scaling 0
```

Lines starting with the star symbol (route symbol can be used too) provide comment lines. The star symbol can also be used to out comment and disable certain options.

### 6.40.4 Scenario Tree Construction

Scenario tree construction is the outstanding all new device of Scenred2. It allows to construct scenario trees as accurate input for multistage stochastic programs (cf. H. Heitsch and W. Römisch, Scenario tree modeling for multistage stochastic programs, Mathematical Programming, 118:371–406, 2009). The input are individual scenarios in form of a fan which must be allocated before calling Scenred2. A lot of options are offered to control the tree construction process. Note that in some cases due to sensibility of certain parameters some tuning is indispensable for producing good results.

**Table: SR Options (basic) - Scenario Tree Construction**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>construction_method</td>
<td>1 - forward, 2 - backward</td>
</tr>
<tr>
<td>reduction_method</td>
<td>1 - forward, 2 - backward, used within the iteration</td>
</tr>
<tr>
<td>first_branch</td>
<td>time period of first branch (integer)</td>
</tr>
<tr>
<td>red_percentage</td>
<td>relative accuracy (level from 0.0 to 1.0)</td>
</tr>
<tr>
<td>eps_growth</td>
<td>1 - linear, 2 - exponential</td>
</tr>
<tr>
<td>eps_evolution</td>
<td>tree structure parameter (from 0.0 to 1.0)</td>
</tr>
<tr>
<td>scaling</td>
<td>0 - scaling off, 1 - scaling on (default)</td>
</tr>
<tr>
<td>order</td>
<td>order of metric</td>
</tr>
</tbody>
</table>
The Table above displays the main options to control the tree construction process. They are very similar to the reduction options. The role of the option \texttt{red\_percentage} is here to prescribe a total epsilon accuracy (level) for the approximation scheme. But the approximation scheme is based on stagewise approximations which requires a splitting of the total level to the stages. Two strategies are offered by Scenred2 a linear and an exponential mapping of the total level to the intermediate levels. Use option \texttt{eps\_growth} to select one of them. Both strategies allow a second tuning parameter \texttt{eps\_evolution} which effects the slope of the epsilon splitting.

Even though this kind of control may generate good results for many applications, sometimes a more individual control can be needed. For example, some applications require a localization of branching stages. Moreover, to setup approximation bounds directly to stages can be very useful. To this end the standard options are extended by a new section environment.

6.40.4.1 Additional options - The section environment

An alternative control for the accurate constructions is provided by using the section environment. The section environment aims to establish a better monitoring of the construction process. There are overall three section types supported by Scenred2 with the same syntax.

Branching control:

This section environment allows to specify branching points, i.e., an explicit selection of stages serving for branching. For example, use

\begin{verbatim}
section branching
  2
  4
  6
end
\end{verbatim}

to allow branching only at time period 2, 4, and 6. Note that each stage statement must be placed in one line. But stages can be merged. A shorter formulation of the same contents can be written in closed form

\begin{verbatim}
section branching
  2\*6  2
end
\end{verbatim}

This statement reads branching within time periods from period 2 to period 6 with increment 2 steps.

Both assignments can be combined and should be used together with the \texttt{red\_percentage} option.

Epsilon control:

In the similar way by the epsilon section it is possible to assign epsilon tolerances for the stage approximations explicitly. This environment overcomes difficulties at times coming across with the automatic epsilon control. Note that this environment disables the option \texttt{red\_percentage}. For example, use

\begin{verbatim}
section epsilon
  2  0.04
  3\*4  0.03
  5  0.02
  6  0.01
end
\end{verbatim}
to control the approximation scheme by assigning different epsilon values per stage. Note that the value 0.03 is assigned to time period 3 and 4 in the example.

**Node control:**

The node control is the most specific control you have over the tree construction. With this environment the number of nodes of the tree which will generated can be assigned for each time stage explicitly. For example, use

```
section num_nodes
  1   1
  2*3 5
  4*5 10
  6   15
end
```

The syntax is the same as before. Note that only one section environment can be use at once. In particular, only the first section environment detected in the option file is used. The section environment can be out commented like a standard option too.

**Experimental option:**

There is one other useful option to speed up computations when building different scenario trees from exactly the same input data. In this case the scenario distances needed to compute the trees could be saved to a external file at the first run and reloaded at later runs. Hence, the distances must be calculated only once. For example, use the option

```
write_distance  dist.sr2
```

To save the computed distances to the file 'dist.sr2'. To reload them at next run use the option

```
read_distance  dist.sr2
```

The option is classified as experimental since no validation of the input file takes place. Before using this option, please ensure that the distances loaded with the `read_distance` option are the right ones.

**Example:**

Finally, look at the following example to see a valid SR-Option-File which can be passed to the scenario tree construction:

```
* tree construction option file

construction_method  2
reduction_method     1
order                 1
scaling              0

section epsilon
  2*4   0.1
  5     0.2
  6     0.1
end
```
6.40.4.2 Example problems 'srtree.gms' and 'srpchase.gms'

Small example problems has been included to the GAMS Model Library.

The implementation can be found in the Gams programs 'srtree.gms' and 'srpchase.gms'. It might help you to practice in building scenario trees using Gams/Scenred2. The problem 'srtree.gms' converts a fan format scenario representation into a tree format representation and then reduces the tree size. The problem 'srpchase.gms' is to solve a simple stochastic purchase problem involving three stages. Sample scenarios which are generated from a fixed distribution using a random value generator serve as input for the tree construction.

6.40.5 Visualization

Visualization is another all new feature of Scenred2. In this section an easy way for making plots of scenario processes and tree structures is described. To this end you need the free Gnuplot software or any other plotting software which allows plotting directly from simple data files.

The concept of plotting tasks is the following. For each plot two files are generated, a Gnuplot access file (name.plt) and a raw data file (name.dat). The access file contains basic Gnuplot options and it can be adjusted for individual liking afterwards. The default output is the display. The supported plotting commands are

\texttt{visual_init, visual_red, plot_scen}

for plotting the initial tree structure, the reduced/constructed tree structure, and the scenario process(es), respectively.

\textbf{Example:}

For example, to visualize the constructed tree use the option

\begin{verbatim}
visual_red tree
\end{verbatim}

within the SR-Command-File to specify the name for the output and activate the ScenRedParms parameter

\begin{verbatim}
ScenRedParms('visual_red') = 1;
\end{verbatim}

in the Gams program. The result are the output files 'tree.plt' and 'tree.dat'. To compute the picture now you simply open the file 'tree.plt' with Gnuplot from the directory, where both output files are located (that should be the working directory). Alternatively, from the command line prompt call

\begin{verbatim}
>gnuplot tree.plt
\end{verbatim}

Gnuplot will automatically generate the picture. Feel free to change any option in the Gnuplot access file for individual requirements. See also the Gnuplot manual for more details. In particular, to compute a well-scaled encapsulated postscript picture (eps), you simply have to uncomment a few lines in the Gnuplot option file above and to open it with Gnuplot once again.

With the command \texttt{plot_scen} the scenario process(es) can be visualized. Note that Scenred2 generates Gnuplot access and data files according to the number of random values.
6.40.6 Command Line Interface

The command line interface allows to run Scenred2 stand alone without using Gams. In this case the
input for scenario reduction and scenario tree construction is handled by special input data files. The
command file will be extended by the parameters having with the ScenRedParms otherwise.

To execute Scenred2 from the command line prompt together with a specified command file (which is
required again), for example, call

>scenred2 command.file -nogams

To avoid diverse error messages do not forget the '-nogams' option to switch off the Gams interface. The
command file can include some of the following options.

    report_level <integer>
    runtime_limit <integer>
    read_scen <input file>
    scen_red <option file>
    tree_con <option file>
    visual_init <name>
    visual_red <name>
    plot_scen <name>
    out_scen <file name>
    out_tree <file name>

The denotation is not accidental the same as in case of using the Gams interface. The meaning of a certain
option is maintained for the command line interface. To compute any scenario reduction or scenario tree
construction the same SR-Option-Files are supported. It remains to clarify the data input format which
comes across with the new read_scen command.

6.40.6.1 Data input format

To feed Scenred2 with data the scenario parameters must be passed by the read_scen command. Two
types of input file formats are accepted.

a) The tree format:

This file is a formatted data file including all information of the input scenarios tree. It must have a header
with dimension information and the scenario data separated for each node. The header includes the type
declaration, the number of nodes, and the number of random values.

The data part starts with the key word DATA (do not forget). The tree data has to be ordered node
by node. For every node the following information is expected separated by white spaces: The unique
predecessor node (root node points to itself) followed by the node probability and followed by the assigned
number of random data values. All information to one node should be written to one line (only for
clarity reasons). Comment lines are allowed.

Match the following conventions:

- Nodes are identified by a sequence of integer numbers.
- The root node is expected to be the node '1'.
- The predecessor of root is '1' too, i.e., the root points to itself.
- All nodes numbers require a canonical order by stages and scenarios (see example).

Example:

```
# input tree example for scenred

TYPE TREE

NOD\_S 9
RAND\_M 4

DATA
  * PRED PROB RAND\_-1 RAND\_-2 RAND\_-3 RAND\_-4
  1 1.0 42.5 9.1 7.5 120.0
  1 1.0 39.8 11.2 8.4 90.0
  2 1.0 37.6 14.0 6.3 110.0
  3 0.5 38.9 12.4 8.1 130.0
  3 0.5 35.7 13.8 7.5 120.0
  4 0.25 40.3 14.9 7.2 120.0
  4 0.25 38.4 15.2 8.9 100.0
  5 0.3 37.6 14.9 9.3 80.0
  5 0.2 36.3 12.8 10.3 90.0

END
```

b) The fan format:

A scenario fan serves as input for the scenario tree construction but it can be used also for the scenario reduction. The scenario fan represents a special form of a scenario tree, where we consider individual scenarios merged to a collective root node (the root node can also be viewed here as some kind of artificial node).

Accordingly, the fan input file is a formatted data file including all information of the scenarios in individual form now. It must have a similar header with dimension information and the scenario data separated now for each scenario. The header gets the type declaration `FAN` instead of `TREE` and includes the number of scenarios, the number of time periods, and the number of random values. The data part is opened again with the `DATA` key word.

Every scenario is specified by a dataset including the scenario probability first followed by the different random values in ascending order w.r.t. time periods. All entries must be separated by a white space. Comment lines can be placed by the star and route symbols again. Note that in case of having an undetermined root node the mean of random values will taken for the first time period to appoint a unique root node. The example tree represented as input in scenario fan format is displayed in the next example.

Example:
# input fan example for scenred

```
TYPE  FAN

TIME  5
SCEN  4
RANDOM  4

DATA
0.2500
42.5  9.1  7.5  120.0
39.8  11.2  8.4  90.0
37.6  14.0  6.3  110.0
38.9  12.4  8.1  130.0
40.3  14.9  7.2  120.0

0.2500
42.5  9.1  7.5  120.0
39.8  11.2  8.4  90.0
37.6  14.0  6.3  110.0
38.9  12.4  8.1  130.0
38.4  15.2  8.9  100.0

0.3000
42.5  9.1  7.5  120.0
39.8  11.2  8.4  90.0
37.6  14.0  6.3  110.0
35.7  13.8  7.5  120.0
37.6  14.9  9.3  80.0

0.2000
42.5  9.1  7.5  120.0
39.8  11.2  8.4  90.0
37.6  14.0  6.3  110.0
35.7  13.8  7.5  120.0
36.3  12.8  10.3  90.0
END
```

Note that even though all scenarios coincide at the first three time periods, in this example, the scenarios will be represented by one node each for every time period by the fan input format. The exception is the first time period, where a unique root node is expected in general and, therefore, only one node is assigned. The following picture shows the structure of the scenario fan which is generated by the example input.
6.40.6.2 Data Export

Scenred2 allows to export scenario data after computing the scenario reduction or scenario tree construction to external data files. Data export is available for both the Gams and the command line interface. To export data from Scenred2 two output options `out_tree` and `out_scen` can be use. These options generate data files according to the tree and fan format, respectively. The name of the data files will be specified in the SR-Command-File. When using the Gams interface the options must be connected by activating the corresponding ScenRedParms parameter, additionally.

6.40.7 A Simplified Interface to Scenred2: $libinclude runscenred2

While the previously described interface between GAMS and Scenred2 provides a maximum of flexibility, it also is rather complex and error-prone. The GAMS utility `runscenred2` tries to hide most of the mechanics of the GAMS/Scenred2 interface. The call to `runscenred2` looks as follows:

```
$libInclude runscenred2 myprefix tree_con n tree p rtree rp rv1 rv2
```

Table: runscenred2 Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 myprefix</td>
<td>base name for files used with Scenred2</td>
</tr>
<tr>
<td>2 tree_con or scen_red</td>
<td>select Scenred2 action: tree construction or scenario reduction</td>
</tr>
<tr>
<td>3 n</td>
<td>the set of nodes in the tree</td>
</tr>
<tr>
<td>4 tree</td>
<td>the set of ancestor relations describing the tree</td>
</tr>
<tr>
<td>5 p</td>
<td>the parameter containing the node probabilities</td>
</tr>
<tr>
<td>6 rtree</td>
<td>the set of ancestor relations of the reduced tree (output)</td>
</tr>
<tr>
<td>7 rp</td>
<td>the parameter containing the node probabilities for the reduced tree (output)</td>
</tr>
<tr>
<td>8 rv1, rv2, ...</td>
<td>parameters containing random values of the nodes</td>
</tr>
</tbody>
</table>

The table above describes the arguments of the `runscenred2` call. Arguments 3, 4, 5, 8 and following correspond to the symbols that need to be exported to the Scenred2 data input file (done with the `execute_unload` call in the complex interface). The output arguments 6 and 7 correspond to the symbols imported from the Scenred2 data output file (done with the `execute_load` call in the complex interface). The parameters ScenRedParms and ScenRedReport are invisibly communicated with Scenred2.

The second argument instructs Scenred2 either to construct a tree (`tree_con`) or to reduce a tree (`scen_red`).

Instead of providing an explicit name for all the different files in the Scenred2 command file, the first argument determines the name of all files using a simple naming scheme. The following name scheme is observed:

<table>
<thead>
<tr>
<th>Filename</th>
<th>Command option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sr2myprefix.log</td>
<td>log_file</td>
<td>log file name</td>
</tr>
<tr>
<td>sr2myprefix.in.gdx</td>
<td>input_gdx</td>
<td>gdx input file name</td>
</tr>
<tr>
<td>sr2myprefix.out.gdx</td>
<td>output_gdx</td>
<td>gdx output file name</td>
</tr>
<tr>
<td>sr2myprefix.opt</td>
<td>sr_option</td>
<td>option file name</td>
</tr>
<tr>
<td>sr2myprefix_vi.plt</td>
<td>visual_init</td>
<td>file name for visualization of input tree</td>
</tr>
<tr>
<td>Filename</td>
<td>Command option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
<td>-----------------------------------------------------</td>
</tr>
<tr>
<td>sr2myprefix_vr.plt</td>
<td>visual_red</td>
<td>file name for visualization of reduced/constructed tree</td>
</tr>
<tr>
<td>sr2myprefix_plot.plt</td>
<td>plot_scen</td>
<td>file name for visualization of scenario process</td>
</tr>
<tr>
<td>sr2myprefix_raw.dat</td>
<td>out_scen</td>
<td>file name for scenario data output in fan format</td>
</tr>
<tr>
<td>sr2myprefix_tree.dat</td>
<td>out_tree</td>
<td>file name for scenario data output in tree format</td>
</tr>
</tbody>
</table>

The first three files (log file, input.gdx and output.gdx) are always used. The only optional input file sr_option is read by Scenred2 if ScenRedParms('sroption')=1. When you create this file, make sure to use the proper file name. The output files are created by Scenred2 if the corresponding option is set to 1 in ScenRedParms, e.g. ScenRedParms('out_tree')=1.

In addition to a simpler communication of data between GAMS and Scenred2, the newer versions of GAMS/Scenred2 (starting with GAMS distribution 23.1) release the user of setting required fields in the ScenRedParms parameter: num_time_steps, num_leaves, num_nodes, and num_random. GAMS/Scenred2 calculates these numbers from its input data. In case the user still sets these fields, Scenred2 will ensure that the internally calculated numbers and the user provided numbers match.

### 6.41 ShellExecute

A Tool for Launching External Programs.

Author

Erwin Kalvelagen

Date

March 25, 2004

### 6.41.1 Overview

shellexecute is a small wrapper program for the ShellExecute Windows API call. It allows you to spawn an external program based on the file type of the document to open.

GAMS provides the execute statement to execute external programs. In some cases we want to let the system figure out what application to start for a given document. This can be accomplished with shellexecute. For instance, when we call:

> shellexecute demo.html

Windows will launch the web browser and show demo.html. This works correctly, irrelevant whether the user installed Microsoft Internet Explorer or Netscape’s web browser.
6.41.2 Usage

The command line for `shellexecute` looks like:

```
shellexecute [/verb=vvv] [/showcmd=flag] [/dir=ddd] filename args
```

The filename is either a document (e.g. `demo.html` or `book1.xls`) or an application (e.g. `winword.exe` or `notepad`). If a document is provided, the associated application will be launched. If a directory name is provided the windows explorer will be launched.

If additional parameters are specified they are considered as command line parameters for the process to be spawned.

The following options are recognized:

- `/verb=vvv` Specifies the action to be performed. The allowed actions are application dependent. Some commonly available verbs include:

<table>
<thead>
<tr>
<th>verb</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>edit</td>
<td>Launches an editor and opens the document for editing.</td>
</tr>
<tr>
<td>find</td>
<td>Initiates a search starting from the specified directory.</td>
</tr>
<tr>
<td>open</td>
<td>Launches an application. If this file is not an executable file, its associated application is launched.</td>
</tr>
<tr>
<td>print</td>
<td>Prints the document file.</td>
</tr>
<tr>
<td>properties</td>
<td>Displays the object’s properties.</td>
</tr>
</tbody>
</table>

If no verb is specified the default command for the file class will be used (in many cases this is `open`).

- `/showcmd=flag` Flag that specifies how an application is to be displayed when it is opened. The actual behavior is up to the launched program. The possible values are:

<table>
<thead>
<tr>
<th>showcmd</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_HIDE</td>
<td>Hides the window and activates another window.</td>
</tr>
<tr>
<td>SW_MAXIMIZE</td>
<td>Maximizes the specified window.</td>
</tr>
<tr>
<td>SW_MINIMIZE</td>
<td>Minimizes the specified window and activates the next top-level window in the $z$-order.</td>
</tr>
<tr>
<td>SW_RESTORE</td>
<td>Activates and displays the window. If the window is minimized or maximized, Windows restores it to its original size and position. An application should specify this flag when restoring a minimized window.</td>
</tr>
<tr>
<td>SW_SHOW</td>
<td>Activates the window and displays it in its current size and position.</td>
</tr>
<tr>
<td>SW_SHOWMAXIMIZED</td>
<td>Activates the window and displays it as a maximized window.</td>
</tr>
<tr>
<td>SW_SHOWMINIMIZED</td>
<td>Activates the window and displays it as a minimized window.</td>
</tr>
<tr>
<td>SW_SHOWMINNOACTIVE</td>
<td>Displays the window as a minimized window. The active window remains active.</td>
</tr>
<tr>
<td>SW_SHOWNA</td>
<td>Displays the window in its current state. The active window remains active.</td>
</tr>
<tr>
<td>SW_SHOWNOACTIVATE</td>
<td>Displays a window in its most recent size and position. The active window remains active.</td>
</tr>
</tbody>
</table>
### showcmd

<table>
<thead>
<tr>
<th>showcmd</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_SHOWNORMAL</td>
<td>Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position. An application should specify this flag when displaying the window for the first time.</td>
</tr>
</tbody>
</table>

The default is `SW_SHOWNORMAL`.

- `/dir=ddd` the default directory for the sub-process.

In many cases you will not need to use any options.

### 6.41.3 Examples

Below are some examples of `ShellExecute`. It is noted that much of the behavior is depending on the file associations that are installed on your machine. These file associations can be inspected and changed with the Windows Explorer, see Figure 1.

#### 6.41.3.1 Spawning a web browser

> shelleexecute turkey.html

#### 6.41.3.2 Spawning notepad

> shelleexecute trnsport.txt

If a different program is associated with a `.TXT` file, a different program will be launched. In my case notepad will be launched due to the file association shown in Figure 1.

#### 6.41.3.3 Spawning the GAMS IDE to view a GDX file

> shelleexecute trnsport.gdx

#### 6.41.3.4 Spawning Excel

> shelleexecute test.xls

#### 6.41.3.5 Calling shelleexecute from GAMS

execute '=shelleexecute trnsport.html';
6.41.3.6 A complete GAMS example

The following model is the transport model from the model library. We write the solution both to an HTML file and a CSV file. HTML is standard ASCII and is easily written using the PUT facility. CSV is even easier, as setting the FILE suffix csv.pct=5; will automatically generate comma separated values. The web browser is launched to view the HTML file, while Excel will be spawned to view the CSV file.

$title A Transportation Problem (TRNSPORT,SEQ=1)

$onText
Write a solution report in HTML and CSV and spawn a browser and Excel to view the results.

Erwin Kalvelagen, May 2004
$offText

No application is associated with the specified file for this operation
```

6.42 SQL2GMS

Author
Erwin Kalvelagen
6.42.1 Overview

**SQL2GMS** is a tool to convert data from an SQL database into GAMS readable format. The source is any data source accessible through Microsoft's Data Access components including ADO, ODBC and OLEDB. The target is a GAMS Include File (.inc) or a GAMS GDX File (.gdx).

When running the executable sql2gms.exe without command line arguments, the tool will run interactively with a built-in GUI interface. Alternatively SQL2GMS can be run in batch mode, which is useful when running it directly from a GAMS model without user intervention using the **$call** command at compile time or the **execute** command at execution time.

Database tables can be considered as a generalization of a GAMS parameter. GAMS parameters have multiple index columns but just one value column. If the table is organized as multi-valued table, a UNION operation in the SQL statement can be used to generate the correct GAMS file.

There are no special requirements on the data types used in the database. The data is converted to strings, which is almost always possible. Data types like LONG BINARY may not be convertible to a string, in which case an exception will be raised. In general NULL's should not be allowed to get into a GAMS data structure. The handling of NULL's can be specified in an option.

Besides parameters it is also possible to generate set data.

If you need to read data from an MS Access database or MS Excel spreadsheet, the accompanying tools **MDB2GMS** or **XLS2GMS** resp. **GDXXRW** may be more appropriate. In some cases it may be more useful to use SQL2GMS to read from Access and Excel data sources.

6.42.2 Requirements

**SQL2GMS** runs only on Windows PC's with MDAC (Microsoft Data Objects) installed. In many cases this will be installed on your computer. Otherwise it can be downloaded from the Microsoft Download Center (direct link to MDAC).

In order to use SQL2GMS effectively, you will need to have a working knowledge of SQL in order to formulate proper database queries. In addition you will need some knowledge on how to connect to your database using ODBC or ADO.

6.42.3 Batch Usage

**SQL2GMS** can be run in batch mode without user intervention from within the GAMS model by using the **$call** resp. **execute** statements or directly from command prompt while specifying all arguments in the command-line. A SQL2GMS batch call is of the following form:

```
sql2gms connectionString outputFile queryString
```

A proper call will at least contain the following three command-line arguments:
1. The name of the database and the instruction for connecting to the database must be specified within the connectionString, which is indicated by the option $C$, i.e. $C=\text{connectionString}$.

2. The name of outputFile, either an include file (.inc) or GDX file (.gdx), must be specified. Using an include file to store the results of the query is indicated by the option $O$, i.e. $O=\text{outputFile}.inc$, while the use of a GDX file is indicated by the option $X$, i.e. $X=\text{outputFile}.gdx$.

3. The SQL query String, containing the SQL statement to be executed on the database, must be specified within the option $Q$, i.e. $Q=\text{queryString}$.

See also Command-line Arguments below for a complete list of all possible command-line arguments. Consider that the $\text{call}$ or $\text{execute}$ usage is rather error prone and you will need to spend a little bit of time to get the call correct and reliable. Alternatively, use the interactive built-in GUI interface or enter the command-line arguments in an external text file in order to write a more structured and readable command. The use of an external parameter file is indicated by preceding the file name with a @ (At sign).

Also consider to take a look at the section Strategies, mentioning some of the drawbacks of the batch usage and how to overcome them.

### 6.42.3.1 Command-line Arguments

The following table summarizes the command-line arguments that can be specified when using SQL2GMS directly from the GAMS model or command prompt.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Interpretation</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>connectionString</td>
<td>none</td>
<td>Specify the connectionString (required).</td>
</tr>
<tr>
<td>O</td>
<td>outputIncludeFile</td>
<td>none</td>
<td>Specify the name of the output file (.inc). Either $O=$ or $X=$ must be specified (or both).</td>
</tr>
<tr>
<td>On</td>
<td>nth outputIncludeFile</td>
<td>none</td>
<td>Match the nth query with the nth output file (.inc format) if multiple queries are used.</td>
</tr>
<tr>
<td>X</td>
<td>outputGDXFile</td>
<td>none</td>
<td>Specify the name of the output file (.gdx). Either $O=$ or $X=$ must be specified (or both).</td>
</tr>
<tr>
<td>Q</td>
<td>Query</td>
<td>none</td>
<td>This option can be used to specify a SQL query (required).</td>
</tr>
<tr>
<td>Qu</td>
<td>nth query</td>
<td>none</td>
<td>Match the nth query with the nth output file (.inc) format or with the nth set- or parameter name when writing to GDX if multiple queries are used.</td>
</tr>
<tr>
<td>S</td>
<td>setName</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file.</td>
</tr>
<tr>
<td>Sn</td>
<td>nth setName</td>
<td>none</td>
<td>Match the nth query with the nth set in the GDX file if multiple queries are used.</td>
</tr>
<tr>
<td>Y</td>
<td>setName (with expl. text)</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. Use this argument to store a set with explanatory text.</td>
</tr>
<tr>
<td>Argument</td>
<td>Interpretation</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>--------------------------------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Yn</td>
<td>nth setName (with expl. text)</td>
<td>none</td>
<td>Match the nth query with the nth set (with explanatory text) in the GDX file if multiple queries are used.</td>
</tr>
<tr>
<td>A</td>
<td>parameterName</td>
<td>none</td>
<td>If we write to a GDX file, use this option to specify the name of a parameter to be used inside the GDX file.</td>
</tr>
<tr>
<td>An</td>
<td>nth parameterName</td>
<td>none</td>
<td>Match the nth query with the nth parameter in the GDX file if multiple queries are used.</td>
</tr>
<tr>
<td>L</td>
<td>Listing</td>
<td>disabled</td>
<td>Controls if the data is embedded in the listing file.</td>
</tr>
<tr>
<td>M</td>
<td>Mute</td>
<td>disabled</td>
<td>Controls if additional information is written to the log and include file.</td>
</tr>
<tr>
<td>B</td>
<td>Quote Blanks</td>
<td>disabled</td>
<td>Quote strings if they contain blanks or embedded quotes.</td>
</tr>
<tr>
<td>@fileName</td>
<td>ext. options file</td>
<td>none</td>
<td>Causes the program to read options from an external text file.</td>
</tr>
<tr>
<td>N</td>
<td>iniFileName</td>
<td>sql2gms.ini</td>
<td>Indicates the usage of a different INI file.</td>
</tr>
<tr>
<td>T1</td>
<td>connectionTimeOut</td>
<td>15</td>
<td>Indicates how long to wait while establishing a connection before terminating the attempt and generating an error.</td>
</tr>
<tr>
<td>T2</td>
<td>commandTimeOut</td>
<td>30</td>
<td>Indicates how long to wait while executing a command before terminating the attempt and generating an error.</td>
</tr>
<tr>
<td>T</td>
<td>timeOut</td>
<td>none</td>
<td>Sets both T1 and T2.</td>
</tr>
<tr>
<td>D</td>
<td>Debug</td>
<td>disabled</td>
<td>Generate debug information.</td>
</tr>
<tr>
<td>E</td>
<td>Empty sets</td>
<td>disabled</td>
<td>Allow an empty result set; without this option an empty result set will generate an error.</td>
</tr>
<tr>
<td>R</td>
<td>rowBatchSize</td>
<td>100</td>
<td>Row batch size; the default is 100 records.</td>
</tr>
<tr>
<td>P</td>
<td>Password</td>
<td>none</td>
<td>Specify a password for the database.</td>
</tr>
<tr>
<td>W</td>
<td>Wiring</td>
<td>none</td>
<td>Maps database columns to GAMS index positions.</td>
</tr>
</tbody>
</table>

Some more detailed remarks on the command-line arguments:

\[ \mathbf{C} = \text{string (connectionString, default = none)} \]

This option is required and specifies which database is to be used and how SQL2GMS talks to the database. A collection of valid connection strings can be found in section Connection Strings. Often the connection string will need to be surrounded by quotes, as in: \( \text{C=}\"DSN=sample\" \). This option is demonstrated in all examples, see Example 1 - Reading a single valued Table for instance.

\[ \mathbf{O} = \text{string (outputIncludeFile, default = none)} \]

This option specifies the name of the output file. The format of the output file will be a GAMS include file for a parameter or set statement. Make sure the directory is
writable. UNC names can be used. An output file must be specified for batch operation: i.e. either O= or X= needs to be specified (or both). The include file will be an ASCII file that can be read by GAMS using the $include command within the data definition of a set, parameter or scalar. If the include file already exists, it will be overwritten. This option is demonstrated in Example 1 - Reading a single valued Table for instance.

\textbf{O=} \textit{string} (outputIncludeFile, default = none)

When using multiple queries in a single SQL2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition:

\begin{verbatim}
Q1=“SELECT a, b FROM table”
O1=ab.inc
Q2=“SELECT c, d FROM table”
O2=cd.inc
\end{verbatim}

See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

\textbf{X=} \textit{string} (outputGDXFile, default = none)

This option specifies the name of the output file. The format of the output file will be a GAMS GDX file. Make sure the directory is writable. UNC names can be used. If the GDX file already exists it will be overwritten - it is not possible to append to a GDX file. An output file must be specified for batch operation: i.e. either O= or X= needs to be specified (or both). This option is demonstrated in Example 5 - Reading Set with Explanatory Text or Example 7 - Multi-Query Batch Example for instance.

\textbf{Q=} \textit{string} (query, default = none)

This option can be used to specify an SQL query. Queries can contain spaces and thus have to be surrounded by double quotes. For the exact syntax of the queries that is accepted by the database we refer to the documentation that comes with your RDBMS (Relational DataBase Management System). The query is passed on directly to the RDBMS so the complete power and expressiveness of SQL is available including stored procedures etc. For an exact description of allowed expressions consult a text on your database system. This option is demonstrated in Example 1 - Reading a single valued Table for instance.

\textbf{Qn=} \textit{string} (query, default = none)

When using multiple queries in a single SQL2GMS call, you can append a number to match a query with an output file, as an include file storing the results for multiples queries cannot be interpreted later on in your GAMS model when using the include file in a set or parameter definition. In addition, you can match the results of a query with a specific set- or parameter name when writing to GDX.

\begin{verbatim}
Q1=“SELECT a, b FROM table”
O1=ab.inc
Q2=“SELECT c, d FROM table”
O2=cd.inc
\end{verbatim}

or (GDX output file format - where several sets and parameters can be stored in a single file):
\begin{quote}
Q1="SELECT a, b FROM table"
A1=abParameter
Q2="SELECT c FROM table"
S2=cSet
\end{quote}

Note the usage of the arguments An resp. Sn in order to store the results as parameter resp. set and to specify the name of the symbols. See also section Multi-Query Batch Usage or Example 7 - Multi-Query Batch Example for instance.

\textbf{S = string} (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be stored in the GDX file (containing the results of the query). This option is demonstrated in Example 4 - Reading a multi dimensional Set.

\textbf{Sn = string} (setName, default = none)

If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth set to be stored in the GDX file (containing the results of the nth query), e.g.

\begin{quote}
Q1="SELECT i FROM table"
S1=iSet
Q2="SELECT j FROM table"
S2=jSet
\end{quote}

See section Multi-Query Batch Usage and Example 7 - Multi-Query Batch Example for instance.

\textbf{Y = string} (setName, default = none)

If we write to a GDX file, use this option to specify the name of a set to be used inside the GDX file. The last column specified within the select clause in the SQL statement will be used as explanatory text. This option is demonstrated in Example 5 - Reading Sets with Explanatory Text for instance.

\textbf{Yn = string} (setName, default = none)

If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth set (with explanatory text) to be stored in the GDX file (containing the results of the nth query), e.g.

\begin{quote}
Q1="SELECT i, explTextForSeti FROM table"
Y1=iSet
Q2="SELECT j, explTextForSetj FROM table"
Y2=jSet
\end{quote}

The last column specified within the select clause in the SQL statements will be used as explanatory text.

\textbf{A = string} (parameterName, default = none)

If we write to a GDX file, use this option to specify the name of a parameter to be stored the GDX file (containing the results of the query). Note: MDB2GMS uses P, but P was already taken in SQL2GMS for specifying the password.

\textbf{An = string} (parameterName, default = none)
If multiple queries are used in a single SQL2GMS call while writing to a GDX file, use this option to specify the name of the nth parameter to be stored in the GDX file (containing the results of the nth query), e.g.

\[
\begin{align*}
Q1 &= \text{"SELECT i, j, value FROM table"} \\
A1 &= \text{ijValue} \\
Q2 &= \text{"SELECT n, m, value FROM table"} \\
A2 &= \text{nmValue}
\end{align*}
\]

See section Multi-Query Batch Usage and Example 7 - Multi-Query Batch Example for instance.

L (Listing, disabled by default)

Embed the data between the \$offListing and \$onListing dollar control options, so the data will not be listed in the listing file. This is a quick way to reduce the size of the listing file when including very large data files into the model. Otherwise the listing file would become too large to be handled comfortably.

M (Mute, disabled by default)

Controls if additional information (GAMS and SQL2GMS version numbers, number of rows in the data, elapsed time, used query etc.) is written to the log and include file.

B (Quote Blanks, disabled by default)

Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. In the special case that the string contains both, the double quotes are replaced by single quotes. For more information see subsection Quotes. This option only applies to an output include file.

\@fileName = string (fileName, default = none)

Causes the program to read options from an external text file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if they were specified directly on the command-line. See also Parameter Files for some further details.

N = string (fileName, default = none)

Use a different INI file than the standard sql2gms.ini located in the same directory as the executable sql2gms.exe.

T1 = integer (connectionTimeOut, default = 15)

Indicates how long to wait while establishing a connection before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for the connection to open. Default is 15. If you set the property to zero, ADO will wait indefinitely until the connection is opened. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

T2 = integer (commandTimeOut, default = 30)
Indicates how long to wait while executing a command before terminating the attempt and generating an error. The value sets, in seconds, how long to wait for a command to execute. Default is 30. If you set the property to zero, ADO will wait indefinitely until the execution is complete. A value of -1 indicates that the default value is to be used. Note: the provider needs to support this functionality.

\[ T = \text{integer} \ (\text{timeOut}, \text{default} = \text{none}) \]

Sets both \( T1 \) and \( T2 \).

\[ D = \text{integer} \ (\text{Debug}, \text{disabled by default}) \]

Generate debug information. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

\[ E = \text{integer} \ (\text{Empty sets}, \text{disabled by default}) \]

Allow an empty result set; without this option an empty result set will generate an error. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

\[ R = \text{integer} \ (\text{rowBatchSize}, \text{default} = 100) \]

Row batch size; the default is 100 records. This option must be specified in an INI file when using the interactive mode of SQL2GMS.

\[ P = \text{string} \ (\text{password}, \text{default} = \text{none}) \]

Specify a password for the database.

\[ W = \text{string} \ (\text{wiring}, \text{default} = \text{none}) \]

By using the \( W \) option, one can map database columns to GAMS index positions. See model [Wiring] for reference (note that MDB2GMS is used to access the MS Access database instead of SQL2MDB, however this does not affect the wiring specification).

### 6.42.3.2 Example 1 - Reading a single valued Table

Suppose we want to read the distances parameter of the [trnsport] model from the GAMS Model Library. The data is stored in the Microsoft Access Database format (file Sample.mdb).

![Figure 6.54 Table: distances](image)

The data can be queried with a simple SQL statement:

```sql
SELECT city1, city2, distance
FROM distances
```

By running the following SQL2GMS statement, the connection to the database Sample.mdb is established. In addition, the data will be queried and the results are written to a GAMS include file afterwards (.inc).
The connection string is specified using the argument \texttt{C}. Note that the string is enclosed by quotes, as the string contains blanks. The database file name \textit{Sample.mdb} is also specified within the connection string. For more information on how to connect to your database, see section \textit{Connection Strings}. The arguments \texttt{Q} and \texttt{O} are used to specify the query and the output file name (and format).

The generated include file \textit{distances.inc} looks like:

\begin{verbatim}
* -----------------------------------------------------
* SQL2GMS 3.0 25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version: 10.0
* Connection string: Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb
* Provider: MSDASQL
* Query: SELECT city1, city2, distance FROM distances
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------
\end{verbatim}

The commented header section summarizes some information about the \texttt{SQL2GMS} resp. GAMS version and about the executed database query. The standard export format is to consider the last column as the value column (containing the distances) and the previous columns as the indices (containing the city names). The indices are separated by a dot, allowing the generated include file to be used as part of a parameter declaration statement in your GAMS model.

Retrieving the data using \texttt{SQL2GMS} from the database and including the queried data in your GAMS model within the parameter declaration statement (at compile time) can be combined in the following way:

\begin{verbatim}
Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;

$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT city1, city2, distance FROM distances"
Parameter d(i,j) 'distance in thousands of miles' /
$include distances.inc
/;

display d;
\end{verbatim}

Finally, the values of the parameter \texttt{d} are displayed:

\begin{verbatim}
new-york  2.500  1.700  1.800
san-diego  2.500  1.800  1.400
\end{verbatim}

This example is also part of the GAMS Data Utilities Library, see model \texttt{[Distances2]} for reference. Note that the query results are written to a GDX file in addition.
6.42.3.3 Example 2 - Reading a multi valued Table

In this scenario, we want to read the three index columns `year`, `loc`, `prod` and the value columns `sales` and `profit` from the database file Sample.mdb. Therefore, we use two separate parameters and queries or alternatively a parameter with an extra index position (for `sales` resp. `profit`) and a UNION select.

Consider the table with two value columns `sales` and `profit`:

```
Figure 6.55 Table: data (shortened for presentation)
```

Two separate Parameters

A simple way to import this into GAMS is to use two parameters and two SQL queries. The SQL queries can look like:

```sql
SELECT year, loc, prod, sales
FROM data
SELECT year, loc, prod, profit
FROM data
```

We can generate an include file `sales.inc` by running the following command:

```
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prod, sales FROM data"
```

Note that we specify the first query in order to select the sales and the relevant index columns within the `Q` argument. The query results are written to `sales.inc` using the `O` argument. Analogously we generate an include file `profit.inc` by running the following command while specifying the second query in order to obtain the profits and the relevant index columns:

```
sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prod, profit FROM data"
```

Retrieving the data using `SQL2GMS` from the database Sample.mdb and including the queried data in your GAMS model within the parameter declaration statements of `sales` and `profit` (at compile time) can be combined in the following way:
Set
   year 'years' / 1997*1998 /
   loc 'locations' / nyc, was, la, sfo /
   prd 'products' / hardware, software /;

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prd FROM data"
$include sales.inc /

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" Q="SELECT year, loc, prd FROM data"
$include profit.inc /

Single Parameter with extra Index Position

The operation can also be performed in one big swoop by using a different GAMS datastructure, i.e. a single parameter is defined with an extra index type to indicate the data type (sales or profit). The index and value columns will be selected by the following SQL statement. Note the UNION operation in order to combine the results and the strings 'sales' resp. 'profit' to identify the data type later on.

SELECT year, loc, prod, 'sales', sales FROM data
UNION
SELECT year, loc, prod, 'profit', profit FROM data

The data is accessed, queried and written to data.inc by running the following command:

sql2gms @howToRead.txt

Note that usage of the external parameter file howToRead.txt shown below in order to increase the readability of the command (one argument per line, quotes can be omitted):

C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc

The generated include file data.inc looks like (shortened for presentation):

* -----------------------------------------------------
* SQL2GMS 3.0 25.2.0 r67636 ALFA Released 15Aug18 VS8 x86 32bit/MS Windows
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version: 10.0
* Connection string: DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
* Provider: MSDASQL
* Query: SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
* -----------------------------------------------------
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
Retrieving the data using SQL2GMS from the database and including the queried data in your GAMS model within the parameter declaration (at compile time) can be combined in the following way (note that the parameter has a fourth index type in order to access the data type sales resp. profit):

```gams
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q=SELECT year, loc, prod, 'sales', sales FROM data UNION SELECT year, loc, prod, 'profit', profit FROM data
O=data.inc
$offEcho
Set
  year 'years' / 1997*1998 /
  loc 'locations' / nyc, was, la, sfo /
  prd 'products' / hardware, software /
  type 'data type' / sales, profit /;
$call sql2gms @howToRead.txt
Parameter data(year,loc,prd,type) /
$include data.inc
/
```

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB5] for reference.

### 6.42.3.4 Example 3 - Reading a one dimensional Set

This example demonstrates how to read set elements of a one dimensional set from a single column of a database file. Suppose we want to read the column City1 (see table distances) in order to define the set i in the GAMS model. Make sure elements are unique by using the distinct operation within the SQL statement (otherwise there will be an error when including the file within the set definition in the GAMS model, as some set elements will be redefined):

```sql
SELECT distinct(City1)
FROM distances
```

The include file city1.inc looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
SAN-DIEGO
SEATTLE
* -----------------------------------------------------
```
All steps (data access via SQL2GMS, set definition) can be combined:

```
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT distinct(city1) FROM distances" O=city_i.inc
Set i 'canning plants' /
$include city_i.inc
/;
```

The display statement generates the following output in the listing file:

```
---- 56 SET i
seattle , san-diego
```

### Example 4 - Reading a multi dimensional Set

When reading a multi dimensional set from database and writing the results to an include file by using the O argument, one has to observe that the elements in the include file must have the correct format in order to be interpreted as element of a multi dimensional set. For instance, a line containing a b c is not recognized as a proper set element of a three dimensional set. In particular, one has to add periods between the single elements, i.e. a.b.c will be interpreted correctly.

Depending on your DBMS (DataBase Management System), these periods must be added explicitly in a different way within the SQL statement. E.g. add a dummy value field by adding a quoted blank to the select clause (index1, index2, index3 and dataTable are some placeholders):

```
SELECT index1, index2, index3, " " FROM dataTable
```

or by adding the periods explicitly within the select clause (|| or & depending on DBMS):

```
SELECT index1||'.'||index2||'.'||index3 FROM dataTable
SELECT index1&'.'&index2&'.'&index3 FROM dataTable
```

For instance, suppose we want to define a two dimensional set

```
Set ij(i,j) 'canning plants - markets';
```

based on the data of the table distances stored in Sample.mdb. The following SQL2GMS statement connects you to the database, queries the columns with the city names and adds an empty value field in order to create periods between the set elements:

```
sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances"
```

The include file city_ij.inc looks like (header informations are removed in order to shorten the representation):
Without adding the empty value field, the resulting include file would look like (shortened):

* -----------------------------------------------------
  SEATTLE NEW-YORK
  SAN-DIEGO NEW-YORK
  SEATTLE CHICAGO
  SAN-DIEGO CHICAGO
  SEATTLE TOPEKA
  SAN-DIEGO TOPEKA
* -----------------------------------------------------

Since the periods are missing, the lines are not recognized as valid elements of a two dimensional set. All steps can be combined in the following way:

Set
  i 'canning plants' / seattle, san-diego /
  j 'markets' / new-york, chicago, topeka /;

$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT city1, city2, ' ' FROM distances" O=city_ij.inc

Set ij(i,j) 'two dimensional set' /
$include city_ij.inc /

display ij;

The display statement generates the following output in the listing file:

---- 75 SET ij two dimensional set

    new-york   chicago   topeka
  SAN-DIEGO   YES       YES      YES
  SEATTLE    YES       YES      YES

Note that there is no need to add periods explicitly when reading multi dimensional sets, if the results are written only to a GDX file by using the X and S resp. Y arguments, i.e. there is no need to modify the query:

SELECT index1, index2, index3 FROM datatable

when using SQL2GMS in the following way:

sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT index1, index2, index3" X=setData.gdx S=setName

which will generate the file setData.gdx with a three dimensional set named setName containing the results of the query.
6.42.3.6 Example 5 - Reading Sets with Explanatory Text

In this example, we will demonstrate how to read set elements with explanatory text from a database file using SQL2GMS. In the first place, we are going to write the query results to an include file, afterwards we use the Y argument in order to store the query results as a set with explanatory text in a GDX file.

![Table: setData](image)

Note the blanks and the mixed quotes in the column containing the explanatory text. The data can be accessed by the following query:

```sql
SELECT setElement, explText
FROM setData
```

### Writing the Query Results in an include File

The last column in the select clause will be used as explanatory text. Take in mind to add the argument B in order to handle text strings with embedded blanks or quotes. The following GAMS code accesses the data and writes the results to an include file setData.inc:

```gams
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" B Q="SELECT setElement, explText FROM setData" O=setData.inc
Set a /
$include setData.inc
/;
```

The resulting include file will look like (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
firstSetElement "Explanatory text for the first 'set element'
secondSetElement "Explanatory text for the second "set element"
thirdSetElement "Explanatory text for the third 'set element'
fourthSetElement "Explanatory text for the fourth set element"
* -----------------------------------------------------

Note the handling of the quotes according to the description in B.

### Writing the Query Results in a GDX File

When storing the results of the query as a set with explanatory text in a GDX file, there is no need to observe embedded blanks or quotes manually, instead one can use the Y argument. The last column specified in the select clause of the SQL statement will be interpreted as explanatory text. The following GAMS code accesses the data and writes the results to a GDX file setData.inc:

```gams
$call sql2gms C="Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb" Q="SELECT setElement, explText FROM setData" X=setData.gdx Y=set_b
Set b;
.gdxIn setData.gdx
$load b = set_b
.gdxIn
```

Note that the name of the set in the GDX file is set.b (specified within the Y argument), while the name of the GDX file was specified within the X argument.
6.42.3.7 Example 6 - Index Mapping

In some cases the index elements used in the database are not the same as in the GAMS model. E.g. consider the case where the GAMS model has defined a set as:

Set i / NY, DC, LA, SF /;

Now assume a data table looks like:

<table>
<thead>
<tr>
<th>city</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>new york</td>
<td>100</td>
</tr>
<tr>
<td>los angeles</td>
<td>120</td>
</tr>
<tr>
<td>san francisco</td>
<td>105</td>
</tr>
<tr>
<td>washington dc</td>
<td>102</td>
</tr>
</tbody>
</table>

This means we have to map 'new york' to 'NY' etc. This mapping can be done in two places: either in GAMS or in the database.

6.42.3.7.1 Index Mapping done in GAMS

When we export the table directly, we get the following include file (header informations are removed in order to shorten the representation):

* -----------------------------------------------------
 'new york' 100
 'los angeles' 120
 'san francisco' 105
 'washington dc' 102
* -----------------------------------------------------

Note that the single quotes are added by activating the option B (quote blanks), as the index elements contain blanks. Accessing the data, importing the resulting include file and converting it to a different index space can be done by the following GAMS code:

Set i / NY, DC, LA, SF /;

Set idb 'from database' / 'new york', 'washington dc', 'los angeles', 'san francisco' /;

$call sql2gms C="DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb" B O="city1.inc" Q="SELECT city, value FROM [example table]"
Parameter dbdata(idb) /
$include city1.inc /
Set mapindx(i,idb) / NY.'new york', DC.'washington dc', LA.'los angeles', SF.'san francisco' /

Parameter data(i);
data(i) = sum(mapindx(i,idb), dbdata(idb));
display data;
The display statement generates the following output in the listing file:

```
---- 47 PARAMETER data
NY 100.000, DC 102.000, LA 120.000, SF 105.000
```

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping3] for reference.

### 6.42.3.7.2 Index mapping done in Database

The second approach is to handle the mapping inside the database. We can introduce a mapping table that looks like:

![CityMapper Table](image)

This table can be used in a join to export the data in a format we can use by executing the query:

```sql
SELECT [GAMS City], value
FROM example_table, CityMapper
WHERE CityMapper.[Access City]=example_table.city
```

The resulting include file looks like (header informations are removed in order to shorten the representation):

```
* -----------------------------------------------------
la 120
ny 100
sf 105
dc 102
* -----------------------------------------------------
```

All steps can be combined in the GAMS model:

```gams
Set i / NY, DC, LA, SF /;
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb
Q=SELECT [GAMS City], [value] FROM example_table, CityMapper WHERE CityMapper.[Access City]=example_table.city
O=city2.inc
$offEcho
$call sql2gms @howToRead.txt
Parameter data(i) / $include city2.inc
/;
display data;
```
The display statement generates the following output in the listing file:

---- 38 PARAMETER data

NY 100.000, DC 102.000, LA 120.000, SF 105.000

Note: MS Access allows table names with embedded blanks. In that case the table name can be surrounded by square brackets. Other databases may not allow this.

This example is also part of the GAMS Data Utilities Library, see model [IndexMapping4] for reference.

6.42.4 Multi-Query Batch Usage

In some cases a number of small queries need to be performed on the same database. However, several individual SQL2GMS execution can become expensive, since there is significant overhead in starting Access and opening the database. For these cases, we have added the option to do multiple queries in one call. To execute several queries in a single SQL2GMS call and write several GAMS include files containing the results of the queries, we can use the command-line arguments Qn and On. The structure of a multi-query call looks like:

```
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=sample.mdb
Q1=firstQuery
O1=outputFileName.inc
Q2=secondQuery
O2=outputFileName.inc
Q3=thirdQuery
O3=outputFileName.inc
```

The terms firstQuery, secondQuery etc. are placeholders for some SQL statements. We see that the argument Qn is matched by an argument On. That means that the results of the n-th query are written to the n-th output file.

In case we want to store the results of a multi-query call to a single GDX file, we can use the command-line arguments Qn, Sn, An and Yn. The structure of a multi-query call when writing to a GDX file looks like:

```
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=sample.mdb
X=sample.gdx
Q1=firstQuery
S1=setName
Q2=secondQuery
S2=setName
Q3=thirdQuery
A3=parameterName
Q4=fourthQuery
A4=setName
```
Again, the terms firstQuery, secondQuery etc. are placeholders for some SQL statements. Here we see that a query Qn is matched by either a set name Sn or a parameter name An (the letter P was taken already: it is used to specify a password), i.e. the results of the first query will be stored as a set whose name is specified within the S1 argument, the results of the third query will be stored as a parameter whose name is specified within the A3 argument etc. The X argument is used to specify the name of the GDX file.

For a complete example see section Example 7 - Multi-Query Batch Example.

6.42.4.1 Example 7 - Multi-Query Batch Example

As an example database we use the following Access table (file Sample.mdb):

![Table: data (shortened for presentation)](image)

We want to extract the following information:

- The set year
- The set loc
- The set prd
- The parameter sales
- The parameter profit

Output: Several include Files

This can be accomplished using the following GAMS code with multiple queries in a single SQL2GMS call (note the usage of the distinct operator in the select clauses of the queries whose results will be used as sets in order to keep the set elements unique):
$onEcho > howToRead.txt
C=DRIVER={Microsoft Access Driver (*.mdb)};dbq=Sample.mdb

Q1=SELECT distinct(year) FROM data
O1=year.inc

Q2=SELECT distinct(loc) FROM data
O2=loc.inc

Q3=SELECT distinct(prod) FROM data
O3=prod.inc

Q4=SELECT prod, loc, year, sales FROM data
O4=sales.inc

Q5=SELECT prod, loc, year, profit FROM data
O5=profit.inc
$offEcho

$call =sql2gms @howToRead.txt

Set y 'years' /
$include year.inc /

Set loc 'locations' /
$include loc.inc /

Set prd 'products' /
$include prod.inc /

Parameter sales(prd,loc,y) /
$include sales.inc /

display sales;

Parameter profit(prd,loc,y) /
$include profit.inc /

display profit;

This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB6] for reference.

Output: A single GDX File

The same example imported through a GDX file can look like:

$onEcho > howToRead.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=Sample.mdb
X=Sample.gdx

Q1=SELECT distinct(year) FROM data
S1=year

Q2=SELECT distinct(loc) FROM data
S2=loc
Q3=SELECT distinct(prod) FROM data
S3=prd

Q4=SELECT prod, loc, year, sales FROM data
A4=sales

Q5=SELECT prod, loc, year, profit FROM data
A5=profit

$offEcho

$call =sql2gms @howToRead.txt
$call =shellExecute gdxviewer Sample.gdx

Set
  y 'years'
  loc 'locations'
  prd 'products';

Parameter
  sales(prd,loc,y)
  profit(prd,loc,y);

$gdxIn sample.gdx
$load y=year prd loc sales profit
$gdxIn

display sales, profit;

The call of the GDXViewer will display the GDX file in the stand-alone GDX viewer. This example is also part of the GAMS Data Utilities Library, see model [SalesProfitDB7] for reference.

6.42.5 Interactive Usage

When the tool is called without command-line arguments, it will startup interactively. Using it this way, one can specify options such as the connection string, the query and the final destination file (a GAMS include file or a GDX file) using the built-in interactive environment. The main screen (see figure below) contains a number of buttons and edit boxes, which are explained below.
• **Output GAMS Include file (.inc).** If you want to create a GAMS include file, then specify here the destination file. See also outputIncludeFile for some more detailed remarks.

```
Output: GAMS include file (.inc)  
D:\gamsmodels\data.inc
```

• **Output GDX file (.gdx).** As an alternative to a GAMS include file, the tool can also generate a GDX file. One or both of the output files need to be specified. See also outputGDXFile for some more detailed notes.

```
Output: GAMS GDX file (.gdx)  
D:\gamsmodels\data.gdx
```
• **SQL Query.** The SQL Query box is the place to provide the query. Note that the actual area for text can be larger than is displayed: use the cursor-keys to scroll. See also [Q](#) for some more detailed notes.

![SQL Query Example](image)

• **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

![Progress Memo Example](image)

• The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

• The **Tables button** will pop up a new window with the contents of the database file selected in the input file edit line. This allows you to see all table names and field names needed to specify a correct SQL query. An exception will be generated if no database file name is specified in the input edit line.

![Tables Button](image)

• The **Options button** will pop up a window where you can specify a number of options. The connection string is an important option, which needs to be set correctly before a query can be submitted successfully.

![Options Button](image)
• Pressing the **Help button** will show this documentation.

![Help](image)

• Pressing the **OK button** will execute the query and an output file will be generated.

![OK](image)

• The **Batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press **Ctrl-C** or choose **Edit|Paste** to copy the contents of the clipboard to a GAMS text file.

![Batch](image)

• Pressing the **Close button** will exit the application. The current settings will be saved in an INI file so when you run SQL2GMS again all current settings will be restored.

![Close](image)

### 6.42.5.1 Options

The **Options** window can be created by pressing the options button:
The following options are available in the options window:

- **User name**: Here you can specify the user name for logging in to the RDBMS. For databases without user authentication, this can be left empty.

- **Password**: This edit box allows you to specify the password for the database system. The characters are echoed as an '∗'.

---

Figure 6.61 Options Menu of the Graphical User Interface
• **Connection String:** The connection string determines how SQL2GMS talks to the database. For more informations see [Connection Strings](#).

```plaintext
Connection String

\[ \text{DRIVER}=\text{Microsoft Access Treiber (*.mda)} \]
```

• **ODBC Data Sources/Drivers:** This drop down list can be used to compose a connection string when an ODBC data source or driver is involved. The list will show all configured data sources and all available ODBC drivers.

```plaintext
ODBC Data Sources/Drivers

- DATA SOURCES
- ODBC DRIVERS
  - DRIVER=Driver de Microsoft para arquivos textos (*.txt; *.csv)
  - DRIVER=Driver de Microsoft Access (*.mda)
  - DRIVER=Driver de Microsoft dBase (*.dbf)
  - DRIVER=Driver de Microsoft Excel (*.xls)
  - DRIVER=Driver de Microsoft Paradox (*.dBase)
  - DRIVER=Microsoft Access Driver (*.mda)
```

• **Quote blanks:** Quote strings if they contain blanks or embedded quotes. See also B for some more detailed notes.

```plaintext
Quote blanks
```

• **Mute:** Don’t include the extra informational text (such as used query etc.) in the include file. The equivalent command-line argument is M.

```plaintext
Mute
```

• **No listing:** Surround the include file by \$offListing and \$onListing so that the data will not be echoed to the listing file. The equivalent command-line argument is L.

```plaintext
No listing
```

• **Format SQL:** If an SQL text is reloaded in the SQL Edit Box, it will be formatted: keywords will be printed in CAPS and the FROM and WHERE clause will be printed on their own line. If this check box is unchecked this formatting will not take place and SQL queries will be shown as is.

```plaintext
Format SQL
```
The following options are only needed in special cases:

- **NULL**: This radio box determines how NULL's are handled. A NULL in an index position or a value column will usually make the result of the query useless: the GAMS record will be invalid. To alert you on NULL's the default to throw an exception is a safe choice. In special cases you may want to map NULL's to an empty string or a 'NULL' string.

- **Time-out** values for connection time and command execution time expressed in seconds. If -1 is specified then it will use the default value which is 15 seconds for the connection and 30 for the commands. See also T1, T2 resp. T for some more detailed notes.

The following buttons have an obvious functionality:

- **OK button** will accept the changes made.

- **Cancel button** will ignore the changes made and all option settings will revert to their previous values.

- **Help button** will show this documentation.
• **Test Connection** will try to make a connection to the database using the given connection string.

If the settings are correct you will see something like:

The following options can only be specified in an INI file; there is no interactive equivalent:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td></td>
<td>Generate debug output</td>
</tr>
<tr>
<td>E</td>
<td>integer</td>
<td>Allow an empty result set; without this option an empty result set will generate an error</td>
</tr>
<tr>
<td>R</td>
<td>integer</td>
<td>Row batch size; the default is 100 records</td>
</tr>
</tbody>
</table>

### 6.42.6 Connection Strings

The connection string determines to which database the tool will try to connect. You can give simply the name of an ODBC Data Source or provide much more elaborate connection strings. Here is an example list:

• **ODBC Examples**

• **OLE DB Examples**

• **MS Remote Examples**

For more information consult the documentation with your database driver. ODBC drivers can be had from several sources: Microsoft delivers ODBC with a number of drivers; database providers may have likely an ODBC driver for their RDBMS available and finally there are a number of third party ODBC drivers available (e.g. from [http://www.easysoft.com](http://www.easysoft.com)).
6.42.7 ODBC Examples

In this section we show a few examples using SQL2GMS with ODBC data sources.

6.42.7.1 ODBC Driver Manager

To configure ODBC data sources use the ODBC Data Source Administrator. This tool can be invoked from the Start button menu: Settings|Control Panel, and click on the ODBC Data Sources icon:

Under Windows XP the sequence is: Control Panel|Performance and Maintenance|Administrative Tools and click on the Data Sources (ODBC) icon. Under Windows 10, access the Control Panel at first, type 'odbc' in the top right box and select either 'Set up ODBC data sources (32-bit)' or 'Set up ODBC data sources (64-bit)'. The ODBC Data Source Administrator tool looks like:

![ODBC Data Source Administrator](image)

To create a new data source, click the Add button, select a driver, give it a name (this is the DSN name) and configure the data source.
6.42.7.2 Example 8 - Reading from an MS Access Database

There are several ways to export data from an SQL database into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Access Export. See also CSV Files.
2. Use the MDB2GMS tool.
3. Use SQL2GMS with a configured ODBC data source. The connection string will look like:

   "DSN=mydsn".

4. Use SQL2GMS with a DSN-less ODBC connection. In this case we need to specify both the driver and the location of the database file explicitly in the connection string. The connection string will look like:

   "Driver=\{Microsoft Access Driver (*.mdb)\};Dbq=D:\data\mydata.mdb".

5. Use SQL2GMS with an OLE DB driver. The connection string can look like:

   "Provider=Microsoft.Jet.OLEDB.4.0;Data Source=D:\data\mydata.mdb"

6.42.7.3 Example 9 - Reading from an MS Excel Spreadsheet

There are numerous ways to export data from an Excel spreadsheet into a GAMS include file:

1. Export a CSV (Comma Separated Values) file using Excel Export.
2. Use the XLS2GMS tool.
3. Use the GDXXRW tool.
4. Use SQL2GMS with an Excel ODBC connection. An example is shown below.

Consider the spreadsheet ExcelDist.xls:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>city1</td>
<td>city2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>SEATTLE</td>
<td>NEW-YORK</td>
<td>2.5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>SAN-DIEGO</td>
<td>NEW-YORK</td>
<td>2.5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>SEATTLE</td>
<td>CHICAGO</td>
<td>1.7</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>SAN-DIEGO</td>
<td>CHICAGO</td>
<td>1.8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>SEATTLE</td>
<td>TOPEKA</td>
<td>1.8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>SAN-DIEGO</td>
<td>TOPEKA</td>
<td>1.4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>9</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

After configuring a data source ExcelDist that uses the Excel ODBC driver and points to the .xls file containing the above sheet, we can use the connection string: "DSN=ExcelDist". With the database browser we see:
I.e. the table name is Sheet1$. We now can formulate the query: `SELECT city1, city2, distance FROM [Sheet1$].` We need the brackets to protect the funny table name. The result is (header removed in order to shorten the presentation=:

```
* -----------------------------------------------------
SEATTLE.NEW-YORK 2.5
SAN-DIEGO.NEW-YORK 2.5
SEATTLE.CHICAGO 1.7
SAN-DIEGO.CHICAGO 1.8
SEATTLE.TOPEKA 1.8
SAN-DIEGO.TOPEKA 1.4
* -----------------------------------------------------
```

Although other tools are often more convenient to use, this approach is useful if you need to select a subsection of the spreadsheet table. It is easy to select just a few columns or rows from a table using a properly formulated SQL query. The skeleton would be: `SELECT columns_to_extract FROM [sheet1$] WHERE rows_to_extract.`

An example of a more complex spreadsheet is (profit.xls):
A DSN-less connection string would be: "DRIVER=Microsoft Excel Driver (*.xls); DBQ=d:\gams projects\sql2gms\ver2.0\profit.xls". The browser will show:

![Database Browser](image)

A possible query that maps the two value columns into a GAMS parameter is:

```sql
SELECT year, loc, prod, 'sales', sales
FROM [profitdata$]
UNION
SELECT year, loc, prod, 'profit', profit
FROM [profitdata$]
```

The result is (shortened for presentation):

```
* -----------------------------------------------------
1997.la.hardware.profit 8
1997.la.hardware.sales 80
1997.la.software.profit 16
1997.la.software.sales 60
1997.nyc.hardware.profit 5
1997.nyc.hardware.sales 110
1997.nyc.software.profit 10
1997.nyc.software.sales 100
1997.sfo.hardware.profit 9
1997.sfo.hardware.sales 80
1997.sfo.software.profit 10
1997.sfo.software.sales 50
1997.was.hardware.profit 7
1997.was.hardware.sales 120
1997.was.software.profit 20
1997.was.software.sales 70
1998.la.hardware.profit 6
1998.la.hardware.sales 70
* -----------------------------------------------------
```

This example is also part of the GAMS Data Utilities Library, see model [Excel] for reference.
Example 10 - Reading from a Text File

Microsoft delivers ODBC with a text file driver which allows you to read a text file as if it is a database table.

A fixed format file such as:

<table>
<thead>
<tr>
<th>City1</th>
<th>City2</th>
<th>Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEATTLE</td>
<td>NEW-YORK</td>
<td>2.5</td>
</tr>
<tr>
<td>SAN-DIEGO</td>
<td>NEW-YORK</td>
<td>2.5</td>
</tr>
<tr>
<td>SEATTLE</td>
<td>CHICAGO</td>
<td>1.7</td>
</tr>
<tr>
<td>SAN-DIEGO</td>
<td>CHICAGO</td>
<td>1.8</td>
</tr>
<tr>
<td>SEATTLE</td>
<td>TOPEKA</td>
<td>1.8</td>
</tr>
<tr>
<td>SAN-DIEGO</td>
<td>TOPEKA</td>
<td>1.4</td>
</tr>
</tbody>
</table>

can be read using Fixed Length setting of the text driver:

![Define Text Format](image)

The resulting include file will look like:

```
* -----------------------------------------------------
* SQL2GMS Version 2.0, January 2004
* Erwin Kalvelagen, GAMS Development Corp
* -----------------------------------------------------
* ADO version: 2.7
* Connection string: DSN=text
* Query: SELECT city1, city2, distance FROM odbcdata.txt
* Provider: MSDASQL
* -----------------------------------------------------
```
Note that the text file is specified directly within the FROM clause.

A CSV file can be interpreted as a table as well, or any other separated format. We will try to read:

```
City1;City2;Distance
SEATTLE;NEW-YORK;2.5
SAN-DIEGO;NEW-YORK;2.5
SEATTLE;CHICAGO;1.7
SAN-DIEGO;CHICAGO;1.8
SEATTLE;TOPEKA;1.8
SAN-DIEGO;TOPEKA;1.4
```

This can be read using:

The actual formats used are stored by ODBC in an INI file schema.ini (located in the directory of the data files) which can be inspected directly:
6.42 SQL2GMS

This example is also part of the GAMS Data Utilities Library, see model [Text] for reference.

### 6.42.8 Strategies

Including SQL statements to extract data from a database inside your model can lead to a number of difficulties:

- The database can change between runs, leading to results that are not reproducible. A possible scenario is a user calling you with a complaint: "the model is giving strange results". You run the model to verify and now the results are ok. The reason may be because the data in the database has changed.

- There is significant overhead in extracting data from a database. If there is no need to get new data from the database it is better to use a snapshot stored locally in a format directly accessible by GAMS.

- It is often beneficial to look at the extracted data. A first reason, is just to make sure the data arrived correctly. Another argument is that viewing data in a different way may lead to a better understanding of the data. A complete "under-the-hood" approach may cause difficulties in understanding certain model behavior.

Often it is a good strategy to separate the data extraction step from the rest of the model logic.

If the sub-models form a chain or a tree, like in:

Data Extraction --> Data Manipulation --> Model Definition --> Model Solution --> Report Writing

we can conveniently use the save/restart facility. The individual submodel are coded as:

- Step 0 - Data Extraction: sr0.gms
$onText
step 0: data extraction from database
execute as: > gams sr0 save=s0
$offText

Set
   i 'suppliers'
   j 'demand centers';

Parameter
demand(j)
supply(i)
dist(i,j) 'distances';

$onEcho > howtoRead.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=%system.fp%transportation.mdb
Q1=SELECT name FROM suppliers
  O1=i.inc
Q2=SELECT name FROM demandcenters
  O2=j.inc
Q3=SELECT name,demand FROM demandcenters
  O3=demand.inc
Q4=SELECT name, supply FROM suppliers
  O4=supply.inc
Q5=SELECT supplier, demandcenter, distance FROM distances
  O5=dist.inc
$offEcho

$call =sql2gms.exe @howtoRead.txt

Set i /
@include i.inc
/;
Set j /
@include j.inc
/;

Parameter demand /
@include demand.inc
/;

Parameter supply /
@include supply.inc
/;

Parameter dist /
@include dist.inc
/;

display i, j, demand, supply, dist;

• Step 1 - Data Manipulation: sr1.gms
Scalar f 'freight in dollars per case per thousand miles' / 90 /;

Parameter c(i,j) 'transport cost in thousands of dollars per case';
c(i,j) = f*dist(i,j)/1000;

- Step 2 - Model Definition: sr2.gms

Variable
   x(i,j) 'shipment quantities in cases'
   z   'total transportation costs in thousands of dollars';
Positive Variable x;

Equation
   ecost    'define objective function'
   esupply(i) 'observe supply limit at plant i'
   edemand(j) 'satisfy demand at market j';
ecost..   z  =e=  sum((i,j), c(i,j)*x(i,j));
esupply(i).. sum(j, x(i,j)) =l=  supply(i);
edemand(j).. sum(i, x(i,j)) =g=  demand(j);

- Step 3 - Model Solution: sr3.gms

Model transport / all /
solve transport using lp minimizing z;

- Step 4 - Report Writing: sr4.gms

 abort$(transport.modelStat <> 1) "model not solved to optimality";
display x.l, z.l;

A model that executes all steps can be written as:
execute 'gams.exe sr0 lo=3 save=s0';
abort$errorLevel "step 0 failed";

execute 'gams.exe sr1 lo=3 restart=s0 save=s1';
abort$errorLevel "step 1 failed";

execute 'gams.exe sr2 lo=3 restart=s1 save=s2';
abort$errorLevel "step 2 failed";

execute 'gams.exe sr3 lo=3 restart=s2 save=s3';
abort$errorLevel "step 3 failed";

execute 'gams.exe sr4 lo=3 restart=s3';
abort$errorLevel "step 4 failed";

If you only change the reporting step, i.e. generating some output using PUT statements, then you only need to change and re-execute step 4. If you change solver or solver options, then only steps 3 and 4 need to be redone. For a small model like this, this exercise may not be very useful, but when the model is large and every step is complex and expensive, this is a convenient way to achieve quicker turn-around times in many cases.

The model [SQLSr5] is also part of the GAMS Data Utilities Library.

In some cases the save/restart facility is not appropriate. A more general approach is to save the data from the database in a GDX file, which can then be used by other models. We can use the model from step 0 to store the data in a GDX file:

SQL2GDX1.gms

$onText
Store data from Access database into a GDX file.
$offText

execute 'gams.exe sr0 lo=3 gdx=trnsport.gdx';
abort$errorLevel "step 0 failed";

execute 'gdxviewer.exe trnsport.gdx';

The model [SQL2GDX1] is also part of the GAMS Data Utilities Library.

We can also let SQL2GMS create the GDX file:

SQL2GDX2.gms

$onText
Store data from Access database into a GDX file.
$offText

$onEcho > howToRead.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=%system.fp%transportation.mdb
X=%system.fp%transportation.gdx
Q1=SELECT name FROM suppliers
S1=i
Q2=SELECT name FROM demandcenters

$offEcho
The first approach has the advantage that a complete audit record is available from the data moved from
the database to the GDX file in the sr0.lst listing file. If someone ever wonders what came out of the
database and how this was stored in the GDX file, that file gives the answer.

The model [SQL2GDX2] is also part of the GAMS Data Utilities Library.

To load the GDX data the following fragment can be used:

**GDXTRNSPORT.gms**

This model demonstrates how to load the transportation data from GDX file at compile time.

Set
   i 'suppliers'
   j 'demand centers';

Parameter
   demand(j)
   supply(i)
   dist(i,j) 'distances';

$gdxIn transportation.gdx
$load i j demand supply dist
$gdxIn

display i, j, demand, supply, dist;

**DBTimestamp2.gms**

In one application I had to retrieve data from the database each morning, at the first run of the model.
The rest of the day, the data extracted that morning could be used. The following logic can implement
this:

$onText
Retrieve data from data base first run each morning.
$offText

$onEcho > getdate.txt
C=Provider=Microsoft.Jet.OLEDB.4.0;Data Source=%system.fp%transportation.mdb
Q=select day(now())
0=dbtimestamp.inc
$offEcho
Scalar dbtimestamp 'day of month when data was retrieved' /
$include dbtimestamp.inc
/
Scalar currentday 'day of this run';
currentday = gday(jnow);
display "compare", dbtimestamp, currentday;
if(dbtimestamp<>currentday,
   execute '=gams.exe sr0 lo=3 gdx=transportation.gdx';
   abort$errorLevel "step 0 (database access) failed";
   execute '=sql2gms.exe @getdate.txt'
);

The include file dbtimestamp.inc contains the day of the month (1...31) on which the data was extracted
from the database. If this file does not exist, we initialize it with 0. We then compare this number with
the current day of the month. If the numbers do not agree, we execute the database extraction step and
rewrite the dbtimestamp.inc file. This last operation could be done using a PUT statement, but in this
case we used an SQL statement.

The model [DBTimestamp2] is also part of the GAMS Data Utilities Library.

6.42.9 Parameter Files

Parameters can be specified in an external parameter file. This is important if the length of the command-
line exceeds 255 characters, which is a hard limit on the length that GAMS allows for command-lines.
Instead of specifying a long command line as in:

$call =sql2gms C="DSN=sample" O="c:\My Documents\data.inc" Q="SELECT * FROM mytable"

we can use a command line like:

$call =sql2gms @"c:\My Documents\options.txt"

The parameter file

c:\My Documents\options.txt

can look like:

C=DSN=sample
O=c:\My Documents\data.inc
Q=SELECT * FROM mytable
It is possible to write the parameter file from inside a GAMS model using the `$echo` command. The following example will illustrate this:

```
$set cmdfile "c:\windows\temp\commands.txt"
$echo "C=DSN=sample" > "%cmdfile%"
$echo "O=E:\models\labor.INC" >> "%cmdfile%"
$echo "Q=SELECT * FROM labor" >> "%cmdfile%"
$call =sql2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

Newer versions of GAMS allow the usage of the `$onEcho` and `$offEcho` commands:

```
$set cmdfile "c:\windows\temp\commands.txt"
$onEcho > "%cmdfile%"
  C=DSN=sample
  O=E:\models\labor.INC
  Q=SELECT * FROM labor
$offEcho

$call =sql2gms @"%cmdfile%"

Parameter p /
$include "E:\models\labor.INC"
/;
display p;
```

If a query becomes very long, it is possible to spread it out over several lines. To signal a setting will continue on the next line insert the character `\` as the last character. E.g.:

```
Q=SELECT prod, loc, year, 'sales', sales FROM data \  
  UNION \  
  SELECT prod, loc, year, 'profit', profit FROM data
```

### 6.42.10 Notes

#### 6.42.10.1 ADO

ActiveX Data Objects. Microsoft's data-access object model. An object-oriented architecture for accessing data stored in SQL databases and related data sources. Accessible from a large number of host languages such as VB, C++, Delphi. Supersedes ODBC. Many SQL databases provide ADO access through either OLEDB or ODBC.
6.42.10.2 ODBC

An API and driver manager system for accessing data stored in an RDBMS. The API provides applications a way to talk to databases while the driver manager application allows users to install, configure and manage ODBC drivers for different databases.

6.42.10.3 OLEDB

Driver architecture for SQL databases. A driver is called a OLE DB provider. This is used from ADO.

6.42.10.4 UNC Names

UNC means Unified Naming Convention. UNC names are a Microsoft convention to name files across a network. The general format is:

```
\<server>\<share>\<path>\<file>
```

Examples:

```
\athlon\c\My Documents\sql2gms.rtf
```

6.42.10.5 GDX Files

A GDX file contains GAMS data in binary format. The following GAMS commands will operate on GDX files: `$gdxIn`, `$load`, `execute_load`, `execute_unload`. The GDX=filename command-line option will save all data to a GDX file. A GDX file can be viewed in the GAMS IDE using File|Open.

6.42.10.6 MDB2GMS

MDB2GMS is a tool to import tables from MS Access databases. This utility directly uses MS Access and DAO (Data Access Objects) resulting in a somewhat simpler interface. It is not needed to specify a connection string, but just a .mdb file. The query mechanism is similar: a query is sent as it is to the database server and the result set is translated into a GAMS representation. For more information see MDB2GMS.

6.42.10.7 XLS2GMS

XLS2GMS is a tool to import data from an Excel spreadsheet. It considers the content of a selected range as GAMS source code. For more information XLS2GMS.
6.42.10.8  GDXXRW

GDXXRW is a utility to read and write Excel spreadsheet data. GDXXRW can read multiple ranges in a spreadsheet and write the data to a GDX file, or read from a GDX file, and write the data to different ranges in a spreadsheet. For more information GDXXRW.

6.42.10.9  Quotes

Examples of handling of indices when the option B for quoting strings containing blanks is used:

6.42.10.10  $CALL Command

The $call command in GAMS will execute an external program at compile time. There are two forms:

$call externalProgram

$call =externalProgram

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

1. Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE. If you want to execute these commands you will need to use the form $call externalProgram which uses the command processor.

2. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call externalProgram.

3. If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalProgram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalProgram.

4. When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /u externalWindowsProgram. Otherwise, it is preferred to use: $call =externalWindowsProgram.

Attention

In general it is recommended to use the $call =externalProgram version for its better error-handling.

When command-line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

$call externalProgram parameter1 parameter2
$call =externalProgram parameter1 parameter2

The total length of the command-line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

$call "external program" "parameter 1" "parameter 2",
$call ="external program" "parameter 1" "parameter 2"

It is noted that the first form needs additional quotes around the whole command-line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes only if the = appears outside the double quotes.
6.42.10.11 Compile Time Commands

All $ commands in GAMS are performed at compile time. All other statements are executed at execution time. This means that a compile time command will be executed before an execution time command, even if it is below. As an example consider:

```gams
File batchfile / x.bat /;
putClose batchfile "dir"/;
$call x.bat
```

This fragment does not work correctly as already during compilation, the $call is executed, while the put statements are only executed after the compilation phase has ended and GAMS has started the execution phase. The above code can be fixed by moving the writing of the batch file to compilation time as in

```gams
$echo "dir" > x.bat
$call x.bat
```

or by moving the external program invocation to execution time:

```gams
File batchfile / x.bat /;
putClose batchfile "dir"/;
execute x.bat;
```

Notice that all $ commands do not include a semi-colon but are terminated by the end-of-line.

6.43 XLS2GMS

Author
Erwin Kalvelagen, GAMS Development Corp

Version
2.4

Date
May 2004

6.43.1 Overview

Note
The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only GDXXRW is under active development. Therefore, we strongly recommend using GDXXRW for data exchange with Excel.

XLS2GMS is a tool to convert spreadsheet data from a Microsoft Excel spreadsheet into GAMS readable format. The source is a MS Excel spreadsheet file (*.XLS) and the target is a GAMS Include File.

When running the executable XLS2GMS.EXE without command line parameters the tool will run interactively with a built-in GUI interface. Alternatively XLS2GMS can be run in batch mode which is useful when calling it directly from a GAMS model using the $call command.

The philosophy of the tool is to consider the content of a spreadsheet as Text. This text can contain GAMS statements, or parts of GAMS statements (e.g. the data part of a table statement). The text is exported to a GAMS include file where some spacing is introduced to maintain cell boundaries. This allows tables to be exported directly to GAMS include files.
6.43.2 Requirements

XLS2GMS runs only on PC's running Windows (95/98/NT/XP) and with MS Excel installed. Microsoft Excel is included in the MS Office suite.

6.43.3 Converting spreadsheet data to GAMS data

Spreadsheet data are often differently organized than is suitable for import into a GAMS model. In some cases the data is scattered around different sheets, and in a format that is not compatible with a more structured multi-dimensional parameter as are used in a GAMS model. To export spreadsheet data to GAMS parameters, tools will either require a strict format to be used inside the spreadsheet or they will need to offer a complex specification step where the data representation in the spreadsheet is described so that it can be understood by the tool. This tool will use the first approach: the modeler is required to lay-out the data in the spreadsheet in a well defined format. Instead of defining a new format, we use the GAMS language syntax as the required representation. In effect the spreadsheet is considered as an alternative editor for GAMS source code.

As an example consider the GAMS table in the model [TRANSPORT] which is part of the GAMS model library:

Table d(i,j) 'distance in thousands of miles'

new-york | chicago | topeka
seattle   | 2.5     | 1.7    | 1.8
san-diego | 2.5     | 1.8    | 1.4;

This table can be expressed comfortably in a spreadsheet as follows:

XLS2GMS can convert this table into a GAMS include file, which results in:

* -----------------------------------------------------
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----------------------------------------------------
* Application: Microsoft Excel
* Version: 9.0
* Workbook: D:\gams projects\xls2gms\ver2.0\Book2.xls
* Sheet: Sheet1
* Range: $A$1:$D$3
* -----------------------------------------------------
  new-york | chicago | topeka
seattle   | 2.5     | 1.7    | 1.8
san-diego | 2.5     | 1.8    | 1.4
* -----------------------------------------------------
The tool will try to keep cells in a column aligned so that table statements can be used in the GAMS model. The above file `book2.inc` can be imported directly into a GAMS model by:

```gams
Table d(i,j) 'distance in thousands of miles'
$include book2.inc
;
```

As the tool does not expect any special formatting, we could have include the table statement in the spreadsheet, as in:

![Spreadsheet image](image)

This would result in:

```
* -----------------------------------------------------
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----------------------------------------------------
* Application: Microsoft Excel
* Version: 9.0
* Workbook: D:\gams projects\xls2gms\ver2.0\Book3.xls
* Sheet: Sheet1
* Range: $A$1:$D$5
* -----------------------------------------------------
```

```
table d(i,j) 'distance in thousands of miles'
    new-york  |  chicago |  topeka
seattle   |  2.5     |  1.7     |  1.8
san-diego |  2.5     |  1.8     |  1.4
;
```

In some cases the data will need to be copied and massaged to fit into the above format. It is convenient to add a sheet dedicated for this purpose to your workbook. This interface sheet can be filled either manually, with formulas that automatically update values, or by macro's (either recorded or programmed in VBA).

### 6.43.4 Importing sets

Sets can be directly imported if they are organized vertically. The following picture shows a spreadsheet with two sets with elements \{a,b,c\} organized vertically (A1:A3) and horizontally (B5:D5).
The first set can be imported directly using:

Set i / $call =xls2gms r=a1:a3 i=book4.xls o=set1.inc $include set1.inc /;
display i;

The second set is somewhat more difficult, as we need to add a separating comma between the elements. This can be accomplished by:

Set j / $call =xls2gms r=b5:d5 s="," i=book4.xls o=set2.inc $include set2.inc /;
display j;

This will generate the include file:

* -----------------------------------------------------
* XLS2GMS Version 2.4, May 2004
* Erwin Kalvelagen, GAMS Development Corp.
* -----------------------------------------------------
* Application: Microsoft Excel
* Version: 9.0
* Workbook: D:\gams projects\xls2gms\ver2.0\Book4.xls
* Sheet: Sheet1
* Range: $B$5:$D$5
* -----------------------------------------------------
  a,b,c
* -----------------------------------------------------

6.43.5 Importing sets and tables

The table
can be considered to contain three pieces of GAMS data:

- The set i (seattle, san-diego)
- The set j (new-york, chicago, topeka)
- The distances

All this information can be read as follows:

```gams
Set i /
$call =xls2gms r=a3:a4 i=book3.xls o=seti.inc
$include seti.inc
/

Set j /
$call =xls2gms r=b2:d2 s="," i=book3.xls o=setj.inc
$include setj.inc
/

Table d(i,j)
$call =xls2gms r=a2:d4 i=book3.xls o=pard.inc
$include pard.inc
;
display i, j, d;
```

The above $call statements can be combined onto one as follows:

```gams
$onEcho > book3a.txt
i=%system.fp%book3.xls
r1=a3:a4
o1=seti.inc
r2=b2:d2
o2=setj.inc
s2=","
r3=a2:d4
o3=pard.inc
$offEcho

$call =xls2gms @book3a.txt

Set i /
```
$\text{include seti.inc}
\;
\text{Set } j / \\
\text{\$include setj.inc}
\;
\text{Table } d(i,j)
\text{\$include pard.inc}
\;
display i, j, d;

The command file generated by the $\text{onecho}$ statement looks like:

\begin{verbatim}
i=E:\wtools\ver000\examples\book3.xls \\
r1=a3:a4 \\
o1=seti.inc \\
r2=b2:d2 \\
o2=setj.inc \\
s2="," \\
r3=a2:d4 \\
o3=pard.inc
\end{verbatim}

\section*{6.43.6 Multidimensional parameters}

Consider the data table:

\begin{center}
\begin{tabular}{l|llllllll}
\hline
   & A & B & C & D & E & F & G & H & I & J \\
\hline
2 & & & & & & & & & & \\
3 & & & & & & & & & & \\
4 & sheep & meat & 10.6 & 11.42 & 10.6 & 9.38 & 8.97 & 6.93 & \\
5 & sheep & milk & 23.7 & 24.1 & 24.2 & 24.2 & 24 & 23.9 & \\
6 & sheep & wool & 1.3 & 1.3 & 1.3 & 1.3 & 1.3 & 1.3 & 1.3 & \\
7 & sheep & hide & 0.5 & 0.6 & 0.6 & 0.5 & 0.6 & 0.4 & \\
9 & goat & milk & 37.7 & 38.1 & 38.2 & 38.2 & 38.3 & 37.8 & \\
10 & goat & wool & 0.6 & 0.6 & 0.6 & 0.6 & 0.6 & 0.6 & \\
11 & goat & hide & 0.2 & 0.3 & 0.3 & 0.3 & 0.2 & 0.3 & \\
12 & angora & meat & 1.77 & 1.77 & 2.86 & 2.21 & 1.77 & 1.77 & \\
13 & angora & milk & 14.9 & 15.2 & 14.8 & 15.2 & 14.8 & 15 & \\
14 & angora & wool & 1.6 & 1.6 & 1.6 & 1.6 & 1.6 & 1.4 & \\
15 & angora & hide & 0.1 & 0.1 & 0.1 & 0.1 & 0.1 & 0.1 & \\
17 & cattle & milk & 210 & 208.1 & 219.8 & 213.8 & 214.8 & 214.8 & 217.5 & \\
18 & cattle & hide & 3.3 & 3.4 & 2.9 & 3 & 2.6 & 3.3 & \\
19 & buffalo & meat & 43.73 & 45.42 & 40.61 & 37.21 & 32.2 & 32.68 & \\
20 & buffalo & milk & 267.1 & 269.2 & 263.8 & 219.6 & 275.5 & 285.1 & \\
21 & buffalo & hide & 4.1 & 3.4 & 3 & 2.4 & 2.5 & 2.6 & \\
22 & poultry & meat & 2.24 & 2.24 & 2.24 & 2.24 & 2.24 & 2.24 & \\
23 & poultry & egg & 62.4 & 62.2 & 64.2 & 78.3 & 78.4 & 73.3 & \\
24 & & & & & & & & & \\
\hline
\end{tabular}
\end{center}
In this spreadsheet the first two columns are index columns. To make this valid GAMS syntax we need to insert a dot between the index elements. A simple way is to insert a (narrow) column with a dot in each cell. This way we can import this table as:

Set
  l 'livestock types' / sheep, goat, angora, cattle, buffalo, mule, poultry /
  cl 'livestk comm' / meat, milk, wool, hide, egg /
  ty 'time periods - years' / 1974*1979 /;

$onEcho > yield.txt
I=%system.fp%yield.xls
R=data!B2:J23
O=yield.inc
$offEcho
$call =xls2gms @yield.txt

Table yieldtl(l,cl,ty) 'livestock "yield" time series (kg per head)'
$include yield.inc
;
display yieldtl;

6.43.7 Interactive use

When the tool is called without command line parameters, it will startup interactively. Using it this way, one can specify the spreadsheet file (.XLS file), the range and the final destination file (a GAMS include file) using the built-in interactive environment. The main screen contains a number of buttons and edit boxes, which are explained below.

- **Input file (*.XLS)**. This is the combo box to specify the input file. The file must be a valid MS Excel spreadsheet file (*.XLS). The browse button can be used to launch a file open dialog which makes it easier to specify a file. The file may be located on a remote machine using the notation `\machine\directory\file.xls`.

- **Range**. The range can be left empty in which case the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). The range can also be a name if the spreadsheet contains named ranges. The browse button will start Excel allowing you to interactively select a range.

- **Output GAMS Include file (*.INC)**. If you want to create a GAMS include file, then specify here the destination file. The include file will be an ASCII file that can be read by GAMS using the `$include` command. If the include file already exists, it will be overwritten.
• **Progress Memo.** This memo field is used to show progress of the application. Also error messages from the database are printed here. This is a read-only field.

<table>
<thead>
<tr>
<th>Application: Microsoft Excel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version: 9.0</td>
</tr>
<tr>
<td>Workbook: D:\gams projects\xls2gms\ver2</td>
</tr>
<tr>
<td>Sheet: data</td>
</tr>
<tr>
<td>Range: $B$2:$J$23</td>
</tr>
<tr>
<td>Done with D:\gams projects\xls2gms\ver2</td>
</tr>
</tbody>
</table>

• The edit boxes above all have a drop down list which can be used to access quickly file names and queries that have been used earlier (even from a previous session).

• **options button** will pop up a window where you can specify a number of options.

• **help button** will show this help.

• the **OK button** is pressed the query will be executed and an include file will be generated.

• the **batch button** will give information on how the current extract command can be executed directly from GAMS in a batch environment. The batch call will be displayed and can be copied onto the clipboard. In the IDE press Ctrl-C or choose Edit|Paste to copy the contents of the clipboard to a GAMS text file.

• **close button** will exit the application. The current settings will be saved in an INI file so when you run XLS2GMS again all current settings will be restored.

### 6.43.8 Options

The **Options** window can be created by pressing the options button:
The following options are available in the options window:

- **Quote blanks**: Quote strings if they contain blanks or embedded quotes. If a string does not contain a blank or embedded quotes, it will remain unquoted. If the string contains a single quote the quotes applied will be double quotes and if the string contains already a double quote, the surrounding quotes will be single quotes. (In the special case the string contains both, double quotes are replaced by single quotes). For more information see this example.

- **Mute**: Don't include the extra informational text (such as used query etc.) in the include file.

- **No listing**: Surround the include file by `$offlisting` and `$onlisting` so that the data will not be echoed to the listing file. This can be useful for very large data files, where the listing file would become too large to be handled comfortably.

- **Separator**: This option allows you to set a separator string to be written between cell entries. By default this is a blank. In some cases it can be useful to make this a comma. See example for an example where this is used to import sets. Note: when this option is set to an empty string, the results may not be syntactically correct for GAMS. As it is difficult to see the difference between a single blank and an empty string, the user interface will give some feedback for these cases. When an empty string is used, a warning is written to the include file.

- **Range Separator**: Multiple ranges can be separated by a range separator symbol. By default this is a semi-colon. When certain non-US locales are used, the semi-colon is a list separator symbol which can be used in multi-area ranges. In case of such a conflict, it is possible to change the range separator symbol.

- **Append**: Append to the output file.

- **Browse Read-Only**: When the Browse Range button is pressed, we launch Excel and try to load the currently specified input file. If this option is checked then the input file is loaded as read-only. If this option is not checked the file is loaded normally, in which case you can change and save it.

The buttons have an obvious functionality:

- **OK button** will accept the changes made.
• Cancel button will ignore the changes made, and all option settings will revert to their previous values.

• Help button will show this help text.

6.43.9 Batch use

When calling XLS2GMS directly from GAMS we want to specify all command and options directly from the command line or from a command file. An example is:

C:\tmp>xls2gms "I=c:\My Documents\test.xls" O=test.inc

This call will perform its task without user intervention. The batch facility can be used from inside a GAMS model, e.g.:

Table c(i,j) 'data from spreadsheet' /
$call =xls2gms I=C:\tmp\test.xls O=C:\tmp\data.inc R=B1:E10
$include C:\tmp\data.inc
/;

The $call statement is rather error prone and you will need to spend a little it of time to get the call correct and reliable.

All the possible command line options are listed in command line arguments section. A proper batch call will at least contain the following command line parameters:

1. I=inputfilename
2. O=outputincludefile

If you only specify I=inputfilename then the interactive user interface is started with an initial setting of the input file name edit box equal to the name given in the command line argument. Only if an input file and an output file is provided, the call will be considered a batch invocation.

6.43.10 Command-line Arguments
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I=</td>
<td>This option is required and specifies the name of the .XLS file containing the Access database. If the file contains blanks the name should be surrounded by double quotes. It is advised to use absolute paths, so Access has no confusion what file to open. If only the file name is used without a path, the file is searched in the current directory (this is the project directory when running under the IDE). On a network UNC names can be used, and files from another computer can be accessed, e.g. &quot;\hostname\c\my documents\a.xls.&quot; This option is required for batch processing.</td>
</tr>
<tr>
<td>O=</td>
<td>option specifies the name of the output file. The format of the output file will be a GAMs include file for a parameter statement. Make sure the directory is writable. UNC names can be used. An output file must be specified for batch operation.</td>
</tr>
<tr>
<td>R=</td>
<td>range is an optional argument. If not specified the whole first sheet is taken. Otherwise the range can be a single cell (e.g. A1), a block (e.g. B2:J23), or a region within a sheet (e.g. Sheet1!A1:C10). To specify a whole sheet use Sheet1!. The range can also be a name if the spreadsheet contains named ranges. Both global names (e.g. R=rangename) and sheet specific range names (e.g. R=Sheet2!rangename) are recognized. To select multiple ranges in one go, you can specify: R=range1;range2;range3. This is just a short-hand for three separate invocations of xls2gms. A multiple-area range can be specified by R=area1,area2,area3. Before exporting, a new range is created consisting of the union of the areas. This can be used to drop certain rows or columns from a table.</td>
</tr>
<tr>
<td>D</td>
<td>Debug. This option can be used for debugging purposes. If specified the import filter will no run minimized but &quot;restored&quot;, i.e. as a normal window. In addition the program will not terminate until the user clicks the Close button. This allows you to monitor possible errors during execution of xls2gms.</td>
</tr>
<tr>
<td>B</td>
<td>If this parameter is specified, strings that have blanks in them will be quoted. If the string is already quoted this step is not performed. If the name contains an embedded single quote, the surrounding quotes will be double quotes. If the name already contains a double quote, the surrounding quotes will be single quotes. If both single and double quotes are present in the string, then all double quotes are replaced by single quotes and the surrounding quotes will be double quotes. By default this option is turned off.</td>
</tr>
<tr>
<td>M</td>
<td>Run in modest or mute mode: no additional information, such as version number etc. is written to the listing file.</td>
</tr>
<tr>
<td>L</td>
<td>Embed the data in $offlisting, $onlisting. A quick way to reduce the size of the listing file.</td>
</tr>
<tr>
<td>@filename</td>
<td>Causes the program to read options from a file. If the file name contains blanks, it can be surrounded by double quotes. The option file contains one option per line, in the same syntax as if it were specified on the command line.</td>
</tr>
<tr>
<td>N=inifilename</td>
<td>Use a different Inifile than the standard xls2gms.ini located in the same directory as the executable xls2gms.exe.</td>
</tr>
<tr>
<td>A</td>
<td>Append to output files instead of overwriting them.</td>
</tr>
<tr>
<td>G=&quot;x&quot;</td>
<td>Sets the range separator symbol</td>
</tr>
<tr>
<td>S=&quot;x&quot;</td>
<td>Sets the output separator symbol</td>
</tr>
</tbody>
</table>

As invocations of xls2gms are reasonably expensive (a copy of Excel is started), there is a way to optimize related calls. From version 1.4, xls2gms allows multiple ranges to be read and multiple include files to be written in one swoop. The syntax is best explained by showing an illustrative example:

```bash
$call =xls2gms I=c:\tmp\x.xls R1=range1 R1=range2 R2=range3 O1=c:\tmp\f1.inc O2=c:\tmp\f2.inc
```
In this example the ranges 'range1' and 'range2' are written to the file 'f1.inc' while the range 'range3' will go to file 'f2.inc'. In general the ranges specified with Rn will be written to the file specified with On.

If multiple ranges are specified, they are written sequentially to the output file.

$call =xls2gms I=c:\tmp\x.xls R=range1 R=range2 O=c:\tmp\f1.inc

In this example the ranges 'range1' and 'range2' are written to 'f1.inc'.

## 6.43.11 $CALL command

The $CALL command in GAMS will execute an external program at compile time. There are two forms:

$call externalprogram

$call =externalprogram

The version without the leading '=' calls the external through the command processor (command.com or cmd.exe). The second version with the '=' bypasses the command processor and directly executes the external program. We mention some of the differences:

- Some commands are not external programs but built-in commands of the command processor. Examples are COPY, DIR, DEL, ERASE, CD, MKDIR, MD, REN, TYPE.

- If you want to execute these commands you will need to use the form $call externalprogram which uses the command processor. If you want to execute a batch file (.bat or .cmd file) then you will need to use the form $call =externalprogram.

- If it is important to stop with an appropriate error message if the external program does not exist, only use the form $call =externalprogram. The other form is not reliable in this respect. This can lead to surprising results and the situation is often difficult to debug, so in general we would recommend to use the form: $call =externalprogram.

- When calling pure Windows programs it is important to call the second form. The first form will not wait until the external Windows program has finished. If it is important to use a command processor in the invocation of a Windows program, use the START command, as in: $call start /w externalwindowsprogram. Otherwise, it is preferred to use: $call =externalwindowsprogram.

Attention

In general it is recommended to use the $call =externalprogram version for its better error-handling.

When command line arguments need to be passed to the external program, they can be added to the line, separated by blanks:

$call externalprogram parameter1 parameter2

$call =externalprogram parameter1 parameter2

The total length of the command line can not exceed 255 characters. If the program name or the parameters contain blanks or quotes you will need to quote them. You can use single or double quotes. In general the following syntax will work:

$call "external program" "parameter 1" "parameter 2"

$call ="external program" "parameter 1" "parameter 2"

It is noted that the first form needs additional quotes around the whole command line due to bugs in the parsing of the $call in GAMS. The second form work without additional quotes only if the '=' appears outside the double quotes.
2908

6.43.12

Tools Manuals

Command files

Parameters can be specified in a command file. This is important if the length of the command line
exceeds 255 characters, which is a hard limit on the length that GAMS allows for command lines. Instead
of specifying a long command line as in:

$call =xls2gms I="c:\My Documents\test.xls" O="c:\My Documents\data.inc" R="Sheet2!A1:F15"

we can use a command line like:

$call =xls2gms @"c:\My Documents\options.txt"

The command file c:\My Documents\options.txt can look like:

I=c:\My Documents\test.xls
O=c:\My Documents\data.inc
R=Sheet2!A1:F15

It is possible to write the command file from inside a GAMS model using the $echo command. The
following example will illustrate this:

$set cmdfile "trnsport.txt"
$echo "I=trnsport.xls" > "%cmdfile%"
$echo "O=trnsport.inc" >> "%cmdfile%"
$call =xls2gms @"%cmdfile%"
$include trnsport.inc

Newer versions of GAMS allow:

$set cmdfile trnsport.txt
$onEcho > "%cmdfile%"
I=trnsport.xls
O=trnsport.inc
$offEcho
$call =xls2gms @"%cmdfile%"
$include trnsport.inc

6.43.13

Multiple-area ranges and post-processing

The following fragment is from a spreadsheet from Unesco:


Assume we want to extract the 1990 percentage distribution of current expenditure for the countries Algeria through Congo. The range to select is not a contiguous area but consists of several pieces. In Excel we can use the mouse and the Ctrl key to make a multiple selection:
The range is A10:E10,A14:E14,G19,A21:A26,E21:G26, where the comma's indicate the range is a multiple-area range. In this case we have six pieces. It is important that Excel understands that the union of the pieces forms a rectangular area. If this is not the case an error will be raised. (You can check this yourself by selecting a multi-area range and copying it to a new sheet: this operation will fail if the areas together don't form a rectangle).

The extracted text file will look like:

<table>
<thead>
<tr>
<th>Country or territory</th>
<th>1990</th>
<th>1996</th>
<th>% of total current expenditure</th>
<th>1996</th>
<th>% of total current expenditure</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Algeria</td>
<td>...</td>
<td>78.6</td>
<td>31.1</td>
<td>...</td>
<td>59.1</td>
</tr>
<tr>
<td>Angola</td>
<td>96.3</td>
<td>54.7</td>
<td>14.6</td>
<td>36.8</td>
<td>35.1</td>
</tr>
<tr>
<td>Benin</td>
<td>37.6</td>
<td>25.5</td>
<td>12.6</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Botswana</td>
<td>46.8</td>
<td>36.8</td>
<td>12.6</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Burkina Faso</td>
<td>32.1</td>
<td>32.1</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Burundi</td>
<td>46.8</td>
<td>46.8</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Cameroon</td>
<td>29.5</td>
<td>29.5</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Cape Verde</td>
<td>37.6</td>
<td>54.7</td>
<td>10.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Central African Republic</td>
<td>52.7</td>
<td>12.6</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Chad</td>
<td>64.4</td>
<td>32.1</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Comoros</td>
<td>70.3</td>
<td>42.4</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
<tr>
<td>Congo</td>
<td>83.7</td>
<td>37.6</td>
<td>25.5</td>
<td>25.5</td>
<td>25.5</td>
</tr>
</tbody>
</table>

The range is A10:E10,A14:E14,G19,A21:A26,E21:G26, where the comma's indicate the range is a multiple-area range. In this case we have six pieces. It is important that Excel understands that the union of the pieces forms a rectangular area. If this is not the case an error will be raised. (You can check this yourself by selecting a multi-area range and copying it to a new sheet: this operation will fail if the areas together don't form a rectangle).

The extracted text file will look like:
This file is not completely suitable for using in a GAMS model. The following edits would need to be made:

1. The header labels should get rid of the trailing dot.
2. Cells with ... should be replaced by blanks.
3. Cells with ./ should be replaced by blanks

In the GAMS distribution a subdirectory gbin contains lots of interesting Unix utilities. Some of these are very suited to do string processing on text files, such as sed and awk. In this case we can use sed with some substitution commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s/prim.prim /</td>
<td>Replace “prim.” by “prim”. We need to be careful to keep the table alignment correctly, so we replace the dot by a blank instead of just removing the dot. A dot is a special character in sed (it means “any character”) so we escape it by specifying “.”.</td>
</tr>
<tr>
<td>s/Sec.sec /</td>
<td>Replace “Sec.” by “sec”.</td>
</tr>
<tr>
<td>s/Tert.tert /</td>
<td>Replace “Tert.” by “tert”.</td>
</tr>
<tr>
<td>s/...... /g</td>
<td>Replace “...” by “”. The dots are escaped. We add g to indicate there may be multiple instances on a line that must be replaced.</td>
</tr>
<tr>
<td>s/.... /g</td>
<td>Replace “./” by “”. Both dots and ‘/’ needs to be escaped.</td>
</tr>
</tbody>
</table>

The complete GAMS formulation can look like:

```plaintext
$onText
New version XLS2GMS ver 2.1 can handle multiple-area ranges.
$offText

Set
c 'countries'
   / Algeria, Angola, Benin, Botswana, 'Burkina Faso', Burundi, Cameroon
   'Cape Verde', 'Central African Republic', Chad, Comoros, Congo /
exp 'percentage distribution of current expenditure'
   / prim, sec, tert /;

$onEcho > commands.txt
I=%system.fp%unesco.xls
R=A10,E10:G10,A14:A19,E14:G19
O=unesco.inc
B
$offEcho

$call =xls2gms @commands.txt

$onEcho > sedcommands.txt
```
XLSDUMP

Note

The Windows GAMS distribution contains several tools to exchange data with MS-Excel: GDX2XLS, GDXXRW, XLS2GMS, and XLSDUMP. While we continue to include all four tools in our distribution, only GDXXRW is under active development. Therefore, we strongly recommend using GDXXRW for data exchange with Excel.

This program will write all worksheets of an Excel workbook to a gdx file. Unlike GDXXRW, the program does not require that Excel is installed. Windows platforms only.

6.44.1 Usage

XLSDump infile outfile

where

infile

A valid Excel workbook

outfile

Optional. The output gdx file. If no output file is specified, the name of the input file will be used to construct the name the output file.

6.44.2 Example

Consider the following working file 'test2.xlsx'.

Converting this workbook using xlsdump:

xlsdump test2.xlsx

Will generate the file test2.gdx. Showing this gdx file in the GAMS IDE:

The parameter VF:
6.45 XLSTALK

XLStalk is not a GDX utility, but as the program is often used with GDXXRW, it is discussed here.

6.45.1 Usage

xlstalk <option> {-V} <file> {<parameters>}

where

<file>

Excel file name with file extension

<option>

One of the following options; see following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
<th>Parameter</th>
<th>Return code</th>
</tr>
</thead>
<tbody>
<tr>
<td>-A</td>
<td>Test if Excel is running</td>
<td></td>
<td>0 Excel not running</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 Excel is running</td>
</tr>
<tr>
<td>-C</td>
<td>Close file; do not save changes.</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>-E</td>
<td>Test if file exists</td>
<td>&lt;file&gt;</td>
<td>0 File does not exist</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 File exists</td>
</tr>
<tr>
<td>-M</td>
<td>Status of file</td>
<td>&lt;file&gt;</td>
<td>0 Not open in Excel</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 File is open and is not modified</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2 File is open and has been modified</td>
</tr>
<tr>
<td>-O</td>
<td>Open file but do not reload</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>-Q</td>
<td>Quit Excel if no workbooks have been modified</td>
<td>&lt;file&gt;</td>
<td>0 Excel is closed</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 Excel is still running</td>
</tr>
<tr>
<td>-R</td>
<td>Run a macro</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>-S</td>
<td>Save and close the file</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>-V</td>
<td>Verbose mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-W</td>
<td>Wait for the user to close the file</td>
<td>&lt;file&gt;</td>
<td></td>
</tr>
<tr>
<td>-X</td>
<td>Excel version</td>
<td></td>
<td>0 Excel is not installed</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 Excel is installed; version 2003 or earlier</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2 Excel is installed; version 2007 or later</td>
</tr>
</tbody>
</table>
6.45.2 Example

In GAMS, the return value can be obtained by using 'errorlevel'.

execute 'xlstalk.exe -X';
Scalar x;
x = errorLevel;
display x;
Chapter 7

Application Programming Interfaces

The Application Programing Interfaces (APIs) to GAMS allow the seamless integration of GAMS into an application. The APIs by provides appropriate classes for the interaction with GAMS. The GAMS\texttt{Database} class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GAMSJob class and by using the GAMS\texttt{ModelInstance} class a sequence of closely related model instances can be solved in the most efficient way. Note that the GAMS object-oriented API was not designed to offer modeling capability. The model needs to be formulated in GAMS and passed on to the GAMSJob class.

Four versions of object-oriented GAMS APIs:

- .NET API with Target Framework Version 4.0,
- C++ API works with C++11 or later,
- Java API works with Java SE 8 or later, and
- Python API works with Python 3.6, 3.7, 3.8, and 3.9.
- Matlab API works with Matlab 2017b (or later) and Octave 5.2 (or later).

In addition to the object-oriented GAMS APIs, there exist expert-level (or low-level) GAMS APIs in which its usage requires advanced knowledge of GAMS component libraries. See Executing GAMS from other Environments if you want to execute GAMS directly from an application without using APIs.

7.1 Object-oriented APIs

The Reference Manuals give an overview of the features provides by GAMS APIs, release notes, and a list of all classes with descriptions. The Tutorials provide an overview of the basic functionality of the GAMS APIs and the Examples provides a list of examples available with GAMS distribution with detailed description. See also Release Notes and Supported Platforms.

7.1.1 Reference Manuals

The GAMS APIs reference manuals give an overview of the features provides by GAMS APIs, release notes, and a list of all classes with descriptions.

- .NET API
- C++ API
- Java API
- Python API
- Matlab API

</table>
These examples are available with the GAMS distribution in 
[Path/To/GAMS]/apifiles/ directory. In
that directory, the file readme.txt describes how to build and execute these examples. A GAMS script to compile and execute each example is available in 
[Path/To/GAMS]/apilib_ml/ directory with a table of contents.

### 7.1.3.1 Alias

The Object-oriented API does not have the concept of a GAMS alias. An alias cannot be entered into a
GAMSDatabase by API methods. Nevertheless, if the GAMSDatabase is loaded from a GDX container
(e.g. the GAMSJob.OutDB), the database can contain aliases. Such an alias can be retrieved as a
GAMSSet and consists of the elements of the aliased set. The method to find out if a GAMSSet in a
GAMSDatabase is indeed an alias is to check if the symbol name is different from the lookup name (i.e.
bool isAlias = db.GetSet("ii").Name != "ii"). This example model goes through the logic of how aliases
are handled in the Object-oriented API.

See Alias example in [.NET, Java, Python].

### 7.1.3.2 Benders2Stage

This example implements a simple Benders decomposition method for a stochastic linear program. The
underlying model implements a simple distribution system with stochastic demand data. This example
actually consists of two programs: A sequential and a parallel implementation. In the sequential version,
the master and the subproblems are implemented with the GAMSModelInstance object which allows
resolving the model with modified input without regenerating the model. A GAMSModelInstance has a
fixed model rim, so this provides a challenge for Benders master problem because every iteration adds
new constraints (the Benders cuts) to the master. We get around this limitation of GAMSModelInstance
by initializing the GAMSModelInstance of the master with a fixed number of empty (i.e. non-binding)
placeholders constraints and during the run of the algorithm turn these placeholder constraints into
valid Benders cuts. The parallel version extends the Benders2Stage example by solving the independent
subproblems in parallel. For that we need to instantiate a separate GAMSModelInstance for each parallel
worker. We use the efficient GAMSModelInstance. CopyInstance method to accomplish this in the most
effective way. The number of demand scenarios can be larger than the number of parallel workers. The
distribution of work is handles through a work queue. The parallel execution of the subproblems is done
in separate threads (the MT in the name of the example stands for Multi Threading), so there is very
little overhead from disk activity.

See Bender2Stage example in [.NET, Java, Python] and Bender2StageMT example in [.NET, Java,
Python].

### 7.1.3.3 Clad

This example demonstrates how to implement a complex termination criterion for a difficult MIP using
GAMS/Cplex. We would like to achieve a globally optimal solution (relative gap 0%) but if solution
time becomes larger than n1 seconds, we can compromise for a 10% gap, and if this is not achieved
after n2 seconds, we compromise for a 20% gap, and again if this is not accomplished in n3 seconds we
take whatever the solver has done so far and terminate the solve. This is implemented by executing
GAMSJob.run in an independent thread and providing new tolerances for the relative gap in the main
thread by supplying new GAMS/Cplex option files and triggers the processing of the new tolerance option
by GAMS/Cplex through the GAMSJob.Interrupt method.

See Clad example in [.NET, Java, Python].
7.1.3.4 CutStock

This example contains two programs that implement a column generation approach to solve the cutting stock problem. In the program SimpleCutsock, the column generation scheme has been implemented in GAMS. Moreover the GAMS model with the input and output data has been wrapped in a class that separates all interaction with GAMS from the driving application. In the second example, the column generation approach has been entirely implemented in the program using GAMSJob for the master and GAMSModelInstance for the pricing problem. GAMS is used to build the master and pricing problems. The logic of the column generation method is in the application program.

See Cutstock Model example in [.NET, Java, Python], SimpleCustock example in [.NET, Java, Python], and Custock example in [.NET, Java, Python].

7.1.3.5 Domain Checking

Enforcing referential integrity also known in the GAMS lingo as domain checking is an essential and important part of GAMS. The Object-oriented API does a delayed domain checking of symbols. So you can add records to a domain controlled parameter (e.g. p(j)) even though the GAMSSet i does not contain the label (yet). The user can trigger an explicit check of the referential integrity by calling the GAMSDatabase.CheckDomains (or GAMSSymbol.CheckDomains). The Object-oriented API provides methods to access the records that violate the referential integrity (see GAMSDatabaseDomainViolation for details). Domain checking is implicitly done when the GAMSDatabase is exported to a GDX file via the GAMSDatabase.Export method or for databases provided in the GAMSJob.Run method. The implicit domain check can be suppressed (and left to GAMS when importing data) via the GAMSDatabase.SuppressAutoDomainChecking property. This example demonstrates how to trigger domain checking and how to access the records that violate the referential integrity.

See Domain checking example in [.NET, C++, Java, Python].

7.1.3.6 GUI Examples

Modern development frameworks like Microsoft’s Visual Studio, Python, and Java allow to quickly build graphical user interfaces. Every example consists of a simple GUI that provides data entry, executing of a GAMSJob and graphically represents the results of a GAMS model.

- **CutstockGUI**: This example allows to either load data from a database or to enter data manually. A cutting stock problem is solved by using both the GAMSJob and the GAMSModelInstance class in order to implement a decomposition approach. See also CutStock Example. See this example in [.NET].

- **InterruptGUI**: This small example demonstrates how to run a GAMS model in a graphical user interface. This has all rudimentary features we know from the GAMS IDE: starting a job, capture the GAMS log in a window, and providing a button to interrupt. The underlying mechanism to interrupt the job is similar to the Interrupt Example (GAMSJob.Interrupt), but the trigger mechanism is very different. See this example in [.NET, Java, Python].

- **FarmGUI**: For this farming model, the input data can be entered directly into several tables. The GAMS model itself is executed by using one single GAMSJob instance. Results are displayed in different charts and tables. See this example in [.NET].

- **TransportGUI**: In this example a series of transportation problems is solved using GAMSModelInstance. Data can be entered into tables or can be loaded from a database. When data is entered into a table, related tables are updated automatically. Results are shown in tables and/or a bar chart. See also Transport Model Sequence Example. See this example in [.NET, Java].
7.1.3.7 GAMS Remote Object

This example demonstrates how to implement a simple GAMS Server. The example has two parts: GAMSServer and GAMSClient. The example is configured to run the client and server on the same machine, but can easily be altered to run on different machines. Both client and server need access to the GAMSRemoteClass that implements the server. The method to communicate is very simple. The client sets up the ingredients for a GAMSJob (model text, GDX input, parameters) and sends them serialized (via a byte representation of the GDX and parameter file) to the server. The server recreates the GAMS objects from the serialized representations, runs the model, and ships GAMSJob.OutDB serialized back to the client for further processing.

See GAMSServer example in [.NET] and GAMSClient in [.NET].

7.1.3.8 Interrupt

Ctrl-C in a regular console application results in the interrupt of the entire job. GAMS users are used to the fact that Ctrl-C interrupts a solve but then continues with the execution of the remaining GAMS job. The example demonstrates how to alter some console properties to get this behavior of Ctrl-C.

See Interrupt example in [.NET, Java, Python].

7.1.3.9 Markowitz

This is a small graphical program that plots the efficient frontier of Markowitz' portfolio selection problem with the two objectives return and risk. The example utilizes the GAMSModelInstance class to solve the parameterized objective max lambda*return - (1-lambda)*risk in the most efficient way.

See Markowitz example in [.NET, Python].

7.1.3.10 MessageReceiver Window

The little example demonstrates how to implement a custom visual log. From GAMS one can send messages to the form started by this program via the put_utility "winmsg". The form also understands some commands (a message that starts with @) to save the content of the form, to put the content into the clipboard, or to terminate the program. The MessageReceiverWindow is also distributed as an executable in the GAMS system directory ready to be used. The model mrw01 in the GAMS Test Library demonstrates the use of the program.

See MessageReceiver Window example in [.NET].

7.1.3.11 Special Values

This example shows how special values of the programming language (e.g. infinity) percolate down to GAMS. Infinity and NaN (not a number) are well defined. The GAMS Undefined and EPS need special considerations.

See Special Values example in [.NET, Java, Python].

7.1.3.12 Transport Model Sequence

This set of examples demonstrates the use of the Object-oriented API on the simple transport model transport.gms: A Transportation Problem [transport]. The detailed description of the various examples is provided in the Object-oriented API tutorials in the GAMS documentation.

See Transport Model example in [ .NET, C++, Java, Python].

7.1.3.13 Traveling Salesman Problem

This example demonstrates how to use a GAMSModelInstance to implement the subtour elimination algorithm for the Traveling Salesman Problem (TSP) problem. Similar to Benders2Stage example, we have a placeholder for the subtour elimination constraint that gets generated in each iteration of the algorithm. In contrast to the Benders example, here we regenerate the GAMSModelInstance if the original number of placeholders was not big enough. We continue this process until all subtours are eliminated.

See Traveling Salesman Problem example in [ .NET, Java, Python].

7.1.3.14 Unit Test

This example contains all the unit tests we run on the .Net Object-oriented API. See Unit Test example in [ .NET].

7.1.3.15 Warehouse

This example demonstrates how to solve a simple GAMS model to assign stores to warehouses for different data sets in parallel. The model has been parameterized. The data can be derived from a few numbers namely the number of warehouses, stores, and some fixed cost scalar. The results of the model are written into a single result database that is protected across the parallel threads via a mutex.

See Warehouse example in [ .NET, C++, Java, Python].

7.1.4 Release Notes

GAMS API Release Notes provide an overview of changes to the GAMS APIs in releases of the GAMS distribution.

- .NET API Release Notes
- Java API Release Notes
- Python API Release Notes

7.2 Expert-Level APIs

In addition to the object-oriented GAMS API, there exist expert-level (or low-level) APIs to some component libraries of the GAMS system. These APIs are used internally in GAMS for a long time and help in the deployment of GAMS models. While they offer high performance and flexibility, they also require advanced knowledge and it is recommended that the object-oriented GAMS API is used if possible. The expert-level APIs are offered for C, C#, Delphi, Fortran, Java, Python, and Visual Basic.

The DCT, GEV, and GMO components are mainly used to build solver links to GAMS (see, e.g., the GAMSLinks project. In fact, all professional GAMS solver links are based on these components. They provide access to an instance of a model generated by a solve statement. If you plan to build advanced algorithms for models or need to solve a sequence of very similar models these components might represent an alternative to an implementing using the GAMS language.

While we also strive for backward compatibility with our component libraries, but programming interfaces are commonly subject to change, so programs based on these APIs might require adjustment when updating to a new GAMS version. The Release Notes have a section on these API changes.

Overviews of the exported function in pseudo code are available in the following summary pages:

- CFG API (GAMS Configuration Object)
- DCT API (GAMS Dictionary Object)
- GAMSx API (GAMS Execution Object)
- GDX API (GAMS Data Exchange Object) with additional information available as PDF and CHM.
- GEV API (GAMS Environment Object) with additional GAMS Environment Object Options.
- GMO API (GAMS Modeling Object) with additional information on philosophy and design.
- IDX API (GAMS IDX Object)
- OPT API (GAMS Option Object)
- PAL API (GAMS Auditing and Licensing Object)

- Fortran API files are based on C code to load dynamic libraries. For Windows pure Fortran API files for Intel and Lahey Fortran compilers are included.

### 7.3 C++ API

GAMS C++ API provides a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

### 7.4 Java API

GAMS Java API provides a Java programming interface to the General Algebraic Model System (GAMS). GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. The use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute_load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object GAMSWorkspace manages the anchor to the file system.

With the exception of GAMSWorkspace the objects in the gams namespace cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GAMSModelInstance class).

Note

If you use multiple instances of the GAMSWorkspace in parallel, you should avoid using the same WorkingDirectory. Otherwise you may end up with conflicting file names.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GAMSModelInstances. Some solvers will not work in a multi-threaded application using GAMSModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GAMSModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Java API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.
7.5 Python API

The gams namespace provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this namespace allow convenient exchange of input data and model results (GamsDatabase), help to create and run GAMS models (GamsJob), that can be customized by GAMS options (GamsOptions). Furthermore, it introduces a way to solve a sequence of closely related model instances in the most efficient way (GamsModelInstance).

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute $load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base class GamsWorkspace manages the anchor to the file system. If external file communication is not an issue in a particular Python application, temporary directories and files will be managed by objects in the namespace.

With the exception of GamsWorkspace the objects in the gams namespace cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GamsModelInstance class).

Note

If you use multiple instances of the GamsWorkspace in parallel, you should avoid using the same working directory. Otherwise you may end up with conflicting file names.

This version of the gams namespace lacks support for the following GAMS components:

- Acronyms, support for GAMS compilation/execution errors (GamsJob.run just throws an exception), structured access to listing file, and proper support for solver options.

- Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GamsModelInstances. Some solvers will not even work in a multi-threaded application using GamsModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GamsModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

The GAMS Python API collection contains further packages and modules for specific applications, some of which are currently in beta status. The gams_magic API (beta) allows to integrate GAMS into Jupyter notebooks. The API gams2numpy (beta) communicates data between GAMS and numpy arrays. gamstransfer (beta) simplifies the work of reading and writing GDX files. The used data structures allow data to be easily converted directly to Pandas DataFrames (or other native Python data types). The gams_engine API allows the creation of Python clients for GAMS Engine.

7.5.1 Jupyter Notebooks

Note

This feature is currently in beta status.

7.5.1.1 Introduction

GAMS Jupyter Notebooks allow to use notebook technology in combination with GAMS. If you just want to learn GAMS there are probably better ways doing this. Notebooks allow you to combine GAMS and Python. The former works great with well structured data and optimization models, while the latter is very rich in features to retrieve, manipulate, and visualize data that comes in all sort of ways. Combining GAMS and Python in a notebook it is relatively easy to tell an optimization story with text, data, graphs, math, and models.
7.5.1.2 Getting Started

The first step in getting started with GAMS Jupyter Notebooks is to make your Python 3 installation aware of the GAMS Python API collection described in the Getting started section of the API tutorial. We recommend to follow the steps below which are specifically tailored for getting started with GAMS Jupyter notebooks. While any Python 3.6, 3.7, 3.8, or 3.9 installation is supported, we recommend the use of Anaconda or Miniconda Python distributions.

In addition to the GAMS Python API collection, the packages jupyterlab, matplotlib, pandas, and tabulate are required in order to enable GAMS Jupyter Notebooks and to run the provided examples which are located in apifiles/Python/jupyter_examples. The following code section shows how to create and set up a Miniconda Python environment for GAMS Jupyter notebooks:

**Windows:**

```bash
conda create -n gmsjupyter python=3.8 jupyterlab pandas tabulate matplotlib
conda activate gmsjupyter
cd C:\GAMS\33\apifiles\Python\api_38
python setup.py install (In case of permission problems run the following instead: python setup.py build
  cd C:\jupyter (or another directory that should be used for your notebooks)
jupyter notebook (this will start the jupyter notebook server)
```

**Linux:**

```bash
conda create -n gmsjupyter python=3.8 jupyterlab pandas tabulate matplotlib
conda activate gmsjupyter
cd ~/gams/gams33.1_linux_x64_64_sfx/apifiles/Python/api_38
python setup.py install (In case of permission problems run the following instead: python setup.py build
  cd ~/jupyter (or another directory that should be used for your notebooks)
jupyter notebook (this will start the jupyter notebook server)
```

**macOS:**

```bash
conda create -n gmsjupyter python=3.8 jupyterlab pandas tabulate matplotlib
conda activate gmsjupyter
python /Library/Frameworks/GAMS.framework/Resources/apifiles/Python/api_38/setup.py build -b $TMPDIR,
  cd ~/jupyter (or another directory that should be used for your notebooks)
jupyter notebook (this will start the jupyter notebook server)
```

The notebooks Millco.ipynb and Introduction.ipynb located in apifiles/Python/jupyter_examples are good starting points to get familiar with Jupyter notebooks and GAMS. The Tutorial in this documentation is derived from the Introduction.ipynb notebook.

7.5.1.3 Tutorial

GAMS Jupyter Notebooks allow to use notebook technology in combination with GAMS. If you just want to learn GAMS there are probably better ways doing this. Notebooks allow you to combine GAMS and Python. The former works great with well structured data and optimization models, while the latter is very rich in features to retrieve, manipulate, and visualize data that comes in all sort of ways. Combining GAMS and Python in a notebook it is relatively easy to tell an optimization story with text, data, graphs, math, and models.
The GAMS Jupyter Notebook builds on top of the Python 3 kernel. So by default the notebook cells are Python cells. Cells can be turned into GAMS cells, i.e. cells with GAMS syntax, using the Jupyter magic facility (first line in a cell is `%gams`). GAMS magic commands enable GAMS support in Python Jupyter notebooks. Beside running GAMS code, it is possible to transfer data between GAMS and Python. In order to enable the GAMS magic commands, it is required to load the extension `gams_magic`:

```
%load_ext gams_magic
```

There are a few other useful command in connection with running GAMS in a Jupyter notebook. Some transformation functions for pandas dataframes useful for exchange with GAMS have been collected in the `DataTransform.ipynb`. The next cell will execute that notebook and make such data transformation function, e.g. `gt_from2dim` (see below) available in this notebook. `%capture` captures the output from the execution of the notebook and does not clutter your output.

```
%capture
%run ~/share/DataTransform.ipynb
```

Somehow one output from a cell is sometimes not enough, e.g. if you want to display a couple of tables. The display function allows you to do this but needs to imported. As an example, we display a Python list:

```
from IPython.display import display
display([1,2,3])
```

```
[1, 2, 3]
```

### 7.5.1.3.1 Running GAMS code

Running GAMS code can be done by using either `gams` (line magic) or `%gams` (cell magic). While `gams` can be used for running a single line of GAMS code, `%gams` makes the whole cell a GAMS cell.

```
%gams set i;
```

```
%%gams
set j;
parameter p(i,j);
p parameter p2(i,j);
```

The GAMS compiler and execution system has been adjusted so one can run a GAMS cell multiple time, even if it contains a declaration or an equation definition, which is normally not possible in the GAMS system. The execution of the next two cells does not create a problem, which mimics the execution, modification, and reexecution of a cell.

```
%%gams
set i / peter,paul,mary /, j / A,B,C /;
p parameter p2(i,j) / set.i.set.j 1 /;
```

```
%%gams
set i / i1*i5 /, j /j1*j5 /;
p parameter p2(i,j) / set.i.set.j 1 /;
```

You won’t see any output from a GAMS cell (unless there is a solve executed in the cell, see below). All output goes to the log and lst file. If you really need to see this you can use magic command `gams_log` and `gams_lst` to display the content of the log and listing file of the most recent GAMS execution. The next cell displays the content of listing file of the last run GAMS cell or line magic. The `-e` only display the section of the listing file associated with the execution:

```
%gams display p2;
%gams_lst -e
```
Execution

---- 11 PARAMETER p2

<table>
<thead>
<tr>
<th></th>
<th>j1</th>
<th>j2</th>
<th>j3</th>
<th>j4</th>
<th>j5</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
</tr>
<tr>
<td>i2</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
</tr>
<tr>
<td>i3</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
</tr>
<tr>
<td>i4</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
</tr>
<tr>
<td>i5</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
<td>1.000</td>
</tr>
</tbody>
</table>

There is a limit to the execution, modification, and reexecution of GAMS cells. If the type or the dimensionality of a symbol changes, you will need to execute the notebook from scratch and do a controlled reset of the entire GAMS database via `gams_reset`. For example, since we declared parameter `p2` already over `(i,j)` we cannot change our mind and redefine `p2` as parameter `p2(i,i,j):

In:
`%gams parameter p2(i,i,j);`

This will give you a compilation error and an exception in the cell execution (uncomment the line in the next cell to do so):

In:
`#%gams parameter p2(i,i,j);`
`#%gams lst`

With a `gams_reset` we can reset the GAMS database and can declare symbols with a different type and domain/dimension. All other things in the GAMS database are gone, too. So we need to redefine the sets `i` and `j`, too. The state of the GAMS database is kept in various files that can easily clutter your directory. The `gams_cleanup` call helps you to clean the directory of temporary files. The option `-k` keeps the most recent GAMS database, hence the `gams_cleanup -k` is a save call anywhere in your notebook.

In:
`%gams_reset`
`%gams lst -e`

7.5.1.3.2 Pushing Data from Python to GAMS  `gams_push` transfers data from Python to GAMS. Supported data types for pushing data are lists, pandas.DataFrame and numpy arrays:

In:
`# Define Python lists with data i = ['i1', 'i2', 'i3'] j = ['j1', 'j2'] p = [('i1', 'j1', 1.1), ('i1', 'j2', 2.2), ('i2', 'j1', 3.3), ('i2', 'j2', 4.4), ('i3', 'j1', 5.5), ('i3', 'j2', 6.6)] %gams_push i j p`

As mentioned above the execution of a `%gams` cell or `gams` and `gams_push` line magic does not produce output. If one wants to verify that the data ended up in GAMS we can display the symbols in GAMS and output the corresponding part of the listing file:

In:
`%gams display i,j,p;`
`%gams_lst -e`
The next cell turns a Python list into a pandas.DataFrame, multiplies the value by 2 and displays the dataframe with IPython’s display. We actually display the transformed p2 (via function `gt.pivot2d` found in the `DataTransformation` notebook run at the top of the notebook), so the table looks nicer. Next, we send the pandas.DataFrame down to GAMS via the `gams_push` command. Via the GAMS `display` and the output of the relevant part of the listing file we see that the `gams_push` succeeded:

```python
import pandas as pd
# turn the Python list p into a pandas.DataFrame p2 and send this down to GAMS
pp = pd.DataFrame(p)
# multiply the value by 2:
# display a nicer version of the dataframe:
display(gt.pivot2d(pp))
gams parameter pp(i,j)
gams_push pp
gams display pp;
gams_lst -e
```

<table>
<thead>
<tr>
<th></th>
<th>j1</th>
<th>j2</th>
</tr>
</thead>
<tbody>
<tr>
<td>i1</td>
<td>2.2</td>
<td>4.4</td>
</tr>
<tr>
<td>i2</td>
<td>6.6</td>
<td>8.8</td>
</tr>
<tr>
<td>i3</td>
<td>11.0</td>
<td>13.2</td>
</tr>
</tbody>
</table>

When using numpy arrays in order to push data into GAMS, the data is assumed to be dense. The corresponding sets are defined automatically from 1..n, 1..m, etc depending on the data that is pushed.
```python
import numpy as np
data = [[[1.1,-1.1], [2.2,-2.2]], [[3.3,-3.3], [4.4,-4.4]], [[5.5,-5.5], [6.6,-6.6]]]
p3 = np.array(data)
```

In:
```
gams set i, j, k; parameter p3(i,j,k);
gams_push p3

gams display i,j,k,p3;
gams_lst -e
```

```
Execution

----- 23 SET i
  1, 2, 3

----- 23 SET j
  1, 2

----- 23 SET k
  1, 2

----- 23 PARAMETER p3 3-dim Matrix

    1         2
1.1  1.100   -1.100
1.2  2.200   -2.200
2.1  3.300   -3.300
2.2  4.400   -4.400
3.1  5.500   -5.500
3.2  6.600   -6.600
```

### 7.5.1.3.3 Pulling Data from GAMS to Python

The line magic `gams_pull` transfers data from GAMS to Python in different formats. Supported formats are lists (default), pandas.DataFrame and numpy arrays. The following example pulls the sets `i`, `j`, and parameter `p3` from GAMS into lists. For multi-dimensional symbols the records become Python tuples. Currently, the renaming functionality `gams_pull gamsSym=pySymbol` is not yet supported.

In:
```
gams_pull p3 i j
display(i,j,p3)
```

```
['1', '2', '3']

['1', '2']

[('1', '1', '1', 1.1),
 ('1', '1', '2', -1.1),
 ('1', '2', '1', 2.2),
 ('1', '2', '2', -2.2),
 ('2', '1', '1', 3.3),
 ('2', '1', '2', 6.6),
 ('2', '2', '1', 5.5),
 ('2', '2', '2', 4.4),
 ('3', '1', '1', 6.6),
 ('3', '1', '2', 5.5),
 ('3', '2', '1', 4.4),
 ('3', '2', '2', 3.3)]
```
The switch -d will populate pandas.DataFrame instead of lists with the GAMS data. The dataframes that are pushed into or pulled from GAMS have a very specific layout. There is a record index and the GAMS domains show up as columns in the dataframe. For parameters, there is an extra value column. For variables and equations we find extra columns level, marginal, lower, upper, and scale. The method head() used in the IPython display provides only the first 5 records of a pandas.DataFrame:

\[
\begin{array}{cccc}
0 & 1 & 1 & 1.1 \\
1 & 2 & 1 & 2.2 \\
2 & 1 & 2 & 3.3 \\
3 & 2 & 1 & 4.4 \\
4 & 2 & 1 & 5.5
\end{array}
\]

The data transformation functions available from DataTransformations.ipynb help to convert between this format and formats more suitable for display of other transformations in Python. The following lines give a quick overview of the transformation functionality:

\[
\begin{array}{cccc}
i & level & marginal & lower & upper & scale \\
0 & 1.0 & 0.0 & -inf & inf & 1.0 \\
1 & 2.0 & 3.0 & -inf & inf & 1.0
\end{array}
\]
The switch `-n` will populate numpy arrays instead lists with the GAMS parameters. This format works with parameters only! The GAMS data will be dropped into a dense numpy array:

```
array([[1., 0.],
       [0., 2.],
       [0., 0.]])
```

### 7.5.1.3.4 Troubleshooting and Hints

- Paths to notebooks must not contain whitespaces. A notebook file itself (*.ipynb) can.
- The directory containing the notebook will clutter up with temporary files. A `gams_cleanup` or `gams_cleanup -k` if you want to continue working in this session
- The temporary file are useful for debugging, see below. The naming of the temporary files is not very sophisticated, so it can come to file naming conflicts if you run two notebooks in the same directory at the same time (in different browser tabs). Create subdirectories and move the notebook into the subdirectories if you run into this problem.
- As soon as an error occurs while running GAMS code (the notebook exception is a GamsException), it can be useful to examine the listing file (*.lst) using `cat path/to/listing.lst` or `gams_lst`. The path of the listing file can be found in the last line of the output of a failing cell.

```
GamsExceptionExecution Traceback (most recent call last)
```

7.6 Matlab API

GAMS Matlab API provides a Matlab programming interface to the General Algebraic Model System (GAMS). GAMS Matlab API objects allow a convenient way to exchange input data and model results with in-memory representation of data (GAMSDatabase), and to create and run GAMS models (GAMSJob) that can be customized by GAMS options (GAMSOptions). Furthermore, they introduce a way to solve a sequence of closely related model instances in a more efficient way (GAMSModelInstance).

Note

There also exists the data exchange tool GDXMRW to exchange data between Matlab and GDX files. Note that the GDXMRW can be more efficient in case of exchanging very large data sets. However, the GAMS Matlab API offers more features, for example, to start and modify a GAMS job.

The underlying GAMS engine relies to some extent on file based communication (e.g. the listing file) and other unmanaged resources. Since the GAMS Matlab API is based on the GAMS Java API, the use of external resources in the Java environment requires special attention. Hence, some objects need to be properly disposed before the Java garbage collector does its job.

A GAMS program can include other source files (e.g. $include), load data from GDX files (e.g. $GDXIN or execute_load), and create PUT files. All these files can be specified with a (relative) path and therefore an anchor into the file system is required. The base object GAMSWorkspace manages the anchor to the file system.

With the exception of GAMSWorkspace the objects in the gams package cannot be accessed across different threads unless the instance is locked. The classes themselves are thread safe and multiple objects of the class can be used from different threads (see below for restrictions on solvers that are not thread safe within the GAMSModelInstance class).
7.7 Tutorial

Note

If you use multiple instances of the GAMSWorkspace in parallel, you should avoid using the same WorkingDirectory. Otherwise you may end up with conflicting file names.

Currently only Cplex, Gurobi, and SoPlex fully utilize the power of solving GAMSModelInstances. Some solvers will not work in a multi-threaded application using GAMSModelInstances. For some solvers this is unavoidable because the solver library is not thread safe (e.g. MINOS), other solvers are in principle thread safe but the GAMS link is not (e.g. SNOPT). Moreover, GAMSModelInstances are not available for quadratic model types (QCP, MIQCP, RMIQCP).

This version of the GAMS Matlab API also does not provide support for the following GAMS components: acronyms, GAMS compilation/execution errors, structured access to listing file, and solver options.

7.7 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C# API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step.

- Getting Started A quick introduction about how to create and configure C# project
- Important Classes of the API Overview of some fundamental classes of the GAMS C# API
- How to use API An extensive set of examples how to use API components

7.7.1 Getting Started

This section takes you through the basic steps of creating and configuring a C# project in Visual Studio 2010 for use with the GAMS C# API. At the end of this section there is also a paragraph about Mono as an alternative to Microsoft Visual Studio.

7.7.1.1 Open a new Project

After opening Microsoft Visual Studio you can open the New Project wizard by choosing File > New > Project from the ribbon menu and type a name for your application, e.g. GAMSApplication.

7.7.1.2 Add a Reference to a Project

Once you opened the project add a reference by a right click on References inside the solution explorer. Then choose Add Reference... and select the Browse tab. Next navigate to the location where you installed GAMS.net4.d1l, typically the GAMS system directory, e.g. C:\GAMS\win64\35.2. Then choose GAMS.net4.dll and click OK.
7.7 Tutorial

7.7.1.3 Solving your first Model

This section illustrates how a model from the GAMS model library can be imported and solved.

Open a new project and reference the GAMS.net4.dll in your project as explained above. Open Program.cs which should be part of your project and replace the content by:

```csharp
using System;
using System.IO;
using System.Collections.Generic;
using System.Text;
using GAMS;
namespace TransportSeq
{
    class Transport0
    {
        static void Main(string[] args)
        {
            GAMSWorkspace ws = new GAMSWorkspace();
            ws.GamsLib("trnsport");
            // create a GAMSJob from file and run it with default settings
            GAMSJob t0 = ws.AddJobFromFile("trnsport.gms");
            t0.Run();
            Console.WriteLine("Ran with Default:");
            foreach (GAMSVariableRecord rec in t0.OutDB.GetVariable("x"))
            {
            }
            Console.WriteLine("z=" + t0.OutDB.GetVariable("z").LastRecord().Level);
        }
    }
}
```

Then click the highlighted button from figure (a) down below or press F5 to start debugging. You can also start the program without debugging by pressing Control + F5 or choosing Debug > Start Without Debugging from the ribbon menu as illustrated in figure (b).
By following the latter instruction the command line shell remains open and show the produced output.

7.7.1.4 Mono

The GAMS .NET API works also on non-Windows platforms where no Visual Studio is available. It can be used for example with the open source .Net framework Mono (http://www.mono-project.com). Mono offers a IDE that could be used similarly to Visual Studio. If one prefers to compile and execute from a shell, the following code shows how this can be done using the example Transport1 which comes with the GAMS system (this assumes that xbuild and mono are in the PATH):

cd <GAMS Dir>/apifiles/CSharp/Transport1
xbuild /t:rebuild /p:Configuration=Release Transport1.csproj
mono bin/Release/Transport1.exe ../..../..

7.7.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples.

- **GAMS Namespace**
- **GAMSWorkspace** Class
- **GAMSJob** Class
- **GAMSDatabase** Class
- **GAMSOptions** Class
- **GAMSModelInstance** Class

7.7.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C# API. <GAMS system directory>/apifiles/CSharp contains a file TransportSeq.sln that can be opened in Microsoft Visual Studio. The contained projects deal with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)
- How to import data from GDX (TransportGDX)
- How to run a GAMSJob from file (Transport1)
- How to specify the solver (Transport1)
- How to run a job with a solver option file and capture its log output (Transport1)
• How to use include files (Transport2)
• How to read data from string and export to GDX (Transport3)
• How to run a job using data from GDX (Transport3)
• How to run a job using implicit database communication (Transport3)
• How to define data using C# data structures (Transport4)
• How to prepare a GAMSDatabase from C# data structures (Transport4)
• How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
• How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
• How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
• How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
• How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)
• How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)
• How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
• How to fill a GAMSDatabase by reading from MS Access (Transport9)
• How to fill a GAMSDatabase by reading from MS Excel (Transport10)
• How to create and use a save/restart file (Transport11)

7.7.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on
your machine, the desired system can be specified via an additional argument when the workspace is created.
When running the examples, we can provide an additional command line argument in order to define the
GAMS system directory that should be used. By executing Transport1.exe with C:/GAMS/win64/35.2
we use the 64-bit version of GAMS 35.2 to run Transport1 even if our default GAMS system might be a
different one. This is managed by the following code:

```csharp
... GAMSWorkspace ws;
if (Environment.GetCommandLineArgs().Length > 1)
  ws = new GAMSWorkspace(systemDirectory: Environment.GetCommandLineArgs()[1]);
else
  ws = new GAMSWorkspace();
...
```

Remember that the bitness of the GAMS system has to match the bitness of your .NET program.

7.7.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented .NET API offers much more than exchanging data between .NET and
GDX, a common use case is the export and import of GDX files. The central class for this purpose is
GAMSDatabase. We assume that the data to be exported is available in .NET data structures.

```csharp
List<string> plants = new List<string>()
{  
  "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{  
  "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{  
  { "Seattle", 350.0 }, { "San-Diego", 600.0 }
```
Different GAMS symbols are represented using different .NET data structures. The data for the GAMS sets is represented using lists of strings (e.g. plants and markets). On the other hand, GAMS parameters are represented by dictionaries (e.g. capacity and demand). Note that the representation of the two dimensional parameter distance uses tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with .NET data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.AddDatabase.

```csharp
// prepare a GAMSDatabase with data from the C# data structures
GAMSDatabase db = ws.AddDatabase();
```

We start adding GAMS sets using the method GAMSDatabase.AddSet which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A foreach-loop iterates through plants and adds new records to the recently created GAMSSet instance i using GAMSSet.AddRecord.

```csharp
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.AddSet("i", 1, "canning plants");
foreach (string p in plants)
  i.AddRecord(p);
```

GAMSParameter instances can be added by using the method GAMSDatabase.AddParameter. It has the same signature as GAMSDatabase.AddSet. Anyhow, in this example we use an overload of the method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```csharp
// add parameter 'a' with domain 'i'
GAMSParameter a = db.AddParameter("a", "capacity of plant i in cases", i);
foreach (string p in plants)
  a.AddRecord(p).Value = capacity[p];
```

As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.Export can be used to create a GDX file.

```csharp
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.Export("data.gdx");
```

### 7.7.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using GAMSWorkspace.AddDatabaseFromGDX. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```csharp
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.AddDatabaseFromGDX("data.gdx");
```

Reading the data from the GAMSSet i into a list can be done as follows:

```csharp
// read data from symbols into .NET data structures
List<string> plants2 = new List<string>();
foreach (GAMSSetRecord item in db2.GetSet("i"))
  plants2.Add(item.Value);
```
A new list `plants2` is created. `i` is retrieved by calling `GAMSDatabase.GetSet` on `db2`. The returned GAMSSet object can be iterated using a foreach-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameters. Instead of creating a list, we want to have the data in the form of a dictionary. GAMSParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `Dictionary<string, double>`.

```csharp
Dictionary<string, double> capacity2 = new Dictionary<string, double>();
foreach (GAMSParameterRecord item in db2.GetParameter("a"))
    capacity2.Add(item.Key(0), item.Value);
```

For multi dimensional symbols, we choose the dictionary keys to be tuples instead of string.

```csharp
Dictionary<Tuple<string, string>, double> distance2 = new Dictionary<Tuple<string, string>, double>();
foreach (GAMSParameterRecord item in db2.GetParameter("d"))
    distance2.Add(new Tuple<string, string>(item.Key(0), item.Key(1)), item.Value);
```

### 7.7.3.4 How to run a GAMSJob from file (Transport1)

Here we load the model `transport` from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the `GAMSWorkspace.AddJobFromFile` Method afterwards. Apparently this method also works with any other.gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob `t1` is defined from that file and run by the `GAMSJob.Run` method.

The following lines create the solution output and illustrate the usage of the GAMSJob.**OutDB** property to get access to the GAMSDatabase created by the Run method. To retrieve the content of variable `x` we use the GAMSVariableRecord class and the GAMSDatabase.**GetVariable** method.

```csharp
ws.GamsLib("transport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.AddJobFromFile("transport.gms");
t1.Run();
Console.WriteLine("Ran with Default:");
foreach (GAMSVariableRecord rec in t1.OutDB.GetVariable("x"))
```

### 7.7.3.5 How to specify the solver (Transport1)

The solver can be specified via the GAMSOptions class and the `GAMSWorkspace.AddOptions` method. The GAMSOptions.AllModelTypes property sets xpress as default solver for all model types which the solver can handle.

```csharp
// run the job again with another solver
using (GAMSOptions opt = ws.AddOptions())
    { opt.AllModelTypes = "xpress";
        t1.Run(opt);
    }
```
7.7.3.6 How to run a job with a solver option file and capture its log output (Transport1)

At first we use the StreamWriter to create the file xpress.opt which will be used as solver option file and is stored in the current working directory. Then we write algorithm=barrier to this file and specify the barrier algorithm as algorithm before we close the solver option file. We choose xpress as solver just like in the preceding example and set the GAMSOptions.OptFile Property to 1 to tell the solver to look for a solver option file. In addition, we specify the argument output in order to write the log of the GAMSJob into the file transport1.xpress.log.

```c
{
    optFile.WriteLine("algorithm=barrier");
    optFile.Close();
    opt.AllModelTypes = "xpress";
    opt.OptFile = 1;
    t1.Run(opt, output: logFile);
}
```

Instead of writing the log output to a file, it can be written into any TextWriter. In order to write the log directly to Console.Out, we can use the following code:

```c
... t1.Run(opt, output: Console.Out);
...
```

7.7.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings GetDataText and GetModelText are using GAMS syntax.

At first we write an include file tdata.gms that contains the data but not the model text:

```c
{
    writer.Write(GetDataText());
}
```

Afterwards we create a GAMSJob using the GAMSWorkspace.AddJobFromString method. The GAMSOptions.Defines field is used like the 'double dash' GAMS parameters, i.e. it corresponds to --incname=tdata on the command line.

```c
using (GAMSOptions opt = ws.AddOptions())
{
    GAMSJob t2 = ws.AddJobFromString(GetModelText());
    opt.Defines.Add("incname", "tdata");
    t2.Run(opt);
}
```

Note that the string GetModelText contains the following lines to read in the data.

```c
$if not set incname $abort 'no include file name for data file provided'
$include $incname
...
```

7.7.3.8 How to read data from string and export to GDX (Transport3)

We read the data from the string GetDataText as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding GAMSJob a GAMSDatabase is created that is available via the GAMSJob.OutDb property. We can use the GAMSDatabase.Export method to write the content of this database to a gdx file tdata.gdx.

```c
GAMSJob t3 = ws.AddJobFromString(GetDataText());
t3.Run();
...
7.7 Tutorial

7.7.3.9 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in Transport2 - How to use include files (Transport2).

```csharp
... t3 = ws.AddJobFromString(GetModelText());
using (GAMSOptions opt = ws.AddOptions())
{
  opt.Defines.Add("gdxincname", "tdata");
  opt.AllModelTypes = "xpress";
  t3.Run(opt);
  ...
}
...
```

Note that there are some changes in GetModelText due to the usage of a GDX file instead of an include file.

```csharp
... if not set gdxincname $abort 'no include file name for data file provided'
gdxin %gdxincname%
gdxin ...
```

7.7.3.10 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `OutDB` can be read in directly just like a gdx file. Note that the database needs to be passed to the `GAMSJob.Run` method as additional argument.

```csharp
... using (GAMSOptions opt = ws.AddOptions())
{
  GAMSJob t3a = ws.AddJobFromString(GetDataText());
  GAMSJob t3b = ws.AddJobFromString(GetModelText());
  t3a.Run();
  opt.Defines.Add("gdxincname", t3a.OutDB.Name);
  opt.AllModelTypes = "xpress";
  t3b.Run(opt, t3a.OutDB);
  ...
}
...
```

7.7.3.11 How to define data using C# data structures (Transport4)

We use the `List<T>` class, the `Dictionary<TKey, TValue>` class and the `Tuple<T1, T2>` class to define C# data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```csharp
... List<string> plants = new List<string>()
{
  "Seattle", "San-Diego"
};
List<string> markets = new List<string>()
{
  "New-York", "Chicago", "Topeka"
};
Dictionary<string, double> capacity = new Dictionary<string, double>()
{
  { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
Dictionary<string, double> demand = new Dictionary<string, double>()
{
  { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
Dictionary<Tuple<string,string>, double> distance = new Dictionary<Tuple<string,string>, double>()
{
  { new Tuple<string,string> ("Seattle", "New-York"), 2.5 },
  { new Tuple<string,string> ("Seattle", "Chicago"), 1.7 },
  { new Tuple<string,string> ("Seattle", "Topeka"), 1.8 },
  { new Tuple<string,string> ("San-Diego", "New-York"), 2.5 },
  { new Tuple<string,string> ("San-Diego", "Chicago"), 1.8 },
  { new Tuple<string,string> ("San-Diego", "Topeka"), 1.4 }
};
...
7.7.3.12 How to prepare a GAMSDatabase from C# data structures (Transport4)

At first we create an empty GAMSDatabase `db` using the `GAMSWorkspace.AddDatabase` method. Afterwards we prepare the database. To add a set to the database we use the `GAMSSet` class and the `GAMSWorkspace.AddSet` method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C# data structure and add them by using the `GAMSSet.AddRecord` method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The `GAMSJob` can be run like explained in the preceding example about implicit database communication.

```csharp
GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob tsa = ws.AddJobFromString(GetModelText());
tsa.Run(cp);
```

This creates the same checkpoint as for example the following code snippet:

```csharp
GAMSCheckpoint cp = ws.AddCheckpoint();
GAMSJob tsa = ws.AddJobFromString(GetModelText());
tsa.Run(cp);
```

7.7.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `GetModelText()` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```plaintext
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
...
Scalar ms 'model status', ss 'solve status';
...
We create a list with eight different values for this demand multiplier:

```csharp
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
```

For each entry of that list we create a GAMSJob `t5` using the `GAMSWorkspace.AddJobFromString` method. Besides the string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a GAMSJob combined from the checkpoint plus the content provided by the string.

We run the GAMSJob and echo some interesting data from the OutDB using the `GAMSDatabase.GetParameter` and `GAMSDatabase.GetVariable` methods, the `GAMSParameter.FindRecord` and `GAMSVariable.FindRecord` methods plus the `GAMSParameterRecord.Value` property and the `GAMSVariableRecord.Level` property.

```csharp
... foreach (double b in bmultlist) {
    GAMSJob t5 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat;
ss=transport.solverstat;", cp);
    t5.Run();
    Console.WriteLine("Scenario bmult=");
    Console.WriteLine(" Modelstatus: " + t5.OutDB.GetParameter("ms").FindRecord().Value);
    Console.WriteLine(" Solvestatus: " + t5.OutDB.GetParameter("ss").FindRecord().Value);
    Console.WriteLine(" Obj: " + t5.OutDB.GetVariable("z").FindRecord().Level);
} ...
```

**Note**

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the **model status** and the **solve status** provide important information for a correct solution interpretation.

7.7.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs known from Transport5 in parallel. We initialize the GAMSCheckpoint `cp` and introduce a demand multiplier as we did before:

```csharp
GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
...
```

Furthermore, we introduce a new object `ioMutex` that will be used to avoid mixed up output from the parallel jobs. For each element `b` from the list of demand multipliers we call a delegate of the function `RunScenario`. Note that these calls are parallel!

```csharp
Object ioMutex = new Object();
System.Threading.Tasks.Parallel.ForEach(bmultlist, delegate(double b) {
    RunScenario(ws, cp, ioMutex, b);
});
...
```

In function `RunScenario` a GAMSJob is created and run just like in the preceding example of Transport5. The output section is also the same except for the fact that it is marked as critical section by the `lock` keyword. That means the delegates of `RunScenario` are running in parallel but the output block of different delegates cannot be executed in parallel since it is 'locked' by the same object `ioMutex` for all delegates.

```csharp
static void RunScenario(GAMSWorkspace ws, GAMSCheckpoint cp, object ioMutex, double b)
{
    GAMSJob t6 = ws.AddJobFromString("bmult=" + b + "; solve transport min z use lp; ns=transport.modelstat;
ss=transport.solverstat;", cp);
    t6.Run();
    // we need to make the output a critical section to avoid messed up report information
    lock (ioMutex)
    {
        Console.WriteLine("Scenario bmult=");
        Console.WriteLine(" Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
        Console.WriteLine(" Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
        Console.WriteLine(" Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
    }
}
```
While the output in Transport5 is strictly ordered subject to the order of the elements of bmultlist, in Transport6 the output blocks might change their order but the blocks describing one scenario are still appearing together due to the lock keyword.

If you want a further impression of the impact of the lock keyword, just rerun Transport6 but comment out the lock as follows and compare the output.

```csharp
    //lock (ioMutex) //
    Console.WriteLine("Scenario bmult=" + b + ":");
    Console.WriteLine(" Modelstatus: " + t6.OutDB.GetParameter("ms").FindRecord().Value);
    Console.WriteLine(" Solvestatus: " + t6.OutDB.GetParameter("ss").FindRecord().Value);
    Console.WriteLine(" Obj: " + t6.OutDB.GetVariable("z").FindRecord().Level);
    //}
    ...
```

### 7.7.3.16 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In Transport7 the usage of GAMS::GAMSModelInstance is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Then we create the GAMSModelInstance `mi` using the GAMSCheckpoint.AddModelInstance method. Note that the GAMSJob again contains no solve statement and the demand multiplier is already included with default value 1.

```csharp
    GAMSCheckpoint cp = ws.AddCheckpoint();
    GAMSJob t7 = ws.AddJobFromString(GetModelText());
    t7.Run(cp);
    GAMSModelInstance mi = cp.AddModelInstance();
    ...
```

### 7.7.3.17 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A GAMSModelInstance uses a SyncDB to maintain the data. We define `bmult` as GAMSPParameter using the GAMSDatabase.AddParameter method and specify gurobi as solver. Afterwards the GAMSModelInstance is instantiated with arguments opt and GAMSModifier `bmult`. The GAMSModifier means that `bmult` is modifiable while all other parameters, variables and equations of ModelInstance `mi` stay unchanged. We use the GAMSPParameter.FirstRecord method to reproduce our well-known example with different demand multipliers.

```csharp
    GAMSParameter bmult = mi.SyncDB.AddParameter("bmult", 0, "demand multiplier";
    GAMSOptions opt = ws.AddOptions();
    opt.AllModelTypes = "gurobi";
    mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
    bmult.AddRecord().Value = 1.0;
    double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
    foreach (double b in bmultlist)
    {
        bmult.FirstRecord().Value = b;
        mi.Solve();
        Console.WriteLine("Scenario bmult=" + b + ":");
        Console.WriteLine(" Modelstatus: " + mi.ModelStatus);
        Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
        Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
    }
    ...
```
7.7 Tutorial

7.7.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier

(Transport7)

We create a GAMSModelInstance just like in the next to last example. We define \( x \) as GAMSVariable and its upper bound as GAMSParameter \( x_{\text{up}} \). At the following instantiate method GAMSModifier has three arguments. The first one says that \( x \) is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```csharp
... mi = cp.AddModelInstance();
GAMSVariable x = mi.SyncDB.AddVariable("x", 2, VarType.Positive, "]");
GAMSParameter xup = mi.SyncDB.AddParameter("xup", 2, "upper bound on x");
mi.Instantiate("transport use lp min z", modifiers: new GAMSModifier(x, UpdateAction.Upper, xup));
foreach (GAMSSetRecord i in t7.OutDB.GetSet("i"))
    foreach (GAMSSetRecord j in t7.OutDB.GetSet("j"))
    {
        xup.Clear();
        xup.AddRecord(i.Keys[0], j.Keys[0]).Value = 0;
        mi.Solve();
        Console.WriteLine("Scenario link blocked: " + i.Keys[0] + " - " + j.Keys[0]);
        Console.WriteLine(" Modelstatus: " + mi.ModelStatus);
        Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
        Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
    }
...
```

7.7.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel

(Transport8)

We initialize a GAMSCheckpoint \( cp \) from a GAMSJob. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out-principle. The objects queueMutex and ioMutex are used later to avoid messed up output. Then we call two delegates of the function ScenSolve in parallel that get the same queue as argument.

```csharp
... GAMSCheckpoint cp = ws.AddCheckpoint();
ws.AddJobFromString(GetModelText()).Run(cp);
Queue<double> bmultQueue = new Queue<double>(new double[]{0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3});
Object queueMutex = new Object();
Object ioMutex = new Object();
Parallel.For(0, 2, delegate(int i) {
    ScenSolve(ws, cp, bmultQueue, queueMutex, ioMutex, i);
});
...
```

In function ScenSolve we create and instantiate a GAMSModelInstance as in the preceding examples and make \( \text{bmutil} \) modifiable. The two delegates of the function extract the elements of the queue using bmultQueue.Dequeue. Note that we chose cplex as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```csharp
private static void ScenSolve(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<double> bmultQueue, Object queueMutex, Object ioMutex, int i)
{
    GAMSModelInstance mi = cp.AddModelInstance();
    GAMSParameter bmutil = mi.SyncDB.AddParameter("bmutil", 0, "demand multiplier");
    GAMSOptions opt = ws.AddOptions();
opt.AllModelTypes = "cplex";
    mi.Instantiate("transport use lp min z", opt, new GAMSModifier(bmutil));
    bmutil.AddRecord().Value = 1.0;
    while (true)
    {
        double b;
        // dynamically get a bmutil value from the queue instead of passing it to the different threads at creation time
        lock (queueMutex)
        {
            if (0 == bmultQueue.Count)
                return;
            b = bmultQueue.Dequeue();
        }
        bmutil.FirstRecord().Value = b;
        mi.Solve();
        // we need to make the output a critical section to avoid messed up report informations
    }
}
```
2946

Application Programming Interfaces

lock (ioMutex)
{
Console.WriteLine("Scenario bmult=" + b + ":");
Console.WriteLine(" Modelstatus: " + mi.ModelStatus);
Console.WriteLine(" Solvestatus: " + mi.SolveStatus);
Console.WriteLine(" Obj: " + mi.SyncDB.GetVariable("z").FindRecord().Level);
}
}
}

7.7.3.20

How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a GAMSDatabase. We call a function
ReadFromAccess that finally returns a GAMSDatabase as shown below.
...
GAMSDatabase db = ReadFromAccess(ws);
...

The data we are going to read can be found in <GAMS system directory>\apifiles\Data\transport.accdb.
It might be helpful to open this file for a better understanding. The function begins with the creation
of an empty GAMSDatabase. Afterwards we connect to the MS Access database by first specifying the
provider and then defining the aforementioned file as data source. The OleDbConnection represents
an open connection to a data source. The following lines initialize the connection and use a try and a
catch block for potential exceptions, i.e. errors that occur during application execution. To finally read
in GAMS sets and parameters we call the functions ReadSet and ReadParameter. We will use several
classes of the System.Data.OleDb namespace that are documented here. Furthermore, we recommend
the OLE DB Tutorial.
static GAMSDatabase ReadFromAccess(GAMSWorkspace ws)
{
GAMSDatabase db = ws.AddDatabase();
// connect to database
string strAccessConn = @"Provider=Microsoft.ACE.OLEDB.12.0;Data Source=..\..\..\..\Data\transport.accdb";
OleDbConnection connection = null;
try
{
connection = new OleDbConnection(strAccessConn);
}
catch (Exception ex)
{
Console.WriteLine("Error: Failed to create a database connection. \n{0}", ex.Message);
Environment.Exit(1);
}
// read GAMS sets
ReadSet(connection, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
ReadSet(connection, db, "SELECT Market FROM Market", "j", 1, "markets");
// read GAMS parameters
ReadParameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
ReadParameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
ReadParameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
return db;
}

The function ReadSet incorporates a try and a catch block. In the try block we prepare the reading from
the MS Access file. Then we add a set symbol to the GAMSDatabase that is filled with the data from the
MS Access file afterwards. The function ReadParameter works quite similar.
static void ReadSet(OleDbConnection connect, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string
setExp = "")
{
try
{
OleDbCommand cmd = new OleDbCommand(strAccessSelect, connect);
connect.Open();
OleDbDataReader reader = cmd.ExecuteReader();
if (reader.FieldCount != setDim)
{
Console.WriteLine("Number of fields in select statement does not match setDim");
Environment.Exit(1);
}
GAMSSet i = db.AddSet(setName, setDim, setExp);
string[] keys = new string[setDim];
while (reader.Read())
{
for (int idx = 0; idx < setDim; idx++)
keys[idx] = reader.GetString(idx);
i.AddRecord(keys);


catch (Exception ex) {
    Console.WriteLine("Error: Failed to retrieve the required data from the DataBase.\n[0]", ex.Message);
    Environment.Exit(1);
}
finally {
    connect.Close();
}
}

Once we read in all the data we can create a GAMSJob from the GAMSDatabase and run it as usual.

7.7.3.21 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from <GAMS system
directory>\apifiles\Data\transport.xls. The model is given as string without data like in in many
examples before. At first we have to add

```csharp
using Excel = Microsoft.Office.Interop.Excel;
```

The following lines address the different worksheets and read in the contained data. Afterwards we make
an error check to ensure that the number of plants and markets is the same in all worksheets.

```csharp
Excel.Worksheet capacity = (Excel.Worksheet)wb.Worksheets.get_Item("capacity");
range = capacity.UsedRange;
Array capacityData = (Array)range.Cells.Value;
int iCount = capacity.UsedRange.Columns.Count;
Excel.Worksheet demand = (Excel.Worksheet)wb.Worksheets.get_Item("demand");
range = demand.UsedRange;
Array demandData = (Array)range.Cells.Value;
int jCount = range.Columns.Count;
Excel.Worksheet distance = (Excel.Worksheet)wb.Worksheets.get_Item("distance");
range = distance.UsedRange;
Array distanceData = (Array)range.Cells.Value;
```

If you have problems to see through the steps above, adding the following output section right after
`wb.Close()` might be helpful to understand where which data is stored.

```csharp
for (int ii = 1; ii <= iCount; ii++)
{
    Console.WriteLine("capacityData(1, " + ii + ") = " + capacityData.GetValue(1, ii));
    Console.WriteLine("capacityData(2, " + ii + ") = " + capacityData.GetValue(2, ii));
}
for (int jj = 1; jj <= jCount; jj++)
{
    Console.WriteLine("demandData(1, " + jj + ") = " + demandData.GetValue(1, jj));
    Console.WriteLine("demandData(2, " + jj + ") = " + demandData.GetValue(2, jj));
}
for (int ii = 1; ii <= iCount; ii++)
{
    for (int jj = 1; jj <= jCount; jj++)
        Console.WriteLine("distanceData(" + (ii+1) + "," + (jj+1) + ") = " + distanceData.GetValue(ii+1, jj+1));
}
```

Now we can create the GAMSWorkspace as usual and afterwards create a GAMSDatabase and fill it with
the workbook data as follows:
GAMSDatabase db = ws.AddDatabase();
GAMSSet Set1 = db.AddSet("i", 1, "Plants");
GAMSSet j = db.AddSet("j", 1, "Markets");
GAMSParameter capacityParam = db.AddParameter("a", 1, "Capacity");
GAMSParameter demandParam = db.AddParameter("b", 1, "Demand");
GAMSParameter distanceParam = db.AddParameter("d", 2, "Distance");
for (int ic = 1; ic <= iCount; ic++)
{/nSet1.AddRecord((string)capacityData.GetValue(1, ic));
capacityParam.AddRecord((string)capacityData.GetValue(1, ic)).Value = (double)capacityData.GetValue(2, ic);
} 
for (int jc = 1; jc <= jCount; jc++)
{/n j.AddRecord((string)demandData.GetValue(1, jc));
demandParam.AddRecord((string)demandData.GetValue(1, jc)).Value = (double)demandData.GetValue(2, jc);
for (int ic = 1; ic <= iCount; ic++)
{/n distanceParam.AddRecord((string)distanceData.GetValue(ic + 1, 1), (string)distanceData.GetValue(1, jc + 1)).Value =
(doule)distanceData.GetValue(ic + 1, 1, (string)distanceData.GetValue(1, jc + 1)).Value =
} }
...
... 
Note that we can name sets and parameters just like in the database but we don't have to. Now we finally
set up the database and can run our GAMSJob as usual.
...
using (GAMSOptions opt = ws.AddOptions())
{/n GAMSJob t10 = ws.AddJobFromString(GetModelText());
opt.Defines.Add("gdxincname", db.Name);
opt.AllModelTypes = "xpress";
t10.Run(opt, db);
foreach (GAMSVariableRecord rec in t10.OutDB.GetVariables("x"))
...

7.7.3.22 How to create and use a save/restart file (Transport11)

In Transport11 we demonstrate how to create and use a save/restart file. Usually such a file should be
supplied by an application provider but in this example we create one for demonstration purpose. Note
that the restart is launched from a GAMSCheckpoint.

In the main function we start with the creation of a folder called tmp that internally is denoted as wDir.
Then we call the function CreateSaveRestart.
...
string wDir = Path.Combine('.', "tmp");
CreateSaveRestart(Path.Combine(wDir, "tbase"));
...

In function CreateSaveRestart we choose the path of the file given as argument as working directory,
so it should be wDir. Then we create a GAMSJob from a string. Note that the string given via
GetBaseModelText() contains the basic definitions of sets without giving them a content (that is what
$onempty is used for). Afterwards we specify a GAMSOption to only compile the job but do not execute
it. Then we create a checkpoint cp that is initialized by the following run of the GAMSJob and stored in
the file given as argument to the function. This becomes possible because the AddCheckpoint method
accepts identifiers as well as file names as argument.
static void CreateSaveRestart(string cpFileName)
{/n GAMSWorkspace ws;
if (Environment.GetCommandLineArgs().Length > 1)
{/n ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName), systemDirectory:
Environment.GetCommandLineArgs()[1]);
else
{/n ws = new GAMSWorkspace(workingDirectory: Path.GetDirectoryName(cpFileName));
GAMSJob j1 = ws.AddJobFromString(GetBaseModelText());
GAMSOptions opt = ws.AddOptions();
opt.Action = GAMSOptions.EAction.CompileOnly;
GAMSCheckpoint cp = ws.AddCheckpoint(Path.GetFileName(cpFileName));
j1.Run(opt, cp);
opt.Dispose();}
So what you should keep in mind before we return to further explanations of the main function is, that now the file base in folder tmp which is denoted as wDir contains a checkpoint. Now in the main function we define some data using C# data structures as we already did in Transport4 before we create the GAMSWorkspace with working directory wDir.

```csharp
GAMSWorkspace ws; if (Environment.GetCommandLineArgs().Length > 1) ws = new GAMSWorkspace(workingDirectory: wDir, systemDirectory: Environment.GetCommandLineArgs()[1]); else ws = new GAMSWorkspace(workingDirectory: wDir);
```

Afterwards we set up the GAMSDatabase like we already did in Transport4. Once this is done we run a GAMSJob using this data plus the checkpoint stored in file base.

```csharp
GAMSCheckpoint cpBase = ws.AddCheckpoint("tbase"); using (GAMSOptions opt = ws.AddOptions())
```

Note that the string from which we create job `t4` is different to the one used to prepare the checkpoint stored in file base and is only responsible for reading in the data from the GAMSDatabase correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

### 7.8 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS C++ API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step. The GAMS distribution comes with a pre compiled binary version of the GAMS C++ API on Windows, Mac OS X and Linux. Furthermore, the C++ API itself and the provided examples are published under MIT license and are hosted at the [GAMS GitHub](https://github.com/gams) organization. Therefore it is possible to compile the library manually (e.g. if a certain compiler is required) The GAMS C++ API is compatible with C++ 11 and is implemented using the [Qt framework](https://www.qt.io).

- **Getting Started** A quick introduction about how to create and configure a C++ project using Qt Creator
- **Important Classes of the API** Overview of some fundamental classes of the GAMS C++ API
- **How to use API** An extensive set of examples how to use API components

### 7.8.1 Getting Started

This section guides you through the basic steps of compiling and running a program from scratch using either [Qt Creator](http://qt-project.org) or [Microsoft Visual Studio](http://www.visualstudio.com). If you want to have a look at the API itself you can directly start with the How to use API section instead. Note that you need to use at least C++ 11 in order to be able to use the GAMS C++ API. While this tutorial uses Qt Creator and Microsoft Visual Studio, other IDE's can be used as well.

**Note**

When using the pre compiled binary distribution of the GAMS C++ API as done in this section, one needs to use a compiler that is compatible with the one that was used during compilation of the library. Depending on the platform, different versions of the prebuilt binaries can be found under `<GAMS system directory>/apifiles/C++/lib`. In GAMS versions before 25.0 the binaries can be found under `<GAMS system directory>`.
7.8.1.1 Getting Started using Qt Creator

After opening Qt Creator click on File > New File or Project. Choose Qt Console Application and click on Choose.... On the next page fill in the name and the location of the new project and click Next. Select the kits you want to use for the project and click on Next. If you use the precompiled library on Windows, you need to use MSVC2015 or MSVC2017. Confirm the creation of the new project by clicking on Finish.

As soon as the project is created open the file GAMSApplication.pro by double clicking on it in the pane on the left hand side. Add the following two lines to the .pro file:

```plaintext
unix : LIBS += -ldl -L$$HOME)/gams32.0
win32: LIBS += -L\GAMS\win64\32.0\apifiles\C++\lib\vs2017 -lgamscpp
```

Note
Depending on your operating system and the location of your GAMS system you need to adjust the paths respectively. Furthermore, all pre build binaries are always located at `<GAMS system directory>\apifiles\C++\lib`, if GAMS 25.0 (or higher) is used. This location may contain additional sub directories, like `<GAMS system directory>\apifiles\C++\lib\vs2017`. In case a previous version of GAMS is used the binaries are located at `<GAMS system directory>`.

Save the changes, right click on the project and choose Run qmake.

The last step of creating a first small example is to write code that makes use of the GAMS C++ API. Open the file main.cpp and replace the content of the file with the following lines of code:

```plaintext
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[]) {
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << "): level=" << rec.level() << " marginal=" << rec.marginal() << endl;
}
```

Make sure that MSVC2017 64bit is chosen as kit using the Release mode.

Click on the play button below to run (and compile) the small example. If everything works, you should see the output of the example displaying results of the solved transportation problem.

7.8.1.2 Getting Started using Visual Studio 2017

After opening Visual Studio click on File > New > Project .... Choose Console App and fill in the name and the location of the project and click on Ok.

As soon as the project is loaded, open the Configuration Manager:

Change the Active solution configuration to Release and the Active solution platform to x64.

The next step is to configure the project to find the GAMS C++ API. Right click on the project and choose Properties from the context menu. Go to Configuration Properties > C/C++ > General and add `<GAMS system directory>\apifiles\C++\api` to Additional Include Directories.

Select Configuration Properties > C/C++ > Precompiled Headers on the left. On the right open the dropdown of Precompiled Header and select Not Using Precompiled Header.

Go to Configuration Properties > Linker > General and add the apifiles path to the matching version of your Visual Studio (e.g. `<GAMS system directory>\apifiles\C++\lib\vs2017`) to Additional Library Directories:
Note

Please mind that the pre build binaries for older GAMS versions (before GAMS 25.0) are located at `<GAMS system directory>`.

Choose Input and add `gamscpp.lib` to Additional Dependencies. Make sure that all previous entries including `%{AdditionalDependencies}` are present as well.

The last required configuration step is to add a post-build event that copies required files next to the generated executable. Click on Build Events > Post-Build Event and add the following code to Command Line. It is helpful to select <Edit...> from the dropdown box as there are two command lines. Note that you might need to adjust the used path depending on the location of your GAMS installation:

```
xcopy /Y "C:\gams\win64\32.0\apifiles\C++\lib\vs2017\gamscpp.dll" "$\{OutDir\}"
xcopy /Y "C:\gams\win64\32.0\apifiles\C++\lib\vs2017\Qt*.dll" "$\{OutDir\}"
```

Open the file `GAMSApplication.cpp` and replace its content by the following code:

```cpp
#include "gams.h"
#include <iostream>
using namespace gams;
using namespace std;
int main(int argc, char* argv[]) {
    GAMSWorkspace ws;
    ws.gamsLib("trnsport");
    // create a GAMSJob from file and run it with default settings
    GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
    t1.run();
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << ")": level=" << rec.level() << " marginal=" << rec.marginal() << endl;
}
```

Click on Debug > Start Without Debugging in order to compile and run the example. If everything works, you should see the output of the example displaying results of the solved transportation problem.

### 7.8.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the gams namespace. Their usage is demonstrated by an extensive set of examples.

- **gams** Namespace
- **gams::GAMSWorkspace** Class
- **gams::GAMSJob** Class
- **gams::GAMSDatabase** Class
- **gams::GAMSOptions** Class
- **gams::GAMSMModelInstance** Class
- **gams::GAMSSymbol** Class
7.8.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the C++ API. `<GAMS system directory>\apifiles\C++` contains the Qt project `examples.pro` and several Visual Studio solutions for different versions of Visual Studio (e.g. `examples-vs2015.sln`, `examples-vs2017.sln`). The code snippets that are explained in this tutorial are taken from these examples. Furthermore there is a `CMakeLists.txt` file that can be used for building the examples using CMake. The well-known transportation problem is discussed step by step and each example introduces new elements of the GAMS C++ API.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)
- How to import data from GDX (TransportGDX)
- How to run a GAMSJob from file (Transport1)
- How to specify the solver (Transport1)
- How to run a job with a solver option file (Transport1)
- How to use include files (Transport2)
- How to read data from string and export to GDX (Transport3)
- How to run a job using data from GDX (Transport3)
- How to run a job using implicit database communication (Transport3)
- How to define data using C++ data structures (Transport4)
- How to prepare a GAMSDatabase from C++ data structures (Transport4)
- How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
- How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
- How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
- How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
- How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)
- How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)
- How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
- How to fill a GAMSDatabase by reading from MS Access (Transport9)
- How to fill a GAMSDatabase by reading from MS Excel (Transport10)
- How to create and use a save/restart file (Transport11)
7.8 Tutorial

7.8.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on
your machine, the desired system can be specified via an additional argument when the workspace is created.
When running the examples, we can provide an additional command line argument in order to define the
GAMS system directory that should be used. By executing Transport1.exe with C:/GAMS/win64/35.2
we use the 64-bit version of GAMS 35.2 to run Transport1 even if our default GAMS system might be a
different one. This is managed by the following code:

```cpp
... 
GAMSWorkspaceInfo wsInfo;
if (argc > 1)
    wsInfo.setSystemDirectory(argv[1]);
GAMSWorkspace ws(wsInfo);
... 
```

Remember that the bitness of the GAMS system has to match the bitness of your C++ program.

7.8.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented C++ API offers much more than exchanging data between C++ and
GDX, a common use case is the export and import of GDX files. The central class for this purpose is
GAMSDatabase. We assume that the data to be exported is available in C++ data structures.

```cpp
vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    {"Seattle", 350.0 }, {"San-Diego", 600.0 }
};
map<string, double> demand = {
    {"New-York", 325.0 }, {"Chicago", 300.0 }, {"Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
    {make_tuple("Seattle", "New-York"), 2.5 },
    {make_tuple("Seattle", "Chicago"), 1.7 },
    {make_tuple("Seattle", "Topeka"), 1.8 },
    {make_tuple("San-Diego", "New-York"), 2.5 },
    {make_tuple("San-Diego", "Chicago"), 1.8 },
    {make_tuple("San-Diego", "Topeka"), 1.4 }
};
... 
```

Different GAMS symbols are represented using different C++ data structures. The data for the GAMS
sets is represented using vectors of strings (e.g. `plants` and `markets`). On the other hand, GAMS
parameters are represented by maps (e.g. `capacity` and `demand`). Note that the representation of the
two dimensional parameter `distance` uses tuples for storing the keys. The choice of data structures can
also be different, but the used structures in this example fit well for representing GAMS data with C++
data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.

```cpp
... // create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();
... 
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the
dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through
`plants` and adds new records to the recently created GAMSSet instance `i` using `GAMSSet.addRecord`.

```cpp
// add 1-dimensional set 'i' with explanatory text 'canning plants' to the GAMSDatabase
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
... 
```

GAMSParameter instances can be added by using the method `GAMSDatabase.addParameter`. It has the
same signature as `GAMSDatabase.addSet`. Anyhow, in this example we use an overload of the method
which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```java
// add parameter 'a' with domain 'i'
GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
```

As soon as all data is prepared in the GAMSDatabase, the method GAMSDatabase.doExport can be used to create a GDX file.

```java
// export the GAMSDatabase to a GDX file with name 'data.gdx' located in the 'workingDirectory' of the GAMSWorkspace
db.doExport("data.gdx");
```

### 7.8.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```java
// add a new GAMSDatabase and initialize it from the GDX file just created
GAMSDatabase db2 = ws.addDatabaseFromGDX("data.gdx");
```

Reading the data from the GAMSSet `i` into a vector can be done as follows:

```java
// read data from symbols into C++ data structures
vector<string> iNew;
for (GAMSSetRecord rec : db2.getSet("i"))
    iNew.push_back(rec.key(0));
```

A new vector `iNew` is created. `i` is retrieved by calling `GAMSDatabase.getSet` on `db2`. The returned GAMSSet object can be iterated using a for-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameters. Instead of creating a vector, we want to have the data in the form of a map. GAMSParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter `a` into a `map<string, double>`.

```java
map<string, double> aNew;
for (GAMSParameterRecord rec : db2.getParameter("a"))
    aNew[rec.key(0)] = rec.value();
```

For multi dimensional symbols, we choose the map keys to be tuples instead of string. We access the individual keys by index and generate a tuple using `make_tuple`.

```java
map<tuple<string, string>, double> dNew;
for (GAMSParameterRecord rec : db2.getParameter("d"))
    dNew[make_tuple(rec.key(0), rec.key(1))] = rec.value();
```

Scalars can be read into a variable of type double by accessing the value of the first and only record.

```java
double fNew = db2.getParameter("f").firstRecord().value();
```
7.8.3.4 How to run a GAMSJob from file (Transport1)

At first we create a GAMSWorkspace. Afterwards we load the model trnsport from the GAMS Model Library. In doing so it is made available in the current working directory and can be loaded by the GAMSWorkspace. AddJobFromFile Method afterwards. Apparently this method also works with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GAMSJob t1 is defined from that file and run by the GAMSJob.run method. The following lines create the solution output and illustrate the usage of the GAMSJob.outDB method to get access to the GAMSDatabase created by the run method. To retrieve the content of variable x we use the GAMSVariableRecord class and the GAMSDatabase.getVariable method.

```c++
GAMSWorkspace ws;
ws.gamsLib("trnsport");
// create a GAMSJob from file and run it with default settings
GAMSJob t1 = ws.addJobFromFile("trnsport.gms");
// Default run
    t1.run();
    cout << "Ran with Defaults:" << endl;
    for (GAMSVariableRecord rec : t1.outDB().getVariable("x"))
        cout << "x(" << rec.key(0) << "," << rec.key(1) << ")": " level=" << rec.level() << ", " marginal=" << rec.marginal()
            << endl;
...
```

7.8.3.5 How to specify the solver (Transport1)

The solver can be specified via the GAMSOptions class and the GAMSWorkspace.addOptions method. The GAMSOptions.setAllModelTypes method sets xpress as default solver for all model types which the solver can handle.

```c++
// Run the job again with another solver
GAMSOptions opt = ws.addOptions();
    opt.setAllModelTypes("xpress");
    t1.run(opt);
...
```

7.8.3.6 How to run a job with a solver option file (Transport1)

At first create the file xpress.opt with content algorithm=barrier which will be used as solver option file and is stored in the current working directory. We choose xpress as solver just like in the preceding example and call GAMSOptions.setOptFile in order to tell the solver to look for a solver option file.

```c++
// Run the job with a solver option file
ofstream xpressopt(ws.workingDirectory() + cPathSep + "xpress.opt");
    xpressopt << "algorithm=barrier" << endl;
    xpressopt.close();
    opt.setAllModelTypes("xpress");
    opt.setOptFile(1);
    t1.run(opt);
...
```

7.8.3.7 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings provided by the methods getDataText and getModelText are using GAMS syntax.

At first we write an include file tdata.gms that contains the data but not the model text:

```c++
ofstream tdata(ws.workingDirectory() + cPathSep + "tdata.gms");
tdata << getDataText();
tdata.close();
```
Afterwards we create a \texttt{GAMSJob} using the \texttt{GAMSWorkspace.addJobFromString} method. The \texttt{GAMSOptions.setDefine} method is used like the 'double dash' GAMS parameters, i.e. it corresponds to \texttt{--incname=tdata} on the command line.

\begin{verbatim}
GAMSOptions opt = ws.addOptions();
GAMSJob t2 = ws.addJobFromString(getModelText());
opt.setDefine("incname", "tdata");
t2.run(opt);
\end{verbatim}

Note that the string provided by \texttt{getModelText} contains the following lines to read in the data.

\begin{verbatim}
$if not set incname $abort 'no include file name for data file provided'
$include $incname$
\end{verbatim}

\subsection*{7.8.3.8 How to read data from string and export to GDX (Transport3)}

We read the data from the string provided by \texttt{getDataText} as we did in the preceding example. Note that this contains no solve statement but only data definition in GAMS syntax. By running the corresponding \texttt{GAMSJob} a \texttt{GAMSDatabase} is created that is available via the \texttt{GAMSJob.outDb} method. We can use the \texttt{GAMSDatabase.doExport} method to write the content of this database to a gdx file \texttt{tdata.gdx}.

\begin{verbatim}
// data from a string with GAMS syntax with explicit export to GDX file
GAMSJob t3 = ws.addJobFromString(getDataText());
t3.run();
t3.outDB().doExport(ws.workingDirectory() + cPathSep + "tdata.gdx");
\end{verbatim}

\subsection*{7.8.3.9 How to run a job using data from GDX (Transport3)}

This works quite similar to the usage of an include file explained in \texttt{Transport2 - How to use include files (Transport2)}.

\begin{verbatim}
t3 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", "tdata");
opt.setAllModelTypes("xpress");
t3.run(opt);
\end{verbatim}

Note that there are some changes in \texttt{getModelText} due to the usage of a GDX file instead of an include file.

\begin{verbatim}
$if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
\end{verbatim}

\subsection*{7.8.3.10 How to run a job using implicit database communication (Transport3)}

This example does basically the same as the two preceding examples together. We create two \texttt{GAMSJobs} \texttt{t3a} and \texttt{t3b} where the first one contains only the data and the second one contains only the model without data. After running \texttt{t3a} the corresponding \texttt{outDB} can be read in directly just like a gdx file. Note that the database needs to be passed to the \texttt{GAMSJob.run} method as additional argument.

\begin{verbatim}
GAMSJob t3a = ws.addJobFromString(getDataText());
GAMSJob t3b = ws.addJobFromString(getModelText());
t3a.run();
opt.setDefine("gdxincname", t3a.outDB().name());
t3b.run(opt, t3a.outDB());
\end{verbatim}
7.8 Tutorial

7.8.3.11 How to define data using C++ data structures (Transport4)

We use the vector<T> and map<Key, Value> to define C++ data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```cpp
vector<string> plants = {
    "Seattle", "San-Diego"
};
vector<string> markets = {
    "New-York", "Chicago", "Topeka"
};
map<string, double> capacity = {
    { "Seattle", 350.0 }, { "San-Diego", 600.0 }
};
map<string, double> demand = {
    { "New-York", 325.0 }, { "Chicago", 300.0 }, { "Topeka", 275.0 }
};
map<tuple<string, string>, double> distance = {
    make_tuple("Seattle", "New-York", 2.5),
    make_tuple("Seattle", "Chicago", 1.7),
    make_tuple("Seattle", "Topeka", 1.8),
    make_tuple("San-Diego", "New-York", 2.5),
    make_tuple("San-Diego", "Chicago", 1.8),
    make_tuple("San-Diego", "Topeka", 1.4)
};
```

7.8.3.12 How to prepare a GAMSDatabase from C++ data structures (Transport4)

At first we create an empty GAMSDatabase db using the GAMSWorkspace.addDatabase method. Afterwards we prepare the database. To add a set to the database we use the GAMSSet class and the GAMSDatabase.addSet method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our C++ data structure and add them by using the GAMSSet.addRecord method. We do pretty much the same thing for the parameters.

Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that the scalars can be treated as parameter with dimension 0.

The GAMSJob can be run like explained in the preceding example about implicit database communication.

```cpp
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for (string p: plants)
    i.addRecord(p);
...
GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (string p: plants)
    a.addRecord(p).setValue(capacity[p]);
...
GAMSParameter d = db.addParameter("d", "distance in thousands of miles", i, j);
for (auto t : distance)
    d.addRecord(get<0>(t.first), get<1>(t.first)).setValue(t.second);
GAMSParameter f = db.addParameter("f", "freight in dollars per case per thousand miles");
f.addRecord().setValue(90);
// run a job using data from the created GAMSDatabase
GAMSJob t4 = ws.addJobFromString(getModelText());
GAMSOptions opt = ws.addOptions();
opt.setDefine("gdxincname", db.name());
opt.addAllModelTypes("xpress");
t4.run(opt, db);
```

7.8.3.13 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following two lines of code conduct several operations. While the first line simply creates a GAMS checkpoint, the second one uses the GAMSWorkspace.addJobFromSring method to create a GAMSJob containing the model text and data but no solve statement. In contrast to the preceding examples it runs the job immediately using the GAMSJob.run method. Furthermore, it passes an additional checkpoint argument to the run method. That means the GAMSCheckpoint cp captures the state of the GAMSJob.

```cpp
GAMSCheckpoint cp = ws.addCheckpoint();
...
ws.addJobFromString(getModelText()).run(cp);
```
7.8.3.14 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function `getModelText()` contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```plaintext
Scalar bmult demand multiplier /1/;

... demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;

Scalar ms 'model status', ss 'solve status';
```

We create a vector with eight different values for this demand multiplier.

```plaintext
vector<double> bmultlist = {0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3};
```

For each entry of the vector we create a GAMSJob `t5` using the `GAMSWorkspace.addJobFromString` method. Besides the string which resets the demand multiplier `bmult`, specifies the solve statement and assigns values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a GAMSJob combined from the checkpoint plus the content provided by the string.

We run the GAMSJob and echo some interesting data from the `outDB` using the `GAMSDatabase.getParameter` and `GAMSDatabase.getVariable` methods, the `GAMSParameter.findRecord` and `GAMSVariable.findRecord` methods plus the `GAMSParameterRecord.value` and the `GAMSVariableRecord.level` methods.

```plaintext
... for (double b : bmultlist)
    {
        GAMSJob t5 = ws.addJobFromString("bmult" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;", cp);
        t5.run();
        cout << "Scenario bmult" << b << ": " << endl;
        cout << " Modelstatus: " << t5.outDB().getParameter("ms").findRecord().value() << endl;
        cout << " Solvestatus: " << t5.outDB().getParameter("ss").findRecord().value() << endl;
        cout << " Obj: " << t5.outDB().getVariable("z").findRecord().level() << endl;
    }
...  
```

Note

Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

7.8.3.15 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)

This example illustrates how to run the jobs we already know from Transport5 in parallel. We create a GAMSCheckpoint `cp` and initialize it by running a GAMSJob. Furthermore we introduce a demand multiplier as we did before.

```plaintext
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromString(getModelText()).run(cp);
vector<double> bmultlist = {0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3};
```

Furthermore, we introduce a new object `ioMutex` that will be used to avoid mixed up output from the parallel jobs. For each element `b` from the vector of demand multipliers we create a thread executing the `runScenario` method.

```plaintext
// run multiple parallel jobs using the created GAMSCheckpoint
mutex ioMutex;
vector<thread> v;
for (double b : bmultlist)
    v.emplace_back([&ws, cp, &ioMutex, b] { runScenario(&ws, cp, &ioMutex, b); });
for (auto & t : v)
    t.join();
```
In function runScenario a GAMSJob is created and run just like in the preceding example of Transport5. The output section is also the same except for the fact that it is locked by using a lock_guard on the ioMutex. That means the threads of runScenario are running in parallel but the output block of different threads cannot be executed in parallel since it is locked using the same ioMutex.

```cpp
... void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat; ", cp);
    t6.run();
    // we need to make the output a critical section to avoid messed up report information
    lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << " Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
...```

While the output in Transport5 is strictly ordered subject to the order of the elements of bmultlist, in Transport6 the output blocks might change their order but the blocks describing one scenario are still appearing together due to the lock_guard mechanism.

If you want a further impression of the impact of the lock_guard, just rerun Transport6 but comment out the lock_guard as follows and compare the output.

```cpp
... void Transport6::runScenario(GAMSWorkspace* ws, const GAMSCheckpoint& cp, mutex* ioMutex, double b)
{
    auto t6 = ws->addJobFromString("bmult=" + to_string(b) + "; solve transport min z use lp; ms=transport.modelstat;
    ss=transport.solvestat; ", cp);
    t6.run();
    // we need to make the output a critical section to avoid messed up report information
    // lock_guard<mutex> lck(*ioMutex);
    cout << "Scenario bmult=" << b << ":" << endl;
    cout << " Modelstatus: " << t6.outDB().getParameter("ms").findRecord().value() << endl;
    cout << " Solvestatus: " << t6.outDB().getParameter("ss").findRecord().value() << endl;
    cout << " Obj: " << t6.outDB().getVariable("z").findRecord().level() << endl;
}
...```

### 7.8.3.16 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In Transport7 the usage of gams::GAMSModelInstance is demonstrated.

At first we create a checkpoint cp as in the preceding examples. Then we create the GAMSModelInstance mi using the GAMSCheckpoint.addModelInstance method. Note that the GAMSJob again contains no solve statement and the demand multiplier is already included with default value 1.

```cpp
GAMSCheckpoint cp = ws.addCheckpoint();
GAMSJob t7 = ws.addJobFromString(getModelText());
t7.run(cp);
GAMSModelInstance mi = cp.addModelInstance();
...```

### 7.8.3.17 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A GAMSModelInstance uses a syncDB to maintain the data. We define bmult as GAMSParameter using the GAMSDatabase.addParameter method and specify cplex as solver. Afterwards the GAMSModelInstance is instantiated with three arguments: the solve statement, the GAMSOptions object opt and bmult. The GAMSModifier means that bmult is modifiable while all other parameters, variables and equations of GAMSModelInstance mi stay unchanged.

We use the GAMSParameter.addRecord method to assign a value to bmult that can be varied afterwards using the GAMSParameter.firstRecord method to reproduce our well-known example with different demand multipliers.

```cpp
...```
GAMSModelInstance mi = cp.addModelInstance();
GAMSParameter bmult = mi.syncDb().addParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("cplex");
// instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
bmult.addRecord().setValue(1.0);
vector<double> bmultlist = { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
for (double b : bmultlist) {
bmult.firstRecord().setValue(b);
m.solve();
cout << "Scenario bmult" << b << " modelStatus: " << mi.modelStatusAsString() << endl;
cout << " Modelstatus: " << mi.modelStatusAsString() << endl;
cout << " Solvestatus: " << mi.solveStatusAsString() << endl;
cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
}

7.8.3.18 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a GAMSModelInstance and define x as GAMSVariable and its upper bound as GAMSParameter xup. At the following instantiate method GAMSModifier has three arguments. The first one says that x is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

... 
mi = cp.addModelInstance();
GAMSvariable x = mi.syncDb().addVariable("x", 2, GAMSEnum::VarType::Positive, "");
GAMSParameter xup = mi.syncDb().addParameter("xup", 2, "upper bound on x");
// instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare upper bound of X mutable
mi.instantiate("transport use lp min z", GAMSModifier(x, GAMSEnum::SymbolUpdateAction::Upper, xup));
for (GAMSSetRecord i : t7.outDB().getSet("i")) {
for (GAMSSetRecord j : t7.outDB().getSet("j")) {
xup.clear();
xup.addRecord(i.key(0), j.key(0)).setValue(0);
mi.solve();
cout << "Scenario link blocked" << i.key(0) << "-" << j.key(0) << endl;
cout << " Modelstatus: " << mi.modelStatusAsString() << endl;
cout << " Solvestatus: " << mi.solveStatusAsString() << endl;
cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
}
... 

7.8.3.19 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint cp from a GAMSJob. Then we define a vector that represents the different values of the demand multiplier. While ioMutex is used to avoid messed up output, vectorMutex synchronizes the access to the vector. Then we start multiple thread executing the method scenSolve. The number of parallel executed threads is specified by nrThreads. All threads share the same vector that provides the different values for bmult.

... 
GAMSCheckpoint cp = ws.addCheckpoint();
ws.addJobFromText(getModelText()).run(cp);
vector<double> bmultVector = { 1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6 };
int nrThreads = 2;
std::mutex vectorMutex;
std::mutex ioMutex;
vector[thread] v;
for (int i = 0; i < nrThreads; i++)
  v.emplace_back([&ws, &cp, &bmultVector, &vectorMutex, &ioMutex] { scenSolve(&ws, &cp, &bmultVector, &vectorMutex, &ioMutex); });
for (auto & t : v)
t.join();
...
In `scenSolve` we create and instantiate a `GAMSModelInstance` as in the preceding examples and make `bmult` modifiable. As long as `bmultVector` is not empty, an elements is taken and removed from the `vector`. The value is used for the scalar `bmult`. Note that we chose `cplex` as solver because it is thread safe (gurobi would also be possible). Once the `vector` is empty the loop terminates.

```c++
void Transport8::scenSolve(GAMSWorkspace* ws, GAMSCheckpoint* cp, vector<double>* bmultVector, std::mutex* vectorMutex, 
std::mutex* ioMutex)
{
    unique_lock<mutex> vectorLock(*vectorMutex);
    GAMSModelInstance mi = cp->addModelInstance();
    vectorLock.unlock();
    GAMSParameter bmult = mi.syncDb().addParameter("bmult", "demand multiplier");
    GAMSOptions opt = ws->addOptions();
    opt.setAllModelTypes("cplex");
    // instantiate the GAMSModelInstance and pass a model definition and GAMSModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", opt, GAMSModifier(bmult));
    bmult.addRecord().setValue(1.0);
    while (true)
    {
        double b;
        // dynamically get a bmult value from the vector instead of passing it to the different threads at creation time
        vectorLock.lock();
        if (bmultVector->empty())
            return;
        b = bmultVector->back();
        bmultVector->pop_back();
        vectorLock.unlock();
        bmult.firstRecord().setValue(b);
        mi.solve();
        // we need to make the output a critical section to avoid messed up report informations
        unique_lock<mutex> ioLock(*ioMutex);
        cout << "Scenario bmult=" << b << ":" << endl;
        cout << " Modelstatus: " << mi.modelStatus() << endl;
        cout << " Solvestatus: " << mi.solveStatus() << endl;
        cout << " Obj: " << mi.syncDb().getVariable("z").findRecord().level() << endl;
        ioLock.unlock();
    }
}
```

### 7.8.3.20 How to fill a `GAMSDatabase` by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a `GAMSDatabase`. It can only be run on Windows since it makes use of the Microsoft Access Driver. Furthermore the example makes use of the Qt SQL module. Note that you need to have Microsoft Access installed and that its bitness needs to match the bitness of your GAMS version. In the example we call a function `readFromAccess` that finally returns a `GAMSDatabase` as shown below.

```c++
GAMSDatabase db = readFromAccess(ws);
...
```

The data we are going to read can be found in `<GAMS system directory>\apifiles\Data\transport.accdb`. It might be helpful to open this file for a better understanding. The function begins with the creation of an empty `GAMSDatabase`. Afterwards we create a `QSqlDatabase`, specify the connection string and open the connection to the database. If opening the connection was successful, data is read from the database into the `GAMSDatabase` using the methods `readSet` and `readParameter`.

```c++
GAMSDatabase readFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    QString strAccessConn = QSL("Driver={Microsoft Access Driver (*.mdb, *.accdb)};DBQ=" + ws.systemDirectory() \ 
    + cPathSep + "apifiles" + cPathSep + "Data" + cPathSep + "transport.accdb").c_str();
    if(!sqlDb.open())
    {
        cout << "Error: Failed to create a database connection. " << sqlDb.lastError().text().toStdString() << endl;
        exit(1);
    }
    else
    {
        cout << "Error: Failed to create a database connection. " << sqlDb.lastError().text().toStdString() << endl;
        exit(1);
    }
    // read GAMS sets
    readSet(sqlDb, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
    readSet(sqlDb, db, "SELECT Market FROM Market", "j", 1, "markets");
    // read GAMS parameters
    readParameter(sqlDb, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
    readParameter(sqlDb, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
    readParameter(sqlDb, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
    sqlDb.close();
}
```
The function \texttt{readSet} creates a \texttt{QSqlQuery} that reads data from a table of the Access database. A \texttt{GAMSSet} is created and populated with the data.

\begin{verbatim}
void readSet(QSqlDatabase sqlDb, GAMSDatabase db, string strAccessSelect, string setName, int setDim, string setExp = "")
{
    QSqlQuery query(sqlDb);
    if (!query.exec(strAccessSelect.c_str()))
        cout << "Error executing query on set '" << setName << "'" << endl;
    cout << query.lastError().text().toStdString() << endl;
    exit(1);
    if (query.size() && (query.record().count() != setDim))
        cout << "Number of fields in select statement does not match setDim" << endl;
    exit(1);
    GAMSSet i = db.addSet(setName, setDim, setExp);
    vector<string> keys = vector<string>(setDim);
    while (query.next())
    {
        for (int idx = 0; idx < setDim; idx++)
            keys[idx] = query.value(idx).toString().toStdString();
        i.addRecord(keys);
    }
}
\end{verbatim}

Once we read in all the data we can create a \texttt{GAMSJob} from the \texttt{GAMSDatabase} and run it as usual. Finally the results are written to \texttt{transport.accdb}.

7.8.3.21 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from \texttt{<GAMS system directory>}\textbackslash\apifiles\Data\transport.xls. It can only be run on Windows. Note that you need to have Microsoft Excel installed and that its bitness needs to match the bitness of your GAMS version. The model is given as string without data like in in many examples before. At first we have to add

\begin{verbatim}
#include <QAxObject>
#include <Windows.h>
\end{verbatim}

to be able to use the \texttt{QAxObject} class, which serves as a wrapper for COM objects. Furthermore we include \texttt{Windows.h} to access the functions \texttt{CoInitialize} and \texttt{CoUninitialize}. In the main function we open the aforementioned file to get access to its content. Note that we need to call \texttt{CoInitialize(0)} first in order to initialize \texttt{ActiveX}. We create an instance of the class \texttt{QAxObject} and use the \texttt{querySubObject} method multiple times to get to the sheets of the workbook.

\begin{verbatim}
QAxObject* excel = new QAxObject( "Excel.Application", 0 );
QAxObject* workbooks = excel->querySubObject( "Workbooks" );
QAxObject* workbook = workbooks->querySubObject( "Open(const QString&)", fileName );
QAxObject* sheets = workbook->querySubObject( "Worksheets" );
\end{verbatim}

The method \texttt{sheetToParameter} is used in order to transfer data from the workbook into \texttt{GAMSParameter} instances. In order to determine from which sheet the actual data needs to be read, the method takes the \texttt{QAxObject} instance referring to the sheets and the actual sheet name. A new \texttt{GAMSParameter} is added to the \texttt{GAMSDatabase} object \texttt{db} using \texttt{set1} and \texttt{set2} as domains. The next step is to determine the number of columns and the number of rows used. The \texttt{for} loop reads the actual data, adds the records to the new \texttt{GAMSParameter} and sets their values.

\begin{verbatim}
GAMSParameter sheetToParameter(QAxObject* sheets, string sheetName, GAMSDatabase db, string paramName, string paramText,
                                GAMSSet set1, GAMSSet set2)
{
    QAxObject* sheet = sheets->querySubObject( "Item( string )", sheetName.c_str() );
    vector<GAMSDomain> sets { set1, set2 };
    GAMSParameter param = db.addParameter(paramName, paramText, sets);
    QAxObject* columns = sheet->querySubObject("Columns");
    int intCols = columns->property("Count").toInt();
    QAxObject* rows = sheet->querySubObject("Rows");
    int intRows = rows->property("Count").toInt();
    ...
for (int j = 2; j <= intCols; j++)
    string namej = sheet->querySubObject("Cells( int, int )", 1, j)->dynamicCall("Value()").toString().toStdString();
for (int i = 2; i <= intRows; ++i)
    string namei = sheet->querySubObject("Cells( int, int )", i, 1)->dynamicCall("Value()").toString().toStdString();
GAMSParameterRecord rec = param.addRecord(namei, namej);
double value = sheet->querySubObject("Cells( int, int )", i, j)->dynamicCall("Value()").toDouble();
rec.setValue(value);
}
return param;
}

After all required data was read from the workbook, we need to close it and quit the Excel application.
...
workbook->dynamicCall("Close()");
excel->dynamicCall("Quit()");
...

Now we can create und run the GAMSJob using the created GAMSDatabase as usual.

GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(getModelText());
opf.define("gdxincname", db.name());
opf.setAllModelTypes("xpress");
t10.run(opt, db);
for (GAMSVariableRecord record : t10.outDB().getVariable("x"))
  cout << "x(" << record.key(0) << "," << record.key(1) << ": level=" << record.level() << " marginal=" << record.marginal() << endl;
...

Finally we need to call 'CoUninitialize' in order to close the COM library.
...::CoUninitialize();
...

7.8.3.22 How to create and use a save/restart file (Transport11)

In Transport11 we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GAMSCheckpoint. We start by creating the save/restart file by calling createSaveRestart.
...
std::string cpName = "tbase";
createSaveRestart(argc, argv, cpName);
...

In function createSaveRestart we choose the checkpointName as relative path to the current directory in order to create a GAMSWorkspace. Then we create a GAMSJob from a string. Note that the string given via getBaseModelText() contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a GAMSOption to only compile the job without executing it. Then we create a checkpoint cp that is initialized by the following run of the GAMSJob and stored in the file given as argument to the function. This becomes possible because the addCheckpoint method accepts identifiers as well as file names as argument.

So what you should keep in mind before we return to further explanations of the main function is, that now the file tbase in folder tbase contains a checkpoint. Now in the main function we define some data using C++ data structures as we already did in Transport4 before we create another GAMSWorkspace.
Afterwards we set up the GAMSDatabase like we already did in Transport4. Once this is done we run a GAMSJob using this data plus the checkpoint stored in file tbase.

Note that the string from which we create job t4 is different to the one used to prepare the checkpoint stored in tbase and is only responsible for reading in the data from the GAMSDatabase correctly. The entire model definition is delivered by the checkpoint cpBase which is equal to the one we saved in tbase.

7.8.4 How to use the pre configured example projects

Depending on the operating system, the GAMS C++ API comes with example project configurations for different development tools like CMake, qmake and Visual Studio. They provide an easy way of building and running the distributed GAMS C++ examples and are located in <GAMS system directory>/apifiles/C++.

7.8.4.1 CMake

Windows:

Create build directory

cd <GAMS system directory>/apifiles/C++
mkdir build & cd build

Run CMake and build project

cmake -G "Visual Studio 15 2017 Win64" -config Release -DVSVERSION:STRING=vs2017 ..
msbuild.exe examples.sln /p:Configuration=Release

Note

For other Visual Studio versions, the generator-name (-G) needs to be adjusted (see cmake documentation).

All generated executables can now be found in the CMake build directory. The exact path depends on the project name and the config setting. Assuming the solution was build with -config Release, a transport1.exe executable is located in <GAMS system directory>/apifiles/C++/build/transport1/Release.

Therefore you can use the following commands to execute the transport1 example:In order to execute an example (e.g. transport1) run the following commands:
cd transport1\Release
set PATH=%PATH%;<GAMS system directory>\apifiles\C++\lib\vs2017
transport1.exe

Linux:

Create build directory

cd <GAMS system directory>/apifiles/C++
mkdir build & cd build

Run CMake and build project

  cmake ..
  make

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

cd transport1
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<GAMS system directory>/apifiles/C++/lib
./transport1

Mac OS X:

Create build directory

cd <GAMS system directory>/apifiles/C++
mkdir build & cd build

Run CMake and build project

  cmake ..
  make

All generated executables can now be found in the CMake build directory. For every project a subdirectory is created. Assuming you want to execute the transport1 example, use the following commands:

cd transport1
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:<GAMS system directory>/apifiles/C++/lib
./transport1
7.8.4.2 qmake

Building the examples can be done by using Qt Creator. Open `<GAMS system directory>\apifiles\C++\examples.pro` with Qt Creator. After the project is loaded, click on Build > Build All in order to compile and link the project. After the build process has carried out, select a subproject and click on Build > Run in order to execute the chosen example.

Alternatively you can run qmake using the command line.

**Windows:**

Create build directory

```
cd <GAMS system directory>\apifiles\C++
mkdir build & cd build
```

Run qmake and build project

```
qmake ..\examples.pro VSVERSION=vs2017
nmake
```

**Note**

For other supported Visual Studio versions change the value of VSVERSION.

All generated executables can now be found in the qmake output directory. In order to execute an example (e.g. transport1) run the following commands:

```
cd ..\bin
set PATH=%PATH%;<GAMS system directory>\apifiles\C++\lib\vs2017
transport1.exe
```

**Linux and Mac OS X:**

In order to run qmake on Linux and Mac OS X refer to the description of using CMake above and call qmake instead of cmake.

7.8.4.3 Microsoft Visual Studio

The Visual Studio solutions are available for Windows only. Open the solution file that matches the version of your Visual Studio installation (e.g. `<GAMS system directory>\apifiles\C++\examples-vs2017.sln`).

As soon as the solution is loaded, click on Build > Configuration Manager and adjust the Active solution configuration and the Active solution platform. The solution configuration needs to be set to Release for using the distributed binaries of the GAMS C++ API. Note that the platform needs to match the version of your GAMS installation.

The examples Transport9 and Transport10 require a Qt installation. If you do not have one, you need to disable these projects. Right click on a project in the Solution Explorer and choose Unload Project from the context menu.

Click on Build > Build Solution in order to compile and link the examples.

**Note**

In some cases the build might return with xcopy errors. Just build the project again. Make sure that you don’t do a rebuild.

In order to run an example, click on Debug > Start Without Debugging. This will execute the current StartUp project. Changing the StartUp project can be achieved by right clicking on a project in the Solution Explorer and choosing Set as StartUp Project.
7.9 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Java API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step.

- **Getting started** A quick introduction about how to compile and run a program from command line or an IDE
- **Important Classes of the API** Overview of some fundamental classes of the GAMS Java API
- **How to use API** An extensive set of examples describing how to use API components

7.9.1 Getting started

A Java program that uses GAMS Java API requires at least Java SE 7 (Since 25.0) to compile and run. For all platforms, assume GAMS system has been installed at [PathToGAMS] directory, called GAMS directory. The directory [PathToGAMS] denotes the path setting according to your GAMS installation on targeted platforms. For instance

- on Windows-based platforms with GAMS distribution 35.2 installed, [PathToGAMS] denotes C:\GAMS\win64\35.2
- on Unix-based platforms with GAMS distribution 35.2 installed, [PathToGAMS] denotes /usr/gams/gams35.2_linux_x64_64.sfx

All GAMS Java API classes are contained within one single jar file GAMSJavaAPI.jar with a namespace com.gams.api. The jar file is distributed with the current GAMS distribution and located at

- on Windows-based platforms: [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar
- on Unix-based platforms: [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

There are two different approaches of how to use the GAMS Java API. Either the Java source files can be edited with any common editor and compiled from command line or a Java IDE can be used. The following sections give a quick introduction about the different possibilities.

7.9.1.1 Compiling a Program

To compile a Java program, one usually provides the following information to Java compiler:

- the directory(ies) containing all required Java class files
- the directory to place the generated class files
- the name of the Java source file

A Java program that uses GAMS Java API requires class files that are contained in GAMSJavaAPI.jar for compilation.
7.9.1.1 Compiling a Program from Command Line  To compile a Java program that uses GAMS Java API, for instance HelloAPI.java, at the command line:

```
javac -cp [CLASSPATH] -d [TARGETDIR] HelloAPI.java
```

where

[CLASSPATH] is 'GAMSJavaAPI.jar' with its location, as it contains classes files that are used by
On Windows-based platform, [CLASSPATH] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar
On Unix-based platforms, [CLASSPATH] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR] is the directory to place the generated classe file.

Please note that it is possible to add [CLASSESPATH] to your CLASSPATH environment variable of the operating system as an alternative to specifying -cp [CLASSESPATH]. Also note that -d [TARGETDIR] is optional. In case -d [TARGETDIR] is omitted and the compilation is successful, the class file will be generated and located under the current directory.

To compile other programs, change the arguments accordingly. See also How to compile and run examples from the GAMS system directory.

7.9.1.2 Compiling a Program from Java IDE  In case of compiling a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), the location of the jar file GAMSJavaAPI.jar shall be added into the Java build path of the IDE's project properties.

For an Eclipse user, see How to import an Eclipse Java Project from the GAMS system directory.

7.9.1.2 Running a Program

To run a Java program, one usually provide the following information to Java Virtual Machine:

- the directory(ies) containing all required Java classes
- the directory(ies) containing all required shared libraries
- the name of an entry point class (in most case containing main method)

A Java program that uses GAMS Java API requires a number of shared libraries for establishing a connection with GAMS software components during run time. These shared libraries are platform dependent and they are located at [PathToGAMS]/apifiles/Java/api directory.
7.9 Tutorial

7.9.1.2.1 Running a Program from Command Line  To run a Java program that uses GAMS Java API, for instance HelloAPI.class containing in [TARGETDIR] directory, at the command line type:

```
java -cp [CLASSPATH] HelloAPI
```

where

[CLASSPATH] is the list of two paths, a path of 'GAMSJavaAPI.jar' and a path of targeted directory containing 'HelloAPI.class', separated by path separator on the targeted platform.

On Windows-based platform, [CLASSESPATHS] denotes [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;[TARGETDIR]

On Unix-based platform, [CLASSESPATHS] denotes
[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar:[TARGETDIR]

HelloAPI is the name of an entry point class containing main method

Please note that it is possible to add [CLASSPATH] to your CLASSPATH environment variable of the operating system as an alternative to specify -cp [CLASSPATH].

Most operations performed by GAMS Java API such as gdx or options operations require shared libraries (located in the folder [PathToGAMS]/apifiles/Java/api by default) when running a program. In case no java.library.path has been specified when running a program, the Java API will determine the path of the shared libraries from the java class path containing GAMSJavaAPI.jar.

Note that it is also possible to pass the following argument to Java Virtual Machine:

```
-Djava.library.path=[LIBRARYPATH]
```

where [LIBRARYPATH] describes the list of paths containing all required shared libraries (as previously mentioned, it is [PathToGAMS]/apifiles/Java/api by default). In such case, the Java API will give priority to the java library path when loading all required JNI libraries during run time. The java API will raise an exception when either the java virtual machine fails to load the required libraries from the specified java library path or there is a version conflict of shared libraries during run time.

To run other programs, change the arguments accordingly. See also How to compile and run examples from the GAMS system directory.

7.9.1.2.2 Running a Program from Java IDE  In case of running a program under a Java IDE (for instance, Eclipse, NetBeans, or IntelliJ), it is possible to set the nessary arguments via the properties of the IDE project.

For an Eclipse user, see How to import an Eclipse Java Project from the GAMS system directory.
7.9.1.3 Setting Up Your Environment

Since 24.3, the GAMS system directory can be specified within the program during run time. Therefore the setting up of execution environment before running a program is no longer required (see also Release Notes 24.3).

Nevertheless, it is still possible to preconfigure the GAMS system directory before running a program and use the default workspace setting within a program. In the default setting, GAMS system directory is not specified by a user within the program. The directory will be searched during run time from environment variable in the following order (depends on the target platform):

- On Windows-based platform: first from PATH environment variable. If not found, from the platform windows registry gams.location,
- On Mac-based platform: first from PATH environment variable. If not found, from DYLD_LIBRARY_PATH,
- On other Unix-based platform: from PATH environment variable. If not found, from LD_LIBRARY_PATH.

The following examples illustrate how to add [PathToGAMS] into the environment variable PATH on different platforms:

- On Windows 2000, XP, Vista, or Windows 7 desktop:
  > right-click on 'My Computer'
  > choose 'Properties' (alternatively, click on 'System' icon in the control panel)
  > click on 'Advanced' tab (or 'Advance system settings')
  > click on 'Environment Variables'
  > edit 'PATH' by adding [PathToGAMS] to the variable using a semi-colon as a separator.

- On Window-based platform via command line terminal:
  set PATH=[PathToGAMS];%PATH%

- On Unix-based platform via command line terminal using Bourne shell and its derivatives:
  export PATH=[PathToGAMS]:${PATH}

- On Unix-based platform via command line terminal using C Shell:
  setenv PATH [PathToGAMS]:${PATH}

7.9.1.4 How to compile and run examples from the GAMS system directory

GAMS provides several examples to demonstrate how to use GAMS Java API. These examples are located in the [PathToGAMS]/apifiles/Java directory containing various examples based on the different optimization problems. The following explanations guide you through the compilation and execution process of one example based on the well-known transportation problem, assuming that Java Runtime System is already installed on your machine.

For instance, Transport1.java under the directory [PathToGAMS]/apifiles/Java/transport demonstrates how to retrieve GAMS transport model from GAMS Model Library, execute the model with various GAMS options, and extract results after execution.

To compile Transport1.java at the command line under the directory [PathToGAMS]/apifiles/Java/transport:
javac -cp [CLASSPATH] -d [TARGETDIR] Transport1.java

where

[CLASSPATH] is a location of 'GAMSJavaAPI.jar', as it contains classes files that are used by 'Transport1.java'.
On Windows-based platform, [CLASSPATH] denotes
   [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;
On Unix-based platforms, [CLASSESPATHS] denotes
   [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar

[TARGETDIR] is the destination directory to place the generated classed file.

As Transport1.java is declared under package com.gams.examples.transport, the output class file will be located in [TARGETDIR] under the directory structure corresponding to package information. This means the compiled output file Transport1.class is located under:

- [TARGETDIR]\com\gams\examples\transport on Windows-based platform, or
- [TARGETDIR]/com/gams/examples/transport on Unix-based platforms.

To run Transport1.class from the command line:

taff -cp [CLASSPATH] com.gams.examples.transport.Transport1

where

[CLASSPATH] is the list of two paths, 'GAMSJavaAPI.jar' with its path and a directory containing 'Transport1.class' and (in this case [TARGETDIR] from the compilation step), separated by path separator on the targeted platform.
On Windows-based platform, [CLASSESPATHS] denotes
   [PathToGAMS]\apifiles\Java\api\GAMSJavaAPI.jar;[TARGETDIR]
On Unix-based platforms, [CLASSESPATHS] denotes
   [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar;[TARGETDIR]

Please note that the path [TARGETDIR] can be either absolute or relative path representing the directory that contains Transport1.class.

To compile and run other examples under the directory [PathToGAMS]/apifiles/Java, adjust the arguments accordingly.

See How to use API for detailed explanations on the series of transportation problem examples located in the folder [PathToGAMS]/apifiles/Java/transport.
7.9.1.5 How to import an Eclipse Java Project from the GAMS system directory

Since GAMS version 24.2 there is a prepared Java project that can be imported into Eclipse. The project is located in folder [PathToGAMS]/apifiles/Java/Eclipse and contains the examples based on the transportation problem. The following explanations guide you through the import and preparation process, assuming that the Eclipse Java IDE is already installed on your machine.

To import the project located in folder [PathToGAMS]/apifiles/Java/Eclipse into the workspace:

1. open the Eclipse IDE with the chosen workspace location, click on File menu and choose Import.
2. In the Import window, choose General > Existing Projects into Workspace then click Next.
3. In the next page of Import window, click Browse.. and select the folder with the prepared project ([PathToGAMS]/apifiles/Java/Eclipse) as root directory.
   We recommend to check for option Copy projects into workspace. Click Finish to finish the Import window.
4. Now the project is imported, and appears in the Package Explorer window on the left hand side of the IDE (shown below with its elements expanded).
5. As every example in the project requires GAMS Java API classes files to compile (all classes are packaged in GAMSJavaAPI.jar located in the folder [PathToGAMS]/apifiles/Java/api), you need to tell eclipse where to find GAMSJavaAPI.jar. To do this, either click on the project then choose Project > Properties or right click on the project name and choose Properties.
6. The Properties window of the project appears. Click Java Build Path on the left of the window, choose Libraries tab, choose Add External JARs,... select GAMSJavaAPI.jar located in the folder [PathToGAMS]/apifiles/Java/api to be opened.
   and click OK to finish adding [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar to Java Build Path.
7. Now all the java files should be successfully compiled without errors except for Transport10 (unsuccessful compilation is denoted with red x mark in front of the file name). This is because Transport10 requires an additional jexcelapi JAR file jxl.jar from jexcelapi. It can be downloaded and unzipped the downloaded archive into a local directory e.g. C:\tools. Then the jar file C:\tools\jexcelapi\jxl.jar can be added to the the Java Build Path of the project in a similar way as explained in 6.
8. To run a transport example, for example Transport1, you need to create a Run Configuration.
   To do this, either click Run menu and choose Run Configurations...
   or open the drop down menu next to the run button and click on Run Configurations....
   Then create a new run configuration by either press the New button in the left hand side of the window or right click at Java Application in the left hand side of the window and choose New.
9. The run configuration for Transport1 appears.
   For each run configuration it is possible to configure the execution of a program, such as the arguments of the virtual machine, class paths, environment variables and so on.
   For instance, to specify the java.library.path for Transport1 run configuration, choose Arguments tab in the run configuration and specify -Djava.library.path=[PathToGAMS]/apifiles/Java/api as one of the VM arguments. Then Click Apply and Run.

Note that the run configuration described in 8. and 9. is needed to be set for every single example. Once this is done you should be able to use the run configuration to repeat the execution of all the transport examples.

For a more detailed explanations on each transport examples see How to use API.
7.9.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples. All GAMS Java API classes are contained within one single jar file GAMSJavaAPI.jar with a namespace com.gams.api. It provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this namespace allow convenient exchange of input data and model results (GAMSDatabase) and help to create and run GAMS models (GAMSJob), that can be customized by GAMS options (GAMSOpts). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (GAMSModelInstance).

Other classes are GAMSWorkspace, GAMSOptions, GMSSymbol, and GAMSException.

7.9.3 How to use API

In the GAMS system directory there are some examples provided that illustrate the usage of the Java API. [PathToGAMS]/apifiles/Java/transport contains multiple examples dealing with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to choose the GAMS system (Transport1)
- How to export data to GDX (TransportGDX)
- How to import data from GDX (TransportGDX)
- How to run a GAMSJob from file (Transport1)
- How to retrieve a solution from an output database (Transport1)
- How to specify the solver using GAMSOpts (Transport1)
- How to run a job with a solver option file and capture its log output (Transport1)
- How to use include files (Transport2)
- How to set a non-default working directory (Transport3)
- How to read data from string and export to GDX (Transport3)
- How to run a job using data from GDX (Transport3)
- How to run a job using implicit database communication (Transport3)
- How to define data using Java data structures (Transport4)
- How to prepare a GAMSDatabase from Java data structures (Transport4)
- How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)
- How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)
- How to run multiple GAMSJobs in parallel using a GAMSCheckpoint (Transport6)
- How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)
- How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)
- How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)
- How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)
- How to fill a GAMSDatabase by reading from MS Access (Transport9)
- How to fill a GAMSDatabase by reading from MS Excel (Transport10)
- How to create and use a save/restart file (Transport11)
7.9.3.1 How to choose the GAMS system (Transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing Transport1 with C:/GAMS/win64/35.2 we use the 64-bit version of GAMS 35.2 to run Transport1 even if our default GAMS system might be a different one. This is managed by the following code:

```java
GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
if (args.length > 0)
    wsInfo.setSystemDirectory(args[0]);
GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
```

Remember that the bitness of the GAMS system has to match the bitness of your Java Runtime Environment.

7.9.3.2 How to export data to GDX (TransportGDX)

Although the Object-oriented Java API offers much more than exchanging data between Java and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in Java data structures.

```java
List<String> plants = Arrays.asList("Seattle", "San-Diego");
List<String> markets = Arrays.asList("New-York", "Chicago", "Topeka");
Map<String, Double> capacity = new HashMap<String, Double>();
    capacity.put("Seattle", Double.valueOf(350.0));
    capacity.put("San-Diego", Double.valueOf(600.0));
Map<String, Double> demand = new HashMap<String, Double>();
    demand.put("New-York", Double.valueOf(325.0));
    demand.put("Chicago", Double.valueOf(300.0));
    demand.put("Topeka", Double.valueOf(275.0));
Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
    distance.put( new Vector<String>(Arrays.asList(new String[]{"Seattle", "New-York"})), Double.valueOf(2.5));
    distance.put( new Vector<String>(Arrays.asList(new String[]{"Seattle", "Chicago"})), Double.valueOf(1.7));
    distance.put( new Vector<String>(Arrays.asList(new String[]{"Seattle", "Topeka"})), Double.valueOf(1.8));
    distance.put( new Vector<String>(Arrays.asList(new String[]{"San-Diego", "New-York"})), Double.valueOf(2.5));
    distance.put( new Vector<String>(Arrays.asList(new String[]{"San-Diego", "Chicago"})), Double.valueOf(1.8));
    distance.put( new Vector<String>(Arrays.asList(new String[]{"San-Diego", "Topeka"})), Double.valueOf(1.4));
```

Different type of GAMS symbols are represented using different Java data structures. The data for the GAMS sets is represented using List of Strings (e.g. plants and markets). On the other hand, GAMS parameters are represented by Map (e.g. capacity and demand). Note that the representation of the two dimensional parameter distance uses Vectors for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Java data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.

```java
// create new GAMSDatabase instance
GAMSDatabase db = ws.addDatabase();
```

We start adding GAMS sets using the method GAMSDatabase.addSet which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through plants and adds new records to the recently created GAMSSet instance i using GAMSSet.addRecord.

```java
GAMSSet i = db.addSet(“i”, 1, “canning plants”);
for(String p : plants)
    i.addRecord(p);
```
GAMSParameter instances can be added by using the method `GAMSDatabase.addParameter`. In this example we use the overloaded method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```gams
GAMSParameter a = db.addParameter("a", "capacity of plant i in cases", i);
for (String p : plants)
    a.addRecord(p).setValue(capacity.get(p));
```

As soon as all data is prepared in the GAMSDatabase, the method `GAMSDatabase.export` can be used to create a GDX file.

```gams
db.export("data.gdx");
```

### 7.9.3.3 How to import data from GDX (TransportGDX)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```gams
GAMSDatabase gdxdb = ws.addDatabaseFromGDX("data.gdx");
```

Reading the data from the GAMSSet `i` into a List of Strings can be done as follows:

```gams
List<String> gdxPlants = new ArrayList<String>();
for (GAMSSetRecord rec : gdxdb.getSet("i"))
    gdxPlants.add(rec.getKey(0));
```

A new List `gdxPlants` is created. `i` is retrieved by calling `GAMSDatabase.getSet` on `gdxdb`. The returned GAMSSet object can be iterated using a for-loop to access the records of the set. Each record is of type GAMSSetRecord and can be asked for its keys.

You can do the same for GAMSParameter. Instead of creating a List, we want to have the data in the form of a Map. GAMSParameterRecord can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter `a` into a `Map<String, Double>`.

```gams
Map<String, Double> gdxCapacity = new HashMap<String, Double>();
for (GAMSParameterRecord rec : gdxdb.getParameter("a"))
    gdxCapacity.put(rec.getKey(0), rec.getValue());
```

For a key of multi dimensional symbol, we choose Vector of String instead of String.

```gams
Map<Vector<String>, Double> gdxDistance = new HashMap<Vector<String>, Double>();
for (GAMSParameterRecord rec : gdxdb.getParameter("d"))
    gdxDistance.put(new Vector<String>(Arrays.asList(new String[]{rec.getKey(0), rec.getKey(1)})), rec.getValue());
```

Scalar can be read into a variable of type double by accessing the value of the first and only record.

```gams
double gdxFreight = gdxdb.getParameter("f").getFirstRecord().getValue();
```

### 7.9.3.4 How to run a GAMSJob from file (Transport1)

At first we create our workspace using `GAMSWorkspace ws = new GAMSWorkspace();`. Afterward we can create a `GAMSJob t1` using the `addJobFromGamsLib` method and run it.

Apparently you can create a `GAMSJob` with any other gms file you might have created on your own as long as it is located in the current working directory. Then the `GAMSJob t1` can be defined using the `GAMSJob.addJobFromFile` method.

```gams
// create GAMSWorkspace "ws" with default working directory
// (the directory named with current data and time under System.getProperty("java.io.tmpdir"))
GAMSWorkspace ws = new GAMSWorkspace();
// create GAMSJob "t1" from "transport" model in GAMS Model Libraries
GAMSJob t1 = ws.addJobFromGamsLib("transport");
// run GAMSJob "t1"
t1.run();
```

See also `Transport1.java`.  

---

7.9 Tutorial 2975
7.9.3.5 How to retrieve a solution from an output database (Transport1)

The following lines create the solution output and illustrate the usage of the `GAMSJob.OutDB` property to get access to the `GAMSDatabase` created by the `run` method. To retrieve the content of variable `x` we use the `getVariable` method and the `GAMSVariableRecord` class.

```java
// create GAMSJob t1
GAMSJob t1 = new GAMSJob();
// run GAMSJob t1 (the default GAMSOptions is used)
t1.run();
```

To retrieve the content of variable `x` we use the `getVariable` method and the `GAMSVariableRecord` class. Here is an example:

```java
// retrieve GAMSVariable "x" from GAMSJob's output databases
GAMSVariable x = t1.OutDB().getVariable("x");
for (GAMSVariableRecord rec : x)
{
    System.out.print("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "): ");
    System.out.print("level = " + rec.getLevel());
    System.out.println("marginal = " + rec.getMarginal());
}
```

See also Transport1.java.

7.9.3.6 How to specify the solver using GAMSOptions (Transport1)

The solver can be specified via the `GAMSOptions` class and the `GAMSWorkspace.addOptions` method. The `GAMSOptions.setAllModelTypes` property sets `xpress` as default solver for all model types which the solver can handle. Then we run our `GAMSJob t1` with the new `GAMSOptions`.

```java
// create GAMSOptions "opt1"
GAMSOptions opt1 = ws.addOptions();
// set all model types of "opt1" for "xpress"
opt1.setAllModelTypes("xpress");
// run GAMSJob "t1" with GAMSOptions "opt1"
t1.run(opt1);
```

See also Transport1.java.

7.9.3.7 How to run a job with a solver option file and capture its log output (Transport1)

At first we create the file `xpress.opt` with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterward we use a `GAMSOptions` just like in the preceding example and `GAMSOptions.setOptFile` property to 1 to tell the solver to look for a solver option file. We specify the argument `output` in order to stream the log of the GAMSJob into the file `transport1_xpress.log`. When the `output` argument is omitted then the log will be written to standard output.

```java
// write file "xpress.opt" under GAMSWorkspace’s working directory
try {
    BufferedWriter optFile = new BufferedWriter(new FileWriter(
        ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "xpress.opt"));
    optFile.write("algorithm=barrier");
    optFile.close();
} catch (IOException e) {
    e.printStackTrace();
    System.exit(-1);
}
// create GAMSOptions "opt2"
GAMSOptions opt2 = ws.addOptions();
// set all model types of "opt2" for "xpress"
opt2.setAllModelTypes("xpress");
// for "opt2", use "xpress.opt" as solver's option file
opt2.setOptFile(1);
try {
    // run GAMSJob "t2" with GAMSOptions "opt2" and capture log into "transport1_xpress.log"
    PrintStream output = new PrintStream(new File(ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "transport1_xpress.log"));
    t1.run(opt2, output);
} catch (FileNotFoundException e) {
    // run GAMSJob "t2" with GAMSOptions "opt2" and log is written to standard output
    t1.run(opt2);
}
```

See also Transport1.java.
7.9 Tutorial

7.9.3.8 How to use include files (Transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings data and model are using GAMS syntax.

At first we write an include file tdata.gms that contains the data but not the model text:

```java
    try {
        BufferedWriter file = new BufferedWriter(new FileWriter(
            ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gms" ));
        file.write(data);
        file.close();
    } catch(IOException e) {
        e.printStackTrace();
        System.exit(-1);
    }
```

Afterwards we create a GAMSJob using the GAMSWorkspace.addJobFromString method. GAMSOptions.defines is used like the the 'double dash' GAMS parameters, i.e. it corresponds to --incname=tdata on the command line where incname is used as name for the include file in the model string.

```java
    // create GAMSJob "t2" from the "model"
    GAMSJob t2 = ws.addJobFromString(model);
    // create GAMSOption "opt" and define "incname" as "tdata"
    GAMSOptions opt = ws.addOptions();
    opt.defines("incname", "tdata");
    // run GAMSJob "t2" with GAMSOptions "opt"
    t2.run(opt);
```

The string model contains the following lines to read in the data.

```java
    $if not set incname $abort 'no include file name for data file provided'
    $include incname;
```

See also Transport2.java.

7.9.3.9 How to set a non-default working directory (Transport3)

At first we create a new directory. Once this is done we can use this directory when creating the GAMSWorkspace and make it the working directory.

```java
    // create a directory
    File workingDirectory = new File(System.getProperty("user.dir"), "Transport3");
    workingDirectory.mkdir();
    // create a workspace
    GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
    wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
    GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
```

See also Transport3.java.

7.9.3.10 How to read data from string and export to GDX (Transport3)

We read the data from the string data. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding GAMSJob a GAMSDatabase is created that is available via the GAMSJob.OutDB property. We can use the GAMSDatabase.export method to write the content of this database to a gdx file tdata.gdx.

```java
    // Create and run a job from a data file, then explicitly export to a GDX file
    GAMSJob t3 = ws.addJobFromString(data);
    t3.run();
    t3.OutDB().export( ws.workingDirectory() + GAMSGlobals.FILE_SEPARATOR + "tdata.gdx" );
```

See also Transport3.java.
7.9.3.11 How to run a job using data from GDX (Transport3)

This works quite similar to the usage of an include file explained in Transport2 - How to use include files (Transport2).

```java
// run a job using an instance of GAMSOptions that defines the data include file
GAMSOptions opt = ws.addOptions();
opt.defines("gdxincname", "tdata");
t3.run(opt);
```

Note that there are some minor changes in model due to the usage of a gdx instead of an include file.

```java
if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
...
```

See also Transport3.java.

7.9.3.12 How to run a job using implicit database communication (Transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs t3a and t3b where the first one contains only the data and the second one contains only the model without data. After running t3a the corresponding OutDB can be read in directly just like a gdx file. Note that the database needs to be passed to the GAMSJob.run method as additional argument.

```java
GAMSVariable x = t3a.OutDB().getVariable("x");
for (GAMSVariableRecord rec : x)
   System.out.println("x(" + rec.getKeys()[0] + ", " + rec.getKeys()[1] + "): level=" + rec.getLevel() + " marginal=" + rec.getMarginal());
System.out.println();
```

See also Transport3.java.

7.9.3.13 How to define data using Java data structures (Transport4)

We use the List<E> class and the Map<Key,Value> to define Java data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```java
// prepare input data
List<String> plants = Arrays.asList("Seattle", "San-Diego");
List<String> markets = Arrays.asList("New-York", "Chicago", "Topeka");
Map<String, Double> capacity = new HashMap<String, Double>();
   { capacity.put("Seattle", Double.valueOf(350.0));
     capacity.put("San-Diego", Double.valueOf(600.0));
   }
Map<String, Double> demand = new HashMap<String, Double>();
   { demand.put("New-York", Double.valueOf(325.0));
     demand.put("Chicago", Double.valueOf(300.0));
     demand.put("Topeka", Double.valueOf(275.0));
   }
Map<Vector<String>, Double> distance = new HashMap<Vector<String>, Double>();
   { distance.put( new Vector<String>(Arrays.asList(new String[]{
                 "Seattle", "New-York"})) , Double.valueOf(2.5));
     distance.put( new Vector<String>(Arrays.asList(new String[]{
                 "Seattle", "Chicago"})) , Double.valueOf(1.7));
     distance.put( new Vector<String>(Arrays.asList(new String[]{
                 "Seattle", "Topeka"})) , Double.valueOf(1.8));
     distance.put( new Vector<String>(Arrays.asList(new String[]{
                 "San-Diego", "New-York"})) , Double.valueOf(2.5));
     distance.put( new Vector<String>(Arrays.asList(new String[]{
                 "San-Diego", "Chicago"})) , Double.valueOf(1.8));
     distance.put( new Vector<String>(Arrays.asList(new String[]{
                 "San-Diego", "Topeka"})) , Double.valueOf(1.4));
   }
```

See also Transport4.java.
7.9 Tutorial

7.9.3.14 How to prepare a GAMSDatabase from Java data structures (Transport4)

At first we create an empty GAMSDatabase db using the GAMSWorkspace.addDatabase method. Afterwards we prepare the database. To add a set to the database we use the GAMSSet class and the GAMSDatabase.addSet method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Java data structure and add them by using the GAMSSet.addRecord method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The GAMSJob can be run like explained in the preceding example about implicit database communication.

```java
// add a database and add input data into the database
GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "canning plants");
for(String p : plants)
    i.addRecord(p);
GAMSSet j = db.addSet("j", 1, "markets");
for(String m : markets)
    j.addRecord(m);
GAMSParameter a = db.addParameter("a", 1, "capacity of plant i in cases");
for(String p : plants)
    a.addRecord(p).setValue( capacity.get(p) );
GAMSParameter b = db.addParameter("b", 1, "demand at market j in cases");
for(String m : markets)
    b.addRecord(m).setValue( demand.get(m) );
GAMSParameter d = db.addParameter("d", 2, "distance in thousands of miles");
for(Vector<String> vd : distance.keySet())
    d.addRecord(vd).setValue( distance.get(vd).doubleValue() );
GAMSParameter f = db.addParameter("f", 0, "freight in dollars per case per thousand miles");
f.addRecord().setValue( 90 );
// create and run a job from the model and read gdx include file from the database
GAMSJob t4 = ws.addJobFromString(model);
GAMSOptions opt = ws.addOptions();
opt.defines("gdxincname", db.getName());
t4.run(opt, db);
...
```

See also Transport4.java.

7.9.3.15 How to initialize a GAMSCheckpoint by running a GAMSJob (Transport5)

The following lines of code conduct several operations. While the first line simply creates a GAMSCheckpoint, the second one uses the GAMSWorkspace.addJobFromString method to create a GAMSJob containing the model text and data but no solve statement. Afterwards the run method gets the GAMSCheckpoint as argument. That means the GAMSCheckpoint cp captures the state of the GAMSJob.

```java
GAMSCheckpoint cp = ws.addCheckpoint();
GAMSJob t5 = ws.addJobFromString(model);
t5.run(cp);
...
```

See also Transport5.java.

7.9.3.16 How to initialize a GAMSJob from a GAMSCheckpoint (Transport5)

Note that the string returned from function model contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```java
Scalar bmult demand multiplier /1/;
...
demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
```
Scalar ms 'model status', ss 'solve status';
...

In Transport5 we create a list with eight different values for this demand multiplier.
...
    double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3);
...

For each entry of that list we create a GAMSJob t5 using the GAMSWorkspace.addJobFromString method. Besides another string which resets the demand multiplier bmult, specifies the solve statement and assigns values to the scalars ms and ss we pass the checkpoint cp as additional argument. This runs in a GAMSJob combined from the checkpoint plus the content provided by the string. We run the GAMSJob and echo some interesting data from the OutDB using the GAMSDatabase.getParameter and GAMSDatabase.getVariable methods, the GAMSParameter.findRecord and GAMSVariable.findRecord methods plus the GAMSParameterRecord.getValue property and the GAMSVariableRecord.getLevel method.

```java
    // create a new GAMSJob that is initialized from the GAMSCheckpoint
    for(double b : bmultlist) {
        t5 = ws.addJobFromString("bmult=" + b + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;", cp);
        t5.run();
        System.out.println("Scenario bmult=" + b + ":");
        System.out.println(" Modelstatus: " + GAMSGlobals.ModelStat.lookup((int) t5.OutDB().getParameter("ms").findRecord().getValue()));
        System.out.println(" Solvestatus: " + GAMSGlobals.SolveStat.lookup((int)t5.OutDB().getParameter("ss").findRecord().getValue()));
        System.out.println(" Obj: " + t5.OutDB().getVariable("z").findRecord().getLevel());
    }
```

Note
Some of demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

See also Transport5.java.

7.9.3.17 How to run multiple GAMSJobs in parallel using a GAMSCheckpoint
(Transport6)

This example illustrates how to run the jobs known from Transport5 in parallel. We initialize the GAMSCheckpoint cp and introduce a demand multiplier as we did before:

```java
    GAMSJob t6 = ws.addJobFromString(model);
    t6.run(cp);
    double[] bmultlist = new double[] { 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 };
    
    // run multiple parallel jobs using the created checkpoint
    Object lockObject = new Object();
    Scenario[] scenarios = new Scenario[bmultlist.length];
    for (int i=0; i<bmultlist.length; i++) {
        scenarios[i] = new Scenario(ws, cp, lockObject, bmultlist[i]);
        scenarios[i].start();
    }
```

Furthermore, we introduce a new object lockObject that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of bmultlist and cause a thread to begin execution.
In class **Scenario** a **GAMSJob** *t6* is created and run just like in the preceding example of **Transport5**. The output section is also the same except for the fact that it is 'locked' by the object `lockObject` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```java
static class Scenario extends Thread {
    GAMSWorkspace workspace;
    GAMSCheckpoint checkpoint;
    Object lockObject;
    double bmult;
    public Scenario(GAMSWorkspace ws, GAMSCheckpoint cp, Object lockObj, double b) {
        workspace = ws;
        checkpoint = cp;
        lockObject = lockObj;
        bmult = b;
    }
    public void run() {
        GAMSJob t6 = workspace.addJobFromString(
            "bmult=" + bmult + "; solve transport min z use lp; ms=transport.modelstat;ss=transport.solvestat;",
            checkpoint
        );
        t6.run();
        // we need to make the output a critical section to avoid messed up report information
        synchronized (lockObject) {
            System.out.println("Scenario bmult=" + bmult + ":");
            System.out.println(" Modelstatus: " + GAMSGlobals.ModelStat.lookup((int) t6.OutDB().getParameter("ms").findRecord().getValue())
            );
            );
            System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
        }
    }
}
```

While the output in **Transport5** is strictly ordered subject to the order of the elements of `bmultlist` in **Transport6** the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `lockObject`.

If you want a further impression of the impact of the `lockObject`, just rerun **Transport6** but comment out the lock as follows and compare the output.

```java
// synchronized (lockObject)
// {
    System.out.println("Scenario bmult=" + bmult + ":");
    System.out.println(" Modelstatus: " + GAMSGlobals.ModelStat.lookup((int) t6.OutDB().getParameter("ms").findRecord().getValue())
    );
    );
    System.out.println(" Obj: " + t6.OutDB().getVariable("z").findRecord().getLevel());
// }
```

See also **Transport6.java**.

### 7.9.3.18 How to create a GAMSModelInstance from a GAMSCheckpoint (Transport7)

In **Transport7** the usage of `com::gams::api::GAMSModelInstance` is demonstrated.
At first checkpoint `cp` is created as in the preceding examples. Then we create the `GAMSModelInstance mi` using the `GAMSCheckpoint.addModelInstance` method. Note that the `GAMSJob` again contains no solve statement and the demand multiplier is already included with default value 1.

```java
GAMSCheckpoint cp = ws.addCheckpoint();
// initialize a checkpoint by running a job
GAMSJob t7 = ws.addJobFromString(model);
t7.run(cp);
GAMSModelInstance mi = cp.addModelInstance();
```

See also `Transport7.java`.

### 7.9.3.19 How to modify a parameter of a GAMSModelInstance using GAMSModifier (Transport7)

A `GAMSModelInstance` uses a `SyncDB` to maintain the data. We define `bmult` as `GAMSParameter` using the `GAMSParameter` method and specify gurobi as solver. Afterwards the `GAMSModelInstance` is instantiated with 3 arguments, the solve statement, `GAMSOptions opt` and `GAMSModifier bmult`. The `GAMSModifier` means that `bmult` is modifiable while all other parameters, variables and equations of ModelInstance `mi` stay unchanged. We use the `GAMSParameter.addRecord` method and the `setValue` function to assign a value to `bmult`. That value can be varied afterwards using the `GAMSParameter.getFirstRecord` method to reproduce our well-known example with different demand multipliers.

```java
GAMSParameter bmult = mi.SyncDB().addParameter("bmult", 0, "demand multiplier");
GAMSOptions opt = ws.addOptions();
opt.setAllModelTypes("gurobi");
// instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable
mi.instantiate("transport use lp min z", opt, new GAMSModifier(bmult));
bmult.addRecord().setValue( 1.0 );
double[] bmultlist = new double[] { 0.6, 0.7 , 0.8, 0.9, 1.0,1.1, 1.2, 1.3 };
for (double b : bmultlist)
{
    bmult.getFirstRecord().setValue( b );
    mi.solve();
    System.out.println("Scenario bmult=" + b + ":");
    System.out.println(" Modelstatus: " + mi.getModelStatus());
    System.out.println(" Solvestatus: " + mi.getSolveStatus());
    System.out.println(" Obj: " + mi.SyncDB().getVariable("z").findRecord().getLevel());
}
```

See also `Transport7.java`.

### 7.9.3.20 How to modify a variable of a GAMSModelInstance using GAMSModifier (Transport7)

We create a `GAMSModelInstance` just like in the next to last example. We define `x` as `GAMSVariable` and its upper bound as `GAMSParameter xup`. At the following `instantiate` method `GAMSModifier` has 3 arguments. The first one says that `x` is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the `GAMSParameter` that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```java
GAMSVariable x = mi.SyncDB().addVariable("x", 2, GAMSGlobalVarType.POSITIVE, "");
GAMSParameter xup = mi.SyncDB().addParameter("xup", 2, "upper bound on x");
// instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable
mi.instantiate("transport use lp min z", new GAMSModifier(x, GAMSGlobalVarUpdateAction.UPPER, xup));
for (GAMSSetRecord i : t7.OutDB().getSet("i"))
{
    for (GAMSSetRecord j : t7.OutDB().getSet("j"))
    {
```
7.9 Tutorial

7.9.3.21 How to use a queue to solve multiple GAMSModelInstances in parallel (Transport8)

We initialize a GAMSCheckpoint cp from a GAMSJob. Then we define a queue that represents the different values of the demand multiplier. A queue follows the first-in-first-out principle. The object IOLockObject is used later to avoid messed up output. Then we call Scenarios multiple times in parallel. The number of parallel calls is specified by numberOfWorkers.

```java
GAMSJob t8 = ws.addJobFromString(model);
t8.run(cp);
Queue<Double> bmultQueue = new LinkedList<Double>(
    Arrays.asList( Double.valueOf(0.6), Double.valueOf(0.7),
    Double.valueOf(0.8), Double.valueOf(0.9),
    Double.valueOf(1.0), Double.valueOf(1.1),
    Double.valueOf(1.2), Double.valueOf(1.3) )
);
// solve multiple model instances in parallel
Object IOLockObject = new Object();
int numberOfWorkers = 2;
Scenarios[] scenarios = new Scenarios[numberOfWorkers];
for (int i=0; i<numberOfWorkers; i++)
    scenarios[i] = new Scenarios( ws, cp, bmultQueue, IOLockObject, i );
    scenarios[i].start();
```

In class Scenarios we create and instantiate a GAMSModelInstance as in the preceding examples and make parameter bmult modifiable. Note that we chose cplex as solver because it is thread safe (gurobi would also be possible). Once the queue is empty the loop terminates.

```java
static class Scenarios extends Thread
{
    GAMSWorkspace workspace;
    GAMSCheckpoint checkpoint;
    Object IOLockObject;
    Queue<Double> bmultQueue;
    int workerNumber;
    public Scenarios(GAMSWorkspace ws, GAMSCheckpoint cp, Queue<Double> que, Object IOLockObj, int i)
    {
        workspace = ws;
        checkpoint = cp;
        IOLockObject = IOLockObj;
        bmultQueue = que;
        workerNumber = i;
    }
    public void run()
    {
        GAMSModelInstance mi = checkpoint.addModelInstance();
        {
            GAMSMultiplier bmult = mi.SyncDB().addParameter("bmult", 0, "demand multiplier");
            GAMSMultiplier opt = workspace.addOptions();
            opt.setAllModelTypes("cplex");
            // instantiate the GAMSModelInstance and pass a model definition and GAMSMultiplier to declare bmult mutable
            mi.instantiate("transport use lp min z", opt, new GAMSMultiplier(bmult));
            bmult.addRecord().setValue(1.0);
            while (true)
            {
                double b = 0.0;
                // dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
                synchronized (bmultQueue)
                {
                    if (bmultQueue.isEmpty())
                        break;
                }
            }
        }
    }
}
```

See also Transport7.java.
else
    b = bmultQueue.remove();
}
bmult.getFirstRecord().setValue(b);
mi.solve();
// we need to make the output a critical section to avoid messed up report informations
synchronized (IOLockObject)
{
    System.out.println("#"+workerNumber+:"Scenario bmult=" + b + ":");
    System.out.println(" Modelstatus: ": + mi.getModelStatus());
    System.out.println(" Solvestatus: ": + mi.getSolveStatus());
    System.out.println(" Obj: ": + mi.SyncDB().getVariable("z").findRecord().getLevel());
}
...

See also Transport8.java.

7.9.3.22 How to fill a GAMSDatabase by reading from MS Access (Transport9)

This example illustrates how to import data from Microsoft Access to a GAMSDatabase (on Windows platform only). There are a few prerequisites required to run Transport9 successfully.

- Install a Microsoft access driver on your machine (if none is available) as the driver must be loaded at runtime to connect to a data source file.
- To access the data source file go to Control Panel \ System and Security \ Administrative Tools \ Data Sources (ODBC) and set up a data source name (DSN) as "transportdsn", leave out user ID and password, and select [PathToGAMS]/apfiles/Data/tansport.accdb as the data source file.
- Note that an architecture mismatch between the Driver and Application might cause problems.

We call a function readDataFromAccess that finally returns a GAMSDatabase as shown below.

```java
GAMSDatabase db = readDataFromAccess(ws);
...
```

The function readDataFromAccess begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database by specifying the aforementioned data source name (DSN). To finally read in GAMS sets and parameters we call the functions readSet and readParameter.

```java
static GAMSDatabase readDataFromAccess(GAMSWorkspace ws)
{
    GAMSDatabase db = ws.addDatabase();
    try {
        // loading the jdbc odbc driver
        Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
        // creating connection to database
        Connection c = DriverManager.getConnection("jdbc:odbc:transportdsn", "", "");
        // read GAMS sets
        readSet(c, db, "SELECT Plant FROM Plant", "i", 1, "canning plants");
        readSet(c, db, "SELECT Market FROM Market", "j", 1, "markets");
        // read GAMS parameters
        readParameter(c, db, "SELECT Plant, Capacity FROM Plant", "a", 1, "capacity of plant i in cases");
        readParameter(c, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases");
        readParameter(c, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles");
        c.close();
    } catch (ClassNotFoundException e) {
        System.err.println("Error: Failed to find a driver for the database.");
e.printStackTrace();
        System.exit(-1);}
    catch (SQLException e) {
        System.err.println("Error: Failed to retrieve data from the database.");
e.printStackTrace();
        System.exit(-1);
    }
    return db;
}
```
7.9 Tutorial

The function `readSet` adds a set to the `GAMSDatabase` that is filled with the data from the MS Access file afterwards. The function `readParameter` works quite similar.

```java
static void readSet(Connection c, GAMSDatabase db, String queryString, String setName, int setDimension, String setExplanatoryText) throws SQLException {
    Statement st = c.createStatement();
    ResultSet rs = st.executeQuery(queryString);
    ResultSetMetaData rsmd = rs.getMetaData();
    if (rsmd.getColumnCount() != setDimension) {
        System.err.println("Error: Number of fields in select statement does not match setDimension.");
        c.close();
        System.exit(-1);
    }
    GAMSSet set = db.addSet(setName, setDimension, setExplanatoryText);
    String[] keys = new String[setDimension];
    while (rs.next()) {
        for (int idx=0; idx < setDimension; idx++)
            keys[idx] = rs.getString(idx+1);
        set.addRecord(keys);
    }
    st.close();
}
```

Once we read in all the data we can create a `GAMSJob` from the `GAMSDatabase` and run it as usual.

See also `Transport9.java`.

7.9.3.23 How to fill a GAMSDatabase by reading from MS Excel (Transport10)

This example illustrates how to read data from Excel, or to be more specific, from `[PathToGAMS]\apifiles\Data\transport.xls`.

At first we have to add an additional jar file to the `[CLASSES_PATH]` since we use the Java Excel API which can be downloaded from `jexcelapi`. We unzipped the Java Excel API folder in `C:\tools`. To compile and run on a Windows platform from the command line go to `C:\GAMS\win64\24.1\apifiles\Java\transport` and use:

```
javac -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar;.. -d . Transport10.java
```

and

```
java -cp C:\GAMS\win64\GAMS_VERSION\apifiles\Java\api\GAMSJavaAPI.jar;C:\tools\jexcelapi\jxl.jar;.. com.gams.examples.transport.Transport10
```

If you are using an IDE like Eclipse add `C:\tools\jexcelapi\jxl.jar` to the class path as explained in the Compiling a Program from Java IDE and Running a Program from Java IDE section.

The model is given as string without data like in many examples before and the Excel file `transport.xls` is located at `[gamsdir]\apifiles\Data`.

At first we define the input string and create the corresponding input file.

```java
String input = gamsdir + "apifiles" + GAMSGlobals.FILE_SEPARATOR + "Data" + GAMSGlobals.FILE_SEPARATOR + "transport.xls";
File inputFile = new File(input);
```

The following lines address the different worksheets and read in the contained data.

```java
int iCount = 0;
int jCount = 0;
String[][] capacityData = null;
String[][] demandData = null;
String[][] distanceData = null;
Workbook w;
```
try {
    Workbook w = Workbook.getWorkbook(inputFile);
    Sheet capacity = w.getSheet("capacity");
    iCount = capacity.getColumns();
    capacityData = new String[capacity.getRows()][capacity.getColumns()];
    for (int j = 0; j < capacity.getColumns(); j++)
        for (int i = 0; i < capacity.getRows(); i++)
            capacityData[i][j] = capacity.getCell(j, i).getContents();
    Sheet demand = w.getSheet("demand");
    jCount = demand.getColumns();
    demandData = new String[demand.getRows()][demand.getColumns()];
    for (int j = 0; j < demand.getColumns(); j++)
        for (int i = 0; i < demand.getRows(); i++)
            demandData[i][j] = demand.getCell(j, i).getContents();
    Sheet distance = w.getSheet("distance");
    distanceData = new String[distance.getRows()][distance.getColumns()];
    for (int j = 0; j < distance.getColumns(); j++)
        for (int i = 0; i < distance.getRows(); i++)
            distanceData[i][j] = distance.getCell(j, i).getContents();
    w.close();
} catch (IOException e) {
    e.printStackTrace();
} catch (BiffException e) {
    e.printStackTrace();
}...

Now we can create the GAMSWorkspace as usual and afterwards create a GAMSDatabase and fill it with the workbook data as follows:

GAMSDatabase db = ws.addDatabase();
GAMSSet i = db.addSet("i", 1, "Plants");
GAMSSet j = db.addSet("j", 1, "Markets");
GAMSParameter capacityParam = db.addParameter("a", 1, "Capacity");
GAMSParameter demandParam = db.addParameter("b", 1, "Demand");
GAMSParameter distanceParam = db.addParameter("d", 2, "Distance");
for (int ic = 0; ic < iCount; ic++)
    i.addRecord( capacityData[0][ic] );
    capacityParam.addRecord( capacityData[0][ic] ).setValue( Double.valueOf(capacityData[1][ic]).doubleValue() );
for (int jc = 0; jc < jCount; jc++)
    j.addRecord( demandData[0][jc] );
    demandParam.addRecord( demandData[0][jc] ).setValue( Double.valueOf(demandData[1][jc]).doubleValue() );
String[] data = null;
for (int ic = 0; ic < iCount; ic++)
    for (int jc = 0; jc < jCount; jc++)
        data = new String[] { distanceData[ic+1][0], distanceData[0][jc+1] };
        distanceParam.addRecord( data ).setValue( Double.valueOf(distanceData[ic+1][jc+1]) );

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our GAMSJob as usual.

GAMSOptions opt = ws.addOptions();
GAMSJob t10 = ws.addJobFromString(model);
    opt.setAllModelTypes("xpress");
    t10.run(opt, db);
    for (GAMSVariableRecord rec : t10.OutDB().getVariable("x"))
        System.out.println("x( + rec.getKeys()[0] + ", + rec.getKeys()[1] + ") : level= + rec.getLevel() + " marginal=" + rec.getMarginal());

See also Transport10.java.

7.9.3.24 How to create and use a save/restart file (Transport11)

In Transport11 we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GAMSCheckpoint. From the main function we call the function CreateSaveRestart giving it the current working directory and the desired file name as arguments.

CreateSaveRestart( workingDirectory, "tbase" );
In function `CreateSaveRestart` create a workspace with the given working directory. Then we create a GAMSJob from a string. Note that the string given via `baseModel` contains the basic definitions of sets without giving them a content (that is what `$onempty` is used for). Afterwards we specify a GAMSOptions to only compile the job but do not execute it. Then we create a checkpoint `cp` that is initialized by the following run of the GAMSJob and stored in the file given as argument to the function, in our case `tbase`. This becomes possible because the addCheckpoint method accepts identifiers as well as file names as argument.

```java
static void CreateSaveRestart(File workingDirectory, String cpFileName)
{
    GAMSWorkspaceInfo wsInfo = new GAMSWorkspaceInfo();
    wsInfo.setWorkingDirectory(workingDirectory.getAbsolutePath());
    GAMSWorkspace ws = new GAMSWorkspace(wsInfo);
    GAMSJob j1 = ws.addJobFromString(baseModel);
    GAMSOptions opt = ws.addOptions();
    opt.setAction( GAMSOptions.EAction.CompileOnly );
    GAMSCheckpoint cp = ws.addCheckpoint(cpFileName);
    j1.run(opt, cp);
    opt.dispose();
}
```

So what you should keep in mind before we return to further explanations of the main function is, that the file `tbase` is now in the current working directory and contains a checkpoint. Now in the main function we define some data using Java data structures as we already did in `Transport4` before we create the GAMSWorkspace and a GAMSDatabase.

```java
...;
    GAMSDatabase db = ws.addDatabase();
    ...
```

Afterwards we set up the GAMSDatabase like we already did in `Transport4`. Once this is done we run a GAMSJob using this data plus the checkpoint stored in file `tbase`.

```java
...;
    GAMSCheckpoint cpBase = ws.addCheckpoint("tbase");
    GAMSOptions opt = ws.addOptions();
    GAMSJob t11 = ws.addJobFromString(model, cpBase);
    opt.defines("gdxincname", db.getName());
    opt.setAllModelTypes("xpress");
    t11.run(opt, db);
    ...
```

Note that the string from which we create job `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the GAMSDatabase correctly. The entire model definition is delivered by the checkpoint `cpBase` which is equal to the one we saved in `tbase`.

See also `Transport11.java`.

7.10 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Python API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step.

- Getting started A quick introduction about how to run a program
- Important Classes of the API Overview of some fundamental classes of the GAMS Python API
- How to use the API An extensive set of examples describing how to use API components
7.10.1 Getting started

The object oriented GAMS Python API is built on top of the different expert-level APIs and provides convenient access to GAMS from within Python. Examples using the API are located in `apifiles/Python`. The expert-level APIs can be found in `apifiles/Python/api_36` for Python 3.6, in `apifiles/Python/api_37` for Python 3.7, in `apifiles/Python/api_38` for Python 3.8, and in `apifiles/Python/api_39` for Python 3.9. The object oriented API is located in `apifiles/Python/gams`. Making your Python installation aware of the modules provided by GAMS can be done in two fundamentally different ways. Which method to choose depends on your preference and your use pattern of GAMS and Python. Note also that the bitness of your Python version has to match the bitness of the GAMS system.

7.10.1.1 Let Python find the GAMS Python files

There are many ways for a Python installation to find locations with additional packages. Here are two:

a) Extend/set the PYTHONPATH environment variable

The environment variable `PYTHONPATH` ([https://docs.python.org/3/using/cmdline.html#environment-variables](https://docs.python.org/3/using/cmdline.html#environment-variables)) can be used to let Python find the GAMS API.

**macOS/Linux:**

export PYTHONPATH=/path/to/gams/apifiles/Python/api_38
export PYTHONPATH=/path/to/gams/apifiles/Python/gams:$PYTHONPATH

**Windows:**

set PYTHONPATH=C:\path\to\gams\apifiles\Python\api_38
set PYTHONPATH=C:\path\to\gams\apifiles\Python\gams;%PYTHONPATH%

b) Use the site package

The `site` package ([https://docs.python.org/3/library/site.html](https://docs.python.org/3/library/site.html)) can be used to include the GAMS directories. For example, create a file `sitecustomize.py` in your `site-packages` directory with the following content:

```python
import sys
sys.path.append(r'C:\path\to\gams\apifiles\Python\api_38')
sys.path.append(r'C:\path\to\gams\apifiles\Python\gams')
```

Change the path separator to `/` for macOS and Linux. You find out where your `site-packages` directory is located by running `python -m site` and inspecting the output. Method b) is preferred if creating permanent environment variables is difficult (e.g. on macOS).
7.10 Tutorial

7.10.1.2 Copy the GAMS Python files to the Python installation

Open a shell/command prompt and make sure your Python interpreter is found. Change directories to your GAMS system directory with the Python 3.X API files and run `python setup.py install`, e.g. on Windows:

```
cd C:\path\to\gams\apifiles\Python\api_38
C:\path\to\my\python\python.exe setup.py install
```

**Note**

Per default, the `setup.py` script tries to create a build directory before installing its content into the `site-packages` directory of the Python interpreter. In case of missing write permissions in the GAMS system directory (e.g. on macOS) it is possible to specify an alternative location using the following command:

```
C:\path\to\my\python\python.exe setup.py build -b C:\path\to\build install
```

**Note**

For the use of the Embedded Code Facility for Python, certain dependencies might be required (e.g. `ply`). The directory `/path/to/gams/apifiles/Python/thirdparty` contains all the third party modules used by GMSPython. The content of this directory indicates which modules and packages should be installed in addition.

**Running the transport1.py example:**

In order to see that the Python installation is set up correctly to be used with GAMS, a simple test is to run the `transport1.py` example. Note that you have to change the path separator to `/` for macOS and Linux:

```
C:\path\to\my\python\python.exe C:\path\to\gams\apifiles\Python\trnsport1.py
```

7.10.1.3 Working with Python and multiple GAMS Installations

GAMS uses SWIG ([http://www.swig.org/](http://www.swig.org/)) to connect Python to GAMS functionality implemented in dynamic link libraries or shared objects (e.g. `gdxdclib64.dll` to access GDX functionality). GAMS provides all files necessary to access these libraries from Python in the `apifiles/Python/api_3X` directories. Due to changes in the library API, SWIG version, Python version, etc, these files, that you might have copied to your Python installation in case you choose the copy method from above, are highly GAMS distribution dependent. If you work with a single GAMS installation this is very easy but if you need to work with different GAMS installations connecting your own Python installation can be a challenge. If you are in this situation we highly recommend to work with a Python installation that supports environment management, like Conda. Create for each major GAMS version a new environment and choose the copy method or the site customization (see entry b)) (e.g. via `sitecustomize.py`) to connect GAMS with this environment. Here is a typical session to create two environments, one for GAMS 31 and one for GAMS 32 using Conda:

```
conda create --name gams31 python=3.8
conda activate gams31
cd /path/to/gams31/apifiles/Python/api_38
python setup.py install
conda create --name gams32 --clone gams31
conda activate gams32
cd /path/to/gams32/apifiles/Python/api_38
python setup.py install
```
7.10.1.4 Specifying a GAMS System Directory

There are several ways to specify which system directory should be used. On all platforms, the system directory can be specified in the GamsWorkspace constructor. If no system directory is specified by the user, The API tries to find one automatically:

- Windows: Try to find a system directory in the Windows registry.
- Linux: Try to find a system directory in the `PATH` first. If none was found, search `LD_LIBRARY_PATH`.
- OS X: Try to find a system directory in the `PATH` first. If none was found, search `DYLD_LIBRARY_PATH`.

The environment variable `PATH` can be set as follows on Linux and macOS:

```bash
export PATH=<Path/To/GAMS>:
```

Note

On Linux and macOS it is recommended to specify the `PATH` only instead of `(D)LD_LIBRARY_PATH` since this might cause problems loading the correct version of certain modules (e.g. `gdx`).

7.10.1.5 Troubleshooting

`AttributeError: module 'gams' has no attribute 'SuffixDLVars'`:

Since GAMS 31, the Object-oriented Python API is distributed as source code (*.py files) instead of binaries (*.pyd files on Windows, *.so files on Linux and macOS). Installing the API with `python setup.py install` copies the API files into the `site-packages` directory of the Python interpreter, but won’t overwrite or delete old (*.so/*.pyd files since those are not part of the distribution anymore. This might lead to wrongly loaded files that are not compatible with each other anymore (e.g. `options.py`). In order to resolve the problem it is required to delete the `gams` directory located in the `site-packages` directory of the used Python installation before installing a new version of the API. Executing `python -m site` will reveal the location of the `site-packages` directory.

7.10.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS Namespace. Their usage is demonstrated by an extensive set of examples in the How to use the API section.

- `gams::workspace::GamsWorkspace` Class
- `gams::execution::GamsJob` Class
- `gams::database::GamsDatabase` Class
- `gams::options::GamsOptions` Class
- `gams::execution::GamsModelInstance` Class
7.10.3 How to use the API

The GAMS distribution provides several examples that illustrate the usage of the Python API. 
[GAMSDIR]/apifiles/Python contains multiple examples dealing with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

- How to import packages/modules from the GAMS Python API (transport1.py)
- How to choose the GAMS system (transport1.py)
- How to export data to GDX (transport_gdx.py)
- How to import data from GDX (transport_gdx.py)
- How to run a GamsJob from file (transport1.py)
- How to retrieve a solution from an output database (transport1.py)
- How to specify the solver using GamsOptions (transport1.py)
- How to run a job with a solver option file and capture its log output (transport1.py)
- How to use include files (transport2.py)
- How to read data from string and export to GDX (transport3.py)
- How to run a job using data from GDX (transport3.py)
- How to run a job using implicit database communication (transport3.py)
- How to define data using Python data structures (transport4.py)
- How to prepare a GamsDatabase from Python data structures (transport4.py)
- How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)
- How to initialize a GamsJob from a GamsCheckpoint (transport5.py)
- How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)
- How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)
- How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)
- How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)
- How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)
- How to fill a GamsDatabase by reading from MS Access (transport9.py)
- How to fill a GamsDatabase by reading from MS Excel (transport10.py)
- How to create and use a save/restart file (transport11.py)

7.10.3.1 How to import packages/modules from the GAMS Python API (transport1.py)

If you followed the instructions from the Getting started section and installed the GAMS Python API there should be a directory [PYTHONDIR]\Lib\site-packages\gams that contains the required packages and modules. We simply import all of them using

```python
from gams import *
```

Conventional Python packages/modules can by imported like that:

```python
import os
import sys
```
7.10.3.2 How to choose the GAMS system (transport1.py)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. If we type python transport1.py C:/GAMS/win64/35.2 we use the 64-bit version of GAMS 35.2 to run transport1.py even if our default GAMS system might be a different one. This is managed by the following code:

```python
if len(sys.argv) > 1:
    ws = GamsWorkspace(system_directory = sys.argv[1])
else:
    ws = GamsWorkspace()
```

Remember that the bitness of the GAMS system has to match the bitness of your Python version.

7.10.3.3 How to export data to GDX (transport_gdx.py)

Although the Object-oriented Python API offers much more than exchanging data between Python and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GamsDatabase. We assume that the data to be exported is available in Python data structures.

```python
plants = [ "Seattle", "San-Diego" ]
maints = [ "New-York", "Chicago", "Topeka" ]
capacity = [ "Seattle" : 350.0, "San-Diego" : 600.0 ]
demand = [ "New-York" : 325.0, "Chicago" : 300.0, "Topeka" : 275.0 ]
distance = [ ("Seattle", "New-York") : 2.5,
             ("Seattle", "Chicago") : 1.7,
             ("Seattle", "Topeka") : 1.8,
             ("San-Diego", "New-York") : 2.5,
             ("San-Diego", "Chicago") : 1.8,
             ("San-Diego", "Topeka") : 1.4
             ]
```

Different GAMS symbols are represented using different Python data structures. The data for the GAMS sets is represented using Python lists of strings (e.g. plants and markets). On the other hand, GAMS parameters are represented by Python dictionaries (e.g. capacity and demand). Note that the representation of the two dimensional parameter distance uses Python tuples for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with standard Python data structures.

A new GamsDatabase instance can be created using GamsWorkspace.add_database.

```python
# create new GamsDatabase instance
db = ws.add_database()
```

We start adding GAMS sets using the method GamsDatabase.add_set which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through plants and adds new records to the recently created GamsSet instance i using GamsSet.add_record.

```python
# add 1-dimensional set 'i' with explanatory text 'canning plants' to the GamsDatabase
i = db.add_set("i", 1, "canning plants")
for p in plants:
    i.add_record(p)
```

GamsParameter instances can be added by using the method GamsDatabase.add_parameter. It has the same signature as GamsDatabase.add_set. Anyhow, in this example we use GamsDatabase.add_parameter_dc instead which takes a list of GamsSet instances instead of the dimension for creating a parameter with domain information.

```python
# add parameter 'a' with domain 'i'
a = db.add_parameter_dc("a", [i], "capacity of plant i in cases")
for p in plants:
    a.add_record(p).value = capacity[p]
```

As soon as all data is prepared in the GamsDatabase, the method GamsDatabase.export can be used to create a GDX file.

```python
# export the GamsDatabase to a GDX file with name 'data.gdx' located in the 'working_directory' of the GamsWorkspace
db.export("data.gdx")
```
7.10.3.4 How to import data from GDX (transport_gdx.py)

Data can be imported from a GDX file using GamsWorkspace.add_database_from_gdx. The method takes a path to a GDX file and creates a GamsDatabase instance.

```python
# add a new GamsDatabase and initialize it from the GDX file just created
db2 = ws.add_database_from_gdx('data.gdx')
```

Reading the data from the GamsSet \( i \) into a list can be done as follows:

```python
# read data from symbols into Python data structures
i = [ rec.keys[0] for rec in db2['i'] ]
```

A Python list is created using list comprehensions. \( i \) is retrieved by querying the GamsDatabase \( \text{db2} \). The returned GamsSet object can be iterated using a for-loop to access the records of the set. Each record is of type GamsSetRecord and can be asked for its keys.

You can do the same for GamsParameters. Instead of creating a Python list, we want to have the data in the form of a Python dictionary. GamsParameterRecords can not only be asked for their keys, but also for their value. The following code snippet shows how to read the one dimensional parameter \( a \) into a Python dictionary using dict comprehensions.

```python
a = { rec.keys[0]:rec.value for rec in db2['a'] }
```

For multi dimensional symbols, we choose the Python dictionary keys to be tuples instead of string. We access the keys as usual, but do not address a specific key. Instead, we take the whole list of keys and turn it into a tuple.

```python
d = dict( (tuple(rec.keys), rec.value) for rec in db2['d'] )
```

Scalars can be read into a Python identifier by accessing the value of the first and only record.

```python
t = db['t'].first_record().value
```

7.10.3.5 How to run a GamsJob from file (transport1.py)

At first we create our workspace using `ws = GamsWorkspace()`. Afterwards we load the `transport` model from the GAMS model library which puts the corresponding gms file in our working directory. Apparently you can create a GamsJob with any other gms file you might have created on your own as long as it is located in the current working directory. Then the GamsJob \( \text{t1} \) can be defined using the `add_job_from_file` method and afterwards we run the job.

```python
ws.gamslib('transport')
t1 = ws.add_job_from_file('transport.gms')
t1.run()
```

7.10.3.6 How to retrieve a solution from an output database (transport1.py)

The following lines create the solution output and illustrate the usage of the GamsJob.out_db property to get access to the GamsDatabase created by the run method. To retrieve the content of variable \( x \) we use squared brackets that internally call the `get_symbol` method.

```python
for rec in t1.out_db['x']:
    print "x(" + rec.keys[0] + "," + rec.keys[1] + "): level=" + str(rec.level) + " marginal=" + str(rec.marginal)
```

Note that instead of using the squared brackets we could also use

```python
for rec in t1.out_db.get_symbol('x'):
```
7.10.3.7 How to specify the solver using GamsOptions (transport1.py)

The solver can be specified via the GamsOptions class and the GamsWorkspace.add_options method. The GamsOptions.all_model_types property sets xpress as default solver for all model types that can be handled by the solver. Then we run our GamsJob t1 with the new GamsOption.

```python
... 
    opt = ws.add_options() 
    opt.all_model_types = "xpress" 
    t1.run(opt) 
... 
```

7.10.3.8 How to run a job with a solver option file and capture its log output (transport1.py)

At first we create the file xpress.opt with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterwards we use a GamsOption just like in the preceding example and set GamsOption.optfile property to 1 to tell the solver to look for a solver option file. In addition, we specify the argument `output` in order to write the log of the GamsJob into the file transport1_xpress.log. Providing `newline=""` to the open function prevents additional newline characters in the log file.

```python
... 
    file = open(os.path.join(ws.working_directory, "xpress.opt"), "w") 
    file.write("algorithm=barrier") 
    file.close() 
    opt.optfile = 1 
    with open("transport1_xpress.log", "w", newline="") as log: 
        t1.run(opt, output=log) 
... 
```

Instead of writing the log output to a file, any object that provides the functions `write` and `flush` can be used. In order to write the log directly to `stdout`, we can use the following code:

```python
... 
    t1.run(opt, output=sys.stdout) 
... 
```

7.10.3.9 How to use include files (transport2.py)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings accessed via functions `get_data_text` and `get_model_text` are using GAMS syntax. At first we write an include file tdata.gms that contains the data but not the model text and save it in our current working directory.

```python
... 
    file = open(os.path.join(ws.working_directory, "tdata.gms"), "w") 
    file.write(get_data_text()) 
    file.close() 
... 
```

Afterwards we create a GamsJob using the GamsWorkspace.add_job_from_string method. GamsOptions.defines is used like the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where `incname` is used as name for the include file in `get_model_text` as shown below.

```python
... 
    t2 = ws.add_job_from_string(get_model_text()) 
    opt = ws.add_options() 
    opt.defines["incname"] = "tdata" 
    t2.run(opt) 
... 
```

The string `get_model_text` contains the following lines to read in the data.

```gams
... 
    $if not set incname $abort 'no include file name for data file provided' 
    $include %incname% 
... 
```
7.10.3.10 How to read data from string and export to GDX (transport3.py)

We read the data from the string accessed via function `get_data_text`. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding `GamsJob` a GamsDatabase is created that is available via the `GamsJob.out.db` property. We can use the `GamsDatabase.export` method to write the content of this database to a gdx file `tdata.gdx` in the current working directory.

```python
... t3 = ws.add_job_from_string(get_data_text()) t3.run() t3.out_db.export(os.path.join(ws.working_directory, "tdata.gdx")) ...
```

7.10.3.11 How to run a job using data from GDX (transport3.py)

This works quite similar to the usage of an include file explained in How to use include files (transport2.py).

```python
... t3 = ws.add_job_from_string(get_model_text()) opt = ws.add_options() opt.defines["gdxincname"] = "tdata" opt.all_model_types = "xpress" t3.run(opt) ...
```

Note that there are some minor changes in `get_model_text` compared to preceding examples due to the usage of a gdx instead of an include file.

```bash
$ if not set gdxincname $abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin ...
```

7.10.3.12 How to run a job using implicit database communication (transport3.py)

This example does basically the same as the two preceding examples together. We create two `GamsJobs` `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding `out_db` can be read in directly just like a gdx file. Note that the database needs to be passed to the `GamsJob.run` method as additional argument.

```python
... t3a = ws.add_job_from_string(get_data_text()) t3b = ws.add_job_from_string(get_model_text()) t3a.run() opt.defines["gdxincname"] = t3a.out_db.name t3b.run(opt, databases=t3a.out_db) ...
```

7.10.3.13 How to define data using Python data structures (transport4.py)

We use squared brackets (Python Lists) to define the sets and curly brackets (Python Dictionaries) for the parameter definition.

```python
```
7.10.3.14 How to prepare a GamsDatabase from Python data structures (transport4.py)

At first we create an empty GamsDatabase db using the GamsWorkspace.add_database method. Afterwards we prepare the database. To add a set to the database we use the GamsSet class and the GamsDatabase.add_set method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Python data structure and add them by using the GamsSet.add_record method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2.

The GamsJob can be run like explained in the preceding example How to run a job using implicit database communication.

```python
db = ws.add_database()
i = db.add_set("i", 1, "canning plants")
for p in plants:
    j = db.add_set("j", 1, "markets")
    for m in markets:
        i.add_record(p)
        j.add_record(m)
a = GamsParameter(db, "a", 1, "capacity of plant i in cases")
for p in plants:
    a.add_record(p).value = capacity[p]
b = GamsParameter(db, "b", 1, "demand at market j in cases")
for m in markets:
    b.add_record(m).value = demand[m]
d = GamsParameter(db, "d", 2, "distance in thousands of miles")
for k, v in distance.iteritems():
    d.add_record(k).value = v
f = GamsParameter(db, "f", 0, "freight in dollars per case per thousand miles")
f.add_record().value = 90
t4 = GamsJob(ws, source=get_model_text())
opt = GamsOptions(ws)
opt.defines["gdxincname"] = db.name
opt.all_model_types = "xpress"
t4.run(opt, databases = db)
```

7.10.3.15 How to initialize a GamsCheckpoint by running a GamsJob (transport5.py)

The following lines of code conduct several operations. While the first line simply creates a GamsCheckpoint, the second one uses the GamsWorkspace.add_job_from_string method to create a GamsJob containing the model text and data but no solve statement. Afterwards the run method gets the GamsCheckpoint as argument. That means the GamsCheckpoint cp captures the state of the GamsJob.

```python
... cp = ws.add_checkpoint()
t5 = ws.add_job_from_string(get_model_text())
t5.run(checkpoint=cp)
```

7.10.3.16 How to initialize a GamsJob from a GamsCheckpoint (transport5.py)

Note that the string returned from function get_model_text contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:

```python
Scalar bmult demand multiplier /1/;
... demand(j) .. sum(i, x(i,j)) =e= bmult*b(j) ;
... Scalar ms 'model status', ss 'solve status';
... 
```

In transport5.py we create a list with eight different values for this demand multiplier.

```python
bmultlist = [ 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3 ]
```

For each entry of that list we create a GamsJob t5 using the GamsWorkspace.add_job_from_string method. Besides another string which resets the demand multiplier bmult, specifies the solve statement and assigns
values to the scalars `ms` and `ss` we pass the checkpoint `cp` as additional argument. This results in a GamsJob combined from the checkpoint plus the content provided by the string.

We run the GamsJob and print some interesting data from the `out_db`.

```python
... for b in bmultlist:
    t5 = ws.add_job_from_string("bmult=" + str(b) + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;", cp)
    t5.run()
    print "Scenario bmult=" + str(b) + ";'
    print " Modelstatus: ' + str(t5.out_db["ms"].find_record().value)
    print " Solvestatus: ' + str(t5.out_db["ss"].find_record().value)
    print " Obj: ' + str(t5.out_db["z"].find_record().level)
...```

NOTE: Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.

### 7.10.3.17 How to run multiple GamsJobs in parallel using a GamsCheckpoint (transport6.py)

This example illustrates how to run the jobs known from transport5.py in parallel. We initialize the GamsCheckpoint `cp` and introduce a demand multiplier as we did before:

```python
... cp = ws.add_checkpoint()
t6 = ws.add_job_from_string(get_model_text())
t6.run(checkpoint=cp)
bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]
...
```

Furthermore, we introduce a lock object `io_lock` that will be used to avoid mixed up output from the parallel jobs. We create one scenario for each entry of `bmultlist` and cause a thread to begin execution.

```python
... io_lock = threading.Lock()
threads = {} for b in bmultlist:
    threads[b] = threading.Thread(target=run_scenario, args=(ws, cp, io_lock, b))
    threads[b].start()
for b in bmultlist:
    threads[b].join()
...
```

In function `run_scenario` a GamsJob `t6` is created and run just like in the preceding example of transport5.py. The output section is also the same except for the fact that it is 'locked' by the object `io_lock` which means that the output section cannot be executed simultaneously for multiple demand multipliers.

```python
... def run_scenario(workspace, checkpoint, io_lock, b):
    t6 = workspace.add_job_from_string("bmult=" + str(b) + "; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;", checkpoint)
    t6.run()
    # we need to make the output a critical section to avoid messed up report informations
    io_lock.acquire()
    print "Scenario bmult=" + str(b) + ";'
    print " Modelstatus: ' + str(t6.out_db["ms"].value)
    print " Solvestatus: ' + str(t6.out_db["ss"].value)
    print " Obj: ' + str(t6.out_db["z"].level)
    io_lock.release()
...```

While the output in transport5.py is strictly ordered subject to the order of the elements of `bmultlist` in transport6.py the output blocks might change their order but the blocks describing one scenario are still appearing together due to the `io_lock` object.
7.10.3.18 How to create a GamsModelInstance from a GamsCheckpoint (transport7.py)

In transport7.py the usage of GamsModelInstance is demonstrated.

At first checkpoint `cp` is created as in the preceding examples. Note that the GamsJob `t7` again contains no solve statement and the demand multiplier is already included with default value 1. We create the GamsModelInstance `mi` using the GamsCheckpoint.add_modelinstance method.

```python
... cp = ws.add_checkpoint()
t7 = ws.add_job_from_string(get_model_text())
t7.run(checkpoint=cp)
mi = cp.add_modelinstance()
...
```

7.10.3.19 How to modify a parameter of a GamsModelInstance using GamsModifier (transport7.py)

A GamsModelInstance uses a sync_db to maintain the data. We define `bmult` as GamsParameter using the GamsDatabase.add_parameter method and specify gurobi as solver. Afterwards the GamsModelInstance is instantiated with 3 arguments, the solve statement, GamsModifier `bmult` and GamsOptions `opt`. The GamsModifier means that `bmult` is modifiable while all other parameters, variables and equations of GamsModelInstance `mi` stay unchanged. We use the GamsParameter.add_record method to assign a value to `bmult`. That value can be varied afterwards using the GamsParameter.first_record method to reproduce our well-known example with different demand multipliers.

```python
... bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
opt = ws.add_options()
opt.all_model_types = "gurobi"
mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
bmult.add_record().value = 1.0
bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]
for b in bmultlist:
    bmult.first_record().value = b
    ...mi.solve()
```

7.10.3.20 How to modify a variable of a GamsModelInstance using GamsModifier (transport7.py)

We create a GamsModelInstance using the GamsCheckpoint.add_modelinstance method. Afterwards we define `x` as GamsVariable and a GamsParameter `xup` that will be used as upper bound for `x`. At the following instantiate method GamsModifier has 3 arguments. The first one says that `x` is modificable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GamsParameter that holds the new value, in this case `xup`.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

```python
... mi = cp.add_modelinstance()
x = mi.sync_db.add_variable("x", 2, VarType.Positive)
xup = mi.sync_db.add_parameter("xup", 2, "upper bound on x")
mi.instantiate("transport use lp min z", GamsModifier(x, UpdateAction.Upper, xup))
mi.solve()
for i in t7.out_db['i']:
    for j in t7.out_db['j']:
        xup.clear()
        xup.add_record((i.keys[0],j.keys[0])).value = 0
        ...mi.solve()
```
7.10 Tutorial

7.10.3.21 How to use a queue to solve multiple GamsModelInstances in parallel (transport8.py)

We initialize a GamsCheckpoint cp from a GamsJob. Then we define a list that represents the different values of the demand multiplier. That list will be used like a queue where we extract the last element first. The objects list_lock and io_lock are used later to avoid multiple reading of one demand multiplier and messed up output. Then we call function scen_solve multiple times in parallel. The number of parallel calls is specified by nr_workers.

```python
... cp = ws.add_checkpoint()
t8 = ws.add_job_from_string(get_model_text())
t8.run(checkpoint=cp)
bmult_list = [1.3, 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6]
list_lock = threading.Lock()
io_lock = threading.Lock()
# start 2 threads
nr_workers = 2
treads = {} 
for i in range(nr_workers):
    threads[i] = threading.Thread(target=scen_solve, args=(ws, cp, bmult_list, list_lock, io_lock))
    threads[i].start()
for i in range(nr_workers):
    threads[i].join()
... 
```

In function scen_solve we create and instantiate a GamsModelInstance as in the preceding examples and make parameter bmult modifiable. Note that we choose cplex as solver because it is thread safe (gurobi would also be possible).

We have two critical sections that are locked by the objects list_lock and io_lock. Note that the pop method removes and returns the last element from the list and deletes it. Once the list is empty the loop terminates.

```python
def scen_solve(workspace, checkpoint, bmult_list, list_lock, io_lock):
    mi = checkpoint.add_modelinstance()
    bmult = mi.sync_db.add_parameter("bmult", 0, "demand multiplier")
    opt = ws.add_options()
    opt.all_model_types = "cplex"
    # instantiate the GamsModelInstance and pass a model definition and GamsModifier to declare bmult mutable
    mi.instantiate("transport use lp min z", GamsModifier(bmult), opt)
    bmult.add_record().value = 1.0
    while True:
        # dynamically get a bmult value from the queue instead of passing it to the different threads at creation time
        list_lock.acquire()
        if 0 == len(bmult_list):
            list_lock.release()
            return
        b = bmult_list.pop()
        list_lock.release()
        bmult.first_record().value = b
        mi.solve()
        # we need to make the output a critical section to avoid messed up report informations
        io_lock.acquire()
        print "Scenario bmult=" + str(b) + ":",
        print " Modelstatus: " + str(mi.model_status)
        print " Solvestatus: " + str(mi.solver_status)
        print " Obj: " + str(mi.sync_db.get_variable("z").find_record().level)
        io_lock.release()
... 
```

7.10.3.22 How to fill a GamsDatabase by reading from MS Access (transport9.py)

This example illustrates how to import data from Microsoft Access to a GamsDatabase. There are a few prerequisites required to run transport9.py successfully.

- We import pyodbc which can be downloaded from http://code.google.com/p/pyodbc/.
- Note that an architecture mismatch might cause problems. The bitness of your MS Access, Python, pyodbc and GAMS should be identical.
We call a function `read_data_from_access` that finally returns a GamsDatabase as shown below.

```python
... 
  db = read_from_access(ws)
  ...
...
```

The function `read_from_access` begins with the creation of an empty database. Afterwards we set up a connection to the MS Access database `transport.accdb` which can be found in `\GAMSDIR\apifiles\Data`. To finally read in GAMS sets and parameters we call the functions `read_set` and `read_parameter` that are explained down below.

```python
... 
  def read_from_access(ws):
    db = ws.add_database()
    # connect to database
    str_access_conn = 'DRIVER={'Microsoft Access Driver (*.mdb, *.accdb)';DBQ=..\\Data\transport.accdb'
    try:
      connection = pyodbc.connect(str_access_conn)
    except Exception as ex:
      print "Error: Failed to create a database connection. \n{0}\n".format(ex)
      sys.exit(1)
    # read GAMS sets
    read_set(connection, db, "SELECT Plant FROM plant", "i", 1, "canning plants")
    read_set(connection, db, "SELECT Market FROM Market", "j", 1, "markets")
    # read GAMS parameters
    read_parameter(connection, db, "SELECT Plant,Capacity FROM Plant", "a", 1, "capacity of plant i in cases")
    read_parameter(connection, db, "SELECT Market,Demand FROM Market", "b", 1, "demand at market j in cases")
    read_parameter(connection, db, "SELECT Plant,Market,Distance FROM Distance", "d", 2, "distance in thousands of miles")
    connection.close()
    return db
... 
```

The function `read_set` adds a set to the GamsDatabase that is filled with the data from the MS Access file afterwards. The function `read_parameter` works quite similar.

```python
... 
  def read_set(connection, db, query_string, set_name, set_dim, set_exp=""):
    try:
      cursor = connection.cursor()
      cursor.execute(query_string)
      data = cursor.fetchall()
      if len(data[0]) != set_dim:
        print "Number of fields in select statement does not match setDim"
        sys.exit(1)
      i = db.add_set(set_name, set_dim, set_exp)
      for row in data:
        keys = []
        for key in row:
          keys.append(str(key))
        i.add_record(keys)
    except Exception as ex:
      print "Error: Failed to retrieve the required data from the DataBase. \n{0}\n".format(ex)
      sys.exit(1)
    finally:
      cursor.close()
... 
```

Once we read in all the data we can create a GamsJob from the GamsDatabase and run it as usual.

### 7.10.3.23 How to fill a GamsDatabase by reading from MS Excel (transport10.py)

This example illustrates how to read data from Excel, or to be more specific, from `\GAMSDIR\apifiles\Data\transport.xls`. At first you have to download an additional package from [pypi](https://pypi.org), e.g. to `\Users\[USERNAME]\Downloads`. Unzip the package and run the following code from command line:

```bash
cd \Users\[Username]\Downloads\xlrd-0.9.2 && python setup.py install && cd \GAMSDIR\apifiles\Python
```

Now you should be able to find the directory `xlrd` in `[PYTHONDIR]\Lib\site-packages` and to run transport10.py.

In transport10.py the model is given as string without data like in many examples before and the Excel file `transport.xls` is located at `\GAMSDIR\apifiles\Data`. At first we define the workbook to read from and the different sheet names. To ensure to have the same number of markets and plants in all
spreadsheets, we conduct a little test that checks for the number of rows and columns. Our workspace is only created if this test yields no errors.

```python
wb = open_workbook("../Data\transport.xls")
capacity = wb.sheet_by_name("capacity")
demand = wb.sheet_by_name("demand")
distance = wb.sheet_by_name("distance")
# number of markets/plants have to be the same in all spreadsheets
assert (distance.ncols-1 == demand.ncols) and (distance.nrows-1 == capacity.ncols),
"Size of the spreadsheets doesn't match"
```

Now we can create a GamsDatabase and read in the data contained in the different worksheets. We iterate over the columns and read in the set names and the corresponding parameter values.

```python
db = ws.add_database()
i = db.add_set("i", 1, "Plants")
j = db.add_set("j", 1, "Markets")
capacity_param = db.add_parameter("a", 1, "Capacity")
demand_param = db.add_parameter("b", 1, "Demand")
distance_param = db.add_parameter("d", 2, "Distance")
for cx in range(capacity.ncols):
    i.add_record(str(capacity.cell_value(rowx=0, colx=cx))).value = capacity.cell_value(rowx=0, colx=cx)
for cx in range(demand.ncols):
    j.add_record(str(demand.cell_value(rowx=0, colx=cx))).value = demand.cell_value(rowx=0, colx=cx)
for cx in range(1, distance.ncols):
    for rx in range(1, distance.nrows):
        keys = (str(distance.cell_value(rowx=rx, colx=0)), str(distance.cell_value(0, colx=cx)))
        distance_param.add_record(keys).value = distance.cell_value(rowx=rx, colx=0)
```

Note that we can name sets and parameters just like in the database but we don't have to. Now we can run our GamsJob as usual.

```python
t10 = ws.add_job_from_string(get_model_text())
opt = ws.add_options()
opt.defines["gdxincname"] = db.name
opt.all_model_types = "xpress"
t10.run(opt, databases=db)
```

7.10.3.24 How to create and use a save/restart file (transport11.py)

In transport11.py we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GamsCheckpoint.

We create a directory tmp with internal identifier w_dir in the directory we are currently in (usually [GAMS_DIR]\apifiles\Python). This file will be used as working directory later. From the main function we call the function create_save_restart giving it directory tmp and the desired name for the save/restart file (tbase) as arguments.

```python
w_dir = os.path.join(\., "tmp")
create_save_restart(os.path.join(w_dir, "tbase"));
```

In function create_save_restart we create a workspace with the given working directory (w_dir refers to tmp). Then we create a GamsJob from a string. Note that the string given via get_base_model_text contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a GamsOption to only compile the job but do not execute it. Then we create a checkpoint cp that is initialized by the following run of the GamsJob and stored in the file given as argument to the function, in our case tbase. This becomes possible because the add_checkpoint method accepts identifiers as well as file names as argument.

```python
def create_save_restart(cp_file_name):
    if len(sys.argv) > 1:
        ws = GamsWorkspace(os.path.dirname(cp_file_name), sys.argv[1])
    else:
```
So what you should keep in mind before we return to further explanations of the main function is, that the file `tbase` is now in the current working directory and contains a checkpoint that will work exactly like a restart file.

In the main function we define some data using Python data structures as we already did in `transport4.py` before we create the GamsWorkspace and a GamsDatabase.

```python
... if len(sys.argv) > 1:
    ws = GamsWorkspace(w_dir, sys.argv[1])
else:
    ws = GamsWorkspace(w_dir)
    db = ws.add_database()
...
```

Afterwards we set up the GamsDatabase like we already did in `transport4.py`. Once this is done we run a GamsJob using this data plus the checkpoint stored in file `tbase`.

```python
... cp_base = ws.add_checkpoint("tbase")
t4 = ws.add_job_from_string(get_model_text(), cp_base)
opt = ws.add_options()
opt.defines["gdxincname"] = db.name
opt.all_model_types = "xpress"
t4.run(opt, databases=db)
...
```

Note that the string from which we create job `t11` is different to the one used to prepare the checkpoint stored in `tbase` and is only responsible for reading in the data from the GamsDatabase correctly. The entire model definition is delivered by the checkpoint `cp_base` which is equal to the one we saved in `tbase`.

### 7.11 Tutorial

The goal of this tutorial is to provide a compact overview of the basic functionality of the GAMS Matlab API. It allows the user to start immediately working with the API by providing a set of small examples based on the well-known transportation problem. These examples introduce several API features step by step.

- **Getting started** A quick introduction about how to add the API to the Matlab path
- **Important Classes of the API** Overview of some fundamental classes of the GAMS Matlab API
- **How to use the API** An extensive set of examples describing how to use API components

#### 7.11.1 Getting started

The object oriented GAMS Matlab API is built on top of the GAMS Java API and provides convenient access to GAMS from within Matlab (2017b or later) and Octave (5.2 or later). Examples using the API are located in `apifiles/Matlab/examples` and `apifiles/Matlab/examples_octave` for Matlab or Octave, respectively. The examples slightly differ for Octave since it does not support the complete Matlab syntax and functionalities - most importantly to note, enumeration classes (see also the note below). The object oriented API is located in `apifiles/Matlab/api`.

For making your Matlab installation aware of the packages provided by GAMS, you need to do the following two steps. First, add the GAMS Java API to the Matlab java class path. This can be done statically or dynamically. The latter is less efficient but more convenient for testing.
• static: Locate the javaclasspath.txt and add the path [PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar.
  You can find the location with cd(prefdir) in Matlab or which javaclasspath in Octave. Finally, restart Matlab or Octave.
• dynamic: Call the function javaaddpath("[PathToGAMS]/apifiles/Java/api/GAMSJavaAPI.jar").

Second, add the GAMS Matlab API to the Matlab path by calling addpath("[PathToGAMS]/apifiles/Matlab/api").

Note
Octave does not support enumeration classes (yet). In order to use the GAMS enumerations, please use the alternative integer or string value. For example, instead of using GAMS.DebugLevel.SHOW_LOG, use 2, see DebugLevel. To tell the GAMS Matlab API to return the alternative values instead of instances of enumeration classes, set the environment variable GAMS_MATLAB_ENUM_ALT to true, i.e., setenv("GAMS_MATLAB_ENUM_ALT", "true");.

You can test your setup by creating a GAMSWorkspaceInfo:
>> wsinfo = GAMS.GAMSWorkspaceInfo()
wsinfo =
GAMSWorkspaceInfo with properties:
  debugLevel: OFF
  systemDirectory: ''
  workingDirectory: ''

Note
In Matlab you can import the GAMS package by import GAMS.*. Then, you don't need to call the GAMS classes with the preceding GAMS.

7.11.2 Important Classes of the API

This section provides a quick overview of some fundamental classes of the GAMS package. Their usage is demonstrated by an extensive set of examples. All GAMS Matlab API classes are contained within one single package GAMS. It provides objects to interact with the General Algebraic Modeling System (GAMS). Objects in this package allow convenient exchange of input data and model results (GAMSDatabase) and help to create and run GAMS models (GAMSJob), that can be customized by GAMS options (GAMSOptions). Furthermore, it introduces a way to solve a sequence of closely related models in the most efficient way (GAMSModelInstance).

Other classes are GAMSWorkspace, GAMSOptions and GAMSSymbol.

7.11.3 How to use the API

In the GAMS system directory there are some examples provided that illustrate the usage of the Matlab API. [PathToGAMS]/apifiles/Matlab/examples contains multiple examples dealing - among others - with the well-known transportation problem. In further course of this tutorial we discuss these examples step by step and introduce new elements of the API in detail.

We recommend to open the aforementioned files to gain a complete overview of the examples. Down below we explain the examples with the help of selected code snippets.

• How to choose the GAMS system (transport1)
• How to export data to GDX (transport_gdx)
• How to import data from GDX (transport_gdx)
7.11.3.1 How to choose the GAMS system (transport1)

By default the GAMS system is determined automatically. In case of having multiple GAMS systems on your machine, the desired system can be specified via an additional argument when the workspace is created. When running the examples, we can provide an additional command line argument in order to define the GAMS system directory that should be used. By executing `transport1` with `C:/GAMS/win64/35.2` we use the 64-bit version of GAMS 35.2 to run `transport1` even if our default GAMS system might be a different one. This is managed by the following code:

```matlab
wsInfo = GAMS.GAMSWorkspaceInfo();
if nargin > 0
  wsInfo.systemDirectory = varargin{1};
end
ws = GAMS.GAMSWorkspace(wsInfo);
```

Note

The API can detect GAMS automatically from the PATH environment variable. Please note that this is not the MATLABPATH. You can inspect the PATH with `getenv("PATH")`. 
7.11.3.2 How to export data to GDX (transport.gdx)

Although the Object-oriented Matlab API offers much more than exchanging data between Matlab and GDX, a common use case is the export and import of GDX files. The central class for this purpose is GAMSDatabase. We assume that the data to be exported is available in Matlab data structures.

```matlab
plants = {'Seattle', 'San-Diego'};
markets = {'New-York', 'Chicago', 'Topeka'};
capacity = containers.Map();
capacity('Seattle') = 350;
capacity('San-Diego') = 600;
demand = containers.Map();
demand('New-York') = 325;
demand('Chicago') = 300;
demand('Topeka') = 275;
distance = containers.Map();
distance('Seattle.New-York') = 2.5;
distance('Seattle.Chicago') = 1.7;
distance('Seattle.Topeka') = 1.8;
distance('San-Diego.New-York') = 2.5;
distance('San-Diego.Chicago') = 1.8;
distance('San-Diego.Topeka') = 1.4;
```

Different type of GAMS symbols are represented using different Matlab data structures. The data for the GAMS sets is represented using a cell of strings (e.g. `plants` and `markets`). On the other hand, GAMS parameters are represented by a containers.Map (e.g. `capacity` and `demand`). Note that the representation of the two dimensional parameter `distance` uses a dot notation for storing the keys. The choice of data structures can also be different, but the used structures in this example fit well for representing GAMS data with Matlab data structures.

A new GAMSDatabase instance can be created using GAMSWorkspace.addDatabase.

```matlab
db = ws.addDatabase();
```

We start adding GAMS sets using the method `GAMSDatabase.addSet` which takes the name and the dimension as arguments. The third argument is an optional explanatory text. A for-loop iterates through `plants` and adds new records to the recently created GAMSSet instance `i` using `GAMSSet.addRecord`.

```matlab
i = db.addSet('i', 1, 'canning plants');
for p = plants
    i.addRecord(p{1});
end
```

GAMSParameter instances can be added by using the method `GAMSDatabase.addParameter`. In this example we use the overloaded method which takes a list of GAMSSet instances instead of the dimension for creating a parameter with domain information.

```matlab
a = db.addParameter('a', 'capacity of plant i in cases', i);
for p = plants
    a.addRecord(p{1}).value = capacity(p{1});
end
```

As soon as all data is prepared in the GAMSDatabase, the method `GAMSDatabase.export` can be used to create a GDX file.

```
db.export('data.gdx');
```

7.11.3.3 How to import data from GDX (transport.gdx)

Data can be imported from a GDX file using `GAMSWorkspace.addDatabaseFromGDX`. The method takes a path to a GDX file and creates a GAMSDatabase instance.

```matlab
gdxdb = ws.addDatabaseFromGDX('data.gdx');
```

Reading the data from the GAMSSet `i` into a cell of strings can be done as follows:

```matlab
gdxPlantsRecords = gdxdb.getSet('i').records;
gdxPlants = cell(size(gdxPlantsRecords));
for i = 1:numel(gdxPlantsRecords)
    gdxPlants{i} = gdxPlantsRecords{i}.key(1);
end
```

`i` is retrieved by calling `GAMSDatabase.getSet` on `gdxdb`. The returned GAMSSet object has an attribute `records` with an cell array of GAMSSetRecords. set. Each record can be asked for its keys.
You can do the same for GAMSParameter. Instead of creating a cell, we want to have the data in the form of a containers.Map. GAMSParameterRecord can not only be asked for its keys, but also for its value. The following code snippet shows how to read the one dimensional parameter $a$ into a map.

```plaintext
gdxCapacity = containers.Map();
for rec = gdxdb.getParameter('a').records
  gdxCapacity(rec.key(1)) = rec.value;
end
```

For a key of multi dimensional symbol, we choose a dot based concatenation of keys.

```plaintext
gdxDistance = containers.Map();
for rec = gdxdb.getParameter('d').records
  gdxDistance([rec.key(1), '.', rec.key(2)]) = rec.value;
end
```

Scalar can be read into a variable of type double by accessing the value of the first and only record.

```plaintext
gdxFreight = gdxdb.getParameter('f').record.value;
```

### 7.11.3.4 How to run a GAMSJob from file (transport1)

At first we create our workspace using GAMSWorkspace

```plaintext
ws = GAMS.GAMSWorkspace();
```

Afterwards, we can create a GAMSJob $t1$ using the addJobFromGamsLib method and run it.

```plaintext
% create GAMSWorkspace "ws" with default working directory
ws = GAMS.GAMSWorkspace();
% create GAMSJob "t1" from "transport" model in GAMS Model Libraries
t1 = ws.addJobFromGamsLib('transport');
% run GAMSJob "t1"
t1.run();
```

### 7.11.3.5 How to retrieve a solution from an output database (transport1)

The following lines create the solution output and illustrate the usage of the GAMSJob.outDB property to get access to the GAMSDatabase created by the run method. To retrieve the content of variable $x$ we use the getVariable method and the GAMSVariableRecord class.

```plaintext
% retrieve GAMSAVariable "x" from GAMSJob's output databases
fprintf('Ran with Default:

for x = t1.outDB.getVariable('x').records
  fprintf('x(%s,%s): level=%g marginal=%g
', x.keys, x.level, x.marginal);
end
```

### 7.11.3.6 How to specify the solver using GAMSOptions (transport1)

The solver can be specified via the GAMSOptions class and the GAMSWorkspace.addOptions method. The GAMSOptions.setAllModelTypes property sets $xpress$ as default solver for all model types which the solver can handle. Then we run our GAMSJob $t1$ with the new GAMSOptions.

```plaintext
% create GAMSOptions 'opt1'
opt1 = ws.addOptions();
% set all model types of 'opt1' for 'xpress'
opt1.setAllModelTypes('xpress');
% run GAMSJob 't1' with GAMSOptions 'opt1'
t1.run(opt1);
```
7.11.3.7 How to run a job with a solver option file and capture its log output (transport1)

At first we create the file xpress.opt with content `algorithm=barrier` which will be used as solver option file and is stored in the current working directory. Afterward we use a GAMSOptions just like in the preceding example and GAMSOptions.optFile property to 1 to tell the solver to look for a solver option file. We specify the argument `output` in order to stream the log of the GAMSJob into the file transport1.xpress.log. When the `output` argument is omitted then the log will be written to standard output.

```plaintext
% write file 'xpress.opt' under GAMSWorkspace's working directory
fid = fopen([ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'xpress.opt'], 'w');
fprintf(fid, 'algorithm=barrier');
close(fid);
% create GAMSOptions 'opt2'
opt2 = ws.addOptions();
% set all model types of 'opt2' for 'xpress'
opt2.addAllModelTypes('xpress');
% for 'opt2', use 'xpress.opt' as solver's option file
opt2.optFile = 1;
% run GAMSJob 't2' with GAMSOptions 'opt2' and capture log into 'transport1.xpress.log'.
t1.run(opt2, [ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'transport1.xpress.log']);
```

7.11.3.8 How to use include files (transport2)

In this example, as in many succeeding, the data text and the model text are separated into two different strings. Note that these strings data and model are using GAMS syntax.

At first we write an include file tdata.gms that contains the data but not the model text:

```plaintext
% write 'data' into file 'tdata.gms' under GAMSWorkspace's working directory
fid = fopen([ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'tdata.gms'], 'w');
fprintf(fid, data);
close(fid);
```

Afterwards we create a GAMSJob using the GAMSWorkspace.addJobFromString method. GAMSOptions.defines is used like the the 'double dash' GAMS parameters, i.e. it corresponds to `--incname=tdata` on the command line where incname is used as name for the include file in the model string.

```plaintext
% create GAMSJob 't2' from the 'model' string variable
t2 = ws.addJobFromString(model);
% create GAMSOption 'opt' and define 'incname' as 'tdata'
opt = ws.addOptions();
opt.defines('incname', 'tdata');
% run GAMSJob 't2' with GAMSOptions 'opt'
t2.run(opt);
```

The string model contains the following lines to read in the data.

```plaintext
$if not set incname $abort 'no include file name for data file provided'
$include incname
```

7.11.3.9 How to set a non-default working directory (transport3)

At first we create a new directory. Once this is done we can use this directory when creating the GAMSWorkspace and make it the working directory.

```plaintext
% create a directory
workingDirectory = fullfile(pwd, 'transport3');
mkdir(workingDirectory);
% create a workspace
wsInfo = GAMS.GAMSWorkspaceInfo();
wsInfo.workingDirectory = workingDirectory;
ws = GAMS.GAMSWorkspace(wsInfo);
```

7.11.3.10 How to read data from string and export to GDX (transport3)

We read the data from the string data. Note that this contains no model but only data definition in GAMS syntax. By running the corresponding GAMSJob a GAMSDatabase is created that is available via the GAMSJob.outDB property. We can use the GAMSDatabase.export method to write the content of this database to a gdx file tdata.gdx.

```plaintext
% create and run a job from a data file, then explicitly export to a GDX file
t3 = ws.addJobFromString(data);
t3.run();
t3.outDB.export([ws.workingDirectory, GAMS.GAMSGlobals.FILE_SEPARATOR, 'tdata.gdx']);
```
7.11.3.11 How to run a job using data from GDX (transport3)

This works quite similar to the usage of an include file explained in transport2 - How to use include files (transport2).

```plaintext
% run a job using an instance of GAMSOptions that defines the data include file
opt = ws.addOptions();
opt.defines('gdxincname', 'tdata');
t3.run(opt);
```

Note that there are some minor changes in the model due to the usage of a gdx instead of an include file.

```plaintext
if not set gdxincname
  abort 'no include file name for data file provided'
$gdxin %gdxincname%
$load i j a b d f
$gdxin
```

7.11.3.12 How to run a job using implicit database communication (transport3)

This example does basically the same as the two preceding examples together. We create two GAMSJobs `t3a` and `t3b` where the first one contains only the data and the second one contains only the model without data. After running `t3a` the corresponding outDB can be read in directly just like a gdx file.

Note that the database needs to be passed to the GAMSJob.run method as additional argument.

```plaintext
t3a = ws.addJobFromString(data);
t3b = ws.addJobFromString(model);
opt = ws.addOptions();
t3a.run();
opt.defines('gdxincname', t3a.outDB.name);
t3b.run(opt, t3a.outDB);
```

7.11.3.13 How to define data using Matlab data structures (transport4)

We use cell arrays and containers.Map to define Matlab data structures that correspond to the sets, parameters and tables used for the data definition in GAMS.

```plaintext
plants = {'Seattle', 'San-Diego'};
markets = {'New-York', 'Chicago', 'Topeka'};
capacity = containers.Map();
capacity('Seattle') = 350;
capacity('San-Diego') = 600;
demand = containers.Map();
demand('New-York') = 325;
demand('Chicago') = 300;
demand('Topeka') = 275;
distance = containers.Map();
distance('Seattle.New-York') = 2.5;
distance('Seattle.Chicago') = 1.7;
distance('Seattle.Topeka') = 1.8;
distance('San-Diego.New-York') = 2.5;
distance('San-Diego.Chicago') = 1.8;
distance('San-Diego.Topeka') = 1.4;
```

7.11.3.14 How to prepare a GAMSDatabase from Matlab data structures (transport4)

At first we create an empty GAMSDatabase `db` using the GAMSWorkspace.addDatabase method. Afterwards we prepare the database. To add a set to the database we use the GAMSSet class and the GAMSDatabase.addSet method with arguments describing the identifier, dimension and explanatory text. To add the records to the database we iterate over the elements of our Matlab data structure and add them by using the GAMSSet.addRecord method.

For parameters the procedure is pretty much the same. Note that the table that specifies the distances in GAMS can be treated as parameter with dimension 2 and that scalars can be treated as parameter with dimension 0.

The GAMSJob can be run like explained in the preceding example about implicit database communication.

```plaintext
db = ws.addDatabase();
```
i = db.addSet('i', 1, 'canning plants');
for p = plants
 i.addRecord(p[i]);
end
j = db.addSet('j', 1, 'markets');
for m = markets
 j.addRecord(m[i]);
end
a = db.addParameter('a', 'capacity of plant i in cases', i);
for p = plants
 a.addRecord(p[i]).value = capacity(p[i]);
end
b = db.addParameter('b', 'demand at market j in cases', j);
for m = markets
 b.addRecord(m[i]).value = demand(m[i]);
end
d = db.addParameter('d', 'distance in thousands of miles', i, j);
for p = plants
 for m = markets
  d.addRecord(p[i], m[i]).value = distance([p[i], '.', m[i]]);
 end
end
f = db.addParameter('f', 'freight in dollars per case per thousand miles');
f.addRecord().value = 90;
% create and run a job from the model and read gdx include file from the database
t4 = ws.addJobFromString(model);
opt = ws.addOptions();
opt.defines('gdxincname', db.name);
t4.run(opt, db);

7.11.3.15 How to initialize a GAMSCheckpoint by running a GAMSJob (transport5)

The following lines of code conduct several operations. While the first line simply creates a GAMSCheckpoint, the second one uses the GAMSWorkspace.addJobFromString method to create a GAMSJob containing the model text and data but no solve statement. Afterwards the run method gets the GAMSCheckpoint as argument. That means the GAMSCheckpoint cp captures the state of the GAMSJob. cp = ws.addCheckpoint();
t5 = ws.addJobFromString(model);
t5.run(cp);

7.11.3.16 How to initialize a GAMSJob from a GAMSCheckpoint (transport5)

Note that the string returned from function model contains the entire model and data definition plus an additional demand multiplier and scalars for model and solve status but no solve statement:
Scalar bmult demand multiplier /1/;
... demand(j) .. sum(i, x(i,j)) =g= bmult*b(j) ;
... Scalar ms 'model status', ss 'solve status'; In transport5 we create a list with eight different values for this demand multiplier.
bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3];
For each entry of that list we create a GAMSJob t5 using the GAMSWorkspace.addJobFromString method. Besides another string which resets the demand multiplier bmult, specifies the solve statement and assigns values to the scalars ms and ss we pass the checkpoint cp as additional argument. This results in a GAMSJob combined from the checkpoint plus the content provided by the string. We run the GAMSJob and echo some interesting data from the outDB using the GAMSDatabase.getParameter and GAMSDatabase.getVariable methods and the GAMSSymbol.record attribute plus the GAMSParameterRecord.value and the GAMSVariableRecord.level properties.
for i = 1:numel(bmultlist)
 job = sprintf('bmult=%f; solve transport min z use lp; ms=transport.modelstat; ss=transport.solvestat;', bmultlist(i));
 t5 = ws.addJobFromString(job, cp);
 t5.run();
 fprintf('Scenario bmult=%f: 
', bmultlist(i));
 fprintf(' Modelstatus: %s 
', GAMS.ModelStat.lookup(t5.outDB.getParameter('ms').record.value));
 fprintf(' Solvestatus: %s 
', GAMS.SolveStat.lookup(t5.outDB.getParameter('ss').record.value));
 fprintf(' Obj: %f 
', t5.outDB.getVariable('z').record.level);
end

Note
Some of the demand multipliers cause infeasibility. Nevertheless, GAMS keeps the incumbent objective function value. Therefore the model status and the solve status provide important information for a correct solution interpretation.
7.11.3.17 How to create a GAMSModelInstance from a GAMSCheckpoint (transport7)

In transport7 the usage of Matlab::GAMS::GAMSModelInstance is demonstrated.

At first checkpoint \( cp \) is created as in the preceding examples. Then we create the GAMSModelInstance \( mi \) using the GAMSCheckpoint.addModelInstance method. Note that the GAMSJob again contains no solve statement and the demand multiplier is already included with default value 1.

\[
\begin{align*}
& cp = ws.addCheckpoint(); \\
& \% initialize a checkpoint by running a job \\
& t7 = ws.addJobFromString(model); \\
& t7.run(cp); \\
& \% create a ModelInstance and solve it multiple times with different scalar \( bmult \) \\
& mi = cp.addModelInstance();
\end{align*}
\]

7.11.3.18 How to modify a parameter of a GAMSModelInstance using GAMSModifier (transport7)

A GAMSModelInstance uses a syncDB to maintain the data. We define \( bmult \) as GAMSParameter using the GAMSParameter method and specify cplex as solver. Afterwards the GAMSModelInstance is instantiated with 3 arguments, the solve statement, GAMSOptions \( opt \) and GAMSModifier \( bmult \). The GAMSModifier means that \( bmult \) is modifiable while all other parameters, variables and equations of ModelInstance \( mi \) stay unchanged. We use the GAMSParameter.addRecord method and the value property to assign a value to \( bmult \). That value can be varied afterwards using the GAMSSymbol.record property to reproduce our well-known example with different demand multipliers.

\[
\begin{align*}
& bmult = mi.syncDB.addParameter('bmult', 'demand multiplier'); \\
& opt = ws.addOptions(); \\
& opt.setAllModelTypes('cplex'); \\
& \% instantiate the ModelInstance and pass a model definition and Modifier to declare bmult mutable \\
& mi.instantiate('transport use lp min z', opt, GAMS.GAMSModifier(bmult)); \\
& bmult.addRecord().value = 1.0; \\
& bmultlist = [0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3]; \\
& for i = 1:numel(bmultlist) \\
& \quad bmult.record.value = bmultlist(i); \\
& \quad mi.solve(); \\
& \quad fprintf('Scenario bmult=%f:
', bmultlist(i)); \\
& \quad fprintf(' Modelstatus: %s
', mi.modelStatus); \\
& \quad fprintf(' Solvestatus: %s
', mi.solveStatus); \\
& \quad fprintf(' Obj: %f
', mi.syncDB.getVariable('z').record.level); \\
& \end{align*}
\]

7.11.3.19 How to modify a variable of a GAMSModelInstance using GAMSModifier (transport7)

We create a GAMSModelInstance just like in the next to last example. We define \( x \) as GAMSVariable and its upper bound as GAMSParameter \( xup \). At the following instantiate method GAMSModifier has 3 arguments. The first one says that \( x \) is modifiable, the second determines which part of the variable (lower bound, upper bound or level) can be modified and the third specifies the GAMSParameter that holds the new value.

In the following loops we set the upper bound of one link of the network to zero, which means that no transportation between the corresponding plant and market is possible, and solve the modified transportation problem.

\[
\begin{align*}
& mi = cp.addModelInstance(); \\
& x = mi.syncDB.addVariable('x', 2, GAMS.VarType.POSITIVE, ''); \\
& xup = mi.syncDB.addParameter('xup', 2, 'upper bound on x'); \\
& \% instantiate the ModelInstance and pass a model definition and Modifier to declare upper bound of X mutable \\
& mi.instantiate('transport use lp min z', GAMS.GAMSModifier(x, GAMS.UpdateAction.UPPER, xup)); \\
& for i = t7.outDB.getSet('i').records \\
& \quad for j = t7.outDB.getSet('j').records \\
& \quad \quad xup.clear(); \\
& \quad \quad keys = {{i(1).key(1), j(1).key(1)}}; \\
& \quad \quad xup.addRecord(keys).value = 0; \\
& \quad \quad mi.solve(); \\
& \quad \quad fprintf('Scenario link blocked: \%s - \%s:
', keys{:}); \\
& \quad \quad fprintf(' Modelstatus: \%s\%s, mi.modelStatus); \\
& \quad \quad fprintf(' Solvestatus: \%s\%s, mi.solveStatus); \\
& \quad \quad fprintf(' Obj: \%s\%s, mi.syncDB.getVariable('z').record.level); \\
& \end{align*}
\]
How to create and use a save/restart file (transport11)

In transport11 we demonstrate how to create and use a save/restart file. Usually such a file should be supplied by an application provider but in this example we create one for demonstration purpose. Note that the restart is launched from a GAMSCheckpoint. From the main function we call the function create\_save\_restart giving it the current workspace settings and the desired file name as arguments.

```plaintext
create\_save\_restart(ws.workingDirectory, ws.systemDirectory, ws.debugLevel, 'tbase');
```

In function create\_save\_restart we create a workspace with the given workspace settings. Then we create a GAMSJob from a string. Note that the string given via basemodel contains the basic definitions of sets without giving them a content (that is what $onempty is used for). Afterwards we specify a GAMSOptions to only compile the job but do not execute it. Then we create a checkpoint cp that is initialized by the following run of the GAMSJob and stored in the file given as argument to the function, in our case tbase. This becomes possible because the addCheckpoint method accepts identifiers as well as file names as argument.

```plaintext
ws = GAMS.GAMSWorkspace(workdir, systemdir, debuglevel);
j1 = ws.addJobFromString(basemodel);
opt = ws.addOptions();
opt.action = GAMS.Action.CompileOnly;
cp = ws.addCheckpoint('tbase');
j1.run(opt, cp);
opt.dispose();
j1.outDB.dispose();
```

So what you should keep in mind before we return to further explanations of the main function is, that the file tbase is now in the current working directory and contains a checkpoint. Now in the main function we define some data using Matlab data structures as we already did in transport4 before we create the GAMSWorkspace and a GAMSDatabase.

```plaintext
ws = GAMS.GAMSWorkspace(wsInfo);
db = ws.addDatabase();
```

Afterwards we set up the GAMSDatabase like we already did in transport4. Once this is done we run a GAMSJob using this data plus the checkpoint stored in file tbase.

```plaintext
cpBase = ws.addCheckpoint('tbase');
opt = ws.addOptions();
t11 = ws.addJobFromString(model, cpBase);
opt.defines('gdxincname', db.name);
opt.setAllModelTypes('xpress');
t11.run(opt, db);
```

Note that the string from which we create job t11 is different to the one used to prepare the checkpoint stored in tbase and is only responsible for reading in the data from the GAMSDatabase correctly. The entire model definition is delivered by the checkpoint cpBase which is equal to the one we saved in tbase.

7.12 Release Notes

7.12.1 35.1.0

- Fixed GAMSOptions.Output parameter being ignored in GAMSJob.Run().

7.12.2 32.1.0

- Automatically finding a GAMS installation from the Windows registry has been changed from using [HKEY_CURRENT_USER\HKEY_CLASSES_ROOT]\gams.location to [HKEY_CURRENT_USER\HKEY_LOCAL_MACHINE]\Software\GAMS\GAMS\13.7.6\gams.location
7.12.3 25.0.1

Changes for GAMSSymbol and GAMSSymbolRecord: Both classes got the IEquatable<T> Interface. As a result the behavior of the Equals function as well as the == and != operators were modified. For both classes Equals and == returns now true, if the internal data reference is the same. Here is an example:

```csharp
GAMSVariable x1 = t1.OutDB.GetVariable("x");
GAMSVariable x2 = t1.OutDB.GetVariable("x");
if(x1 == x2)
    Console.WriteLine("x1==x2");
else
    Console.WriteLine("x1!=x2");
if (x1.Equals(x2))
    Console.WriteLine("x1 equals x2");
else
    Console.WriteLine("x1 does not equal x2");
```

In previous versions we got this output:
```
x1!=x2
x1 does not equal x2
```

Now we get:
```
x1==x2
x1 equals x2
```

7.12.4 24.9.1

- New functions GAMSWorkspace.AddJobFromApiLib, GAMSWorkspace.AddJobFromNoaLib to create GAMSJob from models from the GAMS API Library and the Nonlinear Optimization Applications Library

7.12.5 24.8.1

- New option GAMSOptions.ErrorLog: Max error message lines written to the log for each error

7.12.6 24.7.4

- GAMSModelInstance.Instantiate: Skip creation of GDX file, which was unreachable from within the API anyway

7.12.7 24.7.1

- GAMSWorkspace.AddJobFromFile: Throw an exception if given file does not exist

7.12.8 24.5.4

- Fixed a bug with the property GAMSOptions.IDir

7.12.9 24.5.2

- Fixed a bug that lead to a crash on Linux (using Mono) when the GAMS system directory is a symbolic link
7.12.10  24.5.1

- New functions GAMSWorkspace.ApiLib and GAMSWorkspace.NoaLib that can be used to retrieve models from the GAMS API Library and the Nonlinear Optimization Applications Library

7.12.11  24.4.2

- New property GAMSSymbol.DomainsAsStrings: Domains of Symbol, each element is a string
  Note: If the domain is an alias in GAMS, this call will return the name of the Alias, not the name of the aliased Set
- Disable unwanted debug output from Couenne when running with GAMSModelInstance

7.12.12  24.4.1

- Modified handling of GAMS Aliases:
  - If we ask for the number of GAMSSymbols in a GAMSDatabase, the Aliases will be excluded
  - If we iterate over all GAMSSymbols in a GAMSDatabase, Aliases will be skipped
  - If we ask explicitly for an Alias in a GAMSDatabase (GAMSDatabase.GetSet(“a”) with a being an Alias) we will get a reference to the GAMSSet referenced by the Alias, not the Alias itself
  - Note: Aliases can appear in a GAMSDatabase only, if it was initialized by a GDX file containing an Alias.

7.12.13  24.3.2

- Make more GAMS options available through the GAMSOptions class:
  - GAMSOptions.AppendExpand: Expand file append option
  - GAMSOptions.AppendOut: Output file append option
  - GAMSOptions.DumpOpt: Writes preprocessed input to the file input.dmp
  - GAMSOptions.DumpParms: GAMS parameter logging
  - GAMSOptions.ErrMsg: Placing of compilation error messages
  - GAMSOptions.Expand: Expanded (include) input file name
  - GAMSOptions.FErr: Alternative error message file
  - GAMSOptions.JobTrace: Job trace string to be written to the trace file at the end of a Gams job
  - GAMSOptions.LimCol: Maximum number of columns listed in one variable block
  - GAMSOptions.LimRow: Maximum number of rows listed in one equation block
  - GAMSOptions.LogLine: Amount of line tracing to the log file
  - GAMSOptions.On115: Generate errors for unknown unique element in an equation
  - GAMSOptions.Output: Output file
  - GAMSOptions.PageContr: Output file page control option
  - GAMSOptions.PageSize: Output file page size (=0 no paging)
  - GAMSOptions.PageWidth: Output file page width
  - GAMSOptions.Reference: Symbol reference file
  - GAMSOptions.ScriptExit: Program or script to be executed at the end of a GAMS run
  - GAMSOptions.Suppress: Compiler listing option
  - GAMSOptions.Symbol: Symbol table file
  - GAMSOptions.TraceLevel: Solvestat threshold used in conjunction with a=GT
7.12.14 24.3.1

- GAMSJob.Run creates OutDB now even if it throws a GAMSExceptionExecution
- New function GAMSSymbolRecord.Key(int index): Retrieve key of GAMSSymbolRecord on position index
- GAMSModelInstance.Solve also works now for solvers which require a subsolver, e.g. Dicopt
- GAMSDatabase.Export registers real domains in GDX file now if possible, before relaxed domains were registered always
- GAMSSymbol.CopySymbol works for the Universe of a GAMSDatabase (GAMSDatabase.GetSet("*")) now, when copying into the Universe, a merge will be performed
- Fix default value for systemDirectory argument in GAMSWorkspace constructor when using MONO: If no value is given, first the PATH and then the (DY)LD_LIBRARY_PATH is checked for a valid GAMS system directory

7.12.15 24.2.3

- Fix memory leak in GAMSDatabase

7.12.16 24.2.2

- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the API
- Fix GAMSEnum.GAMSExitCode
- Make sure that GAMSModelInstance.Instantiate() does not solve the model, but only prepares everything required for the following Solve()

7.12.17 24.2.1

- New version of function GAMSWorkspace.AddOptions creating an instance of GAMSOptions initialized by an existing option file
- New properties: GAMSWorkspace.APIVersion, GAMSWorkspace.APIMajorRelNumber, GAMSWorkspace.APIMinorRelNumber and GAMSWorkspace.APIGOLDRelNumber
- New property GAMSWorkspace.MyEPS: Reset value to be stored in and read from GAMSDatabase for Epsilon, default is double.Epsilon
- New function GAMSOptions.Export: Write GAMSOptions into a parameter file
- Switching type of property GAMSOptions.NoNewVarEqu from Integer to Enum (ENoNewVarEqu)
7.12.18 24.1.1

- **GAMSDatabase:**
  - New function `CheckDomains`: Check for all symbols if all records are within the specified domain of the symbol
  - New function `GetDatabaseDVs`: Return all GAMSDatabaseDomainViolations
  - New property `SuppressAutoDomainChecking`: Controls whether domain checking is called in GAMSDatabase export
  - New variants of the functions AddEquation, AddParameter, AddSet, AddVariable: Allow to specify domain information
  - Function `Compact` becomes obsolete and will be dropped in future

- **GAMSModelInstance:**
  - New function `CopyModelInstance`: Copies a ModelInstance to a new ModelInstance which gets constructed at this call
  - New function `Interrupt`: Sends interrupt signal to running GAMSModelInstance

- **GAMSModifier:**
  - Allow to define `SymbolUpdateType` for each GAMSModifier separately

- **GAMSSymbol (GAMSEquation, GAMSParameter, GAMSSet, GAMSVariable):**
  - New function `CheckDomains`: Check if all records are within the specified domain of the symbol
  - New function `CopyToArray`: Copies values of a dense symbol into a dense array
  - New function `CopyToSqdArray`: Copies values of a sparse symbol into a squeezed array
  - New function `CopySparseToDenseArray`: Copies values of a sparse symbol into a dense array
  - New function `CopyFromDenseArray`: Copies values from dense array into a symbol
  - New function `CopySliceFromDenseArray`: Copies values from slice of dense array into a symbol
  - New function `GetSymbolDVs`: Return all GAMSSymbolDomainViolations
  - New function `MergeRecord`: Finds record in GAMSSymbol if it exists, adds it if not
  - New property `Domains`: Domains of Symbol, each element is either a GAMSSet (real domain) or a string (relaxed domain)

- **GAMSWorkspace:**
  - Change the Debug parameter from a Boolean flag to an enum type called `DebugLevel`
  - The Debug parameter can be overwritten by the system environment variable "GAMSOOAPI-DEBUG" if set to one of the following: Off, KeepFiles, ShowLog, Verbose
  - Improve performance significantly for function `AddDatabase(GAMSDatabase)`
  - New functions: `AddJobFromGamsLib`, `AddJobFromTestLib`, `AddJobFromEmpLib`, `AddJobFromDataLib` and `AddJobFromFinLib`
  - New properties: `Version`, `MajorRelNumber`, `MinorRelNumber` and `GOLDRelNumber`
  - New optional parameter `inModelName` for functions `AddDatabaseFromGDX/AddDatabase`: GAMS string constant that is used to access this database

- Add new sub class of GAMSException: `GAMSExceptionExecution`. This provides additional info about the reason of the failed execution.

7.12.19 24.0.2

- Add new function `GAMSSymbol.CopySymbol` which copies all records from one to another GAMSSymbol

- Label and symbol lookup is now case insensitive

- Fixed handling of infinite bounds for GAMSModifiers
7.12.20  24.0.1

- Add function Interrupt to GAMSJob
- Do not throw an exception when hitting an Alias with the GAMSDatabaseEnumerator or GetSymbol function but return the aliased GAMSSet

7.12.21  23.9.3

- Constructor of GAMSWorkspace now appends conditionally the GAMS system directory to the PATH environment variable. This fixes a problem with applications that create and dispose many GAMSWorkspace instances.

7.12.22  23.9.2

- GAMSModelInstance.Instantiate is now thread-safe
- Additional flag createOutDB for method GAMSJob.Solve which allows to switch off automatic outDB creation
- Fix a problem with parallel execution of GAMSModelInstances in Debug mode
- Add new class GAMSException
- Add tighter restriction on adding symbols to GAMSModelInstance.SyncDB
- Add new class GAMSModelInstanceOpt to customize method GAMSModelInstance.Solve
  - GAMSModelInstanceOpt.Debug: produces a gams.gms, jacobian.gdx and dictmap.gdx allowing inspection of the model instance solved in the GAMSModelInstance.Solve method
  - GAMSModelInstanceOpt.NoMatchLimit: controls the maximum number of accepted unmatched scenario records before terminating the solve
  - GAMSModelInstanceOpt.OptFile: allows to choose solver option for GAMSModelInstance.Solve
  - GAMSModelInstanceOpt.Solver: allows to choose solver for GAMSModelInstance.Solve
- Add GAMSWorkspace.ScratchFilePrefix to prefix all scratch files created by GAMS.Net
- GAMSJob no longer implements IDisposable

7.13  Release Notes

7.13.1  35.1.0

- Fixed GAMSOptions.setOutput parameter being ignored in GAMSJob.run().

7.13.2  32.1.0 (July 2020)

- On windows platform, change of window registry configuration used for finding the installed GAMS directory from: [HKEY_CURRENT_USER\HKEY_CLASSES_ROOT]\gams.location to: [HKEY_CURRENT_USER\HKEY_LOCAL_MACHINE]\Software\Classes\gams.location, effective only when the installed GAMS directory is not found from "PATH" environment variable.
7.13 Release Notes

7.13.3 29.1.0 (November 2019)

- Increase the minimum version requirement of the Java Runtime Environment to Java SE 8.

- The remove operation `GAMSDatabaseIterator.remove` is no longer supported. The method now throws an instance of `java.lang.UnsupportedOperationException` and performs no other actions. (To remove all records of the current iterating symbol, use the method `GAMSSymbol.clear` instead.)

- Fixed the behavior of the remove operation `GAMSSymbolIterator.remove`. The method now removes all records of the last GAMSSymbol element returned by an instance of `GAMSSymbolIterator` and can be called only once per call to `GAMSSymbolIterator.next`. The behavior of an iterator is unspecified if the underlying collection is modified while the iteration is in progress in any way other than by calling the method.

7.13.4 28.2.0 (August 2019)

- Added new method `GAMSSymbolRecord.dispose` for on-demand release of external resources hold by non-java library.

7.13.5 28.1.0 (August 2019)

- Announced a plan to increase the minimum version requirement of the Java Runtime Environment to Java SE 8 with the next major release.

7.13.6 25.1.1 (May 2018)

- Changed the naming scheme of a temporary working directory to be created from 'yyyyMM-Mdd_HHmmss' to the prefixed 'gams_' (defined by `GAMSGlobals.workingDirectoryPrefix`), in case no working directory has been specified.

- Fixed the behavior when GAMSDatabase is added with the name that already exists, now GAMSException will be raised. (see `GAMSWorkspace.addDatabase(String databaseName)` and `GAMSWorkspace.addDatabaseFromGDX(String.gdxFileName, String databaseName)`)

- Calls on `GAMSWorkspace.finalize` and `GAMSSymbolIterator.finalize` are no longer available. As calling a finalizer method can arbitrarily delay the reclamation of object instances and potentially create unpredictable outcome. Whenever the object is no longer needed it is recommened to explicitly dispose the object rather than to rely on the Java garbage collector to do the job. See `GAMSDatabase.dispose`, `GAMSModelInstance.dispose`, and `GAMSOptions.dispose`.

- All Java native interfaces to Expert-Level APIs are now included in the distributed `GAMSJavaAPI.jar`, located under the [Path/To/GAMS]/apifiles/Java/api/ directory.
7.13.7  25.0.1 (January 2018)

- The minimum version requirement of Java Runtime Environment for using with GAMS Java API is now Java SE 7.
- New TransportGDX example to demonstrate how to import and export GDX files.
- Removed GAMSSymbol.compact, deprecated since 24.8.1 (December 2016).
- Changed equivalence behavior of GAMSSymbol and GAMSSymbolRecord objects. As a result, two symbol objects with the same internal reference are now equivalent, similar to symbol record objects:
  - Two symbols are equivalent if and only if they have the same internal reference.
  - Two symbol records are equivalent if and only if they have the same internal reference.

The behavior of operator == remains unchanged. The following example illustrates the new equivalence behavior:

```java
GAMSVariable x1 = db.getVariable("x");
GAMSVariable x2 = db.getVariable("x");
x1.x = 1;
assertTrue(x1.equals(x2)); // true, previously false
assertFalse(x1 == x2); // false, previously false
GAMSVariable x3 = x1;
assertTrue(x1.equals(x3)); // true, previously true
assertTrue(x1 == x3); // true, previously true
```

7.13.8  24.8.1 (December 2016)

- Deprecated GAMSSymbol.compact and the method will be removed in the next major release
- an exception or an error thrown by GAMSWorkspace.finalize and GAMSSymbolIterator.finalize now must be caught or declared to be thrown. Note that an explicit call on one of these two methods is not recommended unless it is necessary to do so.

7.13.9  24.7.4 (September 2016)

- GAMSModelInstance.instantiate: Skip creation of GDX file, which was unreachable from within the API anyway

7.13.10  24.7.1 (March 2016)

- Fixed a bug with the property GAMSOptions.defines: When too many entries were added, all of them were ignored.

7.13.11  24.5.1 (August 2015)

- New examples
  - Clad at [Path/To/GAMS]/apifiles/Java/clad/Clad.java
  - SpecialValues at [Path/To/GAMS]/apifiles/Java/specialvalues/SpecialValues.java
- New functions GAMSWorkspace.addJobFromApiLib and GAMSWorkspace.addJobFromNoaLib that can be used to retrieve models from GAMS API Library and Nonlinear Optimization Applications Library.
7.13.12 24.4.2 (March 2015)

- New property `GAMSSymbol.getDomainsAsString`: get domains of symbol, each element is a string
  Note: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set.
- Disable unwanted debug output from Couenne when running with `GAMSModelInstance`
- Change naming scheme of gdx output scratch file to sequence number.

7.13.13 24.4.1 (December 2014)

- Modify the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of `GAMSSymbol` in a `GAMSDatabase`, the Aliases will be excluded.
  - If we iterate over all `GAMSSymbol` in a `GAMSDatabase`, Aliases will be skipped.
  - If we ask explicitly for an Alias in a `GAMSDatabase` (`GAMSDatabase.getSet("a")` with `a` being an Alias) we will get a reference to the `GAMSSet` referenced by the Alias, not the Alias itself.
  - Note:
    - Aliases can appear in a `GAMSDatabase` only, if it was initialized by a GDX file containing an Alias.
    - The new example `Alias` at `[Path/To/GAMS]/apifiles/Java/alias/Alias.java` demonstrates this new behavior.

7.13.14 24.3.3 (September 2014)

Fixed

- a location of listing file when creating a job from (full-path) file without giving a job name

7.13.15 24.3.2 (August 2014)

- Make more GAMS options available through the `GAMSOptiions` class:
  - `GAMSOptions.EAppendExpand` (`enum`, getter, and setter): Expand file append option
  - `GAMSOptions.EAppendOut` (`enum`, getter, and setter): Output file append option
  - `GAMSOptions.EDumpOpt` (`enum`, getter, and setter): Writes preprocessed input to the file input.dmp
  - `GAMSOptions.EDumpParms` (`enum`, getter, and setter): GAMS parameter logging
  - `GAMSOptions.EErrMsg` (`enum`, getter, and setter): Placing of compilation error messages
  - `GAMSOptions.EAppendExpand` (`getter`, and `setter`): Expanded (include) input file name
  - `GAMSOptions.FErr` (`getter`, and `setter`): Alternative error message file
  - `GAMSOptions.JobTrace` (`getter`, and `setter`): Job trace string to be written to the trace file at the end of a Gams job
  - `GAMSOptions.LimCol` (`getter`, and `setter`): Maximum number of columns listed in one variable block
- GAMSOptions.LimRow (getter, and setter): Maximum number of rows listed in one equation block
- GAMSOptions.ELogLine (enum, getter, and setter): Amount of line tracing to the log file
- GAMSOptions.EOn115 (enum, getter, and setter): Generate errors for unknown unique element in an equation
- GAMSOptions.Output (getter, and setter): Output file
- GAMSOptions.EPageContr (enum, getter, and setter): Output file page control option
- GAMSOptions.PageSize (getter, and setter): Output file page size (=0 no paging)
- GAMSOptions.PageWidth (getter, and setter): Output file page width
- GAMSOptions.Reference (getter, and setter): Symbol reference file
- GAMSOptions.ScriptExit (getter, and setter): Program or script to be executed at the end of a GAMS run
- GAMSOptions.ESuppress (enum, getter, and setter): Compiler listing option
- GAMSOptions.Symbol (getter, and setter): Symbol table file
- GAMSOptions.TraceLevel (getter, and setter): Solvestat threshold used in conjunction with a=GT

7.13.16 24.3.1 (July 2014)

New

- Transport14 example at [Path/To/GAMS]/apifiles/Java/transport/Transport14.java.
- GAMSSymbolRecord.getKey method: to retrieve key of GAMSWorkspace on specified position index.

Changed

- no longer necessary to set up environment variable before running a program
  - possible to specify the GAMS system directory during run time using GAMSWorkspace-
    Info.setSystemDirectory(String directory) and GAMSWorkspace(GAMSWorkspaceInfo info)
- no longer necessary to specify -Djava.library.path when running a program
  - if java.library.path is specified, the shared libraries will be loaded from java.library.path
  - otherwise the shared libraries will be loaded from the class path that contains GAMSJavaAPI.jar.
- when exporting a database to GDX: a symbol with real domains from now on will be registered
- in GAMSJob.run: always creates output database OutDB even if GAMSEExecutionException has been raised.
- in GAMSSymbol.copySymbol when copy into the Universe symbol (GAMS-
  Database.getSet("*") of a GAMSDatabase: merge operation will be performed.
- in GAMSWorkspace default constructor: API will apply the default setting, that is, finding GAMS system directory from environment variable in the following order (depends on the target platform):
  - Windows: first from PATH environment variable. If not found, from the platform windows registry gams.location,
  - Mac OS: first from PATH environment variable. If not found, from DYLD_LIBRARY_PATH,
7.13 Release Notes

Unix: from PATH environment variable. If not found, from LD_LIBRARY_PATH.

• in non-default GAMSWorkspace constructor:
  
  – user can specify a GAMS system directory during run time, API will not search for a GAMS system directory from an environment variable.
  
  – in case the specified system directory is null or user specify other workspace attributes but a system directory, API will apply the default setting (see changed in GAMSWorkspace default constructor above).

Fixed

• API memory leak issue in GAMSDatabaseIterator.

• a bug when reading an option file on Unix platform with non-standard locale

Removed

• all deprecated classes and methods since 24.1.

7.13.17  24.2.3 (May 2014)

Fixed

• API memory leak issue in GAMSDatabase.

• a bug in GAMSDatabase.getDatabaseDomainViolations.

7.13.18  24.2.2 (March 2014)

Changed

• null string is treated as an invalid key for all record operations of GAMSSymbol.

Fixed

• a bug when creating GAMSDatabase from source database.

• a bug when initializing a variable type in GAMSVariable.

• a bug in GAMSSymbol: methods getVarType and getEquType.

• a bug in GAMSWorkspaceInfo : method getSystemDirectory.

• exit codes in GAMSGlobal.UseCodeMessage. Improved

• GAMSMModelInstance.instantiate: make sure that the method does not solve the model, but only prepares everything required for the following GAMSMModelInstance.solve.
New

- tutorial: (GAMS_java_Tutorial.pdf) under <Path/To/GAMS>/docs/API. From the GAMSIDE this document can be accessed at Help -> Docs -> API.
- method in GAMSGlobals.SpecialValues: setValue, to set a GAMS special value
- method in GAMSOptions: export, to write an option into a parameter file
- methods in GAMSWorkspace: addOptions to create a GAMSOptions object from either another object or an option file
- methods in GAMSWorkspace: getAPIVersion, getAPIMajorReleaseNumber, getAPIMinorReleaseNumber, and getAPIGoldReleaseNumber, to retrieve API version number

Changed

- default value of GAMSGlobals.SpecialValues: NAN, PLUS_INF, MINUS_INF, and EPS
- deprecated GAMSOptions.PoolFree4, replaced by GAMSOptions.EIntVarUp
- deprecated the type of GAMSOptions.NoNewVarEqu, replaced by enum GAMSOptions.ENoNewVarEqu

Fixed

- a bug when running a job with an input directory IDir added into GAMSOptions object.

7.13.20 24.1.3 (July 2013)

Improve data iterator

- New classes:
  - GAMSDatabaseIterator implements java.util.Iterator
  - GAMSSymbolIterator implements java.util.Iterator
- Deprecated Interface:
  - GAMSSymbolIterable, replaced by GAMSDatabaseIterator and GAMSSymbolIterator
- Changes in GAMSDatabase:
  - GAMSDatabase implements GAMSDatabaseIterator instead of GAMSSymbolIterable
  - deprecated the implemented methods of GAMSSymbolIterable: next(), hasnext(), and remove()
- Changes in GAMSSymbol:
  - GAMSSymbol implements GAMSSymbolIterator instead of GAMSSymbolIterable
  - deprecated the implemented methods of GAMSSymbolIterable: next(), hasnext(), and remove()
- New methods in GAMSSymbolRecord:
  - moveNext: to iterate to the next record using the current data iterator criterion
  - movePrevious: to iterate to the previous record using the current data iterator criterion

Update example:

- Transport12 at [Path/To/GAMS]/apifiles/Java/transport/Transport12.java
7.13 Release Notes

7.13.21 24.1.1 (May 2013)

Changes in GAMSDatabase:

- deprecates the compact method, as it has no effect anymore.

Changes in GAMSGlobals:

- the default value of working directory has been changed from System.getProperty("user.dir") to System.getProperty("java.io.tmpdir").

Changes in GAMSModelInstance:

- deprecates the instantiate(GAMSOptions options), instantiate(GAMSModifier[]), and instantiate(GAMSOptions, GAMSModifier[]) methods and replaced by instantiate(String, GAMSModifier ...) and instantiate(String, GAMSOptions, GAMSModifier ...) methods.

Changes in GAMSWorkspace and GAMSWorkspaceInfo:

- deprecates boolean debug flag and replaced by a debug level flag (type of a new class GAMSGlobals.DebugLevel).
- allows an override of debug level flag from an environment variable GAMS00APIDebug

New methods in GAMSDatabase:

- GAMSDatabase.addEquation, addParameter, addSet, and addVariable: to add symbols with domain information.
- checkDomains: to check whether or not all records of all symbols are within the specified domain of the symbols.
- getDatabaseDomainViolations: to retrieve a domain violation information as a list of GAMSDatabaseDomainViolation objects.
- isAutoDomainCheckingSuppressed and suppressAutoDomainChecking: to control whether domain checking will be called when exporting a database.

New class GAMSDatabaseDomainViolation:

- contains domain violation information of all symbols (if any) in the database.
- returns call from a new method GAMSDatabase.getDatabaseDomainViolations.

New enumeration class GAMSGlobals.DebugLevel:

- defines values of different GAMS Debug Levels.

New methods in GAMSModelInstance:

- copyModelInstance: to copy a GAMSModelInstance object.
• **interrupt**: to send an interrupt signal to a running `GAMSModelInstance` object.

New enumerated value of `GAMSModelInstance.SymbolUpdateType`:

• `GAMSModelInstance.SymbolUpdateType.INHERIT`: to specify `GAMSModelInstance.SymbolUpdateType` separately for each `GAMSModifier`.

New methods in `GAMSModifier`:

• **constructor**: to specify `SymbolUpdateType` for each `GAMSModifier` object.

• **getUpdateType**: to retrieve `SymbolUpdateType` property of the object.

New methods in `GAMSSymbol`:

• **checkDomains**: to check whether or not all records of the symbol are within the specified domain.

• **getDomains**: to retrieve a list of domains of the symbol, each element is either a `GAMSSet` (real domain) or a `String` (relaxed domain).

• **getSymbolDomainViolations**: to retrieve a domain violation information as a list of `GAMSSymbolDomainViolation` objects.

• **mergeRecord**: to add a new symbol record in case the record does not exist.

New class `GAMSSymbolDomainViolation`:

• contains domain violation information of the symbol (if any).

• returns call from a new method `GAMSSymbol.getSymbolDomainViolations`.

New methods in `GAMSWorkspace`:

• **getGAMSVersion**: to retrieve information about GAMS Version.

• **getGoldReleaseNumber**: to retrieve GAMS GOLD Release Number.

• **getMajorReleaseNumber**: to retrieve GAMS Major Release Number.

• **getMinorReleaseNumber**: to retrieve GAMS Minor Release Number.

Fixed a bug when iterating through the records of a `GAMSSymbol`

Changes of location of examples:

• **Bender Examples**: from [Path/To/GAMS]/apifiles/Java/Benders*.java to [Path/To/GAMS]/apifiles/Java/benders/Benders*.java

• **Cutstock**: from [Path/To/GAMS]/apifiles/Java/Custock.java to [Path/To/GAMS]/apifiles/Java/cutstock/Cutstock.java

• **ConsoleInterrupt**: from [Path/To/GAMS]/apifiles/Java/ConsoleInterrupt.java to [Path/To/GAMS]/apifiles/Java/interrupt/ConsoleInterrupt.java

• **Transport Examples**: from [Path/To/GAMS]/apifiles/Java/Transport*.java to [Path/To/GAMS]/apifiles/Java/transport/Transport*.java

• **Warehouse**: from [Path/To/GAMS]/apifiles/Java/Warehouse.java to [Path/To/GAMS]/apifiles/Java/warehouse/Warehouse.java

New examples:

• **SimpleCutstock** at [Path/To/GAMS]/apifiles/Java/cutstock/SimpleCutstock.java

• **DomainCheck** at [Path/To/GAMS]/apifiles/Java/domain/DomainCheck.java

• **Transport13** at `[Path/To/GAMS]/apifiles/Java/transport/Transport13.java`

• **Tsp** at [Path/To/GAMS]/apifiles/Java/tsp/Tsp.java
7.13.22  24.0.2 (February 2013)

New method in **GAMSSymbol**

- added new method **copySymbol**.

7.13.23  24.0.1 (December 2012)

This release contains a beta version of the object-oriented Java API that can be used to control GAMS from a Java program. It allows the seamless integration of GAMS into Java by providing appropriate classes for the interaction with GAMS. GAMS Java API objects allow a convenient way to exchange input data and model results with in-memory representation of data (**GAMSDatabase**), and to create and run GAMS models (**GAMSJob**) that can be customized by GAMS options (**GAMSOptions**). Furthermore, they introduce a way to solve a sequence of closely related model instances in the more efficient way (**GAMSModelInstance**).

- A Java program that uses object-oriented Java API requires at least Java SE 5 to compile and run.
- All classes are distributed within one single jar file **GAMSJavaAPI.jar** with a namespace *com.gams.api*, located under the [Path/To/GAMS]/apifiles/Java/api/ directory.
- Java program examples are distributed with namespace *com.gams.examples*, located under [Path/To/GAMS]/apifiles/Java/ directory.
- Installation and detailed documents can be found in [Path/To/GAMS]/apifiles/readme.txt and [Path/To/GAMS]/docs/API/GAMS_java.pdf.
- Javadoc for **GAMSJavaAPI.jar** can be found under [Path/To/GAMS]/apifiles/java/api/javadoc directory.

7.14 Release Notes

7.14.1  35.1.0

- Fixed **GamsOptions.output** parameter being ignored in **GamsJob.run()**.

7.14.2  34.1.0

- Added support for Python 3.9.

7.14.3  32.1.0

- Dropped support for Python 2.
- Automatically finding a GAMS installation from the Windows registry has been changed from using **[HKEY_CURRENT_USER\HKEY_CLASSES_ROOT]\gams.location** to **[HKEY_CURRENT_USER\HKEY_LOCAL_MACHINE]\Software\GAMS\GAMS\GAMS\gams.location**.
The object-oriented GAMS Python API comes now in source code using the MIT open source license.

For accessing the GAMS API the Python interpreter needs to find files in `<GAMS Systemdirectory>/apifiles/Python/api_XY` and `<GAMS Systemdirectory>/apifiles/Python/gams` where XY corresponds to the Python version X.Y, e.g. 3.7. The GMSPython installation is already set up to find all required files. The documentation section Let Python find the GAMS Python files gives details on how to connect an external Python system with GAMS.

There is a different directory structure in `<GAMS Systemdirectory>/apifiles/Python`. The content of the api directory has been moved to different places:

- `api_27` for the binary Python 2.7 API files
- `src` for the files required to build the expert-level API files from source
- `gams` for source files of the GAMS Python API plus a few extra Python source files for working with indexed EMP syntax, e.g. `emppython1.gms`: Three Simple EMP Models with Indexed EMP Syntax and Python Parser
- `thirdparty` for the Python package `ply` for processing of indexed EMP syntax

Option `pySetup` has been removed from the class `GamsOptions`.

Removed GAMS return code 116 ("Could not find GMSPython").

Fixed a memory leak with `GamsModelInstance.solve`.

Dropped support for Python 3.4.

Added support for Python 3.8.

Added support for Python 3.7.

Dropped support for Python 2.6.

Added implementation of `__eq__()` and `__ne__()` to classes `GamsSymbol` and `GamsSymbolRecord` and its derived classes. As a result the behavior of the operators `==` and `!=` has changed. `==` returns now `True`, if the internal data reference is the same. The behavior of `is` remains unchanged.

New example `transport.gdx.py` that shows how to import and export GDX files.

Added description of example `transport.gdx.py` to the tutorial.
7.14.9  24.9.2

• Fixed a bug in the setup script that prevented files from being installed in the correct location in certain cases.

7.14.10  24.9.1

• New functions GamsWorkspace.add_job_from_apilib, GamsWorkspace.add_job_from_noalib to create GamsJob from models from the GAMS API Library and the Nonlinear Optimization Applications Library
• Added a version check for the setup.py scripts to avoid unintentional installation of wrong versions.

7.14.11  24.8.4

• Added support for Python 3.6
• Fixed a bug in GamsJob.run() that prevented the underlying GAMS model from terminating, if executables spawned by GAMS generate log output that is not captured.

7.14.12  24.8.1

• The option GamsOptions.errorlog was renamed as GamsOptions.errorlog in order to indicate it as public. The option sets the maximum error message lines written to the log for each error.

7.14.13  24.7.4

• Added support for Python 3.4 on Mac OS X
• Skip creation of a GDX file in GamsModelInstance.instantiate that was unreachable from within the API.
• Fixed a problems with Exceptions in GamsWorkspace.

7.14.14  24.7.2

• Fixed a minor bug regarding the names of GamsJob listing files.

7.14.15  24.7.1

• Fixed a bug with the property GamsOptions.defines: When too many entries were added, all of them were ignored
• Fixed a memory leak in GamsDatabase.

7.14.16  24.6.1

• New Python example transport8a.py
7.14.17 24.5.2

- Fixed a bug that lead to a crash on Linux when the GAMS system directory is a symbolic link. The property GamsWorkspace.system_directory now always returns the canonical path with all symbolic links resolved.

7.14.18 24.5.1

- Added support for Python 3.4 (Windows and Linux only)
  - The examples have been changed to be compatible with all supported Python versions
- New Python example special_values.py.
- New Python example clad.py.
- New functions GamsWorkspace.noalib and GamsWorkspace.apilib that can be used to retrieve models from the NOALIB and the APILIB

7.14.19 24.4.2

- Fixed a bug in the constructor of all subclasses of GamsSymbol that occurred when the explanatory text was omitted.
- Disable unwanted debug output from Couenne when running with GamsModelInstance
- New property GamsSymbol.domains_as_strings: Domains of Symbol, each element is a string. Note: If the domain is an alias in GAMS, this call will return the name of the alias, not the name of the aliased set
- Fixed potential problem with GamsModelInstance used with BARON.

7.14.20 24.4.1

- Fixed a bug in GamsDatabase.merge_record that prevented the function from creating a record if none was found.
- We changed the handling of GAMS Aliases in the object oriented APIs:
  - If we ask for the number of GamsSymbols in a GamsDatabase, the Aliases will be excluded.
  - If we iterate over all GamsSymbols in a GamsDatabase, Aliases will be skipped.
  - If we ask explicitly for an Alias in a GamsDatabase (GamsDatabase.get_set("a") with a being an Alias) we will get a reference to the GamsSet referenced by the Alias, not the Alias itself.
  - Note: Aliases can appear in a GamsDatabase only, if it was initialized by a GDX file containing an Alias.
  - The new Python example alias.py demonstrates this new behavior.
7.14.21 24.3.2

- Make more GAMS options available through the GamsOptions class (Removed leading underscores of property identifiers):
  - GamsOptions.appendexpand: Expand file append option
  - GamsOptions.appendout: Output file append option
  - GamsOptions.dumnpopt: Writes preprocessed input to the file input.dmp
  - GamsOptions.dumpparms: GAMS parameter logging
  - GamsOptions.errmsg: Placing of compilation error messages
  - GamsOptions.expand: Expanded (include) input file name
  - GamsOptions.ferr: Alternative error message file
  - GamsOptions.jobtrace: Job trace string to be written to the trace file at the end of a Gams job
  - GamsOptions.limcol: Maximum number of columns listed in one variable block
  - GamsOptions.limrow: Maximum number of rows listed in one equation block
  - GamsOptions.logline: Amount of line tracing to the log file
  - GamsOptions.on115: Generate errors for unknown unique element in an equation
  - GamsOptions.output: Output file
  - GamsOptions.pagecontr: Output file page control option
  - GamsOptionspagesize: Output file page size (=0 no paging)
  - GamsOptionspagewidth: Output file page width
  - GamsOptions.reference: Symbol reference file
  - GamsOptions.scriptexit: Program or script to be executed at the end of a GAMS run
  - GamsOptions.suppress: Compiler listing option
  - GamsOptions.symbol: Symbol table file
  - GamsOptions.tracelevel: Solvestat threshold used in conjunction with a=GT

7.14.22 24.3.1

- On Linux and OS X: LD_LIBRARY_PATH and DYLD_LIBRARY_PATH do not need to contain a GAMS system directory anymore. Anyway, if no system directory is specified in the GamsWorkspace constructor, PATH and LD_LIBRARY_PATH/DYLD_LIBRARY_PATH is used to find a GAMS system directory. The order is as follows:
  - Linux: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check LD_LIBRARY_PATH
  - OS X: If no system directory is specified in the GamsWorkspace constructor, check PATH first. If no system directory was found, check DYLD_LIBRARY_PATH
  - Windows: If no system directory is specified in the GamsWorkspace constructor, check registry.

- GamsJob.run creates out.db now even if it throws a GamsExceptionExecution

- New example transport14

- New function GamsSymbolRecord.key(int index): Retrieve key of GamsSymbolRecord on position index

- GamsModelInstance.solve now also works for solvers which require a subsolver, e.g. Dicopt
7.14.23  24.2.3

- Fix memory leak in GamsDatabase

7.14.24  24.2.2

- Fixed a bug regarding the subtype of equations and their default records, when the equation was added to a GamsDatabase from the API.
- Fixed a bug in GamsSymbol.delete_record.
- Fixed GamsExitCode.
- Make sure that GamsModelInstance.instantiate() does not solve the model, but only prepares everything required for the following solve()

7.14.25  24.2.1

- Add tutorial (GAMS_python_Tutorial.pdf) to <Path/To/GAMS>/docs/API. From the GAMSIDE this document can be accessed at Help -> Docs -> API
- New parameter opt_file in function GamsWorkspace.add_options allows to create an instance of GamsOptions that is initialized by an existing option file
- New function GamsOptions.export: Write GamsOptions into a parameter file
- New properties: GamsWorkspace.api_version, GamsWorkspace.api_major_rel_number, GamsWorkspace.api_minor_rel_number and GamsWorkspace.api_gold_rel_number
- New property GamsWorkspace.my_eps: Reset value to be stored in and read from GamsDatabase for Epsilon.
- New class NoNewVarEqu providing static fields to set option nonewvarreq
- Renaming of GamsOptions.PoolFree4 to GamsOptions.IntVarUp and property poolfree4 to intvarup
- Fixed a bug in GamsSymbol.add_record() that occurred when using empty strings as keys
- Fixed a bug in GamsModelInstance.solve() that affected the logging behavior
- The following functions throw an exception, when a wrong data type is passed for the keys/slice parameter: delete_record, find_record, add_record, merge_record, first_record, last_record. Valid data types are str, list, tuple and their subclasses

7.14.26  24.1.1

- New examples: markowitz.py, tsp.py, transport13.py, simple_cutstock.py, domain_checking.py
- New facility for GamsSymbols with domain information:
  - GamsDatabase:
    * New functions add_parameter_dc, add_variable_dc, add_equation_dc and add_set_dc: Create GamsSymbols with domain information
    * New function check_domains: Check for all symbols if all records are within the specified domain of the symbol
* New function `get_database_dvs`: Return all GamsDatabaseDomainViolations
* New property `suppress_auto_domain_checking`: Controls whether domain checking is called in GamsDatabase export

- `GamsSymbol` and its derived classes:
  * New function `check_domains`: Check if all records are within the specified domain of the symbol
  * New function `get_symbol_dvs`: Return all GamsDatabaseDomainViolations
  * New property `domains`: Domains of Symbol, each element is either a GamsSet (real domain) or a string (relaxed domain)

- New classes GamsDatabaseDomainViolation and GamsSymbolDomainViolation that are returned by GamsDatabase.get_database_dvs and GamsSymbol.get_symbol_dvs

- New functions in GamsModelInstance:
  - `copy_modelinstance`: Copies a GamsModelInstance to a new GamsModelInstance which gets constructed at this call
  - `interrupt`: Sends interrupt signal to running GamsModelInstance

- New function in `GamsSymbol` and its derived classes: `merge_record` finds a record if it exists and adds it if not

- New functions in GamsWorkspace: `add_job_from_gamslib`, `add_job_from_testlib`, `add_job_from_emplib`, `add_job_from_datalib` and `add_job_from_finlib`

- New properties in GamsWorkspace: `version`, `major_rel_number`, `minor_rel_number`, `gold_rel_number`

- New optional parameter in `model_name` for functions `add_database_from_gdx/add_database` in GamsWorkspace: `GAMS` string constant that is used to access this database

- Changed the debug argument passed to the GamsWorkspace constructor. Use members of class `DebugLevel`: Off, KeepFiles, ShowLog and Verbose instead of True and False

- New sub class of GamsException: GamsExceptionExecution, which provides additional info about the reason of the failed execution

- Allow to define `SymbolUpdateType` for each GamsModifier seperately

- Significant performance improvement for function GamsWorkspace.add_database when creating from an already existing database

- Changed the unicode settings on Linux from UCS2 to UCS4

- The Debug parameter of GamsWorkspace can be overwritten by the system environment variable "GAMSOOAPIDEBUG" if set to one of the following: Off, KeepFiles, ShowLog, Verbose

- The compact method of GamsDatabase is obsolete and has no effect anymore. It will be removed in the future.

- Fixed a bug in GamsModelInstance.solve()

- Fixed a bug in GamsDatabase, where the special value for undefined was set to 0 instead of 1.0E300 (SV_UNDEF)

- Fixed a bug when iterating through the records of a GamsSymbol

7.14.27 24.0.2

- Added new function `GamsSymbol.copy_symbol` which copies all records from one to another GamsSymbol
- Label and symbol lookup is now case insensitive
- Fixed handling of infinite bounds for GamsModifiers
This release contains a beta version of the object-oriented Python API that can be used to control GAMS from within Python 2.7. It allows the seamless integration of GAMS into Python by providing appropriate classes for the interaction with GAMS. The GamsDatabase class for in-memory representation of data can be used for convenient exchange of input data and model results. Models written in GAMS can be run with the GamsJob class and by using the GamsModelInstance class a sequence of closely related model instances can be solved in an efficient way. To use this API see the Getting started section.

### 7.16 GAMS Modeling Object Design

This document gives a brief introduction to GAMS' new model-solver API, including a description of its design goals and philosophy. This document is not intended to be used as a user's manual but rather to give a picture of what the new API can do and a description of some of the conceptual underpinnings for the new API.

Further material: Presentation at ICS 2011

### 7.16.1 Introduction

Historically, there have been a number of different GAMS solver interface libraries, i.e. libraries that enabled a solver to get all required information from a GAMS model, compute the solution, and return the solution, status information, and other information (e.g. solver log messages, nonlinear function evaluation error messages, node counts, time used) to GAMS. Each library was unique in some way, e.g. in the computer language or subset of GAMS model types it supported. Each library had its own advantages and disadvantages, but all of them were feature-poor and supported a limited scheme of operation: GAMS/Base would write scratch files containing the model to be solved, the GAMS solver link executable would use one of the solver interface libraries to read the model from scratch file and write a solution file, and GAMS/Base would read this solution file. While this scheme worked for many years it was inconvenient for the library user, difficult to maintain, slow, and a barrier to further development.

To address these issues and others, GAMS developed a new model-solver interface library, called GMO (GAMS Model Object), and a companion library called GEV (GAMS Environment Object). The two libraries are distinct and help to separate the purely model-specific tasks and information handled by GMO from the computing and solver environment that the model will be solved in, handled by GEV. The two libraries are typically used together and we will sometimes refer to them as simply GMO. For legacy reasons the new libraries support the old file-based scheme to communicate a model through scratch files.

In what follows, we first describe the basic structure, organization, and usage of GMO (Basic organization). Client applications can be split into two types: those defining or updating the model (Modeler Access to GMO) and those passing the model to a solver (Solver Access to GMO). We next describe some ways to update a model in Updating a GMO instance.
### 7.16.2 Basic organization

In this section we outline the basic organization of GMO. GMO is implemented as a shared library that interfaces to different languages via language-specific header files and interface code. The header files and code are included in source form with the GAMS distribution. Since the interface code employs dynamic loading, each GMO session begins with a call to initialize the required shared library (i.e. load it and all its symbols) and return an empty model object.

The next step is to load a model into the model object. This is typically done with a single wrapper call, as in the case of loading a model from model scratch files prior to solving in one of the GAMS solver links. It is also possible build up a model from scratch with a sequence of calls to provide the model column-wise or row-wise. If the model is built up column-wise or row-wise, additional information (e.g. about nonlinearities) may be passed to the object after the basic structure is built up. Once the model is complete, a finalization routine is called. This routine prepares the model object for efficient access by the user. Typically the model does not change after this point. There are exceptions to this (see Updating a GMO instance), but they usually involve small modifications to the existing model (like adding alternative bounds) or the addition of constraints and variables that require the re-finalization of the model.

When a model is fully loaded, the GMO client can start accessing the model. Typically the GMO client doing this will be a solver, but other clients (e.g. the CONVERT solver, the Examiner utility, or a model structure browser) exist also. In addition to querying the model, the client can also request that the model be presented or viewed in various different ways. For example, GMO can be requested to use an objective function or an objective variable. Most types of information are available immediately when the model is loaded, but some type of queries (e.g. Hessians, alternative QP forms) are less common and relatively expensive in time and/or space: these require that an initialization routine be called before the information is requested. Once the client has completed its work it reports on the solution found, if any. Typically, the model object is destroyed at this point. Model access by a client, especially solvers, is an important topic that is discussed in Solver Access to GMO.

The variety of data that go into the interface library when a model is defined and that a solver can request during solution is large, but the data can be divided into two types - data defining the model (e.g. number of rows and columns, coefficients, nonlinear functions) and data defining the solver environment (e.g. available and default GAMS solvers, license info, algorithm tolerances and limits). It is sometimes useful to separate these two types of data, so that it is possible to define and work with a model without specifying anything about the environment it exists in. The environment can be specified separately, and multiple models can make use of the same basic environment. To facilitate this, the solver interface is in two parts: the GMO interface deals with model-specific information and the GEV interface with information about the environment. The two environments are linked, since they are typically used together, with one (or multiple) models existing in one environment, but the separation makes it possible to define a model without defining its environment, etc. Since the bulk of the information and the code lies with GMO, we usually speak of the two libraries as one, called GMO, but it is worth remembering that GEV is a separate object.

### 7.16.3 Solver Access to GMO

One of the primary purposes of GMO is to provide convenient, efficient access to the model. GAMS links to many solvers, each solver link using GMO to access the model in different ways, so there is a wide array of possible methods to access the model in GMO. We describe them in this section.

There are multiple but equivalent views possible for the same model. For example, the model can be formulated with an objective function or with an objective variable. Free rows can be removed or left in, and the rows and/or columns can be permuted. Prior to accessing the model, the solver link can choose what view it would like to use. The view can be changed later, but since this can obviate the data obtained previously, the choice of view is usually made early on and left unchanged. Moreover, a view can be stored and restored in case multiple users access the same model.
All solvers will need to get basic information about a model - simple things like row and column counts, nonzero counts, etc. These are available via simple access routines. Since the model is essentially fixed (assuming the view does not change), basic information is pre-computed when the model takes its final form and is available at essentially no cost. Information about the rows and columns (e.g. variable level values, marginal values, variable priorities, row types) is also available, either for single rows/cols or in an array for all rows/cols at once.

For linear models, the only information left to get is the matrix of coefficients. This is available in a number of different forms e.g. column-wise or row-wise, either as a complete matrix returned with one call or as separate rows or columns returned via many calls. For nonlinear models, there are more variants on this theme: calls to return the function value or the function value and derivatives, calls for constraints and calls for the objective function. You can request that the nonlinear model be treated as its linearization around a certain point. There are also routines to do interval evaluations of functions and gradients. The GMO library prepares the model object to handle all these calls efficiently when the model takes its final form.

Nonlinear models present several additional challenges. When NL functions are evaluated, mathematical errors can occur (e.g. \( \sqrt{-1} \)). GMO supports different ways to log and handle these errors. Some algorithms will require or want 2nd-order information. Since this can be relatively expensive to compute, the solver must first call an initialization routine specifying what is desired (e.g. only Hessian-vector products, Lagrangian Hessian, single-row Hessians) and potentially a limit on the memory dedicated to computing Hessians. After this initialization, 2nd-order information is available.

Once the solver finishes, the solution (if any) and related status values must be reported back to GMO. There are a number of convenience routines included in GMO for this purpose.

A convenient interface was and is an important design goal for GMO, especially in the area of solver access to the model. Convenience takes many forms: a number of ways to get the same model data in order to support a variety of different solver libraries, self-contained calls with minimal requirements on previous setup for correct behavior, and a modern interface adhering to design principles like information hiding, encapsulation, and an object model. By keeping these goals at the fore when designing GMO we have made accessing the model convenient and efficient, which greatly simplifies the task of building a correctly-functioning solver link.

### 7.16.4 Modeler Access to GMO

In normal operation the modeler creates a model in GAMS source form and the GAMS/Base module handles all the details necessary to build up model instances in GMO. However, there are cases (e.g. solving a model many times over with different scenario data) where it is useful to access and modify a GMO instance outside of GAMS/Base. GMO provides routines to support this, specifically routines to update the model (see [Updating a GMO instance](#)), solve the model with one of the GAMS solvers available as part of the GAMS environment and GEV, and retrieve the solution.

Access to a GMO instance is usually done using integer indices, \([1..m]\) for the rows and \([1..n]\) for the columns. However, it is also possible to reference rows and columns using the notation from the original GAMS model, e.g. \(x(\text{'seattle'}, \text{'topeka'})\) or \(\text{demand}('\text{chicago}')\). This is more convenient when specifying what data should be updated to define a new scenario. In order to update a model instance in this case, it is useful to have a convenient, efficient way to translate row and column indices from one form to the other. This translation is done by the *model dictionary* interface DCT.

The DCT API provides information about the variables, equations, and sets used to define the GMO model instance. In addition, given a row or column index, it will translate this index into the equation or variable name and the list of set labels that correspond to this index. It will also do the inverse operation, translating an equation/variable name and list of labels into a row or column index. GAMS builds models in a way that makes this translation very efficient.

This organization is also useful when updating models to create new scenarios. Models are organized so that:
• There is one ordered universe of all labels appearing in the variables and equations of a given model. The order for the labeling does not change from symbol to symbol within a model.

• All of the columns in a model corresponding to a given variable are contiguous. (Ditto for rows and equations)

• The columns corresponding to a given variable are sorted by their index labels, using the universal order, with the left-most index varying slowest. (Ditto for rows and equations)

• GDX data is sorted in the same way: sorted by index label order, left-most index varying slowest. This can be very useful, provided the model and the GDX data use the same label ordering.

Using the various GAMS component libraries, it is possible to create a model updating interface that is both convenient for the user (by using the symbolic names referenced in the GAMS source) and efficient in updating the model data.

### 7.16.5 Updating a GMO instance

There are several possible ways to modify a model contained in a GMO instance. By updating, we mean an actual model change, rather than a change in the view that doesn't alter the set of solutions.

In perhaps the simplest case, the user can specify alternate variable bounds, as is useful when implementing a branch and bound code. The original bounds are retained in this case, so that the model can be reverted to the original bounds with a single call.

It is possible to linearize a model around a given point. This requires no information from the point to linearize around and can be undone easily. This is almost a change in view but since the solutions of the original and linearized models may be quite different we can also consider this a model update.

Many algorithms (e.g. outer approximation, Benders decomposition, Danzig-Wolfe decomposition) involve the addition of rows, and columns incident on these rows, to a core model. Such algorithms can be implemented effectively using GMO by taking advantage of GMO facilities to add rows and columns. There will be only a small amount of work required to prepare the GMO instance for use after each round of additional rows and columns. Note that all the changes to the model in this case are additions: the existing structure and data are left as is.

Finally, there are facilities in GMO to update variable bounds (as mentioned before), variable types (e.g. to relax single discrete variables), and the right-hand-side of constraints. The user cannot directly modify matrix coefficients. There is a much better way to safely update exogenous data in a model: GAMS can provide a model instance in which GAMS parameters are visible and can be updated. A reevaluation of the expressions in the models provides the updated matrix elements. The underlying concept is also used in Gather-Update-Solve-Scatter (GUSS) and described in more detail in this paper. This is a powerful tool to efficiently do e.g. Monte-Carlo simulation without the need for GAMS to regenerate the entire model over and over.

distributions
In the image, there is a list of types of probability distributions, such as beta, binomial, cauchy, chiSquare, exponential, gamma, geometric, gumbel, hyperGeo, invGaussian, laplace, logarithmic, logistic, logNormal, negBinomial, normal, pareto, poisson, rayleigh, studentT, triangular, uniform, uniformInt, and weibull. Additionally, there are references to DNLP models, problems, and smooth approximations related to CONOPT.
